A further form of abstraction that Marx objected to was the claim that there are economic laws that apply to all human societies equally. Marx held (preface to *Capital,* Vol. I, 2nd ed.) that each main type of social order develops and functions in its own special ways, so that we cannot conclude from what happens in one type of society that anything similar will happen in another. Indeed, he said that to trace the laws of development of different types of society in this way, keeping the particular and peculiar in view, is the dialectical method. It should be noted, too, that Marx sometimes thought that the various social categories, such as productive forces and productive relations, could not be abstracted from one another, but collapsed one into the other, as Hegelian theories do. We have already seen that Marx treated forms of organization as means of production, thus blurring the distinction between productive forces and productive relationships. In the recently published *Outlines of a Critique of Political Economy* (1857) appears the following note: "Dialectic of the concepts productive force (means of production) and productive relationship, a dialectic to determine their limits, and which does not cancel their real distinction" (p. 29). It seems that Marx hoped to settle the problem by means of a dialectical *coup de main.*

RELATION TO OTHER ENDEAVORS

Marx was not the first to inquire into the history of technology and of industry and commerce, but undoubtedly his work greatly influenced the direction taken by historical research. Marxist historians have been particularly anxious to show how knowledge has been hindered or promoted by the prevailing productive forces and productive relationships. Thus, Benjamin Farrington, in his *Greek Science* (2 vols., London, 1944–1949), argued that the predominantly speculative and unpractical character of Greek science was due to the institution of slavery and the aristocratic contempt for manual work that went with it. George Thomson, in his *Studies in Ancient Greek Society,* 1: *The Prehistoric Aegean* (London, 1949), presented evidence in favor of Engels's views on primitive communism. In Volume II of the same work, subtitled *The First Philosophers* (London, 1955), Thomson linked the categories employed by the pre-Socratic philosophers with economic and class factors and with Marx's notion of a commodity as "the uniform socially recognized" incarnation of human labor, concluding that "the Parmenidean One, together with the later idea of 'substance,' may therefore be described as a reflex or projection of the substance of exchange value" (p. 103). B. Hessen, in an essay titled "The Social and Economic Roots of Newton's *Principia*" (*Science at the Crossroads,* 1931), argued that Isaac Newton was the typical representative of the rising bourgeoisie, and in his philosophy he embodies the characteristic features of his class" (p. 33). This type of view illustrates the more general inquiry into the connections between class and knowledge known as the sociology of knowledge. Karl Mannheim's *Ideology and Utopia* (*Ideologie und Utopie,* Bonn, 1929; translated by Louis Wirth and Edward Shils, London, 1936) shows how Marxism influenced this subject, but Max Scheler, who was not a Marxist, also helped develop it (*Die Wissenformen und die Gesellschaft,* Leipzig, 1926).

It should be emphasized that a materialist view of history is not necessarily linked with Marxist socialism, for it is possible to recognize the historical importance of the means of production and of economic and class interests without concluding that a classless, communist society must emerge. (This was done, for instance, by E. R. A. Seligman in *The Economic Interpretation of History,* New York, 1902). Furthermore, some historians and economists have adopted an economic interpretation of history without committing themselves to the Marxist views about the dominating influence of technology, of the means of production. Thus, Thorold Rogers, an undogmatic free trader, called attention to such influences as the shortage of labor created by the Black Death or the interference with trade routes by the Mongol invaders, but said: "You cannot, of course, separate, except in thought, and then only with no little risk of confusion, economical from social and political facts" (*The Economic Interpretation of History,* London, 1888, p. 281). Marxists have often gone to considerable lengths to distinguish the economic from the materialist conception of history. Thus, the Russian Marxist historian M. N. Pokrovsky has been criticized by orthodox Marxists for placing too much emphasis on market considerations and too little on the influence of the means of production.

Bibliography

HISTORICAL MATERIALIST WORKS

Marx

Misère de la philosophie. Brussels and Paris, 1847. Translated by H. Quelch as *The Poverty of Philosophy.* Chicago: C. H. Kerr, 1910.

Zur Kritik der politischen Ökonomie. Berlin, 1859. Translated by N. I. Stone as *A Contribution to the Critique of Political Economy.* Chicago: C. H. Kerr, 1904.

Das Kapital, 3 vols. Hamburg, 1867–1894. Vols. II and III edited by Friedrich Engels; Vol. III in two parts. English translation, Chicago, 1915: C. H. Kerr. Vol. I translated by Samuel Moore and Edward Aveling, revised and amplified according to the fourth German edition by Ernest Untermann; Vol. II translated from the second German edition by Ernest Untermann; Vol. III translated from the first German edition by Ernest Untermann.

"Oekonomische-philosophische Manuskripte." In *Marx-Engels Gesamtausgabe,* edited by D. Riazanov and V. Adoratski. Berlin, 1932. Division 1, Vol. III. Translated by Martin Milligan as *Economic and Philosophical Manuscripts of 1844.*

Moscow: Foreign Languages Publishing House; and London, 1959.

Grundrisse der Kritik der politischen Ökonomie (Rohentwurf). Berlin, 1953. One section has been translated by J. Cohen as *Pre-Capitalist Economic Formations,* edited by E. J. Hobsbawn. London: Lawrence and Wishart, 1964.

Karl Marx. Selected Writings in Sociology and Social Philosophy. Edited by T. B. Bottomore and Maximilien Rubel. London: Watts, 1956.

Marx and Engels

Manifest der kommunistischen Partei. London, 1848. Many English editions as *The Communist Manifesto.* See especially edition with an introduction by Harold Laski. London: Allen and Unwin, 1948.

Die deutsche Ideologie. Edited by V. Adoratski. Vienna, 1932. Translated as *The German Ideology,* edited by R. Pascal. London: Lawrence and Wishart, 1938.

Selected Correspondence (1846–1895). Edited by Dona Torr. New York: International, 1942. Contains Marx's 1846 letter to Paul Annenkov and important letters written by Engels after Marx's death.

Karl Marx, Frederick Engels: Collected Works, 49+ vols. Translated by Richard Dixon et al. New York: International, 1975–.

Engels

Umrisse zu Kritik der Nationalökonomie (1844). Translated by Martin Milligan as "Outlines of a Critique of Political Economy." In Karl Marx, *Economic and Philosophical Manuscripts of 1844* (op. cit.).

Herr Eugen Dührings Umwälzung der Wissenschaft. Leipzig, 1878. Translated by E. Burns as *Herr Eugen Dühring's Revolution in Science.* London: Lawrence and Wishart, 1934.

Die Entwicklung des Sozialismus von der Utopie zur Wissenschaft. Zürich, 1883. Translated by E. Aveling as *Socialism: Utopian and Scientific.* London: Sonnenschein, 1892.

Der Ursprung der Familie, des Privateigentums und des Staats. Zürich, 1884. Translated by E. Untermann as *The Origin of the Family, Private Property, and the State.* Chicago: C.H. Kerr, 1902.

Lenin

What the "Friends of the People" Are (1894). In his *Collected Works,* Moscow and London, 1960–. Vol. I, 1960.

"Karl Marx." In his *Collected Works.* Moscow and London, 1960–. Vol. 21, 1964.

Plekhanov

K Voprosu o Razvitii Monisticheskago Vzglyada na Istoriyu. St. Petersburg, 1895. Translated by Andrew Rothstein as *In Defence of Materialism: The Development of the Monist View of History.* London: Lawrence and Wishart, 1947.

Osnovnye Problemy Marksizma. 1908. Translated by E. Paul and C. Paul as *Fundamental Problems of Marxism.* London: Lawrence, 1929.

HISTORICAL SCHOOL OF JURISPRUDENCE

The historical school of jurists was founded by Friedrich Karl von Savigny (1779–1861). Its central idea was that a nation's customary law is its truly living law and that the task of jurisprudence is to uncover this law and describe in historical studies its social provenience. As in other schools of thought, acceptance of this approach did not necessarily mean agreement on its theoretical or practical consequences.

GERMANY

To followers of Savigny the identification of law with custom and tradition and the *Volksgeist,* or genius peculiar to a nation or folk, generally meant a rejection of rationalism and natural law; a rejection of the notion of law as the command of the state or sovereign, and therefore a disparagement of legislation and codification; and a denial of the possibility of universally valid rights and duties and of the individual's possession of nonderivable and inalienable rights. In positive terms, historical jurisprudence identified law with the consciousness, or spirit, of a specific people. Law is "found" by the jurist and not "made" by the state or its organs. Law is a national or folk and not a political phenomenon; it is a social and not an individual production; like language, it cannot be abstracted from a particular people and its genius; it is a historical necessity and not an expression of will or reason, and therefore it cannot be transplanted.

In addition to Savigny, the historical school was probably influenced by Johann Gottfried Herder (1744–1803) and the romantic notions of folk culture, by the emphasis on tradition in the work of Edmund Burke (1729–1797), by the stress on historical continuity in the work of Gustav Hugo (1764–1844), and by the Hegelian conception of Spirit. In Germany, the main proponents of

historical jurisprudence were G. F. Puchta, Karl Friedrich Eichhorn, Rudolph von Sohm, and Otto von Gierke.

ENGLAND

In England Henry Maine (1822–1888) was closely identified with the historical school, although there is no evidence that he was directly influenced by the German thinkers. Modern historical jurisprudence in England was born with the publication in London of Maine's *Ancient Law* in 1861, the year of Savigny's death. Until then historical research in law had been neglected, but from that time on, the field was assiduously cultivated. In reaction against natural law and under the influence of Thomas Hobbes, the tendency in England had been to regard law as the command of the state, and the task of the jurist was conceived as a concern with the analysis of positive law without regard to historical or ethical considerations. Maine broke with these traditional attitudes. Probably influenced by Rudolf von Ihering (*Der Geist des römischen Recht,* 3 vols., Leipzig, 1852–1865), Maine was stimulated to apply the historical method to jurisprudence. Charles Darwin's *Origin of Species,* published two years before *Ancient Law,* also probably influenced Maine.

Maine rejected the natural law, rationalistic, and a priori approaches to the nature of law. In his *Early History of Institutions* (London, 1875) he saw a people's law as compounded of opinions, beliefs, and superstitions produced by institutions and human nature as they affected one another. Indeed, English common law seemed better to exemplify Savigny's views than did the law of Germany, which drew heavily on Roman law. But as an Englishman, Maine saw in law more than a people's customs; he observed and took into account the creative and reforming work of Parliament, and so he was led to recognize legislation as an instrument of legal growth. And he found that equity and legal fictions played creative roles in the common law. In these respects he departed radically from Savigny's monistic approach to law and its sources.

Maine's comparative historical studies, which took into account diverse legal systems, kept him from a belief in the mystical uniqueness of a people and its genius and its law; he observed uniformities as well as differences in different legal orders, and so he was led to suggest that similar stages of social development may be correlated with similar stages of legal development in different nations. Maine differed from Savigny also in believing that custom might historically follow an act of judgment, so that the jurist could be seen to have had a creative role in making the law, even though he claimed only to have found it. Maine also noted the part played in early societies by the codification of customary law. In revealing the ideals operative in a society at a particular stage of its development and in relating them to social conditions, Maine stimulated the development of the use of the sociological method in jurisprudence. It thus became apparent that just as law cannot be divorced from history, so, too, it cannot be divorced from philosophy and sociology. Thus, if Savigny's historical jurisprudence was mainly conservative in import, Maine's work had a predominantly liberalizing effect. Then too, Maine's work influenced the development of comparative legal studies.

Other English scholars associated in varying degree with the historical school of jurisprudence are James Bryce (1838–1922), Frederic W. Maitland (1850–1906), Frederick Pollock (1845–1937), and Paul Vinogradoff (1854–1925).

Perhaps the greatness of historical jurisprudence lay in the fact that it provided its own seed of dissolution; for once it is admitted that law is historically conditioned, it is as impossible to limit the conception of law to a *Volksgeist* as to the commands of the sovereign; all forms of social control and all sources of law emerge as subjects for legitimate consideration and study.

HISTORICISM

The early history of the term "historicism" (*Historismus*) has not been sufficiently explored, as Erich Rothacker has pointed out. However, one clear case in which it was used in a sense closely allied to all of the senses which it has subsequently assumed is to be found in Carl Prantl's *Die gegenwärtige Aufgabe der Philosophie* (1852). Although the term was later employed as a means of characterizing the thought of Giambattista Vico, its first widespread use probably dates from methodological debates among German-speaking political economists. In these debates, Carl Menger criticized Gustav Schmoller and his school for making economic theory unduly dependent upon economic history; this he characterized as *Historismus.* Thus, the term took on a depreciatory sense; it suggested an inappropriate use of historical knowledge and a confusion regarding the sorts of questions that could be answered by means of such knowledge. One may conjecture that the extension of its use during the first decades of the twentieth century was fostered by the currency of its depreciatory analogue, "psychologism" (*Psychologismus*): Both terms were used in reference to attempts to extend the methods and results of a particular discipline into provinces in which that discipline was claimed to lack legitimate authority.

It was not until the period immediately following World War I, however, that *Historismus* came to be widely used. The impact of the war and the consequences of the German defeat led to attempts to reappraise the cultural and political traditions of the past, and in this reappraisal a central issue was whether a purely historical approach to human culture provided an adequate basis for the judgment of cultural values. This was not, of course, a new problem for theologians or for philosophers; it was one which had been forced upon their attention by dominant strains in nineteenth-century thought (for example, by Hegelianism, the results of historical biblical criticism, and evolutionism). Nevertheless, for those in Germany who had been reared in the tradition of historical studies and who were encountering the violent upheaval of the times, the question of the relations of cultural standards to historical change took on great immediacy. It was at this point that Ernst Troeltsch attempted to characterize historicism in a nonpolemical way, to examine its origins, and to assess its merits and limitations.

TROELTSCH

In *Der Historismus und Seine Probleme,* Troeltsch used "historicism" to mean a tendency to view all knowledge and all forms of experience in a context of historical change. He regarded this tendency as one of the two fundamental discoveries of the modern mind: The other, with which he compared it, was the generalizing, quantitative approach to nature that he termed *Naturalismus.* Thus, like Wilhelm Dilthey, Wilhelm Windelband, Heinrich Rickert, and others, Troeltsch drew a distinction between the forms of understanding characteristic of the natural sciences and those which are appropriate to what one may perhaps best term the "historical sciences" (*die Geisteswissenschaften*). What was of prime importance to him, however, was not the differences between the methodologies of the natural and the historical sciences, but the fact that each was a fundamentally different way of looking at the world, that is, each constituted a different *Weltanschauung.* Troeltsch documented the scope and the depth of historicism as a *Weltanschauung* by tracing its presence in the thought of a host of philosophers and sociologists of the nineteenth and twentieth centuries. He himself accepted the view that all knowledge and all forms of human experience are caught up in a process of change; however, he believed that this view tended to lead to an unmitigated moral and intellectual skepticism. It was this that constituted the crisis of historicism, and it was this that he sought to overcome. Unlike Rickert and others among his contemporaries, he believed that the skeptical consequences of historicism could be overcome only through history itself and could not be avoided by any appeal to transhistorical values. His own positive, religiously based views, however, received only partial

expression, for he died before he was able to complete the work that he had projected.

MANNHEIM

In 1924, almost immediately after the appearance of Troeltsch's work, Karl Mannheim wrote an essay, "Historismus," in which he too characterized historicism as a basic *Weltanschauung*. According to him, the static, theologically oriented conception of the world that characterized the Middle Ages had been retained in secularized form in the Enlightenment, because both cultures held to the doctrine of the atemporal character of the judgments of reason. According to Mannheim, this static conception had at last been abandoned, and all social and cultural reality was seen as being dominated by change. It was this radically temporalistic view of the world that he designated as historicism. Unlike Troeltsch, to whose work he devoted a portion of his essay, Mannheim did not recoil from the relativism of values that he saw that historicism entailed; rather, he was concerned to affirm it. However, on the basis of his own views regarding the intimate connections between theory and practice, he did not believe that either moral or intellectual skepticism was a necessary consequence of temporalistic relativism. Moral skepticism would not necessarily follow, since Mannheim believed that all values are rooted in the conditions of actual social existence and their discovery is not dependent upon our possession of some unchanging capacity for moral insight; furthermore, intellectual skepticism could be avoided through a recognition of the perspectival character of knowledge, and by means of the capacity of a sociology of knowledge to uncover the nature of divergent perspectives and reconcile them with one another. Thus, in Mannheim's use of "historicism," unlike Troeltsch's, there remained no vestige of the original depreciatory significance of the term.

MEINECKE

In 1936 Friedrich Meinecke published a historical study titled *Die Entstehung des Historismus* in which the term assumed a markedly different connotation. To be sure, Meinecke shared Troeltsch's view that historicism represented a break with those modes of thought which both characterized as naturalism. Furthermore, like Mannheim and others, he believed that there was a fundamental opposition between the modern historical sense and earlier political philosophies that had relied upon the conception of a universal and unchanging natural law as the basis for moral and political judgment. Thus Meinecke regarded historicism as opposed to a static view of the world, and in this he was in agreement with Troeltsch and Mannheim. However, he proceeded to characterize this new world view in terms of an interest in that which is concrete, unique, and individual; he found the clue to the new view expressed in Johann Wolfgang von Goethe's use of the dictum "*Individuum est ineffabile.*" This characterization of historicism was undoubtedly related to the fact that Troeltsch (among others) had viewed historical inquiry as concerned with the concrete, the unique, and the individual, and had contrasted this interest with the methods used in the natural sciences.

However, in translating this particular methodological doctrine into a worldview, Meinecke departed radically from the characterizations offered by Troeltsch and Mannheim. For them it was not the concept of individuality but the concepts of change and development that were fundamental to what they had termed "historicism." As a consequence of this difference in the meaning of the terms, some of the eighteenth-century historians who played dominant roles in Meinecke's account would not have been considered proponents of historicism by Troeltsch or by Mannheim. The difference emerges most strongly in the fact that Meinecke believed the culmination of modern historicism was to be found in the world views of Goethe and Leopold von Ranke, whereas one would expect such a high point to be identified with G. W. F. Hegel, with Karl Marx, or perhaps with later evolutionary thought, were one to take the term in the meaning ascribed to it by Troeltsch and Mannheim. As a consequence of this shift in the meaning of the term, Meinecke naturally did not regard historicism as a force that threatened human values or which could lead to a radical transvaluation of values; thus, for him there was no crisis of historicism as there had been for Troeltsch.

CROCE

The view with which Meinecke's characterization of historicism can best be compared is that of Benedetto Croce, even though Croce criticized Meinecke's work for its failure to emphasize nineteenth-century thought, and in particular because of its failure to appreciate Hegel's importance. Croce's own philosophic views had grown out of a reaction against positivism and materialism, in favor of idealism: in particular, he concerned himself with combating positivist and materialist philosophies of history. What he rejected in these views was not the historicism that Troeltsch and Mannheim correctly discerned in them, but the fact that they attempted to interpret history naturalistically, that is; in ways similar to those used by the sciences in dealing with the nonhuman world. Like Vico and Hegel, with whose thought his own

was directly affiliated, Croce regarded history as the self-development of the human spirit. Furthermore, since Croce, as an idealist, wished to deny that there was any realm of existence external to the human spirit, he interpreted the whole of reality as being encompassed within history: life and reality were nothing but the ever changing manifestations of the spirit.

It was primarily with reference to this radical metaphysical idealism, rather than with reference to any more general currents in Western intellectual history, that Croce used the term "historicism" (*storicismo*). While Croce's own emphasis on the pervasiveness of change did in fact provide an example of what Troeltsch and Mannheim considered to be the basic feature of historicism, it was not with their thought, but with that of Meinecke, that his views had the greater affinity. Like Meinecke, Croce held that the means by which a naturalistic worldview seeks to envision and grasp reality are totally inadequate because of the uniqueness and individuality of that which is historical. He therefore held—as did Meinecke—that genuine knowledge, as opposed to merely practical or pseudo-knowledge, comes only through an understanding of history. Croce endeavored to establish this antinaturalistic position throughout his philosophical writings; for Meinecke, the acceptance of this form of historicism was intimately connected with a religious sense of mystery.

ENGLAND AND THE UNITED STATES

The term "historicism" was adopted into the English language in the late 1930s and the 1940s both in the United States and in England. In neither country, however, was it used to refer primarily to a *Weltanschauung*; rather, what was of concern were questions regarding principles of explanation and of evaluation. In the United States, attention was directed to these issues through works by Morris R. Cohen, Maurice Mandelbaum, and Morton White, among others. In England, fuller discussions were to be found in articles by F. A. Hayek and Karl Popper.

One may plausibly infer from Hayek's discussion of historicism that the sense in which he and Popper conceived the notion probably derived from Menger's original contrast between scientific theory-construction and a primarily historical approach to problems in the social sciences. However, the specific form of historicism that both Hayek and Popper especially attacked was the nineteenth-century doctrine that there are laws of development that characterize social wholes and that it is possible, on the basis of a knowledge of such laws, to make scientific predictions about the future. Thus, the notion

of "holism," which had not previously been directly associated with the definition of historicism, was injected into the discussion, and the chief protagonists of historicism were identified as Hegel, Auguste Comte, and Marx. When taken in this sense, three theses were common to historicist doctrines: (1) a rejection of "methodological individualism" in favor of the view that there are social wholes which are not reducible to the activities of individuals; (2) the doctrine that there are laws of development of these wholes, considered as wholes; (3) the belief that such laws permit predictions as to the course which the future will take. While these three theses were intimately connected with some of the doctrines previously characterized as examples of historicism, there seems to be no necessity for identifying historicism with holistic thought and with a belief in the possibility of prediction, as Popper and Hayek tend to do.

DEFINITION OF "HISTORICISM"

Considering the very great diversity in usage which we have now traced, one may ask whether there is any characterization of historicism which can serve to connect the various ways in which the term has been used and which at the same time can give it a relatively clear meaning. Without suggesting that all problems concerning the deviant meanings of historicism can be solved in this way, the following definition may be proposed as an approximation of that goal: Historicism is the belief that an adequate understanding of the nature of anything and an adequate assessment of its value are to be gained by considering it in terms of the place it occupied and the role it played within a process of development.

It will be noted that this definition does not characterize historicism as a particular *Weltanschauung* but as a methodological belief concerning explanation and evaluation. As Popper's discussion makes clear, in the late eighteenth and nineteenth centuries, forms of what has been termed "naturalism" have closely resembled antinaturalistic theories, with respect to their presuppositions about the relation of historical change to the explanation and evaluation of events. Since it is misleading to regard positions as divergent as those of, say, Hegel, Comte, Marx, and Herbert Spencer as representative of one and the same *Weltanschauung,* it is preferable to conceive of historicism as a methodological principle.

Troeltsch and Mannheim were in agreement with Meinecke and Croce in holding that this new methodological principle was based upon the rise of a new concept of change and of history. Its original challenge to older modes of thought lay partly in its tendency to link

evaluation with genetic explanation. It was this tendency that was fundamental to the so-called crisis of historicism, and it has also been against this tendency that Hayek and Popper, among others, subsequently rebelled. However, the most radical aspect of historicism as a methodological principle has been its conception of what is presupposed in all explanations and evaluations of past events: that each event is to be understood by viewing it in terms of a larger process of which it was a phase, or in which it played a part; and that only through understanding the nature of this process can one fully understand or evaluate concrete events. It is partly because of this emphasis upon relating each event to some larger developmental process that historicism has come to be identified with holism and a belief in historical prediction. Important as this connection has undoubtedly been, a definition in terms of it fails to stress the more fundamental fact that historicism involves a genetic model of explanation and an attempt to base all evaluation upon the nature of the historical process itself. Popper, in his characterization of the position, therefore tends to separate his own use of the term "historicism" from its other, more frequent uses. The definition suggested here constitutes an attempt to epitomize many of these uses and to connect them with one another even where they are found to diverge.

Bibliography

The following bibliography is highly selective and deals only with those works in which historicism is the central topic of discussion and with works specifically mentioned in the article. The order is chronological, except that all works by the same author or concerned primarily with that author are placed together.

Prantl, Carl. *Die gegenwärtige Aufgabe der Philosophie.* Munich, 1852. A speech given before the (Bavarian) Akademie der Wissenschaften on March 27, 1852. In it, the term *Historismus* is used to designate a concrete, historically oriented method by means of which the impasses in the philosophy of the day could be avoided.

Menger, Carl. *Untersuchungen über die Methode der Socialwissenschaften.* Leipzig: Duncker and Humblot, 1883. Reprinted as Volume II (London, 1933) of the *Collected Works.* These four volumes constitute numbers 17–20 of "Reprints of Scarce Tracts in Economics and Political Science," published by the London School of Economics and Political Science.

Menger, Carl. *Die Irrthümer des Historismus in der deutschen Nationalökonomie.* Vienna, 1884. Reprinted in Volume III (London, 1935) of the *Collected Works,* 4 vols. A polemic against Schmoller's methodological views. This and the preceding item represent the first influential introduction of the term "historicism" into the literature of the social sciences.

Ritzel, Gerhard. *Schmoller versus Menger: Eine Analyse des Methodenstreits im Hinblick auf den Historismus in der Nationalökonomie.* Frankfurt am Main, 1950. A helpful doctoral dissertation concerned with the issues involved in the quarrel over method in political economy.

Troeltsch, Ernst. *Der Historismus und seine Probleme.* Tübingen: Mohr, 1922. Only the first volume of this work was completed. It takes its point of departure from the "crisis of historicism" in postwar German intellectual life and treats fundamental problems of both formal and material philosophies of history through detailed discussion of almost all important nineteenth- and twentieth-century figures in these fields. Unfortunately, the structure of the discussion is not clear, largely because Troeltsch used the concept of "value" in discussing both the formal problems of a philosophy of history and the problem of meaning in history. His own solution of the latter problem, which was to have been the theme of his second volume, is briefly adumbrated in posthumously published lectures that he was to have given at Oxford. They were originally published as *Christian Thought, Its History and Application* (London: University of London Press, 1923; reprinted, New York, 1957), but they have been better known under the title *Der Historismus und seine Überwindung* (Berlin: Teubner, 1924).

Troeltsch, Ernst. "Die Krisis des Historismus." *Die Neue Rundschau* 33 (1922): 572–590. An excellent, brief, untechnical statement of the central theme of Troeltsch's classic work.

Hintze, Otto. "Troeltsch und die Probleme des Historismus." *Historische Zeitschrift* 135 (1927): 188–239. Also to be found in Hintze's collected essays, *Zur Theorie der Geschichte* (Leipzig: Koehler and Amelang, 1942). A masterful analytical and critical exposition of Troeltsch's approach to historicism. It is also suggestive in the way in which it provides a rich historiographical background against which the work of Troeltsch and Meinecke can be viewed.

Mannheim, Karl. "Historismus." *Archiv für Sozialwissenschaft und Sozialpolitik* 52 (1924), translated and edited by Paul Kecskemeti and reprinted in *Essays on the Sociology of Knowledge* (London: Routledge, 1952). An important treatment of historicism as the dominant *Weltanschauung* of the post-Enlightenment period, and an attempt to work out its cultural and philosophic implications.

Croce, Benedetto. "Antistoricismo." In *Proceedings of the Seventh International Congress of Philosophy.* London: H. Milford, 1931. Translated into German by K. Vossler, and published in *Historische Zeitschrift* 143 (1931): 457–466. An attack upon what Croce regarded as two antihistorical tendencies in thought: "futurism" and the attempt to escape from historicity to fixed and absolute standards.

Croce, Benedetto. *La storia come pensiero e come axione.* Bari: Laterza, 1938. English translation by Sylvia Sprigge as

History as the Story of Liberty (New York: Norton, 1941). A series of studies representing Croce's most mature reflections on history, historiography, and historicism.

Cohen, Morris R. "History versus Value." In *Reason and Nature,* 369–385. New York: Harcourt Brace, 1931. This essay was originally published in *Journal of Philosophy* 11 (1914): 704–716, but its influence on Morton White and others probably dates from its inclusion in this volume.

Heussi, Karl. *Die Krisis des Historismus.* Tübingen: Mohr, 1932. Contains a useful summary of early uses of the term and helpful references. Heussi's analysis of the concept should be consulted, but lacks an appreciation of the connection between the main currents of nineteenth-century thought and the ways in which the term was used in the twentieth century.

Meinecke, Friedrich. *Die Entstehung des Historismus,* 2 vols. Munich: Oldenbourg, 1936. The classic account of the development of historicism interpreted as a new view of life and of historical experience. Its course is traced by means of a series of individual essays from seventeenth-century forerunners through Goethe and Ranke.

Meinecke, Friedrich. *Zur Theorie und Philosophie der Geschichte,* Vol. 4 of *Werke,* 8 vols. Stuttgart: Koehler, 1957–1979. Collected essays and reviews, including discussions of Heussi and Troeltsch, and additional materials concerning the theme of his own book.

Hofer, Walther. *Geschichtschreibung und Weltanschauung.* Munich: Oldenbourg, 1950. A study of Meinecke's thought, with special reference to historicism.

Rothacker, Erich. "Historismus." *Schmollers Jahrbuch* 62 (1938): 388–399. A noted theorist of the *Geisteswissenschaften* offers an interpretation of the characteristic nature of historicism. Rothacker's "Das Wort 'Historismus,'" *Zeitschrift für Deutsche Wortforschung* 16 (1960): 3–6, is a criticism of those who failed to trace early uses of the term.

Mandelbaum, Maurice. *The Problem of Historical Knowledge.* New York: Liveright, 1938. A brief discussion of historicism is included.

Hayek, F. A. "Scientism and the Study of Society: The Historicism of the Scientistic Approach." In *The Counter-revolution of Science.* Glencoe, IL: Free Press, 1952, Part I, Ch. 7. First published in *Economica* 10 (1943): 50–63. The above study first appeared as a whole in *Economica* 9 (1942), 10 (1943), 11 (1944).

Popper, Karl R. *The Poverty of Historicism.* Boston: Beacon Press, 1957. First published in *Economica* 11 (1944), 12 (1945). (For remarks on its earlier composition, see Popper's "Historical Note" prefixed to the printed volume.) The exposition and attack upon historicism are intimately connected with Popper's theories concerning methodology in the social sciences. With respect to all of these topics, see also Karl Popper, *The Open Society and Its Enemies* (London: Routledge, 1945).

Engel-Janosi, Friedrich. "The Growth of German Historicism." *Johns Hopkins University Studies in History and Political Science,* series 62 (1944), no. 2. Offers a brief survey of a number of leading German-speaking historians, emphasizing the historicist elements in their work.

White, Morton G. "The Attack on Historical Method." *Journal of Philosophy* 42 (1945): 314–331. A reply to some aspects of the attack on historicism.

White, Morton G. *Social Thought in America: The Revolt against Formalism.* New York: Viking, 1949. Includes a characterization of historicism and an estimate of its role in the thought of selected social theorists.

Lee, Dwight E., and Robert N. Beck. "The Meaning of 'Historicism.'" *American Historical Review* 59 (1953–1954): 568–577. A compilation and critical classification of the various ways in which the term "historicism" has been used; it proposes a pair of definitions to cover the most widely established usages.

Antoni, Carlo. *Lo storicismo.* Rome, 1957. Adds some information to that supplied by Heussi on the early uses of the term; offers a brief survey of the development of historicism (in its broadest sense) from the eighteenth century to Croce.

White, Hayden V. "On History and Historicisms." In *From History to Sociology,* by Carlo Antoni; English translation by Hayden V. White. Detroit, MI: Wayne State University Press, 1959. The translator's introduction is a brief, useful historical sketch of types of historicism.

Rand, Calvin G. "Two Meanings of Historicism in the Writings of Dilthey, Troeltsch, and Meinecke." *Journal of the History of Ideas* 25 (1964): 503–518. A further attempt to elucidate the varied meanings of the term.

Maurice Mandelbaum (1967)

HISTORICISM [ADDENDUM]

The debate over the nature of historicism has not yet been resolved, and perhaps never will be; for historicism is a broad, multifaceted phenomenon with highly diverse and often conflicting manifestations. Indeed, the only relationship between the myriad meanings of the term "historicism" seems to be that of family resemblance (i.e. constantly shifting patterns of similarities and differences across the multiple instantiations of the concept).

Nevertheless, it is possible to identify, within the historicist family, one strand that has been significant for the history of philosophy more than any of its counterparts: namely, that which reached its apex in the enormous impact of Martin Heidegger and Hans-Georg Gadamer on the human sciences over the second half of the twentieth century. In this light, historicism's most crucial and enduring legacy appears to be the insistence that the historical character of human existence sets it apart from the world of nature, both in its ontological features and in the epistemological exigencies deriving therefrom. At the ontological level, this worldview unpacks the historicity of the human world in terms of the finitude, temporality,

uniqueness, and the meaning-laden character of all human phenomena. At the epistemological level, these ontological features render erroneous and futile any attempt to understand historical existence through the prism of universal laws, timeless causal mechanisms, or theoretical abstractions.

Ultimately, this outlook not only contests the aspirations of positivist epistemology to universal applicability, but in fact poses a comprehensive challenge to the universalistic worldview of the Enlightenment and its nineteenth- and twentieth-century successors. This major strand of historicism developed chiefly (though not exclusively) within the German intellectual world, with four prominent figures towering above all others in their contribution to historicism's unabated and dramatic impact upon Western thought: Leopold von Ranke, Wilhelm Dilthey, Heidegger, and Gadamer.

Leopold von Ranke (1795–1886), one of the founding fathers of modern historiography, developed his historical thought to a large extent through critical engagement with the idealist, Hegelian philosophy of history. Whereas the latter viewed history as the march of reason, entailing the mediation of historical knowledge by conceptual abstraction and generalization (that is, the subordination of history to philosophy), Ranke on the contrary upheld the primacy of history over philosophy; that is, the irreducibility of the full concreteness and diversity characterizing the flow of human existence to abstract, general categories. Ranke still embraces the idea of the unity of world history, but only in the sense that all historical epochs and phenomena are of equal value before God by virtue of their concrete individuality. Their universal meaning—their essence—resides within their particularity rather than in some general concepts to which they are purportedly reducible. Accordingly, the causal sequences governing historical life are of a contingent nature that has nothing to do with the mechanistic causality of the natural sciences.

Wilhelm Dilthey (1833–1911) sought to place the distinction made by Ranke and others between the natural sciences and the human (*qua* historical) sciences upon firmer, more systematic ontological and epistemological ground. In Dilthey's ontology, human life is construed as a meaningfully structured flow of interconnected experiences through time. These experiences are in turn objectivated in all visible human phenomena: works of art, political and legal formations, religious rituals, and so on. Thus, history consists in meaning-laden expressions of life.

This ontology clears the way for harnessing hermeneutical principles, originally utilized for the interpretation of individual texts, as a key to systematizing the epistemology of the entire human sciences. The possibility of historical knowledge flows, according to Dilthey (1989), from two complementary observations, both of which are hermeneutical by nature. First, the objectivation of life expressions in the realms of art, religion, law, and so forth, renders those expressions visible to the historian. Second, those expressions are not only visible but also intelligible to us by virtue of our ability to reproduce, to re-experience the meaning of objectivated expressions of life within our own field of experience. Dilthey's hermeneutics thus functions both as the basis for a distinctly historical epistemology and as a methodological procedure for extracting meaning out of history.

Although, as we have seen, historicism has always contained ontological as well as epistemological and methodological precepts, Martin Heidegger (1889–1976) was the first to transform historicism into an all-encompassing ontology. This accomplishment was effected through a reversal of the entire Western metaphysical tradition. Instead of searching for the eternal essences of Being underlying external, changing appearances, Heidegger (1996) proposes to construct a universal ontology based on temporality as its most fundamental attribute. Human existence, for Heidegger, is fully contained within its concrete, temporal manifestations; nothing which belongs to Being resides outside of this concrete temporality (that is, outside of historicity), in some abstract universal reason or divine spirit. Concomitantly, there is no need for abstract concepts or scientific classifications in order to grasp truth. Rather, the latter is immediately accessible to us in the form of experience, thus pointing up the ontological status of understanding as a ubiquitous form of (historical) being rather than as a merely cognitive process.

Heidegger's most influential follower, Hans-Georg Gadamer (1900–2002), devoted his magnum opus *Truth and Method* to the systematic development of an ontological hermeneutics based upon Heidegger's insight concerning the historicity of understanding. For Gadamer (1989), we are always, as historical beings, situated within a tradition but at the same time constantly working through that tradition, by way of an interpretive engagement with the texts comprising it. This is the so-called "hermeneutical circle": While tradition is the universal ontological condition within which all understanding occurs, that same tradition is also constantly being reformed in the course of the interpretive process, which in turn entails a perpetual remaking of the interpreter's self-understanding. Thus, the understanding subject, the process of understanding, and that which is understood

(i.e., tradition) are but three facets of one and the same ontological condition: the temporal flux of being.

Gadamer's thought may be regarded as the culmination of a historical process whereby historicism persistently broadened its scope, from the rather impressionistic and quasi-theological observations of Ranke on the nature of history and historiography, to the comprehensive historicist ontology expounded by Heidegger and Gadamer. At the same time, the protracted debate with the universalistic project of the Enlightenment has been accompanying historicism throughout all of its permutations. From Ranke's debate with Hegelianism, through Heidegger's famous encounter with Ernst Cassirer at Davos in 1929, to the Habermas-Gadamer debate, the unresolved battle between historicism and Enlightenment embodies one of the leitmotifs of modern civilization: namely, the perpetual intellectual, cultural, and political tension between the particularizing and the universalizing moments of the modern condition.

See also Philosophy of History.

Bibliography

Ankersmit, Frank R. "Historicism: An Attempt at Synthesis." *History and Theory* 34 (3) (1995): 143–161. This attempt, undertaken by one of today's foremost historical thinkers, to grasp the meaning of historicism serves to point up the importance of understanding this phenomenon in juxtaposition with Enlightenment thought.

Bambach, Charles R. *Heidegger, Dilthey, and the Crisis of Historicism.* Ithaca, NY: Cornell University Press, 1995. Discusses the vicissitudes of historicism within the German philosophical discipline during the late-nineteenth and early-twentieth centuries.

Dilthey, Wilhelm. *Selected Works.* Vol. 1, *Introduction to the Human Sciences.* Translated by Rudolf A. Makkreel and Frithjof Rodi. Princeton, NJ: Princeton University Press, 1989.

Dilthey, Wilhelm. *Selected Works.* Vol. 3, *The Formation of the Historical World in the Human Sciences.* Translated by Rudolf A. Makkreel and Frithjof Rodi. Princeton, NJ: Princeton University Press, 2002. These two works of Dilthey together contain the bulk of his historical thought.

Ermarth, Michael. *Wilhelm Dilthey: The Critique of Historical Reason.* Chicago: University of Chicago Press, 1978. The most systematic discussion of Dilthey's thought.

Gadamer, Hans-Georg. *Truth and Method.* 2nd rev. ed. Translated by Joel Weinsheimer and Donald G. Marshall. New York: Continuum, 1989. In his magnum opus, Gadamer not only lays out his approach in great detail, but also discusses (and clarifies his own position vis-à-vis) many of his predecessors in the historicist and hermeneutical traditions, including Ranke, Droysen, Dilthey, and Heidegger.

Hamilton, Paul. *Historicism.* 2nd ed. London: Routledge, 2003. A useful introduction to the subject, extending the scope of historicism to include Freud, Lacan, Foucault, and Derrida, and placing it in the context of postcolonialism and globalization. Includes a short glossary and suggestions for further reading.

Heidegger, Martin. *Being and Time.* Translated by Joan Stambaugh. Albany: State University of New York Press, 1996. The definitive, though opaque, statement of Heidegger's philosophy.

Iggers, Georg G. *The German Conception of History: The National Tradition of Historical Thought from Herder to the Present.* Rev. ed. Middletown, CT: Wesleyan University Press, 1983. Still the standard account of the historicism that developed within the German historical and social scientific disciplines. Emphasizes the nationalist, illiberal ethical-political dimension of German historical thought through the middle of the twentieth century.

Iggers, Georg G. "Historicism: The History and Meaning of the Term." *Journal of the History of Ideas* 56 (1) (1995): 129–152. An extremely useful recapitulation both of recent trends in the study of historicism and of this authoritative scholar's own understanding of the phenomenon. Includes extensive references to primary and secondary sources.

Krieger, Leonard. *Ranke: The Meaning of History.* Chicago: University of Chicago Press, 1977. The most systematic exposition of Ranke's historical thought.

Reill, Peter Hanns. *The German Enlightenment and the Rise of Historicism.* Berkeley: University of California Press, 1975. A detailed analysis of the complex relationship between historicism and the German Enlightenment.

HISTORY, PHILOSOPHY OF

See *Philosophy of History*

HISTORY AND HISTORIOGRAPHY OF PHILOSOPHY

The term *history of philosophy* is often used in two different senses. In one, it refers to past events (*res gestae*) and, in another, to accounts of those events (*historiae rerum gestarum*). "The history of ancient Greek philosophy" can be taken to indicate views entertained by Greek philosophers, but also the accounts that later historians give of

those views. The positions Aristotle takes in his *Metaphysics* are part of the first but not of the second, whereas those adopted by Joseph Owens in *The Doctrine of Being in the Aristotelian Metaphysics* (1951) are part of the second but not the first.

The term *historiography of philosophy* can also be taken in two senses. According to one, it refers to accounts of past events, and so it is interchangeable with *history* when this term is used in the second sense mentioned above. But *historiography of philosophy* can also be used to mean the discipline that studies and establishes the procedures to be followed in accounts of the views from past philosophers. Aquinas's statement, "whatever is moved is moved by another," is part of the history and historiography of philosophy in the first sense mentioned. But the claim, "A proper understanding of Aquinas's view, that whatever is moved is moved by another, presented in the *Summa theologiae*, requires that we look into what he says about movement elsewhere in his writings," is part of historiography when this is understood as a discipline.

In addition, both the history and the historiography of philosophy need to be distinguished from the philosophy of the history of philosophy. This last studies the history of philosophy understood as past events in order to make claims about its nature and how it develops in general. In doing so, it may refer to particular events of that history, but its primary aim is not to account for them. For example, philosophers of the history of philosophy might claim that philosophy develops according to certain stages, but when they identify the stages through which ancient philosophy passed in particular, they do so to illustrate or establish the first kind of claim.

Because the history of philosophy, the historiography of philosophy, and the philosophy of the history of philosophy are closely connected, their tasks are not often distinguished and philosophers engaged in the pursuit of one also frequently pursue the others. For the sake of clarity, however, this entry will keep them separate, concentrating only on the issues pertaining to the historiography of philosophy when this is understood as the study of the procedures to be followed in the investigation of the philosophical past and of the philosophical issues that this kind of study raises.

Six of these issues have been the focus of most discussions: (1) What kind of claim are historians of philosophy entitled to make? (2) What is the relation between philosophy and the study of its history? (3) What is the value of the study of the history of philosophy for philosophy? (4) What is the role of texts in the study of the history of philosophy? (5) What approach should historians of philosophy use? And (6) what are the main genres historians of philosophy employ?

1. CLAIMS

Disagreements concerning the kind of claim that historians of philosophy are supposed to make center on three possibilities: descriptive, interpretative, and evaluative. A descriptive claim consists of a proposition that accurately (1) presents what particular philosophers said or thought or (2) recounts contemporaneous and later views concerning the positions of the philosophers under study. These claims take forms such as "X stated that P," "X's stating that P is the reason that X gave for holding Q," "M, a contemporary of X, stated that X did not hold that P," "N, a later historian of philosophy, disagreed with M as to X's view," and so on.

In interpretative claims, historians of philosophy go beyond what particular philosophers and their historians said or thought, in order to establish nonexplicit relations between the stated or unstated views of a philosopher or a historian, or between the views of two or more philosophers or historians. They also formulate broad generalizations that purport to characterize the overall approach used by a philosopher or the philosophers from a particular period, and to translate the views of historical figures into the languages and conceptual frameworks of contemporary historians in order effectively to communicate their meaning. Interpretative claims can take various forms, such as: "X held that Q," "X held that Q because X held that P," "X held that Q because Y held that P," "X's view that P led to the abandonment of ~P by her contemporaries," and so on.

Evaluative claims make judgments about the value of philosophical views from the past. These judgments may concern truth, validity, coherence, adequacy, completeness, clarity, social relevance, and so on. Here are some forms that these claims may take: "X's view, that P, is true," "X's argument A is invalid," "X and Y were right in formulating problem P as they did," "X's view that P is a backward step in the history of philosophy," "X's position had an adverse effect on society S," and so on.

The question pertaining to descriptive, interpretative, and evaluative claims that concerns historiographers in particular is the following: Are historians of philosophy supposed to make claims that are descriptive, interpretative, evaluative, or some combination of these? At one extreme, positivist historiographers answer that historians should consign themselves to descriptive claims. Their job is to describe, and not to interpret or to evaluate, the philosophical past (Lafrance 1983). At the other

extreme, historicist historiographers maintain that historians should merely be concerned with interpretation and evaluation because description is impossible. Every historical event is unique and cannot be reproduced either in reality or thought. Therefore, the attempt to describe and understand the past as it was in itself, independently of how it appears to the present, is bound to fail. The job of historians is to present the past as it looks to them at present (Collingwood 1946).

Both positivist and historicist historiographers accuse each other of betraying the historical enterprise. According to the first, the second do so because they fail to account for the past by falling into Anachronism, that is, reading the present into the past. But historicists retort that positivists betray history because they misunderstand the past by falling into Antiquarianism, that is, by failing to grasp the significance of the past for the present.

In between these two extreme positions, various positions attempt to find a more sensible middle ground. Closer to positivism is the view that the history of philosophy needs to be disinterested, that is, it should refrain from any kind of value judgment or interpretation based on value judgments (Garber 1988). Closer to historicism is the position that the history of philosophy should not be conceived as a science at all, but rather, like all philosophy, as a process of edification. Accordingly, it is its current uses and meaning that matter, not what actually happened in the past (Rorty 1984). Closer to the middle, some historiographers argue that historians of philosophy need to engage in description, interpretation, and evaluation: Description, because their aim is to understand and account for the past; interpretation, because the understanding and account of the past requires interpretation; and evaluation, because a history of philosophy without evaluation has no use (Gracia 1992).

2. PHILOSOPHY VS. HISTORY OF PHILOSOPHY

But what is the relationship between philosophy and the history of philosophy? Are they compatible enterprises? And if compatible, how dependent are they on each other? The attempts to answer these questions are plagued with puzzles and difficulties (Powers 1986).

The positions adopted with respect to these questions generally follow those adopted in the previous one. On one side are those historians who draw a sharp distinction between the descriptive aim of the historian of philosophy and the interpretative and evaluative aims followed by the philosopher. According to them, philosophy and the history of philosophy are incompatible insofar as

the philosopher seeks to establish truth in general, whereas the historian of philosophy is merely interested in historical truth, that is, in arriving at accurate descriptions of the philosophical past. The historian studies the history of philosophy in its own terms, not for the philosophical truth it may yield (Frede 1988).

On the other side are those who closely relate the task of description with those of interpretation and evaluation. For some, philosophy necessarily involves the study of its past, so it must be done historically (Cohen 1986); for others, studying the philosophical past requires doing philosophy (Kenny 1995, 1996); and for others still, the relation goes both ways (Taylor 1984). The reason, as given by philosophers with historicist leanings, is that philosophy is a rearticulation of a view about ourselves and the world, and this requires both the understanding of past articulations and a liberation from them. The study of the philosophical past, then, necessarily involves philosophical judgments, and philosophy must study its past to move beyond it; the history of philosophy must be done philosophically and philosophy must be done historically. Indeed, philosophy is a historical enterprise insofar as the thought or statement of a philosophical view is a historical event and thus part of the history of philosophy. So even contemporaneous philosophical discussions necessarily involve historical references and the understanding of the past, even if the history in question is recent (Popkin 1985).

These positions have been criticized in various ways. Some critics point out that they rely on an oversimplification of the issue (Janaway 1988; Alexander 1988), whereas others object that they fail to draw a distinction between objective and methodological necessity (Gracia 1992). Objective necessity holds between a discipline or study on the one hand and its object of study on the other. In this sense, the history of philosophy, considered as past philosophical views, is indeed necessary not just for the study of the history of philosophy but also for philosophy insofar as philosophy studies the world and all human experience of it and the history of philosophy is part of that object. Methodological necessity, however, holds between two studies or disciplines, insofar as there is a necessary dependence of the methods employed by them. This distinction opens the doors to an alternative position to the two mentioned. According to it, the study of the history of philosophy is not methodologically necessary for philosophy, although philosophy is methodologically necessary for the study of its history. One can philosophize without a historical aim or concern; but one cannot investigate the history of philosophy without a

philosophical understanding of the concepts and arguments it contains. The relation of necessity between philosophy and its history, then, is not reciprocal.

3. VALUE

Regardless of the position one takes with respect to the relation between philosophy and the study of its history, one may still ask whether the second is useful or detrimental for the first. Those who argue that the study of the history of philosophy is incompatible with philosophy see only negative influences on it: the study of the history of philosophy stultifies creativity, prevents discoveries, is irrelevant to present concerns, and wastes precious time (Descartes 1970). And for those who hold that doing the history of philosophy is necessary for doing philosophy, the question of the value of the first for the second is obviously irrelevant. However, for those who maintain that the study of the history of philosophy is neither incompatible with nor necessary for doing philosophy, it is pertinent. Some of these believe that the study of the history of philosophy is harmful, whereas others argue that it is beneficial and thus justify it in various ways. At least eight different justifications are common. They can roughly be divided into three groups: rhetorical, pragmatic, and essentialistic.

Rhetorical justifications in turn fall into two groups. According to one, the history of philosophy provides a source of inspiration: past philosophers function as role models whose lives, devoted to the pursuit of truth, inspire us to emulate them (Rée 1978). According to another, the history of philosophy can be a source of support and respectability, and in that way be used to validate the present (Gilson 1955).

Pragmatic justifications can be classified into four types. One argues that the consideration and analysis of a rich historical treasure of philosophical views and arguments can supply present-day philosophers with a fertile ground in which to train for the philosophical task (Yolton 1986). Another proposes that the history of philosophy is a source of solutions to important philosophical problems insofar as many great minds from the past have presented answers to questions still pertinent today and offer us alternatives to contemporary proposals (Curley 1986). A third maintains that the present state of philosophy is one of confusion and "ill health," and the study of the past can help us figure out how and where philosophy went wrong; the study of the history of philosophy can be therapeutic for the present (Bennett 1988). The fourth group combines all three of these justifications, arguing that philosophy can profit from both the failures and successes of the past (Mash 1987).

Essentialistic justifications are cashed out in terms of the nature of philosophy and the way it develops. At least four versions of them have been proposed. One, not explicit among historiographers of philosophy, although applicable to philosophy and used in some sciences, argues that the ontogeny of a discipline recapitulates its phylogeny. The acquisition of philosophical knowledge by an individual person goes through stages that mirror those that the human race as a whole has experienced in its philosophical understanding. The study of the history of philosophy, then, provides a shortcut to the level of understanding that individual philosophers seek. Another argues that the dialectical nature of philosophy requires that we study its past. Regardless of whether this dialectical nature is taken to apply to the dialogue thought to be fundamental to the philosophical enterprise (Veatch 1988) or to a set of stages of development that repeat themselves (Hegel 1974), it appears essential that philosophy engage its past. In the first case, this is because the variety of the past makes it an ideal interlocutor; and, in the second, it is because any stage in the development of philosophy relies on prior stages. A third justification argues that the understanding and management of science and technology is possible only on the basis of historical experience and the history of philosophy supplies it (Krüger 1984). A fourth argues that philosophy is a cultural enterprise that relies on historical elements such as language, values, presuppositions, and so on; to understand the philosophical present, then, we need to go back to the past, for it is from the past that the present has arisen (Gracia 2000).

4. TEXTS

The object studied by historians of philosophy consists of the views of past philosophers, but they have no way of establishing direct contact with those views except through texts. Their access to Kant's philosophy, for example, is only through the texts that express Kant's views, whether they were composed by the author himself or by subsequent historians. The study of the history of philosophy amounts, then, to the study of texts, and this poses a set of questions that fall within what is frequently called hermeneutics. They may be divided roughly into four categories, depending on whether they have to do with texts themselves, their interpretation, their authors, or their audiences.

With respect to texts, the most pertinent questions concern their nature and identity. For purposes of the

history of philosophy, the texts that matter most are written. Oral texts are relevant only insofar as they have survived either in written reports or have been taped. Historians who wish to give an account of William of Ockham's logic, then, begin by looking at copies of the pertinent texts from Ockham, say the *Logica*. But it turns out that the copies of the text they have are not the autograph Ockham wrote. Rather, they are reconstructions produced by editorial processes that took into account various manuscript versions of Ockham's text, and relied on the judgment of various editors as to the most historically accurate reading. This means that historians need to be aware of the distinction between the historical text—the one produced by Ockham—and the text they currently have, which may be called the contemporary text.

Even when historians have access to a philosopher's autograph, however, they may still ask themselves whether the script they have in front of them is the one intended by the author, for the philosopher may have written something he did not intend, or failed to write something he intended. So in addition to the historical text and the contemporary text, historians could take into account what they consider to be the intended text. But there is still more, for some historiographers argue that there is another text that is pertinent, namely the text the author should have written. Ockham may have written something that did not fit his view, because he was distracted or even failed to understand all the implications of his own position. Hence, in addition to the historical, contemporary, and intended, there is also what might be called the ideal text. These different ways of conceiving texts give rise to wide disagreement among historiographers concerning the kind of text that is most pertinent for the study of the history of philosophy.

Two questions in particular are pertinent concerning the interpretation of texts: "What is an interpretation?" and "What is its purpose?" According to a common conception, an interpretation of a text is the understanding that an interpreter has of the text; according to another, it is a text added to the text under interpretation. A example of the first sort is Thomas Aquinas's understanding of Aristotle's *Metaphysics*; an example of the second is Aquinas's *Commentary on Aristotle's "Metaphysics."* The purpose of the interpretation may vary in each case, and this has also been a subject of disagreement, which most frequently occurs along two lines: understanding the meaning of the text or relating the text to something else. The first, in turn, can be broken down depending on various ways of conceiving the meaning of a text: in terms of

the author's understanding or intention, in terms of the understanding of a particular audience, or independently of either the author or any audience. The second purpose of interpretations has been prompted in part by questions raised about the nature and viability of meaning by such Analytic philosophers as W. V. Quine and such Continental philosophers as Jacques Derrida. These questions have undermined meaning-based conceptions of interpretation and have led some historiographers to favor relational ones instead (Daniel 1993). If the purpose of an interpretation is relational, then the interpretation depends on what the text is related to, such as another text, particular historical events, certain conceptual frameworks used in the interpretation, and so on.

Those who make interpretations dependent on authors need to establish the identity of the latter, but this again is contested, for at least three authors need to be considered: historical, pseudohistorical, and contemporary (the terms used to refer to them vary). The first is the person who produced the historical text—the person who wrote Ockham's *Logica* for instance. The pseudohistorical author is the person whom later historians think wrote the text. The pseudohistorical author of the *Logica*, for example, goes by the same proper name as the historical author, but it could in fact be different. The contemporary author is the author of the contemporary text. Recall that the contemporary text is a reconstruction of the autograph carried out by editors on the basis of various texts and readings, so it is likely that it is different from the historical text and, therefore, it would be incorrect to regard the historical author as having sole responsibility for it.

The audience also has frequently been thought pertinent for the interpretation of texts. And here, again, various understandings of it may be considered. For some, authors themselves may be conceived as audiences, whereas others refer to the audiences intended by authors, the audiences contemporary with the composition of the historical text under interpretation, or the audiences contemporary with interpreters. Naturally, these differences in audiences alter the character of an audience-based interpretation. It is one thing to grasp Aristotle's own understanding of his *Metaphysics* and another to comprehend what thirteenth-century scholastics thought of it.

5. APPROACHES

Different views concerning the interpretation of texts generate different approaches to them. Several taxonomies of these have been proposed, but most of them

include some of the following: ideological, sociological, biographical, scholarly, doxographic, apologetic, literary, idealistic, eschatological, dilettantish, and problematic. Ideological approaches use the history of philosophy for the justification of a chosen point of view and treat texts accordingly (Marxist historians). Sociological approaches break down into several, depending on whether they emphasize cultural (Gilson 1955), psychological (Kusch 2000), or generally contextual factors (Peckhaus 2000) in the study of the history of philosophy. Biographical approaches focus on personal histories (Rée 1978). Scholarly approaches seek to establish reliable texts, to produce accurate translations, to determine precise chronologies, and to reconstruct and expound the views of past authors and their relations without engaging in value judgments (Owens 1951). Doxography usually considers facts, figures, and ideas with a primarily informative aim (Diogenes 1925). Apologists see their goal as the defense of a particular author's point of view (John of St. Thomas 1931). The literary approach emphasizes form over content, stressing the need to take the former into consideration for the understanding of the latter (Danto 1985). Idealists consider the views they find in texts as imperfect renditions of what they think are perfect views, so they engage in speculative reconstruction (Russell 1937). Eschatologists view the history of philosophy as progressing toward some end, or as retreating from it (Aristotle 1984). Dilettantes focus on texts in isolation from historical contexts, being interested only in what they can find in them for their own philosophical purposes (Plantinga 1978). And those who adopt a problems approach look at the history of philosophy as a series of attempts to solve philosophical problems (Bennett). A recently proposed variant of the last is the framework approach. According to it, a proper historiographical method should make explicit the conceptual frameworks of problems and views used to study philosophical texts from the past in that such frameworks can be used to understand historical views better both in themselves and in relation to the views of the interpreters and their contexts (Gracia 1992).

A topic of occasional discussion in this context is the nature and value of what is frequently called the Principle of Charity. According to it, historians must attempt to develop the most favorable interpretations of the philosophical views they study. This applies whether the historians agree or disagree with them. If they agree, it is argued that this serves to support their own views, and if they disagree, that then they are presented with the best case against their own positions, forcing them to rethink those views or develop better arguments in their support.

6. GENRES

The genres used in the history of philosophy break down into at least two large categories: textual commentaries and systematic expositions. The first includes more or less literal commentaries. The second breaks down into general or particular histories. General histories of philosophy aim to provide accounts of the whole history of philosophy. Particular histories are concerned with the philosophy of particular periods, regions, nations, ethne, races, and authors, or with specific problems or ideas, and with their comparison. Here are some examples of particular histories: history of medieval philosophy, history of Latin American philosophy, history of French philosophy, history of Hispanic philosophy, history of Black philosophy, Hegel's philosophy, Gustav Bergmann's position on individuation, history of the problem of universals (in general or in a particular period), and the history of the idea of substance. Historiographers disagree on the comparative value of these genres, but they continue to use them.

HOBBES, THOMAS

(1588–1679)

Thomas Hobbes, often called the father of modern analytic philosophy, was born in Malmesbury, Wiltshire, England. Hobbes later enjoyed jesting about the significance of his manner of entry into the world. (He was born prematurely when his mother heard of the approach of the Spanish Armada.) "Fear and I were born twins," he would say, adding color to his conviction that the fear of death and the need for security are the psychological foundations both of worldly prudence and of civilization itself. He died at the age of ninety-one in Hardwick, Derbyshire, after a life of travel, study, polemical controversy, and philosophical and literary activity that in his later years had virtually established him as an English institution.

EARLY YEARS

Hobbes's father, Thomas Hobbes, was vicar of Westport, an adjunct of Malmesbury, but his conduct reflected little credit on his cloth. After being involved in a brawl outside his own church, he had to flee to London, leaving Thomas to be brought up by a wealthy uncle, who took the matter of his education very seriously. When he was only fourteen, Hobbes was sent to Magdalen Hall, Oxford, where he remained for five years before taking his bachelor's degree. He seems to have been bored by his Aristotelian tutors, although he acquired considerable proficiency in logic. The strong Puritan tradition of his college impressed Hobbes, but the drunkenness, gaming, and other vices that were prevalent equally impressed him. On leaving Oxford in 1608, Hobbes had the good fortune to become tutor to the young son of William Cavendish, earl of Devonshire. This circumstance introduced him to influential people, to a first-class library, and to foreign travel.

In 1610, on the first of Hobbes's visits to the Continent, he discovered the disrepute into which the Aristotelian system of thought was beginning to fall. Johannes Kepler had recently published his *Astronomia Nova,* and Galileo Galilei had just discovered the satellites of Jupiter through his telescope. Hobbes returned to England determined to devote himself to the pursuit of learning, a resolve that was probably strengthened by his meetings

with Francis Bacon. Hobbes, however, thought little of Bacon's so-called method of induction, with its stress on observation and experiment, which was later to become the inspiration of the Royal Society. Nevertheless, he agreed with Bacon in his contempt for Aristotelianism, in his conviction that knowledge means power to be used for the improvement of man's estate, and in his advocacy of clear and concrete speech instead of the vague abstractions of the schools.

At this period of his life Hobbes had turned to the classics to gain an understanding of life and of philosophy, which, he thought, could not be found in the schools. After a period of reading and reflection, he decided to translate Thucydides into English, a significant choice. Like Thucydides, Hobbes believed that history was written for instruction, and he wished to instruct his countrymen on the dangers of democracy. In 1628, when Hobbes published his translation, Charles I had been on the throne for three years and was already at loggerheads with Sir John Eliot and John Pym. Hobbes's translation was the first of his many attempts to bring his countrymen to their senses and to make them aware of the tragedy that they courted: that of civil war, from which proceed "slaughter, solitude, and the want of all things."

PHILOSOPHICAL AWAKENING

It was not until the time of his second journey to the Continent that Hobbes's career as a philosopher began. His patron had died, and as a temporary economy, Catherine, the countess of Devonshire, had dispensed with Hobbes's services. Hobbes took similar employment with Sir Gervase Clinton and, in 1629, accompanied Clinton's son on a journey to the Continent. There Hobbes developed a passionate interest in geometry, which impressed him as a method for reaching indubitable conclusions. Could not his convictions about the dangers of democracy be demonstrated? Could not his opinions about man, gleaned from his observation of the contemporary scene, from his insight into his own nature, and from his perusal of the pages of Thucydides and Niccolò Machiavelli, be postulated as axioms from which theorems about the conditions of a commonwealth might be generated?

Hobbes's discovery of geometry gave him a method of analysis and a conception of scientific method, but he still lacked a conceptual scheme to give content to his demonstrations about man and society. In Paris, during his third journey to the Continent (1634–1637), again in the service of the Devonshires as tutor to William, the succeeding earl, he became a member of the intellectual

circle of the Abbé Marin Mersenne, who patronized René Descartes and Pierre Gassendi. (Gassendi later became one of Hobbes's firmest friends.) Hobbes also made a pilgrimage to Italy in 1636 to visit Galileo, the leading exponent of the new natural philosophy. By the time of his return to England in 1637, he had conceived, perhaps at Galileo's suggestion, the main outlines of his philosophical system, in which the method of geometry and the concepts of the new science of motion were to be applied to man in society.

It is a mistake to think of Hobbes's interests as purely political. Hobbes claimed originality for his optics as well as for his civil philosophy, and at some point between his discovery of geometry and his return from his third journey to the Continent, he wrote his first philosophical work, the *Little Treatise,* in geometrical form, in which he sketched an explanation of sensation in terms of the new science of motion. His interest in sensation, according to his prose autobiography, arose from an encounter with some learned men who were discussing the cause of sensation. One of them asked derisively what sensation was, and Hobbes was astonished to find that none of them could say. From then on, he was haunted by the problem of the nature and cause of sense. He began to think he was near an explanation after it struck him that if bodies were always at rest or always moved at a constant rate, the ability to make discriminations would vanish, and with it all sensation. He concluded that the cause of everything, including that of sensation itself, must be in variations of motion.

In his verse autobiography, Hobbes graphically related how, on his third journey, he was obsessed by the omnipresence of motion. He was acclimating himself to Galileo's audacious suggestion that motion is the natural state of bodies and that they continue in motion to infinity unless they are impeded. This went against the crude evidence of the senses as well as against the established Aristotelian worldview, in which rest was regarded as the natural state. But if Galileo's supposition could be entertained, Hobbes thought, even apparition itself could be explained as a meeting place of motions, and from Galileo's law of inertia the phenomena of sense and imagination could be deduced.

The state of turmoil in England on his return drove Hobbes to make his first systematic attempt to employ his geometrical approach and mechanistic psychology to present the realities beneath the appearances of the contemporary issues. His *Elements of Law,* circulated in 1640 in manuscript form during the session of Parliament, was the result. This work, which demonstrated the need for undivided sovereignty, was published in 1650 in two parts, *Human Nature* and *De Corpore Politico.* However, its arguments were taken from general principles of psychology and ethics, rather than from appeals to divine right. Many regard Hobbes's *Human Nature* as one of his best works. It consists largely of traditional psychology coordinated and underpinned by the conceptual scheme he had learned from Galileo.

EXILE IN FRANCE

Hobbes claimed later that his life would have been in danger because of the views expressed in *Elements of Law,* had not the king dissolved Parliament in May 1640. Six months later, when the Long Parliament impeached Thomas Wentworth, earl of Strafford, Hobbes fled to the Continent in fear for his life, later priding himself on being "the first of all that fled." A warm welcome awaited him in Mersenne's circle, and he settled down in Paris to his most productive philosophical period.

His first work was the composition of some sixteen objections to Descartes's *Meditations,* which Mersenne submitted to Descartes in advance of its publication. This led to a rather acrimonious exchange between Descartes and Hobbes. In 1642 Hobbes published his *De Cive,* an expanded version in Latin of Part 2 of his *Elements of Law* (later to appear as *De Corpore Politico*). The additional sections dealt largely with a more detailed treatment of the relationship between the church and the civil power. During the period from 1642 to 1646, Hobbes published his *Minute or First Draught of the Optiques,* which he considered one of his most important and original works. He also started work on his most ambitious scheme—the construction of a trilogy on body, man, and citizen, in which everything in the world of nature and man was to be included in a conceptual scheme provided by the new science of mechanics. Hobbes made a beginning with *De Corpore,* which was to be the first work in the trilogy.

In 1646, however, political events again interfered with Hobbes's more abstract speculations. He was on the verge of accepting an invitation to retire in peace to a friend's house in Languedoc, in the south of France, when he was requested to act as tutor in mathematics to the future Charles II, who had just fled to Paris. Hobbes's tutorship, however, was interrupted, if not terminated, by a severe illness in 1647. He recovered after having consented to receive the sacrament on what he took to be his deathbed, and he was drawn again into political controversy by the presence of so many Royalist *émigrés.* A second edition of *De Cive* was published in 1647, but this was in Latin and had only a limited circulation. Hobbes

therefore decided to blazon abroad his views on man and citizen for all to read, in English, with the arresting title of *Leviathan*. With Mersenne's unfortunate death in 1648, Hobbes began to feel increasingly isolated, for he was suspected of atheism and was an outspoken enemy of the Catholic Church.

Political events in England provided a fitting prelude to the publication of *Leviathan*. Charles I was executed in 1649 and, until 1653, when Oliver Cromwell was made Protector, there was constant discussion and experimentation to find an appropriate form of government. *Leviathan*, published in 1651, was therefore very topical. It came out strongly in favor of absolute and undivided sovereignty, without the usual arguments from divine right. Indeed, Hobbes conceded popular representation but, by an ingenious twisting of the social contract theory, showed that it logically implied the acceptance of undivided sovereignty.

RETURN TO ENGLAND

Hobbes returned to England in 1651 after a severe illness and soon became embroiled in a heated debate with John Bramhall, bishop of Derry, Ulster, on the subject of free will. In 1645, in Paris, Hobbes had discussed the problem of free will with the bishop, and they both wrote their views on the matter soon afterward. A young disciple of Hobbes published his contribution in 1654, without Hobbes's consent, under the title *Of Liberty and Necessity*. Bramhall was understandably indignant and, in 1655, he published the whole controversy under the title *A Defence of True Liberty from Antecedent and Extrinsical Necessity*. In 1656 Hobbes replied by printing Bramhall's book, together with his own observations on it, which he called *The Questions concerning Liberty, Necessity, and Chance*. Bramhall replied in 1658 with *Castigations of Hobbes his Last Animadversions*, which carried an appendix called "The Catching of Leviathan the Great Whale." Bramhall died in 1663, and Hobbes had the last word a few years later.

There was another controversy in which Hobbes was caught up for the major part of the twenty years that were left to him. This one involved John Wallis, professor of geometry at Oxford, who mercilessly exposed Hobbes's attempt in *De Corpore* (1665) to square the circle—not then such a ridiculous enterprise as it now seems—and Seth Ward, professor of astronomy, who launched a polemic against Hobbes's general philosophy. These two men were members of the "invisible college" that the king had recognized as the Royal Society in 1663. They were Puritans in religion and Baconians in their approach to

science. Hobbes had annoyed them not simply by his attack on their religion and his contempt for the method of induction, but also by his diatribes on the universities as hotbeds of vice and sedition. Hobbes replied to their published criticisms with an emended English version of *De Corpore* with "Six Lessons" appended for Wallis. This was in turn attacked by Wallis, and the controversy dragged on for many years, often descending into personal vituperation on both sides.

Not all of Hobbes's remaining years, however, were spent on this abortive controversy. *De Homine*, the second part of his trilogy, was published in 1657. This dealt with optics and human nature, matters on which Hobbes's opinions were already well known; accordingly, it attracted little attention and was not translated.

After the Restoration, Hobbes was granted a pension and "free accesse to his Majesty, who was always much delighted in his witt and smart repartees" (John Aubrey, *Brief Lives*, pp. 152–153). Only once again did he fear for his life. After the Great Plague (1665) and the Great Fire of London (1666), some reason was sought for God's displeasure, and a spasm of witch-hunting shook Parliament. A bill was passed by Parliament for the suppression of atheism, and a committee was set up to investigate *Leviathan*. The matter was eventually dropped, probably through the king's intervention, but Hobbes was forbidden to publish his opinions thereafter.

In 1668 Hobbes finished his *Behemoth*—a history of the period from 1640 to 1660, interpreted in the light of his beliefs about man and society. He submitted it to King Charles, who advised against its publication (it was published posthumously in 1682).

Even at this advanced age Hobbes was still capable of exerting himself both physically (he played tennis until he was seventy-five) and philosophically. John Aubrey, later his biographer, sent him Bacon's *Elements of Common Law* for his comments; and Hobbes, after protesting his age, managed to produce his unfinished *Dialogue between a Philosopher and a Student of the Common Laws of England* (published posthumously in 1681). This minor work was interesting in that Hobbes anticipated in it the analytical school of jurisprudence of the nineteenth century and came out unequivocally in favor of what has been called the command theory of law. At the age of eighty-four Hobbes wrote his autobiography in Latin verse after completing one in prose. At eighty-six, for want of something better to do, he published a verse translation of the *Iliad* and the *Odyssey*.

LOGIC AND METHODOLOGY

Hobbes lived during the emergence of men who challenged not only traditional tenets about political and religious authority but also the wisdom of the past, especially that of Aristotle. Men were exhorted to find out things for themselves, to consult their own consciences, and to communicate with God directly, instead of through the established religious hierarchy. It was widely believed that all men have the gift of reason but that they make poor use of it through lack of a proper method. Books such as Bacon's *Novum Organum,* Descartes's *Regulae* and *Discourse on Method,* and Benedict de Spinoza's *Ethics* were written to remedy this defect. Thus, Hobbes was not exceptional in believing that knowledge, which meant power, could be obtained only by adopting a certain kind of method.

According to Hobbes, the knowledge whereby most men live is the knowledge gleaned from experience, culminating in prudence and history—"the register of knowledge of fact." Hobbes described experience as "nothing but remembrance of what antecedents have been followed by what consequents." Bacon had tried to set out this sort of knowledge explicitly in his *Novum Organum,* and it was taken by the Royal Society to be the paradigm of science.

DOCTRINE OF NAMES. Hobbes, however, was very contemptuous of such grubbing around and peering at nature, not only in natural philosophy but also in civil philosophy. Had Galileo or William Harvey, the pioneers of the new philosophy, made a laborious summary of their experience? And in civil philosophy, what store is to be placed on the dreary saws of practical politicians or the ossified ignorance and superstitions of the common lawyers? Mere prudence, which is the product of experience, should not be mistaken for wisdom. Wisdom is the product of reason, which alone gives knowledge of "general, eternal, and immutable truths," as in geometry.

In geometry, definitions are of paramount importance. Therefore, claimed Hobbes: "The only way to know is by definition." Thus, science is "knowledge of all the consequences of names appertaining to the subject in hand." It gives knowledge not of the nature of things but of the names of things. We start with certain terms or names about whose definition we agree. We connect these into such statements as "A man is a rational, animated body," just as we add items in an account. We then find that if we follow certain methods of combining the statements so created, conclusions can be drawn that are contained in the premises but of which we were ignorant

before we started reckoning. "For REASON, in this sense, is nothing but reckoning, that is adding and subtracting, of the consequences of general names agreed upon for the marking and signifying of our thoughts."

Obvious objections to such an account of scientific knowledge immediately come to mind. How, for instance, can we be sure that such a train of reasoning applies to anything? How are the meanings of Hobbes's names fixed, and how are the rules for their combinations determined?

Hobbes supposed that "names are signs not of things, but of our cogitations." Words are not the only things that can be signs; for instance, a heavy cloud can be a sign of rain. This means that from the cloud we can infer rain. This is an example of a natural sign; other examples are animal warnings of danger and summonses to food. These natural signs are to be distinguished from language proper, which consists of sounds, marks, and other such significations determined—as are the ruler of civil society—by decision. Animal noises come about by necessity, not by decision, as human speech does. That is why, on Hobbes's view, animals, though capable of imagery, cannot reason; for reasoning presupposes words with meanings fixed by decision.

Hobbes thought that every man has his own private world of phantasms or conceptions, for which words are signs that function for him like a private system of mnemonics. These words act as signs to others of what a man thinks and feels. Although some words signify conceptions, they are not names of conceptions; for Hobbes seemed to use the word *name* for the relation of reference between names and things, and words such as *signify* for the relationship between particular occurrences of a name and the idea in a person's mind. Some names are names of things themselves, such as "a man," "a tree," or "a stone," whereas others, such as "future," do not stand for or name things that as yet have any being. Such words signify the knitting together of things past and things present. In a similar way there are names, such as "impossible" and "nothing," that are not names of anything. Such names are signs of our conceptions, but they name or stand for "things" that do not exist.

Hobbes's doctrine was not altogether clear. He seemed to mean that all names serve as mnemonics to us of our conceptions and as signs to others of what we have in mind, but that only some names actually denote things in a strict sense. This leads to the distinctions that Hobbes introduced in relation to the logical function of names. Names can be either concrete or abstract. Concrete names can denote bodies, their accidents, or their names.

Abstract names come into being only with propositions and denote "the cause of concrete names."

UNIVERSALS. There are two classes of concrete names: proper names and universal names. A proper name, such as "Peter," is singular to one thing only; a universal name, such as "man," denotes each member of a class of things. A universal name, "though but one name, is nevertheless the name of diverse particular things; in respect of which together, it is called a universal; there being nothing in the world universal but names; for the things named are every one of them individual and singular."

Hobbes's doctrine of universal names was crucial to his attack on the scholastic belief in essences. The world, Hobbes maintained, contains no such essences for universal names to designate. "Universal" is the name of a class of names, not of a diaphanous type of entity designated by a name. The error of those who believe in essences derives from their tendency to treat a universal name as if it were a peculiar kind of proper name. It is the *use* of a name that makes it universal, not the status of the thing that the name designates.

Hobbes's doctrine of abstract names was more obscure but of cardinal importance in his account of scientific knowledge. Abstract names come into being when names are joined in propositions. A proposition is "a speech consisting of two names copulated, by which he that speaketh signifieth the latter name to be the name of the same thing whereof the former is the name." For instance, in saying "man is a living creature," the speaker conceives "living creature" and "man" to be names of the same thing, the name "man" being comprehended by the name "living creature." This relation of "comprehension" can be brought out in some languages by the order of words without employing the verb "to be." The copulation of the two names "makes us think of the cause for which these names were imposed on that thing," and this search for the causes of names gives rise to such abstract names as "corporeity," "motion," "figure," "quantity," and "likeness." But these denote only the causes of concrete names and not the things themselves. For instance, we see something that is extended and fills space, and we call it by the concrete name "body." The cause of the concrete name is that the thing is extended, "or the extension or corporeity of it." These causes are the same as the causes of our conceptions, "namely, some power of action, or affection of the thing conceived, which some call the manner by which anything works upon our senses, but by most men they are called accidents." Accidents are neither the things themselves nor parts of them, but "do never-

theless accompany the things in such manner, that (saving extension) they may all perish, and be destroyed, but can never be abstracted." Among such accidents some are of particular importance for science, those which Hobbes sometimes referred to as "universal things" or "such accidents as are common to all bodies." These are the abstract concepts by means of which a theory is developed about the underlying structure of nature. The endeavor of the scientist is to understand, by means of the resoluto-compositive method of Galilean mechanics, the universal cause—motion—without knowledge of which such fundamental theories could not be developed.

MISUSES OF WORDS. Hobbes has often been called the precursor of modern analytical philosophy because he was particularly sensitive to the manner in which ridiculous (and dangerous) doctrines can be generated through confusion about how words have meaning. One class of absurdities is generated by failure to understand the different ways in which the copula "is" can function. Such terms as *essence, reality,* and *quiddity,* beloved by the schools, "could never have been heard among such nations as do not copulate their names by the verb 'is,' but by adjective verbs as runneth, readeth." The word *is* in a proposition such as "Man is a living body" has the function of "comprehension" or class inclusion. Something of the form "If *x* is a man, then *x* is a living body" is being stated. There is no commitment to the existence of men that is implied when *is* occurs in such statements as "Here is Thomas Hobbes."

Absurdities also arise if names of accidents are assimilated to names of bodies. For instance, those who say that faith is "infused" or "inspired" into a person treat faith as if it were the name of a body, for only bodies can be poured or breathed into anything. An accident is not in a body in the same sort of way that a body can be in a body—"as if, for example, redness were in blood, in the same manner, as blood is in a bloody cloth." Hobbes was also eloquent on the subject of names that name nothing.

SCIENTIFIC TRUTH. Hobbes's theory of scientific truth was not altogether consistent. He started with the important insight that "true" and "false" are attributes of speech, not of things. Truth, then, "consisteth in the right ordering of names in our affirmations." It characterizes propositions in which names of limited generality are "comprehended" by those of wider generality: For example, "Charity is a virtue." Hobbes held, it therefore seems, that all true propositions are analytically true, which is a plausible enough view if only geometrical truths are at issue. But Hobbes often spoke as if all truth must con-

form to this model. He saw that this raises the question of how the initial definitions are to be fixed, and about these definitions he often seemed to take a conventionist view by suggesting that "truth therefore depends upon the compacts and consents of men." He often linked the contract theory of the origin of civil society with a theory about agreement on definitions. When he was speaking about natural science, however, his position was not so clearly conventionist. The difference was caused by his assumption that men construct states just as they construct circles or triangles. But since they do not construct natural bodies in the same way, the problem therefore arises as to how Hobbes thought that propositions of natural science, which did not come into being through decisions of men, say what is true about the natural world.

Hobbes thought that all the propositions of natural science are deductions from the basic theory of motion, in which there are primary propositions containing such simple unanalyzable concepts as motion, extension, and straightness. These are "well enough defined, when, by speech as short as may be, we raise in the mind of the hearer perfect and clear ideas of the thing named" (*De Corpore*). Such conceptions are featured in Hobbes's account of evidence, which is "the concomitance of a man's *conception* with the *words* that signify such conception in the act of ratiocination" (*Human Nature*). A parrot could speak truth but could not know it, for it would lack the conceptions that accompany the speaking of truth by a man who knows truth. "Evidence is to truth, as the sap to the tree … for this evidence, which is meaning with our words, is the life of truth. Knowledge thereof, which we call *science,* I define to be *evidence of truth,* from some beginning or principle of *sense.*"

Conceptions, in Hobbes's view, are explained causally in terms of motions that arise in the head and persist after the stimulation of sense organs by external bodies. Names, which are joined together in true propositions, are signs of these conceptions in that they mark them for the individual and enable other people to make inferences about what he thinks. Thus, Hobbes must have thought that when a man knows (as distinct from when he merely speaks) what is true, his conceptions, as it were, keep pace with what he is saying. Some of these conceptions, those involved in understanding primary propositions, are clear and distinct ideas of things named. Thus, scientific systems are somehow anchored to the world of nature by means of names that refer to attributes of bodies of which we have a clear and distinct idea.

This theory resembles, in certain respects, the self-evidence theory of the Cartesians. However, it seems inconsistent with the conventionalism of Hobbes's other remarks about basic definitions and is a very confused account in itself, not very helpful in elucidating what makes scientific propositions true. In the empirical sciences the clarity of the ideas in the initial postulates is neither here nor there. What matters is whether statements deduced from them can be observationally confirmed.

SCIENTIFIC INQUIRY. The ambiguity in Hobbes's account of truth is paralleled by the ambiguity in his account of scientific method, which he equated with the search for causes. One of his most famous definitions of philosophy or scientific knowledge (he did not distinguish between the two) occurs at the start of *De Corpore* (Molesworth ed.): "philosophy is such knowledge of effects or appearances, as we acquire by true ratiocination from the knowledge we have first of their causes or generation: And again, of such causes or generations as may be from knowing first their effects." By "cause" Hobbes meant, of course, antecedent motion, and he was unusual in thinking that even geometrical figures are to be explained in terms of motion because of the movements involved in constructing them.

Hobbes's distinction between these two forms of philosophical knowledge is important. In the case of acquiring knowledge of effects from knowledge of causes or generation, his conventionist account of truth holds good. For instance, in the case of deciding that a figure must be a circle from our knowledge of the motions from which it was produced, "the truth of the first principles of our ratiocination, namely definitions, is made and constituted by ourselves, whilst we consent and agree upon the appellation of things." He used this method in *De Corpore* to explain parallel lines, refraction and reflection, circular and other forms of motion, angles, and similar concepts. It also seems that he had this model in mind when he thought about the generation of the artificial machine of the commonwealth.

When dealing with knowledge of causes from effects, however, Hobbes's account is far less clear-cut and conventionist. At the beginning of Part 4 of *De Corpore,* for instance, he said: "The principles, therefore, upon which the following discourse depends, are not such as we ourselves make and pronounce in general terms, as definitions: but such, as being placed in the things themselves by the Author of Nature, are by us observed in them." The explanations that we give in the natural sciences may be true, but it is impossible to demonstrate that they are necessarily true, for the phenomena are not generated by

human contrivance, as are the phenomena of geometry and politics.

The method on which Hobbes was relying in both these types of scientific inquiry was, of course, the resoluto-compositive method of Galilean mechanics. In this method a typical phenomenon, such as the rolling of a stone down a slope, was taken. Such properties as color and smell, which were regarded as scientifically irrelevant, were disregarded, and the situation was resolved into simple elements that could be quantified—the length and angle of the slope, the weight of the stone, the time the stone takes to fall. The mathematical relations disclosed were then manipulated until functional relations between the variables were established. The situation was then synthesized or "composed" in a rational structure of mathematical relations. This is what Hobbes called analysis—the search for causes, given the effects. "Synthesis" consisted in starting from the known causes and deducing effects from them. In Galileo's hands this method was highly successful because he tested such deductions by observation. In Hobbes's hands the method was not so fruitful because it always remained an imaginary experiment.

Similar ambiguities in Hobbes's methodology complicate our effort to understand his conception of his trilogy on body, man, and citizen. He thought of geometry as the science of simple motions that could demonstrate how figures are generated by varieties of motion. Second came the philosophy of motion, as usually understood in the Galilean system, in which the effects of the palpable motions of one body on another were considered. Third came physics, the investigation of the internal and invisible motions that explain why "things when they are the same, yet seem not to be the same, but changed." Sensible qualities, such as light, color, heat, and sound, were to be explained, together with the nature of sensation itself. After physics came moral philosophy, the study of the motions of the mind—appetites and aversions. Such motions of the mind had their causes in sense and imagination. Finally, there was civil philosophy, the study of how states are generated from the qualities of human nature.

It is probable that Hobbes did not view the hierarchy of sciences as a rigorous deductive system. To start with, he never worked out the deductions in any detail—for instance, in the transition from what he called physics to moral philosophy, or psychology. Furthermore, what he said about the possibility of a self-contained science of politics contradicts his suggestion that it must be deduced from the fundamental theory of motion and

that it supports the conventionist account of truth in politics. Hobbes said that even those who are ignorant of the principles of physics and geometry might attain knowledge of the principles of politics by the analytical method. They could start, for instance, with the question of whether an action is just or unjust; "unjust" could be resolved into "fact against law," and "law" into "command of him or them that have coercive power"; "power" could in its turn be derived from the wills of men who established such power so that they might live in peace.

This line of argument, developed in *De Corpore* after admitting the possibility of using the synthetic method to start from the first principles of philosophy and deduce from them the causes and necessity of constituting commonwealths, is confirmed by Hobbes's injunction in the Introduction to *Leviathan* that a man who is to govern a whole nation must "read in himself, not this or that particular man; but mankind: which though it be hard to do, harder than to learn any language of science; yet when I shall have set down my own reading, orderly and perspicuously, the pains left another, will be only to consider, if he find not the same in himself. For this kind of doctrine admitteth no other demonstration." It appears that Hobbes envisaged a relatively self-contained doctrine of politics based on introspection. His trilogy was, therefore, probably not conceived as forming a strictly deductive system. Its various elements were to be more loosely bound together by the fact that all three were sciences of motion.

PHILOSOPHY OF NATURE

Hobbes's natural philosophy seems to have been stimulated largely by the problem of the nature and cause of sensation that had so long haunted him. His theory was that the cause of everything, including sensation itself, lies in the varieties of motion. His first sketches of such a theory were in his *Little Treatise* and his early optical treatises, and his *De Corpore* was an ambitious development of this fundamental idea. Geometry, physics, physiology, and animal psychology were all incorporated within the theory of motion. Sensation occupied a shadowy middle position between the gross motions of the external world and the minute motions of the bodily organs.

The strange thing about Hobbes's preoccupation with sensation is that he seems to have been little troubled by the problems that are almost the stock in trade of philosophers—the problems of epistemology. He assumed that things exist independently of our perceptions of them and was convinced that "conceptions and apparitions are nothing really but motions in some inter-

nal substance of the head." The "nothing but" is very hard to accept, for obviously when we speak of "thoughts" and "conceptions," we do not mean the same as when we talk of motions in the brain.

MOTION AND QUALITIES. On the status of the various sense qualities, Hobbes held, as did such natural philosophers as Kepler and Galileo, that secondary qualities—such as smells, colors, and sounds—are only appearances of bodies, whose real properties are those of extension, figure, and motion. Such secondary qualities are phantasms in the head, caused by the primary properties of external objects interacting with the sense organs, but the secondary qualities represent nothing outside. Hobbes argued that images and colors are "inherent in the sentient" because of illusions and because of images produced in other ways—for example, by blows on the optic nerve. But this proved too much, for representations of primary qualities are equally liable to deceive. Hobbes also proved too little, for he argued that secondary qualities represent no qualities of external objects because tastes, smells, and sounds seem different to different sentients. But there are standard tests for establishing the fact, for example, that a man is colorblind; and, as George Berkeley later showed, the perception of primary qualities is infected with a similar relativity owing to the point of view and peculiarities of the percipient. Hobbes, in fact, gave but a halting philosophical patter to justify a distinction deeply embedded in the thought and practice of the new natural philosophers, for the basic tenet of these thinkers was that bodies in motion exist independently of our perception of them and that mathematical thinking about them discloses their real properties.

Hobbes regarded sensation and apparition as a meeting place of motions. Sense organs, he thought, are agitated by external movements without which there would be no discrimination and, hence, no sensation. Therefore, to give the entire cause of sense, an analysis is required of all movements in external bodies, which are transmitted to the sense through a medium. But sensation is not simply the end product of external motions; it also functions as an efficient cause of actions of sentient beings. Actions, in Hobbes's view, are really reactions to stimuli that are passed on by means of the sense organs. Sensation acts as a bridge between movements in the external world and the behavior of animals and men.

Hobbes's mechanical theory was distinctive in that he extended the Galilean system in two directions: into geometry at one end, and into psychology and politics at the other. He thought that no one could understand the definitions of geometry without grasping how motion is involved in the construction of lines, superficies, and circles. Geometry is the science of simple motions. It paves the way for mechanics, which explains the effects of the motions of one body on another, and for physics, which deals with the generation of sensible qualities from the insensible parts of a body in contact with other moving bodies.

CAUSATION. All causation, in Hobbes's view, consists in motion. "There can be no cause of motion except in a body contiguous and moved." If bodies are not contiguous and yet influence one another, this influence has to be conveyed either by a medium or by emanations of minute bodies that impinge on others (the theory of effluxes). There can be no action at a distance. Hobbes combined this principle with his rendering of Galileo's law of inertia.

Hobbes extended this conception of causation to human actions: "A final cause has no place but in such things as have sense and will; and this also I shall prove hereafter to be an efficient cause." To bring about this transition from mechanics to physiology and psychology, Hobbes introduced the concept of "endeavour," which he defined as "motion made in less space and time than can be given … that is, motion made through the length of a point, and in an instant or point of time." In other words, he used the term to postulate infinitely small motions, and by means of this notion he tried to bridge the gap between mechanics and psychology. He thought that external objects, working on the sense organs, produce not only phantasms but also minute motions that proceed to the heart and make some alteration in the vital motions of the circulation of the blood. When these vital motions are thereby helped, we experience pleasure; when they are hindered, we experience pain. The body will be regulated in such a way that it will preserve the motions that help the vital motions and get rid of or shun those that hinder. This brings about animal motion. Even habits are nothing but motions made more easy by repeated endeavors; they are comparable to the bend of a crossbow.

Hobbes has often been called a materialist, but it is more appropriate to regard him as a great metaphysician of motion. He took concepts that have an obvious application to one realm of phenomena (mechanics) and developed a conceptual scheme that, he thought, could be applied to all phenomena. The plausibility of such a scheme derives from stressing tenuous similarities and ignoring palpable differences. There is a sense in which

social life is a matter of bodies moving toward and away from other bodies, just as there is a sense in which work is moving lumps of matter about. But such descriptions are either unilluminating truisms, or, if they carry the "nothing but" implication, they are misleading. Habits, for example, may be formed in part by a variety of movements, but to suggest that by "habit" we mean nothing but a buildup of movements is ridiculous. This either confuses a question of meaning with a question of genetic explanation or it demonstrates the length to which Hobbes was prepared to go in rigging appearances to suit his metaphysical redescription.

SUBSTANCE AND ACCIDENT. In his *De Corpore* Hobbes defined "body" as "that which having no dependence upon our thought, is coincident and coextended with some part of space." Bodies need not be visible. Indeed, "endeavours," which featured so widely in his system, are movements of minute unobservable bodies. Hobbes held that there is nothing else in the world but bodies, and he therefore did not flinch from the conclusion that "substance incorporeal" is a contradiction in terms. He argued that God cannot be such a substance. To Bishop Bramhall's question of what he took God to be, Hobbes replied, "I answer, I leave him to be a most pure, simple, invisible, spirit corporeal."

By "accident" Hobbes meant a property or characteristic that is not a part of a thing but "the manner by which any body is conceived." Most accidents, with the exception of figure and extension, can be absent without destruction of the body. But Hobbes was not altogether clear about the grounds for such an exception. If the grounds are the inconceivability of a body without figure and extension, why should not color be in the same category as figure? Hobbes regarded color as a subjective appearance brought about by the interaction of sense organs with the primary qualities of external objects; but if the criterion is one of conceivability, as Berkeley pointed out, it is as difficult to conceive of a body without color as it is to conceive of one without figure. Hobbes in fact defined "body" in terms of accidents that are mathematically tractable in mechanics and geometry. He tried to provide some kind of rationale for this basic assumption of the new natural philosophy by introducing the criterion of conceivability, which will not really do the work required of it.

Hobbes defined space as "the phantasm of a thing existing without the mind simply." By this he meant that what is called space is the appearance of externality. If the world were to be destroyed, and a man were left alone with his imagination and memories, some of these would appear external to him, or located in space, for the system of coordinates used to describe the relative position of bodies is a subjective framework. "Place is nothing out of the mind nor magnitude anything within it." A body always keeps the same magnitude, whether in motion or at rest, but it does not keep the same place when it moves. Place cannot, therefore, be an accident of bodies; place is feigned extension—an order of position constructed from experience of real extended things to provide a framework for their externality. Similarly, time is "the phantasm of before and after in motion." Time systems are constructed from the experience of succession.

Hobbes never made clear the relationship between any particular temporal or spatial system that an individual may devise and the system of coordinates adopted by the natural philosophers. Here again, Hobbes typically took for granted the system used by the scientists and tacked on a very brief philosophical story about its relation to the "phantasms" of the individual.

PSYCHOLOGY

Hobbes's psychology was not behavioristic, as it has sometimes been said to be, except insofar as behaviorism has often been associated with a materialistic metaphysical theory or with mechanical modes of explanation. Hobbes stressed the indispensability of introspection in the analysis and explanation of human behavior.

When Hobbes looked into himself he found, of course, motions that were in conformity with Galilean principles. He boldly proclaimed in *De Corpore* that "we have discovered the nature of sense, namely, that it is some internal motion in the sentient." The external body, either directly or via a medium, presses on the organ of sense, "which pressure, by the mediation of the nerves, and other strings and membranes of the body, continues inwards to the brain and heart, causeth there a resistance, or counterpressure, or endeavour of the heart to deliver itself, which endeavour, because outward, seemeth to be some matter without." Sensations are thus nothing but motions. They have the character of externality because of the "outward endeavor" of the heart.

PERCEPTION. Having provided a mechanical starting point for his psychology, Hobbes then tried to describe what was known about psychological phenomena in terms compatible with a mechanical theory. One of the most obvious features of perception is that it involves seeing something as something, some sort of discrimination or recognition. Hobbes's way of saying this was that sense

always has "some memory adhering to it." This was to be explained by the sense organs' property of acting as retainers of the movements of external bodies impinging on them. Without this retention of motions, what we call sense would be impossible, for "by sense we commonly understand the judgment we make of objects by their phantasms; namely, by comparing and distinguishing those phantasms; which we could never do, if that motion in the organ, by which the phantasm is made, did not remain there for some time, and make the same phantasm return."

The selectivity of perception raised a further problem. Why is it that men do not see many things at once? Hobbes again suggested a mechanical explanation: "For seeing the nature of sense consists in motion; as long as the organs are employed about one object, they cannot be so moved by another at the same time, as to make by both their motions one sincere phantasm of each of them at once." But this does nothing to explain why one object rather than another is selected. Hobbes's ideomotor theory made it hard to give a plausible account of the influence of interests, attitudes, and sets on what is selected in perception.

Hobbes also attempted a mechanical explanation of the phenomena of attention and concentration. When a strong motion impinges on the sense organ, the motion from the root of the sense organ's nerves to the heart persists contumaciously and makes the sense organ "stupid" to the registering of other motions.

IMAGINATION AND MEMORY. Hobbes's account of imagination was explicitly a deduction from the law of inertia. "When a body is once in motion, it moveth, unless something else hinder it, eternally … so also it happeneth in that motion, which is made in the internal parts of a man when he sees, dreams, etc. For after the object is removed, or the eye shut, we still retain an image of the thing seen, though more obscure than when we see it." Imagination, therefore, is "nothing but decaying sense." This decay is not a decay in motion, for that would be contrary to the law of inertia. Rather, it comes about because the sense organs are moved by other objects, and subsequent movements obscure previous ones "in such manner as the light of the sun obscureth the light of the stars."

Memory, Hobbes claimed, differs from imagination only in that the fading image is accompanied by a feeling of familiarity. "For he that perceives that he hath perceived remembers," and memory "supposeth the time past." Hobbes thus seems to have more or less equated

what is past with what is familiar, which is most implausible even if familiarity is often a hallmark of what is past. It is also difficult to see how, in his view, remembering something could be distinguished from seeing it for a second time, if the second impression of the thing is not very vivid.

Hobbes's fundamental mistake in all such descriptions and explanations was to attempt to distinguish performances, such as perceiving and remembering, by reference to subjective hallmarks vaguely consistent with his mechanical theory, rather than by reference to the epistemological criteria written into them. The fundamental difference between perception and imagination, for instance, is not one of vividness or any other such accidental property; it is an epistemological difference. To say that a person imagines a tree rather than perceives it is to say something about the status of what is claimed. To perceive is to see something that really is before one's eyes; to imagine is to think one sees something that is not there. Similarly, to remember is to be right in a claim one makes about something in the past that one was in a position to witness, whereas to imagine is to be mistaken in what one claims. There are, of course, further questions about the mechanisms by means of which people perceive, imagine, and remember; and it could be that some such mechanical story as told by Hobbes might be true about such mechanisms. But in the language of such a story the basic epistemological differences between these mental performances could never be made, and although the mechanical story might give an account of some of the necessary conditions of such performances, it is difficult to see how it could ever serve as a sufficient explanation of them.

THOUGHT. The same general critique concerning neglect of epistemological criteria must be made of Hobbes's treatment of thought, which he equated with movements of some substance in the head. There may be movements in the brain that are necessary conditions of thought, but no description of such conditions should be confused with what is meant by "thought." We do speak of "the movement of thought," but this is a description of transitions, as from premises to conclusions or from problems to solutions, not of movements explicable in terms of mechanical laws.

Even though Hobbes's general account of thought was rather hamstrung by his obsession with mechanics, he nevertheless had some quite illuminating things to say about trains of thought, an account that owed more to Aristotle than to Galileo. Hobbes distinguished

"unguided" thought from that directed by a passionate thought or plan. Unguided thought followed principles that later came to be called principles of association—for example, spatiotemporal contiguity and similarity. Hobbes, however, made no attempt to formulate principles of this kind. He was much more interested in, and attached much more importance to, guided thought, in which desire for an end holds the train of thought together and determines the relevance of its content.

Hobbes distinguished two main types of regulated thinking. The first was the classic Aristotelian case of deliberation, where desire provides the end, and the means to this end are traced back until something is reached that is in a person's power to do. This faculty of invention is shared by the animals, but they do not share the other sort of guided thinking that Hobbes called prudence. In prudence the starting place is an action that is in a person's power to perform, and the store of past experience is used to speculate on its probable effects. In this case, deliberation leads forward to an end that is either desired or feared. Hobbes seemed to think that people's prudence is in proportion to the amount of past experience on which they can draw. This sounds improbable, for although children cannot be prudent, many old people miss the relevance of their past experience.

DREAMS. Dreams fascinated Hobbes. He attempted to determine what distinguishes them from waking thoughts and to develop a mechanical theory to explain them. He claimed that they lack coherence because they lack the thought of an end to guide them. Dreams consist of compounded phantasms of past sensations, for "in the silence of sense there is no new motion from the objects, and therefore no new phantasm." Dreams are clearer than the imaginations of waking men because of the predominance of internal motion in the absence of external stimulation. There is no sense of time in dreams, and nothing appears surprising or absurd.

There is an intimate connection between dreams and bodily states. Lying cold, for instance, produces dreams of fear and raises the image of a fearful object. The motions pass both from the brain to the inner parts and from the inner parts to the brain. So, just as anger causes overheating in some parts of the body, overheating of the same parts can cause anger and, with it, the picture of an enemy. Dreams are thus the reverse of waking imaginations. Motion begins at one end during waking life and at the other end during sleep. This tendency to project images produced by bodily states gives rise to belief in apparitions and visions. Hobbes's treatment of dreams typified his approach to such matters. He seemed uninterested in the epistemological questions to which they give rise, as, for instance, in the thought of his contemporary, Descartes.

PASSIONS. Hobbes's mechanical theory of human action hinged on his concept of "endeavour," by means of which he tried to show how the gross movements of the body in desire and aversion could be explained in terms of minute unobservable motions in the body. He postulated two sorts of motion in the body. The first is its vital motion, manifest in such functions as circulation of the blood, breathing, and nutrition, which proceeds without external stimulation or the help of the imagination. The second is animal motion, which is equivalent to such voluntary movements as walking and speaking. This is always "first fancied in our minds" and is produced by the impact of external stimuli on the sense organs, an impact that gives rise both to phantasms in the brain and to internal motions that impinge on the vital motions of the heart. If the motion of the blood is helped, this is felt as pleasure; if it is impeded, as pain. Pleasure, Hobbes said, is "nothing really but motion about the heart, as conception is nothing but motion in the head." In the case of pleasure, the spirits—which were thought of as vaporous substances flowing through the tubes of the nerves—are guided, by the help of the nerves, to preserve and augment the motion. When this endeavor tends toward things known by experience to be pleasant, it is called appetite; when it shuns what is painful, it is called aversion. Appetite and aversion are thus the first endeavors of animal motion. We talk about "will" when there is deliberation before acting, for will is "the last appetite in deliberating."

Hobbes's theory of the passions was an attempt to graft the traditional Aristotelian account of them onto his crude mechanical base. Love and hate are more or less the same as appetite and aversion, the only difference being that they require the actual presence of the object, whereas appetite and aversion presuppose its absence. These, together with joy and grief, which both involve foresight of an end rather than just an immediately perceived object, are the simple passions out of which others are compounded. Social life is a race for precedence that has no final termination save death. "So that in the first place, I put for a general inclination of all mankind, a perpetual and restless striving of power after power, that ceaseth only in death." To endure in the race requires foresight and scheming; to fail to compete is to die. A man who is convinced that his own power is greater than that of others is subject to what Hobbes called glory; its oppo-

site is humility or dejection. Pity is grief for the calamity of another, arising from imagination that a like calamity may befall ourselves. Laughter is the expression of sudden glory caused by something new and unexpected in which we discover some superiority to others in ourselves.

Hobbes also introduced motion into his theory of individual differences. He thought that such differences are derivative from differences in passions and in the ends to which men are led by appetite, as well as to the sluggishness or agility of the animal spirits involved in the vital motions of their respective bodies.

The basic difficulty in understanding Hobbes's theory of motivation arises from his attempt to underpin a psychology derived from introspection, from the shrewd observation of others, and from the tradition going back to Aristotle with a mechanical theory whose outline was only very briefly sketched. Perhaps the essential criticism of any such theory is that actions cannot be analyzed into mere movements because, in any action proper—as distinct from a nervous tic or a reflex—the movements take place because of an end that the person has in mind. This end is what makes the action one of a certain sort, and, provided that the movements are directed toward this end, an almost indefinite range of movements can form part of the same action. Similarly, the movements involved in raising one's hand can form part of quite different actions, depending on the purpose for which the hand is raised—for example, to signal, to test the direction of the wind, to stretch the muscles, and so on.

Having something in mind—which is part of the concept of "action"—is not a movement, still less a movement of some internal substance of the head, if this is what Hobbes really believed. But Hobbes was not at all clear on the relationship between movements, whether observable or unobservable, and the cognitive components of appetites, aversions, and the various passions. Indeed, he seems to have held an extremely paradoxical and overintellectualistic view about the cognitive component of the passions. For he saw that passions are to be distinguished by their objects and by the judgment of the possibility of attaining such objects, yet he injected into his account a bizarre kind of egocentricity. For Hobbes, in all cases of passions the notion of "self" was part of the content of cognition. He seemed to think that all such "phantasms" of objects, by reference to which the passions are to be distinguished, involve the thought of ourselves doing something or of our power to do something. Pity is thus seen as grief arising from our imagining ourselves in the same predicament as that of the one pitied. Hobbes's analysis of laughter palpably suffered from the

same injection of egocentricity. Furthermore, how the highly sophisticated and narcissistic type of appraisal involved in the passions is to be reconciled with any attempt to represent them all as movements of the body and of some internal substance in the head is very difficult to determine.

For all its ambiguities, oversights, and obvious defects, Hobbes's psychology was remarkable, for he attempted to establish it as an objective study untrammeled by theological assumptions. To suggest that man is a machine was a great step forward in thought. Even though the hypothesis is probably untenable, it marked the beginning of the effort to use scientific methods and objective concepts in the sphere of human behavior. In the seventeenth century this was a novel undertaking, as well as a dangerous one.

ETHICS

Hobbes thought that, by employing the resolutive method, he could demonstrate the absolute necessity of leagues and covenants and the rudiments of moral and civil prudence from his two principles of human nature—"the one arising from the concupiscible part, which desires to appropriate to itself the use of those things in which all others have a joint interest; the other proceeding from the rational which teaches every man to fly a contranatural dissolution, as the greatest mischief that can arrive to nature." These two principles underlie Hobbes's account of the personal good, as well as his account of civil duty.

Hobbes was scornful of the notion that "good" and "evil" name any metaphysical essence. These words are "ever used with relation to the person that useth them: there being nothing simply and absolutely so; nor any common rule of good and evil, to be taken from the nature of the objects themselves." They name objects of our desires and aversions. We call a horse "good," for instance, because it is "gentle, strong, and carrieth a man easily." The desires of the individual determine what qualities are selected to furnish the ground for saying that an object is good.

Hobbes introduced a further refinement of this theory when he contrasted short-term goods with long-term goods. "Reason," he said, "declaring peace to be good, it follows by the same reason, that all the necessary means to peace be good also." This he contrasted with the sway of irrational appetite, whereby men "greedily prefer the present good." He thought that a man might not desire peace at a particular moment when influenced by some insistent desire; but when he sat down soberly in a cool

hour, he would see that peace is a necessary condition of satisfying most of his desires in the long run. Thus, peace is something that he must desire both because of his fear of death and because of the other things he desires to do that a state of war would make impossible.

Hobbes was a nominalist, and he thought that all words have meaning, as if they were some kind of name. He did not see, as Berkeley seems to have seen a little later, that words such as *good* have a prescriptive function and cannot be treated merely as if they were names. To say that something is good is to say that it is what it ought to be; it is to commend it. But also it implies that there are grounds for such commendation. It is to guide a person by suggesting grounds for his choice; it is not to order him or goad him. Hobbes saw that "good" is always thus connected with reasons, but he gave a very circumscribed account of what such reasons must be like, that is, characteristics of things desired. This was modified somewhat by what he said a man desires insofar as he uses his reason, that is, insofar as his "rational" as well as his "concupiscible" nature is involved. Hobbes's account of what a man desires would not be implausible if his account of human nature were acceptable, for then what men must desire could be predicted. But, if his account of human nature is rejected as oversimple, there cannot be quite such a tight connection as Hobbes suggested between "good" and what is, or will be, desired.

The connection is probably looser; given that words such as *good* have the practical function of guiding people's choices, it would be impossible to explain their effectiveness in this function if it were not generally the case that what was held up as good was something that people in general wanted. But it does not follow from this that any particular individual desires, or must desire, what is held up to him as good. Indeed, half the business of moral education consists in drawing people's attention to characteristics of things that they ought to desire but do not in fact desire.

STATE OF NATURE AND LAWS OF NATURE. Morality is not concerned simply with the pursuit of personal good; it is also concerned with the acceptance of rules that limit the pursuit of good when it affects that of others. A tradition going back to the Stoics held that there was a small corpus of such rules, called the law of nature; these rules, which were universal preconditions of social life, did not depend, as do custom and law, on local circumstances. The Dutch jurist Hugo Grotius regarded this law of nature as a self-evident set of principles binding on all men (on kings as well as on their subjects) that would

provide a rational basis for a system of international law; it was, he claimed, fundamental in the sphere of social rules in the same sort of way that Galileo's postulates were fundamental in the realm of nature. Morals could be brought within the expanding empire of the mathematical sciences.

Hobbes, therefore, was not original in his claim that "the true doctrine of the laws of nature is the true moral philosophy," nor was he original in likening its precepts to axioms. What was original was his claim that its precepts were axioms of prudence, insofar as "prudence" implies considerations limited to those that affect only the agent. For Grotius, the maintenance of society was a major need of man as a social animal, irrespective of purely private benefits. Hobbes, however, maintained that more or less the same set of rules that Grotius regarded as binding (such as keeping faith and fair dealing) could be shown to be axioms that must be accepted by any man who is both rational and afraid of death. "All society, therefore, is either for gain or for glory; that is, not so much for love of our fellows as for love of ourselves."

Man, Hobbes argued, shuns death "by a certain impulsion of nature, no less than that whereby a stone moves downward." This is what saves man from anarchy and civilizes him, for if man were driven merely by his "concupiscible" part, there would be no society, and the life of man would be "solitary, poor, nasty, brutish, and short." Men are equal enough in body and mind to render negligible any palpable claims to superior benefits, and even the weakest is able to kill the strongest. But man's fear of death brings him up short in his pursuit of power and leads him to reflect upon the predicament of a state of nature. His reason tells him that peace is necessary for survival and also "suggesteth certain articles of peace, upon which men may be drawn to agreement. These articles are they, which otherwise are called the Laws of Nature." One of these laws is that "men perform their covenants made." In this way Hobbes claimed to demonstrate "the absolute necessity of leagues and covenants, and thence the rudiments both of moral and of civil prudence."

Hobbes's demonstration gave only the semblance of validity because he isolated the concupiscible and rational aspects of man's nature from each other and, as in a Galilean imaginary experiment, explored the consequences of each independently. Given only man's self-assertion, then there must be a state of nature; given only his overwhelming aversion to death, then he must accept the conditions necessary for avoiding death. These axioms of prudence are hypothetical in relation to man's

assumed fear of death. They are rules that a rational man must accept insofar as he wants to avoid death. But men are only partly rational and, although they have an overwhelming fear of death, they also want other things, such as power and glory. Presumably Hobbes, like Machiavelli, could also have laid down rules for obtaining power and glory that would have borne no resemblance to the laws of nature. Thus, Hobbes could not have been trying to show that virtue, as defined by adherence to the laws of nature, is natural to man or a deduction from his nature, as have many thinkers who have adopted a psychological starting point. Indeed, the general relationship between Hobbes's psychology and his ethics is too obscure for us to know quite what he was doing.

The key to Hobbes's "demonstration" really lies in what he did with it, for he went on to point out that the laws of nature are only theorems that any rational man would accept. Since these laws need the backing of the sword to ensure peace, men have need of a "common power to keep them in awe, and to direct their actions to the common benefit." The rationale of Hobbes's demonstration can now be seen, for at the time that Hobbes was writing, England was precariously poised between anarchy and civil disorder. Hobbes's analysis was a Galilean "resolution" of such a situation into the simple components of human nature that formed its basis. He pointed out that, insofar as men want peace and security (and all men do want this, although they want other things as well), then they must see that, human nature being what it is, there are certain means that they must accept if they are to have what they want. It is irrational to want something and yet to refuse to take the only means that will ensure that what is wanted is obtained. Since the acceptance of social rules is based only on the fear of death, it is only the fear of death that will ensure that these rules are obeyed. Men therefore cannot have the peace they all desire unless they accept the sword of the sovereign that will make death the consequence of breaking the rules that are a necessary condition of peace.

DETERMINISM AND FREE WILL. The indeterminate position of Hobbes's psychology in relation to his ethics was encouraged by his belief in determinism—or "necessitation," as he usually called it—which he outlined in his controversy with Bishop Bramhall. Hobbes denied that there is any power in men to which the term *will* refers; what is commonly called will is but the last desire in deliberating. Furthermore, he argued, only a man is properly called free, not his desires, will, or inclinations. The liberty of a man "consisteth in this, that he finds no stop, in doing what he has the will, desire, or inclination to do."

Liberty is "the absence of all the impediments to action that are not contained in the nature and intrinsical quality of the agent." To speak of liberty is not to make any suggestions about the determinants or absence of determinants of man's deliberations or decisions; it is to suggest that man is not externally constrained in his actions. There is, therefore, no contradiction in saying that a man acts freely and that his actions are also determined. Since all actions have causes and thus are necessitated, it is pointless to use "free" in the sense of "free from necessitation," as distinct from "free from compulsion." There are no such actions, although we may think that there are because we are ignorant of the causes of actions.

There is much to be said for Hobbes's recommendation on the use of the word *free;* many others, such as John Locke and David Hume, have followed him in confining it to the absence of constraint on a man's actions. But Hobbes's claim that all actions are necessitated is not so straightforward. Certainly he was right in suggesting that all actions are explicable—if that is what is meant by saying that they have causes—but so many different things can count as causes, ranging from deliberation and understanding to a stab of pain or a crack on the skull. Since Hobbes thought of man as a natural machine, he therefore viewed all causes as mechanical pushes. His doctrine carried the suggestion that the behavior of men is not only explicable but also somehow unavoidable because men's decisions and choices are simply manifestations of internal pushes.

Significantly enough, Bramhall did not object to Hobbes's doctrine insofar as it related to actions shared with animals or to spontaneous actions. What he could not allow was that voluntary actions, which follow on election and deliberation, should also be "necessitated." Bramhall pointed out the difficulties of likening actions and the grasp of objects and of means of obtaining them, which are inseparable from the concept of "action," to processes in nature explicable in terms of antecedent motions. In this contention Bramhall was substantially right, for although actions may involve movements, they are not reducible to movements.

Hobbes also disagreed with Bramhall on the implications of his doctrine of "necessitation" for moral judgments and for the operation of the law. Bramhall argued that if human actions are necessitated, then praise and blame, reward and punishment, are both unjust and vain. To the charge that they are vain, Hobbes replied that they are to be viewed as further determinants of choice. Praise and blame, reward and punishment "do by example make and conform the will to good and evil." To the charge of

injustice, Hobbes argued that "the law regardeth the will and no other precedent causes of action"; also that punishments annexed to breaches of the law function as deterrents and necessitate justice. He went out of his way to distinguish punishment from acts of revenge or hostility and to stress its deterrent purpose, which is a sound position. Hobbes saw clearly that retribution is part of the meaning of punishment, but that it is the connection with authority that distinguishes it from other sorts of retributive acts. He also saw that, although retribution may be written into the meaning of punishment, its justification is not therefore necessarily retributive. Rather, it is to be justified for its preventive and deterrent function.

POLITICAL PHILOSOPHY

In his political philosophy Hobbes tried to conceptualize the relationship between the new nation-state, which had been emerging under the Tudors, and the individual citizen, who could no longer be regarded simply as having a set place in a divinely instituted order. In the old medieval society a man was bound by ties attaching to his status and by duties prescribed for him by the church. Tradition was the main form of social control, and traditions stretching back into the distant past assigned to a man his relatively fixed place in society. Aristotle's doctrine of natural kinds and natural places and his account of man as a social animal provided a fitting naturalistic foundation for the theological worldview that was accepted by rulers and ruled alike. But with the rise of individualism and the social mobility that accompanied the rise of commerce and capitalism, this old conception of man in society no longer applied. Men had shaken off the ties of their guilds and local communities, and the new natural philosophy was beginning to render the naturalistic foundations of the former worldview untenable.

Hobbes's picture of life as a race, in which we "must suppose to have no other good, nor other garland, but being foremost," was a gruesome caricature of an age of individualism, restless competition, and social mobility. But if the fetters of tradition were being cast away, what other form of social control could take its place to prevent the anarchy of a state of nature? The answer was to be found, of course, in the increasing executive power of the state and in the growth of statute law, together with the development of the individual conscience, whereby regulation from within replaced the external authority of the Catholic Church. Hobbes distrusted the anarchic tendencies of the individual conscience as much as he loathed the extramundane authority of the Church of Rome. Both were to be banished, along with traditional ties; civil

society could be reconstructed as a simple mechanical system.

SOCIAL CONTRACT. Hobbes had a model ready at hand by means of which he might present his Galilean analysis of the rationale of civil society—the social contract theory. The social contract theory, despite its obvious flaws, was an attempt to rationalize political obligation, to substitute an intelligible bargain for mystifying appeals to tradition and divine right.

The contract theory was resorted to mainly by those who wanted to challenge the absolutist claims of monarchs, to uphold the claims of the common law, or to lay down some sort of moral limits on control and interference by the central executive. Hobbes's feat was to employ this model to demonstrate that absolutism is the only possible logical outcome of consistent concern for individual interests. Indeed, he prided himself on grounding the authority of sovereigns, as well as the liberty and duty of subjects, upon axioms of human nature rather than on tradition and supernatural authority. In his attitude toward tradition and divine right, he was at one with the defenders of government by consent. But because of his overriding concern for security, and because of his rather depressing estimate of human nature, he came to the somewhat gleeful conclusion—highly displeasing to those who believed in government by consent—that absolutism could be the only rationally defensible form of government.

Hobbes did not seriously consider the social contract, as some did, as a quasi-historical hypothesis on how civil society might have come into existence. In his account the contract was featured as a framework for a Galilean resolution of civil society into its simple elements. Hobbes imagined the individual in a state of nature as having an unlimited right to "protect his life and members" and "to use all the means, and do all the actions, without which he cannot preserve himself." But he also has a right to all things "to do what he would, and against whom he thought fit, and to possess, use, and enjoy all that he would, or could get." Hobbes here was employing a very strange concept of right, for usually, when we talk about a right, we are indicating a rule that protects or should protect a person from interference in the doing of something that he might want to do. Hobbes, however, used the term in this way to talk about both what a person is entitled to do (when it is correlative with duties of noninterference on the part of others) and what a person cannot be obliged to renounce. When Hobbes declared that men have a "right of self-

preservation," he meant not that an individual is entitled by some rule (of law, tradition, or morals) to life but that he cannot be obliged to renounce it because it is psychologically impossible for him to do so. "Natural rights" therefore have a quite different meaning in Hobbes's writing than in the works of Locke, Samuel von Pufendorf, and other such defenders of natural rights. In these classical theories, natural rights are interests protected by natural law against the interference of others. Hobbes's natural-law theory is not connected in this way with his rather bizarre concept of natural rights.

Hobbes's "rights" of nature are derivative from man's tendency to assert himself and to seek power. But, as already shown, Hobbes held that man would also be driven by his fear of death to accept certain laws of nature, the second of which prescribed that every man should lay down his right to all things and "be contented with so much liberty against other men, as he would allow other men against himself." This could be done either by not interfering with others' enjoyment of their rights or by transferring one's right to another, in which case the transferrer is obliged not to hinder the recipient. Injustice consists in hindering a person whom it is a duty not to hinder. The mutual transferring of such rights is called a contract, and the third law of nature is "that men perform their covenants made."

COMMONWEALTH. Hobbes deduced a mutual transfer of rights from his postulate of rational action under the impetus of fear. But men are not yet safe, for there may be danger in keeping covenants and it may be, on occasion, in people's interest to break them. "And covenants, without the sword, are but words, and of no strength to secure a man at all." Matters must be arranged so that it will never be in anyone's interest to break covenants, which cannot exist where there is no "common power" to enforce them. Thus, a social contract must be presumed in which it is as if every man should say to every other man, "I authorize and give up my right of governing myself, to this man, or to this assembly of men, on this condition, that thou give up thy right to him, and authorize all his actions in like manner." This contract unites the multitude into one people and marks the generation of "that great leviathan, or rather, to speak more reverently, of that mortal God, to which we owe under the immortal God, our peace and defence." The definition of commonwealth is, therefore, "one person, of whose acts a great multitude, by mutual covenants one with another, have made themselves every one the author, to the end he may use the strength and means of them all, as he shall think expedient, for their peace and common defence." The

person that results is called sovereign, and everyone else is his subject. The sovereign is created by the contract but is not party to it. Thus, the people rule even in monarchies; a multitude becomes a people by having some device, such as that of representation, by means of which decisions binding on all are made on behalf of all. Some such "covenant" is implicit in speaking of a commonwealth as a people, as distinct from a multitude of men.

Up to this point there is much to be said for the sort of analysis that Hobbes gave, although some of its details are peculiar. He had considerable insight into the sort of thing we mean when we speak of a civil society, as distinct from a mere multitude of men. He saw clearly that societies are not natural wholes like toads, turnips, or colonies of termites. They exist because individuals act in accordance with rules that can be rejected, broken, or altered; they are artificial wholes. Therefore, if we are to speak of the "will" or "decision" of such an entity, there must be some higher-order rules of procedure, such as that of representation, by reference to which what is to count as a corporate decision is constituted. Individuals or groups of individuals are put in authority for such a purpose.

When Hobbes proceeded to the more concrete details of what must constitute the duties of rulers and subjects, however, he was not equally convincing, for this next step depended on his questionable account of human nature. The basic principle of human nature revealed by his Galilean resolution was "that the dispositions of men are naturally such that, except they be restrained through fear of some coercive power, every man will dread and distrust each other." No motive in human nature, except the fear of death, is strong enough to counteract the disruptive force of man's self-assertion. The fear of death must, therefore, be the explanation of the existence of civil society (insofar as there is a social order and not anarchy), and security must be the sole reason for the institution of the social order; there is simply no other reason for which men could be induced to give up their natural right to self-assertion. Since this is the sole reason for having a commonwealth, it follows logically that a commonwealth must be devised that will accomplish the end for which it exists. Sovereignty must be perpetual, undivided, and absolute, for to divide or limit sovereignty would be to risk anarchy; and such limitation would be illogical because it would be inconsistent with the raison d'être of sovereignty. *Salus populi suprema lex* (The safety of the people is the supreme law). Moreover, complete safety entails complete submission to an absolute sovereign. Thus, absolutism is the logical conse-

quence of government by consent, once the real interest of individuals, which is the presupposition of the institution of commonwealth, has been clearly understood.

There are two obvious flaws in this stage of Hobbes's argument. The first is the assumption that the desire for security, deriving from the fear of death, is the sole reason for the institution of commonwealth, a reason that Hobbes more or less wrote into the meaning of "commonwealth." It is obviously a very important reason, but that it should be the only reason is plausible only if Hobbes's psychology were to be accepted. Even so, Hobbes should not have written the reason for instituting a commonwealth into what is meant by "commonwealth." The second flaw was well brought out by Locke, who argued that, even if security were the sole reason for the institution of commonwealth, absolute authority is a dangerous expedient from the point of view of individual interest. For the hypothesis is that the timid individual would exchange the possible threat to life presented by 100,000 men, all of whom individually might attack him, for the threat to his life made possible by the arbitrary authority of one man who has 100,000 men under his command. "Are men so foolish that they take care to avoid what mischiefs may be done them by polecats or foxes, but are content, nay think it safety, to be devoured by lions?"

Hobbes was led to his advocacy of undivided sovereignty by his interest in constitutional and legal matters. When Hobbes was writing, there was a clash between the higher-order principles of common law and of statute law. The common-law principle that custom, as interpreted by the judges, is to be consulted in declaring what the law is, existed alongside the principle of statute law, that rules laid down by a determinate body or person (for example, Parliament or the king) determine what the courts must recognize as valid law. Statute law was on the increase during this period, and it was intolerable to any clearheaded man that these two principles should operate side by side. Hobbes advocated the unambiguous supremacy of the principle of statute law and the abolition of common law. The need to introduce clarity and coherence into the confused constitutional situation that prevailed in Hobbes's time was obvious enough. But for Hobbes to suggest that it was a logical truth that there must be an absolute sovereign in any commonwealth was to introduce dubious logical deductions into a field where a solution was more likely to be found by practical adjustments and compromises that reflected the strength of competing interests and were consonant with deep-seated traditions.

One of the traditions that Hobbes's geometric solution ignored was that of the liberty of the subject. In Hobbes's view, civil liberty lay "only in those things, which in regulating their actions, the sovereign hath praetermitted." It is unlikely, Hobbes suggested, that laws would be necessary to regulate buying and selling, and choice of abode, diet, a wife, a trade, and education. But whether such laws are necessary is entirely up to the sovereign. The liberty of the subject also consists in the lack of proscription of such acts that it would be vain to forbid because they are psychologically impossible for the subject to refrain from committing. These acts involve the right of the subject to preserve himself and to resist imprisonment. Hobbes also suggested that "in the act of submission consisteth both our obligation, and our liberty." Both the obligation and the liberty are to derive from the words "I authorize all his actions," which the subject is imagined to have expressed in instituting a commonwealth. The subject is released from his obligation only if the sovereign fails to do what he is there to do, namely, to guarantee security. This marks the extent of the subject's much-lauded "right to resist." Presumably Hobbes meant to stress that subjects submit voluntarily to authority. This is true enough, but what it has to do with the liberty of the subject, in any straightforward sense of "liberty," is difficult to grasp.

LAW. Hobbes's concept of the role of natural law, once the law of the state had been established, was not altogether clear. He maintained that the laws of nature were "but conclusions, or theorems concerning what conduceth to the conservation and defence of themselves; whereas law, properly, is the word of him that by right hath command over others. But yet, if we consider the same theorems, as delivered in the word of God, that by right commandeth all things; then they are properly called laws." These "laws" always obligate *in foro interno*—that is, in matters of private conscience—in prescribing a general readiness of mind; but *in foro externo,* that is, in actions, the laws may not be obligatory if certain conditions, such as peace and security, are absent. Such conditions, when present, will in fact render it to the interest of the subject that he follow the laws of nature. A law properly so called always obligates *in foro externo* because of its source in the command of the sovereign, as well as because civil society, by definition, provides the conditions of security and the sanction that will make it always against a man's interest to disobey it. But do the laws of nature oblige *in foro externo,* if not incorporated in the civil law, when the security of civil society prevails? This depends on how seriously Hobbes meant his reference to

theorems as authoritative edicts from God, for such derivation would give them a determinate source, as in the case of laws properly so called. Some take Hobbes seriously and claim that he really thought that the laws of nature oblige *in foro externo* as well as *in foro interno* whenever conditions of security prevail. Others hold that Hobbes never really thought that laws of nature oblige in a full sense *in foro externo* because his reference to their authoritative source is but a tactful concession to piety. He really thought of them merely as axioms of reason that oblige in a full sense only when they are issued by a temporal sovereign as commands and when conditions of security, together with sanctions, prevail in civil society.

Hobbes took this somewhat ambiguous view about the status of natural laws (or moral precepts) because of his extreme hardheadedness about laws properly so called. Law, he held, is the command of the sovereign, "the word of him that by right hath command over others." It is authority, not conformity with custom or reason, that makes a law. In this forthright view he was attacking the fiction of the common law that the law was there to be discovered, immanent in the customs of the people.

Whatever the merits of Hobbes's view—later adopted by the analytic school of John Austin—that laws are commands, Hobbes made a valuable contribution in helping to distinguish questions about law that are often confused. The question "What is a law?" should be distinguished from such other questions as "Is the law equitable or reasonable?" and "What makes a law valid?" Hobbes argued that a law is simply a rule issued by someone in authority. Whether it is reasonable or equitable is a further question, as are the questions of its validity, of its conformity with custom, and of the grounds on which a man could be obliged to obey it.

To claim that laws are commands was an oversimple and misleading way to bring out the prescriptive force of laws. But it was useful insofar as it connected law with authority, for laws, like commands, are utterances issuing from people in authority. In stressing the necessary connection between law and authority, Hobbes made an important contribution to political philosophy, for there is no necessary connection between authority and moral precepts or "laws of nature."

On the question of the person or body of men by whose authority laws should be made, Hobbes was more open-minded than is often realized. He thought that this was not a matter that could be demonstrated; it was a matter of factual argument. He believed that the relative advantages of each form of government had to be con-

sidered in the light of the sole end of security. It was a factual matter which type of government was most likely to promote such an end. On the whole, he argued, monarchy is preferable because it is more likely to be undivided, strong, and wise.

RELIGION

At the time Hobbes wrote, ethics and politics were inseparable from religion. Even the Royal Society was founded by men who believed that science would reveal more of the details of God's creation and thus enhance his worship. Hobbes was one of the pioneers in the process of distinguishing religious questions from other sorts. He rigorously excluded theology from philosophy and tried to map the proper domains of faith and knowledge. He outlined a theory of the causes of religion and superstition and discussed the grounds of religious belief, and he conducted an elaborate inquiry into the use of various terms in the Scriptures. But all this analysis and theorizing was subordinate to his main interest in religion as a possible source of civil discord. It is seldom realized that more than half of *Leviathan* is concerned with religious matters, with Hobbes trying to defend the "true religion" from both Catholicism and the priesthood of all believers. He saw clearly that these doctrines were two of the main obstacles in the way of the absolutism that he advocated.

Hobbes made some interesting speculations about the natural causes of religion, which he said were "these four things, opinion of ghosts, ignorance of second causes, devotion toward what men fear, and taking of things casual for prognostics." These seeds of religion could be cultivated according to natural invention, which leads to superstition and nature worship, or according to God's commandments. "Fear of power invisible, feigned by the mind, or imagined from tales publicly allowed, religion; not allowed, superstition. And when the power imagined is truly such as we imagine, true religion."

NOTION OF GOD. What, then, constituted true religion for Hobbes? To reasonable men, God's commands amounted to the laws of nature. God's nature, however, was a much more baffling matter, even for a rational man. Certainly God must have "existence," which Hobbes took to be an attribute of God, in spite of his remarks elsewhere about the ambiguities of the verb "to be." In *Leviathan* Hobbes held that God is the cause of the world, "that is, a first and an eternal cause of all things; which is that which men mean by the name of God." In his later *De Corpore,* however, he indicated the difficulties in the

notion of an unmoved mover. This was a difficult question for philosophers to determine and had better be handed over for decision to the lawful authorities. Hobbes also stressed God's irresistible power and maintained that the only solution to the problem of evil was to be found in this power. Did not God reply to Job: "Where wast thou, when I laid the foundations of the earth?" Job had not sinned; his suffering was an unfortunate consequence of God's manifestation of power.

The main function of reason, however, is to show what God cannot be—at ease, finite, figured, having parts, occupying a place, moved or at rest, plural, and having passions, rational appetite, sight, knowledge, and understanding. If we rely on natural reason, we must either qualify God in a negative way by adjectives, such as "infinite" and "incomprehensible," or by a superlative, such as "most high," and an indefinite, such as "holy," which are not really descriptions of his nature but expressions of our admiration. Thus, rational disputations about the nature of God are pointless and a dishonor to him, "for in the attributes which we give to God, we are not to consider the signification of philosophical truth; but the signification of pious intention, to do him the greatest honour we are able." The sovereign, therefore, must decide on God's attributes; and public, uniform worship must be instituted.

REASON AND REVELATION. Reason, however, should not be "folded up in the napkin of an implicit faith, but employed in the purchase of justice, peace, and true religion." There is nothing in God's word contrary to reason. We must, however, be prepared in this world "to captivate our understanding to the words; and not to labour in sifting out a philosophical truth by logic, of such mysteries as are not comprehensible, nor fall under any rule of natural science." Reason should be kept very much to the fore when one is confronted with those who claim revelation, for if a man says that God spoke to him in a dream, this "is no more than to say he dreamed that God spoke to him." There are psychological explanations of such phenomena that cast doubt on their reliability as valid communications with God.

Dreams, visions, and inspiration, however, should not be dismissed altogether, for it is by such means that prophets have been informed of the will of God. What is needed are criteria for detecting true prophets. Hobbes suggested two necessary criteria: the working of miracles and the teaching of doctrines not at variance with those already established. Since miracles had by then ceased, there was no sign left to single out true prophets. And, in

any case, the Scriptures, since the time of Jesus, had taken the place of prophecy.

Reliance on the Scriptures, Hobbes realized, is not altogether straightforward. Even supposing that it could be decided which books are authentic, and that the sovereign, by his authority, could make their teaching law, there is still the problem of what many of the terms used in the Scriptures mean. Hobbes went through most of the key terms in the Scriptures, giving meaning to them in a way consistent with his mechanical theory. He argued, for instance, that God must have a body and that the proper signification of "spirit" in common speech is either a subtle, fluid, and invisible body or a ghost or other idol or phantasm of the imagination; it may also have a figurative use in such a phrase as "spirit of wisdom." "Angels" signify images raised in the mind to indicate the presence of God. Hobbes made acute remarks about the nature of miracles that mingled radical probing with subtle irony (indeed, one often wonders whether his whole treatment of "the true religion" is not a colossal piece of irony).

On the relationship between church and state, Hobbes of course adopted an uncompromising Erastian position. A church he defined as "a company of men professing Christian religion, united in the person of one sovereign, at whose command they ought to assemble, and without whose authority they ought not to assemble." There is, therefore, no universal church to which all Christians owe allegiance, for there is no supreme sovereign over all nations.

Hobbes concluded *Leviathan* with his famous section on the Kingdom of Darkness, in which he castigated superstition and Catholicism as enemies of the true religion. The papacy, he remarked "is no other than the ghost of the deceased Roman empire, sitting crowned upon the grave thereof." The papacy ruthlessly exploits the fears of ignorant men to perpetuate the power of unscrupulous priests as a rival to the secular power.

Hobbes held that there is only one article of faith necessary for salvation: that Jesus is the Christ. On what authority did such a belief rest? Hobbes had some interesting things to say about the difference between knowledge and faith. The object of both is propositions, but in the case of knowledge we consider the proposition and call to mind what its terms signify. Truth here is a matter largely of following the consequences of our definitions. But when reasons for assent derive "not from the proposition itself but from the person propounding, whom we esteem so learned that he is not deceived, and we see no reason why he should deceive us; our assent, because it grows not from any confidence of our own, but from

another man's knowledge, is called faith." Faith, therefore, depends on our trust in a man rather than on our grasp of truth. The faith that Jesus is the Christ must therefore come from the Scriptures and our trust in those who wrote them. But who is to interpret them? "Christian men do not know, but only believe the Scripture to be the word of God." St. Paul said, "Faith cometh by hearing," and that, according to Hobbes, means listening to our lawful pastors, who are appointed by the sovereign to interpret the Scriptures for us. Charles II and Cromwell must have been flattered by the magnitude of the problems on which they were required to issue authoritative edicts: the creation of the world, God's attributes, the authenticity of miracles, and the proper interpretation of the Scriptures. Hobbes regarded religion more as a matter of law than of truth.

Hobbes's treatment of religion leaves obscure exactly what he himself thought about such matters. His technique was always to push radical probing to the limit, and when the basis for the traditional doctrines seemed about to be cut away, the sovereign was summoned as a sort of deus ex machina to put everything in its orthodox place. Hobbes was obviously extremely skeptical about what could be demonstrated in the sphere of religion, but it is difficult to say whether his suggestion that the sovereign should pronounce on such matters as the creation of the world and the attributes of God was a subtle piece of irony, a pious protestation to protect himself against the charge of atheism, or yet another manifestation of his overwhelming conviction that there must be nothing touching the peace of the realm that the sovereign should not decide.

Bibliography

WORKS BY HOBBES

English Works of Thomas Hobbes, 11 vols., and *Opera Philosophica* (Latin works), 5 vols, edited by Sir William Molesworth. London: John Bohn, 1839–1845; reprinted Oxford, 1961. All quotations in the text of this entry are from this edition of the English works.

The Elements of Law, Natural and Political, edited by Ferdinand Tönnies. London: Cambridge University Press, 1928. This also includes extracts from the *Little Treatise, or A Short Tract on First Principles* and *Excerpta de Tractatu Optico.*

Leviathan, edited by Michael Oakeshott. Oxford, 1947; New York, 1962. Latter is paperback with introduction by Richard S. Peters.

Body, Mind, and Citizen, edited by Richard S. Peters. New York, 1962. Paperback, with introduction by Peters, that contains selections from the Molesworth and Tönnies editions.

WORKS ON HOBBES

Aubrey, John. *Brief Lives,* edited by E. O. Dick. London: Secker and Warburg, 1950. Contains biography of Hobbes.

Brandt, Frithiof. *Thomas Hobbes' Mechanical Conception of Nature.* Translated by Vaughan Maxwell and Annie I. Fausbøll. London: Hachette, 1928.

Laird, John. *Hobbes.* New York and London: Oxford University Press, 1934.

Peters, Richard S. *Hobbes.* Harmondsworth, U.K.: Penguin, 1956. Paperback.

Robertson, G. C. *Hobbes.* London and Edinburgh, 1886.

Stephen, Leslie. *Hobbes.* London: Macmillan, 1904.

Strauss, Leo. *The Political Philosophy of Thomas Hobbes.* London: Clarendon Press, 1936; Chicago, 1963. The 1963 edition is paperback.

Warrender, J. H. *The Political Philosophy of Thomas Hobbes.* Oxford: Clarendon Press, 1957.

Watkins, John W. N. *Hobbes's System of Ideas.* London, 1965.

HOBBES, THOMAS [ADDENDUM]

LIFE

Thomas Hobbes, still widely regarded as the greatest of English philosophers, was born on April 5, 1588, in Malmesbury, England, the son of a clergyman who later disappeared into London and left his sons to be raised by their uncle. Thomas died on December 3, 1679, at Hardwick Hall and was buried at Ault Hucknall, having lived a long and eventful life. After study at Magdalen Hall in Oxford, Hobbes was awarded the degree of BA in 1608 and was appointed tutor to William (1591–1628), the son of William Lord Cavendish (d. 1626); he lived much of the rest of his life as a member of the Cavendish household. This position gave him an opportunity, otherwise unlikely because of his relatively humble beginnings, for travel and to meet many of the leading intellectuals of the age, including Marin Mersenne, Pierre Gassendi, and Galileo Galilei. In England he was loaned by the

Cavendishes to Francis Bacon, to whom he acted as amanuensis; according to John Aubrey (1950), Bacon claimed that Hobbes was his best amanuensis because he understood what Bacon was talking about. Hobbes developed a great interest in mathematics and claimed geometry as the model for philosophical work; he took geometry to be descriptive of the properties of space and had little time for uninterpreted calculi, especially algebra. This mathematical interest led him to work for some time on ballistics with the Duke of Newcastle (1592–1676; a Royalist leader during the English civil wars and cousin to Hobbes's employer, who had become the first Earl of Devonshire) and to be appointed in 1646 as reader in mathematics to the Prince of Wales in Paris.

There is a lack of detailed knowledge of Hobbes's life. While Miriam M. Reik (1977), Arnold A. Rogow (1986), and A. P. Martinich (1999) discuss various aspects about Hobbes's life, the most interesting source to read on this subject remains Aubrey (1950).

SYSTEM AND SCIENCE

Though rarely mentioned in modern scientific literature, Hobbes was known in his own day mainly as a natural scientist. Despite increased interest in his work on morals and politics over the last century, no notice is taken of his work in the hard sciences, and little by any scientists except in political science (especially international relations) and economics. In his moral and political theory, Hobbes took his main contribution to be basing his enquiries on scientific principles and thus turning morals and politics into sciences. Hobbes addressed political issues of the day and his writings should be considered in that context, but he was not merely joining in political argument; in his own view, he was changing it by making it scientific and thus capable of producing definitive answers. The period was one of considerable argument about the appropriate methods for science, one account of Hobbes's contribution to this being Steven Shapin and Simon Schaffer's *Leviathan and the Air Pump: Hobbes, Boyle, and the Experimental Life* (1985), which deals with the dispute between Hobbes and Boyle about the value of the experimental method.

Hobbes claimed that he had created a system of philosophy with continuous argument from physics to politics. His grand plan encompassed a set of three books to carry this argument from the one point to the other, but events in England led him to publish the political work first rather than last: *De Cive* was published in Paris in 1642 with *De Corpore* not being published until 1655 and *De Homine* in 1658. By that time, Hobbes's other main

political works had already appeared: *The Elements of Law* in two pirated parts in 1650 and *Leviathan* in 1651. There is much argument about the extent to which Hobbes's philosophy does form a system with the politics eventually following from the physics. Real debate on this issue springs from Leo Strauss's *The Political Philosophy of Hobbes: Its Basis and Its Genesis* (1936), in which he argues that Hobbes's political philosophy is independent of his natural philosophy. Major responses to Strauss can be found in John W. N. Watkins's *Hobbes's System of Ideas: A Study in the Political Significance of Philosophical Theories* (1965), M. M. Goldsmith's *Hobbes's Science of Politics* (1966), and Thomas A. Spragens Jr.'s *The Politics of Motion: The World of Thomas Hobbes* (1973). David Boonin-Vail's *Thomas Hobbes and the Science of Moral Virtue* (1994) includes discussion of the relationship between Hobbes's natural philosophy and his moral philosophy. Hobbes said that his political philosophy could be understood independently of his natural philosophy; many writers have taken him at his word and ignored the question of whether he has produced a system of philosophy of the sort he claimed.

RELIGION

In *The Political Philosophy of Hobbes: His Theory of Obligation* (1957) Howard Warrender argued that it was not science on which Hobbes's political philosophy was based, but God. This set the parameters for much discussion of Hobbes and provoked a renewed interest in Hobbes's religious beliefs. Most notable in this is Aloysius P. Martinich's *The Two Gods of Leviathan: Thomas Hobbes on Religion and Politics* (1992). S. A. Lloyd, in *Ideals as Interests in Hobbes's Leviathan: The Power of Mind over Matter* (1992) takes further the issue of the role of religious belief in Hobbes's moral and political philosophy.

METHOD

Hobbes officially espoused two methods of argument, which he claimed to have taken over from Galileo: the resolutive or analytical method, which involved taking things (at least in imagination) to find an explanation of them, and the compositive or synthetical method, which involved seeing how one had to put things together to construct what was to be explained. The compositive method, he says, is the only method that actually provides demonstration, and it is the method that should be used in teaching. Though he says that the analytical method will provide understanding of civil and moral philosophy to the less philosophically adept who lack a knowledge of geometry, one must conclude that it is the compositive

method he uses in his attempts to create a science of morals and politics.

The standard example of Hobbes's method, his discussion of the watch in the preface to *De Cive*, is a misleading example to take because it is an example of the resolutive method, taking the watch apart to understand how it works. More appropriate is the example of the circle in chapter 1 of *De Corpore*, since that is an example of the compositive method: Hobbes seeks real definitions and, specifically, definitions in terms of a method that is guaranteed to produce what is being defined. A circle, for example, is defined in terms of the movement of a point that remains equidistant from another point. Science, Hobbes says, seeks the causes of things, but care is needed in understanding what he means by "cause." He does not mean matter-of-fact causes in particular cases, as dropping a lighted match onto wood shavings might cause a house to burn down; the cause of something's being a circle, even if it was in fact stamped out by a die, is that it is a shape that could have been produced by moving a point so that it remained equidistant from another point. How a particular circle is, in fact, produced is not Hobbes's concern. His concern is with the compositive method, the setting out of a way of putting things together so as to guarantee that the outcome is whatever one is defining. His arguments about, for example, the state and the laws of nature should be read in the light of this method.

SCIENCE AND KNOWLEDGE

Hobbes distinguished science from "knowledge original," the latter being sense or remembrance of sense and the record of it in books being called history. Science is the knowledge of the truth of propositions and how things are called, the model Hobbes recommended being geometry. The truths of science, as Hobbes used the term and as is to be expected from the method he adopted, are conceptual or necessary truths on his account. One should take it, therefore, that his moral and political philosophy is not to be taken as history, but as applications of his compositive method.

HUMAN NATURE, MORALS, AND POLITICS

There was, in his own time, and still is, today, a common belief that Hobbes believed people to be essentially selfish. This idea of the role of self-interest in Hobbes's philosophy lies behind most of the interest that theoreticians of international affairs and economics show in his work. The most influential book taking this sort of interpretation of Hobbes is David P. Gauthier's *The Logic of*

Leviathan: The Moral and Political Theory of Thomas Hobbes (1969). This book led the reaction to Warrender's (1957) account. Gauthier introduced into discussion of Hobbes's moral theory the use of games theory, starting from the idea that Hobbes took all people to be naturally selfish and then, working from the further claim that, on Hobbes's account, both rights and obligations must have a prudential basis, constructed a Hobbesian argument that rational people must set up a sovereign if they are to achieve their own advantage. He concluded, furthermore, that the Hobbesian "moral" system is nothing more than universal prudence. Despite the work of Bernard Gert (1967) arguing persuasively that Hobbes did not regard people as naturally selfish, this general approach became for some time the received view of Hobbes. Jean Hampton employs the games-theoretical approach to interpreting Hobbes in its finest detail in *Hobbes and the Social Contract Tradition* (1986).

Unlike Hampton, some others taking a games-theoretic approach did not claim to be interpreting Hobbes's arguments but only to be using him as a starting point. Gregory S. Kavka's *Hobbesian Moral and Political Theory* (1986) makes that point explicit at the start. This is also true of many of the attempts to sort out a Hobbesian model for the study of international affairs, a move that has shared with the games-theoretic approach the assumption that the strong form of Hobbes's condition of mere nature (the relationship holding between people who have no common authority over them, so that each is bound only by his or her private judgment) is at least a coherent notion and can therefore constitute part of such a model.

Others followed Gert's (1967) interpretation of Hobbes, according to which Hobbes did not take everybody to be naturally self-interested. This alternative interpretation was present even when the games-theoretic approach was popular and has now come to dominate. Deborah Baumgold's *Hobbes's Political Theory* (1988) develops such an interpretation of Hobbes, as does R. E. Ewin's *Virtues and Rights: The Moral Philosophy of Thomas Hobbes* (1991), which also argues that Hobbes's condition of mere nature is not a coherent notion and was intended by Hobbes as part of a *reductio* argument, and Boonin-Vail's *Thomas Hobbes and the Science of Moral Virtue* (1994).

The different views of human nature led to different accounts of Hobbes's views of morals and politics. On the games-theoretic approach Hobbes was taken to be some sort of an ethical egoist as well as a psychological egoist. The main alternative to this in recent debate, mainly

sparked off by Gert's work (1967), when Hobbes is not taken to be a psychological egoist, has been that Hobbes is a virtues theorist (the view espoused by, for example, Ewin [1991] and Boonin-Vail [1994]), though interpretations of Hobbes's moral theory as depending on God (such as Lloyd's [1992] interpretation) still play a significant part in debate. Hobbes rejected Aristotle's moral theory because Aristotle took the relevant question to be whether a particular quality of character was a mean; the correct question was whether it tended to peace. The laws of nature, Hobbes says (among several different things he says about them), properly understood, are not laws, but are qualities fitting man for peace and for obedience. This suggests a virtues interpretation of Hobbes's moral theory, with his story of people agreeing on these laws of nature being the model produced by the compositive method to explain what these laws are.

Hobbes was clear that honest and intelligent people can disagree (though he often doubted the honesty or intelligence of those who disagreed with him), even in cases of morality. Where private judgments are in conflict and common action is necessary, disruption will occur. He makes the point firmly in, for example, chapter five of *Leviathan*. The only way of avoiding disruption, he believes, is to have a sovereign, a man or body of men, whose judgment is binding on those who disagree. Thus, the necessity of politics appears, in Hobbes's philosophy, as part of the working out of one's moral life.

THE PHILOSOPHERS' HOBBES AND THE HISTORIANS' HOBBES

Much work has been done, by Richard Tuck (1993), Noel Malcolm (2002), Quentin Skinner (1996), and others on the historical context of Hobbes's work and its significance in interpreting what Hobbes wrote. Philosophers, perhaps, had read Hobbes with too much concentration on what he took to be his universal science; historians, perhaps, had read him with too much emphasis on his concern with practical matters of the day. The different approaches became explicit with a disagreement between Warrender (1957) and Skinner (1996), but have largely fallen away as each group has come to pay more attention to the work of the other with a number of writers combining both sorts of interest in Hobbes.

HOBHOUSE, LEONARD TRELAWNEY
(1864–1929)

Leonard Trelawney Hobhouse, the British sociologist and philosopher, was born in a small village near Liskeard, in Cornwall. He was educated at Marlborough School and Corpus Christi College, Oxford, where he took firsts in classical moderations and "greats." During his undergraduate years he engaged in the study of current problems in politics and economics, along with other radically minded students such as Gilbert Murray and Arthur Acland. He was elected to a prize fellowship at Merton College in 1887 and to a fellowship at Corpus Christi in 1894.

Hobhouse's main interest was the study of the evolution of mind as the central factor in historical development. This, combined with an innate humanitarianism, made him dissatisfied with the passive role of an Oxford don, although even at Oxford he was active in the Labour movement, especially in such causes as trade unionism, the cooperative movement, and adult education. After leaving Oxford, Hobhouse became influential among the "New Liberals," who sought to combine Liberalism with a measure of organized collective action. He was very sympathetic to the Labour Party, although he never joined it. Toward the end of his life Hobhouse grew disillusioned with party politics, and by 1927 he had ceased to belong to any party.

On leaving Oxford in 1897, Hobhouse joined the staff of the *Manchester Guardian,* with which he was associated for most of the rest of his life in one capacity or another. Sociology and philosophy, however, were always his main interests. His *Mind in Evolution* (1901) and *Morals in Evolution* (1906)—a remarkable synthesis of anthropology, ethics, and the history of religious and social institutions—led to his appointment to the new Martin White part-time chair of sociology in the University of London, converted in 1925 to a full-time chair. Hobhouse first opposed Britain's entry into World War I, but he came to support the Allied cause wholeheartedly. He saw the war as the direct outcome of Hegelian teaching, and his own contribution to the war effort was *The Metaphysical Theory of the State,* an extreme attack on Hegelian political theory, especially as found in Bernard Bosanquet's *Philosophical Theory of the State.*

Hobhouse, besides being a philosopher of distinction, made important contributions to anthropological techniques and was a pioneer in comparative and social psychology and one of the founders of sociology as a synthesizing science. The encyclopedic scope of his work and the reluctance of English universities to accept the new subject of sociology contributed to an underestimation of his work in any one field. In philosophy his concern with the reconciliation of different schools meant that he did not himself belong to any one school, and this militated against his due recognition by philosophers.

It is impossible to separate Hobhouse's philosophy from the rest of his work, since his achievement lay in interpreting philosophically a wealth of general and detailed knowledge. There was, however, no question of fitting everything into a fixed scheme. His procedure was empirical and undogmatic, leaving a place for new facts from science and life. His comprehensive studies began with epistemology; went on to an evolutionary interpretation, first of mind in animals and humankind and then of moral and religious ideas; turned next to values in man and society; and ended with a grand synthesis of his philosophical and scientific theories.

The strongest influences on Hobhouse were Herbert Spencer's evolutionary philosophy, Auguste Comte's Positivism, and the social philosophy of John Stuart Mill and T. H. Green. He parted company with Spencer in regarding the appearance of minds as a turning point in the evolutionary process and in accepting the idealists' organic view of society. At the same time he rejected the idealists' reduction of all things to the spiritual. His theory of knowledge was realist and empirical; knowledge cannot make its own object, for it is based on experience and is of reality, not appearance. All knowledge is sociologically conditioned, but a positivist philosophy, applying our knowledge of these conditions, provides safeguards against error. The object of the physical sciences ("matter"), subject to mechanical laws, is only one aspect of reality; there is another aspect ("mind"), subject to teleological laws. Hobhouse traced the close relation of the two aspects in the developing world order.

HOCKING, WILLIAM ERNEST
(1873–1966)

William Ernest Hocking, the American idealist and philosopher of religion, was born in Cleveland, Ohio. He spent his early years in the Middle West and studied civil engineering at Iowa State University. Private reading stimulated an interest in philosophy and led him to study at Harvard, where he was influenced chiefly by William James and Josiah Royce. He completed his undergraduate and graduate studies at Harvard University and spent most of his long teaching career there, retiring in 1943.

Although his philosophical system embodies elements of pragmatism and realism, it is primarily an affirmation of Other Mind, or God, as ultimate reality known directly and intuitively. Hocking thus stands in the idealist tradition in modern philosophy and referred to his own position most commonly as "Objective Idealism." Primitive experience, involving the knowledge of other selves and the world, is conditioned by an immediate awareness of Other Mind, standing in an I–Thou relationship to the self. Both sensory and emotive experience have cognitive connections that point beyond self to Other Mind. Hocking's emphasis is on feeling linked inextricably with idea, so that the two are joined in immediate consciousness as an "idea–feeling couple." This concept of the union of idea and feeling is the source of the strong strain of mysticism in Hocking's philosophy, but it is a mysticism that does not abandon the role of intellect in clarifying and correcting intuition. He advances the "principle of alternation" between intuition and intellect as fundamental to the appropriation of metaphysical truth.

In his first book, *The Meaning of God in Human Experience* (1912), Hocking developed an empirical philosophy of religion, grounded in the tradition of classical idealism and at the same time drawing heavily on the mystical experience. In so doing, he sought primarily to defend idealism against arguments of the pragmatists and realists, and he has continued this defense over the years. His Gifford Lectures of 1938–1939 and other later works show a continuing concern with the problem of "meaning in experience," of "fact and destiny," which challenges man to go beyond his day-to-day existence and seek understanding in the wholeness of things. Thus, as a philosopher Hocking dealt primarily with metaphysical and epistemological questions in a manner in which religious sensitivity played a prominent part.

At no point in his long career did Hocking devote himself exclusively to intellectual issues. He played an active role in seeking United States acceptance of the League of Nations and in the 1920s and 1930s he was especially interested in social and political problems of the Middle East. After that time he participated in a study of freedom of the press in the United States and was active in support of the United Nations and other political and ethical causes. These active concerns found expression in at least ten books and scores of articles and extended his influence far beyond the realm of academic philosophy.

See also Idealism; James, William; Royce, Josiah; Other Minds; Pragmatism; Realism.

Bibliography

Hocking's major work is *The Meaning of God* (New Haven, CT: Yale University Press, 1912). Among other works that develop his philosophical and religious views are *Human Nature and Its Remaking* (New Haven, CT: Yale University Press, 1923); *The Self: Its Body and Freedom* (New Haven, CT: Yale University Press, 1928); *Types of Philosophy* (New York: Scribners, 1929; rev. eds., 1939, 1959); *Living Religions*

and a World Faith (New York: Macmillan, 1940); and *Science and the Idea of God* (Chapel Hill: University of North Carolina Press, 1944).

HODGSON, SHADWORTH HOLLOWAY

(1832–1912)

Shadworth Holloway Hodgson, the English metaphysician and epistemologist, was educated at Rugby and Oxford. Although he worked outside the universities, Hodgson was widely respected among English philosophers; he was elected president of the Aristotelian Society at its founding in 1880 and was reelected for thirteen successive years. In the United States, William James recognized the similarity of many of his own doctrines to those of Hodgson, and acknowledged Hodgson's priority despite their profound differences on fundamental points of metaphysics.

Independent and workmanlike, Hodgson was remarkably free from the characteristics and fashions of late Victorian philosophy. He remained steadfast in a central position, attacking the superficial clarities of the associationists on the one side and the vague generalizations of the Germanizing idealists on the other. His primary achievement was to keep alive the firmness of intellectual analysis peculiar to the epoch of Sir William Hamilton and H. L. Mansel. In particular he carried out the line of investigation begun in J. F. Ferrier's *Institutes of Metaphysics.* J. C. Shairp, principal of St. Andrews University and Hodgson's friend and mentor, was his link with Ferrier. Hodgson got from Ferrier a sense of the importance of the relationship of being empirically distinguishable but inseparable, in the way, for example, that color is visually inseparable from shape but nevertheless distinguishable from it. As developed by Hodgson, this principle meant that the notion of logical independence is much more complex than most philosophers have realized. Color, for example, although it is not isolable from shape, does vary independently of shape. From this point of view, Hodgson was able to repudiate the crude logical atomism then prevalent among the associationists with-

out running to the extreme of the sort of logical monism which denies outright the reality of independence.

At a deeper level still, Hodgson applied this same principle of distinguishability with inseparability to elucidate the relationship of consciousness to its objects, that is, of the subjective to the objective. This relationship was basic for Hodgson, and he felt it was disclosed by the kind of reflective analysis that René Descartes used in establishing his *cogito.* Indeed, one might say that Hodgson's starting point was the distinction between this reflective consciousness and a prereflective consciousness in which the distinction between subject and object has not yet emerged.

Although he lacked Ferrier's striking originality, Hodgson was a thinker of great intellectual honesty and thoroughness. What gives his work its special value is the modern manner in which his untiring examination of the fashionable nineteenth-century problems combined technical competence with clarity. The long discussion of G. W. F. Hegel in *The Philosophy of Reflection* is still of interest. So too is Hodgson's treatment of the relationships between particulars and universals and between perception and conception. His careful reconsideration of the problem of free will in *The Metaphysic of Experience* can also be profitably consulted. We are free in the sense that we determine our own actions, but that which does the determining in each case is a set of neurocerebral conditions that is not self-determined, accompanied by consciousness. In this way, he held, free will and determinism are compatible. He explained our awareness of being free as simply our awareness of the uncertainty of the outcome of our acts of volition.

Hodgson held that consciousness gives us knowledge of a reality which is independent of consciousness and which is its condition, even though consciousness is our only evidence for that reality. The material object revealed by consciousness causes sensations in consciousness. It is material, but it is composed of elements that apart from the object would not be material. Consciousness is an epiphenomenon. It is always conditioned by organic and interorganic interaction and never conditions such interactions. The proximate causes of all psychical events lie in the neurocerebral system. There might be immaterial causes of such events, but experience reveals none.

Hodgson resembles Edmund Husserl among later philosophers, rather than Bertrand Russell, G. E. Moore, and their followers. Hodgson's doctrine that things are what they are "known as" anticipated in a way Husserl's phenomenological reduction, and his technique of distinguishing between inseparables approximates to Husserl's reduction to essences. Hodgson's ethics, though

perhaps less interesting than his metaphysics, nevertheless shows the same conscientious struggle to clarify basic distinctions and can be as profitably studied as some other, better-known systems.

HØFFDING, HARALD
(1843–1931)

Harald Høffding, the Danish philosopher and historian of philosophy, was born in Copenhagen and lived there throughout his life. From 1883 to 1915 he was professor of philosophy at the University of Copenhagen. Høffding received a degree in divinity in 1865, but he had already decided not to take orders. A study of Søren Kierkegaard's works, and especially of his views on Christianity, had led to an intense religious crisis ending in a radical break with Christianity. Høffding sought in philosophy a new personal orientation and gradually developed into an extraordinarily many-sided liberal humanist. His philosophical development was influenced during a stay in Paris (1868–1869) by the study of French and English positivism, especially that of Auguste Comte and Herbert Spencer. Høffding always worked hard, and his activity as a scholar ranged over every branch of philosophy, including psychology. His works display a vast knowledge, a keen eye for essentials, and a critically balanced judg-

ment. They were translated into many languages and widely used as textbooks. By the turn of the twentieth century Høffding's reputation was worldwide and he knew personally many leading thinkers. He was the outstanding Danish philosopher of his day, and in 1914 the Royal Danish Academy of Sciences and Letters assigned him the honorary residence of Gammel Carlsberg, where he lived to the end of his life. The residence later passed to the physicist Niels Bohr, a younger friend of Høffding.

Of Høffding's many works only five can be discussed here. *Psykologi i Omrids på Grundlag af Erfaring* (Copenhagen, 1881; translated by M. E. Loundes as *Outlines of Psychology,* London) is based on the traditional tripartite division of the mind into knowledge, feeling, and will but puts primary stress on the will in the widest sense of the term. In this sense the will includes conation, urge, endeavor, need, demand, and desire. The will is seen as primary, knowledge as guiding the will, and feeling as a symptom of need or desire, which are themselves elements of the will. Høffding's view anticipated modern need and dynamic psychology.

In *Etik, en Frernstilling af de etiske Principper og deres Anvendelse på de vigtigste Livsforhold* (Ethics: an account of ethical principles and their application to the chief conditions of life; Copenhagen, 1887) Høffding associated himself with British utilitarianism, which he called welfare ethics. The greatest happiness of the greatest number is the fundamental value. In the conflict between individual and social ethics, Høffding took the liberal view. The psychological basis of ethical valuation is a sympathetic feeling that at its highest development takes on the character of a universal and disinterested sympathy.

Den nyere Filosofis Historie, en Fremstilling af Filosofiens Historie fra Renaissancens Slutning til vore Dage (2 vols., Copenhagen, 1894–1895; translated by B. E. Meyer as *History of Modern Philosophy,* 2 vols., London, 1900; reprinted, 2 vols., New York, 1955) is a concentrated account of the various modern philosophers and philosophical schools marked by a fine balance between exposition and criticism. It is of special interest as the first study of modern philosophy to put the primary stress on the mathematico-mechanical science and methods of Galileo Galilei and Isaac Newton in presenting the development of epistemology. Among the philosophers treated, Høffding found Benedict Spinoza, David Hume, and Immanuel Kant especially congenial.

Religionsfilosofi (Copenhagen, 1901; translated by B. E. Meyer as *Philosophy of Religion,* New York, 1906), in three parts, treats religious experience from the standpoints of epistemology, psychology, and ethics. Høffding

claimed that the basis of all religion is a desire for belief in the existence of values, and that the various religions may be characterized by the kinds of values that they claim exist. The presentation is distinguished by its reasoned objectivity and its respect for religion. Høffding himself was an agnostic.

In *Den menneskelige Tanke, dens Former og dens Opgave* (Human thought: its forms and its problems; Copenhagen, 1910) Høffding set forth his theory of knowledge, including an outline for a doctrine of categories whose usefulness has been reduced by the development of modern logic. Høffding's interest in epistemology was psychological rather than strictly logical, and his interest in the psychological basis of knowledge was constructive rather than phenomenological. In general, Høffding followed Hume and Kant in regarding the forms and principles of human knowledge as being peculiar to human beings and their absolute ontological validity as being incapable of proof. The result is a compromise between empiricism and the Kantian critical philosophy.

Bibliography

There is a brief autobiography containing an account of Høffding's fundamental views in *Die Philosophie der Gegenwart in Selbstdarstellungen,* Vol. IV, edited by Raymund Schmidt (Leipzig: F. Meiner, 1923). Kalle Sandelin, ed., *Harald Høffding in Memoriam* (Copenhagen: Gyldendal, 1932), contains an excellent bibliography that lists 393 publications by Høffding as well as 425 papers and reviews concerning his works.

Frithiof Brandt (1967)

HOLBACH, PAUL-HENRI THIRY, BARON D'
(1723–1789)

Paul-Henri Thiry, Baron d' Holbach, the foremost exponent of atheistic materialism and the most intransigent polemicist against religion in the Enlightenment, was born of honorable but obscure German parents in Edesheim, a small town in the Palatinate; his name was originally Paul Heinrich Dietrich. His upbringing and education were directed by his maternal uncle, Franciscus Adam d'Holbach, who had made a fortune in Paris and assumed French nationality. After studying at the University of Leiden, Holbach came to Paris, in 1749, married his second cousin Basile-Geneviève d'Aine, and soon became a French subject. On his uncle's death in 1753, he inherited the title of Baron d'Holbach, with properties yielding a handsome income of 60,000 livres. The following year his wife died, and in 1756 Holbach married her younger sister, Charlotte Suzanne d'Aine.

On settling in Paris, Holbach had associated with the younger *philosophes* who, with Denis Diderot, Jean Le Rond d'Alembert, and Jean-Jacques Rousseau, were grouping around the *Encyclopédie,* to which he also became a major contributor. His *salon* soon became the main social center, and a sort of intellectual headquarters, for the Encyclopedist movement. The gatherings on Thursdays and Sundays, during more than three decades, at Holbach's house in Rue Royale-Saint-Roch were famous not only for his excellent dinners but also as a unique "clearinghouse" for radical ideas of every type. The more intimate meetings at his country estate of Grandval, near Paris, have been described in fascinating detail in Diderot's letters. The members of Holbach's circle, besides the assiduous Diderot, included Melchior von Grimm, Claude-Adrien Helvétius, d'Alembert, Rousseau, Nicolas-Antoine Boulanger, Étienne Bonnot de Condillac, Jacques-André Naigeon, Baron de l'Aulne Turgot, and Marquis de Condorcet. Holbach also counted among his acquaintances many foreigners, notably David Hume, Edward Gibbon, Adam Smith, Joseph Priestley, Horace Walpole, David Garrick, Laurence Sterne, Cesare Beccaria, and Benjamin Franklin.

Because he left neither a body of correspondence nor personal papers, Holbach's character must be pieced together from contemporary accounts. The composite picture credits him with an impressive erudition, an extremely methodical mind, a collector's interest in art, and with the qualities of affability, discreet generosity, modesty, loyalty to friends, and a taste for virtuous simplicity. Diderot's more private remarks diverge somewhat from this public image, disclosing that the baron, at least with those nearest him, had moments of moodiness, petulance, and gruffness. But these traits just provide a touch of humanity without essentially altering the picture of him as the virtuous atheist. Even Rousseau, despite growing hostility, used him as the model for Monsieur de Wolmar, the altruistic unbeliever of *La nouvelle Héloïse.* Indeed, Holbach's comportment as a social being evidently conformed to his deep desire to illustrate, by his own life and personality, the truth of a most cherished

philosophical opinion, that atheism and morality are as plausibly bound together as religiosity and true virtue are not.

Although Holbach, until some years after his death, was publicly known merely as *le premier maître d'hôtel de la philosophie,* he had surreptitiously played a far greater role, known only to a few. Almost everything he wrote—whether because it expounded atheism and materialism, attacked Christianity, or castigated absolute monarchy, the state church, and feudal privilege—was highly subversive under the *ancien régime* and could have exposed him to the severest penalties. Consequently, his innumerable manuscripts were usually forwarded through secret channels to Holland for publication, after which the books were smuggled back into France. Owing to the strict anonymity that Holbach maintained, bibliographers have since been faced with insoluble problems of exact attribution concerning many texts linked to him.

PHILOSOPHICAL ORIENTATION

Holbach's literary career falls conveniently into three phases. A competent although uncreative student of chemistry, metallurgy, mineralogy, and geology, he translated into French, mainly during the 1750s, a number of works (mostly German) from these fields. He also contributed to the *Encyclopédie,* beginning in 1752, almost 400 articles dealing with the same sciences. These interests shaped Holbach's philosophical outlook, for his materialism corresponded to the methodology and scope of a rigorously scientific explanation of things. In particular, the new evidence offered by geology concerning Earth's history negated, in his view, the doctrine of creation, and with it the existence of God.

The second phase of Holbach's activity, coinciding with the 1760s, consisted of a relentless militancy against organized religion in general and the Catholic church in particular. Not content with the repeated broadsides of his own composition, he also translated anticlerical, deistic, or materialistic works by various British authors (among them Peter Annet, Anthony Collins, Thomas Woolston, John Toland, and Thomas Hobbes), and he published, with the collaboration of Naigeon, a number of French antireligious texts that had long been circulating clandestinely in manuscript copies. Among Holbach's own tracts, the most important were *Le Christianisme dévoilé, ou Examen des principes et des effets de la religion chrétienne* (1761); *Théologie portative, ou Dictionnaire abrégé de la religion chrétienne* (1767); *La contagion sacrée, ou Histoire naturelle de la superstition* (1768); *Lettres à Eugénie, ou Préservatif contre les préjugés* (1768); and *His-*

toire critique de Jésus-Christ, ou Analyse raisonnée des Évangiles (1770).

The themes recurring throughout these and similar books represent a vehement restatement of almost all the arguments for unbelief current in eighteenth-century France. The most characteristic are the following: The idea and cult of God sprang from the ignorant terror of primitive man seeking to placate the destructive powers of nature, and they have survived ever since through superstition; religious history is a catalogue of senseless disputes, intolerance, prejudice, persecution, and crime; the clergy is ordinarily engaged in exploiting the gullibility of the people for its own profit; religions have invariably supported tyrannical governments to further their own ambitions of domination; Scriptural "proofs" of Christianity are worthless as objective historical evidence; theological dogmas are a maze of delusion and mystification on which no rational, just, or useful social institution can be built.

ATHEISTIC MATERIALISM

The third and properly philosophical stage of Holbach's output began in 1770 with the *Système de la nature, ou des Lois du monde physique et du monde moral.* This first—and only—example in the Enlightenment of a comprehensive, unmitigated defense of atheistic materialism was the culmination of a whole trend of ideas already expressed in varying degrees by Julien Offray de La Mettrie, Helvétius, Diderot, and others. It caused much consternation in France, not only among spokesmen for the official faith but among the deistic *philosophes* as well. It was suppressed by judicial decree, and among the flood of refutations it provoked were those of Voltaire (the article "God" in the *Philosophical Dictionary*) and Frederick the Great (*Examen critique du Système de la nature*).

The *Système de la nature* defines man as a product entirely of nature, subject to the laws governing the physical universe that, in turn, constitutes the whole of reality. The soul, or spiritual substance, is an illusion; the moral and intellectual attributes of man are simply his organic machine considered in certain of its special, less visible operations. Since sensibility is a primary function of the animal organism, all our higher faculties are derived ultimately from the different forms that sensation takes. The only means of knowing man in nature is through the empirical and rational investigation of matter.

Nature is the sum of matter and motion. All matter is actually or latently in motion, since energy, or force, is among its inherent properties. The material universe is self-created and eternal. All change in nature represents a

communication of motion, a redistribution of energy, which modifies the corresponding combination or disposition of material particles, elements, or aggregates. The totality of matter and motion are eternal and constant, but the specific forms they exhibit—rocks, plants, animals, oceans, heavenly bodies, and so forth—are forever changing. Each thing or being tends, by the laws of attraction and repulsion, to persist in its essence, until it is finally transformed into something else. Man is no exception: The ephemeral life of his species depends on the stability of the physical environment.

There is neither chance nor disorder in nature: All is necessity and order, an irreversible chain of causes and effects. Freedom is objectively meaningless when applied to human behavior, which, controlled by such factors as temperament, education, and environment, takes part in the universal determinism of nature. Virtue and vice, moreover, need not depend on free will; they simply describe actions favoring or hindering the mutual happiness of society and the individual.

ETHICS

Holbach's principal aim was to construct a system of ethical and political values on materialistic grounds. The supreme natural goal of human existence is happiness, but no one can be happy without the services of others. Ethics, therefore, is the science of human cooperation to promote the well-being of the individual through that of society, and it is based on the positive knowledge of men's reciprocal social needs. If humankind has always been morally corrupt and unhappy, religion has been mainly to blame. Supernatural theology, by falsifying man's nature and linking his salvation to the illusory notions of God and immortality, has entirely subverted ethical truth. Holbach takes pains to show that, all attempted definitions of God being hopelessly self-contradictory, "God" is logically a meaningless term. It is understandable, then, that belief in God should have been historically of no moral utility. For religious morality, founded on dogmatic obscurantism and ritualistic futilities rather than on natural and social realities, has prevented human beings from perceiving and correcting the actual conditions productive of vice and misery. Atheism is thus the prerequisite of all valid ethical teaching. In place of the condemnation of sin, Holbach's exposition of secular and utilitarian ethics is typically accompanied by vibrant appeals to humanitarianism and moving exhortations to civic virtue—all in the name of "nature" and "happiness."

POLITICAL THEORY

In *Le bon-sens, ou Idées naturelles opposées aux idées surnaturelles* (1772), the most widely read of his books, Holbach offered a popular, unsystematic version of his philosophy. Thereafter, with the growing troubles of the Bourbon regime, he focused his attention on national problems and developed at great length the ethical and political sections of the *Système de la nature* in a new series of works: *Politique naturelle, ou Discours sur les vrais principes du gouvernement* (1773); *Système social, ou Principes naturels de la morale et de la politique* (1773); *Éthocratie, ou le Gouvernement fondé sur la morale* (1776); and *La morale universelle, ou les Devoirs de l'homme fondés sur sa nature* (1776).

His own term *ethocracy* describes the gist of Holbachian political thought. The state, whose role is simply an extension of the social ethics of enlightened self-love, ought to nurture, in every possible way, the virtues of cooperation on which the good of society and the felicity of each of its members depend. The social pact itself is based on the useful services that the individual and society are able to render to one another, and it remains valid only to the extent that its mutually beneficial aims are fulfilled. Since, therefore, the legitimacy of any government varies directly with the happiness of one and all living under it, Holbach proclaimed with courageous logic the people's right, if there were no other hope of assuring their welfare, to overthrow and replace their rulers. Where the happiness of a society was at stake, it was the sovereign; governments, which were merely means to an end, had no absolute or divine authority.

More specifically, Holbach proposed radical political and economic reforms for France in keeping with the ethocratic ideal. He advocated, as against the extremes of republicanism and enlightened despotism, a limited, constitutional monarchy, in which intermediate parliamentary bodies would represent the interests of society and would maintain a balance between the opposing dangers of either popular or autocratic tyranny. He called for the abolition of hereditary class privileges and for their replacement by a hierarchy of status based on the degree of socially useful service actually rendered by its members. He defended the principle of progressive taxation according to wealth and wanted individual ownership of property to be as proportionate as possible to the value of work performed, thus eliminating the extremes of opulence and poverty. He insisted on the complete separation of church and state and on the toleration of all religious sects, with the government as a neutral preserving peace among them. Freedom of thought and of the press were

to be inviolable; and government had the duty of providing a system of secular public education, with its main objective the inculcation of the social and civic virtues.

SOURCES AND INFLUENCE

Among the sources of Holbach's philosophy were classical and modern Epicureanism, the Cartesian universe of matter and motion in perpetual flux, the logical and metaphysical materialism of Hobbes, the determinism and "atheism" of Benedict de Spinoza, the sensationalism of John Locke, and Leibnizian dynamics. Nearer in time, Holbach was indebted to Helvétius for the utilitarian conception; to La Mettrie for the physiological psychology of the *homme machine*; and to the experimentalist, evolutionary materialism of Diderot, with whom he had the closest personal and ideological ties.

Despite serious shortcomings, Holbach's ideas are still of considerable interest. Although the value of his critique of Christianity is today limited by the one-sidedness and unimaginativeness resulting from his polemical stance and propagandist aims, historically it led toward the objective and psychological study of religion as a distinctly human invention. The *Système de la nature* suffers, no doubt, from too much reliance on outmoded scientific theories; from an excessive generalization and simplification of the concrete complexities of nature; and from a tiresome combination of doctrinaire tone and humorless prolixity that were, unfortunately, peculiar to the author. Nonetheless, it remains a classic text in the development of atheistic materialism as the philosophical expression par excellence of modern science. The main weakness of Holbach's political thought is that it exaggerated a rationalist, moralistic, and prescriptive approach to the subject at the expense of the perhaps more important role of economic, sociological, and historical laws of development on which political institutions, and the changes to be made in them, must depend. Nevertheless, it served significantly to prepare for the French Revolution and contributed subsequently to the progress of democratic and utilitarian doctrines.

Bibliography

WORKS BY HOLBACH

Holbach's works, despite innumerable editions, have never been published in collected form, and few of them have been reprinted since the first half of the nineteenth century. The following are English translations:

Christianity Unveiled; Being an Examination of the Principles and Effects of the Christian Religion. New York: Columbian Press, 1795; London: R. Carlile, 1819.

Common Sense: or Natural Ideas Opposed to Supernatural. New York, 1795, 1833, 1836. Also published as *Superstition in All Ages.* New York, 1878, 1890, 1920; Chicago: De Laurence Scott, 1910.

The System of Nature; or, The Laws of the Moral and Physical World. London, 1795–1796; 1797, 1816, 1820, 1834, 1839, 1840, 1863, 1884; Philadelphia, 1808; New York, 1835; Boston, 1853.

Ecce Homo! or, A Critical Inquiry into the History of Jesus of Nazareth. Edinburgh, 1799; London, 1813, 1823; New York, 1827.

Letters to Eugenia, on the Absurd, Contradictory, and Demoralizing Dogmas and Mysteries of the Christian Religion. London, 1819; New York, 1833; Boston, 1857.

HÖLDERLIN, JOHANN CHRISTIAN FRIEDRICH
(1770–1843)

Johann Christian Friedrich Hölderlin, a German poet, novelist, philosophical essayist, and dramatist, was born

in Lauffen, Germany. His father died when he was two, leaving Hölderlin an inheritance administered by his mother, who demanded strict obedience to her plans for his future. His mother married Johann Christoph Gok, subsequently the mayor of Nürtingen, in 1774; and a half brother, Karl Gok, with whom Hölderlin maintained a significant correspondence, was born in 1776. His stepfather, whom Hölderlin admired, died in 1779, leaving Hölderlin in his mother's sole charge.

Hölderlin was educated first at the local school in Nürtingen, where he studied Latin, Greek, and rhetoric. He became friends there with Friedrich Wilhelm Joseph von Schelling. He then studied further in Lutheran monastery schools, first at Denkendorf (1784–1786) and then at Maulbronn (1786–1788). During this time he read Ferdinand Canning Scott Schiller, Friedrich Gottlieb Klopstock, and Pindar, and he began composing verses.

Hölderlin entered the Lutheran theological seminary in Tübingen in 1788, at the same time as Georg Wilhelm Friedrich Hegel. Schelling joined the seminary two years later, and Schelling, Hegel, and Hölderlin developed a close friendship. Together, they read Jean-Jacques Rousseau, Benedict (Baruch) de Spinoza, Gottfried Wilhelm Leibniz, Plato, and Immanuel Kant, and they shared enthusiasm for the French Revolution. Throughout his school years Hölderlin displayed intellectual ability, anxiety, emotional intensity, and a readiness to fall in love with intellectually inclined young women. His emotional and intellectual life made him chafe under the regimes and orthodoxies of the seminary, and he found himself pulled more toward poetry than toward a career in the ministry. He published his first poems in 1791, and he began work on the novel *Hyperion, or The Hermit in Greece*.

While continuing to accept the formal control of his future as a minister by the Lutheran consistory, Hölderlin left Tübingen in 1793 to become a private tutor in Waltershausen. From Waltershausen he traveled frequently to Jena in 1794, where he attended Johann Gottlieb Fichte's lectures, met Johann Wolfgang von Goethe, and visited regularly with Schiller, who published "Fragment of Hyperion" in his magazine. In 1795, with Wilhelmine Kirms, a married but separated lady's companion of his employers, he had a daughter, who died of smallpox at thirteen months. Following increasing difficulties in controlling his pupil, Hölderlin was dismissed from Waltershausen in 1795, but was provided with enough money to settle in Jena to study philosophy. There, he lived for a time with Isaac von Sinclair, a close friend and political

radical. Most of his strictly philosophical essays date from the 1794–1795 period of his Jena visits and residence.

In January 1796 Hölderlin again became a private tutor, now in the home of Jakob Friedrich Gontard, a wealthy Frankfurt banker. He continued to work in philosophy, and the famous "Oldest System-Program for German Idealism" fragment, arguably by Hölderlin but only later discovered in Hegel's hand and published first in 1918, dates from this period. Here, Hölderlin also encountered the beautiful and talented twenty-seven-year-old Susette Gontard, the wife of his employer, with whom he began a passionate affair. She figures as the model for Diotima in *Hyperion* and as the addressee in some of his finest poems. Volume one of *Hyperion* was published in April 1797. While in Frankfurt, Hölderlin continued to correspond with Schiller, and he imagined a series of "New Letters on the Aesthetic Education of Man," planning both to explain and to overcome all divisions between subject and object and between theoretical and practical reason. Already his friends had begun to worry about his enthusiasms, anxieties, and depressions. Hölderlin completed some fifty-five poems in Frankfurt and began work on the verse drama *Der Tod des Empedokles*.

In September 1798 the affair with Gontard became evident, and Hölderlin was forced to leave Frankfurt for Bad Homburg. He remained in Bad Homburg, except for occasional visits to Nürtingen, until 1800. During this time he continued work on *Hyperion* and *Empedokles*, and he began translations of Pindar and of the tragedies of Sophocles. He produced his poetological essays during this period, as well as many new poems. Volume two of *Hyperion* was published in 1799.

Beginning in January 1801 Hölderlin worked as a private tutor in Hauptwyl, Switzerland. In April he was dismissed, and he returned to Nürtingen. Schiller broke off their correspondence. Throughout the year he completed a number of great poems, including "Bread and Wine," "Homecoming," and "Voice of the People." In December he left on foot to travel to Bordeaux, France, where he arrived in January and remained for three months. In June 1802 he reappeared in Nürtingen, pale, emaciated, and obviously deranged. Hölderlin was able to continue work on the translations of Sophocles (published 1803) and Pindar, as well as on a few poems. In 1804 Sinclair arranged for Hölderlin a position as a librarian in Bad Homburg, without duties. With Sinclair, Hölderlin met in Stuttgart with political radicals conspiring against the landgrave. Sinclair was tried for treason in

1805 but released for lack of evidence. Hölderlin avoided trial by being judged mentally incompetent.

Sinclair gave up his care of Hölderlin in September 1806, and Hölderlin's mother had him forcibly committed to a clinic in Tübingen for the mentally ill. In the summer of 1807 Hölderlin was released into the care of Ernst Zimmer, a Tübingen carpenter who admired his work. "Patmos," "The Rhein," and "Remembrance" were published. He remained in the Zimmer household for the next thirty-six years, where he spent much of his time playing the piano and flute. Wilhelm Waiblinger began to visit Hölderlin in Tübingen in 1822, and in 1830 Waiblinger published *Friedrich Hölderlin's Life, Poetry, and Madness*. Hölderlin's *Selected Poems* was published in 1826. Hölderlin died in June 1843.

It is difficult to locate Hölderlin's work—poetic, philosophical, or poetological—within standard literary and philosophical categories. Dieter Henrich (1992, 1997) established Hölderlin's continuing Kantianism, both in accepting the separation of discursive consciousness from immersion in and intuitive awareness of absolute being and in accepting independence of free, moral personality as an ideal. But Henrich also emphasized Hölderlin's commitment to love and to connectedness to nature and to other human beings. This commitment lends to his writing a sobriety or earnestness, different from the later Romantic irony of Friedrich von Schlegel and from other projects of purely cultural cultivation that are less freighted with ontology. Nor, given his Kantian antidogmatism, does Hölderlin offer any system of human life in relation to the absolute, in the manner of the absolute idealisms of Hegel or Schelling. In Henrich's terms Hölderlin is best characterized as articulating a *Vereinigungsphilosophie*: an account of human beings as always seeking both independence-moral sublimity and love-connectedness. In this continual seeking, moments of remembrance and of gratitude for one's course of life are possible, but without any lasting conclusiveness.

Hölderlin's poetry—while typically firmly metrically controlled by Greek models, especially ones taken from Pindar, and so is more classical than effusive—is also characteristically difficult syntactically, even hermetic. Argument over Hölderlin's significance has concerned whether Hölderlin is better understood as a confident prophet of an imminent transcendence of one's present cultural plights, as Martin Heidegger (1949a) urges, or rather principally as a paratactic writer, resistant to all formally closed plots of human experience, as Theodor W. Adorno (1992) urges. Here, Henrich's reading of Hölderlin's *Vereinigungsphilosophie* has the advantage of accepting the insights but avoiding the errors of these other, sharply opposed readings.

Hölderlin's sense of the continuing openness, but also provisional formability, of philosophico-poetic thinking is reflected in his *Wechseltonlehre* or theory of the proper modulation of fundamental moods, in poetry and in life, and this sense is enacted in his poetic practice. Together, his theory and poetic practice provide an image of nonfoundationalist seriousness in thinking that is likely to continue to attract substantial attention and interest.

HOLE ARGUMENT

The original "hole argument" (*lochbetrachtung*) was created by Albert Einstein. The point of the argument may be put as follows: If a physical theory's equations are *generally covariant* (that is, invariant under a wide group of continuous coordinate transformations) then the theory is in a certain specific sense *indeterministic*. Einstein put the argument to two different uses. First before the discovery of his final field equations for the General Theory of Relativity (GTR), the argument was put forward as a justification for accepting *non*-generally covariant field equations, namely those of the 1913 Einstein-Grossman *Entwurf* theory. Einstein was not fully satisfied with that theory, in part because he believed that general covariance was necessary if a theory were to capture a fully general relativity of motion, and so the hole argument served to help Einstein reconcile himself (temporarily and only partially) to the *Entwurf* theory. The second use of the hole argument came in 1915 when Einstein came to see the argument, taken in its first form, as a mistake. From his second point of view the argument rests on a mistaken interpretation of the mathematics of general covariance. The indeterminism allegedly shown by the hole argument is spurious, and the argument cuts no ice in favor of any particular theory or interpretation of the nature of space-time.

Seven decades later, after the rediscovery of Einstein's argument by John Stachel and John Norton, history repeated itself. A close cousin of Einstein's hole argument was put forth by John Earman and John Norton (1987) as an argument claiming to show that, if one embraces a *substantival* view of space-time, then in a generally covariant theory such as the GTR, one is committed to an unpleasant form of indeterminism. Earman and Norton argued that the problem is reason enough to justify rejecting a substantival view of space-time in GTR. But within a few years this view of the argument's significance was widely rejected. Instead most philosophers came to think that the hole argument's indeterminism is merely an artifact of a particular interpretation of the mathematical structure of GTR that we are not logically compelled to accept.

Regardless of which viewpoint is better supported, it is indisputable that Earman and Norton's hole argument led to a huge resurgence of interest in the interpretation of space-time in GTR, and lies at the core of much of the philosophy of space-time theories published since 1987. Subsequently philosophers have explored the status of general covariance, and therefore of the hole argument, in the domain of quantum gravity theories.

THE 1987 HOLE ARGUMENT

GTR describes the dynamical interaction of material substances in space-time with other material substances, as well as their interactions with the variably-curved structure of space-time itself. Einstein's field equations describe these interactions, and delimit the set of models, or physically possible worlds, corresponding to the theory.

A model of GTR is usually presented as a triple $<M, \mathbf{g}, \mathbf{T}>$ consisting of a four-dimensional, continuously differentiable manifold M, a metric-field tensor $\mathbf{g}$ (representing the geometry of space-time) defined everywhere on the manifold, and a stress-energy tensor $\mathbf{T}$ representing the material substances in space-time. Like $\mathbf{g}$, $\mathbf{T}$ is defined everywhere in the space-time, but unlike $\mathbf{g}$, $\mathbf{T}$ may be exactly equal to zero at some or even all points of space-time. (In the latter case we say the space-time is "empty," but it may still have an interesting structure as encoded in $\mathbf{g}$.) Notice that each of these objects is *four*-dimensional, representing not just how things are at a specific time but rather how things are over the entire history of the (model-) universe.

The manifold is a collection of points with a local and global topology built-in. For example some models of GTR have M structurally identical to $\mathfrak{R}^4$, which means that space-time can be coordinatized (all the points labeled) with four-dimensional Cartesian coordinates. The metric tensor defines the metric and geometric structure of the space-time: distances between points A

and *B*, whether points *A*, *B* and *C* are collinear, whether line *L* is a straight line (geodesic) or curved, and so on. Note that *M* by itself does not have such geometric structure; there are no distances between points in *M* alone, no straight lines, and so forth. Finally **T** represents the matter, the energy-momentum, existing in space-time.

Physicists and philosophers confront a set of interpretational issues regarding GTR and its model worlds, and one prominent issue is this: Should space-time be thought of as an object existing in its own right, that is as a *substantial entity*? To answer this question in the affirmative is to take GTR as vindicating space-time substantivalism, a close cousin of Newton's absolutism. But what exactly is space-time according to GTR? Earman and Norton (1987) argued that the manifold *M*, by itself, is what deserves the name of substantival space-time in GTR:

> We take all the geometric structure, such as the metric and derivative operator, as fields determined by partial differential equations. Thus we look upon the bare manifold—the "container" of these fields—as space-time …

> The advent of general relativity has made most compelling the identification of the bare manifold with space-time. For in that theory geometric structures, such as the metric tensor, are clearly physical fields in space-time. The metric tensor now incorporates the gravitational field and thus, like other physical fields, carries energy and momentum whose density is represented by the gravitational field stress-energy pseudo-tensor …

> If we do not classify such energy-bearing structures as the [gravitational] wave as contained within space-time, then we do not see how we can consistently divide between container and contained.

> (PP. 518–551)

If space-time substantivalism is understood as the thesis that (a) the manifold *M* by itself represents space-time and (b) its points are substantial entities themselves, then the ground is prepared for the hole argument. The general covariance of the Einstein field equations, interpreted in an active sense, allows one to take a given model $M_1 = <M, \mathbf{g}, \mathbf{T}>$ and construct a second via an automorphism *h* on the manifold. The automorphism maps points of *M* to other points of *M* in a smooth fashion. The effect of this re-arranging of the points is the production of a new model: $M_2 = <M, h^\star\mathbf{g}, h^\star\mathbf{T}>$ which also satisfies the field equations, and in which the "contents" of space-time, **g**

and **T**, have been "slid around" on the manifold. The kind of automorphism employed in the hole argument is usually called a "hole diffeomorphism." Think of M_2 as obtained from M_1 by sliding the metric and matter fields around on the point-manifold in the region of *M* called "the Hole," leaving everything unchanged elsewhere. (Equivalently one can think of the hole diffeomorphism as a kind of shifting-around of the manifold points, moving the points around "underneath" the metric and material contents of the space-time.)

If M_2 and M_1 agree or match for all events before a certain time *t*, but differ for some events afterward (inside the Hole), then we have a form of indeterminism, at least on the most straightforward way of defining determinism in the context of GTR. Relative to our chosen substantial entities, space-time points considered as the elements of *M*, we can say: In GTR, what happens at what space-time locations is radically underdetermined. Earman and Norton (1987) presented this indeterminism as an argument against the kind of substantivalism (*manifold* substantivalism) they see as most natural in GTR:

> Our argument does not stem from a conviction that determinism is or ought to be true. There are many ways in which determinism can and may in fact fail … Rather, our point is this. If a metaphysics, which forces all our theories to be deterministic, is unacceptable, then equally a metaphysics, which automatically decides in favor of indeterminism, is also unacceptable. Determinism may fail, but if it fails it should fail for reasons of physics, not because of a commitment to substantival properties which can be eradicated without affecting the empirical consequences of the theory.

> (P. 524).

Substantivalism about space-time is thus, according to this argument, ruled out as an acceptable interpretive option for GTR. Before we consider responses to the hole argument, we need to note three points. First this indeterminism is unobservable: M_1 and M_2 are qualitatively indistinguishable. Second, a tacit assumption of the hole argument is that the identities of the manifold points may be taken as given or specified, in some sense, independently of the material/observable processes occurring in space-time (represented by **g** and **T**). In fact one way of thinking of a hole automorphism is as a (continuous) *permutation* of the points underlying physical processes, or (equivalently?) as a *re-labeling* of the points. Third, a manifold is a collection of space*time* points, not space points. In other words the points do not have duration;

FIGURE 1

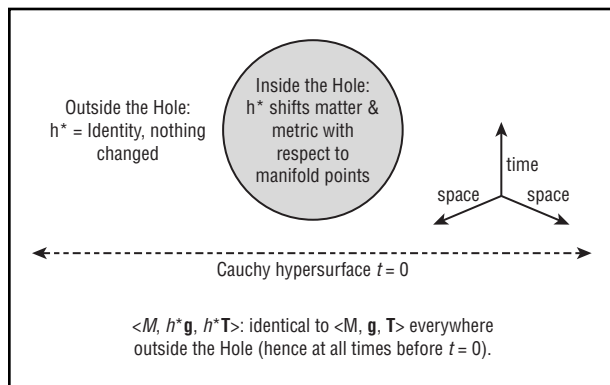
outside the Hole (hence at all times before *t* = 0).


each one is an ideal point-event, a representative of a spatial location at a single instant of time. They do not exist *over* time and hence serve as a structure against which motion may be defined, as Newton's space points did. In light of the second point just above, the indeterminism at issue is not a failure of the determination of future events at pre-existing spatial locations, but rather a failure of the mathematics to specify which individual points would *pop into and out of existence* underneath specified physical events.

Not surprisingly most responses to Earman and Norton's hole argument have departed from these three points, arguing either that the indeterminism is innocuous, or that substantivalism can be reinterpreted in ways that do not lead to the apparent indeterminism.

RESPONSES TO THE HOLE ARGUMENT

Two authors, Cartwright and Hoefer, have responded to the hole argument by denying that it has any *prima facie* force at all. Their response attacks the logic of Earman and Norton's reasoning. Since the indeterminism is both unobservable and peculiarly metaphysical (involving as it does only questions of *which points*, considered as identity-bearing individuals, will underlie *which physical events*, it is not properly speaking a *physical* indeterminism at all and hence not something that ought to be ascribed physical/ ontological importance. Most other authors however have not questioned the logical force of Earman and Norton's argument, agreeing with them that determinism must "be given a fighting chance" (Earman 1989, p. 180). But most authors have also rejected the hole argument's anti-substantivalist conclusion. They argue either for a different understanding of substantivalism, a different definition of determinism, or both.

The first to respond to Earman and Norton's argument were Tim Maudlin (1988) and Jeremy Butterfield (1989). Both accepted the *prima facie* reasonableness of the hole argument but then argued that a metaphysical mistake was nevertheless being committed in the course of the hole argument. For Butterfield, the mistake lay in (a) taking the identities of manifold points between models as an unproblematic given and hence (b) defining indeterminism in too direct and unsubtle a fashion. Butterfield argued that we should avail ourselves of something like David Lewis's apparatus of counterpart theory in order to decide which points in a given model are identical with which points in a different model and accordingly revise the definition of determinism in terms of counterpart relationships. The technical details are too complicated to present here, but the upshot is that GTR turns out not to be indeterministic after all once both point trans-world identity and determinism are properly understood.

Maudlin rejected Earman and Norton's claim that the manifold by itself represents space-time. Instead he argued that the manifold plus metric is what represents space-time, and moreover that we should consider the spatio-temporal, geometric properties ascribed to points of *M* by **g** to be *essential properties* in a strong metaphysical sense. In support of the former point, Maudlin (1988) and Hoefer (1996) adduce the following points:

1) A manifold by itself has few of the paradigmatic spatiotemporal properties we would expect space-time to have: Distance relations between points, collinearity on a straight line, and so forth. In fact there is not always even a distinction to be found between space-like directions and time-like directions! So it is odd to think of *M* alone as representing space-time.

2) There is an easy way to separate between space-time (the "container") and its contents (the "contained"): it is the distinction between *M* + **g** and **T**. Mathematically the distinction is clear. Moreover, as was true for classical substances in the Newtonian tradition, **T** can vanish at some, or even all, space-time locations. **g** cannot vanish anywhere, in any genuine part of a GTR model space-time.

3) If it is accepted that **g** can carry genuine (stress-) energy content, that only makes it even more substantial than Newtonian space-time's structure was; it is hardly a reason for considering **g** not to be part of the characterization of space-time in GTR.

4)"[I]f the metric is classified as a physical field *in* space-time, rather than as representing part of space-time itself, the following odd situation emerges. Space-time itself is not appealed to in explaining the motions of material things; they are explained by relations to a different kind of physical field. Even distances and other geometric relations have nothing to do with space-time, but instead with the relations between two kinds of physical fields in space-time. When substantivalism starts to sound like relationism, something is wrong!" (Hoefer 1996, p. 13).

Most authors now seem to agree that Earman and Norton's identification of *M* as the sole representor of space-time is questionable. This alone does not block their hole argument, though it points the way toward various different versions of substantivalism, incorporating the metric as part-representor of spacetime, which may avoid the hole argument's indeterminism.

Maudlin's essentialism about the metrical properties and relations of space-time points blocks the hole argument by making the metrical properties of individual points be (metaphysically) essential properties: Thus, if model $M_1 = <M, \mathbf{g}, \mathbf{T}>$ represents a genuine physically possible world, then model $M_2 = <M, h^*\mathbf{g}, h^*\mathbf{T}>$ cannot in general do so, since it ascribes metaphysically impossible properties to the points of *M*. Thus, properly interpreted, GTR does not allow a determinism-violating plethora of indistinguishable space-times.

In only slightly different ways, Maidens (1993), Stachel (1993) and Hoefer (1996) diagnose the hole argument as resting on an interpretive mistake: The mistake of considering models such as M_1 and M_2 as representing (meta-) physically distinct space-times. As noted above, the differences between such models concern only *which substantial individuals* (manifold points) underlie *which material happenings and relations*. Without exaggeration one can put the distinction like this: While M_1 says that the point Larry underlies my fingertip at this moment, M_2 says that the (qualitatively identical, in all respects) point Fred does so instead. Earman and Norton's interpretation of substantivalism therefore ascribes *primitive identity* to the points of space-time, and models such as M_1 and M_2 differ only in what philosophers call *haecceitistic* ways, that is, in which properties are ascribed to which individuals, where the individuals are mere "bare particulars".

General relativists routinely deny the significance of such alleged differences, and say that diffeomorphic models like M_1 and M_2 represent just *one* physically possible world (thereby advocating *Leibniz Equivalence*). We should do the same, urge these authors; when we do, the hole argument evaporates, and we are nevertheless left with a strong form of substantivalism, one that takes $M + \mathbf{g}$ to represent space-time and considers any two diffeomorphic mathematical models as representing one and the same physically possible world. The disadvantage of taking this interpretive route is that one loses the ability to describe certain metaphysical possibilities that were accepted by Newton and Samuel Clarke, that is, the possibility that every event in the world's history could have taken place five meters to the East of its actual location. Some philosophers maintain that these metaphysical possibilities are an essential part of any substantivalist view.

Not all those inspired by the hole argument to work on spacetime issues try to shore up substantivalism. The hole argument inspired those with relationist leanings to revive the idea, advocated by Reichenbach earlier in the twentieth century but effectively killed by Earman (1989) and Friedman (1983), that GTR can be interpreted as fully compatible with relationism. Teller (1991), Huggett (1999), and Saunders (2003) are examples of this approach. What makes this position possible is the adoption of a liberal attitude toward the idea of *relations* between material things. If the manifold is viewed as only representing the continuity, dimensionality, and topology of spacetime (as some substantivalists would agree anyway), then what is really indispensable is the metric. Can it be interpreted relationally? Those philosophers who argue that it can are not espousing a Machian reduction of metrical structure to material relations. Instead they claim that the metric itself can be interpreted as merely giving the structure of actual *and possible* spatiotemporal relations between material things. $\mathbf{g}$ is not a thing or substance. Where matter is present, it is crucial to the definition of local standards of acceleration and non-acceleration; the Einstein field equations record just this relationship. In many ways the desires of traditional relationists (especially Leibniz, Huygens, and Mach) are—arguably—met by GTR when interpreted this way.

FURTHER DEVELOPMENTS

By the late 1990s a broad consensus was reached among philosophers of spacetime that there are acceptable interpretations of spacetime in the GTR context that do not run afoul of the hole argument indeterminism (both substantial and relational interpretations). In a series of papers, however, John Earman and Gordon Belot (2001) argued that consideration of the extension of GTR to a quantum theory vindicates the importance of the hole argument, and reveals the vacuity of certain philosophical

responses to it. The issues and arguments involved in this new broaching of the hole argument are complicated and technical; only a cursory review can be attempted here.

One approach to quantizing GTR begins by recasting the theory in the Hamiltonian formalism, wherein a three-dimensional configuration representing the state of the physical world evolves in accordance with the Hamiltonian equations of motion. This is a natural way of formulating GTR preparatory to attempting to quantize it, since there are established recipes for quantizing theories starting in the Hamiltonian framework. But the (active) general covariance of GTR makes for a resulting indeterminism in the Hamiltonian presentation of the theory, just as it did for the standard theory when interpreted as a theory about what happens at individual manifold points. Various ways of dealing with this indeterminism can be linked conceptually to respective philosophical responses to the hole argument, and they appear to lead to genuinely different *theories* after quantization is done. So Earman and Belot (2001) claim:

> There is a correspondence between interpretations of the general covariance of general relativity and approaches to—and interpretations of—quantum gravity … One demands that one's interpretation of general relativity should underwrite an approach to quantization which leads to a viable theory of quantum gravity, and that one's understanding of quantum gravity should lead to a way of viewing general relativity as an appropriate classical limit.
>
> (P. 249)

Different responses to the hole argument make for different interpretations of space-time in GTR, and according to Earman and Belot these correspond to different approaches to quantum gravity. The "relationist" response of Teller, Saunders, and others which rejects the idea that diffeomorphic models are distinct physical possibilities, corresponds to the "gauge invariant" approach to quantum gravity. But the quite similar interpretation of classical GTR that is offered by Maidens, Stachel, Hoefer, and others is pejoratively labeled "sophisticated substantivalism" by Earman and Belot, and they find it the one view unworthy of even entering the playing field of the interpretive game. They claim that these philosophers are obliged to produce a gauge invariant mathematical treatment of classical GTR in the Hamiltonian framework, which may or may not be possible:

> [W]e maintain that there is one sort of response to the hole argument which *is* clearly undesirable: the sort of sophisticated substantival-

ism which mimics relationalism's denial of the Leibniz-Clarke counterfactuals. It would require considerable ingenuity to construct an (intrinsic) gauge-invariant [LE-based] substantivalist interpretation of general relativity. And if one were to accomplish this, one's reward would be to occupy a conceptual space already occupied by relationalism. Meanwhile, one would forgo the most exciting aspect of substantivalism: its link to approaches to quantum gravity.

> (2001, P. 248)

Earman and Belot evidently still characterize substantivalism as essentially a matter of believing in space-time points as individuals with primitive identity (a key conceptual part of manifold substantivalism, as we saw above), and relationism as the denial of such points-as-primitives. Most philosophers would reject both viewpoints, in line with points 1–4 above that argue for including the metric field in our characterization of space-time. It is also unclear why the sophisticated substantivalist faces a technical difficulty of constructing a "gauge-invariant" interpretation of Hamiltonian GTR, unless the relationist that Earman and Belot cites approvingly does too—given that they occupy the same conceptual space.

Earman categorizes the loop quantum gravity approach of Rovelli and others as lined up with relationism. A crucial aspect of such a gauge invariant approach should be its evasion of hole argument-style indeterminism problems. But Rickles (2005) claims that a perfect analog of the hole argument can be constructed within the framework of loop quantum gravity. Rickles argues that indeterminism-via-surplus-structure can infect either relationist or substantivalist interpretations of GTR, whether in classical or quantized form, and therefore that the two issues should henceforth be kept apart.

As for the original hole argument itself, we should note that it was an argument that *used* general covariance to argue against a certain ontological view (manifold substantivalism), in the context of classical GTR. Regardless of what view of general covariance and determinism/indeterminism issues is eventually vindicated in the realm of quantum GTR (if one view is—there is no guarantee this will happen), it will not alter the dialectic of the hole argument itself, or the philosophical issue of whether GTR as a self-standing theory does or does not give us a picture of space-time deserving the label "substantial." Compare with the absolute/ relational debate in the context of classical Newtonian mechanics. Greater mathematical rigor and conceptual clarity in the founda-

tions of Newtonian mechanics did have a bearing on that philosophical debate, and led Earman (1989) and Michael Friedman (1983) to declare a hands-down victory for absolute space. But the nature and status of space-time in General Relativity has not been taken to be relevant to that earlier debate (or the correlate debate about space-time in Special Relativity), even though both of these earlier theories are "appropriate classical limits" of GTR. The moral would appear to be that philosophers should tackle interpretive issues one theory at a time. If and when a successful quantum gravity theory emerges, the substantival/ relational debate can be addressed anew in light of its particular mathematical structure.

HOLISM AND INDIVIDUALISM IN HISTORY AND SOCIAL SCIENCE

In most recent philosophical discussion, the contrast between holism and individualism in history and the social sciences has been presented as a methodological issue. Stated generally, the question is whether we should treat large-scale social events and conditions as mere aggregates or configurations of the actions, attitudes, relations, and circumstances of the individual men and women who participated in, enjoyed, or suffered them. Methodological individualists say we should. Methodological holists (or collectivists, as some prefer to be called) claim, rather, that social phenomena may be studied at their own autonomous, macroscopic level of analysis. Social "wholes," they say, not their human elements, are the true historical individuals.

This issue obviously bears directly upon the way we are to conceive the relations between such social sciences as psychology and sociology, and between these and historical inquiry. But it is commonly thought also to involve us in wide-ranging metaphysical problems—those of historicism and organicism, for example—and to have grave ethical and political implications as well. Sir Isaiah Berlin, in *Historical Inevitability* (Oxford, 1954), moves quickly from methodological to metaphysical issues when he represents holists as believing in "invisible powers and dominions," conceived as "impersonal enti-

ties at once patterns and realities, in terms of which … men and institutions must behave as they do." And May Brodbeck, in "Methodological Individualisms: Definition and Reduction," expresses a common opinion when she writes: "Culturally, holism is intimately connected with hostility toward the liberal political individualism of the Western tradition." Individualists, in their turn, have been castigated by their opponents for encouraging laissez-faire in economics and anarchy in politics, the alleged natural consequences of adopting an "atomistic" view of social life. Indeed, the threat of appropriate social consequences seems to have been regarded by some as a reason for accepting one or the other of these methodological positions. F. A. Hayek and K. R. Popper are well-known champions of the principle of methodological individualism as a bulwark against the supposed horrors of the "planned society"—or at any rate, against anything worse than "piecemeal social engineering."

It is not, in fact, entirely accurate to say that the methodological, metaphysical, and political doctrines have invariably gone together. Thomas Hobbes, for example, was in effect a methodological individualist who advocated something close to political absolutism; and Maurice Mandelbaum, as will appear below, is a contemporary methodological holist who would certainly repudiate "invisible powers" and "impersonal entities." But political or ethical argument has, in any case, a dubious place in an examination of holism and individualism as methodological prescriptions for social and historical research. Even if metaphysical questions cannot ultimately be ignored, it is worthwhile, at least at the outset, to try to consider the contending methodological doctrines in their own terms. The discussion that follows makes no attempt to trace the considerable history of the problem in Western philosophy; rather, it is a report on what some contemporary philosophers have said by way of exposition and defense of the two positions. Since it has generally been the individualists who have taken the initiative in controversy, it will be convenient to set forth their position first.

METHODOLOGICAL INDIVIDUALISM

J. W. N. Watkins, one of the most prominent recent advocates of methodological individualism, has presented it as primarily a theory of sociological or historical explanation. In his "Ideal Types and Historical Explanation," Watkins stated its requirements thus: "Social processes and events should be explained by being deduced from (*a*) principles governing the behaviour of the participating individuals and (*b*) descriptions of their situations."

The elaboration of criteria for acceptable explanation is, of course, an activity characteristic of philosophers. What has most often concerned them, however, has been the formal or structural features of explanation, that is, the logical relation that must hold between an explanans and explanandum. Watkins's criterion, by contrast, is a material one. It makes a stipulation about the content of a social or historical explanans, holding that it must be "psychological," at least in the sense of being, in Watkins's words, about "the situations, dispositions and beliefs of individuals."

In formulating their material requirement, individualists often have in mind successful patterns of explanation in other branches of science. According to Watkins, the principle of methodological individualism is a correlate of the principle of mechanism in physics, which held triumphant sway from the seventeenth to the nineteenth centuries. An especially prestigious example of the application of the mechanistic principle is the explanation of the solar system by reference to Isaac Newton's laws and the positions, masses, and momenta of its component "individuals." Another example, often cited, is the explanation of the macro properties of a gas—its temperature, for example—as a resultant of the micro properties of its molecules. The best illustration of the same explanatory procedure in social science is afforded by classical economics, which regards macro states of the market as resultants of the dispositions and consequent activities of individual producers and consumers. There are differences (some will be discussed later) between the way particles in a mechanistic system are linked with what they explain and the way psychological facts about individuals are linked with social events. Methodological individualists, however, regard the likenesses as more instructive than the differences.

METHODOLOGICAL HOLISM

The rival thesis of methodological holism is that explanations in history and social science may (some would say "must") employ holistic societal laws or dispositions. Social dispositions are envisaged as being holistic, not only in the sense of being macroscopic relative to individual behavior but as being irreducibly so. Except in extreme versions of the theory (usually framed by opponents for polemical purposes), psychological elements are not actually excluded from a social explanans; they are merely regarded as insufficient. Thus, in their most usual form, the two methodological doctrines are not contraries but contradictories.

In elaborating their position, holists often match paradigm cases with the individualists. In economics, for example, they point to the Keynesian theory, which relates such variables as national income and savings, as showing the need to supplement the classical approach with a macroscopic one. In physics they note the decline of mechanism with the development of wave and field notions. And methodological holists do not limit their claims to cases in which social phenomena are explained by other societal factors. The explanation of individual actions themselves, they insist, may often have to be given partly in societal terms, employing laws that link individual behavior with types of social conditions. They deny, however, that this commits them either to organicism or to historicism. For sui generis societal laws can be of various logical types. They need not be organic, in the sense of relating the parts of the social system in a way that makes society self-regulating or self-maintaining, nor need they be developmental. There is thus no necessary connection between methodological holism and the dismal conclusion that men are caught up in some inexorable process that possesses something like a life of its own.

REFINEMENTS OF INDIVIDUALISM

The basic response of methodological holism to the individualist claim is that the procedures of history and social science are in fact largely holistic, and that attempts to apply the principle of individualism do not work. The theory of the social sciences should accept the consequences. To methodological individualists, on the other hand, failures of application simply indicate a need for further analysis and research. Yet the discrepancy between fact and theory has induced individualists to make a few concessions, which are often represented as "refinements" or "clarifications" of the original thesis. A brief look at four of these may help to sharpen the issue.

LEVELS OF EXPLANATION. Individualists generally concede, first, that macro explanations may sometimes be both true and informative. The temperature of a gas, for example, may be explained by referring to a heat source that was applied to it, or to such simultaneous macro conditions as its volume and pressure; the outbreak of a revolution may be similarly explained by referring to economic or social trends in the society as a whole. According to Watkins, all the methodological individualist claims is that until we manage to reduce such explanations to terms of the molecular theory of gases or the psychology of individuals, we fail to achieve a full understanding of what has occurred. Thus, what the indi-

vidualist seems to offer is not a criterion of being an explanation at all (for this, the satisfaction of formal criteria may be enough), but of being an ultimately satisfactory one. Yet the acceptability of "half-way explanations" (to use Watkins's term) is said to depend on the possibility of eventually reducing them to "rock-bottom explanations." The concession, in other words, is only with regard to "practice"; nothing is yielded at the level of "principle."

ANONYMOUS INDIVIDUALS. A second refinement arises out of the suspicion that what is actually possible in social science, even "in principle," is seldom an explanation in terms of the dispositions of the specific individuals involved. We might explain the rise in a stock's value, for example, by pointing out that the individual dispositions that most stockholders may be presumed to share lead them to be willing to pay a higher price under the circumstances; but we could hardly hope to ground our conclusion in knowledge of the detailed motives and beliefs of all the individuals involved. Methodological individualists consequently limit their prescription, even for "rock-bottom explanations," to typical dispositions of anonymous individuals. Such explanations, they will point out, still follow the model of mechanistic physics, in which information about specific particles is not required. Unlike physical particles, it cannot, of course, be presumed that human beings are all alike, or even that they are similar in all respects relevant to the social resultant that is being studied. This is particularly the case in historical inquiry, with its concern for unique rather than recurring circumstances and events. Thus, it will often be impossible to give adequate historical explanations without taking at least some named individuals into account. Even in the field of history, however, there is considerable scope for the anonymous.

UNINTENDED RESULTS. Advocates of individualism often emphasize that if explanation need not be in terms of the actions and dispositions of specific human beings, still less need it show that social phenomena are brought about deliberately, or even knowingly, by individuals. Methodological individualists do not question the contention, constantly reiterated by holists, that social phenomena are largely the *unintended* results of the behavior of hosts of interacting human beings. The individualist principle is thus to be distinguished from what K. R. Popper, in *The Open Society and Its Enemies* (London, 1945), has called the "conspiracy theory of society": the view that for every social effect there is a manipulator (hero or villain) to be found. Not that individualists doubt that public affairs are controllable through the knowledgeable

intervention of people; they hold, rather, that even when events are not so controlled, they can be explained individualistically. The individualist principle is also to be distinguished from a second doctrine with which Watkins felt it is sometimes confused, namely, the view that social phenomena "reflect" the dispositions of component individuals. Social characteristics are often, in fact, quite different qualitatively from the characteristics of the individuals referred to in explaining them. But there is likewise no qualitative similarity between the thermodynamic properties of a gas and the mechanical properties of its elements.

EXCEPTIONS. Some individualists are willing to make a concession that leads to still a fourth refinement of the original doctrine. They allow that there are some social phenomena, at least, that may not be open to individualistic explanation at all, although they usually add that these exceptions are not very important for the theory of the social sciences—certainly not important enough to justify the acceptance of methodological holism as a general principle for explanation in these fields. The exceptions fall into two classes. The first contains phenomena that can be treated only statistically. The second consists of occasional instances of what may be genuinely organic "social" behavior: Watkins mentioned the physical union of mating couples, the ecstatic singing of revival meetings, the rioting of panicking crowds. But, individualists argue, we cannot extrapolate from such cases to the nature of "higher-grade" forms of social organization. The latter, even when unplanned, are related by "ideas" and involve people widely separated in space and time.

ARGUMENTS FOR METHODOLOGICAL INDIVIDUALISM

Clarified and refined, then, the principle of methodological individualism asserts that *ultimate or final* explanation of the more *significant* social phenomena must be given in terms of at least *typical* dispositions (including beliefs, attitudes, and volitions) of *anonymous* individuals involved. Individualists often seem to present this principle as self-evident. Yet arguments for it have been offered, among the most characteristic in contemporary literature being the five that are considered below. No separate presentation of the case for methodological holism will be given, since holists are generally content to offer rebuttals of what their opponents claim.

METAPHYSICAL ARGUMENTS. One common argument appeals directly to ontological considerations. According to Watkins, "the ontological basis of methodological individualism is the assumption that society … really consists only of people." Social "things" may even be said to be "created" by individuals, by their attitudes as well as by their actions. "Remove the attitudes of food officials, shop-keepers, housewives, etc., towards ration books," Watkins observed, "and they shrivel into bits of cardboard." To a methodological individualist it seems paradoxical to suggest that social objects, thus constituted, could be explained other than individualistically. To try to explain individual actions in social terms seems to involve referring what really exists to a mere "construction." Yet although ontological individualism offers the methodological doctrine a "basis," Watkins conceded that the former does not actually entail the latter. It might still be true that what is constituted by individual actions and attitudes is governed by autonomous social law, although the ontology of individualism makes this difficult to believe.

Today, few holists would argue directly from a corresponding ontological thesis, which would rest upon some such principle as "a whole is not equal to the sum of its parts," the social whole thus being conceived as free to operate in accordance with laws which hold true at its own "level of existence." Typical of objections to this are Ernest Nagel's observation, in *The Structure of Science,* that wholes are recognized in physical science, too, apparently without presenting special problems for individualistic explanation; and Popper's jibe, in *The Poverty of Historicism,* that the metaphysical principle of holism, although "trivially true," applies even to three apples on a plate. However, most methodological holists (for example, Maurice Mandelbaum in "Societal Facts") prefer to argue that although social phenomena can be said to be ontologically dependent upon the actions and attitudes of individuals, the two are not simply identical. They point out, too, that their doctrine does not commit them to claiming that societies could exist without people, this being an absurdity eschewed even by full-blooded ontological holists like G. W. F. Hegel. The frequent use, in this connection, of the epiphenomenalist account of the mind-brain relation to show what might be meant by ontological dependence without identity is rather unfortunate. For, whereas a mind with no brain may be conceivable, few, if any, methodological holists would allow that society was conceivable without individuals. Many methodological holists, in fact, profess complete ontological individualism. What they demand of individualists is a willingness to try to *find out* whether there are any irreducible societal laws.

This takes us within range of a second metaphysical argument. According to Watkins, it is a "metaphysical commonplace that social events are brought about by people." He interpreted this "commonplace" to imply that individual men and women "together with their material resources" are the "only moving agents," indeed the "only causal factors," in history. Social wholes, whether or not they can be said really to exist, cannot *do* anything; in particular, they cannot affect the behavior of the concrete human beings who constitute them. Methodological individualists therefore disagree with economists who regard long-term cyclical waves in economic activity as, in Watkins's words, "self-propelling, uncontrollable and inexplicable in terms of human activities." They similarly oppose historical materialism, which, in its more uncompromising forms, at any rate, asserts a one-way causal relation between certain social conditions (the economic substructure) and the thoughts and actions of those who live under them. It is a "central assumption of the individualist position," Watkins declared, that "no social tendency is somehow imposed on human beings 'from above' (or 'from below')." Actually, even the more modest (and more usual) thesis of "interaction" between the social and the individual spheres is often deemed unacceptable by individualists.

The usual response of the holists to this line of argument is to ridicule the implied denial of social conditioning—as if people were not born into social situations in the first place. The "real oddity" of methodological individualism, wrote Ernest Gellner in "Explanations in History," is that "it seems to preclude *a priori* the possibility of human dispositions being the dependent variable in an historical explanation—when in fact this is what they often or always are." An associated peculiarity is that it precludes "the possibility of causes … being a complex fact which is not describable in terms of the characteristics of its constituent parts alone—which again seems often to be the case." Individualists, of course, would regard this charge as a misunderstanding of their doctrine. They would hold that the social conditioning of individuals, although real, is simply their conditioning by other individuals, referred to compendiously by holistic terms. And they would accept this claim that causes may be complex facts as long as the complexity of the cause is regarded as "resultant" from individual actions in the way indicated by the ontological argument. (Some individualists, however, would find it less easy to counter the argument that to speak of causes as "moving agents" at all is tacitly to accept an "activity" view of causation that has been suspect since David Hume.)

Alan Donagan, in *The Later Philosophy of R. G. Collingwood,* provided a version of the individualist's causal argument that turns on a conception of human action made familiar by idealist philosophers. The only way men's actions can be explained, Donagan maintained, is through their "thoughts"; it is not men's actual situations which explain what they do, but their conception of the situations (although it may be necessary to refer to the actual situation in explaining a man's success or failure in translating his intentions into action). Thus, if physical causes, like climate, operate in history, they must operate indirectly; and the same is true of such social events and conditions as an economic depression or a military victory. Unless we are to challenge the common assumption that the causal relation is transitive, however, methodological holists may well feel that such considerations, even if they are acceptable in themselves, do little to establish Watkins's original contention. For to say that social causes require the mediation of individual thoughts and responses is not to establish the latter as the only "moving forces" in history. On the contrary, to cause individuals to cause is still to cause.

EPISTEMOLOGICAL ARGUMENTS. The theory of action thus indicated has a bearing on a third general argument that is sometimes used by methodological individualists. This argument develops Watkins's contention that even if we learned to describe, predict, and control social events and conditions holistically, we still could not properly claim to understand them without treating them as a collection of individual responses. For "understanding," Watkins seemed to insist, requires the explanation of what happened in terms of *intelligible* human dispositions. What he appears to have had in mind is the discerning of the participants' reasons for doing what they did, which allows us the intellectual satisfaction of seeing why they thought their responses were appropriate. As Gellner has pointed out, there is a dual thesis here: first, that social or historical explanation must be couched in terms of the dispositions of individual human beings; second, that these dispositions must be of a special kind. For those who would claim, on general philosophical grounds, that explanation by reference to an agent's reason or motive is logically different from subsuming an occurrence under a law (or even under a "disposition" properly so called), the present claim opens up the possibility of giving individualistic explanations of social phenomena without reference even to psychological laws.

Many methodological holists would agree that to accept the additional thesis would make their position quite untenable, for it might be claimed that "intelligible"

dispositions could be sought at the level of social wholes only on the assumption either of an immanent group mind or of an external historical providence: in other words, methodological holism now *would* require ontological holism. Something just short of this nevertheless sometimes appears to be entertained. Thus Morris Ginsberg, in *On the Diversity of Morals* (London, 1956), while denying for ontological reasons that society is itself a mind, conceded that it has a "mental organization" or "inner side" that is not identical with the mentality of any of its component individuals. Most methodological holists, however, simply deny the necessity of the additional criterion of explanation. They would hold that the essential claim of methodological individualism could be achieved without reference to intelligible dispositions if appropriate psychological laws could be found. And they would similarly claim for their own position that subsumption under autonomous societal laws (if such laws could be found) would yield understanding in the only sense significant to "scientific" inquiry.

A fourth argument makes the even more basic epistemological claim that whereas we can observe human individuals, we cannot similarly obtain knowledge of the macro features of social groups. As Watkins put it: "The social scientist and historian have no 'direct access' to the overall structure and behaviour of a system of interacting individuals (in the sense that a chemist does have 'direct access' to such overall properties of a gas as its volume and pressure and temperature, which he can measure and relate without any knowledge of gas molecules)." Since reliable knowledge of the dispositions and situations of individuals is readily available, Watkins continued, and since these individuals constitute the group, "a theoretical understanding of an abstract social structure should be derived from more empirical beliefs about concrete individuals." How else can what is said about social wholes be verified? Such an appeal to "hardheaded" empiricism is a shrewd blow. For the contenders here are (with a caveat, perhaps, about history) two theories of "scientific" inquiry. It would be odd if they did not both claim to be "empiricist."

Faced with this argument, many methodological holists insist that *some* social phenomena, at least—for example, parades, trials at law, battles—are directly observable. It is true that no one will notice such things if he lacks certain interpretative ideas or concepts. But this is not a peculiarity of social observation. Individual human actions themselves will not be "observed" unless we are able to discern the intentions and motives of the actors; and it may be questioned whether these can be

known "directly" in a sense in which group phenomena cannot. The epistemological criterion of the individualists, in other words, either allows some social phenomena to be counted as observable or excludes the most interesting individual phenomena. Many holists nevertheless concede that the social wholes of most significance for history and social science cannot, in any ordinary sense, be directly observed. They reject instead the implication that this puts them at odds with accepted procedures in natural science. Not all physical theorizing proceeds, as in chemistry, from observables to what explains them: astronomy, for example, "constructs" its wholes as surely as sociology does. They admit, too, that assertions about societies must be verified by discovery of what individuals do. But they deny that this undermines their claim to possess knowledge, not just of the individuals but of the social wholes of which they are elements.

LINGUISTIC ARGUMENT. The fifth argument for methodological individualism, although it obviously has some affinity with both ontological and epistemological ones, is presented as a point of logic or semantics. As L. J. Goldstein stated it, in his "The Two Theses of Methodological Individualism," individualists require, as a condition of their being meaningful, "that all of the concepts used in social science theory be exhaustively analyzable in terms of the interests, activities, volitions and so forth of individual human beings." If this condition were met, the apparent holism of explanations employing societal laws would be tolerable, because it would be eliminable "by translation." Watkins himself denied that this conceptual thesis actually belongs to the central position of methodological individualism. The latter, he maintained, is a theory of explanation, not of concept-formation or description. Yet in arguing for the explanatory thesis, he characteristically slipped into the conceptual one. He maintained, for example, that to an individualist, the statement "The Jewish race is cohesive," if it is to be empirically meaningful, must mean such things as "Jews usually marry Jews"—a statement about anonymous individuals. And he commended Max Weber for insisting that the only way to make the meaning of social terms precise is to *define* them individualistically—as if such concepts appear holistic only when they remain vague or undefined.

Methodological holists have denied both that such analysis, definition, or translation is possible and that the conceptual thesis, even if sound, would establish the explanatory one. In arguing for the first of these positions in "Methodological Individualisms: Definition and Reduction," Brodbeck allowed that there are no insuper-

able problems for conceptual individualism so long as we are dealing with group concepts that are basically statistical—as in "He got his votes from the poor." Less straightforwardly statistical locutions like "Boom follows slump" might present problems for individualistic translation only because their implied statistical reference is vague. The real difficulty arises over such terms as "renaissance" or "the government." There seems to be no finite list of individual actions and attitudes that would count as their exemplifications; yet the problem does not seem to be one simply of vagueness. Appropriate exemplifications, furthermore, seem to vary from culture to culture, without our being able to say that the relevant terms are ambiguous—which suggests, perhaps, an evaluative element in their meanings. Terms within this range of social description appear to be logically holistic. As Mandelbaum has observed, the problem here is analogous to one which phenomenalists have paid great attention to in contemporary theory of perception. The full meaning of a material object statement, it is generally agreed, cannot be given by any finite set of sensation reports alone; we always need reference to "conditions of appearance," which are stated in the material object language. Attempts to translate societal statements into psychological terms founder on the similar need to specify the social conditions under which an action must be performed in order for it to count as an exemplification.

Mandelbaum himself actually wavered on this point. He conceded that partial translatability, at least, is required; otherwise there would be no way of verifying societal statements (an echo of the epistemological argument). He was sufficiently moved, too, by metaphysical considerations (both ontological and causal) to believe that full translation may be possible "in principle," even if this cannot be made the basis for a "practical" methodology. Many methodological holists have claimed, however, that full translatability would still not warrant the acceptance of the individualist thesis as it is most commonly understood, namely, that explanations should be (or should be capable of being) limited to psychological terms, with psychological laws as the only permissible kind of connecting generalizations.

SOME OBSCURITIES

Consideration of the claim that full translatability would not warrant acceptance of the individualist thesis calls attention to three important obscurities that have dogged much contemporary discussion. The first concerns the sense of "explain" in which a methodological individualist asserts that ultimately all explanations must be indi-

vidualistic. The conceptual claim, it should be noted, has been stated not only as an argument for the explanatory one but also as though it were itself a theory of explanation—and so it is, in one important sense of the term. According to Watkins, every complex social situation or event is "the result of a particular configuration of individuals, their dispositions, beliefs, and physical resources and environments." This is often, and plausibly, read as meaning that we must be able to explain large-scale social phenomena as configurations or resultants of individual ones. But to explain something *as* something else is to explicate its nature: It is to explain it in the sense of showing *what it really is.* Although this kind of explanation is common in history and social science, however, it does not seem to be what methodological individualists have usually had in mind when advancing their explanatory thesis. What they envisage is explanation in the sense of showing how or why something *came to be* what it is: explanation that goes on to give causes, for example. It remains to be seen whether the conceptual thesis has any bearing on individualist claims about such explanations.

It may be objected that this ambiguity underlying the notion of being a "resultant" need not destroy the support given by the conceptual thesis to the full explanatory thesis, since what is specified in the productive sense may itself be treated, in its turn, as a resultant in the constitutive sense, thus achieving full "reduction." But this directs attention to a second obscurity in the individualist thesis, the question whether a "why" or "how" explanation in which all societal terms were replaced by psychological ones would involve the reduction of societal to psychological *laws.* Holists such as Nagel and Brodbeck have contended that it would not, at any rate, achieve reduction in the sense most familiar to the philosophy of science. For the derivability of macro laws from micro laws, no matter what the field of inquiry, is at least partly an empirical matter. Even in such exemplary cases as the reduction of chemistry to physics, they have pointed out, composition laws, which specify the way individual behavior changes as groups increase in size, must be added to the ordinary laws of the micro discipline; and these, however "self-evident" they often seem, have an empirical status. If laws of individual psychology are to be related "reductively" to laws of group phenomena, empirical composition laws would similarly have to be found. The reduction could never be just a matter of definition.

Individualists may complain that this involves too restricted an interpretation of their demand that sociological and historical explanations be reduced to "psychological" terms. Thus, when Mandelbaum, a

methodological holist, attacked the conceptual thesis on the assumption that no statement will be counted as psychological if it employs any societal term, his argument was rebutted by Donagan, an individualist, on the ground that hardly any human dispositions would be psychological on such a criterion. Watkins made it clear that, for him, a psychological disposition is simply one which specifies a way of acting and thinking that is open to an individual. Thus, he argued against an anthropological holist that marriage rules are widespread dispositions of anonymous individuals in a society to behave in a certain way, and against a historical holist that the "Calvinistic outlook" of seventeenth-century Huguenot traders was similarly individualistic. Behind the uncertainty about what is to count as "psychological," there in fact appear to lie two different interpretations of the conceptual thesis itself. The first, which imposes a limitation upon the *ways of behaving* that may be cited in a "rock-bottom" explanans, is the translatability thesis. The second, to which many methodological individualists appear to retreat under pressure, is the much weaker demand that an acceptable explanation employ concepts which can be *attributed* to an individual, or jointly to a group of them.

Willingness to move in the latter direction suggests that contemporary methodological individualists and holists are not really as far apart as they often seem. In spite of their insistence that what they put forward is a *methodological* doctrine which is merely supported by metaphysical considerations, it seems clear that what interests methodological individualists most is the related ontological claim that human beings are the "ultimate constituents" of the social world. By contrast, although methodological holists find themselves continually under fire for allegedly flirting with dangerous metaphysical notions, it appears that what they are most concerned to uphold is the *logical* respectability of using holistic collective concepts and macroscopic laws, if need be. As was indicated, many methodological holists protest their allegiance to ontological individualism, and this appears to be a perfectly coherent claim. Some would even accord the corresponding methodological principle of individualism "regulative status" as formulating an ideal to be striven for. What they resist is the conclusion a priori that we can realize the ideal, and the associated temptation to refuse anything less.

HOLISM AND INDIVIDUALISM IN HISTORY AND SOCIAL SCIENCE [ADDENDUM]

The current philosophical discussion on holism and individualism can be considered on the basis of the notions of supervenience and intrinsic properties. A prominent conception of supervenience is David Lewis's thesis of Humean supervenience:

> It is the doctrine that all there is to the world is a vast mosaic of local matters of particular fact, just one little thing and then another. … We have geometry: a system of external relations of spatio-temporal distance between points. Maybe

points of spacetime itself, maybe point-sized bits of matter or aether or fields, maybe both. And at those points we have local qualities: perfectly natural intrinsic properties which need nothing bigger than a point at which to be instantiated. For short: we have an arrangement of qualities. And that is all. There is no difference without difference in the arrangement of qualities. All else supervenes on that. (1986, pp. ix–x)

This is a thesis of global supervenience, applying to the world as a whole. To put the matter in the formulation that tends to be preferred in today's discussion, "Any world which is a *minimal* physical duplicate of our world is a duplicate *simpliciter* of our world" (Jackson 1998, p. 12). Global supervenience thus conceived is not in dispute in the philosophy of social science. No serious holist denies that if you duplicate the whole domain of physical properties that are instantiated in the world, you thereby also duplicate all the social properties that are instantiated in the world.

The dispute is about what exactly has to be included in the supervenience base. According to Lewis (1986), apart from spatiotemporal relations, all the relations that are instantiated in the world supervene on the intrinsic properties of the individuals. If this idea is applied to social science, it is to say: Given the spatiotemporal positions of all the individual persons in the world (their worldlines), the intrinsic properties of all the individual persons in the world fix all the social and historical facts and institutions. The dispositions of individuals count among their intrinsic properties. While individualism implies this thesis, holism disputes it, holding that there are more nonsupervenient relations than the spatiotemporal ones. As regards social science, holists maintain that social relations do not supervene on the intrinsic properties of individual persons and their spatiotemporal arrangement.

The claim about intrinsic properties in Lewis's (1986) thesis of global supervenience is already disputed in fundamental physics. Quantum systems admit what is known as entangled states. Quantum entanglement can be taken to consist in certain relations among quantum systems; there are no intrinsic properties whatsoever that could constitute a supervenience basis for these relations. Quantum entanglement can therefore be considered as indicating the ultimate failure of the explanation paradigm of individualism, which is seen as being tied to classical, atomistic physics (Teller 1986).

The most serious challenge to individualism in the social sciences stems from the rule-following considera-

tions as put forward by Saul A. Kripke (1982) in his interpretation of Ludwig Wittgenstein's *Philosophical Investigations* (1953/1993). According to Kripke, Wittgenstein maintains that the conceptual content of the belief states of people does not supervene on their intrinsic properties—neither mental intrinsic properties such as mental ideas, nor physical intrinsic properties such as dispositions to behavior. Following Kripke's Wittgenstein, any mental idea and any disposition to behavior is finite and therefore insufficient to fix a precise conceptual content, which implies determining an indefinite number of cases. Furthermore, it is thereby insufficient to determine what is the correct application of a rule (concept) in contrast to its incorrect application. The problem of rule-following is an important challenge to individualism in the social sciences, because it calls one central presupposition of any individualistic position in question, namely that the content of our belief states is ontologically independent of social interactions.

The most prominent individualist reply to the problem of rule-following is to develop a sophisticated dispositionalism to overcome the objections from the finitude and the non-normativity of dispositions. The main versions make use of computationalism (Miscevic 1996) or teleosemantics (Millikan 1990), or a combination of both. However, according to teleosemantics the content of a belief state is determined by a biological function, and biological functions depend on the history of the organism in a given environment. Consequently, biological functions are not intrinsic properties so that, according to this view, the content of the belief states of a person does not supervene on intrinsic properties of the person either.

The holist reply to the problem of rule-following takes social relations to be the decisive factor in the determination of the conceptual content of our belief states. It thus implies social holism: Having beliefs with a determinate conceptual content depends on social interactions. The basic idea is that social interactions (social practices) put at the disposal of people a distinction between what they take to be correct and what is correct in the light of others. On this basis social interactions drive, notably via sanctions, a process that determines a conceptual content for the belief states of the people who participate in them.

There are two versions of this position: The more radical one is the skeptical solution to the problem of rule-following that Kripke (1982) himself attributes to Wittgenstein (1953/1993) and according to which there is no standard of correctness beyond communal agreement (see also Kusch 2002). The more moderate position takes

social practices to fix conceptual content, but maintains that there are truth conditions for our beliefs beyond communal agreement (Brandom 1994; see also Esfeld 2001, chapters 3, 5).

The debate that is initiated by the rule-following considerations enables us to cast the discussion between individualism and holism in the social sciences in the following framework: The point at issue is to what extent social facts and institutions depend on social relations that do not supervene on the intrinsic properties of the individuals that stand in these relations (cf. Pettit 1993, part 2). To the extent that one rejects such nonsupervenient social relations, one subscribes to individualism. A social holist goes as far as maintaining that even the conceptual content of the belief states of the individual persons is fixed by such social relations.

HOLKOT, ROBERT
(d. 1349)

Robert Holkot [Holcot] was the most significant Dominican theologian of the fourteenth and fifteenth centuries. He received his doctorate at Oxford, lecturing on Peter Lombard's *Sentences*, the main theology textbook, in the years 1331–1333, and served as regent master there, most likely from 1336–1338. He spent time in London as a clerk for Richard of Bury, the bishop of Durham, and probably lectured on the biblical Book of Wisdom at Cambridge from 1340–1342. From 1343 to his death from the plague in 1349, he resided at the Dominican priory in Northampton.

The Condemnations of 1277 and the arguments of John Duns Scotus at the turn of the fourteenth century established the view that no absolute necessity governs creation: God has always had the power to do other than he does and to create a reality other than this one. The working out of the implications for philosophy and theology of such a contingent reality framed scholarly debate during Holkot's time. The tools available to attack the problem had also undergone major changes. In the generation prior to Holkot, William Ockham had subjected thirteenth-century Aristotelianism to a severe critique. Holkot adopted Ockham's philosophy as his starting point.

The most important and controversial of Holkot's views involve his use of the distinction between God's absolute and ordained power. Omnipotence means that God has the absolute power to do whatever does not involve a contradiction. Because no necessity attaches to the ethical precepts that govern the created order (God could without contradiction have created a world in which merit would accrue to doing the opposite of each of the Ten Commandments), human salvation depends upon a covenant between God and human beings established under the New Law of Christ. God's ordained system, the system that instantiates one or another of the many possible creatable orders, displays his expressed power, but could have been, or in the future could still be, other than it is.

Because, in Holkot's view, divine goodness owes nothing to creation, there would be no contradiction in God's replacing the current order with another, even without fulfilling the promises or covenants integral to the current ordination. The principle of noncontradiction provides the ultimate security. If God were to change the ordained system, he would either inform people of the new conditions for salvation or not. If God did not,

then no one could be held accountable for the new conditions. It would involve a contradiction for God to hold people to account for what they can not know.

To analyze the contingent theological order, Holkot adapted the rules of "obligational" debate, a form of debate in which an "opponent" usually proposed some contingent possibility as the initial starting point, to be held true during the debate, and a "respondent" would admit or exclude further proposed propositions as they were consistent with or contradicted the initial proposition. For Holkot, God's revelations functioned like the initial proposals in such debates, and it was incumbent on the believer to hold them as true and to accept the consequences of supposing them true, all the while knowing that the contingent order of creation might mean they were false and never have been true. Holkot's development of this "obligational" theology was his most distinctive contribution.

HOLOCAUST

A number of philosophical issues arise relating to the destruction of most of the Jewish community in Europe in the twentieth century by the Nazis and their allies. This event has been labeled the Holocaust—or *Shoah* in Hebrew—in order to indicate its unique status.

UNIQUENESS

Was the Holocaust unique? There has been an extended debate on this issue. The obvious response is that it was not unique, because other ethnic groups have also been singled out for destruction—and have been destroyed—by powerful enemies. Hitler famously referred to the massacres of the Armenians in Turkey in the early part of the twentieth century when the question arose as to whether people would object to the Holocaust. Because few were interested in the fate of the Armenians—who had so recently been massacred—who would care about the Jews? Throughout human history groups of people who were in some way distinctive have been singled out for persecution and death, and the Jews are hardly the only target. Nor was the Holocaust the only large-scale act of genocide to occur; even in the same century there were several other instances of attempts to destroy an ethnic group.

It has been argued that the Holocaust is unique because never before, or since, have the entire technological resources of the state been directed in such a protracted manner against an indigenous community. The Holocaust took place over many years, against a group of people who could not be realistically regarded as any sort of threat to the state, and was in many ways carried out in opposition to the main aims of the war. For example, when the German army was short of railway stock in order to transport troops, the organizers of the Holocaust increased their efforts to direct stock away from the military in order to continue with the policy of annihilation. Even when the war was clearly lost the policy continued to be pursued until almost the last moment of practicability.

Why does the issue of uniqueness matter? It matters because if the Holocaust was unique, then it may call for new answers and directions. For example, it may give some validation to the creation of the State of Israel as a home for the Jewish people who survived. It may also call for new responses because it would then represent a break in history, and in particular in Jewish history. After all, Jewish history is replete with disasters of one kind and another, and the large-scale destruction of Jewish communities is a familiar feature of that history over the millennia. Is the Holocaust just another disaster among many similar—albeit more limited—disasters? Or does it represent a change in quality, not just quantity?

RADICAL RESPONSES

One of the most radical responses to the Holocaust is provided by Richard Rubenstein (1966), who argues that the events of the Holocaust rule out the traditional God of the Jewish Bible. The traditional God participated in Jewish history; were such a God to exist he would surely have participated in the Holocaust, and prevented it.

Because he did not, it follows that the concept of God has to change. What is needed is a concept of God that takes people closer to nature rather than away from it. Thus the traditional Jewish laws and rituals that emphasize the denial of nature are to be transcended and replaced with a far more hedonistic form of practice. For Rubenstein the return of the Jews to Israel typifies this, to a degree, because it represents a return to the land and to a more rooted and organic form of existence. By forging a new relationship with nature, Jews can transcend the negativity of history—whose paradigm is the Holocaust—and change Judaism itself.

Irving Greenberg (1981) also takes the Holocaust to compel radical steps—an end to the idea of a covenant between the Jews and God. Whereas to begin with the Jews were the junior partner in the covenant—and later on became equal partners—after the Holocaust the Jews are the senior partner, because God has to show himself prepared to act on behalf of the survivors if he is to play any role in their continuing lives at all. The whole idea of an agreement implies that both parties to it will uphold their side of the agreement, and God has clearly not held up his side because he allowed the Holocaust to occur. While Greenberg does see the hand of God in some events after the Holocaust—in particular in relationship to the State of Israel—he clearly holds God in dereliction of his duty, and calls therefore for a new relationship with him.

Arthur Cohen (2002) derives from the Holocaust the silence of God, and his distance from human affairs. To a degree this is not a new factor, because God has always been remote; he has to be if he is to allow people to be free and make their own decisions. Yet the God who emerges is clearly not the ordinary God of religion, but rather a deity who often hides his face and leaves his creatures to get on with their lives by themselves. Clearly such a God cannot be implicated readily in the State of Israel either, and Cohen is skeptical of the point of such a state, reflecting the doubts of Franz Rosenzweig on Zionism. It is the role of the Jewish people to typify a long and difficult relationship with God, not to live in a state of their own like everyone else.

Clearly these responses to the Holocaust call for a new definition of the relationship between God and the world. They also call for a new understanding of what constitutes religious practice, because the old prayers and rituals of Judaism may seem to be irrelevant given this new concept of God. What is worth noting is the crucial significance of the Holocaust to the propounders of these views. The Holocaust is not taken to be one disaster coming after many other disasters, but as an event with an existential meaning all its own. It is a unique event and so calls for unique responses. If those responses demand an entirely new understanding of Judaism, then it would be intellectually dishonest not to establish such an understanding.

ART AND THE UNIQUENESS DOCTRINE

There are important implications of the uniqueness doctrine for art. Adorno famously is supposed to have said that after Auschwitz there could be no art. As a factual claim this is problematic, because not only has there been art subsequently, there was even art during the Holocaust. However grim the conditions are under which artists work, they always manage to operate—some even believe that the harder the conditions the more important it is to respond aesthetically. What Adorno may be suggesting is that the whole context within which art takes place has changed irrevocably due to the Holocaust, and so art that does get done no longer has the character that it appears to have. For example, it may be that the German language has been so corrupted by its use in Nazi Germany that it can never be used again in a fresh and creative way. Although this may be plausible about German, it hardly would extend to other languages—and in fact does not even seem to describe German. Indeed, there has been no shortage of successful German prose and verse since the Holocaust, and in fact that event has often been its subject. It is difficult to make sweeping claims about art, of course, but it does not seem to have been noticeably altered by the Holocaust, nor has art changed much since the Holocaust.

Adorno probably means something a bit less obvious by his claim. Art rests on a whole range of human practices and expectations, and the Holocaust seriously threatened many of these. A defenseless and inoffensive minority were ruthlessly murdered by their fellow citizens, not as a random act of violence but through the machinery of the state and with little evidence of anyone outside of the minority disapproving. The scientific and rational forces of society were used for this purpose, occurring in what had until then been widely regarded as one of the most civilized and advanced societies in the world.

Adorno is pointing to the end of what is sometimes known as the Enlightenment Project, the idea that over time the world would progress as a result of the growing reliance on rationality and science. During the Holocaust, rationality and science were put entirely at the disposal of the murderers, and those techniques were revealed to be mere tools to be employed without reference to moral

restrictions. The optimism of the Enlightenment was thereby undone and should be replaced to by a thoroughgoing realism about the possibility of human progress.

The implications for art are clear. Whereas in the past it was thought that art has a civilizing impact, the Holocaust taught people that it may be enjoyed just as much by the morally corrupt as by anyone else. Thus its status changes from being an aspect of human nobility and cultural progress to becoming a morally neutral means of distraction. Hence Adorno's claim that art has irretrievably changed after the Holocaust.

OTHER RESPONSES TO THE UNIQUENESS THESIS

Emil Fackenheim (1982) presents a powerful defense of the uniqueness thesis, deriving from it what he calls the 614th commandment (there are traditionally held to be 613 commandments applicable to the Jews) that Hitler is awarded no posthumous victories. Such victories include assimilation and the destruction of the State of Israel, but Fackenheim does not see the Holocaust as calling for a radically new approach to Judaism itself or to the relationship between Jews and God.

Another important thinker is Elie Wiesel (1969), who wrote powerfully on his experiences and those of others during the Holocaust. He also sees it as not calling for a new understanding of faith. In particular, to the question of where was God at Auschwitz, he replies with the question where was humanity? The Holocaust represents an event carried out by human beings against other human beings and it is squarely on the shoulders of the murderers that the responsibility should be placed. One cannot expect God to rescue people from the evil decisions and actions of others, because were he to do so their capacity to act freely would be severely constrained.

This latter point is drawn on extensively by Eliezer Berkovits (1973) and Ignaz Maybaum (1965), different thinkers who agree that the Holocaust can be put within a normal Jewish theological context. The Holocaust does not represent a break in history, it is just one more disaster undergone by the Jewish people, and these disasters do have a point to them. God has a role in mind for the Jews, and this is to represent the divine role in history. That the Jews are never entirely destroyed reveals God's actions on behalf of the Jews. For Berkovits the Jews have to undergo suffering in order to sanctify the Holy Name, the traditional interpretation of Jewish suffering. For Maybaum the Holocaust represents an important stage in human history, and the sufferings of the Jews are supposed to lead the gentile world to reflect on the direction that their actions are leading them to pursue. Both thinkers discuss the difficult balancing act that God undertakes. He has to separate himself sufficiently from his creation in order to allow people to be free, whereas at the same time he has to enter into the human world in order to play a part in history.

THE HOLOCAUST FROM A CHRISTIAN POINT OF VIEW

A theme of many Christian views calls for some introspection into the responsibility of various churches for antiSemitism and its eventual outcome in the Holocaust. There have also been more positive analyses, in particular the argument that only Christianity can properly explain human suffering, because only Christianity has at its heart the notion of a suffering deity, in the person of Jesus Christ. The normal conception of God in Judaism is abstract, and many leading Jewish thinkers—such as Maimonides—have strenuously fought against any anthropomorphizing of the concept of the deity. This rather distant notion of a deity is said to be unhelpful during events such as the Holocaust.

It is certainly true that if people are in pain it is good to be comforted by someone who knows precisely what it is like to share in that condition. However, it may be argued that if such a person were in a position to relieve the pain, and does nothing, then the comfort is somewhat reduced. People may be more interested in pain relief than in sympathy, and indeed the latter may be valued largely as a stage on the route to the former. The Christian approach to the Holocaust does, however, raise the important question that runs through the debate— namely, what concept of God can survive the Holocaust experience? The more radical responses insist that a new concept of God is needed, whereas the less radical approaches defend the continuation of the traditional notion of God, and see the Holocaust as just another stage in Jewish history.

THE INDESCRIBABILITY THESIS

Fackenheim (1982) and others have declared that the Holocaust is indescribable. This follows to a degree from its uniqueness. If it is, as an event, really unique, then it could be argued that it escapes the normal categories of description. The indescribability of the Holocaust also explains to a degree why it has been little discussed by philosophers. The indescribability thesis does not appear to be plausible, because there have been many accounts of the Holocaust, and there seems to be little difficulty in

describing it. Around the world there are museums, memorials, and libraries designed to ensure that the world does not forget the Holocaust. In order not to forget the event itself must be described.

The indescribability thesis is rather like the uniqueness thesis in that it is intended not to literally make a claim about the Holocaust, but instead is a metaphorical indication of the extraordinary nature of the attempted extermination of the Jews in Europe as carried out by Germany and its allies. To say that this is easy to describe and that it is just one example of mass murder among many others has seemed to many commentators to diminish the enormity of the Holocaust.

ISRAEL

As noted earlier, one of the effects of the Holocaust is taken to be the creation of the State of Israel. Fackenheim suggests that the Holocaust represented the breakdown of Christian-Jewish relations, and the State of Israel is a *tikkun*, a repair of those relations. In the same way that the Holocaust is a break in history, so is the creation of Israel. It may well be that there is a factual link between the Holocaust and the State of Israel, but from a philosophical point of view it is difficult to see the logical link. Could God not have brought about a state for the Jews in a less costly manner? Was it really necessary for so many innocent people to die? And what about the rights of the people displaced from Palestine to make room for a Jewish state? These people played no part in the Holocaust, and yet were uprooted from the land by Zionism. The opposition to Zionism frequently compares it as a doctrine with Nazism in order to try to weaken the idea that Israel's existence is justified by the occurrence of the Holocaust.

RELATED MORAL ISSUES

An event of the stature of the Holocaust brings out sharply some interesting moral topics, such as the responsibility of the bystander for what goes on in his or her country, and the possibility of forgiveness for a crime of such enormity. During the Holocaust a large number of civilians apparently could have helped the victims, but did not, or could have expressed their views on what was happening, but declined to do so. Of course, there would have been a cost involved, yet the attitude of many was that the events of the Holocaust were not their responsibility because they were not actually the perpetrators and they had not troubled to find out precisely what was going on.

Since the Holocaust, the responsibility of the bystander—as opposed to the actual criminal actor—has become much more of an issue. For the criminal actor, the excuse of only following orders has become less defensible. Agents are expected to be able to consider the moral acceptability of the orders they are given and not carry them out if they are immoral. Finally, the issue of forgiveness and national responsibility arises. Who if anyone is entitled to forgive the agents of the Holocaust? Under what circumstances should they be forgiven—if they should be forgiven at all? What responsibility do their descendents have for the well-being of the survivors, or the Jews in general, or the State of Israel? Is it appropriate to blame a country—Germany—when most of its citizens were born after the Holocaust? How far can a country be held to be guilty at any time?

HOLT, EDWIN BISSELL
(1873–1946)

Edwin Bissell Holt, an American psychologist and philosopher, was noted for his innovations in philosophical psychology. His influence was greater in psychology than in philosophy. In his time he was the American psy-

chologist best known and most respected by the British. Holt completed his undergraduate and graduate work at Harvard and taught there from 1901 to 1918, first as an instructor and then as assistant professor of psychology. In 1926 he returned from retirement to become visiting professor of social psychology at Princeton, but he retired permanently in 1936.

NEW REALISM

Holt was one of the original six American New Realists who banded together in the first decade of the twentieth century in a polemic against idealism and representational realism. Holt was the only one, however, to attempt a systematic development of New Realism, first in a neutral monism, then, after giving that up, in a behaviorist theory of consciousness. In this attempt, Holt uncovered the fatal problems that were in New Realism from its beginning.

The New Realists took their start from the theory of consciousness of William James. James argued that consciousness was an external relation between a sentient organism and its objects, not a substance or entity. The latter view was the basis of the doctrine of the dualism of psychic and physical substances, and of an idealism that defined objects in terms of psychic or subjective substance, thereby giving them a mental or ideal status.

Holt replaced the dualism and psychic monism with a monism that was neutral, defining Being, or reality, neither in terms of mind (idealism) nor in terms of matter (materialism). The basic category of this neutral monism was "Being," which connoted nothing and denoted everything. This neutral Being could most readily be found in the concepts of logic and mathematics, the simplest known elements of Being. But in thus identifying Being with logical and mathematical terms and propositions, Holt gave it a distinctly mental or conceptual character. He admitted borrowing this approach from the idealist Josiah Royce, but he claimed that rather than arguing for idealism, his neutral monism reaffirmed the "sadly neglected truism" of New Realism: "everything is precisely what it is, and is not to be explained away as something else."

Yet Holt's analysis had an inescapable reductivist outcome. All things turn out to be "really" the same. That is, they turn out to be neutral entities (logical and mathematical terms) and the complexes made out of them (propositions), not the material things of common sense or the particles and elements of science. As one critic pointed out, this meant that it is the mathematical logician, not the physicist, who tells us what things are. By

failing to keep clear the difference between the simplest elements of Being and the simplest known elements of Being, Holt threw doubt on the neutrality of his monism. The supposedly neutral logical and mathematical entities, he said, generate the further terms and propositions that make up all systems of being, or universes of discourse, through a "motion" of their own. Though Holt denied that this motion was a mental process, he did term it a "deduction," an intrinsic activity at work in the universe. Like any other object or aggregate, consciousness thus can be "deduced" from Being, and since Being is neutral, consciousness too is neutral; for all the complex constructions in experience are basically composed of neutral entities that maintain their identity despite the constructions they go into.

It is to these propositions, then, generated by the neutral entities of logic and mathematics through a "motion" of their own, that the nervous system responds. Although he admitted this might be considered fantastic, Holt stood by his position. James had said that the content of knowledge is the object of knowledge; content and object are not two separate things but are numerically one. Holt modified this only by noting that since our knowledge of an object is never complete, our ideas are never completely identical with their objects. When we say "My thought is of an object," we should say "My thought is a portion of the object; a portion of the object is my thought." Holt thought the representationalists had failed to see that an idea can represent an object only to the extent that it is identical with that object. An idea cannot represent space, then, without itself being spatial; the only adequate idea of a minute or an hour is just a minute or an hour. Holt thus passed from a partial qualitative identity of knowledge or consciousness and its objects to a numerical or existential identity. He had forgotten that he had begun with James's idea of consciousness as a relation.

No other New Realist developed monism in this thoroughgoing fashion. Holt carried it to its furthest conclusion. If consciousness and its object are numerically identical, do objects then have the character of consciousness (panpsychism), or does the content of consciousness have the character of objects (an inverted panpsychism, or "panobjectism")? Holt's anti-idealism ruled out panpsychism; consequently the elements of consciousness became objects themselves among all other objects, and the world for Holt is populated with all those entities usually placed in consciousness: error, hallucination, delusion, secondary qualities, even volitions. The objective world contains physical counterparts to the

errors of ordinary sense experience. Errors of thought, always cases of contradictory propositions, are equally objective. The "real," or objective, world is contradictory through and through; nature is a "seething chaos of contradiction."

Holt, in a later paper on the locus of concepts, confessed that his neutral monism had led him to write a mistaken book, an "absurd hocus-pocus" conjured up because he did not know at the time the true locus of these neutral "timeless and changeless entities." His failure to maintain their neutrality is admitted: These entities have no objective existence in nature. Although he promised to return to the subject, Holt never did. Nor did he produce the planned second volume that was to carry out the epistemological implications of his neutral monism. Instead, he turned to the development of a behaviorist theory of consciousness.

BEHAVIORIST THEORY OF CONSCIOUSNESS

Holt saw that an extreme behaviorism would make the materialist's mistake of denying the facts, as well as the theory, of consciousness. While he described his own behaviorism as part of the "objective tendency" to abolish the subjective and to interpret mental phenomena in an "objective relational manner," he consciously sought to avoid slurring over or repudiating the "facts" of consciousness, and he modified his behaviorism accordingly.

Increasingly, ideas suggestive of subjectivity, if not dualism, such as integration of behavior, capacity to respond, suppression, and split personality, appeared in Holt's writings. The result was an oscillation between his objectivist, behaviorist ideas and the subjectivist ideas that he needed in order to do justice to the facts of consciousness.

In *The Freudian Wish,* he described behavior by examining the way in which reflexes are combined and integrated to produce that organized "synthetic novelty" which is the specific response, or behavior, and which is also the point at which awareness is born. He identified this response with Sigmund Freud's "wish," including in it purpose, tendency, desire, impulse, and attitude. It was the replacement, Holt claimed, for sensation as the unifying factor of psychology. But he denied that this view meant he was falling back on the psychic or subjective; the basis for the view was objectively observable in what an organism does. While he did not deny that we have unobservable thoughts, he argued that they are often an "embroidery, a mere irrelevance to action," and eventually

they too can be observed if one looks to behavior that is yet to come.

Holt thought the Freudian wish was the first key that psychology had discovered for an explanation of mind. It meant psychology "with a soul," not the "ghost-soul" but the "wishes" which are the soul. Like Aristotle, he identified the soul with the dynamic form of a body endowed with the capacity of life: it is what it can do. The behavior of such a body is distinguished from its random movements by its purposiveness, an objective reference that is found in every reflex. Behavior occurs when more than one reflex is set off by a stimulus. As the number of reflexes increases, the immediate stimulus "recedes" as the inciting and controlling factor. This recession of the stimulus is part of intelligence and deliberation. Holt also used it to give an account of consciousness and knowledge of spatially and temporally remote objects. Still, Holt could not avoid a basic monism. The "objective" world is the only world. What has been called the "subjective" world is the subtler workings of integrated objective mechanisms. It is the body that is the knower; the environing objects to which it responds are the known. And Holt revived his claim that the mind is the thing of which it is thinking.

By the end of his career, despite his lifelong objectivist-subjectivist oscillations, Holt was committed to an objectivist position. He described his last published book (on the learning process) as an essay toward radical empiricism, and it was supposed to complete James's work of ridding philosophy and psychology of the absurdities of subjectivism and any form of psychophysical parallelism. There is only a sketchy idea at the end as to what direction Holt's epistemology might have taken. He thought at that point that he was but one short step away from a definition of awareness and consciousness in physiological terms. His "objectism" was reaffirmed: he sought to formulate a wholly physical and physiological psychology as a basis for the solution of any psychological problem. But he admitted that such a psychology had not yet given the slightest clue to the problem of secondary qualities.

Holt's last published writing set forth a materialism without apologies. Mind and cognition are neither mental nor cognitive, but physical—a matter of nerves and muscles. The active self is the physical body, that and nothing else. An experience of "self" is an experience of parts of one's body. Anything other than that, whether a self, ego, soul, or knower, does not exist.

Still, Holt modified this objectivism. He admitted that our physiological apparatus of perception and

thought habitually distorts, mutilates, and disguises what it is perceiving. It subtracts from "the objective reality," and with the remainder it fuses inseparably "a vast amount of unreality of its own motor creating (subjective reality)." In a mistaken but significant interpretation of Immanuel Kant, Holt claimed that these distortions are strikingly analogous to the Kantian categories in their distortion of things-in-themselves in intuition and understanding.

The ghost of subjectivism remained. Holt and the New Realists may have exorcised its idealist form, but the need for its inclusion was a constant embarrassment to them and was eventually the reason for the failure of New Realism to be anything more than an anti-idealist polemic.

Bibliography

Works by Holt are *The Concept of Consciousness* (London: George Allen, 1914; manuscript completed in 1908), which presents his doctrine of neutral monism; "The Place of Illusory Experience in a Realistic World," in E. B. Holt et al., *The New Realism* (New York: Macmillan, 1912), pp. 313–376—the book contains essays by the six New Realists elaborating their 1910 platform statement; "Response and Cognition," in *Journal of Philosophy* 12 (1915): 365–373, 393–409, reprinted in *The Freudian Wish; The Freudian Wish and Its Place in Ethics* (New York: Holt, 1915), his most popular and widely read book and one of the first introductions of Freud to a large American audience; "Prof. Henderson's 'Fitness' and the Locus of Concepts," in *Journal of Philosophy* 17 (1920): 365–381; *Animal Drive and the Learning Process: An Essay towards Radical Empiricism* (New York: Holt, 1931), Vol. I, probably Holt's most significant publication in psychology; "The Whimsical Condition of Social Psychology and of Mankind," in Horace M. Kallen and Sidney Hook, eds., *American Philosophy Today and Tomorrow* (New York: Furman, 1935); and "Materialism and the Criterion of the Psychic," in *Psychological Review* 44 (1937): 33–53.

A secondary source is Syed Zafarul Hasan, *Realism: An Attempt to Trace Its Origin and Development in Its Chief Representatives* (Cambridge, U.K.: Cambridge University Press, 1928), an extensive consideration of American philosophic realism in all its variations, including a critical exposition of Holt's philosophy.

Thomas Robischon (1967)

HOME, HENRY
(1696–1782)

Henry Home (Lord Kames), an aesthetician and moral philosopher, was born at Kames, Berwickshire, Scotland. He was educated at home and indentured to a writer of the signet in Edinburgh, but he resolved to become an advocate and was admitted to the Scottish bar in 1724. He became a judge of the Court of Session in 1752 and assumed the judicial title of Lord Kames. He was advanced to the High Court of Justiciary in 1763 and was still serving at the time of his death.

Kames wrote a number of books, several of them on legal subjects. His *Sketches of the History of Man* (2 vols., Edinburgh, 1774) bridged his interests in history and philosophy, and he frequently referred to the *Sketches* in his *Essays on the Principles of Morality and Natural Religion* (3rd ed., Edinburgh, 1779). His other philosophical work is *Elements of Criticism* (2nd ed., Edinburgh, 1763), a discussion of aesthetic principles.

Kames argued that the fundamental principles of the fine arts, or the elements of criticism, must be drawn from human nature. The fine arts are suited to human nature because humans, as sensitive beings, are capable of pleasure; and the fine arts are calculated to give pleasure to eye or ear. Kames devoted the opening chapters of the *Elements* to an account of human emotions and passions. These chapters form the psychological prolegomena that he believed aesthetics requires. Perceptions and ideas occur independently of our wills, though we can sometimes will the cessation of a train of ideas. Ideas follow our perceptions and each other in accordance with the laws of association (resemblance, contiguity in time or place, and cause and effect). Emotions and passions occur in relation to our train of perceptions and ideas. A passion is an emotion that is accompanied by a desire. The general rule for the occurrence of emotions is that we love what is agreeable and hate what is disagreeable. Kames's basic principle of criticism is that every work of art that is conformable to the natural course of our ideas is so far agreeable, and every work of art that reverses that course is so far disagreeable. On the one hand, Kames wanted to establish that the agreeableness or disagreeableness of things is prior to our love or hatred; but on the other, he accounted for our emotional reactions to certain things by saying that the nature of man is originally framed with a relish for regularity, uniformity, proportion, order, and simplicity.

The fine arts that Kames had in mind are painting, sculpture, music, poetry, gardening, and architecture; but

the first three are not discussed systematically in the *Elements.* Poetry is given the most extended criticism. Kames was especially interested in plays, and gardening and architecture share a chapter. He divided aesthetic qualities into two sorts: those that an object may possess in itself and those that it has in relation to other objects. Qualities of the first sort are grandeur, sublimity, motion, force, novelty, "laughableness," and beauty, which he conceded are both intrinsic and relational. The relational qualities that Kames discussed are resemblance and dissimilitude, uniformity and variety.

Kames argued that it should be possible to establish a standard of taste against which productions in the fine arts might be judged. We believe that things of a certain kind have a common nature, and individuals are perfect or right insofar as they conform to the common nature of their kind. Thus, it should be possible to determine the common nature that works of art of a certain kind ought to share and to assess the success with which a given work of art meets the ideal of its kind. Kames noted that every person is not fit to become a judge of the fine arts, since not everyone is capable of the refinement of taste that is required. This is no great hardship on the bulk of humankind. The fine arts only contribute to our pleasure and amusement, and it is not as necessary for everyone to have an authoritative sense of right and wrong in the fine arts as it is for everyone to have an authoritative moral sense.

In *Essays on the Principles of Morality and Natural Religion,* Kames discussed a wide range of philosophical topics, including liberty and necessity, personal identity, belief, external senses, and cause and effect. His thinking is influenced by David Hume, either in quiet concurrence or by vigorous reaction. The two longest and most important essays are Essay II, "The Foundation of Morality," and Essay VIII, "Knowledge of the Deity."

For Kames, the foundation of morality is to be found in human nature. Looking there, he finds the moral sense that approves certain natural principles, which are enforced by natural rewards or punishments of pleasure or pain. These principles bind us to refrain from harming others, to tell the truth, to keep our promises, to act faithfully toward those who rely on us, to be grateful, and to be benevolent. While the moral sense is rooted in the nature of man, it admits of great refinements by culture and education.

A hasty reader might conclude that whenever Kames needed to solve a new perplexity in the foundation of morals, he discovered a new sense in humankind. For instance, he resolved the long-standing dispute over the artificiality of justice by declaring that justice is natural because it is founded on a natural sense of property. He claimed that this sense is necessarily antecedent to any social agreement; and indeed that any agreement to organize a society presupposes the existence in men of a sense of property.

In natural religion, Kames believed that he had brought to light a new argument to prove the existence of a god. In D. Cranz's *The History of Greenland* (London, 1767) Kames found an account of a Greenlander who argued in the following way for the existence of an artisan superior in power to man: A kayak is a work of art that can be made only by the most skilled of men, but a bird is an even greater work of art than a kayak; thus there must be an artisan to make birds who is even greater than man. Kames was most impressed by the fact that this argument came from a savage and concluded that "the perception we have of Deity must proceed from an internal cause, which may be termed the Sense of Deity."

In the *Essays,* Kames generalized the Greenlander argument, contending, "We are so accustomed to human arts, that every work of design and use will be attributed to man, if it exceed not his known powers. *Nor do effects above the powers of man unhinge our notion of a cause*: They only lead the mind to a more powerful cause." The italicized words in the passage above are especially interesting, because in an addendum to the third edition of the *Essays* (1779), Kames complained that Hume ignored the Greenlander argument in his *Dialogues concerning Natural Religion*; and Kames believed that argument immune from any strictures on natural religion was found in Hume's *Dialogues.*

HOMER

The Homeric poems *Iliad* and *Odyssey* (probably eighth century BCE) are of interest to the historian of philosophy because they provide the background, in language

and to some extent in thought, from which Greek philosophy emerged. The hexameters of Parmenides and Empedocles follow the Homeric pattern closely, and they both use Homeric words and coin words for themselves after the Homeric model. They also sometimes use the same thought forms. For instance, a comparison may be drawn between Parmenides' journey (see Fr. 1) and Odysseus's journey to the underworld (*Odyssey,* Book 11). The Homeric simile is the forerunner of the natural philosopher's "working model," by which an unfamiliar process is explained by comparison with a more familiar one. For example, to illuminate his description of an evenly poised battle Homer introduced a "careful working woman" weighing wool in her scales; Empedocles compared the breathing process in animals with operations performed with a household instrument, the *clepsydra.*

Apart from these questions of language and style, the *Iliad* and the *Odyssey* influenced the content of later philosophical thought in various ways.

THE WORLD

The Homeric world picture was of a flat, disk-shaped earth, with the sky set over the top like an inverted metal bowl and Hades underneath the earth in a more or less symmetrical relation to the sky. The sun, moon, and stars were taken to move across the fixed heaven from east to west, but the manner of their return journey was not clear. The space between the earth and the sky contained *aer* (mist), and above that was *aether* (the bright air of the upper heavens). The earth was completely surrounded by the river of Ocean, personified and deified as Okeanos. In one exceptional passage (*Iliad,* Book 14, 200–248) Okeanos is called "the begetter of gods" and "the begetter of all things." Aristotle (*Metaphysics* A 3, 982b27) half seriously suggested that Homer's Okeanos was the forerunner of Thales' cosmogonical water. Plato, even less seriously, suggested (*Theaetetus* 152E) that Okeanos provided the origin of Heraclitus's flux theory. These are farfetched ideas; the cosmology of Homer, such as it was, can hardly be seen as anything but a contrast with Ionian theories (see G. S. Kirk in *The Presocratic Philosophers,* Ch 1). But connections can be traced between some details of Homer's descriptions of the natural world and the speculations of later Greek philosophers of nature (see Charles Mugler, *Les origines de la science grecque chez Homère*).

THE GODS

The historian Herodotus observed that Homer and Hesiod together had determined for all the Greeks what their gods were like, and this is probably the greatest significance of the Homeric poems for the history of philosophy (*History* II, 53). There is one general feature about the Homeric gods that is of much importance: They were not dark gods, accessible only to mystics and appeasable by magic, but on the whole very human and rational. They had powers over the world of human experience, and their powers were defined and hierarchical; in this we can see a hint of the orderly cosmos of later theory.

Some philosophers objected to the Homeric gods. Xenophanes launched the first attack: The gods behaved immorally; moreover, the conception of them was relative to the believer (see Fr. 16: "Ethiopians imagine their gods as black and snub-nosed"). Heraclitus's objections were not explicitly against gods but against Homer as the educator of Greece; the Olympian gods were, however, near the center of his target. Plato's onslaught in the *Republic* (376Eff.) is well known; he wished to censor everything in the Homeric poems that was discreditable to the gods before the poems could be used in the education of the "Guardians" (it was general practice in Greece both before and after Plato's time to use Homer as the basis for moral and religious education).

MAN

The Homeric view of man shows interesting differences from later theories. There was no unified soul, contrasted with body, as in the Pythagorean-Platonic tradition; instead, the psychic functions were distributed without much consistency over a number of entities. The *psyche,* which held the position of greatest importance from the time of Pythagoras, was merely a life-soul in Homer; it played no part in the thoughts, emotions, and actions of the living man. The *psyche* survived after death; it did not, however, retain the complete moral personality, as in the Platonic eschatology, but was a bloodless, helpless shadow. The thoughts and feelings of the living man were attributed to the *phrenes* (roughly speaking, the organs of the chest, although in later Greek the word means "diaphragm"), the heart, and the *thymos* (a mysterious entity probably connected, like *psyche,* with breath). *Nous* (mind), which became the most important part of the *psyche* in the psychology of Plato and Aristotle, was generally restricted in Homer to the intuitive understanding of a situation (like the English "to see" in its metaphorical sense); consequently, it was often connected with sense perception, not contrasted with it as in Plato. Unlike *phrenes, nous* was not a physical thing for Homer but a function.

HUMAN ACTION

The actions of the human characters in the *Iliad* and *Odyssey* are represented as being influenced or manipulated more or less constantly by the gods. Actions that might be otherwise difficult to explain, such as a sudden access of superhuman courage, are especially attributed to the intervention of a god. But it is not only the inexplicable or the uncharacteristic that is described thus; a successful shot with the spear or an unsuccessful one, a plan adopted, a fit of anger, a bad bargain, an untimely sleep—these and many other unremarkable events are described as caused by a god. The gods handle the heroes as arbitrarily as a mortal king might treat his subjects, although not, as a rule, with savagery.

The fact that so much of human action is attributed to the gods has led modern interpreters to say that Homeric man is "an open field," that Homer denies free will, and that he has no concept of the human personality. This is true in a sense, but it is misleading. Homer was not a philosopher who had confronted the free-will problem and decided upon determinism; apart from an occasional exception he offered no theories about motivation and responsibility. From the point of view of the responsibility of human characters, there is no opposition between "caused by a god" and "due to a human agent"; for example, one and the same attack by Sarpedon is described as due to Zeus and a few lines later as due to Sarpedon's *thymos* (*Iliad,* Book 11, 292 and 307). The moral relations between human beings are on the whole, although not entirely, unaffected by the interventions of the gods; a god may stir a man to excessive anger, but it is still felt appropriate to blame the man for his anger. The individual characters of the heroes remain fairly stable; the activity of the gods is not such as to make human beings unpredictable. But the Homeric poems generally show a limited sense of moral responsibility. They were composed at a time when shame still predominated over guilt as a motivating force, and the intention of the agent and his knowledge of the circumstances of his act (the two factors that of course played the chief part in later legal and philosophical theories of responsibility) receive little attention.

Homer provided the material for much of later Greek literature, which examined the relation of Homeric gods and men in a new way. The problem of individual human responsibility for actions in which gods were said to be involved, though hardly seen by Homer, was much discussed by the fifth-century tragedians and Sophists (see, for example, Aeschylus, *Agamemnon* 1497ff.; Euripides, *Troades* 914ff.; Gorgias, *Helen*).

HÖNIGSWALD, RICHARD
(1875–1947)

Richard Hönigswald, the German philosopher, was born in Magyarovar, a small Hungarian town near the Austrian border. He received a degree in medicine from the University of Vienna in 1902 and then studied philosophy under Alexius Meinong at Graz and Alois Riehl at Halle, receiving a doctorate in philosophy in 1904. He taught at the University of Breslau from 1906 until 1930, when he accepted a chair in philosophy at the University of Munich. Because he was a Jew, Hönigswald was deprived

of his academic position in 1933. After the pogrom of 1938 he was sent to Dachau, but in 1939 he managed to immigrate to the United States. He lived in New York and engaged in research and writing until his death.

Hönigswald remained closer to the original doctrine of Immanuel Kant, as exemplified in the Transcendental Aesthetic, the *Critique of Practical Reason,* and the *Critique of Judgment,* than did such Neo-Kantians as Hermann Cohen, Paul Natorp, and Heinrich Rickert. However, he emphasized the insufficient consideration Kant had devoted to the importance of the concrete subject as a historical and empirical entity. Out of this criticism of Kant, Hönigswald developed his own influential theory of concrete subjectivity, the psychology of thinking (*Denkpsychologie*). According to Hönigswald, the concrete subject, an individual monad, is both fact (*Tatsache*) and principle (*Prinzip*)—that is, it is both a constituent of the world and an entity that recognizes itself as the correlate of the world, confronting it in cognition, volition, and artistic productivity. In the concrete subject, ground and grounded, objectivity and object, coincide; in a natural object they are separated. This doctrine forms the basis of Hönigswald's cosmology. In its attempt to determine the concrete subject's position in the world and its specific temporal structure in terms of a regional ontology, Hönigswald's philosophy exhibits similarities to Edmund Husserl's *Konstitutionslehre,* Martin Heidegger's analysis of *Dasein,* and Nicolai Hartmann's theory of stratified being. Hönigswald's approach differs from these in that he adhered to classical principles of validity (*Geltungsprinzipien*) in epistemology, ethics, legal and political philosophy, aesthetics, and the philosophy of religion. He found the key to the differentiation of the corresponding judgments and cultural realms in the constitutive features of the subject (thereby departing from Marburg and southwest German Neo-Kantianism), which he classed as intentionality, self-determination, reference to nature, and unlimitedness.

Hönigswald's philosophy of language made a considerable impact on Continental linguistics. Just as fact and principle coincide in the individual monad, Hönigswald claimed, the intermonadic reference of language constitutes the one other instance of the coincidence of fact and principle. Hönigswald's educational thought influenced such philosophers as Moritz Löwi and Alfred Petzelt, who, like him, emphasized the notions of tradition, concentration, and projection into the future. A number of thinkers, including Bruno Bauch, Theodor Litt, Wolfgang Cramer, and Hans Wagner, have engaged in evaluating Hönigswald's teachings for the study of fundamental problems in philosophy.

HOOKER, RICHARD
(1553–1600)

Richard Hooker, the English theologian and social and political philosopher, was born at Heavitree, near Exeter. His family was poor but well connected, and in 1568 Bishop John Jewel secured for Hooker a clerk's place at Corpus Christi College, Oxford. He became a fellow in 1577 and upon his marriage in 1581 was presented with

the living of Drayton-Beauchamp and a few months later with the mastership of the Temple in London. At the Temple, Hooker came into violent conflict with William Travers, a Calvinist who lectured there in the evenings. Although Hooker always retained a high regard for Travers's intellect and integrity, he was forced by his own convictions to oppose the views of Travers. It was during this controversy that Hooker seems to have conceived the idea of writing a systematic treatise to uphold the establishment of church and state as represented by Queen Elizabeth's policies. In order to carry out this plan, he requested a transfer from the unquiet position in London to a country rectory. Thus he went to Boscombe near Salisbury, where he was able to write and complete the first four books of his projected treatise, *The Laws of Ecclesiastical Polity,* by 1593 or 1594. In 1595 he was promoted to the rectory of Bishopsbourne near Canterbury, where he completed the fifth, purely theological part of his treatise by 1597. During the following three years he wrote another three books for the *Laws,* but he did not live to see them published. He died toward the end of 1600.

HOOKER'S IMPORTANCE

Hooker was not an original thinker. His importance lies in the fact that he drew upon the various currents of medieval thought in order to explain the ecclesiastical and political institutions of Elizabethan England. Together with Francisco Suárez and Cardinal Robert Bellarmine he belonged to the first Counter-Reformation generation, and like the two Jesuits he elaborated the final implications of Aristotelianism and of Thomism in social and political philosophy. But unlike his two Jesuit contemporaries, he did not live in the orbit of the Roman Catholic revival. To both Suárez and Bellarmine the Renaissance, the Protestant Reformation, and the Erastian state were merely threats they had heard of—threats from the outside. But Hooker was an Englishman who had grown up and lived through the turmoil occasioned by the attempt of radical Protestantism to force Queen Elizabeth from her conciliatory path. As a result he had to parry the practical attack of the extreme Protestant wing, and he finally came face to face with the secular state's opposition to that wing. This confrontation lends Hooker's thought an air of real drama; and if he was less systematic in his exposition than Suárez, his writings have the advantage of revealing a genuine intellect at work, wrestling with problems, not merely teaching what is imagined to be the truth.

THE SOURCE OF AUTHORITY

Hooker's analysis of the Puritan attack on the Elizabethan settlement in church and state had revealed to him the essential similarity of that case with a line of argument that had a long and distinguished medieval ancestry and in some ways went back as far as St. Augustine. The attack the Puritans mounted against the Elizabethan settlement drew heavily on John Calvin and to a lesser extent on John Wyclyf, and was ultimately analogous to all those medieval arguments that had denied the validity of natural law and therefore of the justification of secular authority in terms of natural law. Lacking a justification in natural law, the secular state, if it was to have any legal and moral basis at all, had to be subject to divine authority. To medieval writers this divine authority was represented on Earth by the papacy; to the sixteenth-century Calvinists, it resided in the presbyteries of the godly and the elect. In order to combat the view that men have no natural reason with which to discover a natural law, and the view that any law discovered or made by men is incompatible with divine law, Hooker fell back upon the philosophy of St. Thomas Aquinas. That philosophy had been developed during the thirteenth century to establish a doctrine of natural law and natural reason and to show how the rules thus discovered were fully compatible with those supernaturally revealed by God. The first book of Hooker's treatise is therefore a readable sixteenth-century compendium of Thomistic philosophy.

NATURAL AND REVEALED LAW

Like St. Thomas, Hooker believed that man is by nature a social animal and that both the impulse to live in society and the need for some kind of government is inherent in human nature. Man is therefore created by God with the rational endowments necessary for the conduct of society and government. All social and political arrangements are hence subject to natural law, which is immutable. But since conditions of life vary from time to time and place to place, it is necessary to supplement the dictates of natural law with positive or "human" rules. All this was taken from Aristotle, but translated by both St. Thomas and Hooker into the context of Christian thought. Men desire not only to live, however, but also to live well. This further desire implies that they must find their ultimate happiness. Such ultimate happiness cannot be found in the attainment of a temporal, and therefore temporary, good, but only in the ultimate perfection that is God. Owing to the Fall, man cannot know by natural reason what he must do to obtain this final supernatural end. God has therefore revealed to man certain rules to supplement

natural law. Hence it becomes clear that in order to achieve full human stature, man needs both natural law, for social and political purposes, and revealed law, for everlasting felicity. Revealed law is contained in the Bible and the traditions of the church. Natural law and revealed law are jointly, and not separately, the correct guide.

THE "LEX AETERNA"

In order to establish his point that the two sets of laws must be brought into operation jointly, Hooker delved into cosmology. God, he wrote, is the author of everything. He is a law unto himself, and that law is the *lex aeterna,* which is both the source of all other law and itself manifested in all other laws. In the divinely revealed law, it is manifested directly, so to speak; in natural law, indirectly. For natural law is discovered by human reason, and human reason is created by God according to the *lex aeterna*; therefore the dictates of natural law, and even the positive rules of human law, spring from the *lex aeterna.* God has given reason to every man. He has "illuminated" him. Although there is no explicit reference to St. Thomas in Hooker's text, this argument is a transcription of one of the central tenets of Thomism: *signatum est super nos lumen vultus tui, domine* ("the light of thy countenance is signed upon us, Lord"; Psalms 4:6–7). Hence we learn the will of God by using our reason.

OTHER THOMIST DOCTRINES

Hooker identified himself with all the more salient doctrines of St. Thomas. He argued that God is pure act and that in him existence and essence coincide; that angels are immaterial and that they differ from all natural, not purely intellectual creatures in that they behold the face of God directly; that the soul is the form of man, and not a separate substance as St. Thomas's opponents had argued.

The will of man, Hooker wrote, is free. Everything good that reason sees as such has something unpleasant annexed to it. And everything evil that reason sees as such has something pleasant attached to it. For reason cannot see the absolutely good. Hence, although we always will the good, we can never will the absolutely good; as a result the will is always free to choose between several relative goods. Hooker believed that the two springs of human action are knowledge (reason) and will. The will always wills the good; and the good is apprehended by reason. Sin results from the imperfect operation of reason, which can never apprehend the absolutely good. Sin is therefore intimately linked with both the freedom of the will and the imperfection of reason. It is never committed as a positive action or desired for its own sake, but is the result of a loss. Evil, by implication, is a privation.

These subsidiary arguments were important to Hooker not only because they enable the reader to identify the main lines of Thomism but also because they help to lead to the goal of the main argument. To avoid evil, it is necessary to supplement the law of nature. And since the law of nature is embodied in secular government, the revealed law is embodied in the church. Thus Hooker arrived at his main objective, the proof that church and state are intimately connected.

ECCLESIASTICAL AND SECULAR SOCIETY

As long as the argument remained confined to a high level of generality, it was easy to take for granted that this philosophy amounted in fact to a defense of the Elizabethan establishment, in which church and state were closely identified. Such reforms as Henry VIII and Elizabeth introduced into the church never really severed the visible continuity of ecclesiastical institutions and of canon law in England. The Elizabethan settlement, like Henry's acts of law, had been made by Parliament; in a very general sense, Parliament appeared to Hooker not as a purely secular institution. The bishops were part of it; and the electors themselves, being members of the church as well as members of a secular society, could easily be deemed to constitute in fact an ecclesiastical polity.

Hooker was explicit on the importance to his argument of the identity of the people who were the church with the people who were the commonwealth. He admitted that in countries where no such identity could be presumed, the natural society (being hierarchically lower than the ecclesiastical society) could not be deemed capable of making laws for the church. But in England, he was confident, complete identity obtained.

Thus Hooker was able to establish his initial point that the Puritan attack upon the Elizabethan settlement and the Puritan demand for the establishment of presbyteries and congregations was based on a false estimate of human nature. For it assumed that there was no natural law to justify the existence of secular society and of secular government, that all authority would ultimately have to be vested in the congregations representing the godly and the elect who embodied the only law there was, the divine law.

NATURALISM AND ANTI-PLATONISM

When Hooker turned to writing about the more particular arrangements of the Elizabethan settlement, he had difficulty squaring his Thomist theory with political practice, which was Erastian and naturalistic in the extreme. In an attempt to do so he drew heavily upon the ideas of Marsilius of Padua, who had completely subjected the church to the state. Hooker had begun as a confident Thomist; with the discovery that Thomism did not suffice to account for the intricacies of late Tudor politics, he found himself in a tangle once he began drawing upon ideas from the naturalistic thought of Marsilius, which was completely incompatible with Thomism.

The crux of the tangle was Hooker's unflinching Aristotelianism, probably absorbed when he was a student at Oxford. It was his Aristotelianism that prompted the experiment of bringing together the two great Aristotelian strands, that of St. Thomas and that of Marsilius, and yoking them to the defense of the Tudor state as Tudor ecclesiastical polity. If Hooker had been more observant and less wedded to Aristotle, he would have found another growing tradition of thought—Platonism—ready to hand.

Basically, Hooker was a Christian humanist, tolerant and fairly latitudinarian in theology. In the fifth book, which was devoted entirely to theology, he went out of his way to provide theological formulations that embraced to the point of ambiguity all the most controversial issues of the sixteenth century, so that as many disputants as possible would feel at home in his ecclesiastical polity. He was convinced that man was not wholly depraved and that the judicious exercise of human reason was absolutely essential to a Christian life. He saw no great and insurmountable chasm between nature and the supernatural and held that the mark of the Divine Creator can be detected in every creature.

Christian humanism had in a way been the mainstay of medieval Thomism. But in the sixteenth century, with Marsilio Ficino and Desiderius Erasmus, it had severed its connections with Aristotle and had been poured instead into the mold of Plato. Hooker was not only completely unaware of this revolution in thought; he actually went out of his way to attack one of the most popular Platonist teachers of his day, Peter Ramus. It is true that Ramus's variety of Platonism was a vulgar one and that one cannot blame Hooker for taking up cudgels against him. But viewed in perspective, Hooker's stubborn Aristotelianism acquired an unnecessarily aggressive edge when it was led into the fray against the Ramists, who were conspicuously active at Cambridge at that time. Against their nimble handling of Ramus's theories of rhetoric, Hooker reiterated all the old stock in trade of Aristotelianism and thought that he had vanquished his opponents simply by his demonstration that they differed from Aristotle. In this respect Hooker showed himself to be much more medieval than one is led to expect from his high baroque prose style and his freely discursive and informal way of arguing.

Through his conviction that Aristotelianism was the only satisfactory vehicle of Christian humanism, Hooker weakened his own case. For it was this conviction that deprived him of the opportunity of becoming the link between the humanism of John Colet, Erasmus, and Thomas More at the beginning of the sixteenth century and the Platonism of the Cambridge Platonists of the early seventeenth century. Platonism was fashionable enough in the England of Hooker: Edmund Spenser, William Harvey, Roger Ascham, Sir Philip Sidney were all Platonists in one way or another. But their Platonism was purely literary and emotional. Hooker was perhaps the only Elizabethan who could have deepened it. His Aristotelianism kept him aloof from these currents of thought, and thus he missed the unique opportunity that his great learning and the lucidity of his thought afforded him: injecting systematic philosophy into the Platonist current.

NATURAL LAW AFTER HOOKER

Although it may seem that Hooker's grand vindication of natural law helped to prepare the way for the revival of natural law in the seventeenth century, his arguments bear no relation to those of Hugo Grotius or of John Locke. To Hooker natural law was the dictate of reason; and reason was a discursive power of sensibility, capable of intuiting the good. It can therefore provide premises as well as help to draw out conclusions and dictate right conduct. To Grotius, on the other hand, the dictates of right reason were mere calculations of enlightened self-interest. In his theory of natural law, reason merely provided the long-term views necessary for survival, and natural law ceased to be identified with the rules set down, indirectly, by God. They were, on the contrary, made out to be completely independent of God.

HORKHEIMER, MAX
(1894–1972)

Max Horkheimer, a German-American philosopher and social theorist, was born in Stuttgart, Germany, to a wealthy industrialist. After receiving a PhD in philosophy at the university of Frankfurt in 1922 with a dissertation on Kant supervised by Hans Cornelius, Horkheimer joined the *Institut für Sozialforschung* (Institute for Social Research) that was established in Frankfurt in 1923 as the first Marxist-oriented research center affiliated with a major German university. Under its director, Carl Grunberg, the institute's work in the 1920s tended to be empirical, historical, and oriented towards problems of the European working-class movement.

Horkheimer became director of the institute in 1930 and gathered around him many talented theorists, including Erich Fromm, Franz Neumann, Leo Lowenthal, Herbert Marcuse, and T. W. Adorno. Under Horkheimer, the institute sought to develop an interdisciplinary social theory that could serve as an instrument of social transformation. The work of this era was a synthesis of philosophy and social theory, combining sociology, psychology, cultural studies, and political economy.

During the 1930s, Horkheimer wrote many articles in philosophy, validating progressive ideals of reason, democracy, justice, morality, and other traditional concepts, while criticizing assaults on these ideals in the contemporary era and in particular developing critical perspectives on German fascism and its ideology. Most members of the Institute were both Jews and Marxist radicals and were forced to flee Germany after Hitler's ascendancy to power. The majority emigrated to the United States and the Institute became affiliated with Columbia University from 1931 until 1949, when it returned to Frankfurt.

From the mid-1930s, the Institute referred to its work as the "critical theory of society." For many years, "critical theory" stood as a code for the Institute's Marxism and was distinguished by its attempt to found a radical interdisciplinary social theory rooted in Hegelian-Marxian dialectics, historical materialism, and the critique of political economy. Members argued that Marx's concepts of the commodity, money, value, exchange, and fetishism characterized not only the capitalist economy but also social relations under capitalism, where human relations and all forms of life are governed by commodity and exchange relations and values.

In "Traditional and Critical Theory" (1937 [trans. 1972 in *Critical Theory*]), Horkheimer argued that "tradi-

tional theory" (which included modern philosophy and science since Descartes) tended to be overly abstract, objectivistic, and cut off from social practice. "Critical theory," by contrast, was grounded in social theory and (Marxian) political economy, carried out systematic critique of existing society, and allied itself with efforts to produce alternatives to capitalism and bourgeois society (then in its fascist stage in much of Europe). The goal of critical theory is to transform these social conditions, and help produce "an association of free people in which each has the same possibility of self-development" ("Traditional and critical theory," p. 219).

Working collaboratively with T. W. Adorno, their *Dialectic of Enlightenment* (1947 [1972]) sketched out a vision of history from the Greeks to the present that discussed how reason and enlightenment became their opposite, transforming what promised to be instruments of truth and liberation into tools of domination. Under the pressure of societal systems of domination, reason became instrumental, reducing human beings to things and objects and nature to numbers. While such modes of abstraction enabled science and technology to develop apace, it also produced societal reification and domination, culminating in the concentration camps that generated an instrumentalization of death. In the "dialectic of Enlightenment," reason thus turned instrumental, science and technology had created horrific tools of destruction and death, culture was commodified into products of a mass-produced culture industry, and democracy terminated into fascism, in which masses chose despotic and demagogic rulers. Moreover, in their extremely pessimistic vision, individuals were repressing their own bodies and renouncing their own desires as they assimilated and made their own repressive beliefs and allowed themselves to be instruments of alienated labor and war.

Sharply criticizing enlightenment scientism and rationalism, as well as systems of social domination, Adorno and Horkheimer implicitly implicated Marxism within the "dialectic of enlightenment" because it too affirmed the primacy of labor, instrumentalized reason in its scientism and celebration of "socialist production," and participated in Western modernity and the domination of nature. After the Second World War, Adorno, Horkheimer, and Pollock returned to Frankfurt to reestablish the institute in Germany, while Lowenthal, Marcuse and others remained in the United States.

In Germany, Adorno, Horkheimer, and their associates published a series of books and became a dominant intellectual current. At this time, the term "Frankfurt School" became widespread as a characterization of their version of interdisciplinary social research and of the particular social philosophy developed by Adorno, Horkheimer, and their associates. They engaged in frequent methodological and substantive debates with other theories, most notably "the positivism dispute," where they criticized empirical and quantitative approaches to social theory and defended their own more speculative and critical brand of thought. The German group around Adorno and Horkheimer was also increasingly hostile toward orthodox Marxism and were in turn criticized by a variety of types of "Marxism-Leninism" and "scientific Marxists" for their alleged surrender of revolutionary and scientific Marxian perspectives.

Horkheimer's *Eclipse of Reason* (1947) presents a popularized version of *Dialectic of Enlightenment* for an English-speaking audience and *Critique of Instrumental Reason* (1974) brings together Horkheimer's key essays since the end of World War II. The late Horkheimer became increasingly pessimistic and combined Schopenhauer's stoicism with a quest for the "totally other," a religious desire for transcendence that entered his materialist philosophy in later years.

HOW AND WHY

See *Why*

HOWISON, GEORGE HOLMES
(1834–1916)

George Holmes Howison, the American personalist philosopher and mathematician, was a graduate of Marietta College in Ohio and professor of mathematics at Washington University, where he became a member of the St. Louis Philosophical Society. He taught philosophy at the Massachusetts Institute of Technology, at the Harvard Divinity School, and at the Concord School of Philosophy before moving in 1884 to the University of California, where he organized what was to become an influential department of philosophy.

Howison, calling his system "Personal Idealism," maintained that both impersonal, monistic idealism and materialism run contrary to the moral freedom experienced by persons. To deny the freedom to pursue the ideals of truth, beauty, and "benignant love" is to undermine every profound human venture, including science, morality, and philosophy. Thus, even Personalistic Idealism (B. P. Bowne and E. S. Brightman) and Realistic Personal Theism (Thomas Aquinas) are inadequate, for they make finite persons dependent for their existence upon an infinite Person and support this view by an unintelligible doctrine of *creatio ex nihilo.*

Howison's Personal Idealism, therefore, is founded on what he believed to be an undeniable fact: The freedom crucial to human existence is untenable if the individual is dependent for his existence upon any other being, including a Creator-God or an Absolute One. Therefore, self-determining beings must be uncreated and eternal; yet the unique quality of human freedom presupposes that each person stands in an individual relationship to other persons, subpersonal beings, and God.

How, then, does this plurality of uncreated beings compose a universe and not a mere collection of beings, a pluriverse? Howison answers that it is the very nature of undeniable, self-active, unified, thinking beings to define themselves and to fulfill themselves as individuals. In this very act of self-definition and self-fulfillment they find themselves related to other beings. "Thus, in thinking itself as eternally real, each spirit thinks the reality of other spirits."

Is there a God to unify the many grades of self-active beings? Yes, but any unification must not infringe upon individual growth to moral perfection. Creation as efficient cause must give way to creation in accordance with

an Ideal present in each being. The fulfillment of this Ideal calls for a world composed of "*all* the individual differences compatible with the mutual reality of all." Thus, basic harmony is possible because, as each individual defines himself, he finds the Ideal of self-definition by which to measure himself. And God, who is "defined as self-existent by every other self-defining being," is the indispensable standard for measuring reality.

In this Personal Idealism there is, then, no one Prime Mover or Creator. Reality is a republic of self-active, self-defining spirits, each moving toward the Ideal exemplified by God, "changelessly attentive to every other mind, rationally sympathetic with all experiences, and bent on its spiritual success." Nor are the vast number and the gradation of minds that compose the different levels of matter, life, and mind the product of evolution; what we know as nature and evolution is the product of the various kinds of self-active beings, moved ultimately by the final causes of their inner beings toward a common goal.

HSÜN TZU

See *Xunzi*

HUANG ZONGXI
(1610–1695)

Huang Zongxi, also known as Huang Lizhou, was the most important figure during the transitional period from the late Ming to the early Qing dynasty. He was the last in line as a Sung-Ming neo-Confucian philosopher, and was also an intellectual historian who studied in depth the whole Sung-Ming neo-Confucian Movement. Huang was the disciple of Liu Zongzhou (1578–1645),

and compiled the influential *Mingru xue'an* (Cases in Ming Confucianism) according to the guidelines he learned from his teacher.

The dominant trend of philosophy in the Ming dynasty was Wang Yangming's (1472–1529) *xinxue* (learning of mind). It was in sharp contrast to Zhu Xi's (1130–1200) *lixue* (learning of principle), which had been the dominant neo-Confucian philosophy as well as state ideology since the Yüan dynasty, because Zhu's *Commentaries to the Four Books* had been adopted as the basis for civil service examinations since 1313. Zhu had taught a dualism of *li* (principle) and *qi* (material or vital force); *xin* (mind-heart), for Zhu, consisted of the subtlest kind of *qi* that encompasses *li* (principles). Wang felt that Zhu's dualism was detrimental to self-discipline. Instead Wang taught a monism that identified *xin* with *li*.

Liu was in sympathy with Wang, but when Wang put too much emphasis on *liangzhi* (innate knowledge of the good), some of his followers claimed that sages are all over the street. In order to remedy the situation, Liu shifted the emphasis to *chengyi* (sincerity of the will) and *shendu* (vigilance in solitude). Huang inherited his teacher's monistic outlook, and went further, claiming that *li* is but the *li* of *qi*, and that there is no *benti* (substance) aside from *gongfu* (discipline). Such a tendency inadvertently led to a radical naturalistic interpretation of monism, which abandons the transcendent aspect of neo-Confucian philosophy altogether, thus causing a paradigm shift in early Qing philosophy.

Although Huang had firm convictions of his own, he chose not to write on his philosophy; instead, he worked hard to compile case studies. Because Wang Yangming taught different things in different places and periods, Huang took pains to study the different branches of philosophy under the school, devising a scheme to cover them all (although he did not neglect the other schools of philosophy). With its breadth and depth, Huang's *Mingrue xue'an* was unprecedented. It became so dominant, in fact, that when it was published it was taken as the only doorway through which one should study Ming Confucianism. Huang had also planned to provide case studies in Sung-Yüan Confucianism, but he never completed the task; the study was finally put together by Quan Zuwang (1705–1755).

Huang was also an expert on textual studies of the Classics. A case in point was his study of *Yijing* (Book of changes). He and his brother argued that the diagrams attached to this classic, which had been around since the Sung dynasty, were spurious. Huang's influence was contagious; Yan Rouju (1636–1704), who claimed Huang as his mentor, produced a critical study that showed the *Book of History* in ancient script was spurious. It is well known that Zhu Xi had established the orthodox line of transmission of the Way by quoting from the alleged fabricated document. With Yan's study, the foundation of Zhu's claim was now apparently undermined. Again, inadvertently, Huang appeared to have helped Qing Confucianism undergo a paradigm shift from philosophy to philology.

When the Ming dynasty was overthrown by the Manchus, Huang reflected deeply on politics and wrote the *Mingyi daifang lu* (Waiting for the dawn: A plan for the prince). He felt that since the establishment of the dynasties the rulers had taken the country as their private property, thus causing much misfortune. Huang urged a return to the ancient time when sage-emperors served the country and the people without selfish desires. (Although the *Mingyi daifang lu* has nothing to do with democracy in the West. Huang's book was used as propaganda against the Qing regime, inadvertently propelling the intellectuals to hope for a republican government of, for, and by the people.) The last dynasty was overthrown in 1912.

HUET, PIERRE-DANIEL
(1630–1721)

Pierre-Daniel Huet, the last Christian skeptic in the line of Michel Eyquem de Montaigne and Pierre Charron, was born in Caen, Normandy. His father had been converted from Calvinism. Young Huet studied with the Jesuits and, after taking a degree in mathematics, went in 1652 with the Protestant scholar Samuel Bochart to the court of

Queen Christina of Sweden. There, he discovered a manuscript of Origen, which later led him to write *Origenis Commentaria in Sacrum Scripturam* (Rouen, 1668). En route home in 1653 he stopped in The Netherlands, where he met many savants. A discussion with one of them, Rabbi Menasseh (Manasseh) ben Israel, led Huet to write *Demonstratio Evangelica* (1679).

From The Netherlands Huet returned to Caen, where he founded the Academy of Sciences, corresponded with learned men throughout the world, and worked on his studies on Origen. He often traveled to Paris and entered several of the learned literary salons. His reputation as a man of letters and science grew, and in 1670 Louis XIV appointed him to be Jacques Bénigne Bossuet's assistant as the dauphin's teacher. While holding this post, Huet started a famous set of editions of classical authors, *Ad Usum Delphini*.

After several years Huet decided to become a priest and was appointed abbot of Aunay and afterward bishop of Soissons. He did not like that post and exchanged it for the bishopric of Avranches. In 1699 he retired to a Jesuit institution in Paris, to which he had donated his enormous library (transferred after the suppression of the Jesuit order to the Bibliothèque Nationale, where it constitutes a basic part of the collection).

Huet wrote many works on history, philosophy, theology, and literature and was regarded by figures like Gottfried Wilhelm Leibniz as the most learned man of his age and as an excellent Latin poet. His most philosophically interesting works are the *Demonstratio Evangelica*, *Censura Philosophiae Cartesianae* (1689), *Nouveaux Mémoires pour servir à l'Histoire du cartésianisme* (1692), *Questiones Alnetae de Concordia Rationis et Fidei* (1692), and its notorious concluding section, the *Traité philosophique de la foiblesse de l'esprit humain*, published posthumously in 1723.

HUET'S SKEPTICISM

Demonstratio Evangelica shows signs of philosophical skepticism and empirical and liberal views. After arguing that no absolute certainty could be attained in mathematics or theology, Huet tries to establish religious truth inductively, by showing the common elements in all religions, ancient and modern. The privileged position of Christianity was primarily because of its expressing best the features of natural revelation. (Doctrinal differences within Christianity had little interest for Huet. Hence, he could join his friend Leibniz in trying to reunite all the churches.)

In Huet's papers there is some material that indicates the special flavor of his skepticism and religious approach. While he was bishop of Avranches, somebody noticed that a Jesuit from Normandy had received a doctorate for a dissertation claiming that there is no evidence that Christianity is true and that of all the religions in the world Christianity is the least probable. This raised a scandal, and the case was turned over to Huet to examine the Jesuit. Huet sent back a report saying that he agreed on everything. Since Christianity is a matter of faith, there should be no evidence and if it were at all probable, that would count as evidence. Further material about this may be found in the massive collection of his papers in the Medici library in Florence, Italy.

Huet's writings against Cartesianism show a much more developed epistemological skepticism. He utilizes all of Sextus Empiricus's weapons to attack René Descartes's claims that the *cogito* is the fundamental, indubitable truth and that whatever is clearly and distinctly conceived is true. Joining the previous critics Pierre Gassendi, Thomas Hobbes, and Simon Foucher, Huet, in an intensive examination of the Cartesian theory of knowledge, contends that "I think, therefore I am" is a dubious claim and that no certain knowledge about the world could be attained by Descartes's "way of ideas." In *Censura* and in an unpublished defense of it Huet argues not only that "I think, therefore I am" is an inference but also that it involves a time sequence from the moment when thinking is occurring to the moment when one realizes that one thought and that memory may be inaccurate. If one is immediately conscious of thinking, the realization about the existence is a possible future event. Hence, one cannot be simultaneously aware and certain of the ingredients of the cogito and, thus, of its indubitability.

Besides analyzing the Cartesian arguments, Huet ridicules both the theory and its founder. *Nouveaux Mémoires* is a spoof about Descartes's life after his supposed death in Stockholm, Sweden, in which Descartes tries to expound his philosophy in Lapland. Huet also joins the Jesuit anti-Cartesians in accusing Cartesianism of irreligion and incoherence, advocating, instead, a type of probabilistic nonmetaphysical view of the world.

THE 'TRAITÉ PHILOSOPHIQUE'

The full presentation of Huet's skepticism appears in the posthumous *Traité philosophique*, which the Jesuits denounced as a forgery written to embarrass the church. (The manuscript, which is in Huet's handwriting, and discussions in his correspondence eliminate any doubts

about Huet's authorship.) The traditional Pyrrhonian position is set forth, criticisms of skepticism are considered and refuted, and a modern skepticism are advocated in opposition to Cartesianism. Huet's skepticism consists of doubting that any genuine knowledge about reality can be attained by human means while offering experimental science and pure fideism as the means for finding out something about nature, God, and man. In *Traité philosophique*, in his correspondence, and in his marginalia, especially in his copy of Blaise Pascal's *Pensées*, an extreme fideism appears, in which it is denied that there can be any rational defense of religion. Huet thought Pascal too rationalistic because of his wager argument. Faith, and faith alone, could lead to any religious views. It is difficult to determine what or how much Huet himself actually believed. As a prelate and theologian, he was extremely latitudinarian and was in friendly contact with scholars everywhere, regardless of their religious or non-religious affiliations.

Huet's *Traité philosophique*, first published in 1723, was quickly translated into English, Italian, German, and Latin and was studied throughout the eighteenth century. David Hume read it and, like many others, was amused that the author was a total skeptic and a learned clergyman. Huet's contribution to skeptical discussion of the period underlines his explanation of how the skeptic can deal with normal human situations. Huet states, "It is one thing to philosophize, another to live." He then points out that the skeptic, like everybody else, lives according to customs and habits while at the same time doubting that there can be any justification. At the end of book 1, part 4 of *A Treatise of Human Nature* (1737), Hume gives pretty much the same explanation as Huet. Hume also cites Huet in the *Dialogues on Natural Religion*, posthumously published in 1779.

In his day Huet was influential and was taken seriously by Leibniz, Pierre Bayle, and others (Benedict [Baruch] de Spinoza even feared that Huet was writing a refutation of his views). A major transitional figure, he helped to destroy Cartesianism and to further empirical science. His immense erudition provided some of the basic materials for the Enlightenment. His pioneering work in comparative religion was taken by later scholars and was used as ammunition against traditional religion. However, his skeptical argumentation was taken less seriously than that of Bayle or Hume.

Recent studies suggest that Huet had an overall theological and philosophical perspective that would be united in the total corpus of his works. So far, there are only piecemeal pictures of it, which show him to be an important scholar of the early Enlightenment. There is still an enormous amount of unpublished material in his correspondence, his markings and notes on books in his library, and in manuscripts of works not completed.

HÜGEL, BARON FRIEDRICH VON

(1852–1925)

Baron Friedrich von Hügel, the Roman Catholic philosopher of religion and writer on mysticism, was born in Florence, Italy, and succeeded to his father's (Austrian) title in 1870. Most of his life was spent in England. His most important writings were *The Mystical Element of Religion as Studied in St. Catherine of Genoa and Her Friends* (London, 1908), *Essays and Addresses on the Philosophy of Religion* (London, 1921 and 1926), and *The Reality of God* (published posthumously; London, 1931).

Von Hügel's philosophical position was opposed both to idealism and to what he called positivism. By positivism he meant the doctrine that knowledge is exclusively confined to sense perceptions and to the laws that connect them. He rejected this position on the grounds that sense experience is accompanied by a strong "pressure on our minds" to credit it with "trans-subjective validity" (that is, to accept that it tells us something about an external world existing independently of our experience of it) and that refusal to assent to this pressure would mean that positivism collapses into skepticism, which is self-defeating. Moreover, since it is our own minds that we are immediately aware of, our apprehension of reality will be more certain if there is no phenomenal content. This idea paves the way for von Hügel's justification of the epistemological importance of mystical experience. He criticized idealism for a subjectivism similar to that implicit in positivism.

Von Hügel distinguished between knowledge of abstract ideas and of numerical and spatial relations, on the one hand, and knowledge of real existences on the other. The former is clear and readily intelligible; the latter is never totally clear, since any statement or set of statements about a real object will fail to exhaust what is to be discovered in it. The "higher," or more complex, the entity, the less clear is one's apprehension of it. Von Hügel was therefore concerned with opposing philosophical theories that claimed to give a clear and exhaustive analysis of types of existence (for example, he criticized David Hume's account of the individual). Reality, according to

von Hügel, is indefinitely apprehensible, a fact that serves to explain both the revisionism of science and the gropings of religion. The obscurity involved in religion is an index of the richness of its subject matter. "Religion," he said, "can't be clear if it is worth anything."

The concept of the Infinite occupies a central position in von Hügel's philosophy. He held that there was no good reason for neglecting or doubting the validity of man's sense of the Infinite, which should be taken quite as seriously as sense experience; in this, he in effect conjoined a critique of religious experience and traditional Catholic natural theology. The critique of religious experience involved the examination of the claims of great religious figures of all ages. He was opposed to simply accepting the testimony of the individual; rather, he pointed to the errors and excesses of many individual interpretations of religion, some of which involved the denial of plain facts. At the same time, he was sympathetic to the insights claimed by non-Christian religions. His doctrine of religious knowledge was not exclusive to any one tradition, although he was opposed to relativism. Von Hügel also argued against various theories arising from religious experience, such as the extreme dualism of Søren Kierkegaard and the monism of some mystics (for instance, the doctrine of the identification of the soul with God). He maintained that Kierkegaard differentiated to such an extent between God and man that intercourse between the two became incomprehensible. A crucial argument of von Hügel's was that the impinging of the Infinite on man's experience, emotions, and will implies the spiritual nature of the Infinite; for otherwise it would be hard to account for its inspiring power.

According to von Hügel's theory of knowledge, it is artificial to divorce the cognitive aspects of experience from the affective and volitional aspects; and therefore the religious apprehension of the Infinite is not limited to grasping a theoretical concept but includes a vital response. For this and other reasons, von Hügel defended a sacramental and institutional faith—namely, that of Catholicism. But in his openness to and sympathy with the critical evaluation of the biblical tradition by the methods of scientific history, von Hügel belonged to the Catholic Modernist movement.

HUI SHI
(370–318 BCE)

Hui Shi (also Hui Shih) was an ancient Chinese logician and a major figure of the School of Names (*Ming-Jia*) whose members are also known as dialecticians or sophists for the sake of their emphasis on rational argumentations and their focus on deep structures of concepts. Hui Shi's philosophical thoughts are primarily delivered in his ten seemingly paradoxical propositions as recorded in the part "*Tian-Xia*" (ch. 33) of the *Zhuang-Zi*; these ten propositions are given as follows (with this author's brief explanation in brackets attached to each).

(1) "The greatest dimension [of the universe] has nothing beyond itself and is thus called 'the great unity,' while the smallest dimension [of the universe] has nothing within itself and is thus called 'the small unity.'" [The universe as a whole unity is both the greatest and the smallest in infinity; and the greatest and the smallest are intrinsically connected.]

(2) "That which has no thickness cannot be increased in thickness, and yet in extent it covers one thousand li [miles]." [This is one way to illustrate the point that being (extension) and non-being (non-thickness) come from each other.]

(3) "The heaven is as low as the earth; mountains are on the same level as marshes." [The high and the low in nature are not absolute but relative.]

(4) "The moment the sun reaches the zenith at noon, it is declining; the moment the creature is born, it is dying." [This characterizes the two features of changing and becoming process in nature: things will develop in the opposite direction when they become extreme; being and non-being interpenetrate each other.]

(5) "A great similarity differs from a little similarity; this is called 'the little similarity-and-difference.' All things are both similar/identical to one another and dif-ferent from one another; this is called 'the great similarity/identity-and-difference.'" [Things have not only their more or less similar or identical aspects but also their distinct aspects that distinguish one from another.]

(6) "The South has no limit and has a limit." [Some things have both their finite aspects and their infinite aspects at the same time. For example, the South as a location has its limit in space but has no limit in regard to, say, its development in time.]

(7) "One goes to the State of Yüe today and arrives there yesterday." [This highlights temporal relativity.]

(8) "Connected rings can be in separation." [Connected rings themselves are separated from each other in regard to the identity of each ring; each ring is at the same in connection with and separation from the other rings. The point is that seemingly opposed and unrelated states or processes can be possessed by the same thing and thus be interpenetrating and complementary.]

(9) "I know where the center of the world is; it is in the north of the State of Yan and the south of the State of Yüe." [This stresses spatial relativity.]

(10) "Extend love to all things; Heaven and Earth are the one unity." [The fundamental unification-character of all things in the universe constitutes the metaphysical foundation for extending love to all things.]

Hui Shi puts more emphasis on common aspects, connections, and unification of things in the universe (as highlighted in propositions 1 and 10) and relativity of their distinctions (as illustrated in propositions 2, 3, 4, 6, 7 and 9). In contrast, Gongsun Long, another major figure of the School of Names, stresses distinct aspects of things. Nevertheless, though the two thinkers appear to have different orientations, their difference is rather in emphasis. Hui Shi also pays attention to, or even stresses, distinct aspects, as suggested in propositions 5 and 8. Indeed, one central point suggested in Hui Shi's ten propositions is that many seemingly paradoxical or opposed contraries turn out to be interdependent, interpenetrating, and complementary. This essentially reflects the crucial point of the fundamental *Yin-Yang* way of thinking in view of cosmological and ontological characters of the universe. Moreover, as suggested by the points of all the ten propositions, Hui Shi, as "logician," is primarily concerned with metaphysical foundation of logical discourse rather than with its purely formal character.

HUMAN GENOME PROJECT

It was the Moravian monk Gregor Mendel, working in his monastery's garden in the 1860s, who cracked the secrets of heredity, but it was not until the beginning of the twentieth century that his insights were recognized and developed. Thanks particularly to the work of Thomas Hunt Morgan and his associates, working at Columbia University in New York, it was learned that the basic units of heredity, the genes, lie along thin, paired strings (chromosomes), in the centers of cells, and that these are not only the units of function—the things that carry the information used in building the finished organism—but also the units of heredity—the things passed on from one generation to the next.

In 1953, working in Cambridge, England, James Watson and Francis Crick confirmed the growing suspicion that the genes are long macromolecules of deoxyribonucleic acid (DNA), and famously they showed that the genes themselves consist of paired strings, twisted together in a double helix. The information carried by the genes comes not so much from the content of the DNA itself—a string or chain of four basic submolecules (nucleotides or bases)—but rather in the order of these submolecules along the chain. Information is read off from the DNA by another nucleic acid (RNA), and then this is used to pick up amino acids within the cell, which are then in turn strung together to make polypeptide chains, the building blocks (proteins) of new cells. Because there are twenty different amino acids used by the body, and because there are four different molecules in the DNA chain, in order take information from the DNA, there had to be (at a minimum) at least three nucleotides used in each transfer of information to catch without ambiguity a particular amino acid. Cracking this genetic code was the second great triumph of molecular biology of the 1950s.

With the basic theory now in place, biologists could turn their attentions to the discovering of the particular genes in particular organisms, a task made much easier, in the 1970s, by the discovery of powerful tools (recombinant DNA techniques) for dissecting the parts of the genome—the totality of a particular organism's genetic components. Thus was made realistically possible the idea of mapping the complete genetic content (the whole genome) of any particular animal or plant. Naturally, because people are humans, the idea of mapping human genes came to the fore, and thus the Human Genome Project (HGP) was conceived. Visionary credit is usually given to the biologist Robert Sinsheimer, who convened a crucial meeting of pertinent molecular scientists in California in 1985 to discuss and explore the feasibility of the project.

A task such as this is incredibly expensive, and governments of the world were soon asked for support and became involved both financially and organizationally. In the United States, the Department of Energy (DOE) was an early backer, a somewhat strange connection explained by the Department's involvement in the genetic effects of radiation on humans—a connection dating back to the Japanese atomic bombs and the testing of the subsequent Cold War. Less surprisingly, the National Institutes of Health (NIH) became involved and soon took the lead. By 1988, the codiscoverer of the structure of DNA, James Watson, had been appointed head of the project. (Watson resigned in 1992 and his post was then taken by the molecular biologist Francis Collins.)

The approach taken was basically one of brute force, squeezing out the information from the genome step by step, base by base. However, work in the 1990s was transformed not just by ever more powerful and rapid methods of getting results, but by the researcher J. Craig Venter. He argued for different strategies, initially aiming just to skim the genome for the really interesting results and leaving the rest until later, and then leaving governmentally supported institutions and going after private money, aiming to use even more powerful techniques to beat the NIH at its own game. In the end, both sides, public and private, announced a first draft of the human genome in 2000, and in 2003 a more detailed map was produced. The HGP was completed. Over 99 percent of the human genome has been mapped ("sequenced"), to an accuracy of 99.99 percent. Functionally speaking, there are about thirty thousand genes (a lot fewer than many would have estimated before the project began),

and a huge amount of the genome seems to be nonfunctional (it is estimated that "junk" DNA may be over 90%). The cost of this enterprise, factored in at 1991 U.S. dollars (when the estimates and projections were being done), was $2.7 billion. The genome sequenced was not taken from one individual person, but was a mixture of different people for the different chromosomes.

Focusing now on philosophical questions arising from the HGP, there are those more epistemological and those more ethical and social. This entry will take them in turn.

WORTHWHILE SCIENCE?

The big epistemological question that has haunted the HGP is whether it should have been done in the first place. As it was being discussed, many top-notch molecular biologists argued that it was unneeded and would divert resources and attentions from far more worthwhile projects. They felt that the project was motivated mainly by biologists who, feeling insecure around physical scientists, wanted their own equivalent of the moon-landing project—and it would have about as much scientific value.

Concerns such as this keep reappearing. Simply given a list of bases seems to have little or no scientific merit. The philosopher Alex Rosenberg gives a memorable metaphor. Imagine two stacks of phone books twisted around each other in a helix and reaching a mile and a half into the sky. The covers have been removed so each book leads at once to the next; the names have been removed so there are only lists of numbers—not in columns but one after another with no punctuation; area codes are assigned here, there, and everywhere at random, and no one has any idea what code corresponds to what geographical region. The only certainty is that 90 percent or more of the codes are fictitious and have no region to which they refer.

What, asks Rosenberg, is the point of having information on something such as this? Why bother to go to the effort of feeding all of these numbers into a computer? No one in their right mind would think it worth the effort. And yet this is equivalent to just what the HGP set out to do. And now that there is a string of numbers, so what? It is not that sequencing as such is worthless, but that unless there is some idea of what is being sequencing and why, it is misconceived effort. Far better to concentrate on specific problems—finding particular genes of interest and tracing their effects—than simply scooping up everything in one massive project.

Not surprisingly, from the beginning many biologists have disagreed. The junk DNA is a particularly sore issue because it does seem as if huge effort is being given over to mapping something—the vast portion of the genome—that is without function or purpose. The biologist and ethicist Frederick Grinnell argues that an attitude such as Rosenberg's is intellectual ludditism. It is precisely because scientists do not now see any function behind junk DNA that it should be explored and uncovered. Only then can its true nature be seen, and perhaps in fact they will find that far from being without purpose, perhaps junk DNA plays a crucial role in the living being.

Above the level of detail however—and more importantly—is that the project has never been simply one of listing bases on a line. From the start, biologists have been using the data to locate and to identify particular genes of interest, and to explore their functioning. As a tool, the results of the HGP have been made far more powerful because, from the beginning, the human genome was not the only genome being sequenced. Many others—bacteria such as *E. coli*, insects such as the fruit fly Drosophila, and mammals such as the mouse, as well as yeasts and plants—have been studied and mapped. The comparative results to which these have led have given rise to some of the most exciting and forward-looking branches of pure science active today. Particularly noteworthy is the field of so-called evolutionary development ("evo-devo"), where comparisons between gene sequences are a vital component of understanding and have led to insights as surprisingly unexpected as they are of far-reaching consequence. It is now known, for instance, that almost identical sequences of genes are to be found in organisms as separate as fruit flies and humans, pointing not only to shared ancestry but also to the fact that even today the ways in which these different organisms develop are identical, and for the same reasons. Results such as these are calling for significant rethinking of the workings of evolution. As Charles Darwin himself always suspected, so much change is a matter of making do with what one has rather than regrouping and starting again to go for an ideal solution.

No doubt more results will come in future years. While one may probably legitimately question the motives of all of the early backers of the HGP—the DOE certainly seemed to be looking for a project to justify its existence—it would be incorrect to say that no good science has emerged and churlish to say that the project has set molecular biology entirely down a misguided path.

EUGENICS

Even more than its potential scientific worth, the HGP was promoted as something that would have major social and ethical virtues, particularly in areas of medical care. As one moves toward these topics, what is first encountered is a cluster of issues around the topic of eugenics—however it may be called and described. Traditionally, "eugenics" referred to programs designed to improve the human race by interfering with or modifying its genetic constitutions. This could be thought of in two ways—positively, trying actively to perfect human genomes; and negatively, trying simply to eliminate the worst effects of the genes. The whole program fell into great disrepute because of the horrific activities of the Nazis, and today eugenics tends to be one of the topics from which people of all persuasions flee. Naturally, any suggestion that the HGP may in some way be an excuse for a new eugenical program is something that fills people with horror. It is something from which the promoters of the program have been at pains to divorce themselves.

Prima facie, one can see why there are worries. If the aim is simply to list the human genes, then the next move could well be trying to produce designer babies of some kind. But before one rushes to this as an inevitable conclusion, it is worth stopping and asking whether eugenics is necessarily always a bad thing. In particular, one may well reject positive eugenics—one may deplore the attempt to produce a race of superhumans—and yet endorse negative eugenics—attempting to eliminate horrendous genetic diseases. In fact, by another name, namely "genetic counseling," negative eugenics has never stopped. Paradoxically, although it was Jews who were the focus of the Nazi race laws, it is Jews who have been at the fore of genetic counseling as they try to discover carriers of the gene for Tay-Sachs disease, and through selective abortion prevent children being born with the affliction.

In this sense, therefore, one can see the completion of the HGP as a powerful tool in this direction, but at the same time argue that it is of positive moral and social worth rather than the other. Of course, one can see how this could be the thin end of the wedge to more draconian—perhaps even state-enforced—policies designed to eliminate even minor or idiosyncratic traits, or to eliminate those who may carry traits that could in certain circumstances prove wrong or disliked by some others in society. Perhaps Tay-Sachs disease yesterday, alcoholism (if it proves to have a genetic link) today, and homosexuality (again, if there is a link) tomorrow. This is clearly a danger, although whether the HGP as such should be faulted or whether any kind of genetic approach to humankind is more truly to blame is another matter.

In fact, one may argue that the HGP is a good thing in this respect, precisely because it takes the focus from individual genes and shows that the human being is a conglomeration of genetic factors. That (as the late Stephen Jay Gould pointed out) blunt "reductionistic" approaches to human nature—where each feature is supposedly controlled by one gene—are highly simplistic. Thirty thousand genes are not many to produce a complex entity such as a human being. It is clear that much about us is a product not just of one gene working in splendid isolation, but rather of many genes interacting to give rise to many complex traits. Hence, one starts to realize that, even with the best of intentions, thoughts of eliminating all genetic diseases are probably unrealistic. As one eliminates one gene, one affects the workings of others, which may in itself have negative effects. There is no simple route to perfection, and the HGP underlines this fact.

In any case, as has also been hinted at by the reference to evo-devo, the HGP is part of an ever-increasing awareness brought on by molecular biology. Simply thinking of genes leading to completed features is as naive as unqualified reductionism. There is no such thing as unadulterated genetic determinism, where people are the product of and only of their genes. It is always the genes in interaction with the environment, whether this be the physical environment or culture or whatever. Rather than argue that the HGP will at once lead to programs for genetic elimination, one could argue that the HGP will lead to programs to manipulate environments so that deleterious genes will not have full effect. Suppose that alcoholism is a function of the genes in some way. Rather than eliminating the genes and their carriers, one may rather try for programs that help people to learn to live adequately and happily with their biologically informed natures.

The point is that, as always in dealing with moral and social issues, scientific findings are never definitive or the last word. How one deals with these findings—including the findings of the HGP—is going to be a function of many things. While new knowledge can be dangerous, it is unfair to think that it will always be disastrous.

PARIAHS?

This leads at once to what is already an immediate and pressing concern. Now that there is the information from the HGP in the public domain, what is to stop institutions—public and private—from using this information

for their own ends, ends that may not necessarily be the ends of individuals? Take most obviously the question of insurance. The idea behind insurance is that people bet on ignorance, with a group of other people, to protect themselves if things go wrong. People buy health insurance knowing that 10 percent of the population will need a procedure; each individual in the group hopes he or she will not need the procedure, but knows that if so it will have cost (approximately) 10 percent of what it would have cost without the insurance. If people know they do not need the procedure, they will not buy the insurance— no man is going to buy insurance for gynecological problems. But, if a person is known to need the procedure, no one will sell that person the insurance—no one will sell cancer protection to someone with leukemia.

The worry is that the HGP is going to render some people pariahs and ineligible for insurance. Even worse, these will not necessarily be people who are or ever become physically sick. Thanks to the HGP, scientists are increasingly discovering genes that lead to various ailments or the predispositions to such ailments. This means that individuals can be tested against such standards to see if they are or are not possessors of the pertinent genes. Suppose that the knowledge obtained from the project enables a test for the disposition to a certain ailment or habit, alcoholism for instance. Normally, one may think that alcoholics should be discriminated against because of their habits; people with drunk driving convictions should pay more in car insurance. But is it fair to discriminate against the person who has a gene that simply sets up a predisposition? Does the state have the right to demand of a private insurance company that it not test for such a gene? Is this not unfair to others who buy insurance from that company? Do they not have the right to demand that their company obtain all pertinent information? The company surely has the right—the obligation—to discover if their would-be clients have drunk driving convictions.

The general problem has led some, notably the philosopher Philip Kitcher, to argue that the only viable solution to the new knowledge pouring forth from the HGP is some kind of state-supported, universal health care. Private insurers are simply going to be unwilling and unable to carry on with such plans unless there are massive, state-enforced rules preventing the obtaining of pertinent knowledge—which in itself is not necessarily a good thing (because, apart from anything else, one may need such knowledge), and probably not enforceable anyway. Society generally frowns upon fetal sex-determina-

tion, but that is little barrier for those determined to find and act on such information.

Even if Kitcher's proposal is followed through—after all, virtually every sophisticated society other than the United States already has such health care—this does not solve other related problems, such as life insurance. The moral ambiguity of such issues and the difficulties of working toward satisfactory solutions presents two notions of prejudice. On the one hand is the social prejudice that will be shown against those unable to buy such insurance. On the other hand is the potential for the prejudice abhorred by insurers, namely that society should not discriminate unfairly against the fortunate for the benefit of the unfortunate. A business deal is a business deal, not a policy of social welfare.

ASSESSMENT

One point is clear. The HGP is not some isolated phenomenon; it is part of a general move toward the understanding of organisms at the genetic level, and of technological applications that stem from such understanding. It is hardly a philosophical argument to point out that no amount of bemoaning the fact is going to stop this process. But philosophical argument does show that although there are great dangers and problems, there are also exciting opportunities and prospects, theoretical and practical. The philosopher's aim must be to guide in the right direction the bounties that stem from this new knowledge and its powers.

HUMANISM

Humanism in the present era signifies an ideological doctrine that places human beings, as opposed to God, at the center of the universe. Although a focus on human nature and human life can be traced back ultimately to ancient Greek thought, humanism in the modern sense, with its anthropocentric belief in the boundless potentiality of unfettered human reason and its secular conviction that human destiny is entirely in human hands, has its roots in the Enlightenment of the eighteenth century. This philosophical orientation should not be confused with the intellectual movement known as Renaissance humanism. Unlike its contemporary namesake, Renaissance humanism was not specifically concerned with promoting and exalting human values. It was, instead, a hugely influential cultural and educational program dedicated to the revival of the classical ideal of cultivated and civilized learning, referred to in Latin as *humanitas* and in Greek as *paideia*. For humanists of the Renaissance and their successors, the only way to achieve this ideal was through the *studia humanitatis*, the study of Graeco-Roman civilization through its literature, history, philosophy, and surviving artifacts. The zeal for recovering and reviving antiquity reached its height from 1300 to 1650. Recent scholarship has, however, highlighted earlier periods in which brief bursts of enthusiasm for ancient learning can be identified.

HUMANISM IN THE MIDDLE AGES

An intensified interest in the classical legacy, leading to a general cultural revival, occurred in the Islamic world during the tenth century. In contrast to Western Europe, where the Latin heritage was always supreme, Arab scholars, both Christian and Muslim, were concerned exclusively with Greek erudition. Moreover, their interest was entirely in the scientific and philosophical patrimony of ancient Greece, leaving aside its literary and historical works. During this period a large number of texts by Plato, Aristotle, Euclid, Ptolemy, Hippocrates, and Galen were translated into Arabic, sometimes via Syriac intermediaries. The philological efforts that went into this enterprise bore fruit in the achievements of thinkers such as Avicenna (980–1037) who were able to build up their own philosophical, scientific, and medical systems by drawing on the Greek material newly available to them.

Two epochs during the Western European Middle Ages witnessed revivals of ancient learning that have been seen as foreshadowing the humanism of the Renaissance. The first, associated with the reign of Charlemagne,

occurred in the eighth and ninth centuries. In this period a small group of scholars, most notably Lupus of Ferrières (c. 805–862), studied, edited, and copied texts by Cicero, Valerius Maximus, and Aulus Gellius, among other Latin authors. It was partly thanks to their philological interests and skills that these works survived and were transmitted to later generations. Another Carolingian intellectual, John Scotus Eriugena (c. 810–c. 877), used his knowledge of Greek, a rare accomplishment in the Middle Ages, to gain access to Neoplatonic sources, which played a significant role in his highly original philosophical and theological writings.

The second period of medieval humanist activity took place in the twelfth century. A coterie of scholars, mainly located in northern France, began to study writings from classical antiquity with a new intensity and sense of purpose. They explored a wider range of Latin texts than their Carolingian predecessors, including late ancient translations of Greek works, such as Chalcidius's partial version of and commentary on Plato's *Timaeus*, dating from the fourth century, and the Aristotelian translations and commentaries of Boethius (c. 480–c. 524). They pursued predominantly scientific and philosophical interests, though less single-mindedly than the Arab scholars of the tenth century, and with a considerable emphasis on the Roman as well as the Greek tradition. The outlook of John of Salisbury (c. 1115–1180), an Englishman educated in Chartres and Paris, reflects the characteristic strains of humanism in this era. His knowledge of Latin literature, much of it culled from medieval *florilegia*, or anthologies, rather than through direct acquaintance with the ancient texts, was impressively broad though often shallow and perforce patchy. He wrote in a fluent and accomplished Latin style though without any attempt to imitate classical authors; and though he peppered his treatises with quotations and anecdotes from ancient literature, these snippets were deployed solely for his own purposes with no concern for their original context and import. Other twelfth-century scholars engaged in cosmological speculation and provoked accusations of heresy by employing Platonic concepts to investigate the relationship between God and the created universe.

FROM MEDIEVAL TO RENAISSANCE HUMANISM

Another product of twelfth-century France was the development of a new approach to Latin grammar based on a philosophical and logical analysis of syntax rather than on the careful study of Roman authors. Codified in two

enormously influential manuals, Alexander of Villedieu's *Doctrinale* (1199) and Evrard of Béthune's *Graecismus* (1216), both written in verse for easy memorization, this unclassical method of teaching grammar quickly spread to Italy where it remained the staple of elementary education in Latin until the end of the fifteenth century. Equally successful was Geoffrey of Vinsauf's *Poetria nova*, a verse textbook on rhetoric written between 1208 and 1213. Devoid of classical examples, it provided rules for obtaining an abstract eloquence unrelated to the prose of ancient Roman authors. This technique fitted in well with the *ars dictaminis*, a simplified method of composing public letters that had been widely adopted in Italy for the training of notaries, lawyers, and chancery officials. Their need for a practical, efficient, and uncluttered form of Latin expression led to a rejection of Roman models.

The first glimmerings of humanism appeared against the background of—and most likely in reaction to—this neglect of the classical tradition in thirteenth-century Italy. The Paduan notary and judge Lovato dei Lovati (c. 1240–1309), usually described as a *pre-* or *proto-humanist*, broke new ground with his attempt to write Latin verse epistles in the style of Roman poets. Medieval scholars who took an interest in classical literature had not aspired to write Latin in an authentically ancient manner. Lovati, by contrast, made a deliberate (though far from successful) effort to imitate the vocabulary, meter, and tone of the Roman poetry he admired, including the tragedies of Seneca, whose metrics he explained in a brief treatise, and the lyric poems of Catullus, Tibullus, and Propertius, which were hardly known at the time. In his official capacity, however, Lovati continued to write the traditional Latin of the *ars dictaminis*. His disciple Albertino Mussato (1261–1329) not only composed a Senecan verse tragedy, *Ecerinis*, but also extended the classicizing reform of Latin to prose by modeling his history of Emperor Henry VII on Livy. Yet he, too, continued to use medieval Latin in public letters and speeches, as did other humanists throughout the fourteenth century.

It was with Petrarch (Francesco Petrarca, 1304–1374) that the nascent humanist movement came into its own. He became an exemplary figure whose predilections, interests, and activities set the agenda for later generations of humanists. In his own Latin compositions, he emulated both the prose and poetry of Roman authors as well as working out a sophisticated theory of imitation. He collated and edited manuscripts of Livy and applied his philological acumen to the correction of other classical texts. He recovered works that had been effectively lost since antiquity, including Cicero's letters to Atticus. He

rejected medieval scholasticism, with its emphasis on Aristotelian logic, natural philosophy, and metaphysics, and favored instead the rhetoric of Cicero and Seneca, which had the power to move hearts and stir emotions. He felt that he was living at the dawn of a new era following a dark age of ignorance and barbarism; and he believed that the moving force behind this large-scale cultural transformation was the gradual recovery of the heritage of classical antiquity through his own efforts and those of like-minded scholars.

RENAISSANCE HUMANISM IN FIFTEENTH-CENTURY ITALY

There have been attempts by modern scholars to connect the rise of Renaissance humanism with the political circumstances of fifteenth-century Italy. Its origins have been linked to the struggle of republican Florence against the monarchical tyranny of Milan in the early years of the century, or it has been seen as both reflecting and fostering a new spirit of active engagement of the citizenry in communal affairs. This notion of *civic humanism* has not stood up well in the face of overwhelming evidence showing that humanism flourished in a wide variety of political and social contexts. Similarly, the multiplicity of mutually contradictory views held by humanists on any given subject has undermined persistent efforts to align the movement with a particular ideological bent or philosophical persuasion. The only conviction that humanists demonstrably held in common was their passionate dedication to study of classical antiquity.

Paul Oskar Kristeller's definition of a humanist as a professional teacher of the *studia humanitatis* therefore corresponds most closely to the historical facts and has consequently won widespread acceptance. The term humanist, or *umanista*, in fact derives from late fifteenth-century Italian university slang that denoted a teacher or student of the *studia humanitatis*, just as a *legista* was someone who taught or studied law. The expression *studia humanitatis* itself had even longer associations with the movement. Petrarch noted it in his manuscript of Cicero's *Pro Archia*, a speech he himself discovered in 1333, and his devoted follower Coluccio Salutati (1331–1406), the first in a long line of humanist chancellors of Florence, began using it in 1369 to describe the study of classical literature. It soon became a frequent refrain, indeed a battle cry, among humanists defending or promoting their own activities.

Although Kristeller's account of the *studia humanitatis* as consisting of five academic subjects—grammar, rhetoric, poetry, history, and moral philosophy—has also

been widely adopted, it needs further refinement. These subjects may have been at the center of the Italian humanist curriculum during the fifteenth century. Yet their own interests ranged far beyond these fields, extending into all disciplines that relied on the wisdom of the ancients. In the Renaissance this meant almost every branch of learning: medicine, law, science, political thought, music, architecture, and all branches of philosophy. It was on this basis that Angelo Poliziano (1454–1494), the most learned classical scholar of the Italian Renaissance, decided that he would no longer lecture at the University of Florence on Latin and Greek literature, the normal subjects for a humanist professor but, instead, give a course on Aristotelian logic. Such an audacious move predictably provoked cries of derision from the philosophers whose academic territory he was invading. He responded to this outrage by maintaining, in his inaugural lecture of 1492, that as an expert on antiquity he was qualified to interpret any ancient text, not just poetry, history, and rhetoric, but also medicine, law, and philosophy. He further demonstrated this point in a dazzling series of philological investigations ranging over a broad spectrum of texts, including the *Corpus iuris civilis* (the sixth-century codification of Roman law), the scientific writings of Pliny the Elder, and the Greek sources of Latin medical terminology.

Fifteenth-century Italian humanists contributed to the *studia humanitatis*, broadly construed, in a number of ways. In the first place, they uncovered manuscripts of classical Latin texts that had been virtually unknown throughout the Middle Ages. In the wake of Petrarch's discovery of Cicero's letters to Atticus and *Pro Archia*, Salutati turned up a copy of his familiar letters while a humanist of the next generation, Poggio Bracciolini (1380–1459), found more unknown speeches of Cicero. Poggio's energetic hunt through monastic libraries in northern Europe also produced a complete copy of Quintilian's *Education of the Orator*, previously circulating in fragmentary form, and a masterpiece of Roman poetry, Lucretius's *On the Nature of Things*. Other important works unearthed by Italian humanists include the histories of Tacitus and the *Brutus* of Cicero.

When humanists found new works, or more accurate copies of ones that were already known to them, they ensured their further survival and diffusion, before the invention of printing, by copying and circulating them in manuscript. One of the innovations introduced by Italian humanists was to replace the crabbed and illegible gothic handwriting used in the late Middle Ages with an elegant and readable script that they believed was modeled on ancient Roman letter forms but that, in reality, dated from the Carolingian era. They also devised a cursive script, which is the ancestor of our italic character. In addition to copying texts, humanists also attempted to correct the errors that had inevitably crept into those texts through centuries of scribal transmission. They did this by comparing readings in different manuscripts or by making conjectural emendations—techniques that classicists still use today though with far greater methodological sophistication.

The next stage in dealing with the text of an ancient author was to explain and interpret it, often for the benefit of students. A large number of humanist commentaries on classical works grew out of university lectures. At a lower level, humanists also made their living as schoolteachers, equipping youngsters with the basic tools of Latin literacy that would enable them to gain access to the literary monuments of antiquity. Humanists such as Pier Paolo Vergerio (1370–1444) and Battista Guarino (1434–1503) wrote treatises touting the novelty of their teaching methods and boasting that the classical education they provided would inculcate a love of virtue and nobility in their young charges. Such extravagant claims no doubt assisted humanists to corner the educational market in the Renaissance. As is now known, however, the textbooks used in elementary Latin training changed relatively little from the thirteenth to the end of the fifteenth century. Moreover, the pedagogical techniques employed by humanists, which emphasized rote memorization and focused on grammatical, historical, and literary minutiae, were ill-suited to produce moral improvement. At the later stages of schooling, humanists made a greater impact, giving Virgil and Cicero a more prominent place in the curriculum than they had previously enjoyed and downgrading late ancient authors such as Boethius.

Fifteenth-century Italian humanists continued the classicizing reform of Latin style initiated by Lovati, Mussato, and Petrarch. By the early decades Cicero had become the accepted model for prose writers though it was not until the end of the century that a slavish and exclusive imitation of Cicero came into fashion. As an aid to writing correct classical Latin, Lorenzo Valla (1407–1457) compiled his *Elegantiae*, a catalogue of subtle linguistic distinctions, fine shades of meaning, and nuances of usage, based on his exhaustive knowledge of the entire Roman literary canon. In a bravura display of humanist historical scholarship, Valla deployed this same knowledge to discredit the "Donation of Constantine," a document underwriting papal claims to temporal sovereignty, as a crude medieval forgery. He also believed, like

Poliziano, that his superior command of Latin permitted him to interpret the *Corpus iuris civilis* more accurately than the legal scholars of his day.

Valla not only had an unrivaled mastery of classical Latin, he also knew ancient Greek well enough to translate the historians Herodotus and Thucydides. His expertise in both languages also allowed him to point out errors in the Vulgate, the standard Latin version of the New Testament, by comparing it with the Greek original. The revival of the study of Greek, which was well on its way by Valla's time, was one of the most important achievements of humanism. Very few medieval scholars had any acquaintance with Greek; and even though the works of some authors, including Aristotle, had been translated into Latin, the bulk of Greek philosophy, science, history, and literature was unknown in Western Europe. Beginning with Petrarch, humanists recognized the importance of recovering the Greek as well as the Latin heritage of antiquity. By traveling to Greece or studying with Byzantine émigrés in Italy, they learned the language and started to apply the techniques of editing and interpretation that had been developed for Latin texts to Greek ones. Greek, nonetheless, remained the preserve of a minority of humanists who served the larger intellectual community by translating a large body of texts into Latin. The writings of the Greek Church Fathers, many of them translated by Ambrogio Traversari (1386–1439), general of the Camaldulensian Order, formed an important element in this corpus.

Humanists were not concerned solely with texts. The material remains of antiquity, which were especially plentiful in Italy, were also of great interest to them. They visited architectural ruins and avidly collected Roman coins, inscriptions, and sculptures. Humanist historians, such as Flavio Biondo (1392–1463), subjected these artifacts to critical scrutiny and used them to supplement written records. This aspect of humanism laid the groundwork on which the disciplines of archaeology, numismatics, and epigraphy were later constructed.

RENAISSANCE HUMANISM IN SIXTEENTH-CENTURY EUROPE

By the turn of the sixteenth century, humanism had begun to spread from Italy to other European countries. The movement took on new contours and colors, reflecting the different cultures into which it was transplanted. Nonetheless, the humanist program that had taken shape in fifteenth-century Italy did not undergo radical changes but continued to develop within the same broad outlines. This process is well illustrated in the writings of the most

outstanding and influential humanist of the period, Erasmus (c. 1469–1536). In his educational works the Dutch scholar banished the last vestiges of the medieval tradition of learning Latin and presented a thoroughly humanist pedagogical method firmly based on the study of Roman and Greek authors. Erasmus also brought the humanist reform of Latin style to new heights. With the entire resources of classical Latin at his command, he adopted and promoted a flexible and eclectic approach to prose composition, rejecting the rigid Ciceronianism of his day. Carrying forward the achievements of Valla and Traversari, Erasmus demonstrated the relevance of humanism to Christian as well as pagan antiquity by applying philological techniques to the text of the New Testament and producing numerous critical editions and translations of the Church Fathers.

The inroads that fifteenth-century Italian humanists had made into disciplines such as medicine, philosophy, and law were extended during the sixteenth century by scholars from all over Europe. The Englishman Thomas Linacre (c. 1460–1524) helped to edit the Greek text of Galen and translated many of his treatises into Latin. The Flemish scholar Justus Lipsius (1547–1606) reconstructed the philosophical system of the ancient Stoics, relying on Greek as well as Latin sources, and gave impetus to a popular fad for Stoicism that lasted until the 1660s. The French humanist Guillaume Budé (c. 1467–1540) brought the weight of his vast classical erudition to bear on the elucidation of obscure passages and terms in Roman law. He also wrote learned treatises on Roman coinage and Greek grammar.

Though Latin remained the *lingua franca* of humanism, facilitating communication among scholars of different nations, a feature of the movement in the sixteenth century was the increase of humanist writings in the vernacular. This phenomenon was not unheard of in the fifteenth century: Leon Battista Alberti (1404–1472) wrote a humanist treatise on household management in Italian, partly in order to demonstrate that the language was a suitable vehicle for scholarly discourse. Now, however, it proliferated and attained a respectability that it had previously lacked so that even a hard-core humanist such as Budé was prepared to write his treatise on the education of the prince in French. *The Prince* of Niccolò Machiavelli (1469–1527) and the *Essays* of Michel de Montaigne (1533–1592) are just two examples of influential works in the vernacular that were steeped in humanist culture.

THE LEGACY OF RENAISSANCE HUMANISM

The humanists' aim of reviving and restoring the heritage of classical antiquity was largely achieved by the seventeenth century. Although a few discoveries were yet to be made, almost all ancient Greek and Latin writings known today were available to scholars who could consult them in printed editions, often accompanied by learned commentaries and, in the case of Greek works, Latin translations. It was at this stage, however, that the seismic changes in European culture brought about by the Scientific Revolution, and the rise of modern philosophy made this body of knowledge, so revered by the humanists, increasingly irrelevant to contemporary needs. They continued to develop ever more sophisticated methods of investigating the textual and material remains of antiquity, gradually transforming themselves into the classicists and archaeologists of the present day. By 1809, when the term *humanism* was first coined by a German philologist to defend the study of Greek and Latin, the movement had become synonymous with the profession of classical scholarship. Although greatly marginalized since its heyday in the Renaissance, humanism continued to exert a significant and widespread cultural influence until well into the twentieth century through the resilient ideal of the classical education.

HUMAN NATURE

The phrase "human nature" is multiply ambiguous. Some early modern thinkers such as Thomas Hobbes, John

Locke, and Jean-Jacques Rousseau tended to mean by it the supposed nature of human beings before the advent of organized human society. But there is every reason to believe that human beings have always been highly social creatures, and that the idea of individuals coming together to form society is a myth.

Another ambiguity, exemplified in the opposition between Mencius and Hsun-tzu in the ancient Confucian tradition in China, and between differing traditions within Christianity, is over whether human nature is basically good and in need only of appropriate sustenance and education, or whether we are inherently evil and stand in need of discipline or radical transformation.

A further difference is between a conception of human nature as what is in each individual at birth (or, given modern understanding of genetics, at conception), as opposed to the nature of the fully formed adult after maturation, socialization and education. This has given rise to endless nature versus nurture debates.

The distinction between a priori and a posteriori truths allows us place both for philosophical analysis of concepts of human nature, and for the discovery of empirical facts in physiology, psychology, anthropology, sociology, and history.

A PRIORI THEORY: RATIONALITY

What is most distinctive of human beings as opposed to other animals— rationality, language, consciousness, self-consciousness, freewill, moral responsibility, the ability to love? (And must all these go together?) How would we recognize beings from outer space as having any of these capacities? Perhaps the most obvious criterion they would have to meet to count as rational thinkers and agents is that they should be able to give reasons for their beliefs and their actions, in language of some sort that we could come to understand.

What makes such rationality possible in us? Plato and René Descartes believed that we are essentially immaterial souls, so our distinctively rational nature lies beyond scientific investigation. But must minds, consciousness and rationality involve something nonmaterial, or are we made of matter alone? Aristotle saw our rationality as superimposed on what we share with the animals (perception and self-movement), which is itself superimposed on the basic functions of all life including plants (metabolism and reproduction). According to this understanding, we are animals of a special rational kind.

But even if we reject a dualism of substances, and say that mind or soul is whatever the brain enables us to do,

we find an unavoidable duality of aspects. There are mental descriptions of our beliefs, desires, hopes and fears, and there are physical descriptions of neuron firings and chemical changes. We thus use an irreducible duality of explanations—justifying our actions and beliefs in terms of reasons, and explaining brain events in terms of their physiological causes.

EMPIRICAL THEORY: HUMAN NATURE AND NURTURE

Into this a priori conceptual framework we can fit empirical discoveries about human nature (and perhaps one day, about other rational beings elsewhere). There are plenty of such facts about the structure and functioning of our bodies—it is surely the size and complexity of our brains that explains our linguistic and rational abilities. There are also facts about our mental capacities, for example our recognition of faces, our tendency toward pair-bonding, and the need of children for attachment to parents.

In the light of Charles Darwin's theory of evolution, we can offer a scientific account of how the basic physical and mental commonalities of humans have evolved on this planet. With the aid of genetics and the fossil record, scientists are now piecing together the complicated story of how the faculties of rational thought and agency have come to be embodied in the human species. But we have to be very careful in applying Darwinian theory to human phenomena. Sociobiologists and evolutionary psychologists have tended to exaggerate. It is highly disputable whether every detail of contemporary human behavior has an evolutionary explanation; for example, donations to charity, the pursuit of religious vocations, and politicians' decisions to go to war.

Our reasons for action involve our beliefs and values, expressed in terms of our culturally developed concepts. Culture is at least as crucial to the realities of our contemporary human nature as evolution. It is superimposed on basic human biology, of course. That there are *some* innate tendencies in human nature is indisputable—for example, our sexual behavior. But the forms sexuality takes vary considerably between societies, and over time, and in devotedly celibate individuals its expression may be suppressed. The details of our behavior depend on the particular culture we have been brought up in. In the high-tech capitalist economy that now dominates the world, much of the social influence is exerted through the power of money, advertising, and the media. But it should not be forgotten that much behavior

depends on individual choices, as existentialists and religious traditions have emphasized.

HUMAN NEEDS AND RIGHTS

Like Plato and Aristotle, Immanuel Kant offered an objective basis for ethics, appealing both to pure reason and to empirical facts about human nature. Though Kant seemed to want to derive morality from rationality alone, he can be seen as appealing to a fundamental moral principle of respect for all rational beings "as ends in themselves." In this, he was obviously inspired by the Judeo-Christian ideal of love for one's neighbor as oneself, whereas Plato and Aristotle were more selective in their bestowal of respect for others. Karl Marx's and Jean-Paul Sartre's sense of human possibilities and the injustice of their denial were surely also influenced by the Judeo-Christian tradition. The Confucian notion of benevolence, and the Hindu and Buddhist programs of detachment from self, seem to point in the same direction of universal compassion.

Respect for all rational beings implies recognition of the rights and needs of all human beings. Rights imply corresponding obligations on other people, and the most appropriate place for talk of rights is in the negative cases: the rights not to be killed, injured, tortured, enslaved, imprisoned without trial, or exploited for someone else's benefit.

In his "second ethics," Sartre thought of human needs as objective values which demand to be fulfilled, if human beings are to flourish. The notion of need applies at several levels. There are things we need to maintain life and health—air, water, carbohydrates, protein, vitamins, medicines. There are psychological needs—most fundamentally the need of children for loving care, and there are typical adult needs for friendship, for sexual fulfillment, and for children of one's own. There are also needs for education and group membership, and needs to work, or contribute in some way to society.

When a human need is not met, it does not follow that someone is to blame. But when a human right is abused, then some person or group or social agency has done or encouraged the killing or torture, the enslavement or exploitation. And why have they done it? The answer will typically involve their seeing some advantage to themselves. There may be sadistic individuals who find intrinsic pleasure in causing pain, and many more are prepared to inflict suffering in the name of a "greater" cause (nation, party, or church), but most people do what they see as best for themselves. As Kant said, there is a "radical evil" in human nature, which consists in the tendency to prefer one's own interests over those of everyone else. But this is consistent with saying that we also have a potential for goodness and love.

LOVE

In the light of scarcity of resources, and individual and social evils, can we still entertain any hope for ethical and social progress, like Kant and other Enlightenment thinkers? Scarcity may perhaps be alleviated by scientific discovery and technological ingenuity. But new affluence breeds new needs and demands. There is an inherently competitive streak in human nature; we constantly rank ourselves against others. Our competitive tendencies may be acceptable in business and sport and in scientific and artistic achievement, but they easily turn into ruthlessness, cheating or greed. They may help drive social and cultural progress, but they need limitation by higher ideals of compassion and the common good.

What remedies are there? The first step is surely to name the evils, to try to make people aware of what is wrong, in ourselves and in society. For we are adept at finding good names for what we do: there are many possibilities of self-justification, self-deception, Freudian repression or Sartrian bad faith, and what Marx called "ideology," which covers up exploitation.

The notion of rationality alone does not give us much guidance as to what is ultimately worth aiming at, which of our desires are to be encouraged and developed, and which should be suppressed or transformed. People can be superbly intelligent and energetically persistent in action, yet utterly selfish or perverse.

The notion of love is perhaps more promising, provided we distinguish it, as in the Christian tradition exemplified in C. S. Lewis, from erotic and parental love, and from merely human friendship (as in Aristotle). The New Testament presents us with the ideal of *agape* (divine love, traditionally translated as "charity"), as presented in I Corinthians 13, Galatians 5, and I John 4. Sigmund Freud thought it impossible to fulfill, but even that dour old pessimist Arthur Schopenhauer recognized the possibility of saintly renunciation of self (and also, aesthetic contemplation) as a way that human beings can sometimes escape the near-universal domination of biologically based "will."

HUMBOLDT, WILHELM VON

(1767–1835)

Wilhelm von Humboldt, the Prussian statesman, humanist, and linguistic scholar, was born in Potsdam; a younger brother was the scientist and explorer Alexander von Humboldt. Wilhelm von Humboldt's early education was placed in the hands of private tutors and was augmented by private instruction in Greek, philosophy, natural law, and political economy from distinguished men of Germany's Enlightenment. From these youthful studies Plato's idea of the soul and Gottfried Wilhelm Leibniz's concept of force left lasting impressions on his thought.

During and after his university years at Frankfurt an der Oder (1787) and at Göttingen (1788–1789), Humboldt began to question the rationalistic presuppositions of the Enlightenment. Like Johann Gottfried Herder, he viewed human society as a manifold of organic forces, closer to nature than to reason, and came to believe that true knowledge of humanity depended on the cultivation not of pure analytical reason but of deep-lying intuitive faculties.

Humboldt's political philosophy was outlined in a long essay, *Ideen zu einem Versuch die Grenzen der Wirksamkeit des Staats zu bestimmen*, written in 1791. Focused on the central theme of his thought—the inalienable value of the individual—this work propounds the humanistic creed that man's goal is "the highest and most proportional development of his powers to a complete and consistent whole." Reason must guide this development, but reason for Humboldt was a formative rather than a generative faculty. He criticized state control of education and religion for inflicting an arbitrary framework on diverse, organically developing human forces, whose unity could not be imposed from without but sought only from within.

In the last decade of the eighteenth century Humboldt was occupied with various scholarly projects, none of which he completed; at the same time his growing friendship with Friedrich Schiller and Johann Wolfgang von Goethe brought him into contact with contemporary aesthetic problems. From 1802 to 1807 he was Prussian ambassador to the Vatican, and in 1808 he was appointed to the ministry of religious and educational affairs in Berlin, in which position he drafted several papers on education and was chiefly responsible for the foundation of the University of Berlin. Thereafter, he served as Prussian diplomatic representative in Vienna (1810–1813), at the peace negotiations before and after Napoleon Bonaparte's downfall (1814–1815), and in London (1817–1818). Defeated in his effort to achieve a constitutional monarchy for Prussia in 1819, he retired from public service and devoted the remainder of his life to study.

HISTORY

Humboldt's humanism was based on his idea of historical experience. "The broadening of our existence and of our knowledge," he wrote in a letter of 1823, "is possible historically only through the contemplation of previous existence." Searching for a discipline by which man's accumulated historical experience could become the

foundation for a philosophy of man, Humboldt had already written several essays and drafts outlining principles for the study of Greek antiquity (*Über das Studium des Altertums und des griechischen insbesondere*, 1793), for a comparative anthropology (*Plan einer vergleichenden Anthropologie*, 1795), and finally for the historian's profession (*Die Aufgabe des Geschichtschreibers*, 1821). Sharing his generation's enthusiasm for ancient Greece, Humboldt believed that the study of Greek culture in its broadest aspects would promote a true philosophical knowledge of men, including "the knowledge of the manifold intellectual, sentient, and moral human powers." For Humboldt the Hellenic world was a unity of diverse forces, a cultural unity that his own times lacked but might regain through a comprehensive study of the Greeks. His plan for a comparative anthropology was to study the moral character of different human types; a great variety of sources would provide the data for establishing an ideal norm, which was not adequately represented by any specific individuality. To comprehend the wholeness in the diversity of human types required aesthetic insight, which was fundamental to the art of the historian. In an essay on Goethe's *Hermann und Dorothea*, he concluded that epic poetry, of which Goethe's drama was an example, could be compared to history. "The condition of the soul which gives rise to the necessity of history (in the truest and highest sense of the word) is similar to that out of which an epic is produced with the help of imagination and art." In Humboldt's essay *Die Aufgabe des Geschichtschreibers*, in which the affinity of his thought to Friedrich von Schelling's philosophy is clearly manifested, the historian's imagination is likened to the poet's. It differs from the free fantasy of the poet's in that it is more strictly subordinated to the historian's experience and feeling for reality; it is actually a "divining faculty" (*Ahndungsvermögen*) and a "connecting ability" (*Verknüpfungsgabe*).

The most notable feature of this essay is Humboldt's attempt to elucidate the role of ideas in history. "Everything that is active in world history," he declared, "is also stirring in the inner being of man." The ideas in history have preserved human experience in the mind. "The eternal original ideas of everything conceivable provide existence and value, the beauty of all physical and spiritual forms, the truth in the unalterable working of every force according to its indwelling law, the justice in the inexorable course of events which are eternally regulated and meted their just reward." For Humboldt the goal of history is "the realization of the idea representing itself through humanity from all sides and in all forms in which the finite forms can be connected with the idea."

The task of the historian is therefore to represent this process of ideas being actualized in history.

LANGUAGE

Humboldt's language studies represent his chief legacy to posterity and marked, according to Ernst Cassirer, a new epoch in the history of the philosophy of language. Humboldt saw in the origin of language that crucial moment when man emerged from nature and, thus, the moment of connection between nature and idea. Language is for Humboldt the faculty by which man is identified as man. Speech and understanding are only different products of the power of language. The formation of languages depends on the spiritual forces of humanity, and languages are thus not merely an intermediary between individuals but "the most radiant sign and certain proof that man does not possess intrinsically separate individuality." Languages delineate the cultural characteristics of nations, each of which has its own individuality and arouses a sense of unity in men.

Humboldt's chief contribution to the study of linguistics was his concept of the "inner form" of languages (*innere Sprachform*), which consists of more than just external grammatical principles; it implies a deep-rooted subjective view of the world, a spiritual attitude, that controls the formation of concepts. "Because of the mutual dependency of thought and word," he wrote, "it is evident that the languages are not really means of representing the truth that has already been ascertained, but far more, means of discovering a truth not previously known. Their diversity is not a diversity of sounds, but of world outlook."

Humboldt's idea that each language has its own characteristic outlook, or inner form, found support in the linguistic studies of A. F. Pott and Heymann Steinthal in the nineteenth century and was suggested anew in the twentieth in the works of Benjamin Lee Whorf and Edward Sapir. His influence can also be traced in other areas of nineteenth-century thought—a passage from his political treatise provided the motto for J. S. Mill's essay *On Liberty*; his notion of the idea in history is closely related to Leopold von Ranke's doctrine of ideas; and his notion of historical experience is basic to the philosophy of Wilhelm Dilthey. In the twentieth century Cassirer, in the first volume of *The Philosophy of Symbolic Forms*, provided a penetrating evaluation of Humboldt's linguistic insights and a general philosophical context for the unmethodical profusion of his thought.

HUME, DAVID
(1711–1776)

David Hume, considered by many the finest Anglophone philosopher, one of the first fully modern secular minds, and, along with Adam Smith, the leading light of the Scottish Enlightenment, was the author of four major philosophical works and many essays.

Born on April 26, 1711, in Edinburgh, Scotland, Hume spent his childhood mostly at Ninewells, the family estate near Berwick. Though his family was of good social standing, they were not rich, and, as the second son, he had to be prepared to earn a living to supplement an inadequate inherited income. He attended Edinburgh University from the ages of eleven to fifteen, in which city he remained to study law. Finding this not to his taste, Hume returned to Ninewells and threw himself into an intensive program of intellectual self-development. He read widely in ancient and modern literature, improved his knowledge of science and languages, and devoted himself above all to philosophy. In this way, sometime before he turned eighteen, Hume achieved the breakthrough that, he reported, "open'd up to me a new Scene of thought, which transported me beyond Measure, & made me, with an Ardor natural to young men, throw up every other Pleasure or Business to apply entirely to it" (*The Letters of David Hume* 1932, vol. 1, pp. 13–14).

However, the strain eventually told on Hume's health, and he was obliged to curtail his studies and pursue a more active life. To this end, he secured employment with a Bristol merchant in 1734. Though this venture into the world of commerce was brief, his health was sufficiently restored to enable him to undertake the composition of the systematic philosophical treatise by which he hoped to make his literary mark. To stretch his meager

income further than was possible in Britain, Hume relocated to France—first to Reims, then to La Flèche in Anjou—where he was able to benefit from the outstanding library of the Jesuit college.

Hume returned to England in 1737 with the intention of publishing the first two books, *Of the Understanding* and *Of the Passions*, of the work he decided to call *A Treatise of Human Nature: Being an Attempt to Introduce the Experimental Method of Reasoning into Moral Subjects*. After publishing them as volume 1 in 1739, he went home to Scotland to revise the third book, *Of Morals*, which he published as volume 2 the following year. Never before or since has anyone so young published a philosophical work so comprehensive, ambitious, original, or accomplished. Still, Hume's obvious aspiration to be acknowledged the Isaac Newton of philosophy did not sit well with contemporaries. Reviewers were mostly hostile and uncomprehending, so that the *Treatise* "fell *dead-born from the Press*; without reaching such distinction as even to excite a Murmur among the Zealots" (1987, p. xxxiv).

Having wisely taken the precaution to publish anonymously, Hume soon recovered from his failure and decided to apply his immense literary gifts to the more widely accessible medium of the essay. His *Essays, Moral and Political* of 1741 and 1742 duly succeeded where the *Treatise* failed. With a public won, together with a keen sense of its tastes, Hume presented a selection of the doctrines of the *Treatise* with some previously unpublished material in the form of *Philosophical Essays concerning Human Understanding* in 1748 (retitled *An Enquiry concerning Human Understanding* in 1758). With its companion published three years later, *An Enquiry concerning the Principles of Morals*, Hume firmly established his reputation as one of the leading philosophical thinkers of his day. Around the same time Hume composed his *Dialogues concerning Natural Religion*, but was prevailed on not to publish it during his lifetime. From that point on, Hume devoted himself to essays and wrote his most popularly successful work of all: the six-volume *History of England: From the Invasion of Julius Caesar to the Revolution of 1688* (1754–1762).

Hume held a number of posts during his life, though he never succeeded in securing an academic position. In 1745 he served as tutor to the mentally unbalanced Marquess of Annandale. From 1746 to 1749 he was secretary to Lieutenant-General James St. Clair (1720–1806), whom he accompanied on a military expedition to Brittany. He was keeper of the Advocates Library in Edinburgh from 1752 to 1757. In 1763 Hume became private secretary to Lord Hertford (1718–1794), the British ambassador to France, where he spent the next three years being continually fêted and forming friendships with several leading figures of the French Enlightenment, including Denis Diderot, Jean Le Rond d'Alembert, and Jean-Jacques Rousseau (though this last connection was to end in conflict). The last position he held was that of secretary of state in the Northern Department, from 1767 to 1768.

Physically, Hume was tall, somewhat ungainly, and, by the mid-1740s, corpulent. He never married, initially for lack of means to support a family, and afterward from a preference for bachelor life. Hume's most extraordinary quality was his personality. Warm, generous, even-tempered, and honorable in all matters, he gained and kept an enormous number of close, devoted friends. This included many prominent clergymen who time and again staunchly defended him against his persecutors. Hume was thus able to spend his final years in Scotland in tranquillity, surrounded by well-wishing friends and family. When death came on August 25, 1776, he took it in the best spirit imaginable, while also making sure that no tales could be spread that his religious skepticism had weakened in the end.

Hume's influence on philosophy during his lifetime was nothing like what it later became. His moral theory undoubtedly made an impact on Smith's *Theory of Moral Sentiments* (1759), while his theory of the understanding provided Thomas Reid with his principal foil in *Inquiry into the Human Mind, on the Principles of Common Sense* (1764). Reid and other less respectful philosophers of the Scottish "commonsense" school focused many of their severest criticisms on the *Treatise*. Their misunderstandings and misrepresentations of that work so infuriated Hume that he published an advertisement with the final edition of the *Enquiries* produced under his supervision (1777), desiring that these maturer efforts would "alone be regarded as containing his philosophical sentiments and principles."

A sea change in the reception of Hume's theory of understanding occurred in 1783, when Immanuel Kant declared that Hume's treatment of cause and effect was responsible for awakening him from his dogmatic slumber. Kant's own transcendent importance in the history of philosophy, and the scholarly attention devoted to almost his every word, led to a reappraisal of the worth and importance of the philosopher Kant credited with making his achievements possible, and it was not long till the *Treatise* came to be recognized as Hume's masterpiece.

Being cast as Kant's John the Baptist did, however, have its downside, and many have labored to bring

Hume's legacy out from under the shadow of Kant. Influenced by the latter, philosophers in the nineteenth century, and for much of the twentieth as well, tended to esteem Hume almost exclusively for the power of his skeptical arguments regarding reason, the natural world, and religion. Since then, the positive, constructivist aspects of his theory of understanding have come to be equally prized, as have his theories of passion, actions, morality, and aesthetics. Today, interest in Hume's philosophy is greater than ever and the wave shows no sign of cresting.

THE TREATISE AND THE ENQUIRIES

Most scholars accept the essential correctness of Hume's assertion that there are few substantive differences between the *Treatise* and the *Enquiries*, and none of great consequence. Instead, the earlier and later works differ primarily in inclusiveness and style. The *Treatise* was pitched at the highest level, to pass muster with the most learned, exigent readers. Questions left unraised in the *Enquiries* were pursued at considerable length, whole batteries of arguments were assembled in support of major theses, and every effort was made to be both systematic and comprehensive.

By contrast, the *Enquiries* were aimed at the same readers who enjoyed Hume's more philosophical essays. This seems to have been the principal reason for his decision to omit from the first *Enquiry* almost everything in parts 2, "Of the Ideas of Space and Time," and 4, "Of the Skeptical and Other Systems of Philosophy," of book 1 of the *Treatise*. Much of parts 1, "Of Ideas," and 3, "Of Knowledge and Probability," were also sacrificed, so that what remains seems less like a condensation of the *Treatise* than a greatly expanded and improved version of the abstract of the *Treatise* that Hume published in 1740. The second *Enquiry* drew on the moral philosophy of book 3 of the *Treatise*, while eschewing the theoretical framework of the latter in favor of a more strictly literary approach (which both explains why Hume thought it his finest work and why so few today agree). Neither *Enquiry* contains any considerable trace of book 2 of the *Treatise*, on the passions, and though occasional echoes of it are to be found in Hume's essays, they give no idea of the impressive, highly sophisticated theoretical framework one finds in book 2 of the *Treatise* (and the same is true of Hume's *A Dissertation on the Passions* [1757]). Thus, despite Hume's wish not to be judged by the *Treatise*, its unity, scope, and rigor make it the work that best represents what is most important and enduring in his philosophy.

HUME'S SCIENCE OF HUMAN NATURE

Hume believed human nature to be the proper focus of the philosopher because its first principles necessarily carry over to every human endeavor, cognitive and conative alike. A science of human nature affords fundamental insight not only into such domains as morals, aesthetics, and politics but "even *Mathematics, Natural Philosophy, and Natural Religion*," which "are in some measure dependent on the science of MAN; since they lie under the cognizance of men, and are judged of by their powers and faculties" (1978, p. xv). Situating himself in the line of British empiricist thinkers extending from Francis Bacon and John Locke, Hume restricted the investigation of human nature to evidence gleaned from "careful and exact experiments, and the observation of those particular effects, which result from its different circumstances and situations" (p. xvii). It constitutes a science insofar as one "must endeavour to render all our principles as universal as possible, by tracing up our experiments to the utmost, and explaining all effects from the simplest and fewest causes." This may require one to revise initial determinations in the light of new experiments (Hume's evolving characterization of the difference between memory and imagination is a prime example), and obliges one to determine whether the fundamental principles of human nature have even wider scope (thus, Hume considered it a plus that much of his account of human nature extends to animals as well). Finally, the mandate for maximal simplicity means that the science of man should take the form of a system, deriving its principal authority from "the agreement of [its] parts, and the necessity of one to explain another" (p. 154).

THE ELEMENTS OF HUME'S SCIENCE OF HUMAN NATURE

OBJECTS. Hume considered human nature always and only in terms of perceptions. *Perception* is Hume's substitute for Locke's term *idea*, and it refers to all objects insofar as they are immediately present to one by consciousness, be it in sensation, reflexion, or thought (*reflexion* is Hume's catch-all term for the objects present to internal sense or inward sentiment, including passions, emotions, desires, volitions, and mental operations generally). For Hume, just as for Locke with *idea*, the indeterminacy of *perception*—the impossibility of contrasting it with anything that is not a perception because "[t]he mind never has anything present to it but the perceptions"—is its principal virtue. If things other than perceptions exist, then, as what never "can be present to the

mind, whether we employ our senses, or are actuated with passion, or exercise our thought and reflection" (1999, p. 202), they are no different from perfect nonentities so far as one's thoughts and actions are concerned. By contrast, even objects as fanciful as a billiard ball that transforms itself into wedding cake on being struck, though never present to the senses, are still objects of one's thought, and so too perceptions.

Perceptions come in two kinds: impressions and ideas. Impressions comprise sensations and reflexions, and ideas thoughts (the mental contents of thought, considered in themselves rather than in the capacity of signs used to signify other perceptions, whether by resemblance, linguistically, or in any other significative capacity). According to Hume, the difference between impressions and ideas consists in the greater "force and vivacity" of the former. This does not mean that impressions always make a forceful impression, for they can be so gentle as altogether to escape notice. Nor does it mean that they are vivid in the usual sense, since seeing a gray blur on an otherwise black night (visual sensation) is still more vivid than a brilliantly lit, detailed image in a daydream (visual idea).

The best indication of what Hume had in mind by "force and vivacity" is his subsequent equation of it with belief in the real existence of a content present to one in sensation, reflexion, or thought, all perceptions. According to Hume one believes in the reality of something that one merely thinks if one's conception of it exhibits force and vivacity, as when, on seeing smoke coming into the room, one not only thinks of a fire somewhere outside the room but believes that a fire really exists. Similarly, "the *belief* or *assent*, which always attends the … senses, is nothing but the vivacity of those perceptions they present" (1978, p. 86). More particularly, the vivacity of a perception seems to consist in a feeling distinctive of the manner in which an object in sensation or reflexion is apprehended, or an object in thought is conceived, in virtue of which it is regarded as really existent—actual rather than merely possible, fact rather than fiction.

If this reading is correct, then one needs to distinguish two senses of *exists* in Hume: an object, even if it is a mere fiction, exists simply in being present to consciousness (p. 66–67), but it is taken to be really existent if, in addition, it is perceived or conceived in a lively manner (pp. 84–123). Sensations and reflexions are impressions because human (and animal) nature is so constituted that these objects have only to appear to be believed really existent, whereas objects present to one only in thought are not believed really to exist unless cir-

cumstances intervene to induce one to conceive them with a high enough degree of force and vivacity. One of the principal occupations of Hume's theory of understanding was to determine what those circumstances are and to identify the underlying principles.

Finally, Hume distinguished perceptions according to whether they are complex or simple. In general, an impression or idea counts as simple if it cannot be distinguished into two or more components (different significative uses to which the same simple perception may be put do not compromise its intrinsic simplicity). But Hume also seems to allow that perceptions distinguishable in this way may still be simple if it is impossible for them to be derived by the combination or blending of perceptions already in one's possession (e.g., "The impressions of touch are simple impressions, except when consider'd with regard to their extension" [1978, pp. 230–231]).

THE COPY PRINCIPLE AND HUME'S THEORY OF ORIGINS. The "*full* examination" of the question of how impressions and ideas "stand with regard to their existence, and which of the impressions and ideas are causes and which effects" is "the subject of the present treatise" (1978, p. 4). To this end, Hume notes that one's simplest perceptions all seem to come in duplicate impressions and nearly exactly resembling ideas, and asks if there is any causal significance to this relation. He then formulates perhaps the most important principle of his science of human nature: because experience shows that simple impressions invariably precede their resembling ideas, "all our simple ideas in their first appearance are deriv'd from simple impressions, which are correspondent to them, and which they exactly represent" (p. 4). The causal dependence of ideas on impressions expressed in Hume's copy principle owes its importance to his preeminent methodological concern to find a better method of clarifying the ideas at the heart of traditional metaphysical disputes than definition can provide:

> Complex ideas may, perhaps, be well known by definition, which is nothing but an enumeration of those parts or simple ideas, that compose them. But when we have pushed up definitions to the most simple ideas, and find still some ambiguity and obscurity; what resource are we then possessed of? By what invention can we throw light upon these ideas, and render them altogether precise and determinate to our intellectual view? Produce the impressions or original sentiments, from which the ideas are copied. These impressions are all strong and sensible.

They admit not of ambiguity. They are not only placed in a full light themselves, but may throw light on their correspondent ideas, which lie in obscurity. And by this means, we may perhaps attain a new microscope or species of optics, by which, in the moral sciences, the most minute, and most simple ideas may be so enlarged as to fall readily under our apprehension, and be equally known with the grossest and most sensible ideas, that can be the object of our enquiry.

<div align="right">(1999, PP. 135–136)</div>

Hume's science of human nature is, in the first instance, a critique of traditional philosophical definitions whereby they are supplemented or, more usually, supplanted, by psychological accounts tracing ideas to their originating impressions. These accounts inform everything else in the science, and it is often impossible to understand the positions Hume takes without returning to his explications of the relevant ideas in terms of their originating impressions.

RELATIONS. To understand the nature of relation for Hume, one first needs to consider the two ways in which relations may be affirmed. If one can affirm a relation independently of the senses, and so of all matters of fact and real existence, one's affirmation is a case of knowledge and the relation affirmed is a necessary one. For "the necessity, which makes two times two equal to four, or three angles of a triangle equal to two right ones, lies only in the act of the understanding, by which we consider and compare these ideas" (1978, p. 166). When immediate, the knowledge of a relation is intuition, when it consists of a continuous sequence of intuitions, it is a demonstration.

Knowledge of a relation of ideas is attainable (1) when one is sensible of the impossibility of forming one idea without including another as a constituent, as, for example, one cannot form the idea of a valley without incorporating into one's conception the idea of mountains (p. 32), or, (2) even if the ideas can be conceived separately, one is sensible of the impossibility of conceiving a change in their relation without conceiving a change in the ideas themselves (p. 69), as "the shortest distance between two points is sa straight line" is known to be necessary even though shortness (a quantity) and straightness (a quality) are conceivable independently (pp. 49–50). (The first type coincides with Kant's notion of an analytic judgment, the second with that of a synthetic *a priori* judgment; Hume did not, however, see fit to subdivide intuitive knowledge this way, that is, he either did

not recognize or did not attribute to the question of the possibility of synthetic *a priori* judgments the same importance Kant would afterward accord it.) Either way, one's affirmation of a relation amounts to knowledge if and only if one is sensible of the impossibility of conceiving the ideas concerned in any other relation (pp. 652–653).

Where knowledge is lacking, and other relations between the ideas (or none at all) are conceivable, one can still affirm a relation between distinct perceptions with probability, that is, with a certainty extending anywhere from just above logical possibility all the way to a certainty so great as to be immune to doubt (termed *proofs* by Hume, e.g. "the sun will rise tomorrow" and "all men must die"). Such relations consist essentially in transitions of thought characterized by a quality Hume termed *facility* (1978, pp. 99, 204, 220, 260). There is considerable evidence that Hume conceived of facility as affective; that is, like the vivacity of impressions or ideas in virtue of which one believes them really to exist, the facility constitutive of probable relations is a content the mind does not conceive but feels. Facility and vivacity tend to go together in Hume's theorizing. When a relation between ideas is known, facility and vivacity affect are redundant to the relation and its affirmation since one is "necessarily determin'd to conceive them in that manner" (p. 95). Only when one remains free to conceive both sides of the question can assent be supposed to be a matter of feeling rather than an act of thought. In this regard, one of the most important principles of Hume's theory of understanding is that the more facile the transition from a lively perception to an idea in thought (= the stronger the relation), the more nearly the vivacity of one's conception of it (= belief in its real existence) approaches that of the lively perception itself (pp. 98–99).

Association. The effect of a facile transition between perceptions is to associate them in reflexion or thought, and it is in this association that their relation consists. With the precedent of Newtonian gravitation in mind, Hume saw fit to characterize association as "a kind of ATTRACTION, which in the mental world will be found to have as extraordinary effects as in the natural, and to shew itself in as many and as various forms" (1978, pp. 12–13). In the absence of the real connections falsely imputed to perceptions by the sophisticated and simple alike, the associative ties felt between perceptions are the source of all order and unity among them. Finally, in accordance with his scientific ideal of maximal generality and simplicity, Hume resolved all species of association into expressions of three fundamental associative princi-

ples: the contiguity of perceptions in space or time, their resemblance, and their connection as cause and effect—as "these are the only ties of our thoughts, they are really to us the cement of the universe, and all the operations of the mind must, in great measure, depend on them" (p. 662).

Natural and philosophical relations. Not all relations are constituted by facile transitions of thought. Hume designated those that are natural and those that are not philosophical relations. Since one can arbitrarily compare anything with anything else, and since no two objects admit comparison unless they have some degree of resemblance, resemblance counts not only as a natural but also as a philosophical relation; and philosophical resemblance is, in turn, the condition for other natural relations to assume a nonassociative philosophical dimension: identity, space and time, quantity (in number), quality (in degree), cause and effect, and contrariety. The crucial thing to remark here is that, except in cases of intuitive or demonstrative knowledge, philosophical relations seem to have no independent power to generate belief (vivacity), and so are parasitic on natural relations for their power to influence one's thoughts and actions. Hume made this explicit in the case of the cognitively preeminent relation, causation, for "tho' causation be a *philosophical* relation, as implying contiguity, succession, and constant conjunction, yet 'tis only so far as it is a *natural* relation, and produces an union among our ideas, that we are able to reason upon it, or draw any inference from it" (1978, p. 94).

HUME'S REJECTION OF ABSTRACT IDEAS. Hume expressed complete agreement with George Berkeley's exclusion of abstract ideas from the explanation of general ideas and terms. The keystone of this critique of abstraction is the separability principle that Hume, like Berkeley before him, made a centerpiece of his philosophizing. According to this principle, whatever objects (perceptions) are different are distinguishable, and so separable in thought; and vice versa (1978, p. 18). So far as abstraction is concerned, this means that one cannot abstract any X from any Y unless X can be perceived and conceived even in the absence of Y. For example, because the distinction between the shape and color of a visible object fails to satisfy the separability principle, the notion that these are distinct perceptions (different abstract ideas, as Locke supposed) has to be rejected as an illusion cast by language. For while there is indeed a significant distinction to be drawn in the use of the idea of a visible object to designate, on the one hand, things resembling it in shape and, on the other hand, things resembling it in color, when the idea is considered in itself, apart from any

significative use to which it may be put, its shape and color are ineluctably one.

Accordingly, differences of aspect—that is, distinctions that fail to conform to the separability principle (sometimes called distinctions of reason)—are never intrinsic to the object to which they are ascribed, but are instead always the by-product of the relations in which it stands to other objects. Thus, a globe of white marble may be found to resemble a black globe of papier-mâché, a white cube of sugar, or an oblong piece of red marble; and since resemblance is an associative relation, the facile transition from a white globe to a black globe will set up an relational dynamic in which it becomes easier to make a transition next to the idea of a blue globe, red globe, or yellow globe, than to any nonspherical white or red object. In the same way, a transition from the white globe to a white cube will make it easier to transition next to the idea of a white oblong or any other white shape than to a black globe or red oblong. It is in these divergent axes of resemblance relations, ramifying in various directions from the same object, as it were, that aspects have their basis.

Resemblance association alone does not, however, suffice to explicate general representation. Custom is equally indispensable, "If ideas be particular in their nature, and at the same time finite in their number, 'tis only by custom they can become general in their representation, and contain an infinite number of other ideas under them" (1978, p. 24). The habits instilled by frequently encountered axes of resemblance association lie in readiness to be triggered by any of the infinitely many possible stimuli (determinate, nonabstract impressions or ideas) capable of triggering it (= representational generality); and which of the many habits it happens to trigger will determine to which species a given stimulus will be recognized as belonging (i.e., under which general sort it will be subsumed or classified). For example, a single, fully determinate (nonabstract) perception of an equilateral triangle one inch in circumference can serve as a general representation of figures, rectilinear figures, regular figures, triangles, or equilateral triangles, according to which custom one uses it to represent or which custom it triggers in a particular context (pp. 21–22). Finally, with the addition of words to overcome the confusion that would otherwise result either from the capacity of the same idea to trigger any of various customs, or from the same custom to be triggered by dissimilar ideas, one arrives at Berkeley's principle "that all general ideas are nothing but particular ones, annexed to a certain term, which gives them a more extensive signification, and

makes them recall upon occasion other individuals, which are similar to them" (p. 17).

SPACE AND TIME. Hume's treatment of abstract ideas exemplifies his general method of tracing ideas to their originating impressions; only here, where association and custom are indispensable, the experience of the operations of one's own mind (transitions of thought, the facility affect essential to associative relation, and the triggering of customs) proves to be the source of contents essential to these ideas. The abstract ideas of space and time are a case in point. Just as the shape and color of a visible object are one and indistinguishable, so, too, are extension and color. That is, the only idea one can derive from an impression of, say, uniform purple is the idea of uniform purple. To distinguish the extension from the color, one must compare the impression to others, associate them according to their resemblances, and, from the different axes of resemblances thus formed, arrive at last at an ineluctably relational conception of their difference.

Even so, to form a visual idea of space it is not enough simply to find what is resembling between purple, green, yellow, and other uniformly colored expanses, or between these and nonuniformly colored expanses. Visual space is the idea of something in which visible objects do or can appear and disappear, change their color and contour, grow, shrink, and alter their relative visible positions and situations inside, outside, alongside, adjacent, separated, above, below, right, left, in front, or behind one another. An idea with such limitless determinability is impossible except when visual perceptions are conceived of as an ordered manifold, or nexus, formed of coexistent loci (points) that preserve their relative positions to one another (their situation and relations) through any and all changes in respect of light and color ("co-existent parts dispos'd in a certain order, and capable of being at once present to the sight" [1978, p. 429]). That is, for Hume, the visual idea of space is the outcome of comparing visible objects, associating them according to their various resemblances, and forming habits when these associations are continuously reinforced, whether by frequent recurrence or some other cause. The key, as with aspects and distinctions of reason generally, is that visible space is never anything present to our eyes, prior to and independently of experience and habit, but rather something that exists only in and through the actions and affects of associative imagination (imagination in its associative capacity).

Unless this is appreciated, one cannot hope to understand how, on Hume's view, it is possible to form an idea of space common to vision and touch alike, notwithstanding the qualitative incommensurability of the objects of the two senses. For, lacking the ability to discriminate aspects immediately (nonrelationally), one can no more distinguish the extension of a tangible object from its other distinctively tactual qualities (hard or soft, smooth or rough, and wet or dry) than one can distinguish the extension of a visible object from its color. Consequently, to find visible and tangible space in any way resembling in appearance (sensible quality), one would have to find wet to be "like" yellow, red "like" softness, and so on, which of course is impossible. The locus of resemblance in virtue of which tangible and visible objects alike are supposed to instantiate the same general idea of space must instead lie in the operations the mind performs on these otherwise incommensurable appearances.

In particular, by contrast with data of the other senses, one is able to discern, and keep track of, distinctions of the finest, subtlest kind among visible and tangible appearances—distinctions sufficient in each case for association and custom to yield the abstract idea of an ordered manifold of coexistent loci (points) that preserve their relative positions to one another (their situation and relations) through any and all changes. To the imagination, then, producing and operating with two such similar manifolds feels so similar that, notwithstanding their radical qualitative disparity as appearances, it ranks them under a single, highly general idea of space. Moreover, thanks to the innumerable correlations (constant conjunctions) disclosed by experience between the objects situated in the respective imaginary spaces of each sense, one fancies that one is dealing not with distinct instances of the same general idea, but with a single, mulitsensory space, with its own, sense-divide transcending objects.

Hume's account of the origin of the idea of time differs from that of space in two principal regards: (1) whereas ideas of spatial features originate only in vision and touch, temporal ideas can be "deriv'd from the succession of our perceptions of every kind, ideas as well as impressions, and impressions of reflection as well as of sensation" (1978, pp. 34–35); and (2) whereas the manner of appearance of the spatial is defined by "that quality of the co-existence of parts," the temporal "is compos'd of parts that are not co-existent … and consequently that idea must be deriv'd from a succession of changeable objects" (p. 36). These differences aside, the psychological processes whereby ideas of the temporal are acquired are identical to those that give rise to ideas of the spatial.

From an unchanging object no idea of time can be derived "since it produces none but co-existent impres-

sions"; only "a succession of changeable objects" can yield the idea of something composed of noncoexistent parts. But since the successiveness of, say, five notes played on the flute cannot be perceived or conceived independently of the sounds—"The ideas of some objects it [the mind] certainly must have, nor is it possible for it without these ideas ever to arrive at any conception of time" (p. 37)—any supposition that the former, as the manner of appearance of these auditory objects, is something really distinct from these objects themselves falls foul of Hume's antiabstractionist separability principle. So, just like the idea of space, that of time can only be formed by comparing distinct perceptions and associating them in resemblance relations, until a custom is produced that stands in readiness to be triggered by all and only those stimuli to which ideas of succession and duration are applied. Time, understood as an ordered manifold of determinable positions composed of indivisible, noncoexistent instants, is thus, on Hume's account, as much an amalgam of the senses and associative imagination as space.

It is in connection with time that Hume formulated another of his principles, restricting the application of ideas according to the copy principle, "Ideas always represent the objects or impressions, from which they are deriv'd, and can never without a fiction represent or be apply'd to any other" (1978, p. 37). Like the copy, separability, and other principles of concern to Hume, this principle governs only one's perception of objects in sensation, reflexion, and thought, and does not imply any restriction on one's talk of objects. Nevertheless, since perceptions are the only objects that can ever be present to one's mind, the principle restricting the application of ideas according to the copy principle restricts one's discourse to the extent that objective meaning can attach to what one says only insofar as it cashes out ideationally. And temporal ideas are a case in point: While one is free to speak of unchanging objects, no objective meaning can attach to one's discourse since one has no ideas other than those copied from fleetingly existent perceptions.

Denial of infinite divisibility. Because one's abstract ideas of space and time "are really nothing but particular ones, consider'd in a certain light" (1978, p. 34), Hume concluded that infinitely divisible space and time are impossible even to conceive. For since particular ideas are one and all copied from particular impressions, and since experience shows that one's impressions admit being divided to the point where an indivisible temporal and/or spatial minimum is reached, it follows that the ideas one derives from these impressions can never serve to conceive an infinitely divisible spatial or temporal object.

(For similar reasons, Hume denied the conceivability of a vacuum in space or time.) Thus, whatever mathematicians may pretend to the contrary, the first principles of mathematics "are founded on the imagination and senses: The conclusions, therefore, can never go beyond, much less contradict these faculties" (p. 638).

HUME'S THEORY OF UNDERSTANDING

Causal relations are the centerpiece of Hume's theory of understanding. Without them, "[i]nference and reasoning concerning the operations of nature would, from that moment, be at an end; and the memory and senses remain the only canals, by which the knowledge of any real existence could possibly have access to the mind" (1999, p. 149). This is because, of all relations linking ideas to impressions, none approaches cause and effect in its power to produce belief (enliven ideas). If I see smoke coming into the room, my belief in the reality of the unseen fire causing it is as great as in the smoke itself. If the hearing of voices on the other side of the fence brings persons to mind as their cause, I not only think there are people there, I believe them really to be there. Thus, whenever I infer a cause for a given effect or an effect for a given cause, I thereby expand the scope of what for me constitutes reality beyond the immediate evidence of my senses and memory.

Although the other principles of association, contiguity and resemblance, also have power to enliven the ideas they associate with impressions, without the support of causal relations "their influence is very feeble and uncertain" (1978, p. 109). For while I can think constant relations of time and place exist beyond the scope of my senses and memory, or think an identity based on the resemblance between nonsimultaneous resembling objects, it is only insofar as causal relations underlie them that I am able to believe these relations really to exist (pp. 73–74). Thus, when it comes to explaining reasoning in matters of fact and real existence, one has no choice but to focus on the relation of cause and effect, as "the only one, that can be trac'd beyond our senses, and informs us of existence and objects, which we do not see or feel" (p. 74).

ANALYSIS OF CAUSE AND EFFECT. Hume identified four constituents crucial to the idea of cause and effect: objects relatable as cause and effect must be distinct in the sense specified in the separability principle; they must be contiguous in time and (where the objects concerned are spatial) in place; the cause must precede the effect; and there must be a necessary connection between them.

Since the first three are fairly straightforward, Hume focused on necessary connection, with an eye to clarifying the idea by tracing it to its originating impression.

To understand why Hume proceeded as he did in this matter, the inherently paradoxical character of the idea of a necessary connection between distinct existents must first be taken into account. It stipulates a necessary connection between the existence of items presupposed as distinct. For example, one does not consider valleys and mountains candidates for terms of a causal relation because their necessary connection is merely conceptual, incorporated into the ideas themselves: Valleys cannot be conceived to exist in the absence of mountains and vice versa. By contrast, fire and smoke qualify as candidates for terms of a causal relation precisely because each can be conceived to exist without necessitating one to conceive the existence of the other. But there lies the rub: If to conceive them as distinct is to conceive the existence of the one to be possible even in the absence of the other, and to conceive them as necessarily connected is to conceive the existence of the one to be impossible in the absence of the other, then their combination in a single concept seems self-contradictory.

The general causal maxim. By far the most important illustration of the unintelligibility of the notion of necessary connection is Hume's analysis of the general causal maxim that everything that begins to exist must have a cause of its existence (1978, pp. 78–82). While recognition of the contingency of any determination in accordance with the maxim was a commonplace among pre-Humeans—that this specific thing causes that one—the truth of the maxim itself—that everything that comes into existence must have some cause—was taken to be an intuitively certain necessary truth, and so "one of those maxims, which tho' they may be deny'd with the lips, 'tis impossible for men in their hearts really to doubt of" (p. 79). Still, for Hume, the notion that the general maxim is a matter of knowledge rather than probability is easily refuted by a simple consideration of the concept of necessary connection itself. Its presupposition that the objects to be related in it are distinct already of itself implies the possibility that each of the objects can be conceived to exist in the absence of the other (pp. 79–80). Since even so much as a single conceivable exception is sufficient to show that a general proposition is not knowable intuitively or demonstrably, Hume concluded that the certainty of the general causal maxim is of a completely different nature, consisting not in any necessity of thought (relation of ideas) but in irresistible feeling (great force and vivacity), founded on experience and rooted in

the nature of human (and much nonhuman-animal) associative psychology (pp. 82 and 172; Kant rightly recognized in this result a challenge to the possibility of metaphysics itself).

THE ORIGIN OF THE IDEA OF NECESSARY CONNECTION. A source of the idea of necessary connection in the objects present to one in sensation or reflexion is precluded by the fact that all perceptions as such conform to the separability principle, and so are "distinct" in the sense implying that it is always possible to conceive any one to exist in the absence of any other, or all others. Accordingly, Hume sought the origin of the idea in the experiencing subject and the ways it regards its objects, and, in particular, in the acts and affects incident to customary transitions from impressions to ideas (1978, pp. 165–166). When one object is found by experience to constantly succeed another, a habit is formed so that when one of them is present in sensation or reflexion, it straightaway brings to mind its constant concomitant, and one not only conceives it but believes it really to exist. The facility of this transition, with the force and vivacity felt in the conception of the idea when the transition to it is from an impression, constitutes the sole and entire content of the impression-of-reflexion original of the idea of necessary connection (1999, p. 145). To be sure, a projective illusion induces one to ascribe the impression of reflexion immanent to associative imagination to the objects it considers (1978, p. 167). Nevertheless, the necessity of causes is never anything but a subjective necessity felt in the mind that considers objects, and it is in this sense that the "necessary connexion betwixt causes and effects," and "the transition arising from the accustom'd union … are, therefore, the same" (p. 165).

Since Hume defined causal necessity both as a philosophical relation, in terms of constant precedence, and as a natural relation, in terms of customary association, many interpreters have supposed that the former has a meaning and scope of application unrestricted to associative imagination. Against this, one should note that, for Hume, (1) the idea of necessary connection is an essential element in all ideas of causal relations, (2) constant precedence as such does not include an idea of necessary connection, (3) the only source from which the idea of a necessary connection can be derived is customary association, and (4) ideas can never represent any objects other than those from which they are derived.

Accordingly, the only thing that can distinguish philosophical causation from constant precedence is the addition of the idea of necessity derived from customary

association, so that the necessity that "makes an essential part" of both definitions of causality is "at bottom the same" (1999, p. 160). This means that philosophical causation owes its influence on one's thoughts and actions entirely to its inclusion of a content no less bound up with conscious mind than pleasure, fear, or love; and to forget this by attempting to apply causal concepts directly to objects, apart from "that determination of the mind, which is acquir'd by custom," is to "either contradict ourselves, or talk without a meaning" (1978, p. 267).

EMPIRICAL RATIONALITY. In matters of fact and real existence, reasoning, as Hume understood it, is a transition in thought from a more vivid impression or idea to a less vivid idea in which the latter is conceived with more vivacity because of the relation the transition effects between them (where facility feeling is the essence of the relation). Since, in Hume's view, the enlivening of ideas primarily depends on their association with impressions, and since causal relations far exceed any other in their ability to enliven ideas to the point where they approach the vivacity of impressions, customary transitions from impressions to ideas are at once the source of the impression originals of ideas of necessary connection and the template of all empirical reasoning. This is just to say that the one indispensable item of evidence in any inferential matter of fact or real existence is an impression of necessary connection. For, in the absence of such an impression (maximally vivid perception), there could be no belief that an idea is connected to an impression in the manner requisite to enliven it, with the consequence that the impression would not then be regarded as a reason to affirm the idea. Thus, to explicate the nature of empirical reasoning, and to distinguish reasonable (factually justified) cases of reasoning from unreasonable ones, Hume undertook an investigation into the causes of such impressions.

The nonrational basis of empirical reasoning. The principal, and the most efficacious cause, of impressions of necessary connection is frequent experience of the items connected in them in an unvarying sequence— termed *constant conjunction* by Hume. As the evidence for this causal connection is itself a remembered constant conjunction (between relations of constant conjunction and subsequently felt impressions of necessary connection), Hume queried whether one infers the necessary connection from experience "by means of the understanding or of the imagination; whether we are determin'd by reason to make the transition, or by a certain association and relation of perceptions" (1978, pp. 88–89).

Nothing in Hume's philosophy has received more attention than his solution to this question (usually called the problem of induction). He began by premising that if reason were responsible for the conclusion that a necessary connection exists whenever a relation of constant conjunction is found, then the inference would be grounded on the "principle, *that instances, of which we have had no experience, must resemble those, of which we have had experience, and that the course of nature continues always uniformly the same*" (1978, p. 89). The question thus becomes whether one's belief in this uniformity principle is itself a product of rational argument, demonstrative or probable, or whether the implicit confidence one places in it derives from a different, nonrational source (associative imagination). Demonstrative reasoning (knowledge) is easily ruled out, since "[w]e can at least conceive a change in the course of nature" and "[t]o form a clear idea of any thing, is an undeniable argument for its possibility, and is alone a refutation of any pretended demonstration against it" (p. 89). Hume next excluded probable reasoning on the ground that it cannot be the source of a belief it presupposes:

> We have said, that all arguments concerning existence are founded on the relation of cause and effect; that our knowledge of that relation is derived entirely from experience; and that all our experimental conclusions proceed upon the supposition, that the future will be conformable to the past. To endeavour, therefore, the proof of this last supposition by probable arguments, or arguments regarding existence, must be evidently going in a circle, and taking that for granted, which is the very point in question.
>
> (1999, P. 115)

Since the past can only matter to one in forming of beliefs about the present or future in probable reasoning if one already believes the future is conformable to the past, one's belief in this uniformity must have a basis other than probable reasoning. According to Hume its basis is none other than customary association, which instills in one a belief in the uniformity of nature long before one has left one's cradle and determines the reasoning of brute beasts in the same way it does humans (1999, p. 118 and 1978, p. 178).

Philosophical and unphilosophical probability. When conjunctions of perceptions are remembered to be less than constant, one's evidence of necessary connection falls short of the certainty of proof. How much credence should one accord each of the competing causes and/or effects? That is, what constitutes reasonable belief here?

According to Hume the natural procedure is also the rational one: the accumulated belief (vivacity feeling) is distributed among the contrary causes or effects according to their relative constancy in past experience, subtract the lesser from the greater, and accord only so much credence (vivacity) to the latter as remains (1978, pp. 132–140). In other words, experience shows that one proportions belief in causal connections according to the constancy of the conjunction of the items concerned in them in the past and that this experience is so natural and universal that such proportioning has in all times and places been regarded as the hallmark, if not indeed the essence, of reasonable belief, or philosophical probability.

Of course, Hume was well aware that experience shows there to be many other causes of impressions of necessary connection than experienced conjunction and that these causes sometimes prevail over the evidence of experience: the ebb and flow of passions, calculations of interest and gain, laziness, hastiness, credulity, the persistence of tenets in education that have ceased to be proportioned to experience, and so on. One may be tempted to object that Hume's distinction between such unphilosophical (unreasonable or even irrational) reasoning and reasonable inferences proportioned to experience is arbitrary, since both alike are functions of feeling (vivacity transference effected by facile transitions of thought). Was he simply endeavoring to reflect linguistic practice? More likely, Hume's distinction derives from the account of the origin of impressions of necessary connection on which all causal inference depends. Experience is the natural and original cause of ideas of causal relations: It operates most constantly and steadily on the imagination and is most inseparable from the nature of that faculty (compare to 1978, p. 280). So, even in the absence of any objective or normative paradigm of rationality, nature itself, on Hume's account, sets experience at the foundation of empirical rationality.

A WORLD IN IMAGINATION. In denying that one has intuitive or demonstrative knowledge of the truth of the general causal maxim, Hume at the same time affirmed that one has another kind of certainty that everything must have a cause of its existence, arising from observation and experience (1978, p. 82) and consisting in the great vivacity of one's idea of the relation of any beginning of existence (thing, action, or state) to something precedent from which its existence follows by necessity (p. 172). The consequence is an unquestioning assumption, in any particular instance, that a cause inferred for a given effect is itself the effect of some other cause. For example, if the sight of smoke makes me think and believe that there is a fire in the hall outside, I at the same time take for granted a cause of this fire, a cause of this cause, and so on. If I reflect on this regress, I might attribute the fire to the frayed wiring I saw earlier, this to the gnawing of mice, the presence of mice in the building to the construction going on next door, the construction to the renovation plans of the new owner, the purchase of the building to the death of the old owner and the greed of the new one, and so on. But even if my theory should turn out to be mistaken (it was arson), I still remain absolutely certain of the existence of some chain of causes leading to the fire.

Since similar causal chains, with fewer or more of the blanks filled in, are taken for granted in respect of every beginning of existence, the space and time of real things demarcated by the purview of one's senses and memory comes to be dwarfed by the sphere comprised of the realities one infers to exist by means of customary association in relations of cause and effect:

> 'Tis this latter principle, which peoples the world, and brings us acquainted with such existences, as by their removal in time and place, lie beyond the reach of the senses and memory. By means of it I paint the universe in my imagination, and fix my attention on any part of it I please. I form an idea of ROME, which I neither see nor remember; but which is connected with such impressions as I remember to have received from the conversation and books of travellers and historians. This idea of Rome I place in a certain situation on the idea of an object, which I call the globe. I join to it the conception of a particular government, and religion, and manners. I look backward and consider its first foundation; its several revolutions, successes, and misfortunes. All this, and every thing else, which I believe, are nothing but ideas; tho' by their force and settled order, arising from custom and the relation of cause and effect, they distinguish themselves from the other ideas, which are merely the offspring of the imagination.
>
> (P. 108)

INDIVIDUALS

Hume explicated one's ideas of complex individuals (bodies and minds), both at a time (which he called simplicity) and over time (identity), as fictions resulting from failures to distinguish relations of genuine individuals from these individuals themselves. While granting that, in appearance, these fictitious individuals do not resemble

genuine ones, he insisted that their feeling to the imagination in contemplating its objects is so similar in the two cases, and the associative influence of the resemblance relation so strong, that one affirms their simplicity or identity even in the face of contrary appearances (1978, pp. 202–204 and 253–254).

Hume opted for associationist explications of these ideas because he could find no way to make sense of complex individuals objectively. The only kind of simplicity one is capable of conceiving in objects (impressions and ideas) is incompatible with complexity and manifestly different from it: Perceptions may be simple, in which case there must be only one, or complex, in which case there must be more than one, but since they cannot be both one and more than one at once, the notion of a complex individual is, strictly speaking, unintelligible. The predicament is even worse when it comes to the identity of an object over time. Since "all impressions are internal and perishing existences, and appear as such" (1978, p. 194), no idea can be copied from them that is not of existents "interrupted, and perishing, and different at every different return" (p. 211). Hume took this so far as to insist that duration is inconceivable apart from succession, and so can never be represented otherwise than as a multiplicity (p. 37). To be sure, one can represent something as the same as itself at one and the same time; but this is unity, not identity (pp. 200–201). Thus, unlike simplicity, the notion of identity seems to premise a combination of unity with number that, objectively at any rate, seems unintelligible.

PERFECT IDENTITY. While there may be nothing objectively to distinguish the presence to consciousness of a single continuing existent from a succession of distinct qualitatively identical fleeting existents, on the subjective side there is a feeling that suffices to mark a difference:

> The faculties of the mind repose themselves in a manner, and take no more exercise, than what is necessary to continue that idea, of which we were formerly possest, and which subsists without variation or interruption. The passage from one moment to another is scarce felt, and distinguishes not itself by a different perception or idea, which may require a different direction of the spirits, in order to its conception.

(1978, P. 203)

Presumably, one's mind might have been so constituted that, instead of being all but effortless, the act of successively repeating the same idea might have required great exertion and a continuous redirection of the spirits to effect it. In that case, however, the change (succession of the distinct) would be as unmistakable here as with a kaleidoscopically varying flux. Alternatively, instead of being "scarce felt," contemplating a qualitatively invariant succession might involve no feeling at all. Still, in that case, there would be nothing to induce the imagination to confuse the observation of a continued, invariant sequence of perceptions with interrupted or variable ones and Hume's account of complex individuals could not even get off the ground. Thus, the original of the idea of what Hume called *perfect identity* lies not merely in the objects contemplated but also in the sustained affective disposition of the imagination in successively reproducing the same idea.

THE IMPERFECT IDENTITY OF BODY (CONTINUED AND DISTINCT EXISTENCE). Perfect identity is terminated by the first interruption or variation sufficient to necessitate a new direction of the spirits. However, "a succession of related objects places the mind in this disposition, and is consider'd with the same smooth and uninterrupted progress of the imagination, as attends the view of the same invariable object" (1978, p. 204). Since the very nature or essence of relation is facility, a succession of a single relation of ideas (facility feelings) produces the same continuity of affective disposition distinctive of a successive repetition of the same idea, and so leads one to confound them (= imperfect identity). In the case of bodies (continued and distinct existents) the principal relation is resemblance:

> We find by experience, that there is such a *constancy* in almost all the impressions of the senses, that their interruption produces no alteration on them, and hinders them not from returning the same in appearance and situation as at their first appearance. … This resemblance is observ'd in a thousand instances, and naturally connects together our ideas of these interrupted perceptions by the strongest relation, and conveys the mind with an easy transition from one to another. An easy transition or passage of the imagination, along the ideas of these different and interrupted perceptions, is almost the same disposition of mind with that in which we consider one constant and uninterrupted perception. 'Tis therefore very natural for us to mistake the one for the other.

(P. 204)

To be sure, the identity the imagination wishes to ascribe to these appearances directly conflicts with the new direction of the spirits necessitated by their interrupted

appearances. Since these interruptions "are so long and frequent, that 'tis impossible to overlook them; and as the *appearance* of a perception in the mind and its *existence* seem at first sight entirely the same, it may be doubted, whether we can ever assent to so palpable a contradiction, and suppose a perception to exist without being present to the mind" (1978, p. 206). Given that one does so virtually every moment of one's life, the question for Hume was not whether but how one reckons with the contradiction. He found the answer in the associative nature of the idea of the mind to which perceptions appear. If the mind is not, as most of Hume's predecessors believed, a real substantial unity on which perceptions essentially depend, but something conceivable only associatively, as a "connected mass of perceptions," then "there is no absurdity in separating any particular perception from the mind" (p. 207). That is, if, in accordance with the separability principle, one can conceive any perception to exist in the absence of any other or even all others, then one can conceive any perception to exist in the absence of the mind if the mind is, indeed, just another perception (namely, a complex idea produced in associative imagination).

By calling such absences interruptions in its appearance, one can attribute to the perception a reality independent of the mind. Of course, since the separability principle holds of all perceptions without exception, this is something one is capable of doing with any perception whatsoever—smells, pains, fears, desires, volitions, and thoughts no less than spatial (visible and tangible) objects. That one only exercises this conceptual capacity in the case of spatial objects is due solely to the fact that they alone exhibit the constancy requisite to produce resemblances sufficiently strong between interrupted perceptions to generate an affective disposition liable to be mistaken for perfect identity.

Even so, the distinction between the appearance and reality of spatial objects employed here is merely external (relative). Consequently, it can only disguise, not eliminate, the feature that sets up the palpable contradiction in the first place: the appearance and reality of perceptions are one and indistinguishable. Given that "all impressions are internal and perishing existences, and appear as such," the distinct, continued existence one accords to visual and tactual impressions has nothing whatsoever to do with either the reality or the appearance of these perceptions, and everything to do with operations of the imagination that considers them. That is, the only idea one is capable of forming of the identity of bodies is inseparably bound up by content with the subjective acts and affects of association imagination, and so is fictitious through and through.

In designating body a fiction, it was by no means Hume's intent to imply that one does or even can doubt its reality. For not only is the fiction rooted in fundamental principles of human nature, it is in effect self-confirming. The memories whereof ideas of bodies consist are, in general, one's most vivid ideas. Since the effect of the fiction of a continued existence is to unite the scattered memories of resembling appearances in a single idea, their vivacity feelings are pooled together in that idea, thereby producing the strongest conviction in the real existence of the continued existent thereby conceived (1978, pp. 208–209). For this reason, "[w]e may well ask, *What causes induce us to believe in the existence of body?*, but 'tis vain to ask, *Whether there be body or not? That is a point, which we must take for granted in all our reasonings*" (p. 187).

THE SIMPLICITY OF BODY: THE IDEA OF SUBSTANCE. Hume explicated the idea of simplicity of bodies (their individuality at a time) by means of an associative fiction closely analogous to that responsible for one's idea of their identity. The appearance and reality of one's perceptions are ignored because of the powerful influence on the imagination of its own affective disposition when it contemplates coexistent perceptions bound together by customary associations of contiguity and causality:

> The connexion of parts in the compound object has almost the same effect, and so unites the object within itself, that the fancy feels not the transition in passing from one part to another. Hence the colour, taste, figure, solidity, and other qualities, combin'd in a peach or melon, are conceiv'd to form *one thing*; and on account of their close relation, which makes them affect the thought in the same manner, as if perfectly uncompounded.
>
> (1978, P. 221)

Here, too, the contradiction between one's feelings and the manifest difference in appearance between a genuinely simple object and a body—that is, the distinctness in the latter, according to the separability principle, of the color from the taste, these from the visible figure, these in turn from its tangible solidity, and so on—is too pronounced to ignore, and so must be palliated by some fiction, even if the contradiction can only be disguised thereby, not eliminated. Accordingly, we "feign an unknown something, or *original* substance and matter, as

a principle of union or cohesion among the qualities, as what may give the compound object a title to be call'd one thing, notwithstanding its diversity and composition" (p. 221).

THE IMPERFECT IDENTITY OF THE MIND (SELF AND PERSON). In the case of the mind, one is induced to attribute identity in the face of recalcitrant appearances more by causal relations than by resemblance:

> As to *causation*; we may observe, that the true idea of the human mind, is to consider it as a system of different perceptions or different existences, which are link'd together by the relation of cause and effect, and mutually produce, destroy, influence, and modify each other. Our impressions give rise to their correspondent ideas; and these in turn produce other impressions. One thought chaces another, and draws after it a third, by which it is expell'd in its turn.
>
> (1978, P. 261)

One is a witness continuously, almost from the beginning of conscious life, to impressions causing idea copies of themselves to be formed, of these ideas being the occasion of further thoughts, passions, desires, and/or volitions, these in turn causing copies of them to be formed, and so on. One's perceptions may be subject to constant change, but never, even for a moment, is a causal relation between them of some kind absent from one's purview. Since "the very essence of these relations consists in their producing an easy transition of ideas" (1978, p. 260), the facility feelings incident to contemplating an unvarying, uninterrupted series of causal relations signify the presence in one of an unvarying, uninterrupted affective disposition. The strength of this disposition, with the strength of the feeling of its resemblance to the affective disposition incident to perfect identity, leads one to attribute an identity to this system of causal relations (pp. 253–254), notwithstanding that, on the side of the appearances, one's perceptions are "a perpetual flux and movement" and nothing "remains unalterably the same, perhaps for one moment" (pp. 252–253). (Hume's account of the simplicity of the self is essentially the same as that of body [p. 263].)

Second thoughts. Hume's explication of the idea one has of oneself thus shows it to be no less fictitious than that of the idea of external objects: nothing "really binds our several perceptions together," it merely "associates their ideas in the imagination"; one never observes any "real bond" among them, one "only feel one among the ideas we form of them" (1978, p. 259). Still, by excluding

all real relations from the account of the self, Hume eventually came to realize that he had no way to "explain the principles, that unite our successive perceptions in our thought or consciousness" (appendix published with the second volume [book 3 1978, p. 636] of the *Treatise*). Hume saw no way out of this quandary, nor did he ever return to this topic in any subsequent work.

SKEPTICISM

Was Hume a skeptic? Though generally reputed to be among the most extreme of skeptics, the question is not so absurd as it may seem. If a skeptic is one who doubts or even rejects the use of reason as a means of arriving at truth, then Hume was no skeptic. So long as one is guided by intuition in one's inferences in mathematics and by experience in matters of fact, "Our reason must be consider'd as a kind of cause, of which truth is the natural effect" (1978, p. 180). Furthermore, Hume recognized that many beliefs are pointless to doubt because one is literally incapable of disbelieving them or not taking them for granted in all one's reasoning, including such philosophically contentious topics as the existence of external objects and the self, space and time, and the necessity of a cause to every beginning of existence.

Consequently, many commentators have come to regard Hume's skepticism as considerably more moderate and narrowly focused than traditionally supposed. For them, what makes Hume a skeptic is that he supposed one's ineliminable beliefs skeptically unassailable not because they are founded on reasons too strong to be undermined by skeptical argument but because they are not founded on reasons at all. It is nature, not reason, that has determined one to believe certain things. Nor is reason, when understood as Hume would have one do, capable of supplying these beliefs with a rational basis immune to skeptical assault.

The problem with this view is that it focuses almost exclusively on beliefs to the neglect of their ideational contents. If Hume did indeed deem belief in the existence of body skeptically unassailable, it must also be remembered that psychological processes—the actions and affects of associative imagination—are not merely essential to the formation of the idea in which this belief is reposed but also contribute elements essential to its content (i.e., apart from which bodies are inconceivable), and limit its application accordingly. Indeed, what is perhaps most distinctive of Humean skepticism is the conceptual dimension, in which association supplies subjective-psychological surrogates, as the only way around the "contradictions which adhere to the very ideas of matter,

cause and effect, extension, space, time, motion; and, in a word, quantity of all kinds" (1992, pp. 189–190).

For Hume, it is impossible even so much as to conceive these things without incorporating into one's ideas of them contents copied from impressions as irreducibly subjective as pain or disgust. What does it matter that the belief (vivacity) conferred on these ideas renders them skeptically unassailable if the ideas themselves are of such a nature that no skeptic would think to contend against them? One's reliance on associative imagination for the content of one's ideas comes at a price. If, for example, "we suppose necessity and power to lie in the objects we consider, not in our mind, that considers them," then, apart from this, "it is not possible for us to form the most distant idea of that quality" (1978, p. 167). This restriction on the scope of application of concepts so fundamental to human understanding as causation and body to the purview of a suitably constitutive experiencing mind unquestionably qualifies as a form of extreme skepticism.

VARIETIES OF HUME'S SKEPTICISM. When Hume himself characterized his philosophy as skeptical, he meant that it abounds with "discoveries concerning the weakness and narrow limits of human reason and capacity" (1999, p. 145). Although virtually everything in Hume's philosophy is directed to this end, among the arguments, analyses, and approaches to which he explicitly appended the term *skeptical*, three seem most deserving of being singled out.

Skepticism with regard to reason. After explicating empirical rationality as inferential belief proportioned to the evidence of past experience in *Treatise* I.iii, Hume advanced an argument in I.iv.1 to show that the result of adhering always and only to the canons of empirical rationality leads inexorably to the conclusion that "all is uncertain, and that our judgment is not in *any* thing possest of *any* measures of truth and falsity," so that "the understanding, when it acts alone, and according to its most general principles, entirely subverts itself, and leaves not the lowest degree of evidence in any proposition, either in philosophy or common life" (pp. 183 and 267–268). While most commentators consider his reasoning fallacious, Hume himself clearly deemed it impeccable and irresistible on any conception of empirical rationality, his own included (pp. 184–185). What interested him was why the argument nevertheless fails to convince. The reason he offered is that "[n]ature, by an absolute and uncontroulable necessity has determin'd us to judge as well as to breathe and feel" (p. 183).

More particularly, the argument lacks the affective force on which all relation (facility) and belief (vivacity) depend, "Where the mind reaches not its object with easiness and facility, the same principles have not the same effect as in a more natural conception of the ideas; nor does the imagination feel a sensation, which holds any proportion with that which arises from its common judgments and opinions" (p. 185). Vivacity (belief) follows facility (relation); so even if experience and custom support a certain inference, if for some reason, however trivial, facility feeling fails, vivacity will as well. And the circumstance in which understanding would subvert itself is a case in point:

> We save ourselves from this total scepticism only by means of that singular and seemingly trivial property of the fancy, by which we enter with difficulty into remote views of things, and are not able to accompany them with so sensible an impression, as we do those, which are more easy and natural.… We have, therefore, no choice left but betwixt a false reason and none at all.
>
> (P. 268)

Skepticism with regard to the senses. However impossible it may be for one in ordinary life not to believe in the distinct, continued existence of the bodies one sees and touches, only "a very little reflection and philosophy is sufficient for us to perceive the fallacy of that opinion" (1978, p. 210). Still, even if the more philosophical part of humankind recognizes this, they typically attempt to salvage the common opinion by arguing that unperceived objects correspond to perceptions that resemble them in various particulars but not their internal perishing existence. Many interpreters believe that Hume judged the philosophical view capable of sustaining skeptical scrutiny. This, however, is hard to credit in the face of his assertion that the philosophical view "contains all the difficulties of the vulgar system, with some others, that are peculiar to itself" (p. 211). If it contains all the difficulties, how can it withstand skeptical scrutiny any better? Hume's skepticism regarding the vulgar view centered on the content of the idea of a distinct, continued existence: the indispensability to it of something of the nature of an affective disposition (as is true of the idea of identity itself, this being the only means whereby the manifest differences between an interrupted or varying existence and a genuine identity can be overlooked and the two confounded).

Since the idea carries this content with it into all its applications, Hume cannot have exempted its philosophical employment from the same skeptical arguments to

which he subjected its vulgar. Indeed, because the philosophical view was erected in express opposition to the verdict of the most powerful, deep-seated natural human psychological propensity to believe in the distinct, continued existence of immediately perceived visible and tangible objects (sensations), only the weakest, most ephemeral conviction can be accorded to the philosophers' objects (p. 213). Finally, Hume contended that philosophers, having no means of conceiving their would-be objects except their own perceptions, in effect do no more than "arbitrarily invent a new set of perceptions" (p. 218). If, to avoid this implication, they suppose their objects to be specifically different from everything one can conceive, the result will be an "unknown, inexplicable *something* … a notion so imperfect, that no sceptic will think it worth while to contend against it" (1999, p. 203).

Academic, or mitigated, skepticism. Despite the extremity of the skepticism resulting from the "deficiency of our ideas" (1978, p. 267), Hume saw fit to describe his philosophy as an exercise in "mitigated scepticism" (1999, pp. 207–211). A skepticism qualifies as such if, instead of advocating the rejection of reason in all its forms, it counsels one to reject all abstract reasoning other than mathematics, and all reasoning regarding matters of fact and experience that is not carefully and precisely calibrated to accord with the deliverances of experience.

Does Hume's own philosophical reasoning meet these criteria? It was because the empirical investigation of human understanding turns up no evidence of any other faculties besides sense and imagination that he endeavored to account for all the phenomena of perception, judgment, and reasoning (mathematics included) in terms of their operations. And it was because the only empirical source to which ideas of causal connection, substance, real existence, space, time, and the mind could plausibly be ascribed as associative imagination that he was compelled to conclude that even one's most basic, indispensable concepts of objects incorporate an ineliminably subjective element of feeling into their content (facility and vivacity). To be sure, with the understanding thus transformed (in part) into an organ of feeling, Hume's philosophy became the first to set reason on a par with pleasure and pain, passions, desires, and everything else previous philosophers had denigrated as belonging to the baser, animal part of human nature; and this may seem skeptical indeed. But since his conclusions are fully consonant with the strictures of a mitigated skepticism, he could at least be confident that his books would not be

incinerated by anyone answering his call to "commit to the flames" any volume that fails to respect them.

THE WILL

Will is "the internal impression we feel and are conscious of, when we knowingly give rise to any new motion of our body, or new perception of our mind" (1978, p. 399). There is no implicit proposition the affirmation of which constitutes the act of volition. Volitions, for Hume, are not ideas or manners of conceiving, but feelings, felt excitations to mental or physical action. They are full-fledged perceptions (impressions of reflexion) in their own right, distinct from all others under the separability principle, capable of existing in complete isolation (p. 625). As such, they are completely indefinable: like flavors, to know volitions—to be able to form (copy) clear ideas of them—it is necessary to have the corresponding impressions; to lack the impressions is to be completely ignorant of will, to be unable to form even the most obscure idea of it.

With nothing more to be said of the will *per se*, Hume focused on the causes of its actuation. Nothing precludes reason from doing so since here, as always, "to consider the matter *a priori*, any thing may produce any thing" (1978, p. 247). Still, as a matter of fact, one finds "that reason alone can never be a motive to any action of the will" (p. 413). Convinced by reason that I am about to be devoured by a ravenous beast, for example, I would be completely indifferent to the fact, and not be provoked by this belief to any exercise of will, without the mediation of some passion in response to (caused by) the belief. Indeed, if human nature was such that being devoured by the beast was one of our fondest desires—because, say, passing through the digestive tract of a beast of that species was indispensable to reproduction—then this belief, with the passion, would excite actions to facilitate our capture. Alternately, our passionate response to the belief might be as tepid as that of a fifth grader to his or her belief regarding the result of the fifteenth of a series of long-division homework problems, so that we merely yawn at the imminent prospect of being devoured. Only passions actuate the will. Reason, according to Hume, is neither a necessary nor sufficient to do so.

For similar reasons, Hume argued that reason can never directly oppose, curb, or in any way act as a counterweight to the actuation of the will by passions. It can do so only indirectly, by giving rise to some new passion, as when it informs one that the object of one's desire is unattainable, or attainable only by a different course of action, whereupon it will produce an aversion to counter, or a desire to override, the existing passion. Conse-

quently, when one speaks of "sweet reason" prevailing over "brute passion," it is not passionless, volitionally impotent, reason that is being invoked, but other, calmer passions. Their gentleness should not, however, be confused with weakness:

> 'Tis evident passions influence not the will in proportion to their violence, or the disorder they occasion in the temper; but on the contrary, that when a passion has once become a settled principle of action, and is the predominant inclination of the soul, it commonly produces no longer any sensible agitation. … We must, therefore, distinguish betwixt a calm and a weak passion; betwixt a violent and a strong one.

(1978, PP. 418–419)

Is there such a thing as a rational passion? According to Hume, no. For even though a belief can be the invariable cause of a certain passion, passions are one and all original existences: none of their features are copied from the ideas that cause them or in any way derivable from them (1978, p. 415); and even when a passion has an object—as pride takes the idea of oneself for its object and love the idea of someone else—the object remains distinct (by the separability principle) from the passion itself, and only becomes an object to it by the mediation of some feeling of pleasure, such as that given by the beauty of the beloved or the opulence of a house that has passed into one's ownership (p. 279). Passions are therefore never rational in and of themselves; and since experience shows that only passions can actuate the will, reason

> is, and ought only to be the slave of the passions, and can never pretend to any other office than to serve and obey them. … 'Tis not contrary to reason to prefer the destruction of the whole world to the scratching of my finger. 'Tis not contrary to reason for me to chuse my total ruin, to prevent the least uneasiness of an *Indian* or person wholly unknown to me. 'Tis as little contrary to reason to prefer even my own acknowledg'd lesser good to my greater, and have a more ardent affection for the former than the latter.

(PP. 415–416)

GOOD/BAD AND PLEASANT/UNPLEASANT ARE INDISTINGUISHABLE. Since reason, considered apart from whichever passions its deliverances may provoke, leaves the will indifferent, it cannot be the source of any of one's ideas of good and bad. This means that nothing propositional in character (rule, maxim, principle) can be

intrinsically good or bad: carnally, spiritually, aesthetically, or in any other way. Since the only place left to look for the impression originals of ideas of good and bad are pleasant and unpleasant feelings (sensations and passions), goods and ills must all be pleasures and pains of one sort or another (1978, p. 439). Thus, for Hume, the standards one applies in all one's value judgments have their origin exclusively in pleasant and unpleasant sensations or reflexions, and neither the goals of one's actions, the deeds themselves, one's volitions to perform them, nor the character of the person who wills can be supposed good or bad either intrinsically or in relation to any rule of conduct (maxim and principle) under which they fall; they are good or bad solely by virtue of the feelings that caused them and/or the feelings they arouse.

DENIAL OF FREE WILL. The question of freedom of the will takes on a different aspect according to how a philosopher analyzes volition. If one deems will and reason inseparable, as Berkeley did, and conceives of volition as the affirmation or denial of a proposition, like René Descartes, then any external cause that necessitates one to affirm or deny will be construed as a constraint on the freedom of one's will. But if, like Hume, one distinguishes reason from will and equates volition with a nonintellectual feeling of excitation to action (impression of reflexion), then a free will, unrestrained by any necessitating cause, would be one that acted blindly and randomly, unresponsive to one's desires and heedless of one's beliefs, and so is something rather to be dreaded. Thus, from his standpoint, it is fortunate that experience shows one will not to be free, but instead to act only when necessitated to do so by some passion, be it calm or violent, beneficial or destructive, responsive or unresponsive to the deliverances of reason.

Complementing Hume's denial of free will is his analysis of causal necessity in the operations of bodies as consisting of nothing more than facile transitions of thought from one perception to its customary conjunct. For this means that there is nothing "the mind can perceive, in the operations of matter, some farther connexion between cause and effect … that has not place in the voluntary actions of intelligent beings" (1999, p. 157). All there is to causal necessity is what one experiences in every facile transition from an impression to the idea of its usual antecedent or successor. Thus, Hume's necessitarianism does "not ascribe to the will that unintelligible necessity, which is suppos'd to lie in matter," but "ascribe[s] to matter, that intelligible quality, call it necessity or not, which does or must allow to belong to the will" (1978, p. 410).

Consequently, to prove that one is in practice a necessitarian, protestations to the contrary notwithstanding, he had only to assemble reminders that one naturally and inevitably draws on one's past experience of regularities in human voluntary behavior to predict the actions of minds in precisely the same way one does to predict the actions of physical objects (1999, p. 150). To object that one encounters contrariety in the human sphere and often finds the actions of minds puzzling and unpredictable is futile since the same is true in the physical sphere as well, nor does one infer the freedom of bodies from causal necessitation because of the contrariety one finds there.

Illusions of freedom. Hume identified several reasons why one nonetheless insists on supposing oneself to be free. First, by not distinguishing the will as effect from the will as cause, one confuses two different notions of freedom. The will is free as a cause to the extent the actions of one's body and mind are subject to its control, that is, causally necessitated by it. This is the freedom one would lose if one's body or mind became unresponsive to the will or responded only to some external control. By contrast, the will is free as an effect only if its action is not necessitated by any cause, including one's own passions and beliefs, and so acts at random. The latter is the kind of freedom no one wants and, on the evidence of experience, no one has. But it is precisely this sort that matters philosophically, since the other is not only compatible with universal causal necessitation but would not be worth having otherwise.

There is also a psychological illusion of freedom implicit in the idea of necessity itself. When one perceives two objects, one does not feel a causal connection between them unless and until one observes their similarity to past constantly conjoined objects between which such a connection is felt, and then transfer the idea copied from this feeling (the reflexive impression of necessary connection) to the objects presently before one. By contrast, when one is not an observer but a performer of actions, no such reflection occurs, and consequently no connection is felt between one's perceptions (1978, pp. 408–409). For example, if I believe someone has betrayed me, and I become enraged and smash a vase against the wall, I feel no causative forces necessitating my actions; it is only afterward, when I reflect on what happened, that I recognize the necessitation of my action by the passion and the passion by my belief. Even so, I am still apt to resist the claim that in so doing my will and action were no less necessitated than a body released from a height is necessitated to fall. But apart from the fact that "there is

no known circumstance, that enters into the connexion and production of the actions of matter, that is not to be found in all the operations of the mind" (p. 404), this is simply to say I can reimagine the situation so that, instead of the vase, I hurled something else or nothing at all, or that I somehow stopped myself from becoming enraged in the first place. That is not the same as supposing my volition to have been unnecessitated. It only means that, given different antecedents, different causes would have necessitated something other than the action I performed under the circumstances that actually prevailed.

THE PASSIONS

Though Hume devoted as much of the *Treatise* to developing a theory of the passions as he did to the understanding, the former has never attracted as much attention as the latter has. This is regrettable. Hume's theory of the passions is the mirror image of his theory of understanding: just as he was able to show the understanding to be as much an organ of feeling as of thought by explaining its most basic and important operations in terms of principles of association, so, too, by showing how surprisingly far these same principles go toward explaining the operations of the passions, he was able to reveal a deeper, underlying affinity between reason and feeling that otherwise, apart from his associationist doctrine, must remain concealed. This fundamental unity of perceptions that, to all appearances, seem disparate, or even opposed, was surely prominent in Hume's mind when he compared the place of association in the science of man to that of universal gravitation in Newtonian science of nature. One may therefore hope that Hume's theory of passions will someday receive the same amount of careful study and attention that has hitherto been reserved for other topics in his philosophy.

DIRECT PASSIONS. Hume distinguished passions into two basic types: direct and indirect. Direct passions such as grief, joy, hope, fear, despair, and security arise immediately from some good or ill (pleasure or pain), or are themselves productive of good or ill (natural impulses such as punishing enemies and rewarding friends, as well as natural instincts such as hunger, lust, and other bodily appetites). Because their immediate cause or effect is some impression or idea of pleasure or pain, Hume could identify no role for the association of ideas in explaining their origin and only an occasional, incidental role for the association of impressions (where there is only association by resemblance). Nevertheless, he found a number of cases in which associative imagination proves crucial to

enable passions already present in the mind either to commingle (or not) or to oppose one another (or not).

INDIRECT PASSIONS. The passions of principal interest for Hume's associationist science are those he classified as indirect ideas and their associative relations are found to be causally essential to their production. The most fundamental indirect passions are pride/humility and love/hatred, but they also include ambition, vanity, envy, pity, and malice. These share a causation that takes the form of a "double relation of ideas and impressions" (1978, p. 286). Thus, an object causes a pleasure of some kind; if the object happens to be related to me by a strong enough relation, this relation of ideas (of the object to me), together with the pleasurable quality (impression) of the object, causes me to feel the resembling (because also pleasing) passion of pride (impression), whereas that same object, if productive of something unpleasant, will, given the same relation to me, cause the resembling (displeasing) passion of humility. Take away that object's relation to me, and I will feel neither pride nor humility in response to its pleasing or displeasing quality; take away its pleasing or displeasing quality and again I will neither passion. Consequently, pride and humility are found by experience to exist only in conjunction with an idea of myself, another object strongly related to (associated with) me, and some pleasing or displeasing quality related to (associated with) that object.

What differentiates love and hate from pride and humility is simply the object of the passion. For just as I take pride in my body or mind, or some object, insofar as it possesses some pleasing quality and has a strong relation to me—my looks, my brilliance, the imposing house I own, the beautiful painting I created, the coveted office to which I have been elected, and so on—so, too, I love or esteem someone else from precisely the same causes. Otherwise, these passions exhibit the same double relational structure.

Hume was well aware of the profusion of seeming counterexamples to this structure and spared no effort to rebut or deflect them. Still, to many, these efforts have something ad hoc about them, and Hume tends to be condemned for too rigid an adherence to theory in the face of recalcitrant phenomena. But much of this criticism may be due to a failure to appreciate the significance that double relations in question are associative in character, that is, their essence consists in facile transitions felt between impressions and ideas (1978, pp. 289, 309, 335–336, 378). This is never clearer than when, in the last three of Hume's "Experiments to Confirm This System"

(pp. 332–347), he shows what seem to be counterexamples are really cases in which something interferes not with the relation considered abstractly (philosophically) but with the degree of facility felt in it, so that one or both of the relations requisite to produce an indirect passion are deprived of their associating quality, either by losing facility or because some opposing, even more facile transition prevails. Thus, when one factors in the affective dimension of Humean associationism, one can begin to appreciate Hume's evident excitement at the prospect of an explanatory principle that, for the first time, permits a systematic exposition of the human conative mind (pp. 346–347).

SYMPATHY. The compass of one's passions would be narrowly confined to those with whom one has close personal relations if sympathy did not overcome one's indifference by communicating to one the feelings of others and enabling these to arouse one's own feelings, whether they be strangers, those known to one only by reputation, persons long dead, members of far away societies, even characters in myth. Thus, sympathy plays a key role in the operation of the passions in the wider context of human society. Regarded from Hume's perspective, however, sympathy is simply an extension of the associationist principle into the societal sphere. For, in and of itself, it is just one among species of the general associationist operation of enlivening ideas related to impressions to the point where they approach or equal the vivacity of the impressions themselves; one can call it sympathy when it increases the vivacity of an idea related to the passion felt by another to the point where it equals or approaches the original impression (1978, p. 319).

MORALITY

Hume's approach to morality is of a piece with the rest of his philosophy. Are there specifically moral ideas, or does moral discourse have nothing in the only object ever present to one—one's perceptions—to confer objective meaning on its pronouncements? If there are ideas, then their content must be determined by tracing them back to their originating impressions: whether they have their source in the perception of some object in sensation or reflexion (impression) or in acts of associating ideas of these objects. With the origin of moral ideas determined, enough would become evident about their place in the cognitive and/or conative economy of the human mind to permit the discovery of the fundamental principles governing moral judgment and action.

The question whether causal discourse has a basis in the objects present to one's mind came down to the question whether one experiences nothing but constant conjunctions or whether there is something more—even if that something should turn out not to be the objectively real necessary connections one's discourse might lead one to expect. In the case of moral discourse the question that was decisive for Hume regarding its objective significance is whether one's experience of good and ill is limited to passions and desires, or whether there is, in addition, a source of distinctively moral ideas.

Hume's confidence that there is more to causal discourse than experienced constant conjunction stemmed from a conviction that, given only this, reality, for one, would be restricted to the narrow compass of the senses and memory. Where morality is concerned, his confidence in its ideational foundations seems to have derived from the abundant evidence of morally motivated actions: action undertaken not for selfish reasons, from partiality for those one loves, from dread of the consequences of not performing them, or for any identifiable purpose other than the sheer morality of it. Accordingly, in tracing ideas of moral good and ill to their origin, Hume's first task was to determine whether they derive from the features or relations of the objects immediately present to one in perception or, like ideas of necessary connection, from something felt in their contemplation.

MORAL IDEAS ARE COPIED NEITHER FROM OBJECTS NOR THEIR RELATIONS. For Hume, morality would count as objective if actions or things were moral or immoral prior to and independently of any course of reflection on them and, *a fortiori*, any feeling that arises only in the course of such reflection. For example, if willful murder were objectively immoral, then some impression embodying its immorality must exist to be copied in an idea. But what does one find when one considers such crimes objectively but a sequence of thoughts, passions, motives, volitions, and actions? The action itself is not immoral or else an avalanche would be immoral for taking the lives of skiers. That the action is voluntary does not of itself make it immoral or else lions would be guilty of immorality every time they killed. Nor does its immorality consist in the anger, greed, or other passion that determined the will, since these feelings are in themselves neither moral nor immoral. Finally, even if the course of reasoning that eventuated in the resolve to murder included an awareness that murder is wrong, its immorality, if objective, would derive not from this thought as such, but from the preexisting objective state of affairs recognized in it.

If not in the objects whereof willful murder consists, does its immorality reside in some relation of these objects discoverable by reason? Reason, as explicated by Hume, consists either in (intuitive or demonstrative) knowledge of the relations of ideas derived from objects or in belief (a vivid idea) regarding a matter of fact inferred from some other matter of fact. Against the former supposition, Hume argued that none of the knowable relations into which ideas can enter—resemblance, contrariety, degrees in quality, and proportions in quantity and number—seem capable even of distinguishing the moral from the nonmoral, much less the moral from the immoral.

If there is some other kind of knowable relation in which objective morality consists, Hume confessed to being ignorant of it. But even if there were, it would have to satisfy two conditions that seem impossible to meet. In the first place, to be a knowable yet genuinely moral relation, it could only relate two species of objects to the exclusion of all others: internal actions of the mind to external objects. Otherwise, internal actions of the mind that never eventuate in any deed could be moral or immoral, as could deeds with no mental components (thoughts and volitions). Still, so selective a relation of ideas seemed to Hume beyond the scope of what is intuitable or demonstrable by mere human minds. Second, even if such a relation did exist and were known, it would still remain for one actually to intuit or demonstrate its power to determine the will of every being possessed of a knowledge of it, divine no less than human. Since the components of the relation—knowledge and volition—are distinct perceptions, such determination could only take place via causal necessitation. Still, if Hume's analysis of causal connections shows anything at all, it is that no connection is ever intuitable or demonstrable "by the simple consideration of the objects," since "[a]ll beings in the universe, consider'd in themselves, appear entirely loose and independent of each other. 'Tis only by experience we learn their influence and connexion; and this influence we ought never to extend beyond experience" (1978, p. 466). Therefore, it seems that no moral relation can ever be knowable and vice versa.

Objective morality is also not discoverable by probable reason. Deeds objectively comprise thoughts, passions, volitions, and bodily actions. In which relation of these does its morality consist? Even if experiment revealed the existence of some hidden object, a neurochemical perhaps, that reliably tracked the distinctions one makes between the moral and nonmoral, and the moral and immoral, one's ideas of the moral and

immoral could still not be originally derived from such a source since, in and of itself, neurochemicals are just as nonmoral as any of the more obvious objects concerned in moral and immoral deeds. Thus, there is nothing rationally discoverable in the objects, and expressible by an "is" or "is not," that can lead one simply by reasoning to any properly moral recognition, expressible by an "ought" or "ought not" (1978, pp. 469–470).

THE SUBJECTIVE ORIGIN OF MORAL IDEAS IN INTERNAL SENTIMENT. With objects excluded as the source of moral ideas, Hume saw no alternative but to conclude that, like ideas of cause connections, they have their origin in something one feels in the act of contemplating objects. However, the exclusion of empirical reason as their source ipso facto precludes the facility and vivacity affects immanent to associative imagination. Instead, moral ideas originate in a species of impression of reflexion that is entirely independent of imagination. This, for Hume, is not to deny that experience shows that certain processes of thought are causally essential to moral impressions; it is only to say that these processes—by contrast with the impression originals of ideas of necessary connection and identity—contribute nothing to their content. As such, moral sentiments are distinct from these processes, and from every other perception, under the separability principle, and so might conceivably have arisen in total isolation from processes of thought, as hunger and sexual appetites do, or from causes different from those experience in fact reveals. The special status of the impression of reflexion source of moral ideas therefore derives not from any special authority intrinsic to these feelings themselves—they are simply one among many other varieties of pleasure and pain—but from the unique circumstances of their causation and the special place in one's life they derive therefrom.

THE CAUSATION OF MORAL SENTIMENTS. Experience reveals that moral sentiments are aroused only in the course of reflecting on the doings of human beings, specifically the mental characteristics responsible for their voluntary actions, and of these only those most firmly rooted in a person's character: the most efficacious and enduring characteristics of the identity that constitutes an individual human mind. This causation explains why moral feeling weakens or vanishes altogether when one contemplates actions not considered to be tests of character, because, say, their performance was prompted by an uncharacteristic whim, an excusable misjudgment regarding the facts, fever, disease, medicinal side effects,

or involuntarily through some unavoidable external cause.

The causal structure of moral feeling resembles that of the indirect passions of pride/humility and love/hate in that it involves a double relation of impressions and ideas: an object (idea) related to a person (another idea) is the subject of some pleasant or unpleasant feeling (impression) that, because of the relation between the objects, gives rise to its resembling (pleasing or displeasing) moral feeling (another impression). Indeed, with the proviso that the causes of moral feelings are restricted to mental characteristics strongly related to the person, the pleasures and pains that arouse moral feelings prove to be precisely the same ones that arouse feelings of pride/humility in oneself and to love/hate toward others (1978, pp. 574–575), so that moral feelings may be regarded as "nothing but a fainter or more imperceptible" (p. 614) variety of these passions themselves.

There are, however, two further features of the causation of moral sentiments that distinguish them from indirect passions:

Moral feeling requires a general point of view. The indirect passions are invariably partial for or against their particular object (oneself or another). Moral sentiments, by contrast, tend to be felt only when "we fix on some *steady* and *general* point of view" in which one abstracts from "our situation of nearness or remoteness, with regard to the person blam'd or prais'd, and … the present disposition of our mind" (1978, pp. 581–582). Moral feelings are at their strongest (remembering that, for Hume, the strength of a sentiment is often inversely proportional to its violence) when the character of the person is viewed from the standpoint where it

> appears the same to every spectator. … And tho' such interests and pleasures touch us more faintly than our own, yet being more constant and universal, they counter-ballance the latter even in practice, and are alone admitted in speculation as the standard of virtue and morality. They alone produce that particular feeling or sentiment, on which moral distinctions depend.
>
> (P. 591)

From a personal perspective, one may be far more moved by the moral perfections of a best friend than by those of some moral giant of the past like Gandhi. Still, this delight is not moral sentiment. That feeling can arise only when one brackets out one's personal feelings for the person, whereon one cannot help feeling a far stronger feeling in contemplating Gandhi than one's friend (though

this is no guarantee that, when it comes to determining the will, one's moral sentiments will be strong enough to prevail over nonmoral ones).

Moral feeling requires sympathy. Since reason is impotent to determine the will and useless by itself to distinguish moral right from wrong, moral action is wholly at the mercy of moral sentiment. But if moral sentiments can arise only through their association with other pleasures or pains (in the context of a double relation of impressions and ideas), how is it possible for moral feeling to arise if it requires one to regard persons from a general point of view in which abstraction is made from everything determinative of one's present affective disposition? Hume's answer is that the capacity to remain affectively engaged depends on one's ability to sympathize with the persons one considers from a general point of view. Thanks to this societal variety of association, one continues to feel pleasure or displeasure from the consideration of the mental qualities rooted in the characters of persons one considers impartially. Since this permits the condition for the double relation of impressions and ideas requisite to produce moral sentiment is met, one then has only to contemplate the character from the general point of view requisite for moral sentiment for the pleasant or unpleasant feelings produced by sympathy to cause a corresponding pleasant or unpleasant moral sentiment.

VIRTUE AND VICE. Another way in which the impression of reflexion originals of moral ideas and those of ideas of necessary connection are alike is that, despite being subjective (felt only in contemplating objects), they are illusorily projected onto the objects contemplated and treated as though they were properties of the objects themselves (1978, pp. 167, 224–225). In the case of moral feelings, the objects that take on moral attributes are the mental characteristics whose agreeableness or disagreeableness cause moral feelings, whereon they count as virtues or vices: "*taste* … gives the sentiment of … vice and virtue … [and] has a productive faculty, and gilding or staining all natural objects with the colours, borrowed from internal sentiment, raises, in a manner, a new creation" (1998, p. 163).

Hume's typology of virtue of and vice. Hume distinguished four (nonexclusive) types of virtue:

(1) Mental qualities immediately agreeable to their possessors, such as skill, greatness of mind, cheer, equanimity in the face of adversity, and courage

(2) Qualities immediately agreeable to others, such as tact, delicacy, wit, and good manners

(3) Qualities useful to their possessors, such as intelligence, industriousness, skill, patience, and perseverance

(4) Qualities useful to others, such as gratitude, faithfulness, reliability, and charity

The pleasure one takes in these mental qualities in and of themselves is enhanced by the moral pleasure with which one responds to them, thereby adding a moral beauty to their original, nonmoral beauty. Similarly, the displeasure occasioned by their contraries is augmented by moral displeasure, and to their natural ugliness moral repugnancy is added. This, in turn, increases the effects these qualities have on other passions, above all the pride or love and humility or hatred felt on their account. Indeed, as mental qualities capable of stirring moral sentiments in one when considered with sympathy from a general point of view, pride/humility and love/hate now take on a moral value in their own right. Thus, if the pride another takes in his or her character is the effect of real virtues and proportionate to them, our contemplation of his or her pride (a pleasing quality) can only add to the pleasure we derive from contemplating the pleasing qualities in which he or she takes pride, whereas if his or her pride is a perverse pleasure deriving from morally repugnant mental qualities, his or her feelings about him- or herself can only increase the contempt we feel in contemplating those qualities.

Hume seems convinced that many of the qualities commonly deemed virtuous in his and other societies would not be considered virtues, or even be deemed vices, if people could overcome the distorting influences that prevent them from attaining a truly impartial, sympathetic perspective on human characters. Religious education, for example, can condition one to regard as virtuous the asceticism of monks, the fanaticism of zealots, or the credulity of the faithful—qualities of mind that would otherwise be certain to strike one as both repellant in themselves and harmful (1998, pp. 146–147). But, for Hume, the fact that miseducation, harsh conditions of life, and other factors can lead people to mistake virtues for vices and vices for virtues no more makes the one really the other than the fact that people are often influenced to discount or ignore past experience in their reasoning means that there is no real difference, rooted in human nature, between good and bad empirical reasoning. Nothing—interest, expediency, or serendipity—can make disagreeable or harmful mental qualities be, or appear to be, anything other than they really are. Nevertheless, outside influences may intervene to prevent one from attaining the constancy and universality of perspective, and/or the sympathetic engagement, requisite to

bring one's moral sense to bear on such disagreeable or harmful qualities and respond to them with the contempt they would otherwise naturally and universally inspire.

Of course, even if human nature ensures that universal agreement regarding virtue and vice is possible in the abstract, things are different when it comes to judging, in any particular instance, whether an action issued mainly from moral, immoral, or amoral motives, and in which proportions. Hume was keenly aware, in his capacity as philosopher no less than that of essayist or historian, that motives for particular actions can be complex and obscure, even to the agent, and that agreement in one's judgments regarding the morality may be impossible owing to differences in experience, education, access to information, and individual mental abilities. Matters are further complicated by the fact that moral sentiments must compete with other passions for influence on the wills of agents and the hearts of judges. Nonetheless, even if human nature cannot always reveal what one ought to do in each particular instance, Hume still deemed moral sentiment a universally valid standard accessible to anyone concerned to know what kind of person he or she ought to be; and, in this regard, moral sentiment serves as a dependable guide in moral decision making and judgment.

ARTIFICIAL VIRTUES. Institutions such as property, contracts, government, intergovernmental relations, and marriage must exist before the virtues of justice (the rightful possession of property), promise-keeping, allegiance, treaty-keeping, and chastity are even possible. A first precondition is that everyone, or nearly everyone, realize that they stand to benefit when every member of society, selves included, adheres to the rules requisite for these institutions to exist and flourish. Second, each person's recognition of their interest in everything that promotes universal adherence to these rules leads them to take pleasure in those mental qualities of persons that contribute most to making them just, faithful keepers of promises, loyal subjects, good treaty-makers and -keepers, and good husbands or wives. Only then, when reflecting on these pleasing qualities of persons from a general point of view, will each person's moral sense respond to these qualities with its own distinctive feeling, whereupon qualities originally prized only from self-interest at last come to elicit one's admiration as virtues.

What prompted Hume to classify these and other virtues as artificial rather than as natural, even though their origin in a recognition of the utility of certain mental qualities is no different from many natural virtues? Justice, for example, presupposes property, which, as an institution founded on a tacit convention, is, in Hume's view, thoroughly artificial, and in that sense unnatural. Although there is possession, property in the strict sense (as carrying an obligation not to hinder possession) does not yet exist in a state of nature, where something is mine if, by strength or wit, I can get it and keep anyone else who wants it from taking it. When goods are either too plentiful or too scarce, and generosity is confined to one's closest relations, there is no interest or intrinsic virtue to inhibit one from taking anything one wants from anyone else, even if one's need for it is not desperate. But when goods are neither too plentiful nor too scarce, a condition in which everyone takes whatever they want whenever they can prevents anyone from enjoying the benefit of secure possession of the goods they want or need for future use. The resulting dissatisfaction with the existing state of things thus creates an openness to change.

The problem is that it is not in my interest to leave anyone else in secure possession of my goods if I cannot be assured that the other person will do the same for me. This impasse is broken only with the establishment of a tacit convention, based on self-interest, of leaving others in possession of their goods provided they are prepared to leave one in possession of oneself. Moreover, since it is in the interest of all to be able to exchange some of the goods one has for others one needs or desires more, the convention of secure possession must also provide means whereby the goods of another can become one's own and vice versa, so that secure possession is transferred with them. Thus, through the artifice of tacit conventions, property in goods, over and above their mere possession, first comes into existence.

The reason that Hume classified justice in matters of property as an artificial virtue is that there is nothing about any good one desires to possess or retain, considered in and of itself, that can convey to one an idea of it as property. Property is unintelligible apart from established conventions, and conventions, however universal, tacit, and informal, are always artificial. For this reason, Hume denied that there is any natural interest or virtue in justice. Only after one has been inducted into the mysteries of the institution of property can one arrive at a recognition of one's interest in universal adherence to the rules requisite to maintaining it and so, *a fortiori*, come to prize as virtues the mental qualities most conducive to that interest. The same is true of every other virtue that presupposes human institutions founded on tacit conventions secured by a recognition of self-interest: contracts, laws, public offices, government, and so on. So, even though artificial virtues are no less genuine or powerful

expressions of moral sentiment than natural ones, Hume deemed them as unnatural to one's species as speaking English or paying in British currency.

RELIGION

One cannot be certain what Hume's actual views were with regard to belief in God. He was quite clear that he was not a Christian, and he seems to have regarded all religions as expressions of superstition, vestiges from less enlightened times that might (or might not) someday be superseded or wither away. However, Hume was also somewhat skeptical concerning contemporary atheistic conceptions. Matters are further complicated by the times in which he lived. Apart from legal sanctions (after a period of relative openness, new censorship laws began appearing in the late 1730s), a person's career prospects, social position, and tranquillity would be put in jeopardy by too open an expression of views liable to be construed as impious. For anyone unconcerned with mundane matters, zealous in the cause of atheism and enlightenment, desirous of being the focus of controversy, or sufficiently naive, these impediments might not matter. But Hume was not such a person. He was too worldly wise and fond of his place in society to bring down on himself the consequences of a frontal assault on the religious beliefs and institutions dear to the overwhelming majority of humankind. So, while many would agree with contemporary charges that his views on such matters as the general causal maxim and freedom of the will are implicative of atheism, Hume himself always professed the contrary (1978, pp. 409–10, 633n; 1999, pp. 160–164 1745/1967). And though his writings on religion seem to lead inexorably to the conclusion that a rational faith in God or revealed religion is an impossibility, he never ceased to proclaim that "the existence of a DEITY is plainly ascertained by reason" (1992, p. 280).

What is one to make of Hume's claims that his philosophy is consistent with, even supportive of, a rational belief in God? If these pretensions had been sincere, he would have had every reason to advertise the opinion, as other philosophers did who employed skepticism to humble reason to elevate faith. But one finds no evidence of this in his philosophizing beyond occasional brief asides, which seem too casually thrown out for one not to suspect that they are there merely to provide cover for his skeptical forays. It seems unquestionable that Philo, rightly regarded as Hume's principal mouthpiece in the *Dialogues concerning Natural Religion*, was not serving in that capacity when he declared that "[t]o be a philosophical skeptic is, in a man of letters, the first and most essen-

tial step towards being a sound, believing Christian" (1992, p. 292). Hume's actual skepticism points in a different direction, as a close examination of the arguments in his writings on religion reveals.

THE IDEA OF GOD. Hume professed agreement with Locke and other anti-innatists that the idea of "an infinitely intelligent, wise, and good Being" has its origin in one's "reflecting on the operations of our own mind, and augmenting, without limit, those qualities of goodness and wisdom" (1999, pp. 97–98). Nevertheless, he also maintained that the attempt to realize this definition in an idea is fraught with difficulty. Not only is "the capacity of the mind … limited, and can never attain a full and adequate conception of infinity" (1978, p. 26), even large numbers are representable only by means of the power of multiplying ideas, and, like all powers, rests ultimately on custom (pp. 22–23). The case of qualitative superlatives such as wisdom and goodness is even more problematic, for, finite or infinite, they "are not, like quantity or number, susceptible of any exact mensuration, which may be the standard" (1992, p. 281). In addition, Hume devoted the greater part of the *Dialogues* to showing that the empiricist definition of the divine founded on qualities of the human mind can never provide one with an idea remotely adequate to underwriting the conception of God featured in the discourse of philosophical theologians. Had he been bolder, he might also have applied to the case of God the implications of his associationist explications of the ideas of power and efficacy (necessary connection), substance, identity over time, the simplicity of complex beings, personhood, and reason. For their result is to show that these ideas are all inseparably bound up by content with the actions and affects of associative imagination, and so cannot be used to comprehend anything that exists prior to and independently of idea-enlivening, transition-facilitating. Therefore, it is ironic (no doubt intentionally so) that Hume ended up on the same side as the most pious monotheists (represented by Demea in the *Dialogues*) in insisting on the incomprehensibility of the nature of the divine.

A PRIORI ARGUMENTS FOR THE EXISTENCE OF GOD. The ontological argument for the existence of God advanced by many philosophers before Hume depends on treating existence as a property of God in the same sense in which goodness, wisdom, power, and other attributes are ascribed to the nature of divinity, and, moreover, like them, a necessary property. Hume argued against the first part of the thesis by denying that existence can ever be conceived of as a property, be it of God

or any other being. For to be able to do so, existence would have to be a distinct idea in its own right, capable of being combined with other ideas to form a complex idea, and there is no such idea in one's possession. Nor is the real existence attributed to God when, instead of merely conceiving him to exist, one believes him actually to exist, any new addition to the idea either, "When I think of God, when I think of him as existent, and when I believe him to be existent, my idea of him neither encreases nor diminishes" (1978, p. 94).

Even if there was an idea of real existence one could conjoin with one's idea of God, one still could not suppose it to apply necessarily, "Nothing that is distinctly conceivable implies a contradiction. Whatever we conceive as existent, we can also conceive as non-existent. There is no being, therefore, whose non-existence implies a contradiction. … The words, therefore, 'necessary existence' have no meaning; or, which is the same thing, none that is consistent" (1992, p. 251). If it is objected that God might in fact be a necessary existent even if existence does not attach to God of necessity in the idea one's feeble mind is able to form of divinity, the reply is that the same may be true of the unknown nature of any object, sensible objects included. The point is that one can never have reason to include existence in one's idea of God as a necessary attribute.

A POSTERIORI ARGUMENTS FOR THE EXISTENCE OF GOD.

Insofar as Hume's explications of ideas such as cause and effect show them to be bound up by content with the actions and affects of associative imagination, the scope of their application is limited to the purview of appropriately constituted conscious minds. Consequently, in order to even to raise the question whether experience provides any justification for inferring the existence of God, Hume had first to set aside these explications. This should not be forgotten when trying to assess the true nature and scope of his critique of *a posteriori* theistic reasoning.

COSMOLOGICAL ARGUMENTS FOR THE EXISTENCE OF GOD.

Many philosophical theists employ the general causal maxim to argue from the fact that something exists that some first cause must exist as well, since the supposition of an infinite regress of causes implies that the whole chain of causes and effects would lack a cause or reason for existing, and this is inconsistent with the maxim. Hume regarded such reasoning as fallacious:

> [T]he uniting of these parts into a whole, like the uniting of several distinct countries into one kingdom, or several distinct members into one

body, is performed merely by an arbitrary act of the mind, and has no influence on the nature of things. Did I show you the particular causes of each individual in a collection of twenty particles of matter, I should think it very unreasonable should you afterwards ask me what was the cause of the whole twenty. This is sufficiently explained in explaining the cause of these parts.

(1992, PP. 252–253)

ARGUMENTS FROM DESIGN.

Though given a pass in the *Treatise* and elsewhere in Hume's corpus, Hume subjected the design argument for the existence of God to critical scrutiny in section 11 of *Enquiry concerning Human Understanding*, "Of a Particular Providence and of a Future State." The discussion takes the form of a dialogue between Hume and a paradox-loving skeptical friend who imagines what Epicurus might have said in his defense if brought before a tribunal on charges of impiety and endangering the state because of his denial that religion (the existence of God and of a providence and future) can be established "upon principles of reason" (1999, p. 189).

For the sake of argument, Epicurus grants that the order, beauty, and wise arrangement everywhere observed in the universe cannot have resulted from material causes alone, so that the point at issue is what kind of author(s) can be inferred from the work according to the canons of empirical reasoning. Since the cause is something that has never been observed by any mortal, and since the given effect (the totality of design in nature) is so singular as to afford no basis for determining the general characteristics (species) of its cause, Epicurus maintains that one has no choice here but to subject one's reasoning to the "maxim, that where any cause is known only by its particular effects, it must be impossible to infer any new effects from that cause, since the qualities, which are requisite to produce these new effects along with the former, must either be different, or superior, or of more extensive operation, than those which simply produced the effect, whence alone the cause is supposed to be known to us" (1999, p. 196n).

This means that one must incorporate into one's conception of the cause the abundant empirical evidence of disorder, ugliness, indifference to human welfare, and the unjust distribution of talents, goods, and fates. So, even with the concession that matter and motion are insufficient to account for the world, the cause one is warranted in inferring from the effect as one empirically finds it falls far short of the superlative, benevolent intel-

ligence proponents of the design argument claim to be able to infer.

In the *Dialogues* this line of argument is deepened and expanded, even while Hume maintains the pretense that the design argument suffices to prove the existence of a deity and fails only when it comes to providing insight into the nature of that deity (like Kant after him, Hume suggests, in the *Dialogues* [dialogue 5], that empirical reasoning would need to be supplemented by *a priori* if this want were to be made good). It is impossible here to do justice to this splendid work, possibly the finest philosophical dialogue since Plato. Suffice it to say that its conclusion is "that the causes or causes of order in the universe probably bear some remote analogy to human intelligence" (1992, p. 291).

What this means becomes clearer in the light of Philo's observation in dialogue 7 that intelligence is just one of four known causes of order in the world and that the same claim of a remote analogy with the cause(s) of order in the universe can, with equal reason, be made for instinct (a bird's design of its nest), generation (of offspring by animals), and vegetation (seeding). Since even an atheist can admit that, in this highly attenuated analogical sense, it is proper to think of the cause of order in the world as similar to intelligence—and possibly to many other, as yet unknown principles of order as well—nothing of any consequence seems to be warranted by the conclusion reached in the *Dialogues*. Indeed, it is no wonder that Hume has Philo argue that the difference between atheists and certain theists is merely verbal (1992, pp. 280–281).

Nor does Philo deny that, among the unknown principles of order in the world, some may be inherent in matter itself, such that over vast periods of time, a minute probability that the motions of particles will eventuate in the production and replication of stable, orderly forms must eventually be realized (1992, pp. 244–247). Since other principles of order, known and unknown, may themselves be explicable in terms of principles inherent in matter, even the modest conclusion reached at the end of the *Dialogues* is put in jeopardy by this concession— "So dangerous is it to introduce this idea of necessity into the present question! And so naturally does it afford an inference directly opposite the religious hypothesis!" (p. 1992, p. 253) Since Hume elsewhere made no secret that he embraced necessity in precisely this sense, one cannot help wondering if the neo-Epicurean excursus in *Dialogues* (dialogue 7) was not intended to remind his reader of Hume's own explication of cause and effect, to the end of rejecting all causal reasoning in matters of religion—as

happens overtly in *Enquiry concerning Human Understanding*:

> It is only when two *species* of objects are found to be constantly conjoined, that we can infer the one from the other; and were an effect presented, which was entirely singular, and could not be comprehended under any known *species*, I do not see, that we could form any conjecture or inference at all concerning its cause. If experience and observation and analogy be, indeed, the only guides which we can reasonably follow in inferences of this nature, both the effect and cause must bear a similarity and resemblance to other effects and causes, which we know, and have found, in many instances, to be conjoined with each other. I leave it to your own reflections to pursue the consequences of this principle.
>

REASON AND REVELATION. Is it ever rational to accept the truth of revealed religion? Those who answer affirmatively typically point to prophecies fulfilled and miracles performed. Since such evidence comes to nearly all of us by way of oral or scriptural testimony, Hume asked if conditions exist under which one could rationally credit reports of prophesies and miracles and, if so, whether any revelation has ever met these conditions. The key to his reasoning in this matter is the recognition that human testimony on any topic owes whatever authority it has in the eyes of reason to the same source causal inferences do: past experience. Finding there to be a fairly constant conjunction between the facts as reported by witnesses and as ascertained by other means, one has only to hear or read (have an impression of) a report for one's mind not only to think (form an idea) of the event reported but also to believe it to the extent (enliven the idea to the degree) warranted by experience. For, besides lending authority to testimony in general, experience also teaches one that particular reports are more or less credible depending on the reporter, the circumstances under which the report is given and received, and the event reported itself. If a report falls short of maximum credibility on any of these counts, then reasonable persons must refuse to give it the same credence they accord to empirical beliefs founded on a frequently encountered, perfectly constant conjunction, having the certainty of proofs.

Reports of miracles are intrinsically suspect because the events they report are, by their nature, the least creditable. As defined by Hume, an event is miraculous only if it meets two conditions: it contradicts a law of nature and

does so "by the particular volition of the Deity, or by the interposition of some invisible agent" (1999, p. 173n). A law of nature is a causal sequence found by constant experience to be invariable, and so has the highest authority empirical reason can confer. Accordingly, to determine whether one can rationally credit any report of a miracle, one must follow the procedure empirical reason prescribes whenever two beliefs regarding matters of fact are found to conflict: deduct from the empirical support of one of the beliefs the amount of support possessed by the other and, if any support remains, accord it only so much credence as that remainder warrants; otherwise, discount it or (if the beliefs have equal support) refrain from believing either way. However, when one does this, one finds that

> no testimony is sufficient to establish a miracle, unless the testimony be of such a kind, that its falsehood would be more miraculous, than the fact, which it endeavours to establish: And even in that case, there is a mutual destruction of arguments, and the superior only gives us an assurance suitable to that degree of force, which remains, after deducting the inferior.
>
> (P. 174)

Since it is impossible that experience could ever give one reason to regard the falsehood of any report of miracles as more improbable than the falsehood of a law of nature, even the most credible testimony imaginable could not win one's acceptance if belief were always proportioned to experience. The same is true of prophecies, for these are simply a species of miracle ("If it did not exceed the capacity of human nature to foretel future events, it would be absurd to employ any prophecy as an argument for a divine mission or authority from heaven" [1999, p. 186]). Thus, one's acceptance of revealed religion can never possess the rational authority to which belief proportioned to the evidence of experience can alone lay claim.

RELIGIOUS BELIEF. Having established that one has no clear idea of God to underwrite religious discourse nor any rational basis for religious belief, Hume devoted the remainder of his discussion of miracles, as well as other writings ("The Natural History of Religion" [1757] most notably), to examining the nature and causes of religious belief. The upshot is that one believes in God and accepts the proofs of purported revelation from the same causes that lead one to form other beliefs not proportioned to experience (unphilosophical probabilities): failure to clarify one's ideas or to ascertain the existence of ideas

corresponding to one's words; education; credulity; self-interest; the influence of the passions; eloquence and other appeals to imagination that detach reason from its moorings in experience; the errors and exaggerations that tend to creep in with each new telling of a story; and so on. The implication is that, however widespread a religious belief may be, it is not imposed on one by human nature, and so is not irresistible in the way that belief in causes, continued distinct existents, and the self are.

Hume did not deny that religious belief can ever be agreeable or useful, either for the individual or society, but he did seem to think that, in the forms it actually takes—especially when vitiated by superstition or enthusiasm—it is neither. For example, in two essays, "Of Suicide" and "Of the Immortality of the Soul" (written in 1755 but published posthumously in 1777 [though a French edition appeared in 1770]), he argued that there is no rational or moral basis for the prohibition of the former or for belief in the latter. Still, his single most important philosophical contribution to the effort of combating the deleterious influence of religion is the example set by his theory of morals: It illustrates how universally valid moral standards can be understood nontheologically, in terms exclusively of natural sentiment and artificial interest.

HUMOR

Although the laughable is not usually thought of as a subclass of the beautiful (Aristotle, indeed, said that it was a subclass of the ugly), the problem of "humor" is a special case of the central problem of aesthetic theory. To find something laughable is to have a special kind of aesthetic emotion, but it is not at all easy to say just what features of the laughable situation evoke this emotion. Theories of humor attempt to answer this question.

TYPES OF HUMOR

The only way to evaluate theories of humor is to see how well they apply to different types of jokes or humorous situations. For this we need a list of the main types of humor. The attempt to provide one may, however, prejudge the issue, since the basis of classification may itself presuppose a theory of humor. Moreover, if any one theory is right, then in the final analysis jokes will be of only one type: They will all turn on release of inhibitions, or superiority to the misfortune of others, or whatever it may be.

With these reservations, the following may be regarded as the main types of humorous situations: (*a*) Any breach of the usual order of events, as wearing an unusual costume or eating with chopsticks when one is used to knife and fork (or with knife and fork when one is used to chopsticks). (*b*) Any breach of the usual order of events that is also felt to break a rule, whether of morality or etiquette. The drunkard, the glutton, the hypocrite, the miser are all stock figures of comedy, on the stage and elsewhere. (*c*) A special case of the second type is indecency, as in Restoration comedy or any smoking-room story. This has a different flavor from comic vice,

just as comic vice has a different flavor from mere novelty and oddity. (*d*) Introduction into one situation of what is felt to belong to another, as George Bernard Shaw's reference to conventional sexual morality as "the trade unionism of married women" or Mark Twain's introduction of a Connecticut Yankee into the Court of King Arthur. Finding connections between things we usually keep in separate compartments of our minds is, according to one version of the incongruity theory, the ultimate source of all humor. Whether this is correct or not, it is certainly one source that needs to be noted. (*e*) Anything masquerading as something it is not. This has been a favorite stage device, from *Twelfth Night* to *Charley's Aunt,* and is common enough in other forms of comedy. (*f*) Wordplay, of which puns are the most obvious, but not of course the only, example. (*g*) Nonsense, especially of the Edward Lear or Lewis Carroll type, which often turns on wordplay but is distinct from it. (*h*) Small misfortunes, like those provided by the banana skin, the custard pie, the thumb beneath the hammer. (*i*) Want of knowledge and skill, as in the schoolboy howler or the circus clown clumsily attempting to imitate the acrobat. (*j*) Veiled insults, as in the catty remarks in *The School for Scandal.*

THEORIES OF HUMOR

Most theories find the essence of humor in one or another of the following: superiority, incongruity, and relief from restraint. It has also been suggested that humor derives from ambivalent feelings, in which attraction and repulsion are both present.

SUPERIORITY THEORIES. If we laugh at the miser, the drunkard, the glutton, the henpecked husband, the man who gets hit by the custard pie, the schoolboy howler, the person with faulty pronunciation, may it not be because we feel superior to all of these? This could account for our pleasure in humor. Accordingly, Thomas Hobbes regarded laughter as the result of a sudden access of self-esteem ("sudden glory") when we realize that our own situations compare favorably with the misfortunes or infirmities of others. We also laugh, he said, at our own past follies—provided we are conscious of having surmounted them—or at unexpected successes.

In support of Hobbes, or perhaps as a modification of his view, it may be said that in humor at its best we are conscious of surveying the whole human scene from some godlike level at which all men and women look pretty much alike: all weak, all lovable, all transparently obvious in their petty pretenses. If "superiority" is interpreted as this god's-eye view rather than as simply a

sneering contempt for some failing we do not have, it is possible to account for laughter not merely at comic vice but also at comic virtue, as in Mr. Pickwick or Don Quixote. It may even explain why we often laugh with comic vice rather than at it. No one feels superior to Falstaff, but we may feel pleasantly conscious of "seeing through" him, and perhaps, in sympathizing with him, we feel superior, if only for the time being, to the conventional morality he flouts.

By extending Hobbes's theory in this way, it is possible to account for many of our classes of humor: indecency and masquerade as well as comic vice, small misfortunes, and ignorance. Alexander Bain extended Hobbes in two directions. Sometimes, Bain suggested, our laughter may be a manifestation not of our own feeling of superiority but of our sympathy with someone else who has triumphed in some way. This would account for laughter at veiled insults. Second, the triumph need not be over a person; it can be over anything at all that is conventionally treated with respect. Mark Twain's debunking of feudal values was not directed at any individual, and Samuel Butler degraded a sunrise by comparing it to a boiled lobster. According to Bain, the essential feature of humor is degradation. Some writers have argued, not very plausibly, that in wordplay we triumph over the degradation of words. More credibly, nonsense may be regarded as the degradation of what Arthur Schopenhauer called "that strict, untiring, troublesome governess, the reason." Even incongruity, it is argued, always involves degradation. Typically, the incongruous effect is obtained by the bringing of something exalted into contact with something trivial or disreputable. Shaw's phrase has its force because trade unionism is much lower on the conventional scale of values than is chastity: The pleasure in seeing them linked is, at least in part, malicious.

Henri Bergson maintained that the particular characteristic exciting derision is inflexibility, the inability to adapt oneself to the ever-changing demands of life. Laughter is always at "something mechanical encrusted upon the living." With Molière in mind, Bergson claimed that the comic character is usually a man with a fixed idea. This fits in with early stage comedy and with the etymology of the word *humor:* A humor was originally a quirk, a kink, a mental (and primarily a physiological) oddity that throws a man off balance and twists his view of life. Hence, the comic character is simply a man with an obsession. The joke is to see how this obsession crops up again and again in the most varied situations, so that he always behaves in a manner wildly inappropriate to the circumstances as others see them but entirely appropriate to his own ruling passion.

With more ingenuity than plausibility, Bergson attempted to apply his formula to wordplay, which consists, he claimed, in showing that language is too rigid to be an accurate mirror of an infinitely fluid universe. His main emphasis, however, was on the social function of laughter; it is leveled, according to him, at the eccentric or nonconformist. This seems an unduly restricted view: The most penetrating humor is often aimed at the social code itself. There is nothing in Bergson's theory of humor that need have prevented him from conceding this: The conventions of society may often enough be characterized as "something mechanical encrusted upon the living."

INCONGRUITY THEORIES. It can be doubted whether the concepts of "superiority" or "degradation" or even "inelasticity" do justice to the very large element of humor that consists in the intellectual and emotional pleasure of finding connections where none were thought to exist. It is true that if this were the whole of humor, humor would be indistinguishable from fancy or imagination; but then, if "degradation" were the whole of humor, humor would be indistinguishable from malice.

Immanuel Kant asserted that humor arises "from the sudden transformation of a strained expectation into nothing," and since his time incongruity has often been identified with "frustrated expectation." But there is more to incongruity than mere surprise, or even anticlimax; we must be, as it were, jolted out of one mental attitude into another completely and violently opposed to it. Usually this results from bringing together two things normally kept in separate compartments of our minds. Shaw's aphorism about the trade unionism of married women may once again serve as an example. Another is Butler's "God and the Devil are an effort after specialisation and division of labour." In Kant's view, the "degradation" of one of the two disparate ideas is quite incidental. What is important is that they normally evoke very different attitudes and that the connection between them appears to be genuine, not artificially contrived. It is on these two features that the neatness of a joke depends.

Kant's formula may be regarded as defective in that by putting the emphasis on surprise it ignores the logical connection between the two ideas that are linked. This is Schopenhauer's criticism. He claimed that all humor can be "traced to syllogism in the first figure with an undisputed major and an unexpected minor, which to a certain extent is only sophistically valid."

This formula applies most obviously to the mock-heroic or to certain types of satire. The point of Henry Fielding's *Jonathan Wild,* for example, might be summarized syllogistically as: All generals and those who behave like generals are heroes; highwaymen behave like generals; therefore, highwaymen are heroes. Here the major premise is, conventionally, undisputed. The minor is, no doubt, "only sophistically valid," but only "to a certain extent"; there is enough resemblance in behavior to give the satire sting.

The formula applies, however, to other types of humor as well. Oscar Wilde is reported to have said, when he was in prison, "If this is the way the Queen treats her convicts, she doesn't deserve to have any." Here the major premise is: "Those who ill-treat their dependents deserve to lose them." This generalization is then made to apply to a case in which losing them would be no hardship and deserving to lose them no demerit. What is sophistical about the minor premise is the assumption that a convict is, along with a servant, a child, and the like, the kind of dependent to whom the generalization applies.

The objection to Schopenhauer's analysis is that it stresses the formal side of a joke to the exclusion of the content. For him, humor was purely a matter of finding connections where (except in a "sophistical" sense) none exist. By this view, all humor is of the type of Richard Whately's *Historic Doubts Relative to Napoleon Bonaparte.* The essence of it lies in the ingenuity of the argument, underlined by the absurdity of the conclusion. If any derision creeps in, it is at the expense of the reasoning, or perhaps of the governess Reason herself.

What this overlooks is the part that the abrupt dissolution of an attitude plays in our emotional lives. Kant's phrase "strained expectation" hints at this but does not characterize it adequately. *Jonathan Wild* would not be funny if it were not for the whole complex of emotions that cluster round the concepts of patriotism and national glory. To take another example, Gerald Bullett's adaptation of Alfred, Lord Tennyson, "Wearing the white feather of a blameless life," is funny, not merely because of its close resemblance to the wording of the original ("the white *flower* of a blameless life") but because of the startling difference in attitude that results from the alteration of a single word.

So far as superiority theories call attention to the emotional element in humor, they do something to correct this inadequacy. It is doubtful, however, whether the emotion involved is either self-congratulation or malice. In any community certain attitudes are felt to be appropriate to some things and not to others, and there develop

"stereotypes" of such figures as the typical politician, poet, businessman. The humorist drags into light the inconvenient facts that shatter these attitudes and puncture these stereotypes. Sometimes, as Bergson pointed out, the humor is at the expense of the person who is unable to live up to the conventional requirements, and here malice may creep in, but often enough the effect is to cast doubt on the conventional attitudes and values. Sometimes it is not clear which effect is intended. Wilde's witticism "Work is the curse of the drinking classes" may be taken either as a gibe at the working classes or as a questioning of the conventional Victorian attitudes to work and to drink. In either case one element in our enjoyment is certainly the sense of enlarged horizons that comes from seeing unexpected connections. This is in part an intellectual pleasure. So far as it is a conventional attitude that has been convicted of inadequacy, the accompanying emotion may be not malice or superiority but a feeling of liberation at the removal of intellectual blinkers.

RELIEF THEORIES. Liberation, or relief from restraint, is regarded in a third type of theory as the central element in humor.

It is well known that people who have been undergoing a strain will sometimes burst into laughter if the strain is suddenly removed. It has been argued that all laughter is of this type and that any joke will be found, in one way or another, to remove the restraints which society imposes on our natural impulses. It is the liberation of our impulses from social constraints, not of our intellects from too narrow a point of view, that is emphasized by this type of theory.

What are these impulses that need liberating? One obvious one is the sexual impulse. Since the mention of the (conventionally) unmentionable is in itself a sufficient cause of laughter, it seems reasonable to say that at least one important type of humor depends on our being able to give vent to forbidden thoughts and feelings.

But thoughts about sex are not the only ones that society calls on us to suppress. Our aggressive impulses are also repressed. Children are taught that it is "rude" both to expose their bodies and to speak insultingly to others. Consequently, the relief theory can account, plausibly enough, for the malicious element in humor and, in general, for most of the aspects of humor that have given rise to superiority theories. Even nonsense can be explained, if it is conceded that trying to be rational all the time is a strain for most of us.

Relief theories have been given considerable impetus by the rise of psychoanalysis. Sigmund Freud himself wrote a book on humor, in which he suggested that there is a basic resemblance between jokes and dreams. Both are essentially means of outwitting the "censor," the name by means of which Freud personified our internal inhibitions. In dreams forbidden thoughts are distorted and disguised; in humor insults are veiled, masquerading perhaps as compliments, and sexual references lurk behind apparently innocent remarks.

Freud did not, however, regard all humor as the release of inhibition. He distinguished between "harmless wit," indulged in for its own sake, and "tendency wit," which gives us the additional gratification of giving rein to repressed sexual or aggressive impulses. Harmless wit delights us because it provides us with "infantile play-pleasure." In learning to use words, Freud pointed out, children "experience pleasurable effects which originate from the repetition of similarities, the rediscovery of the familiar, sound-associations," and the like. In other words, the pleasure of playing with words and ideas, on which incongruity theories place so much stress, is admitted by Freud to be enjoyable for its own sake, not just as a means of seeking relief from restraint. It is, indeed, because this intellectual play is enjoyable in itself that we can use it to beguile the censor. When Wilde, for example, complained that "the youth of to-day are quite monstrous; they have absolutely no respect for dyed hair," we must suppose that the censor is so diverted by the discovery that this remark differs only in one word from the conventional headshaking of the stuffier kind of matron that the malice in the remark (its complete exposure of the matron's pretensions and its revelation of her envy of youth) is allowed to go unchecked.

Freud explained "infantile play-pleasure" by invoking the concept of "psychic economy." In this he was influenced by Herbert Spencer. Spencer thought that humor consists essentially in the abrupt transition of thought from a noble or elevated idea to a trivial or degrading one, leaving the psyche with an unexpended fund of nervous energy that overflows into laughter, which is, according to him, a physical release of energy. Freud adapted this notion for his own purposes, identifying "psychic economy" first with the line of least resistance and then with the brevity and neatness that is the soul of wit.

Neither Spencer's nor Freud's use of the concept is very satisfactory. It may be pointed out against Spencer that when, for example, an innocent remark is transformed into a sexual reference, the second might be expected to call forth more emotional energy than the first. Against Freud it may be said that the lazy pleasure of following the path of least resistance is very different from our appreciation of the skill with which a master of humor links disparate ideas. When writers such as François Rabelais, G. K. Chesterton, Christopher Fry, James Joyce, and even Laurence Sterne play with words and ideas, it is exuberance rather than economy that they display.

RELATION OF THE THEORIES TO THE TYPES

If the theories are evaluated by their ability to explain the main types of humor listed earlier, it would seem that none is completely adequate by itself. Each of them relies mainly on particular kinds of humor, either ignoring the rest or giving relatively lame accounts of them. Satire and laughter at small misfortunes are very well explained by superiority theories. Incongruity theories find difficulty in dealing with these but are much more satisfactory than superiority theories in dealing with wordplay, nonsense, and indecency. Relief theories can explain malice and indecency, and perhaps nonsense, but are driven to admit that wordplay and the finding of unexpected connections have an intrinsic appeal that cannot be reduced to relief from restraint.

HUMOR [ADDENDUM]

Since 1980 a number of philosophers have explored the psychology, aesthetics, and ethics of humor. The incongruity theory dominates though, as in earlier theorizing, the precise relation of humor to incongruity is seldom made clear. Not just any experience of incongruity constitutes humor. Coming home to find one's family murdered would be incongruous but not funny. Even incongruity intended to be humorous may not be funny to everyone. What seems necessary for humorous amusement is that the incongruity be enjoyed.

The enjoyment of incongruity is not sufficient for amusement, however, for one may enjoy something bizarre or fantastic for its incongruity without being amused. Some people also enjoy grotesque and macabre works of art and horror movies and novels in part for their incongruity. In aesthetics there is no general agreement on what distinguishes amusement from such cases; one suggestion is that in amusement we tend to laugh.

Another psychological and aesthetic issue is the relation of humor to emotions. Since Plato most philosophers have treated amusement as an emotion, but there are significant differences between amusement and standard emotions. The practical orientation of standard emotions is lacking in amusement. Emotions evolved in early mammals as adaptive reactions to threats and opportunities. The bodily changes in fear and anger, for example, energize animals and humans for fighting or fleeing. Sexual love motivates reproductive activity and parental love motivates nurturing. But the bodily changes in amusement do not prepare us to take action; indeed, uncontrollable laughter is incapacitating.

A second difference is that amusement does not require belief in the reality of its object as emotions typically require belief in the reality of their objects. News that I have won the lottery might make me feel joy, but that joy evaporates when I discover that the news was false. Humor, by contrast, seems to work as well with playful, merely entertained thoughts as with beliefs. Indeed, those who produce jokes and other forms of comedy work mostly with intentional objects known by

everyone to be fictional. A third difference is that in standard emotions, there is a positive or negative attitude toward the object of those emotions while in amusement there need be no positive attitude toward the amusing object. People value what they love and what brings them joy, but they need not value the things they find funny. If at a funeral one sees someone dressed in a garish yellow and pink outfit, one may be amused without having a positive attitude toward that person or the outfit. Indeed, Aristotle classified the humorous as a species of the ugly.

These differences between amusement and standard emotions suggest that humor involves a more sophisticated kind of mental processing than is found in at least the basic emotions, and a different relation between its mental and physical components. Those who want to continue the Platonic classification of amusement as an emotion, then, one should at least provide an explanation of why these differences should not push amusement out of the category of emotion.

Turning lastly to the ethics of humor, since the mid-1970s, philosophers have examined humor that seems to express morally objectionable beliefs and attitudes, such as racism and sexism. Joke telling is often based on stereotypes representing various groups as stupid, lazy, greedy, or promiscuous. Are those who tell such jokes asserting or presupposing the truth of those stereotypes? One strong position, called *moralism* by Berys Gaut, says that appreciating a joke involves subscribing to the beliefs and attitudes it expresses, and so joke tellers are fully answerable to ethical considerations. At the other extreme is *antimoralism*, which treats humor as a form of play in which ideas and attitudes are merely entertained and not subscribed to, so that joke telling is not bound by ethical constraints. Antimoralists often point out that one can laugh at an ethnic joke merely for its cleverness. A joke about stupid Frisians can be amusing even though one has no idea who Frisians are! However, moralists point out that racists tell racist jokes to express and spread their beliefs and attitudes and not simply to play with ideas.

Whereas ethical examinations of humor have focused on what can be wrong with it, a few have shown how humor, particularly about oneself, can foster virtues such as humility, patience, tolerance, and forgiveness. The person with a rich sense of humor also tends to think critically, which has made humor a natural accompaniment to philosophy since Socrates.

HUS, JOHN
(c. 1369–1415)

John Hus, the Czech church reformer and national hero, was born at Husinec in southern Bohemia. He made his way through the University of Prague, receiving his A.B. in 1393, his M.A. in 1396, and his B.D. in 1404. Some of the logical works of John Wyclyf were known in Prague in the early 1390s, and there is still extant a copy of a half dozen of Wyclyf's philosophical works in Hus's hand, made in 1398. Wyclyf's realism (*universalia ante rem*) found a warm welcome among Czech professors and students, not least because the German community at the university was strongly Ockhamist and Wyclyf's vigorous defense of universals (prior to individuals) fortified the Czechs' position. He was deeply influenced by the Augustinianism of the Victorine school of the twelfth century.

Hus became well known and popular, partly for his teaching and partly for his preaching in the vernacular. In 1402 Hus was named stated preacher in the Bethlehem Chapel, and his sermons in Czech were well attended by Czechs of all classes. In October 1401 Hus was elected dean of the arts faculty and in 1403 rector of the university (though there is some uncertainty as to this first rectorate). By this time disputes over Wyclyf's teachings had become acrimonious, and Hus with some of his friends undertook to defend Wyclyf from charges of heresy against a party largely of German professors, who demanded strict condemnation of Wyclyf's teachings. Hus continued his preaching and writing in the interest of reform, but in 1408 the Prague conservative hierarchy (mainly German) lodged specific charges of heresy against him. Soon thereafter the struggle for predominance in the university broke out between Czech and German. The Germans had three votes, the Czechs only one. Hus led the fight for a reversal of the proportion, and King Wenceslaus decided in the Kutná Hora decree of 1409 that the Czech professors and students should have three votes and all others combined, one vote. The Germans left in a body to form the University of Leipzig. Hus, as leader of the national Czech party, was elected rector of the university.

Opposition to Hus on the part of the conservative Czech clergy remained, and the serious charges of 1408 were renewed in 1409 and 1410. He disobeyed a summons to Rome and was excommunicated in 1411. Hus had formed his opinions clearly by then and was prepared to defend them under any conditions. He believed firmly in predestination and the unity of the church under the headship of Christ. He was deeply influenced by the teaching of Wyclyf but in one important matter he categorically disagreed. He rejected Wyclyf's teaching on the Eucharist, accepting completely the church's doctrine of transubstantiation. Realist philosophy was important in the formulation of his theological positions, and his competence in Scholastic exposition is evident in all his writings. From the excommunication of 1411 to his death four years later it was clear that his position and that of the established hierarchy were irreconcilable. In 1412 King Wenceslaus reluctantly had to withdraw his protection, and Hus went into exile to relieve the city of Prague from the interdict. It was during his exile that he finished his most important work, the *De Ecclesia,* very similar to a book under the same title by Wyclyf. He argued against

the authority of the pope and the cardinalate over the church and their control of the means of salvation, basing his conclusions on the doctrine of predestination. "The church is the body of the predestinate." Inasmuch as only God knows who is predestinate, the pope's function and power are readily dispensable. The hierarchy could not tolerate so basic an attack on its existence. Hus appealed to the general council called for November 1414 at Constance and, receiving a safe-conduct from Emperor Sigismund, arrived in Constance on November 3. However, the safe-conduct was soon disregarded; Hus was imprisoned and interrogated at length. He asked simply to be shown from Scriptures or the Fathers where he was in error. The council demanded that he make a blanket recantation. No compromise was possible. Hus's concept of the church as the body of the predestinate, regardless of the decision of the pope and the hierarchy, was declared pure heresy. He was "relaxed to the secular arm" on July 6, 1415, and burned at the stake that morning. His martyrdom set off the Hussite Wars (1419–1434), which in turn isolated Bohemia from the rest of Europe for several generations. Hussitism, as it developed, took forms that Hus might not have approved.

Hus may not have been one of the leading minds of his century. On the other hand his commentary on the *Sententiae* of Peter Lombard, composed in 1407–1409, is a very impressive work and shows complete familiarity with the dominant currents of philosophical thought in the fourteenth and fifteenth centuries and an easy ability in the handling of contradictory arguments. His realism is confident and precise.

Bibliography

WORKS BY HUS

The early edition of his collected works (1558; reprinted in 1715) is still indispensable. Some of his works have been published in modern critical editions: *Opera,* edited by V. Flajšhans (Prague, 1903–1912), and *De Ecclesia,* edited by S. H. Thomson (Boulder, CO, 1956). Also indispensable is *Documenta … Mag. Joannis Hus,* edited by Francis Palacký (1869), containing his correspondence and salient documents of his career.

The Letters of John Hus. Manchester, U.K.: Manchester University Press, 1972.

WORKS ON HUS

There are several useful biographies in English, including D. S. Schaff, *John Huss* (New York: Scribners, 1915), and Francis Lützow, *Life and Times of Master John Hus* (London: Dent, 1909). Johann Loserth, *Hus and Wiclif* (London: Hodder and Stoughton, 1884), is bitterly anti-Hus, arguing that Hus borrowed all his ideas from Wyclyf. The classic study in Czech is by V. Novotný and V. Kybal, *M.J. Hus, Život a Učení,* 5 vols. (Prague: Laichter, 1919–1931). See also two more recent and important studies by P. de Vooght, *L'hérésie de Jean Huss* (Louvain, 1960) and *Hussiana* (Louvain: Bibliothèque de l'Université, Bureaux de la Revue, 1960).

HU SHI
(1891–1962)

Hu Shi, the Chinese pragmatist, was educated in China, at Cornell University, and at Columbia University under John Dewey. He was successively professor, chancellor of Peking National University, ambassador to the United States, and president of Academia Sinica in Taipei, Taiwan.

In 1916 he inaugurated the Literary Revolution in China by advocating the use of the vernacular style for writing instead of the formal, classical style, which, radically different from the spoken language, had become rigid and decadent. He succeeded in spite of strong opposition and thus set Chinese literature free. Since freedom of expression means also freedom of thought, the new literature led to the Intellectual Renaissance in China in 1917.

Hu did not claim to be a philosopher, but his own credo represented a new philosophy in China at the time. According to Hu Shi the universe, infinite in space and time, was not supernaturally created but is naturalistic and is governed by natural laws. All things, including psychological phenomena, have a scientific basis and can therefore be scientifically understood. Immortality is not personal but the sum total of individual achievement living on in the Larger Self. Truth must be historically and scientifically tested and is best expressed in democracy, freedom, progress, and social action.

His contributions to Chinese philosophy are important. As the leading disciple of Dewey in China, in 1919 he introduced pragmatism, which exerted tremendous influence and became the first concerted philosophical movement in twentieth-century China. Although the philosophy declined in influence in the later 1920s, its spirit of practical application, emphasis on problems

instead of theories, the insistence on results, the critical approach, and the scientific method had become the generally accepted outlook in China.

In his writings on Chinese philosophy Hu Shi was the first to give it a clear outline, free from religious beliefs and legendary philosophy. He provided it with a historical and social environment. Laozi, for example, was presented as a rebel against oppressive government and hypocritical society. Hu Shi discovered the methodology in Chinese philosophy, notably the "rectification of names" in Confucianism, the "three standards" or "laws of reasoning" in Mohism, and the method of "names and actuality" in other philosophers. He removed the mysticism of Laozi and Zhuangzi, whom he regarded as realists championing the cause of complete individual freedom. While these views are extreme, he created an entirely new atmosphere in Chinese philosophy.

HUSSERL, EDMUND
(1859–1938)

Edmund Husserl (1859–1938), the founding figure of the philosophical movement known as phenomenology, was born in Prossnitz in Mähren, then part of the Hapsburg Austro-Hungarian Empire but now Prostějow in Moravia in the Czech Republic. Husserl studied astronomy at Leipzig from 1876 to 1878 and mathematics in Berlin from mid-1878 to 1881 under the eminent mathematicians Karl Weierstrass (1815–1897) and Leopold Kronecker (1823–1891). Husserl completed his mathematical training in Vienna, receiving the PhD in January of 1883, and while completing his degree, he attended the philos-

ophy lectures of Franz Brentano (1838–1917). Husserl went back to Berlin briefly for further study with Weierstrass, but soon returned to Vienna to study philosophy again with Brentano from 1884 to 1886. At Brentano's suggestion, Husserl studied with Carl Stumpf (1849–1936) at the university at Halle, where in 1887 he submitted a *Habilitationsschrift* titled "Über den Begriff der Zahl. Psychologische Analysen." Husserl taught at Halle from 1887 to 1901, at Göttingen from 1901 to 1916, and at Freiburg from 1916 until his retirement in 1928.

Husserl published relatively little during his lifetime, and his publications were for the most part a series of introductions to phenomenology that were largely methodological and programmatic. However, these works were far from the total of his output. At his death he left more than forty-five thousand pages of unedited manuscripts written in shorthand, the continuing publication of which since 1950 has shed much light on the details and development of Husserl's philosophy.

PSYCHOLOGISM, PSYCHOLOGY, AND PHENOMENOLOGY

Husserl's *Philosophie der Arithmetik* (1891) attempts to realize Weierstrass's program of grounding mathematics in the cardinal numbers by describing those mental acts in which we are conscious of cardinal numbers. While Husserl was satisfied with his discussion of the intuitive presentation of the lower cardinals, he was dissatisfied with the psychologism in his analysis of the symbolic presentation of the higher cardinal numbers. Internal exigencies in Husserl's continued reflections on logic and mathematics—even by 1891—eventually turned him away from psychologism. By 1893 and 1894, Husserl clearly distinguished the subjective presentation, that is, the psychological act presenting an object, from both the logical content of the presentation and the object presented in the presentation, a threefold distinction much indebted to Bernard Bolzano (1781–1848) and Kasimir Twardowski (1866–1938). Husserl in the following years completed his critique of psychologism, culminating in his lectures on logic at Halle, lectures that form the basis for the *Prolegomena* to the *Logische Untersuchungen* (1900–1901), which is considered by many the locus classicus of the critique of psychologism.

Husserl criticizes psychologism for its reduction of the ideality and transcendence of logical objects (e.g., meanings, concepts, judgments, number, and so forth) to the reality and immanence of psychological contents, and for its reduction of the ideality and universality of logical laws to the factuality and generality of empirical, psycho-

logical laws. While rejecting psychologism, Husserl does not, however, altogether reject the descriptive-psychological approach of the *Philosophie der Arithmetik* or its results, for his anti-psychologism is united with the recognition that insofar as logical laws govern the ideal, objective content of acts of thinking, the relation between these ideal contents and the acts in which they are thought must be elucidated. Husserl's problematic in the main body of the *Logische Untersuchungen*, then, is to account for the relation between meaning and mind while preserving the objectivity and ideality of meaning. He typically poses this problem as a problem in epistemology, specifically, the problem concerning the relationship between the subjectivity of knowing and the objectivity of what is known. So, Husserl is committed to finding a new, nonpsychologistic epistemology to account for the relations among acts, ideal contents, and objects.

In the first edition of the fifth of the *Logische Untersuchungen* Husserl identifies phenomenological contents with psychological contents and distinguishes these from intentional contents. Ideal, intentional contents, in other words, are not properly included within the scope of a phenomenological description, and Husserl must account for meaning by appealing solely to the phenomenological-psychological contents. This is suspiciously close to a psychologism that accounts for meaning by focusing on the act. In the discussion of expressive acts in the first investigation Husserl avoids this conclusion by making the contents of the act that account for its intentional directedness the instantiation of an ideal essence, a meaning-species. The meaning itself remains objective and ideal, and the particular act's relation to this ideal meaning is one of instantiation such that the expressive act intends an object, whether or not that object exists, by means of conferring this meaning on a sensible sign.

Husserl contrasts these meaning-conferring intentions with fulfilling intentions that involve the actual presence of the object to consciousness and therefore involve some intuitive dimension. As Husserl later in the sixth of the *Logische Untersuchungen* turns to the discussion of these fulfilling acts, he recognizes that there are problems in his general account of meaning. Because fulfilling acts present the objects emptily intended in expressive acts, the sense of the fulfilling act is rooted in the object itself rather than in an ideal meaning-species. It is the sense of the object, the significance it has for us in its actual presence, that confirms or disconfirms what we intend as its sense in the expressive act that confers meaning on a sensible sign. Hence, Husserl recognizes that an

account of meaning cannot focus exclusively on the subjective conditions of objective knowledge.

In the second edition of the *Logische Untersuchungen* and *Ideen zu einer reinen Phänomenologie und phänomenologischen Philosophie. Erstes Buch* (both 1913), Husserl incorporates the intentional contents into the phenomenological contents on which he reflects. He thereby turns to the investigation of the correlation between what he in *Ideen* calls the *noesis*, that is, the intending act, and the *noema*, that is, the object just as intended. Some interpreters of Husserl's theory of intentionality as expressed in *Ideen* understand the noema to be an abstract, ideal intensional entity ontologically distinct from the intended object. This abstract entity can in turn be understood on the model of the *Logische Untersuchungen* as a type that is tokened in different acts having the same determinate object, or it can be understood as an abstract particular by means of which an object is intended. On both interpretations, the noema serves as a mediator between the act and its intended object. Other interpreters, however, claim that Husserl's continuing reflections on intentionality, especially those acts that can serve as fulfilling acts in which the object is intuitively grasped, made him aware of the philosophical difficulties in saying that the act's intentional relation to an object is mediated by an abstract entity. For these interpreters, the noema is the intended object just as intended (whether or not that object actually exists), and the object is the identity in the manifold of noematic presentations (whether veridical or not).

THE PHENOMENOLOGICAL REDUCTION AND TRANSCENDENTAL PHENOMENOLOGY

Husserl's goal was to develop a new philosophical science as the radical critique of the possibility of experience, a science that did not take the possibility of cognition for granted. However, because any science existing on the same plane as the natural and psychological sciences already presupposes both the possibility and the general validity of the experience of the world, this new science must exist on a different plane. This new plane—the plane of transcendental subjectivity—is disclosed by the methodological technique of the phenomenological reduction. Reminiscent of the universal Cartesian doubt, it is nevertheless different therefrom. Whereas the distinguishing characteristic of Cartesian doubt is that it annuls the positing of an object's existence or the validity of a judgment, the distinguishing characteristic of the phenomenological reduction is that it withholds participa-

tion in the positing of the existence of objects and the general validity of experience that characterizes one's natural experience—a positing Husserl characterizes as the general thesis of the natural attitude.

In suspending one's participation in the affirmation characteristic of ordinary experience, the objects given in experience are not lost to reflection but are instead considered only as presumed existents. They remain available for reflection just insofar as they are experienced; the index attaching to them, however, has changed, and their status as objects of experience has been modified so that they are now viewed exclusively in their being as objects of that experience in which they are originally posited. Concrete transcendental subjectivity includes its object as intended without reducing that object to an immanent, psychological content.

The reduction is a change in attitude that leads our attention back to the subjective achievements in which the object as experienced is disclosed in a determinate manner and to the achievements in which we realize the evidence appropriate to confirming or disconfirming their natural experiences. The reduction, in other words, leads our attention to the intentional correlation itself, and Husserl's discussions of intentionality and the reduction are inseparable. The subjective achievements, insofar as they are the medium of access to objects as experienced, have a certain kind of priority over the object that they disclose, but Husserl does not believe that all intelligibility derives from these achievements. The investigation of intentional achievements reveals: (1) how it is that we come to experience objects in determinate manners, including those objects that are always already there for us as transcendental subject before thinking becomes active in the world; (2) how our different experiences are related to one another, and, therefore (3) how the different kinds and levels of objectivity are related; and, finally (4) how our experience confirms or disconfirms in fulfilling intentions what was emptily or mistakenly intended.

Natural straightforward experience is directed to objects in their significance for us. However, it is possible to adjust the manner in which we attend to the object, and when doing so we focus attention not on the object as such but on its significance for us, its noematic sense. This is not to turn our attention to some different entity called a *sense* or *meaning*; it is simply to refocus attention from the significant object to the significance of the object as the object of an intending act. The methodological point picks out what the substantive analyses of meaning reveal as a way of proceeding; that is, we need to focus our attention on both the subjective and objective

conditions of meaning by focusing on the essential features of the correlation between the noetic and noematic dimensions of the experiences in which objects are disclosed in determinate ways. To turn our attention to this correlation is to perform the phenomenological reduction.

TEMPORALITY AND PASSIVE SYNTHESIS

The revision of the theory of intentionality and the development of the methodological principle of the phenomenological reduction are two of the three major developments in Husserl's thought during the Göttingen years. The third is the development of his views on the nature of the consciousness of inner time, a development that leads to the disclosure of absolute consciousness. A phenomenological description of the awareness of experience as temporally extended—that is, as beginning in the past, enduring in the present, and aimed at the future—requires that Husserl distinguish two strata in consciousness: (1) the nontemporal, time-constituting absolute consciousness that makes possible the awareness of inner time by virtue of a compound intentionality directed at once to the now, the just elapsed, and the yet to come; and (2) the flow of temporally ordered experiences themselves. This distinction accounts at once for the temporality of lived experience, for the momentary, prereflective awareness of that experience as a temporal unity, and for the prereflective self-awareness of one's own temporally ordered and unified stream of experiences.

Whereas the revisions in the theory of intentionality and the methodological discussions centered around the phenomenological reduction find their way into *Ideen*, the reflections on the nature of inner time-consciousness and absolute consciousness, which had reached a mature form by 1911, do not. The implications of the reflections on time-consciousness point toward a less static and more genetic account of the origin of sense or meaning, an account whose development becomes a dominant aspect of Husserl's reflections in the 1920s. These analyses, which develop an approach known as genetic phenomenology, take the form of extensions of the theory of time-consciousness, and in them Husserl describes the intentionalities at work in what he calls passive syntheses. These syntheses occur on two levels: the primary passivities of near and distant association and the secondary passivities of history, tradition, and community. This project comes to fruition in *Formale und transzendentale Logik* (1929) and *Die Krisis der europäischen Wis-*

senschaften und die transzendentale Phänomenologie (1936).

TRANSCENDENTAL LOGIC

Formale und transzendentale Logik, in which Husserl returns to the issue of the grounding of logical and mathematical sciences, brings his career full circle. The nature of logic cannot be fully clarified without the phenomenological reduction, for the reduction enables us to see more clearly how sense—in a manner relevant for logic—arises in our experience. Acts of judging are directed to categorially formed, complex states of affairs. The logical or apophantic domain first emerges in a critical turn occasioned by a concern with the truth or falsity of judgments. The positing involved in the straightforward encounter of objects and states of affairs is neutralized. However, this positing is not denied or negated; nor does the original state of affairs disappear from view to be replaced by a new entity—the proposition—that was always there but an unnoticed mediator in our intentional relation to the state of affairs. Instead attention is turned to the objective sense of the state of affairs as intended in the judging, and this objective sense is considered simply as a supposition in order to seek confirmation or disconfirmation of the state of affairs as supposed.

The judged state of affairs and the proposition are properly distinguished, therefore, by means of a difference in the way the meant objectivity is apprehended. Straightforward experience apprehends the categorial objectivity or state of affairs as such; critical reflection apprehends the state of affairs as supposed—that is, the supposition or proposition and, more precisely, the noematic sense of the intended state of affairs. Such critical or propositional reflection is continuous with our natural concern with the way things are. The natural concern with the truth of things is addressed in the interplay between the critical and natural attitudes, between the judgment as such and the state of affairs as such, between propositional reflection and the categorial intuition of states of affairs. Although it is only phenomenological reflection that grasps clearly what occurs in our apprehension of the logical domain, the critical reflection that focuses on the sense or logical content of an experience is different from the phenomenological reflection that views the object as the correlate of an intending. In a phenomenological reflection, the proposition is considered not in relation to the state of affairs straightforwardly experienced, but in relation to the critical experience in which it is intended.

Formale und transzendentale Logik also explores the relation between the Aristotelian and Leibnizian traditions in logic. Husserl contrasts formal apophantics derived from Aristotle with formal ontology derived from Leibniz's notion of mathesis universalis, but he also views them as inseparably united. The ground of their unity is the intentional relation between acts and their objects. Formal ontology results from the articulation of the formal structures, relations, and combinations of objects. Formal logic arises from the articulation of these same formal structures, relations, and combinations considered as meanings, as objective states of affairs merely as supposed. The meaning-forms are teleologically ordered toward fulfillment in our intuitive apprehension of object-forms. If the meanings are confirmed in fulfilling experiences, then the identity obtaining between meaning-forms and object-forms is disclosed. The identity-in-correlation of the logical and the ontological, therefore, is properly and fully a mathesis universalis realized only at what Husserl calls the third level of logic, the logic of truth.

While both the Méditations cartésiennes (1931), which, like Ideen, present an overview of Husserl's transcendental philosophy, and Formale und transzendentale Logik incorporate the results of Husserl's reflections on time-consciousness and passive synthesis, they remain focused on the nature of theoretical knowledge and the objectivity appropriate to it. They point to the need for regressive inquiries into the constitution of sense, inquiries that reveal the layering of sense over time and its development in intersubjective communities of inquirers. However, they continue to neglect in large part the historicality of the experiences themselves. Husserl addresses this question most explicitly in his last work Die Krisis der europäischen Wissenschaften und die transzendentale Phänomenologie (1936), as well as in texts collected and published posthumously as Erfahrung und Urteil (1939) and Analysen zur passiven Synthesis (1966).

HISTORY AND ETHICS.

The Krisis emphasizes how experiences in both the natural sciences and philosophy itself are formed within the context of living traditions. In this context, Husserl identifies the important notion of the life-world. His account of the life-world is somewhat ambiguous. It means at different times: (1) an abstractly conceived world on which higher meanings of the sort belonging to science, philosophy, and culture in general are grounded; and (2) the concrete world that is already pregiven and taken for granted in our experience, a world that already includes

the sedimented deposits of the history of science, philosophy, and culture. The first sense captures Husserl's idea that different levels of experience are built on more fundamental levels, and this abstract notion of the life-world is the meaning-fundament on which higher levels of sense are built. The second sense captures the idea that experience of the world is already historically formed in secondary passivities before someone comes to think actively about that world. This world is already rich in emotional dimensions, functional and practical dimensions, theoretical dimensions, and cultural dimensions. New experiences—new ways of making sense—both depart from this world and contribute to it. Although experience has an appropriate historicality, this does not negate Husserl's view that the ideal meanings constituted in experience can, in certain cases such as logic and mathematics, be trans-temporal in character.

Another dimension in which the concrete historicality of experience plays an important role is in Husserl's ethical reflections. His move to Freiburg had occurred in a period of political turmoil that soon turned into personal tragedy and that affected his philosophy profoundly. Husserl, who lost one son and whose other son suffered serious injuries in World War I, saw both the war and its aftermath as a sign of a loss of faith in reason. Moreover, although Husserl's postretirement years were active with continued writing and speaking, he was, after the rise of the Nazis to power, no longer free to teach or lecture in Germany. What for Husserl had, early in his career, been a philosophical crisis regarding the proper grounding of knowledge now at Freiburg revealed itself as a cultural crisis, the loss of faith in reason itself. In hindsight it can be said that there was always a moral urgency at the center of Husserl's philosophy, a moral imperative to retrieve a proper sense of rationality and to develop a sense of self-responsibility in which each person seeks the truth and decides about it for himself or herself in the light of evidence.

Husserl's early ethical reflections are centered around two themes: (1) values are constituted in emotional experiences that are grounded in objectifying acts; and (2) there is a need for a formal axiology and a formal theory of practice—both analogous to formal logic—that will counter ethical empiricism, analogous to psychologism, and establish universal moral norms. These two themes are in some tension. After World War I, however, Husserl focuses on the first theme and speaks of vocations—that is, commitments to certain goods that order and give moral meaning to life—and of absolute values grounded in love. Such language makes the enunciation of universal moral principles more difficult, but Husserl never abandoned his commitment to rationality in ethics. But his notion of reason was an expanded one; it is not merely theoretical reason, but axiological reason and practical reason. Just as theoretical reason is teleologically ordered toward the fulfillment of empty cognitive intentions, both axiological reason and practical reason are teleologically ordered toward the evidential fulfillment of empty axiological and volitional intentions.

It is just this commitment to reason and to fulfilling evidences that characterize the moral urgency at the center of all of Husserl's reflections. All are born into moral communities, but all must decide for themselves about what is truly good and about what emotions and actions are appropriate for different circumstances. And if one's vocation is a theoretical or philosophical one, then the search for truth regarding the transcendental conditions for truthfully encountering a world that has intertwined cognitive, affective, axiological, practical, and cultural dimensions must be the unwavering goal of one's reflections.

HUSSERL'S SUCCESSORS

The continual publication of Husserl's unedited manuscripts not only provides a more complete view of Husserl's thought and its development, but also affects one's view of the relations between Husserl and his successors. Discussions of embodiment, intersubjectivity, passive synthesis, community, tradition, and the life-world were all present in Husserl's work before any of the major works of his successors appeared. This implies that the understanding of these differences between Husserl and his successors must be carefully nuanced. In particular, the idea of a pure consciousness or ego separate from both the empirical ego and the world must be rejected in the light of the discussions of embodiment, volition, and historical community. Nevertheless, Husserl could criticize Merleau-Ponty and Heidegger for failing properly to distinguish, respectively, psychology and transcendental phenomenology or anthropology and transcendental phenomenology. Moreover, given his views on temporality and intentionality, Husserl could criticize Sartre for an inadequate view of the ego and a too voluntaristic account of intentionality. Just as his successors' critiques of him must be nuanced by what is known of Husserl's unedited writings, so too Husserl's critiques or potential critiques must not rely on too sharp a distinction between himself and his successors. This is especially the case with those analyses undertaken by his successors that in their own way involve a transcendental reduction even as they

emphasize more than Husserl did the worldliness and existential condition of the subject.

Bibliography

WORKS BY HUSSERL

Edmund Husserl Collected Works. The Hague: Martinus Nijhoff, and Dordrecht: Kluwer, 1980–. Ten volumes to date of English translations of Husserl's works supervised by the Husserl Archives:

Vol. 1. *Ideas Pertaining to a Pure Phenomenology and to a Phenomenological Philosophy*. Third Book: *Phenomenology and the Foundations of the Sciences*. Translated by Ted E. Klein and William E. Pohl, 1980.

Vol. 2. *Ideas Pertaining to a Pure Phenomenology and to a Phenomenological Philosophy*. First Book: *General Introduction to a Pure Phenomenology*. Translated by Fred Kersten, 1983.

Vol. 3. *Ideas Pertaining to a Pure Phenomenology and to a Phenomenological Philosophy*. Second Book: *Studies in the Phenomenology of Constitution*. Translated by Richard Rojcewicz and André Schuwer, 1989.

Vol. 4. *On the Phenomenology of the Consciousness of Internal Time (1893–1917)*. Translated by John B. Brough, 1991.

Vol. 5. *Early Writings in the Philosophy of Logic and Mathematics* Translated by Dallas Willard, 1994.

Vol. 6. *Psychological and Transcendental Phenomenology and the Confrontation with Heidegger (1927–1931)* Translated by Thomas Sheehan and Richard E. Palmer, 1997.

Vol. 7. *The Idea of Phenomenology*. Translated by Lee Hardy, 1999.

Vol. 8. *Thing and Space: Lectures of 1907*. Translated by Richard Rojcewicz, 1997.

Vol. 9. *Analyses concerning Passive and Active Synthesis: Lectures on Transcendental Logic*. Translated by Anthony J. Steinbock, 2001.

Vol. 10. *Philosophy of Arithmetic: Psychological and Logical Investigations, with Supplementary Texts from 1887–1901*. Translated by Dallas Willard, 2003.

Cartesian Meditations: An Introduction to Phenomenology. Translated by Dorion Cairns. The Hague: Martinus Nijhoff, 1960.

Formal and Transcendental Logic. Translated by Dorion Cairns. The Hague: Martinus Nijhoff, 1969.

Logical Investigations. Translated by J. N. Findlay. London: Routledge and Kegan Paul, 1970.

The Crisis of European Sciences and Transcendental Phenomenology: An Introduction to Phenomenological Philosophy. Translated by David Carr. Evanston, IL: Northwestern University Press, 1970.

Experience and Judgment: Investigations in a Genealogy of Logic. Translated by James S. Churchill and Karl Ameriks. Evanston, IL: Northwestern University Press, 1973.

HUTCHESON, FRANCIS
(1694–1746)

Francis Hutcheson, a moral-sense theorist, was born at Drumalig in County Down, Ulster. His father and grandfather were Presbyterian ministers. In 1711 he entered the University of Glasgow, taking both the arts and theological courses and probably finishing in 1717. He was licensed as a probationer preacher by the Ulster Presbyterians in 1719. Not long after, he was invited by the Presbyterians of Dublin to found a dissenting academy for their youth, and he remained in Dublin for the next ten years as head of the academy. His stay there was a turning point in the development of his thought, for he came under the influence of admirers of the Earl of Shaftesbury's philosophy. Hutcheson's first two, and perhaps most important, books were published during this period. The University of Glasgow elected Hutcheson to its professorship of moral philosophy in 1730, a position that he held until his death. In 1746, while visiting Dublin, he contracted a fever and died.

At Glasgow, Hutcheson devoted himself to enriching the culture and softening the Calvinism of his fellow Presbyterians. The Presbytery of Glasgow tried him for teaching, in contravention to the Westminster Confession, the following "false and dangerous" doctrines: (*a*) that the standard of moral goodness is the promotion of the happiness of others and (*b*) that it is possible to have a knowledge of good and evil without, and prior to, a knowledge of God. Afterward, Hutcheson was able to speak of the matter as the "whimsical buffoonery" about his heresy, but the fact that the charges were brought is doubtless a measure of the effectiveness of his teaching. David Hume sent a draft of Part III of *The Treatise of Human Nature,* "Of Morals," to Hutcheson for his comments prior to publication. Some indication of the spirit in which Hutcheson wrote his own work can be gathered from his rebuking Hume for a lack of warmth in the cause of virtue, which "all good men would relish, and could not displease among abstract enquiries."

THE MORAL SENSE

Hutcheson's contributions to philosophy lie in aesthetics and moral philosophy. In the one he offers a theory of an internal sense by which we perceive beauty, and in the other he offers a theory of a moral sense by which we perceive and approve virtue and perceive and condemn vice. Hutcheson meant his theory of the moral sense to be a contribution to the contemporary discussion of how to analyze man's moral knowledge. There were two sides in the discussion. Samuel Clarke and his followers held that moral distinctions are made by reason on the basis of our knowledge of the unchanging and unchangeable fitness of things. The other side, owing its original allegiance to Shaftesbury, held that moral distinctions are the deliverances of a moral sense.

Both sides held two points in common. First, moral knowledge must be accounted for by showing how it can be acquired by the exercise of some human faculty. In this respect they were all Lockeans: If something is knowable, you must show how it can be perceived. Second, moral knowledge cannot be simply a revelation from God, though of course God may enter the picture indirectly by having endowed us with our moral faculty. And when it came to picking out actual instances of virtue and vice, both sides were in agreement about the value of benevolence and the wrongness of acts of violence against other persons. Their debate, then, was over the character of the moral faculty.

PERCEPTION AND APPROVAL OF VIRTUE. Hutcheson plucked from Shaftesbury's rhapsodies the notion of a moral sense and endeavored to give a systematic account of it as the moral faculty of humankind. To see what Hutcheson's claim means, we must first of all consider what led him to make it. When you see someone doing something that is helpful to another, you say that his action is a virtuous one. But why is a helpful action counted as virtuous? It might be said that a helpful action is virtuous because it exhibits benevolence. But this does not take us very far, for we may still ask why benevolence is a criterion of virtue. Hutcheson knew the answer that some moral writers had given to this question: Helpfulness or benevolence is a possible relation between two human beings, and it is a fitting one. Therefore, it is virtuous. But how do you tell what is fitting and what is not? Your reason tells you. At this point, however, Hutcheson asked whether fittingness could be discovered by reason. After all, reason can tell us only that a certain relation does or does not exist; the moral quality of the relation, if any, remains to be apprehended. But by what?

Certainly not by reason, Hutcheson argued, because the moral quality is not a relation. And if not by reason, then the only thing left is a sense: the moral sense.

Hutcheson's task was to offer an account of how the moral sense works. He located the moral sense on the map of Lockean psychology. Its deliverances are ideas of reflection that arise from our original perceptions of human actions. As he first described the moral sense, it is a determination of our minds "to receive amiable or disagreeable ideas of actions." The "amiable idea" or, as he sometimes spoke of it, "our determination to be pleased," has two jobs. It is both our perception of the virtue of an action and our approval of it. It so happens that those actions which we discern to be virtuous are always benevolent actions, and we are necessarily determined to discern their virtue as soon as we observe them. Hutcheson attributed both the connection between virtue and benevolence and our necessary perception of the virtuousness of benevolence to arrangements superintended by God. Like sight, the moral sense is universal in humankind. But just as some men are born blind, and others have defective sight, some men have no moral sense at all and others have defective moral senses.

The strength of Hutcheson's theory of the moral sense lies in his having given an account of how we know that benevolent actions are virtuous: They are virtuous because they please. He was careful to point out that they please irrespective of any advantage they may have to ourselves. He noticed that we may indeed perceive as virtuous an action that displeases us because it goes against our selfish interest, and we may desire that someone act in a certain way even though we should call it vicious. He also argued that in the first instance the moral sense works independently of education, custom, and example. These factors may strengthen the moral sense but cannot create it, for they really presuppose a moral sense. In order for a person to be given an education in morality, he must already be able to discern moral qualities. Similarly, in order for customs to be moral customs and for examples to be moral examples, morality must already have been discovered in order to give these factors a moral character.

In saying that virtue is what it is because it pleases, Hutcheson thought that he had given a completely satisfactory account of the nature of virtue. By means of the moral sense, virtue is perceived for what it is. It is an end to be sought for itself, and no further characterization of it is required. Hutcheson's critics, however, found that he had paid a disastrous price for making virtue comprehensible by the human understanding. If virtue is that which pleases, then must any action that pleases be virtuous? Why are the actions that exhibit benevolence the only ones that are counted as virtuous? These questions seem bound to be asked despite the stipulations with which Hutcheson hedged his account of our knowledge of virtue.

Both his theory and its difficulties stem from Hutcheson's tacit assumption of the Lockean guide that a piece of knowledge must be accounted for through an appeal to the faculty by which it is known. It was not open to Hutcheson to try the gambit that it would be logically odd to call an act of highway robbery, for example, virtuous. His first line of defense was to insist that the deliverances of the moral sense with respect to virtue are a distinctive kind of pleasure. But in later editions of his *Inquiry concerning Moral Good and Evil,* Hutcheson played down the perceptual function and stressed approving and disapproving. Thus, the moral sense becomes a "determination of our minds to receive the simple ideas of approbation or condemnation, from actions observed … ." To call these ideas simple is to claim that they are not subject to further analysis and, hence, to further characterization. But this new position is not without its own difficulties. Approbation and condemnation are dispositions, not sensations; and only a most slavish allegiance to John Locke's model of the mind could lead one to construe all mental acts as perceptions.

MOTIVATION TO VIRTUOUS ACTION. Hutcheson's theory of the moral sense has yet a third part. As well as using it to account for the perception and approbation of virtue, he also used it to account for a person's motivation to behave in a virtuous way. A person pursues virtue because virtuous acts are pleasing to him and avoids vicious acts because they pain him. This account of moral motivation is perhaps the most convincing part of Hutcheson's theory. It enabled him to close the gap between someone's knowing what ways of acting are virtuous and his being inclined to act virtuously. Yet even here the theory gives us less than we might hope, for someone will be motivated to act benevolently only if benevolence pleases. And if other ways of acting please, even malevolence, perhaps, what then? Once more Hutcheson entered a stipulation too pat to be absolutely convincing: God has determined most people to be benevolent. Once again we must admit that he took this position for the best of reasons, for he was opposing those who would reduce all human motives to self-interest—and the many disinterested actions that people perform show the absurdity of this contention. But what Hutcheson's account of moral motivation requires is not the sensation of being pleased

with benevolence but a disposition to be benevolent. Unfortunately, the psychological theory on which Hutcheson relied required him to reduce all mental phenomena to some sort of perception. Thus, his account of motives lacks an effective analysis of dispositions.

AESTHETICS

Hutcheson's aesthetics closely parallels his theory of the moral sense. He found that we have an internal sense of beauty, a determination to be pleased by regular, harmonious, uniform objects, by grandeur, or by novelty. These perceptions occur necessarily and independently of our wills, but there is no corresponding "pain or disgust, any farther than what arises from disappointment." This limitation seems to have the curious consequence of leaving Hutcheson no room to account for perceptions of the ugly. The task of approving of the beautiful is not assigned to our sense of beauty. Presumably Hutcheson thought indifference to beauty allowable but indifference to virtue never so.

ROLE OF PASSIONS AND REASON IN MORAL LIFE

Hutcheson's *Essay on the Nature and Conduct of the Passions and Affections* and *Illustrations upon the Moral Sense* (published jointly in London, 1728) supplement the part of the *Inquiry* devoted to morals. In the essay on the passions, Hutcheson defined *sense* as every determination of the mind either to receive ideas independently of the will or to have perceptions of pleasure or pain. This definition led to the introduction of several new senses into Hutcheson's system. For instance, there is a public sense, which is our determination to be pleased by the happiness of others and to be uneasy at their misery. There is also the sense of honor, which makes the approbation or gratitude of others for any actions we have done the necessary occasion of pleasure.

In the *Illustrations upon the Moral Sense,* Hutcheson's general aim was to characterize the role of reason in the moral life. With regard to actions, Hutcheson said that we may reason either to account for what excites someone to act as he does or to account for what justifies our approbation of an act. For example, we give the "exciting" reason when we account for a luxury-loving man's pursuit of money by pointing out that money may be used to purchase pleasures. We give the "justifying" reason when we account for our approving of a man's risking his life in war by pointing out that his conduct evidences public spirit. But it is never true that reasons are to be found independently of feelings, for "exciting" reasons presuppose instincts and affections, and "justifying" reasons presuppose the moral sense.

Supposing that we get our ideas of virtue and vice through a moral sense, Hutcheson acknowledged that there are certain truths which might be proved by reason. These are (1) what actions or affections obtain the approbation of any observer, and what actions or affections obtain condemnation; (2) what quality of actions gains approbation; (3) what actions really evidence kind affections and tend to the greatest public good; and (4) what motives excite men to publicly useful actions.

Bibliography

Hutcheson first presented his philosophy in the *Inquiry into the Original of Our Ideas of Beauty and Virtue* (London, 1725). The *Inquiry* is divided into two parts: "Concerning Beauty, Order, Harmony, Design" and "concerning Moral Good and Evil." It is a much-revised work, the most notable changes occurring in the fourth edition (Glasgow, 1738). Lewis Amherst Selby-Bigge, ed., *The British Moralists* (Oxford: Clarendon Press, 1897), Vol. I, reproduces a substantial part of the second edition of the "Inquiry concerning Moral Good and Evil," which taken by itself is an incomplete representation of Hutcheson's thought. In *A Short Introduction to Moral Philosophy* (Glasgow: R. Foulis, 1747), an English version of the *Philosophiae Moralis Institutio Compendiaria* (Glasgow, 1742), Hutcheson uses "conscience" interchangeably with "moral sense," a possible sign of Butler's influence. Hutcheson is also the author of *A System of Moral Philosophy,* published posthumously in two volumes (London: A. Millar, 1755) by his son Francis. The *System* contains a biography by William Leechman. Other works by Hutcheson are *Metaphysical Synopsis* (Glasgow, 1742) and *Logical Compendium* (Glasgow, 1756).

For Hume's letters to Hutcheson, see J. Y. T. Grieg, ed., *The Letters of David Hume* (Oxford: Clarendon Press, 1932), Vol. I.

Contemporary criticism may be found in *Letters concerning the True Foundation of Virtue or Moral Goodness, wrote in Correspondence between Mr. Gilbert Burnet and Mr. Francis Hutcheson,* edited by Hutcheson (Glasgow, 1772), first published in the *London Journal* (1728).

Biographical and analytical material is contained in W. R. Scott, *Francis Hutcheson* (Cambridge, U.K.: Cambridge University Press, 1900); Ernest Albee, *History of English Utilitarianism* (London: Swan Sonnenschein, 1902); and T. Fowler, *Shaftesbury and Hutcheson* (London: Sampson, Low, Marston, Searle & Rivington, 1882).

For critical discussions, see James Bonar, *Moral Sense* (London: Allen and Unwin, 1930), and D. D. Raphael, *The Moral Sense* (London: Oxford University Press, 1947).

Elmer Sprague (1967)

HUTCHESON, FRANCIS [ADDENDUM]

Although Francis Hutcheson's name is frequently associated with the third Earl of Shaftesbury (1671–1713), the truth is that once he rejects John Locke's (1632–1704) contention that beauty is a complex idea, his aesthetic theory is thoroughly Lockean. That beauty is a simple idea, for Hutcheson, is made clear when he postulates a sense of beauty as necessary to perceive it. And such a move is fully sanctioned by Locke himself when he writes that "I have here followed the common opinion of men's having but five senses, though, perhaps there may justly be counted more" (John Locke, *Essay concerning Human Understanding*, II, ii, 3).

Hutcheson's most succinct and influential statement of his basic position goes as follows: "[T]he word *beauty* is taken for *the idea raised in us*, and a *sense* of beauty for *our power of receiving this idea*" (*Inquiry concerning Beauty*, I, ix, p. 34).

The idea of beauty, which is a simple idea, is caused to be excited in the sense of beauty, however, by a complex idea, namely any collection of ideas that possesses what Hutcheson calls "uniformity amidst variety." The sense of beauty perceives ideas, and not the external world directly, because it is what Hutcheson calls a "reflex" or "subsequent" sense, requiring the five "external" senses to provide its objects.

Few today will find this Lockean account of beauty and its perception at all plausible. Nonetheless, it is no exaggeration that it defined and drove aesthetic speculation through the whole of the eighteenth century in Great Britain. And because it was philosophy at the cutting edge, the influence was good, even though it turned out the doctrine was not.

HUXLEY, THOMAS HENRY
(1825–1895)

Thomas Henry Huxley, the biologist and the most versatile man of science of nineteenth-century England, was born at Ealing, near London. Like many eminent Victorians, Huxley was self-educated. While still an adolescent he read extensively in history and philosophy, learned several foreign languages, and began a medical apprenticeship. In 1842 he entered Charing Cross Hospital, where he distinguished himself by winning prizes in chemistry, anatomy, and physiology, and by publishing his first research paper. From 1846 to 1850 he was assistant surgeon on H.M.S. *Rattlesnake* while it conducted surveying operations in Australian waters. Huxley made capital out of this voyage, as Charles Darwin had done on the voyage of the *Beagle,* and sent home a number of scientific papers dealing with marine animals. These papers established his reputation as a first-rate biologist, and in 1851 he was elected a fellow of the Royal Society. After leaving the navy he settled in London, where he eventually obtained several small appointments, the chief one being that of naturalist at the Government School of Mines. Here he began his paleontological investigations, which resulted in more than twenty memoirs on the anatomy and classification of fossils. During the next four decades Huxley became one of the intellectual leaders of England. His strong, skeptical, earnest mind was enlisted on behalf of a great variety of causes. He championed Darwin's theory of evolution, disputed with churchmen about the Bible, worked for educational reforms, served on eight royal commissions, and refused a professorship at Oxford. As a public lecturer he was brilliant at clarifying abstruse subjects and developing polemical arguments. He also wrote copiously in forceful, eloquent prose. Yet he produced no really seminal ideas or magnum opus, partly because his efforts were so dispersed. In the following discussion, attention will be limited his views on the nature of science, metaphysics, ethics, and religion.

THE NATURE OF SCIENCE

For Huxley, two aspects of the sciences were of special importance. One was their historical continuity with modes of thought used by men in the ordinary commerce of life. "Science," he once said, "is nothing but trained and organized common sense, differing from the latter only as a veteran may differ from a raw recruit … . The man of science, in fact, simply uses with scrupulous exactness the methods which we all habitually use carelessly" (*Collected Essays,* Vol. III, pp. 45–46). Hence there is a unity of pro-

cedure in all the sciences. This was the other aspect of the sciences that he deemed important, because it allowed a specification to be given of the steps that must be taken if the procedure is to be properly carried out. In an essay of 1854, "On the Educational Value of the Natural History Sciences" (*Collected Essays,* Vol. III), Huxley listed the steps as: (1) observation of the facts, including those elicited by experiment; (2) comparison and classification, leading to general propositions; (3) deduction from the general propositions to the facts again; and (4) verification. Later he came to see that hypotheses are essential to the procedure of science, especially as devices for "anticipating nature." But he did not sufficiently stress the connection between a hypothesis and the scientific problem that initiates an inquiry, or the role of the hypothesis in determining what facts are to be observed.

EVOLUTION

It was the effective use of scientific method in Darwin's *Origin of Species* that helped to convert Huxley to the doctrine of evolution by natural selection. As a young man he had held antievolutionary views, not because he believed in the special creation of species, but because he failed to find a scientific explanation of how their transmutation could have been effected. Darwin's book proved to be "a flash of light which, to a man who has lost himself in a dark night, suddenly reveals a road that, whether it takes him straight home or not, certainly goes his way" (*Life and Letters of T. H. Huxley,* Vol. I, pp. 245–246). His reflection on having mastered Darwin's central thesis was, "How exceedingly stupid not to have thought of that."

Huxley espoused Darwinism not as a dogma, however, but as a "most ingenious hypothesis" that offered a rational account of how the organic world came to be what it is. The hypothesis was not contradicted by any known evidence, nor was it seriously rivaled; yet it was not established beyond a shadow of doubt. For instance, certain physiological peculiarities of organisms, such as hybrid sterility, had still to be explained in terms of natural selection. To Huxley, some of Darwin's formulations seemed quite unsatisfactory. To speak of variations "arising spontaneously" was to employ "a conveniently erroneous phrase." To commit oneself to the principle *natura non facit saltum* ("nature makes no leap") was to invite needless trouble. For in fact, Huxley declared, "Nature does make jumps now and then, and a recognition of this is of no small importance in disposing of many minor objections to the doctrine of transmutation" (*Collected Essays,* Vol. II, p. 77). But even if it remained to be shown that natural selection sufficed for the production of

species, "few can doubt that it is a very important factor in this operation." To that extent Darwinism was certainly here to stay.

Huxley was sensitive to a number of philosophical questions generated by the theory of evolution. The questions that particularly interested him arose when three considerations were taken seriously. First, like all scientific theories, Darwinism "starts with certain postulates … and the validity of these postulates is a problem of metaphysics." Second, the theory of evolution had to be extended to the cosmos as a whole, if its scope was not to be arbitrarily restricted. But at that point philosophical issues had to be faced. Did the cosmos evolve from some "epicurean chance-world," or had its order been eternally the same? Finally, the study of organisms pointed to the conclusion that they began as, and are now, physico-chemical systems. It could therefore be assumed that molecular motions are the basis of all vital processes, including so-called conscious ones. But if this was so, metaphysical materialism gained strong support.

METAPHYSICS AND EPISTEMOLOGY

The philosophical standpoint most congenial to Huxley was derived from his reading of René Descartes, George Berkeley, and David Hume. Of prime importance was the contention "that our certain knowledge does not extend beyond states of consciousness, or the phenomena of mind. … Our sensations, our pleasures, our pains, and the relations of these, make up the sum total of the elements of positive, unquestionable knowledge" (*Collected Essays,* Vol. VI, pp. 317–318). Beyond this we have only uncertain inferences or beliefs. Hence, when we talk about "matter" and "the physical world," we are interpreting some mental phenomena, just as we are interpreting other phenomena when we talk about "mind" and "the self." For matter is only a postulated cause of certain conscious states, in the same way that mind is a postulated substratum of those same states. This is all that criticism leaves of "the idols set up by the spurious metaphysics of vulgar common sense."

Huxley expressed many of his philosophical ideas in a book on Hume that he wrote for the English Men of Letters series in 1878. He agreed with Hume's account of perception as a process that yields only sense impressions, but he held that Hume had failed "to recognize the elementary character of impressions of relation" and also had failed to make clear that having a sense impression is a case of knowing. Hume had correctly represented the order of nature as an unbroken succession of causes and effects, so that there can be no uncaused volitions such as

proponents of "free will" postulate. But determinism, Huxley affirmed, is entirely compatible with ascribing responsibility to human beings for their deliberate actions. As Hume had rightly understood, "the very idea of responsibility implies the belief in the necessary connexion of certain actions with certain states of mind" (*Collected Essays,* Vol. VI, p. 222).

METAPHYSICAL PRESUPPOSITIONS OF SCIENCE. From this philosophical standpoint, Huxley dealt with questions that fall under the three considerations mentioned above. Science, he affirmed, postulates a rational order of nature, the operation of material forces, the universality of causation, and the immutable necessity of laws. All these factors need to be properly interpreted. Thus, "nature" is simply the totality of phenomena, whose regular occurrence constitutes nature's "rational order." Material forces are at best hypothetical entities which Huxley said he could not conceive clearly. As Hume had insisted, "causation" refers to the relation of invariable succession among phenomena. "Necessity" is a term that should be limited to logic and has no warranted application to the physical world. For the laws that science formulates are records of observed regularities, not agents which "force" things to happen as they do. Hence, "our highest and surest generalizations remain on the level of justifiable expectations, that is, very high probabilities." The quest for certainty in science is an irrational pursuit.

AGNOSTICISM. It is also irrational to hope that we can ever know anything about the ultimate origin or ultimate nature of the universe. Speculation about such matters is fruitless, for they lie outside the limits of philosophical inquiry. To identify his position on this issue, Huxley coined the name "agnostic" about 1869. "It came into my head," he said, "as suggestively antithetical to the "agnostic" of Church history, who professed to know so much about the very things of which I was ignorant" (*Life and Letters of T. H. Huxley,* Vol. I, p. 462). Agnosticism, however, is not another creed; it is an outlook that results from the adoption of a principle, at once intellectual and moral, which states that a man ought not to assert that he knows a proposition to be true unless he can produce adequate evidence to support it. Conversely, an agnostic repudiates as immoral "the doctrine that there are propositions which men ought to believe without logically satisfactory evidence." The justification of this principle lies in the success which follows upon its application, whether in the field of natural or of human history.

Because of an agnostic's outlook, he cannot accept the tenets of metaphysical materialism, according to which nothing exists in the world save matter, force, and necessity. For these three concepts are intelligible only insofar as they are related to the phenomena of mind. Hence, "Materialism is as utterly devoid of justification as the most baseless of theological dogmas." Yet to reject materialism is by no means to espouse idealism or spiritualism. "Spiritualism is, after all, little better than Materialism turned upside down" (*Collected Essays,* Vol. IX, p. 133). Nor does it follow that the sciences must eschew materialistic language. On the contrary, such language is often useful in investigating the order of nature, as Huxley himself showed in more than one paper. But to use materialistic language for scientific purposes is quite different from accepting a metaphysics based on materialism.

EPIPHENOMENALISM. As a biologist, Huxley took the view that the bodies of animals, including humans are best regarded as mechanical systems. Yet the mind and states of consciousness undeniably exist, and their relation to the working of the physical body has to be explained. This was the question Huxley discussed in a well-known paper of 1874, "On the Hypothesis that Animals are Automata." States of consciousness are represented as being no more than effects of bodily processes—chiefly, the molecular changes in brain substance that has attained a certain degree of organization. Furthermore, no evidence can be found for supposing "that any state of consciousness is the cause of change in the motion of the matter of the organism." Animals, then, are conscious automata. The working of their bodily mechanism is unaffected by their mental activity. "The mind stands related to the body as the bell of the clock to the works, and consciousness answers to the sound which the bell gives out when it is struck." This is Huxley's version of epiphenomenalism. The doctrine did not purport to give an ultimate explanation of the mind-body relationship. It did not even purport to explain how the passage from molecular movement to conscious states is effected. Concerning the details of this passage, he declared, "I really know nothing and never hope to know anything."

RELIGION

The greatest impact of Huxley's agnosticism was on the religious dogmas of his time. As a young man he accepted a form of theism. In a paper of 1856, "On Natural History as Knowledge, Discipline, and Power" (*Royal Institution Proceedings,* London, Vol. II, 1854–1858, pp. 187–195), he

contended that the design revealed by nature pointed to the existence of an Infinite Mind as its author. But he discarded this view when he became a Darwinian, on the ground that the argument from design had received its deathblow. Thenceforth, he attacked those who claimed to prove that a supernatural God exists, or who affirmed that biblical and Christian doctrines are rationally credible. His most dramatic clash was with Bishop Wilberforce at the Oxford meeting of the British Association in June 1860, and his most protracted controversy was with W. E Gladstone in the pages of the *Nineteenth Century,* from 1885 to 1891. Neither of these defenders of the faith was a match for Huxley.

MIRACLES. Huxley hammered away at the inconsistencies in, and the lack of evidence for, the biblical cosmology, the creation stories, and the belief in demons, spirits, and miraculous occurrences that Christianity requires. The subject of miracles was of deep interest to him; miracles could not be rejected as impossible, he thought, because they are logically conceivable. Hence Hume's a priori reasoning against them was mistaken. Yet one can say that the occurrence of an alleged miracle, being antecedently a most improbable event, needs strong supporting evidence. But in each recorded case, evidence of this kind was lacking. In several essays Huxley discussed particular biblical reports of miracles and found them unconvincing.

GOD. Although he rejected supernaturalism, Huxley was prepared to accept a Spinozistic conception of God as being identical with nature in its infinite complexity. "The God so conceived is one that only a very great fool would deny, even in his heart. Physical science is as little Atheistic as it is Materialistic" (*Collected Essays,* Vol. IX, p. 140). Once, in a letter to Charles Kingsley, he said that he believed in "the Divine Government" of the universe. The phrase expressed his conviction that the cosmic process is rational rather than random, that the reign of law is universal, and that the order of nature has existed "throughout all duration." Yet the governing principles of the universe appear to be amoral, since what happens to men is "accompanied by pleasures and pains, the incidence of which, in the majority of cases, has not the slightest reference to moral desert" (*Collected Essays,* Vol. IX, p. 202).

ETHICS

Toward the close of his life Huxley thought a good deal about the foundations of morality. He was dissatisfied with the attempts of Darwin and Herbert Spencer to harmonize man's moral sentiments and the theory of evolu-

tion. It was not that he doubted the evolutionary origin of those sentiments; what he doubted was whether Darwin or Spencer had appreciated the extent to which morality and nature are at war with each other. This was the theme with which he startled the Victorian world in his famous Romanes lecture, "Evolution and Ethics" (*Collected Essays,* Vol. IX, pp. 46–116), on May 18, 1893.

Its central contention is that "ethical nature, while born of cosmic nature, is necessarily at enmity with its parent." For a dominant feature of the natural world is "the intense and unceasing competition of the struggle for existence." Thomas Hobbes's depiction of nature as the war of all against all is correct. In this world, ruthless and predatory action is "best" for the individual. But in human society, "ape and tiger methods" are precisely what man's moral sense condemns. Hence, the practice of that which is *morally* best involves a repudiation of "the gladiatorial theory of existence" portrayed by Darwinism: "Let us understand, once for all, that the ethical progress of society depends, not on imitating the cosmic process, still less in running away from it, but in combating it." Accordingly, man although himself a product of evolution, has an obligation to subjugate the amoral or immoral aspects of evolution to moral ends. Yet Huxley's grounds for this conclusion are by no means clear. His only recourse was to fall back on a kind of ethical intuitionism which is hardly compatible with his other views.

The philosophical garment that Huxley wove is coarsely textured and has a number of loose ends. Thus his radical phenomenalism is not carefully interwoven with his evolutionism, and his agnosticism seems unconnected with his Spinozistic affirmations. Yet his grasp of philosophical issues was remarkable for a man who was also a leading scientist, educator, and public figure of his time.

HYPATIA
(370/75–415 CE)

Hypatia was a philosopher, mathematician, and astronomer who, though female and pagan, achieved the honor of being named by the Christian Roman government to the position of philosopher at the museum of Alexandria. Students reading philosophy at the Alexandrian School would also study mathematics and astronomy as technical, applied disciplines of the more traditional studies of metaphysics and cosmology. Hypatia's father, Theon of Alexandria, was the museum's most famous mathematician-astronomer, and it is largely through Theon that we have a reliable source of Ptolemy's *Syntaxis Mathematica* (*Almagest*).

Hypatia likely assumed the directorship of the school of philosophy in about 400. The recently converted Christian, Synesius of Cyrene, later the bishop of Ptolemais, became her student in 393. From Synesius's works we surmise that Hypatia's early philosophical teachings concentrated on Plato's metaphysical works, especially the *Timeaus*. Her mathematical and astronomical writings can be understood primarily as applications of Neoplatonist metaphysical and cosmological theories to mathematical problems whose solution informed astronomical theories. These in turn were considered to illuminate Neoplatonist cosmological theories. Six of Hypatia's works have been tentatively identified. They include an edition of Diophantus's *Arithmetica* with new lemmas, a lost prototype based on Archimedes's *Sphere and Cylinder* surviving as John of Tynemouth's *De Curvis Superficibus*, a text on isoperimetric figures incorporated by a later author into *Introduction to the Almagest*, a commentary on Archimedes's *Dimension of the Circle*, and a commentary edition of Apollonius Pergaeus's *Conics* upon which later commentary editions were based. But her most important work appears to have been a revision of a work by her father Theon appearing in Book III of his *Commentary of Ptolemy's Syntaxis Mathematica*.

Hypatia was an eclectic philosopher with a Cynic's literary and personal style that may have had as much to do with her risky status as both woman and pagan as with her philosophical affiliation. Accounts of outrageous tactics to counter sexist male student behavior may be apocryphal (Lewis 1921, Toland 1720). Nevertheless, they provide insight into the personality of a defensive female professor in a brutally misogynist environment. A traditional middle Platonist, Hypatia was sympathetic to Porphyrian metaphysics and to Stoicism. She preferred Euclidean methodology to the Archimedean in formulat-

ing results of problems and as a pedagogical tool for teaching philosophical mathematics. In 415, she was savagely dismembered by a gang of monks. She appears to have been succeeded by Hierocles.

HYPPOLITE, JEAN
(1907–1968)

Born at Jonzac, France, Jean Hyppolite had an illustrious university career: professor at Université de Strasbourg in 1945; at the Sorbonne in Paris in 1949; director of the Ecole Normale Supérieure in 1954; and finally, the chair at the Collège de France in "Histoire des systèmes" from 1963 until his death. He belonged to the post–World War II generation of French philosophers that included Maurice Merleau-Ponty, Jean-Paul Sartre, and Jacques Lacan. However, Hyppolite's most enduring legacy is his students from the Sorbonne and the Ecole Normale Supérieure: Jacques Derrida, Gilles Deleuze, and Michel Foucault.

Hyppolite became famous as the French translator of Hegel's *The Phenomenology of Spirit* in 1941. He then produced a commentary, *Genesis and Structure of Hegel's Phenomenology of Spirit*, in 1947. In many essays, Hyppolite recounts the French reception of Hegel. The French reception had first been formed by Jean Wahl, but during the 1930s especially by the humanistic reading Kojève produced. Kojève's reading had oriented the philosophies of Sartre and the early Merleau-Ponty. Hyppolite, how-

ever, tried to show that Hegel goes beyond the human, an attempt that is obvious in his *Genesis and Structure*: Its chapter on the master-slave dialectic—the foundation for Kojève's humanistic reading—is its shortest, about three pages long.

Nevertheless, *Genesis and Structure* aims to be a comprehensive reading of Hegel's *Phenomenology of Spirit*. Indeed, it is a classic reading of a philosophical text, for it not only tracks all of the dialectical movement or procedures of the *Phenomenology*, but also shows how they are connected to the history of philosophy, how they are connected to other German idealists such as Friedrich Wilhelm Joseph von Schelling, and finally how the book itself grew out of Hegel's earlier reflections—in particular, his earlier Jena Logic. But Hyppolite's text is not only a classic reading, it is a masterful philosophical text in its own right. Unlike Kojève—for whom the leading question was how man take possession of himself as the purpose of all dialectical development—Hyppolite's leading question was: "How is the *Phenomenology* connected to the later *Logic*?" In other words, even if there is an ambiguity in Hegelianism between phenomenology (as the science of the appearances of the forms of consciousness, resulting in absolute knowledge) and ontology (as the science of all being), which one is the authentic mode of procedure in Hegelianism? Is Hegel's ontologic independent of all phenomenology? All of *Genesis and Structure* is directed at responding to this question. For Hyppolite, the intersection of knowledge and being is central to Hegelianism.

The centrality of this intersection becomes most evident in Hyppolite's 1952 *Logic and Existence*, a text that makes three basic claims. First, Hyppolite tries to show that Hegel's philosophy is a logic in the literal sense of the word, a *logos*: language. If we start from language, we can see that Hegel's philosophy attempts to reconstruct the genesis from sensible (experience) to sense (or essence). But second, again if we start from language, we can see that Hegel's thought "completes immanence," as Hyppolite says. This claim means that Hegel, like Nietzsche, is an anti-Platonist; there is no second world of ideas or essences behind the first sensible one; there is only sense. In this second claim, Hyppolite is returning to *Genesis and Structure*, in which he claimed that the most difficult idea in Hegel's thought was the difference between essence and appearance—that is, the *difference* within immanence itself. For Hyppolite, following Hegel, difference must be "pushed all the way up to contradiction" (Hyppolite 1997, p. 113). In other words, if we are to remain true to the thought of immanence, we must think totality. But to think totality, we must have opposites be internal to themselves. The infinite, for example, cannot be opposed externally to the finite; if it were, then the infinite would be finite because it would have the finite as its boundary. So, the infinite must include the finite inside of itself; it must be both finite and infinite and thus contradict itself. For Hyppolite, following Hegel, there can be difference within immanence only through self-contradiction. Is self-contradiction really difference? This question is explored further below.

The difference within immanence leads to the third and final claim made by Hyppolite in *Logic and Existence*. Hegel is not a humanist because sense (which has now replaced the old metaphysical concept of essence) is indeed different from man. Hegel therefore is trying to think not man but across man, and through this *antihumanism* Hyppolite's reading no longer shares any similarity with that of Kojève.

Logic and Existence sets up the philosophies of Derrida, Deleuze, and Foucault. Indeed, in his inaugural address to the Collège de France in 1970, Foucault, who was then assuming the chair vacated by Hyppolite's death, said that "*Logic and Existence* established all the problems that are ours" (Foucault 1972, p. 236). In other words, when Hyppolite discusses the problem of difference in Hegel, he is setting up the entire philosophy of difference that will arise in France in the 1960s. Yet as seen above, for Hyppolite difference must be pushed all the way up to contradiction. This occurs by indeterminate differences being converted into oppositions; each thing that is different must find *its* other, as Hyppolite says. Then, after having pushed all the indeterminate differences up into oppositions, one can see that each position makes sense only with or through its opposition. Nature, for instance, makes sense only through *its* opposite, which is culture. Thus each position includes its opposition in itself; each position is a self-contradiction. But, the philosophy of difference that arises in France during the 1960s consists of the attempt to push difference back down from self-contradiction to indeterminate difference. We can see this project already in Deleuze's 1954 review of *Logic and Existence*. But, the project is fulfilled in at least two different ways. On the one hand, one reconceives what looks to be a position and an opposition as two positivities or two positions; this is Deleuze (and Foucault). On the other hand, one reconceives what looks to be a position and an opposition as mutual contamination; this is Derrida. These two fulfillments are the legacy of Hyppolite's thought.

IAMBLICHUS

(c. 245–320 CE)

The sources available for our knowledge of Iamblichus's life are highly unsatisfactory, consisting as they do largely of a rather hagiographical and ill-informed *Life* by the sophist Eunapius, who was a pupil of Chrysanthius, who had been in turn a pupil of Iamblichus's pupil Aedesius, but enough evidence can be gathered to give a general view of his life-span and activities.

LIFE AND WORKS

The evidence points to a date of birth around 245 CE, in the town of Chalcis-ad-Belum (modern Qinnesrin) in Northern Syria. Iamblichus's family was prominent in the area, and the retention of an old Aramaic name (*yamliku*) in the family points to some relationship with the dynasts of Emesa in the previous centuries, one of whose names this was. This noble ancestry does seem to somewhat color Iamblichus's attitude to tradition—he likes to appeal on occasion for authority to "the most ancient of the priests" (*Iamblichus: De Anima*, §37).

As teachers, Eunapius provides (*VP* 457–8) us with two names: first, a certain Anatolius, described as second in command to the distinguished Neoplatonic philoso-

pher Porphyry, the pupil of Plotinus, and then Porphyry himself. We are left quite uncertain as to where these contacts took place, but we must presume in Rome, at some time in the 270s or 280s, when Porphyry had reconstituted Plotinus's school. If that is so—and it is plain that Iamblichus knew Porphyry's work well, even though he was far from a faithful follower—then it seems probable that he left Porphyry's circle long before the latter's death, and returned to his native Syria (probably in the 290s) to set up his own school, not to his home town, but rather to the city of Apamea, already famous in philosophical circles as the home of the Neopythagorean Numenius. There he presided over a circle of pupils, including a local grandee, Sopater, who seems to have supported him materially, and as long as Licinius ruled in the East, the school flourished. After the triumph of Constantine, however, the writing had to be on the wall for such an overtly Hellenic and theurgically-inclined group, and on Iamblichus's death in the early 320s the school broke up; his senior pupil Aedesius moved to Pergamum, where the Iamblichean tradition was carried on quietly for another generation or so.

Iamblichus was a prolific author. Unfortunately, with the exception of *Reply to the Letter of Porphyry to Anebo* (popularly known, since the Renaissance, as *On the Mys-*

teries of the Egyptians), only his more elementary works survive intact. Chief among these is a sequence of nine, or possibly ten, works in which he presented a comprehensive introduction to Pythagorean philosophy. Of these, the first four are still in existence, beginning with a *Bios Pythagorikos*. This work is not simply a *life of Pythagoras*, but rather an account of the Pythagorean way of life, with a biography of Pythagoras woven into it. It was followed by *Exhortation to Philosophy*, the treatise *On the General Science of Mathematics*, and a commentary on the *Introduction to Arithmetic*, the second-century Neopythagorean Nicomachus of Gerasa. The doxographical portion of a treatise *On the Soul*, and extracts from a series of philosophical letters also survive in the *Anthology* of John of Stobi.

Other than those, however, we have considerable evidence of commentaries on works of both Plato and Aristotle, fragments of which survive (mainly) in the later commentaries of Proclus. Most notable among these are commentaries on the *Alcibiades*, *Phaedrus*, *Timaeus*, and *Parmenides* of Plato, and the *Categories* of Aristotle (this latter preserved extensively by Simplicius). He is also on record as having composed a commentary on the *Chaldaean Oracles*, and a Platonic Theology. The *Reply to the letter of Porphyry to Anebo* mentioned above is an odd production, in that it is a response to a polemical open letter by Porphyry attacking the practice and theory of theurgy, which Iamblichus, taking on the persona of a senior Egyptian priest, Abammon, elects to defend.

PHILOSOPHY

Iamblichus's system of philosophy is essentially an elaboration of Plotinus's Platonism, though strongly influenced by Neopythagorean writings and the *Chaldaean Oracles*. He accepts the triadic system of principles, the One, Intellect and Soul, but he introduces elaborations at every turn.

First of all, in an attempt to resolve the contradiction between a One which is utterly transcendent but which also constitutes the first principle of all creation, he postulates a totally ineffable first Principle above a more positive One, which itself presides over a dyad of Limit and Unlimitedness. These in turn generate a third principle, the One-Existent (*hen on*), which constitutes a link with the next hypostasis, that of Intellect (*Nous*), whose highest element it also is. Inhering in the One-Existent, we may also discern a multiplicity of *henads*, which serve as unitary prefigurations of the system of Forms which are the contents of Intellect.

Intellect, meanwhile, also suffers elaborate subdivision in Iamblichus's system, first into a triad of three *moments* or aspects, Being, Life, and Intellect proper, and then into a series of three triads (again, of Being, Life, Intellect) arising out of each of these. He thus becomes the ancestor of the elaborate system of the later Athenian School of Syrianus and Proclus. The impulse for such elaborations seem to stem from a consciousness of the complexity of the spiritual world, and of the many levels of divinity which inhabit it.

Soul, likewise, is distinguished into Pure, or Unparticipated Soul, and Participated Soul, which is in a way the sum-total of individual souls. Some individual souls, likewise, transcend any contact with body, while others are destined to be embodied, and even these descend into body on various different terms.

Iamblichus, in his treatise *On the Soul*, sought to differentiate himself from his predecessors Plotinus and Porphyry, on the issue of the relation of the soul with what is above it, postulating a less direct contact with Intellect and the One, and a corresponding need of theurgy, or *sacramental* ritual, to secure personal salvation. He may thus be reasonably accused of making Platonism much more of a religion, a characteristic which endeared him in particular to the Emperor Julian, a generation after his death.

IBN AL-ʿARABĪ
(1165–1240)

Muhyī al-Dīn Muhammad ibn ʿAlī, known as Ibn al-ʿArabī (or Ibn ʿArabī, without the definite article), was arguably the most influential philosopher of the second half of Islamic history. Born in Murcia in Muslim Spain in the year 1165, he left the west permanently in 1200, settled in Damascus in 1223, and died there in 1240. He is not normally classified as a philosopher (*faylasūf*) because he made no attempt to fall into line with the schools of thought that adopted Greek methodologies. Nonetheless, "love of wisdom" was central to his project, and he praised the high aspiration of "the divine Plato" and others who engaged in the philosophical quest. With extraordinary faithfulness to the sources of the Islamic tradition and unprecedented originality, he offered diverse interpretations of the fundamental issues of philosophical and theological thought. He was enormously prolific, yet maintained a consistently high level of discourse without repeating himself. He has typically been classified as a "Sufi" or a "mystic," but this simply means that he supplemented rational investigation with suprarational intuition, not that he avoided philosophical issues. His pervasive influence was not eclipsed until the collapse of Islamic institutions under the pressure of colonialism and modernity. Current renewed interest in his legacy throughout the Muslim world stems largely from the realization that the Enlightenment project has reached a dead end.

Henry Corbin (1969) suggests that Ibn al-ʿArabī's meeting during his teenage years with Averroes (d. 1198), the last of the great peripatetics, symbolizes the parting of the ways between Islamic and Christian civilizations. According to Ibn al-ʿArabī's account, his father had told Averroes that his son had been opened up to the invisible realms, and Averroes requested a meeting. He asked the boy if philosophical theory (*nazar*) reached the same conclusions as divine unveiling (*kashf*). Ibn al-ʿArabī replied, "Yes and no: Between the yes and the no, spirits fly from their matter and heads from their bodies" (*al-Futûhât al-makkiyya*, p. 154). In Corbin's reading, Ibn al-ʿArabī and subsequent Muslim philosophers preserved

the creative tension between the "yes," or the affirmation of the legitimacy of rational thought, and the "no," or the declaration of its inadequacy in face of the divine. In contrast, European thought, partly under the influence of Latin Averroism, lost the balance between reason and intuition and fell into deep dichotomies between philosophy and theology, science and religion, history and symbol, mind and heart.

Corbin considered Ibn al-ʿArabī's main theoretical contribution to lie in his stress on *khayâl*, "imagination" or "image," specifically the human faculty of creative imagination and the cosmic *mundus imaginalis*, the "imaginal"—not imaginary—world located between the sensible and intelligible realms. Though this world had been implicitly affirmed by Avicenna's cosmology, it was denied by Averroes. When Ibn al-ʿArabī reformulated Avicenna's thought in terms of imagination, the eventual result was a synthetic rather than analytic philosophical vision that stressed the essential unity of human beings and the cosmos.

Corbin, however, neglects a third and deeper meaning of the word *khayâl*. It also denotes the cosmos as a whole, the realm of contingency and becoming. While discussing the cosmos as image, Ibn al-ʿArabī offers unprecedented analyses of *wujûd*, "being" or "existence," the basic topic of the philosophers. He follows the Avicennan picture by classifying *wujûd* into two basic sorts—necessary (*wâjib*) and contingent (or possible, *mumkin*)—but he reminds us that the Arabic word *wujûd* also signifies consciousness, awareness, finding, ecstasy, and bliss; and he reformulates the whole discussion in terms of the Qurʾanic doctrine of divine names and attributes. The Necessary *Wujûd* is not only that which is and cannot not be, but also that which knows and cannot not know, lives and cannot not live, loves and cannot not love. To say that the cosmos is the realm of contingent *wujûd* means that it stands halfway between being and nothingness, awareness and unconsciousness, life and death, mercy and wrath. In the same way, the *mundus imaginalis* is the intermediate realm of cosmic becoming, situated between the luminosity of the angelic realm and the darkness of corporeality. As for the human self (*nafs*), it is the imagination of the microcosm, hanging between heaven and earth, spirit and body, intelligence and ignorance, virtue and vice.

In later times Ibn al-ʿArabī came to be known as the great expositor of *wahdat al-wujûd* or "the Oneness of Being," even though he and his immediate followers did not employ the expression (at least not in a technical sense). Ontology was unquestionably central to his proj-

ect, but so were epistemology, hermeneutics, theology, cosmology, spiritual psychology, ethics, and jurisprudence. He addressed all of the basic fields of human understanding, yet he was not attempting to provide an overarching system. Rather, he was adumbrating the major categories of human cognitive participation in the infinite and never-repeating disclosures of the Necessary *Wujûd*, disclosures that are none other than the imaginal realm known as the cosmos. He employs the mythic language of the Qurʾan to provide a broad framework for the stations of wisdom that designate the realms of human possibility, and he assures us that each of the 124,000 prophets sent by God embodies a distinct archetype of human perfection. His most famous book, *Fusûs al-hikam*, is arranged in terms of twenty-seven prophetic Logoi, each of which incarnates a specific divine attribute.

To provide some sense of the scope of his work, a few of the many themes that he discussed with unparalleled thoroughness and which then reverberated down through Islamic intellectual history will be outlined:

WISDOM AS REALIZATION

According to the Qurʾan, one of God's names is *haqq*, a word that designates reality, truth, appropriateness, rightness, right (as in "human rights"), and justice, along with the corresponding adjectives. From al-Kindī onwards, Muslim philosophers often defined their discipline in terms of this word. As al-Kindī put it at the beginning of his *Metaphysics*, "The philosophers' purpose in their knowledge is to hit upon the *haqq* and, in their practice, to practice according to the *haqq*" (*Rasâʾil al-Kindī al-falsafiyya*, p. 25) They took *haqq* in its purest sense as a designation for the Necessary *Wujûd* in itself, but they also recognized that it denotes the realm of contingency known as the cosmos, the truth that is to be grasped (right understanding), and the embodiment of truth in correct activity (ethics and virtue). To say that the cosmos is the realm of *haqq* means that human beings, like everything else, manifest truth, reality, and right in their essential nature.

In contrast to other things, however, human beings partake of enough freedom to affect the degree to which they understand and embody *haqq*, and it is this that necessitates praxis. The quest for wisdom is then called *tahqīq* (from the same root as *haqq*), that is, "realization"—literally "actualizing *haqq*." *Tahqīq* is contrasted with *taqlīd*, "imitation" of the beliefs and opinions of others. To be a sage demands far more than studying philosophy and memorizing the words of Aristotle and Avicenna. The real goal is to see *haqq* for oneself (*theôria* as vision) and to act in keeping with one's own impartial seeing. To the extent that people remain imitators, they are held back from their human substance. To the extent that they achieve realization, they participate in *haqq*, that is, the reality and consciousness of the Necessary *Wujûd*. The quest for wisdom remains intensely personal, for the cumulative theories of philosophers and scientists, not to speak of the conventional, imitative knowledge of society, are as nothing compared to the knowledge of self that only the self can achieve for itself.

THE COMPLEMENTARITY OF LOGIC AND MYSTICISM

Ibn al-ʿArabī's account of his encounter with Averroes highlights two terms, "theory" and "unveiling." The former designates the rational and discursive knowledge achieved by philosophers and theologians, the latter the suprarational intuition granted to mystics and visionaries. A good deal of Ibn al-ʿArabī's writing deals with the inadequacies of exclusive reliance on one or the other of these two modes of understanding. Theory he calls "the eye of reason," and unveiling "the eye of imagination." Both are located in the "heart" (*qalb*), which, in Islam as in China and other traditional contexts, is the seat of consciousness and selfhood. The quest for realization is the attempt to actualize the vision of both eyes and to achieve the harmonious marriage of logos and mythos, philosophy and poetry, science and art.

THE HARMONY OF THE ONE AND THE MANY

The eye of reason has the capacity to discern the individual reality—the essence or quiddity—of each thing. In contrast, the eye of imagination is able to perceive the actual presence of the Necessary *Wujûd* in all that exists. Reason acknowledges difference and recognizes its *haqq*—its reality, appropriateness, and rightness. It grasps that the Necessary *Wujûd* is utterly other than the cosmos and the existents (*mawjûdât*). In contrast, imagination perceives sameness and denies otherness. It finds the face of the Necessary *Wujûd* in every contingency. Theologically, this means that reason perceives God as distant and asserts his incomparability or transcendence (*tanzîh*); imagination sees God as present and asserts his similarity or immanence (*tashbîh*). Only the heart that sees simultaneously with both eyes can understand God, the universe, and the self as they truly are. The sage does not fall into the traps laid down by the principle of noncontradiction. Instead he grasps the exact manner in which all

things pertain to the imaginal realm of both/and, or neither/nor. According to Ibn al-ʿArabī's most succinct formulation of the actual state of affairs, the sage sees that everything in the cosmos is "He/not He" (*huwa lâ huwa*)—God/not God, being/nothingness, necessity/impossibility, consciousness/unawareness.

LANGUAGE AS THE DETERMINANT OF REALITY

We perceive only language, for at root nothing is accessible to us but the Logos, the self-expression of the Necessary *Wujûd* (called the "Active Intellect" by the peripatetic philosophers). According to the Qur'an, "When God desires a thing, He says to it 'Be!', and it comes to be." In Ibn al-ʿArabī's terms, what "comes to be" is the infinite words of God articulated in "the Breath of the All-Merciful" (*nafas al-rahmân*). God's mercy, his all-embracing bounty and kindness, is the Necessary *Wujûd* itself, which demands the existence of every possibility. Within the Breath, God voices all things as letters, words, and sentences, arranging them in three grand books: the cosmos, the human self, and revelation. All language, whether divine, cosmic, or human, pertains to the imaginal realm, for words are neither the speaker nor other than the speaker, neither the spoken nor other than the spoken. The key to deciphering the message inscribed in cosmos and self lies in prophetic revelation, which explicates the Logos in the language most accessible to human understanding.

THE CORRELATION BETWEEN MACROCOSM AND MICROCOSM

The Breath of the All-Merciful deploys itself as a hierarchy of being and consciousness on three basic levels: intelligence or spirit, imagination or soul, and corporeality. Each of these ontological levels is inhabited by appropriate entities (e.g., angels, jinn or psychic beings, inanimate objects). The sum total of the three levels along with the infinite proliferation of inhabitants is the cosmos. The cosmos is then called the "macrocosm" when contrasted with the human being as microcosm. What differentiates the human microcosm from all other creatures is its all-comprehensive image of the Necessary *Wujûd*. The macrocosm embraces all contingent beings in their distinctiveness, all the individual words uttered by the All-Merciful Breath. The microcosm combines all the characteristics of macrocosmic reality in a unified and focused whole that opens up inwardly in the direction of the undifferentiated Logos.

ANTHROPOCOSMIC TELEOLOGY

The cosmos can be looked upon as a static hierarchy, but Ibn al-ʿArabī more typically describes it in terms of the dynamism of its unfolding. We and all things come into existence from the One in a quasi-neoplatonic manner, but our existential concerns are determined by the path we follow in retracing our steps to the Origin. Given that consciousness and self-awareness are centralized in the human microcosm, the way back to the One—which is the Necessary *Wujûd*, the unity of Being, Consciousness, and Bliss—goes by way of the full realization of the human self as the immanent Logos. The purpose of human life is the recovery of the original unity of being and intelligence by way of self-understanding. But self-understanding cannot be achieved without understanding the cosmos and revelation, and none of these three grand books can be deciphered unless they are read with both eyes of the heart. The cosmic subjectivity of the human state is so central that it provides the raison d'être for the existence of the world. Human beings—or rather, those whom Ibn al-ʿArabī calls "perfect human beings" (*al-insân al-kâmil*)—are the final cause of the contingent realm. In them alone are realized God's words as related by Muhammad in the famous saying, "I was a Hidden Treasure and I desired to be known, so I created the creatures that I might be known."

IBN BĀJJA
(d. 533 AH/1138 CE)

Abū-Bakr Muḥammad ibn Yaḥyā ibn al-Sāyigh ibn Bājja, the Islamic philosopher, was known to the medieval Scholastics as Avempace. He was born in Saragossa at the end of the fifth century AH, eleventh century CE, and died in Fez, Morocco, in 533 AH/1138 CE. During his brief life he endured the tribulations occasioned by the Christian "reconquest" of Andalusia. It is known that he wrote several commentaries on Aristotle's treatises and that he was very learned in medicine, mathematics, and astronomy. He was involved in the quarrel initiated by the Peripatetics, during which al-Bītrogī, whom the Scholastics called Alpetragius, distinguished himself. Ibn Bājja opposed his own hypotheses to Ptolemy's system.

Ibn Bājja's philosophical works have remained incomplete, notably the treatise that gained him his reputation, *Tadbīr al-motawaḥḥid* (The rule of the solitary). For a considerable length of time this treatise was known only through a detailed analysis of it in Hebrew by Moses of Narbonne (fourteenth century) in his commentary on the *Ḥayy ibn Yaqẓān* of Ibn Ṭufayl, the pupil of Ibn Bājja. Salomon Munk based his account of Ibn Bājja on this analysis. The Arabic original (now in the Bodleian Library at Oxford) was rediscovered by Miguel Asin Palacios.

The work's central theme is that of an *itinerarium* leading the man-spirit to unite itself with the Active Intellect (ʿAql faʿʿal, Intellegentia agens). He who speaks of a "rule" or "discipline" assumes a mode of life regulated by actions demanding reflection, and this can be found only in the solitary man. This is why the solitary man's discipline should be the model for a member of the perfect City and the ideal State. The ideal State, it must be noted, is not the result of a priori conceptions, nor can it come into being by a political coup d'état; much more than a mere "social" reform, it is the fruit of a reform of customs that seeks to realize the fullness of human existence in each individual. For the time being, the solitary individuals live in imperfect states, with neither judge nor doctor except God. Their task is to become members of the perfect City. In order to found the regime of these individuals it is necessary at first to analyze and classify human actions, using the forms that they strive to fulfill as the point of departure.

For this reason the treatise is presented essentially as a "theory of spiritual forms," a sketch of the phenomenology of the spirit. The spirit progressively evolves from forms engaged in matter to forms that have been abstracted from it. Having then become intelligible in act, these forms thereby attain the level of intellect in act, reaching the level of pure spiritual forms, those forms that, inasmuch as they exist for the Active Intellect, have not had to pass from power to act.

Ibn Bājja imposed upon Islamic philosophy in Spain a completely different orientation than did Mohammad al-Ghazali. The motives of the solitary individual, of the stranger, and of the *allogène,* however, merge with the motives typical of the mystical gnosis in Islam. The same type of spiritual man is realized in these individuals, although their perception of the common goal differs and thereby the choice that determines their course. One of these courses in Spain was that of Ibn Masarra, which was continued by Ibn al-Arabi. Another was that of Ibn Bājja, later continued by Averroes.

Bibliography

Ibn Bājja's *Tadbīr al-motawaḥḥid* has been edited and translated into Spanish by Miguel Asin Palacios as *Avempace, El régimen del solitario* (Madrid and Granada, 1946); the first section has been translated into English by D. M. Dunlop in *Journal of the Royal Asiatic Society* (1945): 61–81.

For discussions of Ibn Bājja's philosophy, see Henry Corbin, *Histoire de la philosophie islamique,* Vol. I (paperback, Paris: Gallimard, 1964), pp. 317–325; S. H. Masumi, *Ibn Bajjah's ʿIlm al-Nafs* (Karachi: Pakistan Historical Society, 1961); and Salomon Munk, *Mélanges de philosophie juive et arabe* (Paris: A. Franck, 1859; new ed., Paris: J. Vrin, 1955).

Henry Corbin (1967)

IBN BĀJJA [ADDENDUM]

One of the unusual aspects of Ibn Bājja's political philosophy is the doctrine that in imperfect societies the philosopher has the status of weeds or *nawabit*. In a society governed by reason, the representatives of reason—the philosophers—find an important place. They are important people in the state because the state requires them to help it pursue the most rational course. But where the state is not governed by reason and instead by some less perfect rationale, philosophers will find themselves out of favor; they will be regarded as useless—like weeds—and possibly even dangerous to the state itself. The only happiness that philsophers will be able to establish for themselves is a private happiness because they will not be able to use publicly their knowledge of how the state ought to be run. Ibn Bājja's remarks on this topic are poignant, bringing out nicely the alienation experienced by intellectuals in a culture where their views are disregarded.

IBN GABIROL, SOLOMON BEN JUDAH
(c. 1021–1058 or 1070)

Solomon ben Judah ibn Gabirol was first mentioned by Sāʿd the Qadi of Toledo (c. 1029–1070), who claimed that ibn Gabirol lived in Saragossa, was a keen student of philosophy, especially logic, and died sometime around 1058 CE, after he had passed the age of thirty. The Andalusian Jewish poet Moses ibn Ezra (c. 1060–1139) claimed that ibn Gabirol was born in Malaga and reared in Saragossa and spent a short but fruitful life in the service of philosophy and poetry. The Jewish philosopher Abraham ibn Daud (c. 1110–1180) said that ibn Gabirol died in 1070, but 1058 is more generally accepted.

The tone of some of Ibn Gabirol's secular songs, gloomy and bitter, is sometimes considered an indication of his unhappy lot—orphaned at an early age, poor, and ostracized by many of his contemporaries because of his irascible disposition and unorthodox philosophy. He did find some favor with Yequtiel ben Ishaq ibn Hasan, a veritable Maecenas, at the court in Saragossa, and later with his patron, Samuel ibn Nagrella, at the court of Zirid in Granada. Most, if not all, of this patronage seems to have resulted from his reputation as the greatest Jewish poet of his time in the West.

There are some 400 extant secular and religious poems attributed to ibn Gabirol. One, *The Kingly Crown,* has become a part of the Sephardic Jewish liturgy for the Day of Atonement. Its rhythmical, rhymed simplicity gives it a distinct biblical flavor. In this poem of forty stanzas, ibn Gabirol celebrated the divine attributes, the last of which is Will, so prominent in his philosophical work *The Fountain of Life,* and the wonders of creation, reminiscent of an Aristotelian-Ptolemaic worldview. He concluded with an Augustinian self-analysis, marked by confession, penitence, and supplication.

In addition to his work in poetry, an anthology of ethical and sapiential sayings, *Choice of Pearls,* is attributed to him, but its authenticity is doubted by some.

Ibn Gabirol's *The Improvement of the Moral Qualities* exists in one known Arabic text and four Hebrew versions, as well as in translations into other languages. The ethical aspect of Ibn Gabirol's philosophy is interesting because it appears to be an early, if not the first, attempt to systematize the basic principles of medieval Jewish ethics independently of religious dogma, ritual, or belief. The impulses of the human soul and how they can be trained to virtue or permitted to fall into vice are explained in relation to the five external senses, which are in turn explained by the four-element, or simple-body, theory of Aristotle. Stephen S. Wise claimed that "Gabirol's object is to establish a system of purely physio-psychological ethics." Certainly it is true that his interest was mainly in the animal rather than the rational soul. He emphasized the virtuous order that can be achieved in the external senses under the direction of the rational soul. In his treatment of the virtues and vices, Ibn Gabirol did refer to biblical writings, but in a superficial and summary way, as a support of his own allegorical-poetic viewpoint.

It was not until nearly the end of the first half of the nineteenth century that Salomon Munk showed conclusively that ibn Gabirol, the great Jewish poet, was the same man as Avicebron, the recognized author of *The Fountain of Life.* An examination of the abstracts translated into Hebrew from the original Arabic by Shem Tob

Falaquera in the thirteenth century and attributed to ibn Gabirol showed substantial agreement with related passages of the *Fons Vitae* attributed to Avicebron by the twelfth-century translators John of Spain (Ibn Daud, Avendehut) and Dominic Gundissalin. In the text of *The Fountain of Life* are found references to two other works by ibn Gabirol, "The Treatise on *Esse*," Book 5.8, and the book of the Will, which is titled "*Origo Largitatis et Causa Essendi*," Book 5.40. Unfortunately, these works cannot be found or identified. They may constitute, with *The Fountain*, the three parts of Wisdom: knowledge of matter and form (*The Fountain*), knowledge of Will (*The Origo*), and knowledge of the First Essence (*De Esse*). *The Fountain* is like the ethical work in its purely rational approach but differs in its complete lack of references to the Bible, the Talmud, or the Midrash. It is a treatise in the strict philosophical area of Neoplatonism as related to an eleventh-century Jewish mind. In it we find a Neoplatonic universe dependent on the Will of the First Author, supreme and holy.

The Fountain of Life, though composed in a dialogue form involving master and pupil, has none of the beauty and charm of the dramatic dialogues of Plato, the only other person mentioned by name in the work. The pupil seems to be a fictitious straight man, asking the proper questions at the proper time and giving a verbal nod of the head when appropriate. The opening section tells us that the discussion concerns the first part of Wisdom, the science of universal matter and universal form. Because of the nature of the topics involved, the work falls neatly into five parts:

(1) What we must presuppose in order to assign universal matter and form and predicate them of composite substances.

(2) The substance upholding the corporeity of the world.

(3) The acceptance of simple substances, such as the separated intelligences (i.e., angels).

(4) The science of understanding matter and form in simple substances.

(5) Universal matter and universal form in themselves.

The general method followed in this dialectical investigation is a search for the nature and existence of certain properties, which when found reveal the existence of the being that has these properties. In things we find there is something that "exists in itself," "is of one nature," is the "vehicle of diversity," and "gives everything its essence and name." These are the properties of universal matter. If one abstracts every sensible and intelligible form from things, the remainder is the common denominator called universal matter. Universal form is found "to subsist in another," "to perfect the essence of that in which it is," and "to give it being." By inspecting universal and particular sensible things, one finds four grades of matter and form: artificial-particular matter and its appropriate form, natural-particular matter (the matter of art products) and its form, natural-universal matter and its form, and celestial matter (the matter of the simple intelligences) and its form. Hence, there are common denominators for both matter and form: universal matter and universal form.

Every reality, except the First Essence, when viewed with its form is called a substance; when one conceives of something as receptive of form, then it is called matter, or hyle. Sensible forms require an extended substrate or body. The corporeal body is formed out of matter (which is itself incorporeal) and the corporeity-form, quantity. The first and simplest form and the highest matter are those that when united constitute the Intelligence. The Intelligence is the highest existence next to the First Essence. Below this are the rest of the hylomorphically composed souls—rational, sensitive, and vegetative—and then nature, the foundation of all inorganic things. Nature serves as the matter for the corporeity-form, quantity; the resulting substance is the matter of sensible qualities, like color.

One might say that Ibn Gabirol's universal hylomorphism represents an intermediate between the universal formlessness of Augustine and the later Franciscan variations. There are many differences from, as well as similarities to, scholastic thought, but the influence of Jewish religious ideas provides a basis for creation in his Neoplatonic universe. It seems that the Neoplatonic element in his thinking led ibn Gabirol to consider the origin of all things as a necessary emanation from the First Author. But the Jewish element may have rebelled against this, as a necessary emanation would be in conflict with the absolute transcendence of God. The solution results in an intuitive view of the relation of all things to the First Author. This relation is necessary because matter is an expression of the essence of God, who is himself necessary. However, the dynamism of the Will of God leads to the need for a variety of forms that are initiated by God. Hence, the relation is voluntary and therefore free. In *The Fountain of Life* we have at times a strange mixture of Jewish religious ideas, Arabian Aristotelianism, and Alexandrine Neoplatonism, though we cannot be

absolutely sure of the source of the ingredients because of the absence of definite historical information.

Solomon ibn Gabirol's direct influence in philosophy seems to have been confined to certain Franciscans of the Augustinian tradition in the thirteenth and fourteenth centuries. They thought that ibn Gabirol's universal hylomorphism supplied them with a suitable philosophical way of expressing the difference between creatures and God. The universal principle of limitation—namely, matter—becomes spiritual matter in all other creatures.

IBN KHALDŪN
(1332–1406)

Ab-Ar-Rahman ibn Khaldūn, the Muslim statesman, historian, philosopher of history, sociologist, and political thinker of the fourteenth century, is probably the greatest creative genius produced by Muslim civilization. To Arnold Toynbee, Ibn Khaldūn's philosophy of history "is undoubtedly the greatest work of its kind that has ever yet been created by any mind in any time or place."

Ibn Khaldūn was born in Tunis into a family of southern Arabian origin that had immigrated to Andalusia in the eighth century. With the decline of Muslim rule in Spain the family immigrated to northwest Africa, establishing itself first in Morocco and then in Tunisia. Muslim emigrants from Spain constituted an aristocracy in the Maghreb, and the Khaldūn family won fame in scholarship and statesmanship.

Ibn Khaldūn surpassed the achievements of all the members of his family. Brought up in the traditional religious sciences and the philosophical-rational sciences that formed the two major streams of Islamic culture, he studied the Qur'an, Arabic, traditions, jurisprudence, logic, and philosophy under several of the best scholars of his time and studied, taught, and occupied high positions in Tunis, Algeria, Morocco, southern Spain, and Egypt.

Medieval Muslim rulers were eager to enlist scholars either for government service or for the prestige that goes with their presence in the court. Ibn Khaldūn enjoyed all the privileges of princely positions and suffered the odds of their fluctuations in medieval courts. He shared in the political maneuvers and conspiracies that accompanied the rise and fall of different rulers, and in trying periods, when he was in prison or was forced into exile, he devoted himself to the study of power and meditated on its historic laws and social dynamics.

Ibn Khaldūn's greatest work, *Al-Muqaddimah* (The prolegomena), was the first of seven volumes of his universal history of the Arabs and Berbers, *Kitab al-'Ibar.*

Although the last two volumes are of special value to historians as the best source for the history of northwest Africa, especially for the history of the Berbers, the introduction that outlines ibn Khaldūn's philosophy of history overshadowed the narrative. The philosophic originality of this introduction was so great that ibn Khaldūn became known as the author of *Al-Muqaddimah.*

Prior to ibn Khaldūn, Muslim philosophers had concerned themselves with the reconciliation of Qurʾanic truth and rational truth, but this had led to an assimilation of Greek rationalism by Muslim theology rather than to the emergence of Muslim rationalism. The concern with religion and philosophy penetrated all Muslim disciplines—law, history, and the like. By the fourteenth century this method, which had its religious origins in the Qurʾan and the traditions of the Prophet and its philosophic origins in Greek rationalism, had reached its height.

Ibn Khaldūn was an accomplished student of Muslim learning, but witnessing the decline of Muslim power and metaphysics, he decided to seek the concrete causes of this decline. History rather than metaphysics gave the answers to his questions about the changes in Islam's fortunes.

Ibn Khaldūn sought not only historic truth but history as the way to truth. The Preface of his *Muqaddimah* reveals him to be a forerunner of all modern historicists. His Muslim predecessors had narrated the train of historic events; as he said, they saw history on the surface as no more "than information about political events. … They over-looked its inner meaning," which "involves speculation and an attempt to get at the truth, subtle explanation of the causes and origins of existing things, and deep knowledge of the how and why of events." For Ibn Khaldūn history is therefore firmly rooted in philosophy and deserves to be accounted a branch of philosophy.

Traditional Muslim theologians, who were best represented by Mohammad al-Ghazālī, rejected the Aristotelian notion of natural causality. They conceived of God as the first and only cause of all that is. Ibn Khaldūn, as a Muslim believer, agreed with their ontology but introduced natural causality into history. Reason can see historic causes, not ontological causes. God in revelation is the teacher of ontological causes. Reason can grasp the limited phenomenon, but revelation introduces the limitless.

Ibn Khaldūn's concern with historic methodology led him to historicism. For historic accuracy Muslim historiography had relied on the criticism of the sources. It elaborated on the method of *hadith,* the study of the traditions and sayings of the Prophet. Ibn Khaldūn criticized this method and called for philosophical and rational methodology. The test of the accuracy of an event is not the reliability of the source but its conformity to the natural character or the natural law that the event should manifest.

To attain accuracy, the historian should therefore be a student of sociological and political causes and laws. He ought to be a philosopher of history.

> [If the historian] trusts historical information in its plain transmitted form and has no clear knowledge of the principles resulting from custom, the fundamental facts of politics, the nature of civilization, or the conditions governing social organization, and if, further-more, he does not evaluate remote or ancient material through comparison with near or contemporary material, he often cannot avoid … deviating from the high road of truth.

Ibn Khaldūn called this introductory science to the study of history the science of ʿumran, or the science of civilization, and claimed to be its originator.

Civilization is the beginning and end of social development and political organization. Man is born naturally sociable. Society rises through man's ability to cooperate with other men for the satisfaction of his natural needs. Countrymen or nomads in primitive or tribal societies seek the satisfaction of their elementary need for food; townsmen in urban and more complex societies pursue higher economic, intellectual, and spiritual needs. Political organization, or the state, arises from individual and social needs for restraint, arbitrage, defense, and prosperity.

Asabyia, or group feeling, is the way to achieve leadership, enforce authority, and expand. Political organization or statehood leads to power and prosperity. The state is the form of civilization.

Arts and sciences can prosper only within a state. Resulting luxury is conducive to social and political disintegration. Like individual human beings, all societies, states, and civilizations go through cyclical states of emergence, growth, and decay. Civilizations, however, live longer than states, for the cultural faculties acquired by individuals and societies enable civilizations to survive political disintegration. The systematic formulation of this organistic theory of civilization is full of original observations about the influence of climate on social organization, the forms of society, the economic forces, the relation between labor and value, the psychological, social, and economic foundations of power, the forms of the state, the relation of state and religion, the role of edu-

cation in society, the interdependence of prosperity and culture, and many other subjects.

Because these observations were formulated as natural laws, Ibn Khaldūn has been studied not only as a philosopher of history but also as a sociologist, political thinker, economist, educator, epistemologist, and historian of Muslim sciences. Guided by their own disciplines or convictions, different scholars have proclaimed him a forerunner of Niccolo Machiavelli, Giambattista Vico, Baron de Montesquieu, G. W. F. Hegel, Charles Darwin, Herbert Spencer, Karl Marx, Toynbee, and others. In his methodology and style Ibn Khaldūn is more a modernist than a medievalist. This partially explains his limited influence in medieval times and growing influence in modern times.

Al-Muqaddimah was written at a time when translation from Arabic into Latin had waned. Rediscovered by modern scholars and orientalists in the nineteenth century, excerpts of the book have been translated into French, German, Italian, English, and Japanese.

Ibn Khaldūn has also been rediscovered by modern Muslim and Arab authors. More books in Arabic have been written about him than about any other medieval Muslim thinker. He has influenced historic, sociological, and political writings.

IBN KHALDŪN [ADDENDUM]

Although most attention has been paid to Ibn Khaldūn's writings on history and society, he made an important contribution to other aspects of Islamic thought. He played a role in the extensive debate over Sufism, and defended its position in Islamic culture, provided that it adhered to the proprieties of religious law. The idea of coming to mystical knowledge by abandoning Islamic law and practices is a constant source of attack by Ibn Khaldūn; he emphasizes the role of the *shaykh*, or spiritual guide, and the place of mysticism within an orthodox understanding of Islam. He was also rather critical of many of the ambitious claims of the philosophers who thought that they could acquire knowledge of the most important features of reality by using reason alone.

Ibn Khaldūn is certainly no enemy of reason, but he argues that it operates within limits, and that religion is required for acquiring deeper knowledge than reason can provide. Similarly, when it comes to political philosophy, he criticizes the highly theoretical approaches of the philosophers who talk about the constitution of the ideal state as though this is something that could be established by reason and nothing else. The state cannot, he argues, be divorced from its history and social structure, and religion has to play a crucial role in its organization and goals. Although his ideas are heavily influenced by the philosophical concepts and arguments current at his time, Ibn Khaldūn was consistently skeptical of the ability of philosophy to reveal much of interest in either political or religious theory.

IBN ṬUFAYL
(d. 580 AH/1185 CE)

Abū Bakr Muḥammad ibn ʿAbd al-Malik ibn Ṭufayl, the Islamic philosopher, was known to medieval Scholastics as Abubacer. Few details are known about the life of Ibn Ṭufayl, who was born at Guadix in the province of Granada and died in Morocco. Like all his colleagues, he was a scholar whose knowledge was encyclopedic; he was a mathematician, astronomer, philosopher, and poet. He served as vizier for and was a friend of the Almohad sovereign Abū Yaʿqūb Yūsuf, and it was he who recommended that his friend Averroes be assigned the task of analyzing the works of Aristotle. Ibn Ṭufayl became known to medieval Scholastics (Abū Bakr having become Abubacer) through Averroes's translation of *De Anima*, which contained a brief criticism of Ibn Ṭufayl's doctrine identifying the possible (or passive) intellect with the imagination.

It was, however, because of his "philosophical novel," *Ḥayy ibn Yaqẓān,* a work that remained unknown to the Scholastics, that Ibn Ṭufayl later gained fame. It is worth noting that in the same era in the East Shihāb al-Dīn Yaḥyā Suhrawardī composed his own tales of symbolic initiations, in which he introduced, by extending the cycle of Avicennian tales, the "oriental philosophy" that Avicenna had already opposed to Peripatetic philosophy, but with only partial success. Ibn Ṭufayl referred to the Avicennian tales in the prologue to his philosophical novel, because he knew that the secret of Avicenna's "oriental philosophy" was partially contained therein.

Ibn Ṭufayl's work, however, is completely original and not in the least a mere amplification of an Avicennian tale. All it owes to Avicenna are the names of the *dramatis personae*: Ḥayy ibn Yaqẓān (*Vivens filius Vigilantis*), and Salamān and Absāl (a spelling certainly preferable to the mutilated form "Asāl," which figures in certain manuscripts).

In the works of Avicenna the name Ḥayy ibn Yaqẓān typified the Active Intellect, the central figure of Islamic Neoplatonism, simultaneously angel of knowledge and angel of revelation (the Holy Ghost and the angel Gabriel). For Ibn Ṭufayl this name is also that of the absolute hermit, mysteriously abandoned or spontaneously born on a desert island; in the absence of any human master and of all social falsification, the hermit becomes the perfect Sage. The superior pedagogy of the Active Intellect alone develops in him its natural faculties through a slow, rhythmic process evolving over the years. On a neighboring, inhabited island live two friends, Salamān, who typifies the practical and social spirit, and Absāl, contemplative and mystical, who lives like one in exile in his own country and finally decides to immigrate to the hermit's island, where he meets Ḥayy ibn Yaqẓān. In the course of their long conversations Absāl discovers that all that had been taught to him in matters of religion Ḥayy ibn Yaqẓān, the solitary, philosophical wise man, already knows, but in a purer form. Absāl discovers that religion is the *symbol* of a truth otherwise inaccessible to the common run of men. Together they attempt to deliver their spiritual message to the men on the island opposite them. Alas! in the face of the growing hostility that they encounter, they must accept an inescapable truth: The ordinary man is not able to understand.

Ibn Ṭufayl's novel is not an anticipation of Robinson Crusoe; each external episode must be understood on a spiritual level. On the other hand, in spite of its pes-

simistic ending it should not be concluded that the conflict Ibn Ṭufayl set forth (that between religion and philosophy) attained desperate proportions in the Muslim faith. In fact, another position and solution to the problem are sought in the "prophetic philosophy" of Shi'ism.

Henry Corbin (1967)

IBN ṬUFAYL [ADDENDUM]

There is indeed a rather pessimistic strand in Ibn Ṭufayl's philosophical novel. When Ḥayy travels to Absāl's island the former is an instant celebrity, but he discovers that the inhabitants are not interested in really coming close to the truth; they are only prepared to adhere to the symbols of their religion and have no interest in peering behind those symbols at the deeper truth they represent. When Ḥayy investigates the rules of religion he finds a good deal of discussion on matters for which he has no time at all, issues about money and possessions and other material topics. Ḥayy and Absāl eventually give up and return to Ḥayy's island where they can live in seclusion and avoid the infelicities of social life among a population unconcerned about spiritual truth. The implication is that religions such as Islam are built on solid principles, but most of their adherents never appreciate the nature of these principles—they remain at a more superficial level of understanding and merely carry out the rituals of the religion without investigating their roots. Ibn Ṭufayl's version of the story of Ḥayy ibn Yaqẓān is much more radical than that of his predecessor Ibn Sīnā, who hinted at the role of mystical knowledge but did not explicate its centrality in religion. Ibn Sīnā is guarded throughout his account, using allusion rather than direct argument to make his points. Ibn Ṭufayl writes with boldness and clar-

ity and does not hesitate to present his highly critical analysis of traditional religion as it is normally understood.

IBN ZADDIK, JOSEPH BEN JACOB
(d. 1149)

Joseph ben Jacob ibn Zaddik, like other Jewish philosophers of a Neoplatonic cast, such as Yehuda Halevi and Abraham ibn Ezra, was a poet as well as a philosopher and legist. Very few of his poems survive, and although he was highly praised as a Talmudist and served for the last eleven years of his life (1138–1149) as judge (*dayyan*) of the Jewish community of Córdoba, he does not seem to have written any systematic legal work. His philosophic work, on which his chief reputation rests, was originally written in Arabic, but the original no longer survives; a Hebrew translation, under the title *Olam Katon* (The Microcosm), was circulated in manuscript during the Middle Ages but was not printed until the mid-nineteenth century.

The general thesis of Joseph ibn Zaddik's work is that since man's nature duplicates in reduced form the nature of the universe, knowledge of the self provides a key to all knowledge. It is unnecessary to study the special sciences. The study of man, the microcosm, will lead to the understanding of the universe, the macrocosm.

Ibn Zaddik's *Olam Katon,* in fulfillment of this program, develops in its first part a metaphysical basis for the theory of man as the microcosm. Here the author showed acquaintance with both the Platonic and the Aristotelian traditions in the form in which they were maintained by

Muslim philosophers. The second part of the work discusses both the physical and the psychological natures of man; it asserts a point-for-point correspondence between human nature and the physics of the universe. In the third part Ibn Zaddik turned to theological questions, particularly the question of divine unity. His theological discussion includes a proof of creation from the finiteness of the world: Where there is creation, there must be a Creator; hence God exists. The philosopher was aware of the difficulties presented by a naive doctrine of divine attributes and resolved these difficulties by denying to the attributes a positive character. The fourth and final division of the work, continuing the pattern established by the Muslim philosophers, is devoted to God's justice and the implications of the divine government of the universe for man's duties. Ibn Zaddik was firmly committed to a belief in human free will; he believed that a man must use his freedom to imitate the goodness of God and to seek knowledge of him. Success or failure in so doing leads to reward or punishment in the future life, but apparent rewards and punishments in this world are merely natural happenings and should not be understood as indications of divine favor or disfavor.

IDEALISM

"Idealism" in its philosophical sense, is the view that mind and spiritual values are fundamental in the world as a whole. Thus, idealism is opposed to naturalism, that is, to the view that mind and spiritual values have emerged from or are reducible to material things and processes. Philosophical idealism is also opposed to realism and is thus the denial of the commonsense realist view that material things exist independently of being perceived.

Some philosophers who have held the idealist view in its antinaturalist form have not opposed commonsense realism, and thus it is possible to be a metaphysical idealist and an epistemological realist. More often, however, arguments against commonsense realism have been used in order to establish metaphysical idealism. The description "subjective idealism" is sometimes used for idealism based on antirealist epistemological arguments, and the description "objective idealism" for idealism that is antinaturalist without being antirealist.

In terms of these definitions, philosophical theism is an idealist view, for according to theism God is a perfect, uncreated spirit who has created everything else and is hence more fundamental in the world than any material things he has created. Marxist philosophers have therefore held that there are in principle only two main philosophical systems: idealism, according to which mind or spirit is primary in the universe, and materialism, according to which matter is primary in the universe. If "primary" is taken not to mean "earlier in time" but rather to mean "fundamental" or "basic," then these Marxist definitions agree with those given above. The only objection to them is that many philosophers who accept theism would be unwilling to be labeled idealists, since they would take the view that idealists belittle the material world and regard it as illusory by comparison with mind or even as less real than mind, whereas theists do not belittle matter or regard it as in any way less real than mind. Certainly this is a difference between theism and some forms of idealism, but there is force in the argument that theism and both subjective and objective idealism may be classed together as opposed to materialism. Pantheism may be regarded as a more thoroughly idealist view than theism, since pantheism is the view that nothing exists except God and his modes and attributes, so that the material world must be an aspect or appearance of God. Theism, in contrast, is the view that God has created a world beyond or outside himself so that the material world, although dependent on him, is not an aspect or appearance of him. What unites idealism both with theism and with pantheism is the rejection of materialism and the assertion of a metaphysic that is favorable to religious belief.

HISTORY AND ORIGIN OF THE TERM

The word *idealism* came to be used as a philosophical term in the eighteenth century. Gottfried Wilhelm Leibniz, in his *Réponse aux réflexions de Bayle* (written 1702; published in *Philosophischen Schriften*, edited by C. I. Gerhardt, 7 vols. Berlin, 1875–1890), criticized "those

who like Epicurus and [Thomas] Hobbes, believe that the soul is material" and held that in his own system "whatever of good there is in the hypotheses of Epicurus and of Plato, of the greatest materialists and the greatest idealists, is combined here" (Vol. IV, pp. 559–560). In this passage Leibniz clearly means by "idealists" philosophers who uphold an antimaterialist metaphysic like that of Plato and himself. When, later in the century, George Berkeley's views came to be discussed, the word *idealism* was applied, however, to the view that nothing could be known to exist or did exist except the ideas in the mind of the percipient. (Berkeley called his own view "immaterialism," not "idealism.") Thus, Christian Wolff (1679–1754), a follower of Leibniz, included idealists, along with materialists and skeptics, among "three bad sects" that he reprobated, and Denis Diderot (1713–1784) wrote in 1749: "We call *idealists* those philosophers who, knowing only their own existence and that of the sensations that follow one another within them, do not grant anything else" (*Lettre sur les aveugles*, London, 1749). The term *egoists* was also applied to holders of this view, as can be seen from the article titled "Égoistes" in the *Encyclopédie*, edited by Jean Le Rond d'Alembert and Diderot, which started publication in 1750. Today the word *solipsists* is applied to what were then called "egoists" or "idealists." In the *Critique of Pure Reason* (Riga, 1781) Immanuel Kant referred to his own view as "transcendental idealism," and in his *Prolegomena to any Future Metaphysics* (Riga, 1783) he called it "critical idealism." Thus, by this time the word *idealism* was beginning to lose the pejorative meaning that had linked it with extreme subjectivism.

The word *idealism* is derived from the Greek word *ιδέα*, which simply means something seen, or the look of something. Plato used the word as a technical term of his philosophy to mean a universal (such as whiteness) in contrast to a particular (such as something white) or to mean an ideal limit or standard (such as absolute Beauty) in contrast to the things that approximate or conform to it (such as the more or less beautiful things). According to Plato an Idea, or Form, is apprehended by the intellect, does not exist in time, and cannot come into existence or cease to exist as temporal things do and is hence more real than they are. In medieval philosophy Ideas or Forms were regarded as the patterns in accordance with which God conceived of things and created them, and hence they were thought of as existing in the mind of God. René Descartes used the word *idea* for thoughts existing in the human mind, sometimes retaining, however, the intellectual and objective character of ideas as understood in the Platonic tradition. But he also used the word *idea* for the effects in embodied minds of external objects acting on

the sense organs, and hence the word came to stand for changing sense perceptions as well as for unchanging objects of the intellect. Descartes also used the word *idea* for a shape or form stamped upon a soft material, as when he said in Section XII of his *Rules for the Direction of the Mind* (1628) that "shapes or ideas" are formed *in the brain* by things outside the body acting upon it. John Locke, in *An Essay concerning Human Understanding* (London, 1690), used the word *idea* for perceptions of "sensible qualities" conveyed into the mind by the senses and for "the perception of the operations of our own mind within us, as it is employed about the ideas it has got" (Bk. II, Ch. I, Sec. 4). The mind, he held, "stirs not one jot beyond those ideas which *sense* or *reflection* have offered for its contemplation" (ibid., Sec. 24). Berkeley adopted Locke's terminology and held that by our senses "we have the knowledge *only of our sensations*, ideas, or those things that are immediately perceived by sense" (*Principles of Human Knowledge*, Dublin, 1710, Sec. XVIII). Thus, Berkeley here repeats a view already held by Locke.

Thus, the word *idea* was used variously to mean a Form in the Platonic sense, a Form as apprehended in the mind of God or by the human mind, a shape impressed on soft, yielding material, and, apparently by analogy with this last sense, a modification produced in a mind by the influence on it of external things that affect the sense organs. Neither a Platonic Form nor a shape is a mental entity. "Operations of the mind" clearly are, and so would be the effects in minds of material objects that produce "impressions" in them. Ideas in this last sense would seem to be like mental images, but mental images produced not by imagining but by the operation of external objects. This variation in meanings can be seen in Berkeley's *A New Theory of Vision* (Dublin, 1709), where he writes (Sec. XLI): "a man born blind being made to see, would, at first, have no idea of distance by sight; the sun and stars, the remotest objects as well as the hearer, would all seem to be in his eye, or rather in his mind. The objects intromitted by sight, would seem to him (as in truth they are) no other than a new set of thoughts or sensations, each whereof is as near to him as the perceptions of pain or pleasure, or the most inward passions of his soul." It will be noticed that in his passage Berkeley comes close to assimilating "in his eye," a physical condition, to "in his mind," meant presumably to be a mental condition. Again, he puts "sensations" in apposition with "thoughts," although sensations and thoughts would seem to be as different as pains and concepts. There is also the suggestion that what is near to us is "in the mind," so that if colors and shapes are not, as they seem to be, at a distance

from us, they must be in our minds. The passage is an important one for indicating the conflicts and confusions involved in the word *idea* and carried over into some of the arguments for idealism.

IMMATERIALISM

Berkeley gave the name "immaterialism" to the central thesis of his philosophy, the thesis that there is no such thing as material substance. Immaterialism has been prominent in idealist theories just because to prove that there is no material substance would be the most effective and spectacular way of disproving materialism. If there is no material substance, then matter cannot be the basis of what is or all that there is. Immaterialism has been supported by two main lines of argument. Along one line it has been argued that it is impossible that matter could be independently real. The arguments to this effect may be called the metaphysical arguments for immaterialism. Along the other line it has been argued that the colors, shapes, and sounds that are naturally taken to belong to independently existing material objects are in fact sensible qualities that cannot exist apart from being perceived.

The arguments to establish this may be called the epistemological arguments for immaterialism. Although he did not call himself an immaterialist, Leibniz, on the evidence of the passage we have quoted, would have regarded himself as an idealist, and his arguments were metaphysical rather than epistemological. Berkeley, of course, is best known for his epistemological arguments, even though his argument that the very notion of something existing totally unperceived is self-contradictory may be classed as metaphysical. Arthur Collier, in his *Clavis Universalis* (London, 1713), used both epistemological and metaphysical arguments; the subtitle of his book, "a Demonstration of the Non-existence or Impossibility of an External World," allowed for both types of approach.

LEIBNIZ. Leibniz's metaphysical idealism consisted of two main theses: (1) that matter is necessarily composite and hence cannot be substantially or independently real, and (2) that simple (that is, noncomposite) substances must be perceiving and appetitive beings even though they are not necessarily conscious or self-conscious. He gave the name "monad" to these independently real and essentially active substances, and he argued that space and time cannot be real containers in which substances exist but must be the order in which monads are related to one another. Thus, he held that space and time are not absolute existences but relations of coexistence and suc-

cession among created monads. He did not conclude from this, however, that space and time and material objects are mere illusions or delusions; delusions and dreams, he held, are by their very nature inconsistent and unpredictable, whereas the material world in space and time is regular and in part predictable. Leibniz was not quite explicit on the matter, but he seems to have believed that space and time were a sort of mental construction or *ens rationis* and that material things are regular appearances rather than real substances. Sometimes, however, he used the expression *phenomena bene fundata* for space and time.

However this may be, Leibniz argued for an idealist system in which there is a series of realms of being with God as the supreme, uncreated spiritual substance. In the realm of created substances all the members are active and immaterial and some are self-conscious substances created in God's image. In the realm of appearances the elements are "well-founded" in the substantial realities, and in consequence they show a rational order even though, like the rainbow, they disappear when closely examined. Finally, there are isolated realms of mere illusion and delusion that, however, have their place in the total scheme of things. Leibniz believed that this metaphysical system could be proved by reason. He held, too, that sense experience is not an independent source of knowledge but is reason in a state of obscurity and indistinctness. Thus, he held that "we use the external senses as … a blind man does a stick" and that the world is revealed as it is by means of reason, not by means of the senses (*Letter to Queen Charlotte of Prussia*, 1702). Thus, he denied not only the substantial reality of matter but also the efficacy and even the possibility of mere sense experience. This is a theme that many later idealists have developed. It runs counter, however, to the empiricist immaterialism of Berkeley.

BERKELEY. Berkeley is the best-known exponent of immaterialism on epistemological grounds. His basic argument is that what we immediately perceive are sensations or ideas, that sensations or ideas are necessarily objects of perception (their *esse*, as he put it, *is percipi*, their essence is to be perceived), and that what we call physical things, such as trees and rocks and tables, are orderly groups or collections of sensations or ideas and are hence mind-dependent like the sensations or ideas that compose them. This argument proceeds on the assumption that sense experience is basic and reliable. Matter is rejected on the ground that the senses inform us of ideas but not of material substances to which these ideas belong. The very notion of a material substance dis-

tinct from sensible qualities or ideas is, according to Berkeley, unimaginable and inconceivable.

Berkeley made the surprising claim that this view is in full accordance with common sense. According to common sense, he argued, trees and rocks and tables are immediately perceived and have the characteristics they are immediately perceived to have. But according to those who believe in material substance, what is immediately perceived are the ideas produced in the mind by material substances of which we can only have mediate or indirect knowledge. Furthermore, these indirectly perceived material substances do not have the characteristics of color, hardness, etc., which common sense says they have. Hence, Berkeley thought that material substances, even if they were conceivable, would be problematic existents, so that the theory in which they figured would give rise to skepticism about the existence of familiar things like trees and rocks and tables. Immaterialism, in contrast, with its claim that such things, being ideas, are immediately perceived, does not lead to skepticism about them.

In its reliance on sense experience, then, and in its acceptance of the view that trees and rocks and tables are immediately perceived and are as they seem to be, Berkeley's immaterialism is very different from that of Leibniz. On the other hand, there is an important point of similarity between their views that is often overlooked. Leibniz held that substances, or monads, that is, the basically real things that make up the world, must be active, perceiving beings. Berkeley held this too, for he argued that sensible qualities or ideas are dependent and passive existences that depend on independent and active beings. These independent and active beings, according to Berkeley, are selves. The difference between Berkeley and Leibniz is that Berkeley held that only selves are active, whereas Leibniz held that activity is possible at a lower level than that of selves. However, this view that what is real is active is an element in a number of idealist theories.

Berkeley also supported immaterialism with the argument that it is not possible even to conceive of anything existing apart from being thought of, for it must be thought of in the very act of being conceived. This argument was not used by Leibniz, but it has played an important part in the arguments of many idealists since Berkeley.

COLLIER. Arthur Collier's *Clavis Universalis*, which appeared posthumously in 1713, was possibly written before Berkeley's *Principles of Human Knowledge* (1710), in which Berkeley's immaterialist philosophy was first published. Collier used epistemological arguments to prove immaterialism, but, unlike Berkeley, he made no attempt to reconcile immaterialism with common sense. On the contrary, he said that in denying the existence of the material world he meant that bodies are as delusory as the visions of lunatics. Collier also produced metaphysical arguments for immaterialism, maintaining, for example, that matter can be proved to be both infinite in extent and not infinite in extent, infinitely divisible and not infinitely divisible, and since nothing can in fact have contradictory characteristics, matter cannot exist.

Knowledge of immaterialism was spread in Germany by the publication of a book that contained German translations of Berkeley's *Three Dialogues between Hylas and Philonous* (London, 1713) and Collier's *Clavis Universalis* and whose title was *Sammlung der vornehmsten Schriftsteller die die Wirklichkeit ihren eigenen Körper und der ganzen Körperwelt leugnen* (Rostock, 1756). The translator and editor, Johann C. Eschenbach, set out to refute as well as to translate the two books.

TRANSCENDENTAL IDEALISM

Kant, in his *Critique of Pure Reason*, described his own view as formal, critical, or transcendental idealism. Nevertheless, a famous passage of that book (B 274) is headed "Refutation of Idealism." Kant called the types of idealism he claimed to be refuting problematic idealism and dogmatic idealism, respectively. By problematic idealism he meant the view, which he attributed to Descartes, that the existence of objects in space outside us is doubtful. By dogmatic idealism he meant the view, which he attributed to Berkeley, that "space and all the things to which it belongs as an inseparable condition" is "something impossible in itself and hence looks upon things in space as mere imaginations" (B 274). Kant's interpretation of Descartes is not quite adequate, but his interpretation of Berkeley is so completely at fault that it seems possible that he had made use of Eschenbach's book and confused Collier's arguments with those of Berkeley.

In any case, Kant's transcendental idealism is very different from the types of idealism we have so far considered. Kant held that it is not possible to gain knowledge of the world by rational thought alone, and thus he rejected all attempts such as those of Leibniz and Wolff to do so. Nonetheless, he also held that mere sense experience does not give knowledge of the world either, since in the absence of interpretation, sense experience is "blind." Thus, Kant argued that unless our perceptions were organized within what he called the pure a priori intuitions of space and time in terms of rational principles

such as the requirement that our perceptions refer to things in causal relation with one another, knowledge of an objective world would be impossible. Without the a priori intuitions of space and time and the categories of the understanding, there would be a manifold of fluctuating sensations but no knowledge of the natural world. When Kant refuted the two types of idealism mentioned above, he argued that no one could become aware of himself unless there were enduring material substances with which he could contrast his own fleeting experiences. We should not be aware of selves unless we were also aware of material things. This line of argument disposes of the view that we could be certain of our own existence but doubtful about the material world and also of the view that material things are "mere imaginations." Unless there were material things in space, we should not know of our own existence or of our own imaginations.

Kant's transcendental idealism, therefore, is his view that space and time and the categories are conditions of the possibility of experience rather than features of things as they are in themselves. Whether things-in-themselves are in space and time and whether they form a causally interacting system we do not know, but unless we were so constituted as to place everything in spatiotemporal contexts and to synthesize our sensations according to the categories of the understanding, we should not have knowledge of an objective world. Kant did not think that this synthesizing was carried out by the empirical selves we are aware of in ourselves and others. He thought, rather, that a transcendental self had to be postulated as doing this, but of this transcendental self nothing could be known, since it was a condition of knowledge and not an object of knowledge. The natural world, or the world of appearances, as he calls it, somehow depends on a transcendental self of which we can know nothing except that it is. Whereas at the empirical level selves and material things are equally real, the knowledge we have at this level presupposes the synthesizing activities of a transcendental self of which we can know nothing.

Kant was regarded in his own day as a destroyer not only because he maintained that there was no basis for the rationalist, metaphysical constructions of Leibniz and Wolff but also because he held that no single one of the traditionally accepted arguments for the existence of God was valid and that it is impossible to prove the immateriality and immortality of the soul. Idealists such as Leibniz and Berkeley and Collier had considered that they had framed philosophical arguments that favored religious belief. Berkeley, for example, emphasized that his conclusions made atheism and skepticism untenable. He also

claimed to have provided a new and cogent argument for the existence of God. According to Kant, however, sense experience cannot lead us beyond the natural world, and the categories of the understanding can be validly applied only where there are sense experiences and if applied beyond them can lead only to insoluble antinomies. For example, if the category of cause is used to transcend sense experience, then equally valid proofs can be made to show that there must be a first cause and that there cannot be a first cause. In the appendix to the *Prolegomena* Kant says that "idealism proper always has a mystical tendency" but that his form of idealism was not intended for such purposes but only as a solution of certain problems of philosophy. All this seems to place Kant outside the main idealist tradition and to indicate that he was developing a positivistic view. Nevertheless, at the end of the eighteenth century a group of philosophers who are known as Absolute idealists claimed to have been inspired by him. What, then, are the features of Kant's idealism that gave rise to views so different from his?

One is that Kant called specific attention to the elements of activity and spontaneity in knowledge. His view that knowledge of nature would be impossible apart from the activity of the understanding in synthesizing sensations in accordance with the categories led some of his successors to regard knowledge as analogous to construction or making. Another feature of Kant's philosophy that pointed in the direction of Absolute idealism was the thesis that synthesizing in terms of the categories presupposed a unitary transcendental self. It is true that Kant himself said that as a presupposition of experience the transcendental self could not be an object of knowledge, but some of his successors claimed to be rather more familiar with it.

Some of Kant's views on morality and on freedom of the will also gave scope for development in an idealist direction. Kant held that the free will problem is insoluble by metaphysical argumentation, for it can be proved both that there must be a freedom of spontaneity and that there is no freedom and everything takes place according to laws of nature. But in his ethical writings that followed the *Critique of Pure Reason*, Kant argued that our knowledge of and respect for the moral law presupposed freedom of the will. He emphasized that this was not a metaphysical or speculative proof; his point was that metaphysics could not disprove freedom of the will, so that we are justified in accepting what morality presupposes. He argued, furthermore, that the existence of God and the immortality of the soul might also be accepted as practical concomitants of morality, as long as the fundamental impossibility of their being theoretically

proved was recognized. Again, Kant introduced into his account of knowledge a faculty of reason (*Vernunft*), which, remaining dissatisfied with the understanding's confinement to the ordering of sense experiences, constantly strove for completeness and totality. Kant thought that the reason might in practice advance our knowledge by seeking for a completeness that is not in fact to be found—Kant used the expression *focus imaginarius* in this connection. Some of his successors transformed this suggestion into the claim that reason reveals a real, not an imaginary or merely methodological, totality.

ABSOLUTE IDEALISM

FICHTE. The development from Kant's idealism to Absolute idealism can be most readily seen in the writings of Johann Gottlieb Fichte (1762–1814). Like Kant, Fichte believed that strict determinism is incompatible with morality and that our knowledge of the moral law presupposes the freedom of the will. Therefore, the philosopher is faced with choosing between two systems of thought, the deterministic system that Fichte called "dogmatism," of which Benedict de Spinoza is the chief representative, and "critical idealism." Fichte recognized that the philosophy a man chooses depends on the sort of man he is, but he also thought that reasons could be given for preferring the idealist course. A reason on which Fichte placed great weight is that thought and intelligence cannot be accounted for within a system of causes and effects, for, in comprehending causal determination, they necessarily go beyond it. If, therefore, there is to be a fundamental account of things, it must start from the intellect. Fichte was here developing a suggestion by Kant in the *Groundwork of the Metaphysic of Morals* that the operations of the intellect transcend the phenomenal series of causes and effects. Thus, according to Fichte a free, intelligent ego (*Ich*) must be the starting point of philosophy, and everything else must somehow be "deduced" from this ego. Fichte, therefore, endeavored to go beyond Kant by showing that space and time and the categories are not just facts that must be accepted as they are but necessary conditions of intelligence. Even the material world is not merely matter of fact but is presented as a series of obstacles that must be overcome in the performance of our duties.

SCHELLING. Friedrich Wilhelm Joseph von Schelling (1775–1854) began his philosophical career as a supporter of Fichte—as the titles of two of his early works show: *Vom Ich als Prinzip der Philosophie* (Tübingen, 1795) and "Philosophische Briefe über Dogmatismus

und Kritizismus" (in *Philosophische Journal*, 1796). Schelling's first account of his distinctive views was titled *System des transzendentalen Idealismus* (Tübingen, 1800), but he later described his view as "absolute idealism," explaining that things are always conditioned by other things, whereas mind is undetermined and absolute. Fichte's idealism has sometimes been called a "moral idealism," since its basis is a system of active moral beings. Schelling's has sometimes been called an "aesthetic idealism," since Schelling argued that it is the artist who makes men aware of the Absolute. Although, like Fichte, he believed that free activity is basic in the world, he placed less emphasis on the distinction between individuals and came nearer to pantheism.

HEGEL. Georg Wilhelm Friedrich Hegel (1770–1831) is too individual a philosopher to be readily classifiable, but he was undoubtedly the most comprehensive and the most influential of the Absolute idealists. In his *Encyclopedia* (Sec. 95) he writes of "the ideality of the finite," which he says is "the main principle of philosophy," and says that "every genuine philosophy is on that account idealism." Like much that Hegel wrote, this is somewhat cryptic, but it appears to mean that what is finite is not real and that the true philosophy, idealism, recognizes this. The matter is more fully discussed in the *Science of Logic* (Bk. 1, Sec. 1, Ch. 2), where Hegel says that philosophical idealism is the view that "the finite is not genuinely real." Here he also contrasts his form of idealism with subjective idealism and says that in denying the reality of the finite, idealist philosophy is at one with religion, "for religion no more admits finitude to be a genuine reality, than it admits finitude to be ultimate, absolute, or as basic (*ein Nicht-Gesetztes*), uncreated, eternal."

We need not linger over Hegel's rejection of subjective idealism, except to refer to what he says about Berkeley's immaterialism in the *Lectures on the History of Philosophy*. Hegel there argues that Berkeley says very little when he says that things are ideas, for this only amounts to recommending a change of nomenclature and calling things ideas, and this throws no new light on the status of things and ideas. Hegel's arguments are metaphysical rather than epistemological. He thought that Fichte was right when he tried to deduce or give reasons for the categories, and Hegel's *Science of Logic* may be regarded as his view of how the deduction should be carried out. Insofar as such a compact work can be summarized, its argument is that we say very little about the world when we say that it is, rather more when we say that it is measurable, or that it is a series of interacting things, more again when we think of it in terms of chemical

combinations, still more when we apply the categories of life, more again when we apply the categories of theoretical reason, and most of all when we come to the categories of will and the pursuit of the good. What remains of the older metaphysical arguments is his view that the incomplete and inadequate categories lead to contradictions. These contradictions, Hegel held, are resolved as the higher categories are reached, in particular the category of the Absolute idea.

Hegel also tried to show that rudimentary mind operates in the natural world. But what most concerned him was the working of mind in human society. He set out a series of stages of human achievement proceeding from the family organization to "civil society" (what today we call the market economy), from civil society to the state, and then, at the highest levels, to art, religion, and philosophy. The idealist character of this construction may be seen from the fact that when Marx wished to set out a materialist view of society he took the economy as basic, the state as dependent on it, and regarded art, religion, and philosophy as ideologies that had no real influence.

Hegel's philosophy was elaborated after his death by a series of able successors and criticized from many points of view. It came to be known in England about the middle of the century, and Benjamin Jowett translated some passages (which he never published) for the use of his students. Absolute idealism was made known to a larger British public by James Hutchinson Stirling's *The Secret of Hegel* (2 vols., London, 1865), (Fichte's moral idealism had earlier influenced Thomas Carlyle, and Samuel Taylor Coleridge had been influenced by his reading of Schelling, although he had not accepted all of Schelling's views. William Wordsworth's definition of poetry as "emotion recollected in tranquillity" seems to be a translation of a phrase of Schelling's that Coleridge noticed and copied into his notebook).

NEO-HEGELIANISM

About the time when German Absolute idealism was becoming known in England through the writings of Coleridge and Carlyle, it was also becoming known in the United States through a group of writers (mostly Unitarians) who came to be called the transcendentalists. Later, in the 1860s, idealist philosophy received more detailed and professional attention on both sides of the Atlantic. In 1867 at St. Louis, William Torrey Harris founded the *Journal of Speculative Philosophy*, in the first issue of which he referred disparagingly to the prevailing "brittle individualism" that he considered should be replaced by a

philosophy in which the state was properly comprehended as a support for freedom. In the same period Thomas Hill Green was teaching philosophy at Oxford with the support of Jowett. The nature of Green's influence may be seen from a letter sent to Green in 1872 asking him to speak to an essay society whose members felt the need for "earnest effort to bring speculation into relation with modern life instead of making it an intellectual luxury, and to deal with various branches of science, physical, social, political, metaphysical, theological, aesthetic, as part of a whole instead of in abstract separation," and sought for "co-operation instead of the present suspicious isolation." This letter was signed by, among others, F. H. Bradley, who had recently become a fellow of Merton College (Melvin Richter, *The Politics of Conscience. T. H. Green and His Age*, London, 1964, pp. 159–160). Both Harris and his circle and Green and his were critical of social individualism as well as of positivism and materialism. They aimed to provide an alternative to utilitarianism, which they thought was based on an inadequate pluralistic metaphysics.

Green's form of idealism was rather closer to that of Kant than to that of Hegel. It was built around two main themes, that the natural world cannot be self-contained and ultimate, and that there is no merely given experience. The first theme is an extension of Kant's theory of the transcendental ego, which Green held implied that nature presupposes "a principle which is not natural," a "spiritual principle" (*Prolegomena to Ethics*, Oxford, 1883, Sec. 54). The second theme, on the other hand, goes well beyond Kant, who believed that there was a "manifold of sense" which the understanding synthesized. Green's view that there is no merely given sense experience, and that all experience implies some sort of intelligent organization, was a central theme of subsequent idealist argument. It has a certain kinship with Leibniz's theory that ideas of sense are confused ideas of reason.

Green died in 1882, and the leading English idealist philosophers after that were F. H. Bradley and Bernard Bosanquet. In Scotland, where idealism very soon prevailed in the universities, Edward Caird's *A Critical Account of the Philosophy of Kant* (Glasgow, 1877) and Andrew Seth's (later Pringle-Pattison's) *Hegelianism and Personality* (London and Edinburgh, 1887) were notable contributions. But from the 1880s to the 1920s Bradley and Bosanquet dominated the philosophical scene in Great Britain. Bradley attempted to discredit the commonsense view of the world by bringing to bear a multitude of arguments to show that it involved self-contradictions, and he argued that these contradictions could

be eliminated only if the world is shown to be a single, harmonious experience. The central theme of Bosanquet's idealism was that every finite existence necessarily transcends itself and points toward other existences and finally to the whole. Thus, he advocated a system very close to that in which Hegel had argued for the ideality of the finite. Bradley and Bosanquet influenced one another a great deal. For example, Bradley's *Ethical Studies* (London and Edinburgh, 1876) influenced Bosanquet's account of society, and Bosanquet's *Knowledge and Reality* (London, 1885) led Bradley to modify very considerably the views he had set out in his *Principles of Logic* (London, 1883).

In the United States the most impressive contribution to the philosophy of idealism is Josiah Royce's *The World and the Individual* (first series, New York, 1900; second series, New York, 1902). Royce was extremely learned in the literature of idealism, both German and British, and *The World and the Individual* was written in the light of his study of Kant, Fichte, Schelling, and Hegel and of his reading of Bradley's *Appearance and Reality* (London, 1893). Furthermore, Royce was acquainted with the empiricism and pragmatism of C. S. Peirce and William James and with Peirce's work in formal logic. Like Pringle-Pattison, Royce considered that Bradley went too far in regarding the individual mind as "fused" or "transformed" in the Absolute. The mystic who regards finite experience as mere illusion, Royce held, is an improvement on the realist who uncritically accepts it just as it is, but nevertheless the very point of idealism would be lost if the individual self is deprived of all cosmic significance. Royce believed he could show that the "world … is a realm of individuals, self-possessed, morally free, and sufficiently independent of one another to make their freedom of action possible and finally significant" (*The World and the Individual*, first series, p. 395). Like Fichte, Royce endeavored to support this view by an analysis of the moral, rational will.

By the beginning of the twentieth century idealism had become a powerful force in the universities of the English-speaking world. Empiricism and realism were held to have been finally discredited, along with the utilitarianism and individualism that had so often accompanied them. Philosophical truth was thought to be a unity, so that similar principles animated idealist works on aesthetics, ethics, religion, and politics. Such leading British statesmen as Arthur J. Balfour and Richard B. Haldane and the South African prime minister Jan C. Smuts wrote books defending the idealist point of view. When the new provincial universities were being founded in Great Britain at that time, Haldane used his influence to foster the study of philosophy in them, as a central, unifying subject.

At the same time, however, points of view opposed to idealism were being vigorously developed. An example is G. E. Moore's "The Refutation of Idealism," which appeared in *Mind* (n.s. 12 [1903]: 433–453). Another example is *The New Realism*, a collection of articles by American philosophers critical of idealism that was published in New York in 1912. Bertrand Russell urged that idealists were ignorant of new developments in logic and that this rendered their theories untenable. Ludwig Wittgenstein's *Tractatus Logico-Philosophicus* (London, 1922) was symptomatic of a new, pluralist, antispeculative approach to philosophical problems. Moore's "The Conception of Reality" (*PAS*, 1913–1914) attempted to show that one of Bradley's theses was nothing but a consequence of his not realizing that the proposition "Unicorns are thought of" is of quite a different logical form from the proposition "Lions are hunted." In the 1920s the very possibility of speculative metaphysics was denied on the basis of the allegedly empiricist principle of verifiability. Furthermore, the idealist theses about the "unreality" of finite individuals and the "reality" of society or the state were held to be evil as well as meaningless.

But during this period when the idealist movement was under increasing attack, three important treatises appeared in which comprehensive idealist theories were developed. John M. E. McTaggart's *The Nature of Existence* (Cambridge, U.K., 2 vols., 1921–1927) defended a pluralistic idealism by means of metaphysical arguments designed to show that space, time, and matter cannot possibly be real. Michael Oakeshott's *Experience and Its Modes* (Cambridge, U.K., 1933), unlike McTaggart's work, seems to have been completely unaffected by the realist and empiricist arguments so widely accepted at that time. Brand Blanshard's *The Nature of Thought* (2 vols., London, 1939), on the other hand, maintains a constant and detailed criticism of behaviorist and empiricist arguments. It is noteworthy that in none of these elegantly written idealist works is there any attempt to defend a theistic position. Indeed, *The Nature of Existence* concludes its discussion of God by saying that "there can be no being who is a God, or who is anything so resembling a God that the name would not be very deceptive" (Sec. 500).

IDEALIST SOCIAL THEORY

Most nineteenth-century and twentieth-century idealist philosophers were agreed that utilitarians and individual-

ists had a false view of what constitutes an individual person. They believed that since individuals are constituted by their relations to one another, the idea that society is an association of independently existing individuals is absurd. They thought, too, that it follows from this that freedom is something more positive than just being left alone by the government. Insofar as government is concerned with the common aims of individuals, it is not merely a constraint on them but a manifestation of their most rational purposes. Some idealist writers, therefore, saw no serious harm in Rousseau's claim that men can be forced to be free. T. H. Green was thus able to support temperance legislation on the ground that it enabled those protected by it to fulfill their abiding aims rather than their passing whims.

Even so, Green had no doubts about the ultimate reality of individual persons, whereas Bosanquet, in his *Philosophical Theory of the State* (London, 1899) argued that the state is the real individual and that individual persons are unreal by comparison with it. But Bosanquet did not think that this justified socialist control. On the contrary, he believed that if society is organic and individual, then its elements can cooperate apart from a centralized organ of control, the need for which presupposes that harmony has to be imposed upon something that is naturally unharmonious.

McTaggart was the one leading idealist who denied the relevance of metaphysics to social and political action. He was a Hegelian scholar who was in general agreement with Hegel's views, but he thought that Hegel was wrong in supposing that metaphysics could show that the state is more than a means to the good of the individuals who compose it. McTaggart concluded that "philosophy can give us very little, if any guidance in action.… Why should a Hegelian citizen be surprised that his belief as to the organic nature of the Absolute does not help him in deciding how to vote? Would a Hegelian engineer be reasonable in expecting that his belief that all matter is spirit should help him in planning a bridge?" (*Studies in Hegelian Cosmology*, Cambridge, U.K., 1901, p. 196).

SOME COMMENTS ON IDEALISM

ACT AND OBJECT. Moore, Russell, and other realist philosophers at the beginning of the twentieth century objected to idealism that its exponents failed to distinguish between the act of perception and the object of the act. It was rightly argued that the words *idea* and *sensation* were used vaguely and thus encouraged the confusion. According to the realist argument, colors and shapes are objects of the mind, whereas pains and feelings are states of mind, and what the idealists do is to say of the former that they are essentially mental, when this is true only of the latter. It may be questioned, however, whether the idealists were thus confused. Certainly Berkeley was not, since in the first of the *Three Dialogues between Hylas and Philonous* he himself made this objection only to reject it on the ground that the only acts of mind are acts of will, and in perceiving we are passive and do not exert acts of will.

In any case it is not easy to be sure that we can recognize or identify acts of perception. William James, for example, said he could distinguish no such thing (*Essays in Radical Empiricism*, New York, 1912), and Russell later took this view as well (*The Analysis of Mind*, London, 1921). Furthermore, even if the distinction is acceptable, what the object of perception is still remains to be determined. It is hard to maintain that what is immediately perceived is a physical object, since this seems to be inconsistent with the physiology of perception. If the immediate object is a sense datum, as Moore and Russell argued, then this suggests a representative theory of perception. But representative theories of perception are liable to the objection that they make our knowledge of physical objects problematical. If, on the other hand, sense data are not intended to play their part in a representative theory of perception but are meant to be all that can be perceived, then commonsense realism has been abandoned and Berkeley is vindicated. Apart from this, the very notion of a sense datum is dubious, since it is impossible to specify what a sense datum is without reference to physical objects. The distinction between act and object does not, therefore, lead to any effective arguments against idealism.

EXISTENCE APART FROM MIND. We have seen that Berkeley supported his immaterialist theory with the argument that nothing could exist apart from mind, since if we try to think of something existing unthought of we have to think of it, so that there is a contradiction in the very notion of thinking of something unthought of. Berkeley was by no means the only idealist who used this argument. It seems to have been accepted by Bradley, for example, when he wrote in Chapter 14 of *Appearance and Reality*:

> We perceive, on reflection, that to be real, or even barely to exist, must be to fall within sentience …. Find any piece of existence, take up anything that any one could possibly call a fact, or could in any sense assert to have being, and then judge if it does not consist in sentient expe-

rience. Try to discover any sense in which you can still continue to speak of it, when all perception and feeling have been removed; or point out any fragment of its matter, any aspect of its being, which is not derived from and is not still relative to this source. When the experiment is made strictly, I can myself conceive of nothing else than the experienced.

This general line of argument came under attack in *The New Realism*, where the objection to it was that it falsely concludes that whatever is must be experienced from the evident tautology that whatever is experienced is experienced. From the fact that nothing can be experienced without being experienced it does not follow that everything must be experienced. Another way of stating this objection is to distinguish (*a*) it is impossible to-think-of-something-existing-unthought-of and (*b*) it is impossible to think of something-existing-unthought-of. Berkeley and Bradley are accused of denying the possibility of (*b*) because of the obvious impossibility of (*a*) (G. Dawes Hicks, *Berkeley*, London, 1932).

IDEALIST METAPHYSICS. Idealism involves the existence of some ultimate spiritual reality beyond what appears to common sense and ordinary sense experience. If it could be proved, therefore, that it does not make sense to speak of something that transcends sense experience, then idealism, like all other metaphysical systems, would be meaningless, as is claimed by logical positivism. Logical positivism, however, has been subjected to serious criticism and is by no means the chief alternative to idealism. It is linguistic philosophy, the philosophy that seeks to solve or to dissolve philosophical problems by showing that they arise out of linguistic misunderstandings, that today is the strongest opponent of idealism.

Moore's insistence on the act-object distinction was not, as we have seen, a successful mode of attack on idealism. But when he criticized Bradley for misunderstanding the logic of propositions in which something is said to be real, he was starting a sort of philosophizing that has proved most inhospitable to idealist theories. Moore saw that when Bradley said that time is unreal he had no wish to deny such things as that people are sometimes late for their trains. Yet if there were no temporal facts, there would be no trains and no people to catch or to lose them. Moore felt that something had gone wrong with Bradley's argument, and he tried to locate the fault. He thought that Bradley believed that even though time is unreal, if it can be thought of then it must have some sort of existence. Moore thought he could show that this belief

is groundless and arises from a misunderstanding of what is being said when something is said to be real. But Moore also came to believe that we know for certain such things as that there are trains and people and that in consequence we are justified in denying out of hand those philosophical views that would require trains and people and space and time and matter to be mere appearances or not to be real at all. It was through his attempts to understand the prevailing idealist metaphysics that Moore came to adopt his philosophy of common sense. This philosophy and the linguistic philosophy that grew out of it regard our prephilosophical beliefs and concepts as in a certain sense unassailable. If this view is correct, then idealism is based on misunderstandings. If it is not correct, then the idealist criticisms of our prephilosophical beliefs have to be taken seriously.

IDEALISM AND THE NATURE OF THOUGHT. The idealist movement is important in the history of philosophy quite apart from the success or failure of idealist metaphysics. Idealists have insisted from Kant onward that thinking is an activity. This view of thinking was Kant's particular contribution to philosophy and is opposed to the Cartesian theory of knowledge. According to Descartes knowledge consists in the intuition of clear and distinct natures. What keeps us from obtaining knowledge, Descartes held, is the existence of prejudices that keep us from getting face to face with the ultimate clarities; once the prejudices are removed, the world shows itself as it really is. On this view the human mind is like a mirror that reflects what is there when it has been wiped clean. According to Kant, however, the mind approaches the world with concepts and presuppositions of its own. It does not reflect the world but tries to understand and interpret it. The activity of synthesizing is an activity of interpreting, and this can be done only by means of concepts that we already possess. According to Descartes we must wipe the mirror clean to be ready for undistorted visions; inquiry ends in revelation. According to Kant we gain knowledge as we improve and test our theories. Apart from natural science, nature is nothing but what men have to contend with in their daily concerns. This view was metaphysically elaborated by Kant's idealist successors, but they did not lose sight of an important implication of it that Kant had seen, the implication that the pursuit of knowledge was a spontaneous activity. They argued that knowledge and freedom go together and that therefore determinism and reductive materialism cannot be true. This would appear to be the essence of the idealist argument.

IDEAL OBSERVER THEORIES OF ETHICS

The ideal observer theory (IOT) offers an account of the truth/objectivity of moral judgments in terms of the approval or disapproval of an ideal observer. The theory receives explicit treatment by Adam Smith and Henry Sidgwick; Roderick Firth is the most well-known proponent of the theory in the twentieth century.

There are two versions of the theory. On one account the IOT is an analysis of what (some, all) moral judgments mean: A judgment that some act (or event or state of character) is good may be analyzed in terms of that act being approved of by an ideal observer (IO); some act is wrong if it would be disapproved of by an IO. Most, but not all, such accounts conceive of the IO in hypothetical terms, leaving open the question of whether there actually is an IO. The traits of the IO vary between ethical theories, but they often include impartiality, knowledge of all of what may be called nonmoral facts (facts that may be conceived of and known without ipso facto knowing the moral status of the fact), and an affective awareness of the points of view of all involved parties. The reason for employing a term such as *nonmoral facts* is to avoid an explicit circularity, for the theory must be more informative than claiming that some act is morally right if and only if it would be approved of by a being who is omniscient with respect to all moral facts.

While strong versions of the IO theory offer an analysis of what moral rightness and wrongness mean, moderate proposals hold that the IO point of view amounts to an analysis of the moral point of view; that is, the point of view from which ideal moral judgments are made. On this account, what it means for persons to carry out an inquiry into the moral status of some act is to engage in an inquiry aimed at achieving impartiality, knowledge of the relevant nonmoral facts, and an affective awareness of the points of view of all involved parties. Arguably, these conditions might be both necessary and sufficient for moral inquiry, and yet the IOT would not amount to an analysis of what it means for some act to be right.

Both versions are subject to objections. Against both accounts philosophers have questioned the feasibility and desirability of impartiality. IO accounts that appeal to the hypothetical responses of an IO face a problem in terms of moral psychology; someone making a moral judgment about some act need have no interest in the responses of some other, hypothetical observer. There is also the recurrent charge against both versions that the theory is circu-

lar. They build into the concept of an IO the notion that the observer is in fact ideal; being impartial, for example, is a positive moral ideal. If so, the theories presuppose a moral ideal and so cannot be used to analyze what it is to be morally ideal. Some argue that neither account is able to avoid conflict between IOs or those seeking the moral point of view. There is also the charge that both accounts fail because it is coherent to claim that an IO or one who achieves the ideal moral point of view may get matters wrong.

The first two objections may be played against each other. Evidence that philosophers disagree about the moral desirability of impartiality is evidence that impartiality is not an obvious moral ideal. If the case against the moral desirability of impartiality is successful, the IO theory will need amending to allow for specific, partial duties and goods. Some versions of the IO theory have been articulated that accommodate the thesis that IOs disagree (Thomas Carson 1984), while others argue that there is no reason to suppose that there would be disagreement (Charles Taliaferro 1988).

There have been several replies to the charge that IOs or those taking the ideal moral point of view may be wrong. Some link the IO theory with a divine command theory according to which moral rightness and wrongness is constitutive of an actual IO's God's approval and disapproval. The apparent coherence of there being something approved of by God that is morally wrong is accommodated the way in which some philosophers accommodate the apparent possibility that one might have water without H20.

On behalf of using the second, modest form of the IO theory, it has also been charged that the following state of affairs is incoherent. A person morally disapproves of some act but she believes that if she were an IO she would approve of the act. According to the moderate version of the theory, the person disapproves of the act but simultaneously believes that she would reverse her view if she were actually impartial, knew more of the relevant nonmoral facts, and had an affective understanding of the points of view of those affected. Arguably, when we disapprove of some act morally, we often allow the *possibility* that we may not be impartial, we may be ignorant of the nonmoral facts, and we may lack an awareness of the feelings of those involved, but it would be peculiar for a person to disapprove of an act while believing that one is *actually* mistaken about the nonmoral facts, and so on.

IDEAS

The word "idea" is a transliteration of a Greek word of which the root meaning is "see." In classical Greek it never lost the possible meaning "visual aspect"; thus Plato writes of a person as being "very beautiful in idea," meaning "beautiful in visual aspect" or "good-looking" (*Protagoras* 315E). Very often visual shape is primarily involved, as when Plato refers to the "idea of the earth," meaning "the visible shape of the earth" (*Phaedo* 108D). The transferred sense of "type" or "kind" springs quite naturally from this use. Thus Thucydides writes of "many ideas [kinds] of warfare" (*Histories* I, 109).

In Plato's more technical use, the Ideas or Forms are always spoken of as (1) the objects of intelligence, in contrast with the objects of perception; (2) things that truly *are,* in contrast with changing objects of perception, which are in a state of *becoming*; (3) eternal, in contrast with the perishable world of change. But there are at least two irreconcilable strands in Plato's thought about Ideas. Sometimes he seems to have thought of Ideas much as later philosophers have thought of universals, as when he says that "we are accustomed to posit a single form for each group of many things to which we give the same name" (*Republic* 596A); consistent with this he speaks sometimes of the *presence* of the form in the particular or

of the particulars as participating in the form (*Phaedo* 100D). But sometimes Plato writes as if his Forms were, rather, perfect exemplars or paradigms of which the sensible world is an imperfect copy or imitation; thus in the *Parmenides* Socrates says that the Forms are "as it were paradigms" and that "other things are like them and are copies of them" (132D). When the Forms are thus described, we also find Plato insisting that they are "separate," a doctrine in conflict with the language of "presence" and "participation" noted above. It is plausible to suggest that there is here a tension between the theory of universals and the theory of resemblance to standard objects as explanations of common names.

But it is the theory of Ideas as separate and eternal paradigms that appears in the *Timaeus,* the dialogue that had incomparably the greatest influence on later antiquity and the Middle Ages; there the divine demiurge is depicted as forming the world on the pattern of the eternal Forms. It will therefore be the aspect of Forms as paradigms, perfect exemplars, blueprints, particularly as patterns used by a divine agent in creation, which will be important in the development of the philosophical notion of an idea.

In the *Timaeus* the Forms, or Ideas, are eternal and independent objects to which the demiurge looks as patterns. But one of the most important and early modifications of this Platonic view is the religious conception of the Ideas as the thoughts of God. This is the view of Plotinus (*Ennead* III, 9, i), of Philo (*De Opificio Mundi* 4) and of Augustine (*De Diversis Quaestionibus LXXXIII,* Question 46). Clement of Alexandria simply defines an idea as a "thought of God" (*Stromateis* V, iii, 16.3). The ideas are still perfect and eternal exemplars, but now they are in the mind of God.

It is not a very long step to extend the term *idea* to cover patterns, blueprints, or plans in anybody's mind, not only in God's. Thus we find Thomas Aquinas saying that "the word 'idea' signifies a certain form thought of by an agent in the likeness of which he intends to produce an external work" (*Quaestiones Quodlibetales* IV, I, lc); similarly Goclenius says that "in general an idea is a form or exemplar of a thing with an eye on which a workman makes what he has planned in his mind" (*Lexicon Philosophicum* 208A).

When the word *idea* was taken over into the French and English vernacular by learned men in the sixteenth century, there were thus two elements in the concept of an idea—that it was an exemplar or pattern and that it was a thought in a mind. Using the pattern element alone, François Rabelais could speak of Pantagruel as being the "idea and exemplar of every joyous perfection" (*Pantagruel,* Book III, Ch. 51); but a pattern and its copy could be easily muddled so that Rabelais also could say, "En leur mariage semble reluire quelque idée et représentation des joyes de paradis" ("In their marriage some idea and representation of the joys of paradise seems to be reflected"; *Pantagruel,* Book III, Ch. 10). When the other, mental element is introduced, the meaning of "idea" quickly becomes "mental representation"; this is a very common meaning in sixteenth-century French and English, and the phrase of Michel Eyquem de Montaigne, "Ayant par longue conversation planté vivement dans son âme unc générale idée de celle de Plutarque" ("Having by long communion vividly emplanted in his own a general idea of the mind of Plutarch"; *Essays,* II, 4), could be paralleled many times.

DESCARTES

Thus when René Descartes first began to write, the meaning "image or representation," often but not necessarily "in the mind," was already well known in the vernacular. In spite of the fact that Descartes is usually credited with the invention of the non-Platonic use of the term, we find him at first following this vernacular use. In his first Latin work, the *Regulae,* the word *idea* appears infrequently, but Descartes always uses it to mean an image or representation; when he first introduces it in the *Meditations,* he at once says, "Quelques-unes [de mes pensées] sont comme les images des choses, et c'est à celles-là seules que convient proprement le nom d'idée" ("Some [of my thoughts] are like images of things, and it is to these alone that the name 'idea' properly belongs"). It is only under the pressure of philosophical difficulties that he extends the term *idea* to cover the unimaginable, for which Thomas Hobbes duly reprimanded him: "When I think of a man I represent to myself an idea or image composed of colour and shape. … of God we have no image or idea" (*The Third Set of Objections,* Objection 5). There is therefore no need for any explanation why the word *idea* tends to mean "mental image" to seventeenth-century philosophers; this is what the word ordinarily meant in their time.

What does need explanation is why, if Descartes found the word *idea* to mean "properly" only "an image of a thing," he and other philosophers could use "having an idea" as a proper designation of all thought and could define an idea as the object of a mind when it thinks, in a liberal sense of "think" that includes sense perception. Part of the explanation is to be found in the representative theory of perception, held in some form by all the

philosophers of the period; there was no extension of meaning in using "idea" of sense perception because it was believed that what was directly perceived was not things, but images of things—the images caused by and more or less resembling the things themselves. Another part of the explanation is the "image theory" of thinking: To think of something is or includes having either a mental image of that thing or, as some believed, a physical image on that part of the brain termed the "corporeal phantasy." Such a view was in the air at the beginning of the seventeenth century and was accepted by Pierre Gassendi and Hobbes without reservation. Descartes never doubted that many of our thoughts are images of things; his extension of the term arises from his gradual realization of the inadequacy of the image theory to account for all our thought even while he persevered in the use of its terminology. His use of the term to denote any object of thought became the standard one in philosophy, via such influential writings as the *Port-Royal Logic* and John Locke's *Essay.* Only a few scholastically trained philosophers, such as Immanuel Kant, have stood out for a more Platonic usage; thus Kant in the *Critique of Pure Reason* holds to the terminology of the transcendental ideas of reason to which no corresponding object can be perceptually given, as distinct from the concepts of the understanding ("Transcendental Dialectic," I, 2).

Most of the confusions in the "way of ideas" arise at least in part from the use of the term *idea* to cover both the representative percept and the object of conceptual thought. This can be illustrated in terms of the doctrines of innate ideas, concrete and abstract ideas, and simple and complex ideas.

INNATE IDEAS

The mature Gottfried Wilhelm Leibniz always maintained, and Descartes sometimes maintained, that all our ideas are innate. Thus Leibniz said that "all the thoughts and acts of the soul come from its own depths, with no possibility of their being given to it by the senses" (*New Essays concerning Human Understanding,* Book I, Ch. i, 1). But this is a theory of *perception,* as is made clear by Descartes in his *Notes Directed against a Certain Program,* his defense of the view:

> Nothing comes from external objects to our mind through the organs of sense save certain corporeal motions … but not even these motions, and the configurations to which they give rise, are conceived by us as they occur in the sense-organs. … Whence it follows that the very ideas of motions and configurations are innate

in us. So much more must the ideas of pain, colours, sounds, and the like be innate, so that our mind can, on the occasion of certain corporeal motions, display them to itself; for they have no similarity to the corporeal motions.

There is nothing here from which Locke would dissent, except verbally; no wonder that Leibniz said, in the preface to his *New Essays,* "I am led to believe that at bottom his [Locke's] view upon this point is not different from mine." The true controversy with Locke is, rather, exhibited by Descartes's view of concepts, expressed in the same terms as and never distinguished from the perceptual theory by philosophers of the time. According to this theory, some ideas are innate—for example, those of God, mind, body; others are adventitious—one's ordinary idea of the sun; still others are made (*factae*) or factitious—the ideas of the sun astronomers construct by reasoning. It is those innate and factitious ideas—which Descartes could as little say were *occasioned* by "corporeal motions" as Locke could say they were *caused* by "corporeal motions"—which raised a still-pressing difficulty.

ABSTRACT AND CONCRETE IDEAS

The distinction between abstract and concrete ideas is virtually the distinction, misleadingly put, of concepts and percepts. The doctrine of abstract ideas was held by the Cartesians, and the best statement of it is to be found in *Port-Royal Logic,* Book I, Ch. 6. To have an abstract idea is to think of some feature or features of the perceptible without attending to other features that it has and that are as inseparable from it (except in thought) as are the length and breadth of a road. Locke took over the Port-Royal account of what abstraction was without change, even echoing its language, but tried to give a more thorough account of what it involved. He tried to give an account of abstraction in terms of a doctrine of simple and complex ideas, but by failing to distinguish thought and perception, he gives two incompatible accounts of this distinction. In Book III of the *Essay* he tells us that all ideas save those denoted by proper nouns are abstract. Of these some are indefinable; they are simple ideas. Others are definable; these are complex ideas. "The ideas first in the mind, it is evident, are those of particular things" (*Essay,* Book IV, Ch. vii, Sec. 9)—that is, we first perceive particular things; in thinking about them, we may come to form some very general ideas by omitting less interesting features and concentrating on those common to a whole group, which taken together form a complex idea; by further abstraction we can get to less and less complex ideas. It is clear that according to this view simple ideas

involve the highest degree of abstraction. But in Book II we are told that the simple ideas enter the mind in perception simple and unmixed; they are objects of perception. Thus a theoretical analysis of the construction of concepts is inextricably confused with an atomistic doctrine of perception. If simple ideas are objects of perception and complex ideas are formed from them, then all abstract ideas ought to be imaginable, and George Berkeley's famous sneers about the abstract idea of a triangle have some justification. But neither Berkeley nor David Hume could emancipate himself from the basic confusion; this is true of Hume in spite of his famous distinction between ideas and impressions.

Thus the classical theory of ideas, which had held virtually undisputed sway in the seventeenth and eighteenth centuries among rationalists and empiricists, was based on the theories of representative perception and image-thinking. To continue to use the terminology after these theories had been abandoned as inadequate could lead only to confusion and a skepticism which, consistently developed, would be even more extreme than Hume's.

Reasonably, therefore, outside the empiricist tradition the term *idea,* as employed in the seventeenth and eighteenth centuries, soon ceased to appear in philosophical writings. Kant's representations have, indeed, some resemblance to ideas of sensation, and the thing-in-itself plays a part somewhat analogous to Locke's substratum. But there are important differences, and his concepts of the understanding are very far from being copies of representations. He does, indeed, use the term *idea* technically, but with a yet further removed significance. In the *Critique of Pure Reason,* he says: "I understand by 'Idea' a necessary concept of reason to which no corresponding object can be given in sensation" ("Transcendental Dialectic," I, 2). These ideas, such as that of the absolute unity of the subject, have, Kant holds, a valid regulative employment, but if we try to apply them to experience we become involved in metaphysical paralogisms. Insofar as the term continued to be used in Continental philosophy it was used, as by G. W. F. Hegel, in senses far removed from that in pre-Kantian philosophy.

But in British philosophy the terminology did not die an easy death. The empiricists could not abandon it, especially in their philosophical psychology in which the doctrine of the association of ideas continued to play the dominant role given to it by Hume. It was largely F. H. Bradley's polemic against psychologistic logic that finally led to the abandonment of the "way of ideas." But even Bradley, in the first chapter of his *Logic,* which is a locus

classicus for the attack on psychologism, showed that he had not completely emancipated himself. He could still write that "the idea, in the sense of mental-image, is a sign of the idea in the sense of meaning," and added "without ideas no judgment," though in a note of 1922 he rejected these statements. By 1922 his own work and that of G. E. Moore had led to the elimination of the term *idea* from British philosophy, except as a part of nontechnical idiom.

In the United States, also, the term *idea* continued to have considerable currency. It was a key term in the pragmatism of Charles Sanders Peirce, William James, and John Dewey, reflecting the fact that they, too, were heirs to the empiricist tradition though not to Humean skepticism. They avoided this skepticism in part by wholly abandoning the image theory of thinking with which the terminology of ideas was traditionally linked. In Dewey's instrumentalism, ideas became tools for directing our activities, responses to sensation rather than sensations. They were tied to practical transactions. In calling the idea a law of action, Dewey reminds us rather of the definition given by Thomas Aquinas quoted earlier in this article than of the traditional empiricist position. But Peirce could still think, like Bradley, of ideas as psychological entities, as well as in terms of pragmatic epistemology; and in James also the pragmatic doctrine that our ideas of an object have to be explained in terms of the sensations we expect from it and the reactions we make toward it had still not been completely disentangled from a more traditional empiricism.

J. O. Urmson (1967)

IDENTITY

The word *is* is multiply ambiguous. When it can be expanded to read "is the same thing as," or "is identical with," or (in numerical contexts) "is equal to," it expresses the relation of identity. The simplest identity statements contain the "is" of identity flanked by singular terms, either names or definite descriptions: "Samuel Clemens is Mark Twain"; "The U.S. president in 1996 was Bill Clinton"; "Four is the sum of two and two." A more complex identity statement might, for example, combine the "is" of identity with quantifiers: "Every even number is the sum of two primes."

Identity, on its face, is simple and unproblematic: It is that relation that everything bears to itself and to nothing else. Yet discussions of identity in contemporary philosophical logic and metaphysics are brimming with controversy. From where does this controversy arise? Some of it is not genuine, being based on confusion; and some of it, though genuine, is not genuinely about identity. However, a residue of controversy survives, owing to the view, perpetrated by Peter Geach, that identity statements are meaningless unless relativized, that there is no absolute relation of identity.

SOURCES OF CONFUSION

One source of confusion is the ambiguity of "identical" in English. We do sometimes say that two things are identical, as when we speak of identical twins, or say that some coat is identical with some other. This is qualitative identity: Things are qualitatively identical if they resemble one another sufficiently in relevant qualitative respects. Numerical identity is different: Two things, no matter how closely they resemble one another, are never numerically identical. Numerical identity is the topic of this article.

A second source of confusion is English grammar, which allows, for example, "Clemens is identical with Twain" to be rewritten equivalently as "Clemens and Twain are identical" or as "they are identical." But then it seems that two persons (or two *somethings*) are being said to be identical, which is absurd. A general response is familiar from other cases: Surface grammar often misrepresents the underlying logic: One must beware inferring logical from grammatical form. More specifically, it can be verified that plural noun phrases in English do not, in all contexts, entail or presuppose reference to a plurality.

A third source of confusion is Gottlob Frege's puzzle of informative identity statements, sometimes introduced by the following argument. To say of something that it is identical with itself is trivial, to say of something that it is identical with something else is false; therefore, identity statements are all either trivial or false, and there can be no point in asserting them. This conclusion is manifestly incorrect: Identity statements are often both true and informative, as witness, "the capital of Honduras is Tegucigalpa." The puzzle is to say where the argument goes wrong.

One response rejects the second premise by taking identity to be a relation between names or descriptions rather than between the objects named or described: Identity is then the relation of codesignation, the relation that holds between singular terms whenever those terms designate the same object. That would indeed allow identity statements to be both true and informative. But the response is not viable, for many reasons. For one, it fails to account for uses of identity that do not involve singular terms, such as: "Everything is identical with itself." For another, it fails to allow identity statements between different singular terms to be uninformative, as they are when the singular terms are synonymous. For another, it fails to provide a unified solution to analogous puzzles of informativeness, such as how "the capital of Honduras is in Honduras" and "Tegucigalpa is in Honduras" can differ in informativeness, even though both ascribe the same property to the same thing.

A better response is due to Frege. Identity is a relation between objects; a simple identity statement is true just in case the objects referred to by the singular terms stand in that relation. But singular terms have sense in addition to reference; a true identity statement is informative just in case its singular terms differ in sense. (Just what is included in the sense of a singular term varies from theory to theory; but note that senses must be rich enough to allow codesignative proper names—such as "Mark Twain" and "Samuel Clemens"—to differ in

sense.) Now the puzzle may be solved by rejecting the argument's first premise: One can say informatively of an object that it is identical with itself by referring to the object twice over, using singular terms that differ in sense. That is how "The capital of Honduras is Tegucigalpa" manages to be both true and informative. Identity statements are useful in ordinary language because we often refer to the same object from different points of view, using terms with different senses. (Frege's statement of the puzzle, and his solution, is in Frege 1892; see also Kripke 1980, Salmon 1986.)

THE LOGIC OF IDENTITY: LEIBNIZ'S LAW

Relations may be classified according to their general, logical characteristics. The logical characteristics of the identity relation are easily enumerated. First, as already noted, identity is reflexive: Every object is identical with itself. Second, identity is symmetric: If an object x is identical with an object y, then y is identical with x. Third, identity is transitive: If an object x is identical with an object y, and y is identical with an object z, then x is identical with z. A relation that is reflexive, symmetric, and transitive is called an equivalence relation. Finally, identity is the strongest equivalence relation, entailing all other equivalence relations: If an object x is identical with an object y, then x bears R to y, for every equivalence relation R. Since being the strongest equivalence relation (or, equivalently, being the strongest reflexive relation) uniquely characterizes identity in purely logical terms, identity may properly be classified as a logical relation and the theory of identity as a branch of logic.

All of the logical characteristics of identity can be derived from a single principle, sometimes called Leibniz's law: An object x is identical with an object y if and only if every property of x is a property of y and vice versa. Leibniz's law is a biconditional and thus the conjunction of two conditionals, one giving a necessary, the other a sufficient, condition for identity to hold. Say that an object x is indiscernible from an object y just in case every property of x is a property of y and vice versa. The half of Leibniz's law that gives a necessary condition proclaims the indiscernibility of identicals: If x is identical with y, then x is indiscernible from y. This principle is useful for establishing nonidentity: To show that x is not identical with y, it suffices to find a property had by x but not by y or vice versa. Most famously, perhaps, the principle has been used to argue that persons are not identical with their bodies. The half of Leibniz's law that gives a sufficient condition proclaims the identity of indis-

cernibles: If x is indiscernible from y, then x is identical with y (more on this below).

(Note that Leibniz's law is stated within second-order logic: It involves quantification over properties. The first-order theory of identity substitutes for Leibniz's law an axiom schema containing, for each [monadic] predicate of the language, an axiom stating: If x is identical with y, then x satisfies the predicate if and only if y satisfies the predicate. This schema, together with an axiom of reflexivity, entails the entire first-order theory of identity. The first-order theory is weaker than the full second-order theory; in particular, no logically sufficient condition for identity is expressible within first-order logic.)

The indiscernibility of identicals is beyond dispute: If x and y are identical, then there is only one thing; how can that one thing both have and not have some property? Nonetheless, the principle has been disputed. Consider the following attempt at a counterexample (discussed in Quine, 1953). It is true that Giorgione was so called because of his size, let us suppose, and that Giorgione is identical with Barbarelli; yet, apparently contrary to the principle, it is not true that Barbarelli was so called because of his size. But to see this as a violation of the indiscernibility of identicals, one would have to hold that the predicate "is so called because of his size" expresses some genuine property of objects and expresses the same property when applied to "Giorgione" as when applied to "Barbarelli." On the contrary, when considered in isolation the predicate expresses no property at all but rather a relation between objects and names. When applied to "Giorgione" it expresses the property was-called-Giorgione-because-of-his-size; and that property is true of Barbarelli, in accord with the indiscernibility of identicals. Other attempts at counterexamples are more subtle than this: But all seem to involve naively reading subject–predicate sentences as simple property-to-object attributions. (For examples involving modality see Cartwright 1971, Quine 1953).

IDENTITY OF INDISCERNIBLES

The other half of Leibniz's law proclaims the identity of indiscernibles; but now one must be careful just what "indiscernible" means. If indiscernibles have *all* of their properties in common, where properties are conceived abundantly, then the identity of indiscernibles is trivially true. For, on an abundant conception of property, for any object y there is the property is-identical-with-y. Now suppose that x is indiscernible from y. Then, since y has the property is-identical-with-y, x must have this property too; that is, x is identical with y, as was to be shown.

If we interpret "indiscernible" instead in terms of properties more sparsely conceived, for example, as "indiscernible in all qualitative respects," then we arrive at a substantial metaphysical principle, the identity of qualitative indiscernibles; the trivial "proof" above is blocked because properties such as is-identical-with-*a* (where "*a*" names some object) are not (or, at any rate, are not trivially) qualitative. There are different versions of the principle, however, corresponding to different interpretations of "qualitatively indiscernible"; and for each version one might ask whether the principle is logically necessary, is contingently true, or neither. Let us consider three versions.

According to the strongest (and least plausible) version, objects that share all of their intrinsic qualitative properties—intrinsic duplicates—are identical. This principle seems to be false even at the actual world: According to current physics, distinct elementary particles of the same kind—for example, distinct electrons—have all of their intrinsic properties (charge, mass, etc.) in common.

According to the second (and most familiar) version, objects that share all of their intrinsic and extrinsic qualitative properties—absolute indiscernibles—are identical. Absolute indiscernibles must not only be intrinsic duplicates, they must be exactly similarly situated with respect to all of their surroundings. But, surely it is at least possible that there be distinct yet absolutely indiscernible objects; that is, the principle is not necessarily true. For, to take the standard counterexample (from Black 1952), it is logically possible that the world contains nothing but two perfectly round globes, exactly similar down to their smallest parts and separated, say, by one meter. The globes share all of their intrinsic qualitative properties, having the same mass, shape, and so on. And the globes share all of their extrinsic qualitative properties—for example, each is one meter from a globe of a certain mass, shape, and so on. (Note that properties that would only be expressible using names for the globes, such as is-one-meter-from-globe$_1$, are not qualitative). In short, the globes are absolutely indiscernible; yet they are two, not one.

A defender of the identity of absolute indiscernibles might simply deny that there is any such possibility; but there is a substantial cost. The claim that it is logically possible that there be nothing but two absolutely indiscernible globes can be backed up by a subsidiary argument (Adams 1979). Surely, there could be nothing but two almost indiscernible globes, differing, say, only in the placement of a single atom. To hold that that atom could

not have been shifted in a certain way (because, if it had, there would have been two absolutely indiscernible globes), but that any other atom could have been shifted in that way, would amount to an implausibly inegalitarian approach to what is and is not possible.

Perhaps an even weaker version of the principle should be considered: Objects that share all of their qualitative properties, and stand in the same qualitative relations to any given object—relative indiscernibles—are identical. (On absolute vs. relative indiscernibility, see Quine 1960.) The possibility just considered of the two globes is not a counterexample to the necessity of this version: The globes are discerned by spatial relations; each globe is one meter from the other globe but not one meter from itself. A counterexample, however, is not far to seek. Consider the possibility that there be nothing but two absolutely indiscernible globes standing in no spatial relation (or other qualitative external relation) to one another, two absolutely indiscernible "island universes." (This possibility can be motivated, too, by first considering "almost" island universes, connected, say, by a single "wormhole.") Such globes would be relatively, as well as absolutely, indiscernible; they stand in no relations that could serve to discern them. So even this weakest version of the identity of qualitative indiscernibles seems not to be a necessary truth. (Indeed, it may not be contingently true: So-called identical particles in quantum mechanics are arguably distinct but absolutely and relatively indiscernible.)

IS IDENTITY DEFINABLE?

Identity has been characterized many times over. Do any of these characterizations provide a (noncircular) definition of the identity relation? Can identity be understood in terms not involving identity? Our initial characterization—that everything is identical with itself and with nothing else—clearly will not do as a definition: To be "else" is to be other, that is, nonidentical. Moreover, the characterization of identity as the strongest equivalence relation fares no better: Identity characterized by quantifying over all relations, identity included.

Leibniz's law gives a necessary and sufficient condition for identity by quantifying instead over properties. But among the quantified properties are haecceities, properties of being identical with some given object. The question whether an object *x* shares with an object *y* the property of being identical with *y* is just the question whether *x* is identical with *y*; the purported definition takes one around in a circle. Similarly defective is the oft-heard definition "*x* is identical with *y* if and only if *x* and

y belong to the same classes." The question whether *x,* like *y,* belongs to the class whose only member is *y* is just the question whether *x* is identical with *y.*

What if some version of the identity of qualitative indiscernibles were necessarily true (contrary to what was argued above)? That would indeed provide a noncircular criterion for the identity of *objects.* But the identity or distinctness of qualitative properties (and relations) would remain undefined. Indeed, any purported definition of identity would have to quantify over some sort of entity; the definition could not be understood without a prior understanding of the identity and distinctness of the entities quantified over. We must conclude, then, that identity, at least as applied to the most basic entities, must be taken as primitive and unanalyzable; there is no fully general (noncircular) definition of identity.

Questions remain, some of which might seem to pose problems for the classical conception of identity. We shall see, however, that in each case replies exist that leave classical identity unscathed. (Each of the issues raised below is discussed in Lewis 1993.)

PARTIAL IDENTITY

Classical identity is all or nothing; it never comes in degrees. Yet, when objects overlap, we may say they are "partially identical, partially distinct": And when objects extensively overlap, we may say they are "almost identical." Do we have here a challenge to classical identity? No, we have an ambiguity: Identity, in the sense that admits of degrees, is simply overlap; identity, in the classical sense, is equivalent to the extreme case of total overlap. The two notions of identity are not in conflict; they fit together as well as you please.

VAGUE IDENTITY

Classical identity is determinate and admits of no borderline cases. That is not to say that identity statements cannot be vague or indeterminate in truth-value. If I say "that cloud in the sky is identical with *A,*" where "*A*" names some precisely specified aggregate of water molecules, what I say may be neither determinately true nor false. But such vagueness resides in the reference of singular terms—in this case, "that cloud in the sky"—not in the identity relation itself.

Some philosophers, however, hold that there is vagueness, not only in our reference to objects, but in the objects themselves; not only in our language and thought, but in the world. Let us suppose, charitably, that such a view makes sense. Might not these vague objects be

vaguely identical? That depends. If vague identity is understood so that vaguely identical objects are neither determinately identical nor determinately not identical, then the answer is no, as the following argument shows. (Versions are in Evans 1978, Salmon 1981). Suppose *a* and *b* are vaguely identical; then they differ in some property, namely, being vaguely identical with *b.* For although *a* has the property, *b* does not: Nothing is vaguely identical with itself. By the indiscernibility of identicals, then, *a* is (determinately) not identical with *b.* So, vaguely identical objects are (determinately) not identical! That sounds odd; but there is no contradiction if vague identity is understood in some way that detaches it from indeterminacy of truth-value. So understood, vague identity poses no challenge to classical identity.

TEMPORARY IDENTITY

The Greek philosopher Heraclitus argued that one cannot bathe in the same river twice, something as follows. Rivers flow. The stretch of water that comprises the river on Monday is not the same as the stretch of water that comprises the river on Tuesday. But a river is not something separate and distinct from the stretch of water that comprises it; be it on Monday or on Tuesday, the river and the stretch of water are one and the same. It follows, by a double application of the indiscernibility of identicals, that the river on Monday is not the same as the river on Tuesday. If one bathes in the river on Monday, and returns to bathe at the same place on Tuesday, one has not bathed in the same river twice.

One wants to say: On Monday, the river is identical with a certain stretch of water; on Tuesday, the same river is identical with a different stretch of water. More generally, identity can be temporary, holding at some times but not at others. Temporary identity, however, is disallowed by the above argument, not just for rivers, but for all entities whatsoever. Should we abandon the classical notion of identity that the argument presupposes?

There are at least two responses to Heraclitus's problem compatible with classical identity. According to the first response (inspired by Aristotle, when we say that a river *is* just a certain stretch of water, we are using not the "is" of identity but the "is" of constitution; and constitution is never identity (see Lowe 1989). On this view there are two fundamentally different kinds of entities that occupy space and persist through time. There are ordinary material objects, such as rivers, trees, statues, and tables; and there are portions of matter that may temporarily constitute the ordinary objects. At any time an ordinary object is constituted by some portion of matter

or other; but at no time is it identical with that portion of matter, either wholly or in part. In particular, the very same river is constituted by one stretch of water on Monday and by a different stretch of water on Tuesday. No conflict arises with the laws of classical identity, and Heraclitus's problem is solved.

This response, however, is not without problems. A dualism of ordinary objects and the portions of matter that constitute them is neither necessary nor sufficient to solve the general problem of temporary identity. It is not sufficient, because some cases of temporary identity have nothing to do with constitution. Consider a tree that, at some bleak stage of its career, consists of nothing but a trunk. Later, however, the tree sprouts new branches and leaves. Then we have another prima facie case of temporary identity: The tree is identical with the trunk at the bleak time but not identical with the trunk at the happier time. In this case, however, invoking constitution is of no avail: Neither the trunk nor the tree constitutes the other, in the relevant sense. (This example is from Hirsch 1982.)

Nor is such a dualism necessary to solve the problem of temporary identity, because another response is available, one (arguably) more economical in its ontological commitments (see Hirsch 1982, Quine 1950). On this second response objects that persist through time are composed of (more-or-less) momentary stages, of temporal parts. A persisting river is a sum of stages unified in a way appropriate for rivers; a persisting aggregate of water molecules is a sum of stages unified in a way appropriate for portions of matter. A persisting river and a persisting aggregate of water molecules may overlap by having a stage in common; in that case a stage of the river and a contemporaneous stage of the aggregate of water molecules are identical. But the persisting river is not identical with the persisting aggregate of water molecules: Later stages of the river are in about the same place as earlier stages and are no less spatially continuous; later stages of the aggregate of water molecules are downstream of earlier stages and are spatially scattered. When we say that, at any time, a river is nothing separate and distinct from the water that comprises it, this must be understood as asserting not an identity between persisting objects but an identity between stages. Identity between stages, however, is all one needs to avoid the uneconomical dualism of the constitution view. All objects that occupy space and persist through time are composed of a single kind of entity: Stages of portions of matter. (The stage view of persistence is argued for in Lewis 1986.)

Heraclitus's problem is now easily solved. One cannot bathe in the same river stage twice; but one can bathe in the same river twice by bathing successively in two river stages belonging to a single persisting river. That these two stages are not stages of a single persisting aggregate of water molecules is irrelevant. There is no conflict with classical identity.

CONTINGENT IDENTITY

A change in example, however, makes trouble for the stage view of persistence. Consider a statue called *Goliath* that consists entirely of a lump of clay called *Lumpl*; and suppose that the statue and the lump came into being, and ceased to exist, at exactly the same times. Then, on the stage view, every stage of *Goliath* is identical with a stage of *Lumpl* and vice versa; *Goliath* and *Lumpl* are the same sum of stages and so are identical. But, surely, they are not necessarily identical. *Goliath* could have been destroyed without destroying *Lumpl*—say, by being squashed—in which case *Goliath* would have lacked *Lumpl*'s final stages and would have been a distinct sum from *Lumpl*. So, *Goliath* and *Lumpl* are identical, but only contingently identical. (The example is from Gibbard 1975.)

Trouble arises because contingent identity, no less than temporary identity, is incompatible with identity, classically conceived—or so the following argument seems to show. Consider the property is-necessarily-identical-with-*y*, for some object *y*. Surely *y* has it: Everything is necessarily identical with itself. Now suppose an object *x* is identical with *y*. Then, by the indiscernibility of identicals, *x* has the property as well; that is, *x* is necessarily identical with *y*. Thus, objects are necessarily identical if identical at all; objects are never contingently identical.

Whether this argument is unassailable will depend upon one's interpretation of modal properties, of modality *de re*. If objects have their modal properties absolutely, in and of themselves, then the argument is sound. Since *Goliath* and *Lumpl* are not necessarily identical, they are not identical at all. *Goliath* and *Lumpl* are numerically distinct objects that occupy the same place at all times that they exist. *Goliath* is not identical with any sum of matter-stages, contradicting the stage view of persistence.

The stage view can be preserved, however, if one takes the view that modal predicates do not apply to objects absolutely, in and of themselves; their application is relative to how the objects are conceived, classified, or referred to. For example, could the lump of clay—that is, the statue—have survived a squashing? *Qua* lump of clay, it could; *qua* statue, it could not. There is no violation of the indiscernibility of identicals because the modal predicate "could survive a squashing" expresses no property

when considered out of context and expresses different properties when attached to "the lump of clay" (or "Lumpl") and to "the statue" (or *Goliath*). In this way the stage view can accept the contingent identity of Lumpl and *Goliath,* without forfeiting classical identity. (For versions of this strategy, see Gibbard 1975, Lewis 1971.)

RELATIVE IDENTITY

Classical identity is absolute: Whether identity holds between objects does not depend upon how those objects are conceived, classified, or referred to. In ordinary language we often say "*a* is the same *F* as *b*," for some general term "*F*"; but this is naturally analyzed as a restriction of absolute identity: *a* is *F,* and *b* is *F,* and *a* is (absolutely) identical with *b*.

Geach has argued, on the contrary, that all identity statements are relative: "*a* is the same *F* as *b*" cannot be analyzed as restricted absolute identity, because there is no absolute identity; when we say simply "*a* is the same as *b*," some general term "*F*" must be supplied by context, or what we say is meaningless (Geach 1970). To support his claim, Geach has presented examples in which we would say: *a* and *b* are the same *F*, and *a* and *b* are *G*'s, but *a* and *b* are not the same *G*. Consider the word *tot*. It contains three letter tokens, two letter types. The first letter token and the last letter token are not the same letter token, but they are the same letter type. That contradicts the claim that "the same *F*" is to be analyzed as restricted absolute identity.

The defender of classical identity has a simple and natural reply: Sometimes the relation is-the-same-*F*-as is not restricted identity but rather some weaker equivalence relation; that is, sometimes it is a species of qualitative, rather than numerical, identity (see Perry 1970). For example: If I say that you are wearing the same coat as I am, I (probably) do not mean the numerically same coat. Similarly, letter tokens of the same type are qualitatively similar—equiform—not numerically identical. To the extent that Geach's point is just that "the same *F*" cannot always be analyzed as restricted identity, it is a point no one should deny.

Any rejection of absolute identity, it seems, must be based upon arguments of a more abstract sort. Indeed. Geach explicitly rejects the standard characterization of identity through Leibniz's law on the grounds that second-order quantification over properties leads to paradox. And he rightly points out that, within first-order logic, characterizations of identity are inevitably relative to the predicates of the language. But how does this impugn the meaningfulness of absolute identity? Does Geach's argument simply amount to the demand, Define absolute identity, or count it as meaningless? That demand, certainly, is too strong. No fundamental notion of logic or metaphysics could meet it.

IDEOLOGY

Though often employed as a catchall term in contemporary usage, including some philosophers' usage, *ideology* has a clearly identifiable historical origin and since its invention has borne some clear though disparate meanings (as well as, to be sure, some unclear ones) in several traditions of thought, most notably in the Marxian tradition.

It was Antoine Destutt de Tracy who, toward the end of the eighteenth century, conceived the notion of developing a science of ideas that would trace them back to their supposed material elements. The group around him became known as the *Idéologues* and at first found favor with Napoleon Bonaparte, whose coup ending the period of the French Revolution and its immediate aftermath they at first applauded. But they soon became his vehement critics (concerning, for example, his policy-driven revival of religion), and Napoleon returned the compliment by denouncing them for, among other things, allegedly indulging in wild ideas rather than respecting the exigencies of the concrete political situation. Thus did "ideologists" become an epithet, an expression of contempt.

As such, the term was picked up and used by Karl Marx and Friedrich Engels some four decades later. In *Die Deutsche Ideologie* (*The German Ideology*, 1976), a lengthy work, they lampoon their neo-Hegelian near-contemporaries, notably Ludwig Feuerbach, Bruno Bauer, and Max Stirner, on the ground that the supposedly weighty disputes of the latter are pseudobattles among merely abstract, primarily theologically based ideas, lacking any influence on, or even much connection with, the actual sociohistorical world. Here, "ideology" is equated with religion, metaphysics, moral theory, and similar products of pure consciousness and is given roughly the same highly pejorative valence, though affixed to an entirely different object, as that formerly given by Napoleon to the objects of his wrath.

But, unlike some of Marx's criticisms of the idealist philosophy of G. W. F. Hegel himself, which were printed during Marx's lifetime, *The German Ideology* was not actually published, and hence its textual details were not generally known, until 1932. Marx does, however, mention it, in a brief autobiographical sketch that appeared in 1859, as having been the early outcome—one left to the "gnawing criticism of the mice" when the original arrangement to have it published fell through—of his and Engels's newly elaborated systematic opposition to the "ideological" standpoint of German philosophy. At the same time, in their widely circulated *Manifesto of the Communist Party* of 1848 they at one point allude to the anticipated defection from class solidarity of a section of the bourgeois class, notably some (though by implication just a few) of the bourgeois ideologists, by virtue of the latter's having achieved a comprehensive overview of the process of history. While this passage is revealing as a veiled self-reference, it is equally interesting for its suggestion that "ideology" can have a positive connotation, as well. Hence the later ambivalence of the term in Marxist and non-Marxist contexts alike is already to be found in the classical writings of the Marxian tradition.

CONNOTATIONS IN LATER MARXISMS

The pejorative understanding of "ideology," linked as it is to the idea that *most* philosophers and other intellectuals typically engage in mystificatory, distortive justifications, or legitimizations, of the existing social order with the effect of reinforcing the dominant insitutions of the ruling class of which they are a part, continued to predominate especially in so-called "Western Marxism." By this is meant those strands of neo-Marxist thought that preserved their independence from the Communist Party, based primarily in the Soviet Union from the time of the Russian Revolution until the final decade of the twentieth century, the successive leaders of which stipulated the terms of what they considered to be orthodox Marxist theory.

Western Marxists, accused of "revisionism" by these leaders and their followers, tended rather to consider the wooden, dogmatic style and content of "orthodox Marxist" writings to constitute a serious distortion of Marx's ideas. For example, Herbert Marcuse, a leading figure in the early Frankfurt School in Germany before migrating to the United States, retained, analyzed, and applied the pejorative sense of the term "ideology" both in his 1958 critique of the Soviet Union, *Soviet Marxism*, and in his

early 1960s indictment of Western society as tranquilized, democratic, but profoundly unfree, *One-Dimensional Man* (1966). Similarly, his erstwhile Frankfurt colleague, Theodor Adorno, another strong social critic, equated "ideology" with "false consciousness" and regarded it as being characteristic of those who are obsessed with enforcing identity and conformity and who fail to respect differences. The best-known member of the "later" Frankfurt School, Jürgen Habermas, while he has diverged from Marxism in a great many respects, has continued to equate ideology with systematically distorted communication, to be combated through what he calls emancipatory critique.

The self-styled "orthodox" Marxists, however, took their cue on the question of the meaning of ideology above all from the Russian revolutionary leader, V. I. Lenin, who in his early call to arms, *What Is to Be Done?*, insisted that a clear-cut choice had to be made between bourgeois ideology, which he contemned, and "socialist" ideology, which he espoused and thought it necessary for professional revolutionaries to inculcate in the minds of the masses. Most of the subtler thinkers within the orbit of the Communist Party, such as the Hungarian György (Georg) Lukács (1971) and the Italian Antonio Gramsci, also saw ideology as a potentially and at least partially positive phenomenon, with Lukács depicting Marxism as the ideological expression of the proletarian class. One of the most complex and idiosyncratic conceptions of ideology to be developed by someone who was at the time a Communist Party member was that of the once influential French philosopher Louis Althusser (1969): He contrasted ideology with science, of which he saw Marx's theory of history as a leading instance, but at the same time he took ideology to be a pervasive and ineliminable part of human experience, regardless of a given historical society's class configurations.

NON-MARXIST CONCEPTIONS

In *Ideology and Utopia* Karl Mannheim (1986), the German sociologist of knowledge who was himself influenced by the early Lukács, distinguished between what he called the "particular" and the "total" concepts of the term, the former being linked with suspicion concerning the motives of others as interested and biased—in other words, "ideology" as more purely pejorative—and the latter characterizing the comprehensive views of many large groups, such as classes, in the modern world. "Ideology" in the latter sense is to be seen as a pervasive historical phenomenon. Espousing a nonevaluative approach to the understanding of diverse worldviews (*Weltan-schauungen*) that he denomi-

nated "relationism," Mannheim in effect paved the way for the much broader, more all-encompassing, less critical usage of the term "ideology" that has become common.

No treatment of the meandering evolution of this term could pretend to adequacy without noting the curious recurrence of announcements that its supposed referent has, or may have, ceased to exist. Political scientists, such as Seymour Lipset, and other philosophically oriented sociologists, such as Raymond Aron, have evoked this as at least a possibility, but no doubt its most famous assertion occurred in a lengthy tome by Daniel Bell, an American sociologist strongly influenced by the Marx scholar and philosopher turned fervent anticommunist, Sidney Hook. The title of Bell's book, especially its less well-known subtitle, accurately captures its principal claim; it is *The End of Ideology: On the Exhaustion of Political Ideas in the Fifties* (1960). Understandably, but rather unfortunately, Bell's main title led to oversimplified interpretations of what he actually intended, which was *not* an umbrella thesis supposedly applicable to all future times and places.

To some (e.g., Hannah Arendt), ideology means totalitarianism, of which Communist ideology is a salient example; to others (e.g., Edward Shils attempting to define the term in the *International Encyclopedia of the Social Sciences*), it means, above all, intolerant belief systems that are by and large inimical to science. It is in any case evident that the confusion and even contradictoriness of meanings of the term that are traceable to its historical origins have continued to characterize its deployment, which remains widespread in the literatures of philosophy, political science, sociology, psychology, literary theory, and even popular journalism despite its alleged demise as a phenomenon at the end of the 1950s.

EVALUATION

Apart from those, if there are any, who still share Destutt de Tracy's youthful confidence in the possibility of generating a materialist science of ideas based on an analysis of the origins of their components, it would seem that "ideology" would indeed lose its purpose as a part of our vocabulary if all negative, critical connotations were to be excised from it. At least one important meaning of it remains, and should continue to remain, that of suspect generalized claims, often entire theories, which purport to be true but are in fact intellectual constructions designed to reinforce particular interests, especially the interests of those in power. Although many of those who believe in particular "ideologies" as so understood may do so unreflectively—in an important sense, after all, it is

the aim of skilful ideologists to maximize the number of such believers—ideologies in this sense of the word should in the last analysis be capable of being unmasked as sophistic and in bad faith.

But there are a number of philosophical problems involved in elaborating a coherent conception of ideology. The first of these concerns the question of one's basis for designating another's set of propositions or beliefs as ideological: How can one be sure that one's own supposedly critical standpoint is not itself ideological? May it not also be, in the last analysis, merely an elaborate apologia for an alternative special interest aspiring to social dominance? Marx and Engels thought to evade this difficulty by painting the proletariat as the class, the coming to power of which would usher in a classless society, without particular interests or internal relationships of dominance and subordination; hence, they believed, the class consciousness of the proletariat, history's first truly "universal class," should be regarded as radically different in kind from the bourgeois, feudal, and other ideological standpoints of the past. But may this not be just one more intellectual sleight of hand?

Another problem inherent in the conception of ideology as critical and "suspicious" is that of its explicit or implicit tendency to relegate philosophy itself, in its various branches, to the realm of ideology. At times Marx and Engels wrote as if philosophical and other ideas were in fact just epiphenomena, ghostly by-products of a real world of which the "base" consisted of the dominant forces of production; that is, the crafts, industries, and technologies of any given historical period, and the "superstructure" consisted of the political, legal, and other institutions developed in conformity with those forces. This conception, taken to its extreme, would deny that ideological phenomena have any autonomy, any force—in other words, that ideas as such can ever have real consequences. But such a claim runs counter to much of human experience. (Engels himself lived long enough to express regret over this misinterpretation of his views. He located its origin in the long past *Zeitgeist* of the era when he and Marx had begun formulating their own ideas, an era when the Hegelian and neo-Hegelian idealist philosophies, to which they were so opposed, were in the ascendancy.)

Ultimately, of course, the fundamental problem concerning ideology is the fundamental problem of virtually all of philosophy; that is, the problem of truth itself. How could we ever succeed in assuring ourselves and others, beyond all doubt, that a claim or set of claims that we assert to be an ideological distortion of the "true" state of affairs actually is such? For to do so would presuppose, contrary to *all* past experience, a complete and comprehensive grasp, on our part, of the true state of affairs.

IKHWĀN AL-ṢAFĀ'

The Ikhwān al-Ṣafā' (The Brethren of Purity or The Sincere Brethren) were the anonymous adepts of an esoteric fraternity of lettered urbanites that was principally based in the Mesopotamian cities of Basra and Baghdad in the second half of the tenth century CE. This learned brotherhood occupied a prominent station in the history of science and philosophy in Islam due to the wide intellectual reception of their famed tracts the *Rasā'il Ikhwān al-Ṣafā'* (The epistles of the brethren of purity). The exact

dating and authorship of this encyclopedic compendium remain unsettled polemical questions, and it is widely assumed that the provenance of the Ikhwān's ideas is primarily ascribable to Ismāʿīlī sources. Nonetheless, this is controversial, and it is rather more circumspect to attribute their outlook to a broadly Shīʿī lineage.

The Ikhwān's corpus displays a tolerance for multifarious pagan and monotheistic traditions. Besides their filial observance of the teachings of the Qurʾān, the Ikhwān also reverently appealed to the Torah of Judaism and to the Gospels of Christianity, primarily in their accounts of prophetology. In addition, they heeded the legacies of the Stoics and of Pythagoras, Hermes, Socrates, Plato, Aristotle, Plotinus, Euclid, Ptolemy, Porphyry, and Iamblichus. They moreover strived to establish some form of harmony between faith and reason, in a manner that is partly reminiscent of the practices of al-Fārābī (d. 950), Avicenna (Ibn Sīnā) (d. 1037) and Averroes (Ibn Rushd) (d. 1198).

Motivated by an active soteriological pursuit of happiness, the Ikhwān promoted a convivial and earnest companionship of virtue. Their eschatological views were furthermore articulated by way of an intricate cyclical view of history and an uncanny hermeneutic interpretation of the microcosm and macrocosm analogy. The multiplicity of the voices that were expressed in their tracts reflect a genuine quest for wisdom that is driven by an impetus that is not reducible to a mere eclecticism. Their ecumenical syncretism, which may have been partly influenced by the outlooks of the Sabaeans of Harran, grounded their aspiration to establish a spiritual refuge that would transcend the sectarian divisions that beset their era.

Customarily enumerated as fifty-two epistles, the Ikhwān's *Rasāʾil* offer synoptic explications of the classical sciences of the ancients and the moderns of the age. Divided into four classificatory parts, these treatises treated themes in mathematics, logic, physics, psychology, and theology. This series was also accompanied by a concise tract titled: *al-Risāla al-Jāmiʿa* (*The Comprehensive Epistle*), which acted as the summary of their corpus, and was supplemented by an abridged appendage known as *Risālat Jāmiʿat al-Jāmiʿa* (*The Condensed Comprehensive Epistle*).

The eloquent literary style of the *Rasāʾil* covers the technicalities of mathematics, logic, physics, and medicine, together with religious speculations, occultist incantations, along with the poetic elaborateness of fables, odes, and didactic parables. Although the influence of the *Rasāʾil* in Ismāʿīlī circles was prominent, and in spite of being partially manifest in various doctrinal citations in Islam, the impact that these epistles may have had on the philosophers and the dialectical theologians has been rather exaggerated. In spite of the extensive thematic scope of the *Rasāʾil*, which may have occasionally been plagued by repetitions, these epistles do not establish a convincing intellectual relationship with the achievements of the classical authorities of Arabic sciences and philosophy. Despite being usually classed as philosophers, the Ikhwān would more fairly rank as learned compilers of knowledge when compared with the philosophical luminaries of the period.

Although the Ikhwān's erudite reflections on spirituality show signs of originality, this does not make the *Rasāʾil* the principal reference for all the disciplines that they endeavored to tackle. Their investigations in geometry, arithmetic, logic, and physics remained diluted in essence, and although these inquiries were complemented by oral instructions in seminars, they nevertheless represented a minor aspect of the disciplines they addressed. Even though it is usually claimed that Avicenna may have been implicitly influenced in his intellectual formation by their teachings, his philosophical acumen remained superior to that of the Ikhwān. A similar observation may be made concerning the Ikhwān's impact on the unfolding of the Illuminationist and emanationist tenets in Islam, or the implicit influence that they may have exercised on the dialectical doctrines of the exponents of *kalām*. Moreover, although some Shīʿī illuminati and Sunnī literati may have professedly cited the tutelage of the Ikhwān, this did not entail that they were affiliates of this line in thinking. Despite some of these scholarly shortcomings, the *Rasāʾil* represent a commendable populist adaptation of science and philosophy that merits the privilege of being ranked among the high literature of Islam.

IL'IN, IVAN ALEKSANDROVICH
(1883–1954)

Ivan Aleksandrovich Il'in was a Russian religious philosopher, legal and political theorist, philosopher of Russian national identity, orator, and publicist. Born in Moscow of a noble family, he studied law at Moscow University, from which he graduated in 1906. Deemed an extraordinary scholarly achievement, his dissertation on Georg Hegel (1770–1831) earned him at once master's and doctoral degrees in 1918. The two volumes of his published dissertation, *Filosofiia Gegelia kak uchenie o konkretnosti Boga i cheloveka* (The philosophy of Hegel as a doctrine of the concreteness of God and man, 1918), have been described as one of the more significant commentaries on Hegel published in the twentieth century in any language (Grier 1997). As a resolute foe of the Bolsheviks, he was exiled from Soviet Russia under threat of execution. Il'in and his wife left Russia for Germany in 1922. He was a renowned anti-Bolshevik and anticommunist, which suited the Nazis, but his critique of totalitarianism was not at all appreciated by the Nazi regime. Moreover, in 1934 he refused to accept their orders to spread Nazi propaganda in the Russian Academic Institute and was subsequently removed from his post by them and banned from all further employment. Finally, in 1938 he and his wife escaped from Nazi Germany and found refuge in Switzerland.

In his book *Religioznyi smysl filosofii* (The religious meaning of philosophy, 1925) Il'in proposed the following task to his readers: "To find authentic, spiritually objective environments." The spiritual labor of such a philosopher approximates that of the monk. They differ only in that the former occurs in the realm of cognition, while the latter seeks redemption. Both the philosopher and the monk comprehend, Il'in believed, that the world is "really a school where reasonable souls exercise themselves, a training ground where they learn to know God" (see St. Basil the Great's [c. 329–379] *Hexaëmeron* 1.6).

POLITICAL THEORY OF LEGAL CONSCIOUSNESS

Convinced that Hegel's doctrine of right and the state was ultimately a failure, Il'in began to elaborate his own theory in 1919, while still in Soviet Russia. It was published posthumously as *O sushchnosti pravosoznaniia* (On the essence of legal consciousness) in 1956. The central notion in it is *pravosoznanie*, from *pravo* (right or law) and *soznanie* (consciousness), which can perhaps best be translated as "legal consciousness." He formulated three axioms of legal consciousness—"a feeling of one's own spirit dignity; an ability to self-obligation and self-government; a mutual respect and trust of people to each other" (1956b, chapters 15, 17, 19)—and added nine axioms of authority, which included its *pravovoe polnomochie* (legal plenary powers), that the state authority must be *edina* (singular) and that it must be realized by "the best" people who meet ethical and political qualification (chapter 14). Then he joined natural law and positive law (i.e., legal norms including agreement with morality and justice, and legal norms established by legal authority and being subject to application) in an appropriate way: "A rational system of positive law would reflect the structure of natural law" (chapters 5, 6). Unfortunately, our political reality does not give a good example of even an approximate realization of such a doctrine.

ETHICS DOCTRINE

On the Essence of Legal Consciousness contains a number of uncommon but profound observations that are useful

to any national leader who wishes to have "a deeper religious and moral motivation" for ruling, for example, to follow Il'in's conception in which "the ultimate justification of state authority would be the development in the citizenry of a moral, legal and spiritual culture in which the requirements of natural rights would be so widely exemplified in human conduct as to make genuine self-government a reality" (Grier 1998, p. 693)

In 1925 Il'in published his polemical book *O sopro-tivlenii zlu siloiu* (On resistance to evil by force), concerning an important dual ethical problem: "May a human being who is trying to achieve ethical perfection *resist* evil by force, using the sword?" and "May a human being who believes in God and accepts His creation, and who knows his place in this created world *not resist* evil by force, using the sword?" (1925, chapter 19). Il'in gave a single direct answer to both: that one not only *may* but *must* also resist evil by force. He wrote:

> Physical intervention and coercion may become the direct religious and patriotic duty of a human being; and once this happens one must not evade it. To fulfill this duty is to become a participant in the great historical battle between God's servants and the forces of the underworld; and this battle will force him not only to draw his sword but to take upon himself the burden of homicide. (chapter 19)

This book evoked a strong response not only in the Russian émigré community but in the Soviet Union as well (Poltoratzky 1975, Lisitsa 1996).

Il'in lived and worked with the single-minded purpose of reconstructing Russia in an authentic way in the aftermath of the Bolshevik regime. He wrote *Osnovy gosudarstvennogo ustroistva: Proekt Osnovnogo Zakona Rossii* (The foundations of government: A proposal for the fundamental law of Russia, 1996) as a post-Bolshevik constitution. Between 1940 and 1954 he produced 215 anonymous bulletins for a restricted list of readers only, and these *Nashi zadachi: Stat'i 1948–1954* (Our tasks: Articles 1948–1954) were published in 1956 in two volumes only after his death. This two-volume work is nothing other than an "Axiomatics of Political Life," analogous to his *Aksiomy religioznogo opyta* (Axioms of religious experience, 1953); it is clearly intended to treat the disease of "political nihilism."

RELIGIOUS THOUGHTS

Between 1938 and 1945 Il'in created in German a wonderful literary triptych—*Ich schaue in Leben: Ein Buch der*

Besinnung (I am peering into life: A book of thoughts, 1938–1939), *Das verloschollene Herz: Ein Buch stiller Betrachtungen* (The singing heart: A book of quiet contemplations, 1943), and *Blick in die Ferne: Ein Buch der Einsichten und Hoffnungen* (A look in the distance: A book of reflections and hopes, 1945)—and described it as "devoted not to theology, but to a quiet, philosophical praising of God." Despite all the striving of humanity to unveil the mystery of world creation, it has been losing access to this mystery on the path that it has selected. "For the world remains as before," wrote Il'in, "i.e., a great mysterious wonder, created by a rational inner Authority, carried by a rational inner force, and moving toward a certain inner goal" (*Put' k ochevidnosti* [The path to self-evidence], 1957, chapter 18). And this "lost mystery" might be returned to humanity through a contemplative heart, but only if the heart is open, loving, and marveling.

In 1953 Il'in published in Paris *Axioms of Religious Experience*, his main work, in two volumes on which he had been working for thirty-three years. It was a profound and original investigation of the personal "religious act." One of its axioms, "The autonomy of religious experience," and the motifs connected with it, such as "loneliness" and "tragedy in the world," were received somewhat critically by the Russian theologians Archimandrite Kostantin Zaitsev and Father Vladislav Sveshnikov. And yet Il'in derived this axiom from one of the Church Fathers, Petrus Chrysologus, who described God as *solus, sed non solitarius* (God alone is, but He is not lonely).

When Il'in died on December 21, 1954, and was buried in a cemetery in the village of Zollikon, near Zürich, there appeared on his monument an epitaph composed by the philosopher himself:

Alles empfunden	(Felt it all
So viel gelitten	Suffered so much
In Liebe geschauet	Had it revealed through love
Manches verschuldet	Guilty of some things
Und wenig verstanden	Understood very little
Danke Dir, ewige Güte!	Thank you, eternal Goodness!)
	(Il'in 1993).

Il'in's legacy is enormous and well preserved. It contains more than 40 books and brochures, 600 articles, 100 lectures, a large collection of letters, humorous poems, several "naive political fairy tales," memoirs, and documents that are in several archives in various countries. Il'in's largest archive was organized in 1963 by Professor Nikolai Poltoratsky at Michigan State University

Libraries. This collection and other materials are being published as a project of the publisher Russkaia Kniga (Russian Book) in Moscow, and are expected to contain forty volumes in the series *I. A. Il'in: Sobranie sochinenii v desiati tomakh* (Il'in, I. A., Collected Works), Moscow: Russkaia Kniga, 1993–1999.

ILLUMINATION

The idea of a divine "illumination" in the mind occurs in both philosophical and religious contexts. Often it forms one of the links between the two types of thought, and sometimes it bears distinctly religious overtones even in its more philosophical applications. This is one of the characteristic features of the theory of illumination in the thought of Plato, where it played, for the first time in its long history, a major part. Plato, like many other thinkers, creative artists, prophets, and mystics, spoke readily of the sudden flash of understanding or insight in the mind as a flood of light (see, for example, his *Seventh Letter,* 341C, 344B). The image is, indeed, one that occurs naturally in many languages and is especially apt for the description of insight thought to have been achieved as a result of external aid of some kind, of an "inspiration." The language of inspiration is based on the entry of breath, and that of illumination on the entry of light into the mind. The Stoic tradition can be said to have developed the former analogy in its metaphysics; Plato was undoubtedly the father of the philosophical tradition to which the analogy of light is fundamental.

In his *Republic,* Plato employed the analogy of light and vision to describe the process of understanding or of knowledge in general (Books V–VIII). The mind's knowledge of the world of intelligible reality, of the forms or ideas, was held to be analogous to the awareness of material objects accessible to the eye's vision when illuminated by the light of the sun. Plato developed a detailed correspondence between physical and intellectual sight (*Republic* 507f.), according to which the mind corresponds to the eye and the form to the physical object seen; an "intellectual light" emanating from the supreme

form, the Good, and pervasive of the whole intelligible world as well as the mind, corresponds to the sun. Understanding, in terms of this analogy, depends on the intellectual illumination of the mind and its objects, just as vision depends on a physical illumination of the eye and its objects.

A theory of this type, in one or another of many variant forms, became an essential part of a vast body of thought cast in Platonic molds. During the Hellenistic and Roman periods it was widely diffused and incorporated into Jewish and Christian thought. In the Hellenized Judaic milieu of Alexandria the divine wisdom was sometimes spoken of in terms of light, for instance, by the author of the book of Wisdom, who referred to it as "an effulgence of eternal light," which he interpreted as an image of God's goodness (7, 26). Thoughts of this kind found a place in the work of Philo and in the prologue to the Fourth Gospel. Middle-Platonist thinkers, such as Albinus, took the step—perhaps already hinted at by Plato in some passages—of placing the forms within a divine mind and, in effect, identifying the "intelligible world" with the mind of God. In this way a long and rich future was prepared for the theory of illumination within the body of Christian thought.

In Christian thought it is in the work of St. Augustine of Hippo that the theory of illumination is found in its most highly developed form. Like Plato, Augustine thought of understanding as analogous to seeing. Understanding, or intellectual sight, was therefore, he held, conditional on illumination, just as physical sight was; only here the light was the intelligible light that emanated from the divine mind and in illuminating the human mind endowed it with understanding. Understanding, in the last resort, was an inward participation of the human mind in the divine. The scope of illumination was further extended, at the cost of precision, in the work of the pseudo-Dionysius. His favorite designation for God, the absolutely transcendent One, was in terms of light. God is the intelligible light beyond all light and the inexhaustibly rich source of brightness that extends to all intelligence. His illuminating activity gathers and reunites all that it touches; it perfects creatures endowed with reason and understanding by uniting them with the one all-pervading light (*De Divinus Nominibus,* IV, 6). In true Neoplatonic fashion, the pseudo-Dionysius conceived of the cosmos as a hierarchically ordered system, descending in order of reality and value from its source, the One. Illumination, in general terms, is the means by which intellectual creatures ascend and return to unity, and the "hierarchy" (understood as extending through both the cosmos and the church) is defined as the divine arrangement whereby all things, participating in their measure in the divine light, are brought back to as close a union with the source of this light as is possible for them (*De Coelestia Hierarchia,* III, 1). In a more special sense, illumination is the second of three phases—namely purification, illumination, and perfection—of man's return to the One. In this more specialized sense the church's sacramental system and the grades in the ecclesiastical hierarchy concerned with its administration are agencies of divine illumination. Illumination is the intermediate stage of approach to God, between initial purification and final perfection (*De Ecclesiastica Hierarchia,* V, 1, 3). In the most restricted sacramental contexts "illumination" thus becomes synonymous, in accordance with an old Christian usage, with "baptism." In the work of the pseudo-Dionysius the theory of illumination was merged with an inclusive conception of the spiritual life formulated in the language of light and illumination.

The reputation enjoyed by Augustine and by the writings of the pseudo-Dionysius in the Middle Ages assured their views a long future. In the thirteenth century the rise of Christian Aristotelianism provided the first serious alternative theory of knowledge. In this there was no place for the intervention of a divine illumination as an essential constituent of knowledge. Knowledge was accounted for entirely in terms of mental activity and its objects, and no reference to God was necessary to explain it. Nevertheless, the *lumen intellectuale* of the mind was held to be a participation in the *lumen divinum* of the divine mind, since God was present everywhere, in the mind no less than in other things. In this way Christian Aristotelians, such as St. Thomas Aquinas, were able to endorse some characteristically Augustinian statements in spite of the fact that their theories of knowledge were built on a radically different structure. The Augustinian version of the theory of illumination continued to have a vogue among some thinkers of the thirteenth century, such as St. Bonaventure, and even later. It found echoes in the thought of some modern philosophers, such as Nicolas Malebranche. Increasingly, however, in the later Middle Ages and after, the language of illumination, especially as elaborated by the pseudo-Dionysius, became the special property of mystical writers and writers on the spiritual life.

ILLUMINATIONISM

Illuminationism (also, Illuminationist philosophy) is the name given to a school of philosophy founded in the twelfth century by the innovative Persian philosopher, Shihāb al-Dīn Suhrawardī (d. 1191), who is well-known by the honorific epithet, "Master of Illumination" (Shaykh al-Ishrāq).

BACKGROUND

The philosophy of Illumination is a holistically constructed system that aims to refine the period's peripatetic philosophy, which was known predominantly in the corpus of philosophical writings by the acclaimed Persian philosopher and scientist, Abū ʿAlī Sīnā, well-known in European traditions as Avicenna, the latinized version of his name. The intense Greek-inspired scientific and philosophical activity from the ninth to the eleventh centuries, centered mainly in Baghdad (the Abbasid Caliphate's political, cultural, and scientific capital), but also in the emerging centers of learning in Iran (such as the cities Rayy, Hamadan, Isfahān, and Nayshpur) as well as central Asian centers of Pesianate.

Linguistic and cultural influence produced remarkable results manifest in many texts covering the range of pure and applied sciences, including medicine, astronomy, mathematics, logic and philosophy, and so on. In this, the creative period of Islamic philosophy, two domains of intellectual endeavor, political philosophy and holistic theoretical philosophy, are defined and creatively expressed in texts that together constitute the dominant side of Islamic philosophy to this day. In practical philosophy the Persian thinker Abu Naṣr Fārābī (875–950)—Abunaser, or Alfarabius in medieval Latin texts, also called "The Second Teacher"—creates seminal works of political philosophy, such as *Opinions of the Inhabitants of the Virtuous City*, where he redefined Greek political philosophy and theorized that human beings could gain access to "prophetic" yet objective knowledge through conjunction with the Active Intellect, not restricted to Divine Will. His political order, legislated by a founding prophet-lawgiver and "scientifically" reformed by learned (ʿulamā) guardians, ensured just rule necessary for the universal pursuit of earthly and eternal happiness.

In theoretical philosophy Avicenna's texts, *Healing* (*al-Shifā*); *Directives and Remarks* (*al-Ishārāt wa al-Tanbīhāt*); and *Deliverance* (*al-Najāt*) define Islamic Peripatetic philosophy, which has had the greatest impact on all subsequent philosophical works to this day. This highly creative rationalist philosophical endeavor was, however, seriously curtailed by the antirationalist movement of Ashʾarite theology augmented by the antiphilosophical polemics of the state-sponsored theologian, Abu Ḥāmid Ghazzālī (d. 1111). This is where Illuminationism is critical, for had it not been for the definition and construction of the philosophy of Illumination by Suhrawardī the unbound and creative philosophical endeavor could have died out altogether in the history of Islam. As is, in part due to antirational polemics and fundamentalist religious zeal, much of Islam's intellectual life became confined by structures defined and dictated by Juridical creed.

The impact of such polemics is seen in the philosophical sphere where scholastic philosophical compositions after Avicenna are reduced to the production of "textbooks" (e.g., Athīr al-Dīn Abharī's Guide to Philosophy [*Ḥidāyat al-ḥikma*]) limited by theological presuppositions, whereas philosophy, if allowed, is employed solely as the handmaiden of theology. For awhile the Mongol rule of eastern Islam did allow for a properly free and creative scientific endeavor, which in the philosophical domain is exemplified by noted thinkers who, starting in the thirteenth century, wrote commentaries on Suhrawardī's texts and also composed independent works, some distinctly inspired by the Illuminationist system.

It is in this respect that one can witness an Illuminationist-inspired analytical trend that helped rescue genuine philosophy from deteriorating altogether to dogmatic theology or to ideological mysticism. In part the origins of Illuminationism may be viewed as attempts to respond to antiphilosophical polemics. The Illuminationists' daring philosophical position, however, was that peripatetic philosophy itself needs to be refined and reconstructed to remove a set of presumed logical gaps, and to provide epistemological and other theories to better explain being, knowing, and cosmology. For the most part—specifically in philosophical circles—Aristotle's authority was unquestioned, and Avicenna's work was considered the perfect and consistent Arabic and Persian expression of Aristotelian philosophy. Suhrawardī is among the first philosophers to raise well-reasoned, non-polemic, and nonideologically driven objections against Aristotelian philosophy. His aim—to refine philosophical arguments by rethinking the set of questions that constitute holistic systems—does lead to novel analysis covering the principles of knowledge, ways of examining being, and of new cosmological constructs. The Illuminationist legacy exemplifies refined rational process, and must not be confused with polemics to refute reason, nor to change reason to subjective, social, and ethical mysticism.

II. ORIGINS AND CONSTRUCTION OF ILLUMINATIONIST PHILOSOPHY

The most important and clearly stipulated aim of the philosophy of Illumination is the construction of a holistic system to define a new method of science, named "Science of Lights"(*ʿilm al-anwār*), a refinement of Aristotelian method, and capable of describing an inclusive range of phenomena where peripatetic theory has been thought to have failed. Suhrawardī's novel ideas are expressed in four major texts that together constitute the new system and form an integral and ordered syllabus on the philosophy of Illumination. They are: the first text, *the Intimations* (*al-Talwīḥāt*); and second its addendum, *the Apposites* (*al-Muqāwamāt*), composed in standard peripatetic structure and language with the aim to present a working synopsis of Avicenna's philosophical system, but also to point out the elements where the Illuminationist position differs from that of the peripatetic and to introduce arguments to prove the former. The third text is *the Paths and Havens* (*al-Mashāriʿ wa al-Muʔāraḥāt*), the longest of Suhrawardī's compositions, in which he presents detailed arguments concerning Illuminationist principles in every domain of philosophical inquiry set

against those of the peripatetics, mainly the strictly Avicennan.

The fourth text of the corpus is the text eponymous with the system itself, *the Philosophy of Illumination* (*Ḥikmat al-Ishrāq*), and is the most well-known of all of Suhrawardī's works. This text is the final expression of the new analysis and its systematic construction; it is structured differently than the standard three-part logic, physics, and metaphysics of peripatetic texts, and it employs a constructed symbolic metalanguage named the "Language of Illumination" (*lisān al-ishrāq*). All things pertaining to the domains knowing, being, and cosmology are depicted as lights, where distinction is determined by equivocation—that is, in terms of degrees of the intensity of luminosity. The One origin of the system is the most luminous, hence most self-conscious light, named the Light of Lights, and all other entities are propagated from it in accordance with the increasing sequence 2^n—where n is the rank of the propagated light starting with the First Light—and together they form the continuum luminous whole of reality.

The foundations of the new philosophy commence in logic, where Suhrawardī draws on an earlier twelfth-century Persian thinker, ʿUmar ibn Sahlān Sāvī, and his perhaps Stoic-inspired views in semantics and other parts of logic, and restructures the Peripatetic nine books of the *Organon*. The restructuring of peripatetic work becomes the most apparent distinguishing characteristic of Illuminationist texts since the twelfth century. For example, topics pertaining to semantics, and formal and material logic, plus a novel set of questions on fallacies, are placed together—this for the first time in the history of logic—and given the title "Rules of Thought." There are technical innovations in Illuminationist formal logic, such as reduction of terms; formal redefinitions of the Second and Third Figures of Syllogism as simple inferences based on the First Figure; and the critical reevaluation of negation in simple and compound propositions, where negation is defined as an independent operator that distributes.

The traditional nine books of the Arabic *Organon* are rearranged according to a more well-defined concept of logic as a whole, where expository propositions (the Stoic *logos apophantikos*) are distinguished from proof theory, and indicate a clear view of three-part logic: semantics, formal logic, and material logic. The *Philosophy of Illumination*'s restructured logic is seen as follows: Book Two of the *Organon* (the *Categories*) is removed from logic and a reformulated theory that reduces the number of Aristotelian categories to five—the Stoic four, substance, quality, quantity, relation, plus the fifth, motion, which is

the common continuous category in all existent things—is introduced in physics. Selected subjects introduced in Book One (the *Isagoge*), Book Three (*De Interpretatione*), and Book Six (the *Topics*) are brought together in Section One, titled "On Things Known and On Definitions." Other selected subjects from Book Four (*Prior Analytics*), Book Five (*Posterior Analytics*), and Book Six (the *Topics*) are brought together in the Section Two, which is titled "On Proofs and Their Principles."

Finally, selections from the remaining three Books of the *Organon* (*Sophistical Refutations*, *Rhetoric*, and *Poetics*)—but mostly from Book Seven (*Sophistical Refutations*)—are brought together in the Third Section, which is titled "On Sophistical Refutations and Disputations On the Validity of Illuminationist Principles Vs. the Peripatetic Principles," which further includes subjects traditionally treated in other Aristotelian texts (e.g., selections from *De Anima*; questions on the physics of sight and sound; a critique of the Aristotelian dyad Prime Matter-Form; discussion of Platonic Forms; plus a novel discussion of subjects best described as foundations of mathematics). The Three Sections together are placed in Part One, titled "On Rules of Thought," from the book *Philosophy of Illumination*.

THE PARAMOUNT PROBLEM IN ILLUMINATIONIST PHILOSOPHY. The most important philosophical problem in which Illuminationist philosophy diverges from the peripatetics concerns the epistemology of obtaining primary principles and the first step taken in the construction of scientific systems. The Illuminationist position argues that: (1) the first step in science cannot be demonstrated based on the construction of essentialist definitions (*al-Ḥadd al-tāmm*); (2) laws of science cannot be formulated as universal affirmative propositions (because of future contingency there may be always elements discovered that negate universality); and (3) the peripatetic conjunction with the Active Intellect is a false position or law.

Suhrawardī argues in his "destruction" (*hadam*) of the peripatetic formula that the essentialist definition is based on (1) an elaborate critique of predication aimed at rejecting it as tautological; and (2) the impossibility of counting each and every member of the constituents of the thing to be defined, a condition that must be met for the peripatetic essentialist definition to indicate the essence of the *definiendum*, which is similar the impossibility of a definition by extension. The alternative, as stipulated by Suhrawardī, is that primary principles must be known by "other" ways, which is then stipulated to be an immediate intuitive mode. Suhrawardī's Illuminationist critique of predication may be summed this way: to say "x is y" without knowing the essence of x prior to the predication does not inform of anything other than a change in terms x to y without added signification. Moreover, x includes $\{x_i\}$, then for the predicative definition to inform of the essence, y must be identical to Σx_i, which is not possible as $\{x_i\}$ may be uncountible, or unbound.

The peripatetic position, based on the Stagirites's own view stipulated in many of his texts, was that primary principles may be known through the cognitive mode named "immediate knowledge" but Suhrawardī argues that Aristotle's position on immediate knowledge had not been fully explained and was left ambiguous. This point is best exemplified in early passages of the *Posterior Analytics*, I.2: 71b.20–72a.25, which may be summed up as follows: Science rests on necessary, true, primary, and most prior premises, which are known not through syllogistic demonstration, but by an "immediate," intuitive way. The Illuminationist position, however, is that Aristotle does not systematically present what is the intuitive, immediate cognitive mode; that he does not discuss an epistemological well-structured process that could describe primary intuition; and that he leaves this question in an ambiguous state—because Aristotle refers to immediate knowledge as "opinion" (*doxa*) in his works. Suhrawardī's Illuminationist construction of a unified epistemological theory, named "Knowledge by Presence," is claimed to resolve the ambiguity in Aristotle's position, and Suhrawardī is acclaimed for having, for the first time in Islamic philosophy, described intuitive knowledge in a systematic, "scientific" way.

The Illuminationist ontological position, called "primacy of quiddity," distinguishes philosophical schools in the development of Islamic philosophy in Iran up to the present day. It is also a matter of considerable controversy. Those who believe in the primacy of being, or existence (*wujūd*), consider essence (*māhiyya*) to be a derived, mental concept (*amr iʿtibārī*, a term of secondary intention), whereas those who believe in the primacy of quiddity consider existence to be a derived, mental concept. The Illuminationist position is this: if existence is real outside the mind (*mutaḥaqqaq fī khārij al-dhihn*), then the real must consist of two things—the principle of the reality of existence, and the being of existence, which requires a referent outside the mind (*miṣdāq fī khārij al-dhihn*). And its referent outside the mind must also consist of two things, which are subdivided, and so on, ad infinitum. This is clearly absurd. Therefore existence must be considered an abstract, derived, mental concept.

III. SUMMARY OF THE MAIN TOPICS OF THE ILLUMINATIONIST HOLISTIC SYSTEM

(1) Principles of knowledge, and the first step in science, rest on the primary and immediate intuitive cognitive mode. This knowledge is of essence, is pre-propositional, and rests on the atemporal Illuminationist relation between the self-conscious knower (*mudrik*) and the essentially knowable thing—the object of knowledge—the known (*mudrak*). This "relation" between the knower and the known, or knowing and being, is an identity preserving "sameness" and replaces the peripatetic principle of "conjunction" between the elevated human intellect and the Active Intellect.

(2) Reality is a continuum of monad-like "light" entities that are distinguished only by equivocation in terms of degrees of "luminousity" (*nuriyya, istināra*). Self-consciousness is an essential specific aspect of all lights determining rank of each and every entity propagated from the One source, the Light of Lights. All entities are propagated according to the sequence 2^n, where n is the ordered rank. Consciousness and degrees of abstraction from material extension decrease as n increases, and are associated with each and every member of the Whole (*al-kull*), which is also conscious of self.

(3) There is a two-fold process, "vision-illumination" (*mushāhada-ishrāq*), that acts on all levels of reality. In the corporeal realm of sense-perception, the process acts as sight (*ibṣār*). The eye (*al-baṣar*; or the seeing subject, *al-bāṣir*), when capable of seeing, sees an object (*al-mubṣar*) when the object itself is illuminated (*mustanīr*). In the incorporeal realm every "abstract light" "sees" the "lights" that are above it in rank, whereas the higher illuminates it instantaneously, at the moment of vision. The Light of Lights (*Nur al-anwār*) illuminates everything. Knowledge is obtained through this "coupled" activity of vision-illumination, and the impetus underlying the operation of this principle is self-consciousness. Thus every being comes to know its own degree of perfection, an act of self-knowledge that induces a desire (*shawq*) to "see" the being just above it in perfection, and this act of "seeing" triggers the process of illumination. By means of the process of illumination, "light " is propagated from its highest origin to the lowest elements.

(4) The Illuminationist cosmos adds a fourth realm of being to the standard three—Intellect, Soul, and Matter—of the peripatetic named "Mundus Imaginalis" (*al-ʿālam al-khayāl*), and is a boundary between the intellect and the soul. This realm, described as the "essence of wonders" (*dhāt al-ʿajāʾib*), is the veritable wonderland of visionary experience as described in the Illuminationist allegorical recitals, where time and space are different from time as measure and euclidean space. Movement into this realm brings about qualitative change described in amazing allegorical tales.

IV. ILLUMINATIONIST PHILOSOPHY AFTER SUHRAWARDĪ

The Illuminationist system continues after Suhrawardī's execution in 1191 through the composition of scholastic commentaries on his texts, and also by the gradual creation of independent work in the Illuminationist tradition by a number of leading philosophers, and thus gains widespread acceptance in scholastic centers of learning in Iran. There are two ways in which Illuminationist philosophy continues. Firstly, the thirteenth-century Persian philosopher and historian of philosophy, Shams al-Dīn Shahrazurī in his commentaries on Suhrawardī's texts, *Commentary on the Philosophy of Illumination* (*Sharḥ Ḥikmat al-Ishrāq*); *Commentary on the Intimations* (*Sharḥ al-Talwīḥāt*); and in his independent magnum opus encyclopedic text *The Metaphysical Tree* (*al-Shajara al-Ilāhiyya*), emphasizes the symbolic, and the distinctly nonperipatetic components of Illuminationist philosophy. He also further extends and greatly embellishes the inspirational, allegorical, and fantastic side of Illuminationist texts. Secondly, later in the thirteenth century the well known Jewish philosopher and occulist of Baghdad, Saʿd ibn Manṣur Ibn Kammunam in his *Commentry on the Intimations* (*al-Tanqīḥāt fī Sharḥ al-Talwīḥāt*), and in his major independent philosophical work, *The New Philosophy* (*al-Jadīd fī al-Ḥikma*), as well as in his shorter works, such as *Treatise on the Soul* (*Risāla fi al-Nafs*) emphasizes the purely discursive and systematically philosophical side of Illuminationist Philosophy.

The most philosophically important impact of the Illuminationist system is seen in the latest, creative, and holistic work in Islamic philosophy. This is the constructed system named "Metaphysical Philosophy" (*al-Ḥikma al-Mutaʿāliya*) by the famous Persian thinker Ṣadr al-Dīn al-Shīrāzī, best known as Mullā Ṣadrā (d. 1640). The most widely studied text by Mullā Ṣadrā is his *The Four Intellectual Journeys* (*al-Asfār al-Arbaʿa al-ʿAqliyya*), where in almost the entire range of philosophical investigation the author draws heavily from the Illumina-

tionist tradition—this after the texts of Avicenna and Suhrawardī are first carefully analyzed and then problems and arguments are reconstructed usually along the systematic principles of the Illuminationist system. The most enduring impact of Illuminationist systematic philosophy is in the domain of epistemology, where Mullā Ṣadrā adopts and refines Suhrawardī's unified theory Knowledge by Presence to discuss, among other things, God's knowledge, and the "scientific" validity of inspirational knowledge as well as of revelation. Mullā Ṣadrā's discussion of the proposition "sameness of knowing and being," or "unity of the knower and the known" (*ittiḥād al-ʿāqil wa al-maʿqūl*), is distinctly Illuminationist, whereas sameness, or "unity," is nonpredicative.

ILLUSIONS

Most of the major philosophical problems of perception derive from the fact of "illusions." These problems center on the question whether perception can give us true and direct knowledge of the world, and thus they are basic to epistemology. This entry will describe illusions and set forth and examine the argument from illusion that perception cannot be trusted as a source of knowledge of the external world but affords direct awareness only of appearances or sensa.

THREE KINDS OF ILLUSORY EXPERIENCE

The term *illusion* is used by philosophers to cover a range of phenomena approximately classifiable as follows.

ILLUSIONS PROPER. Illusions proper occur when the percipient is deceived or is liable to be deceived in identifying the object perceived or its properties. Psychologists have produced a number of optical illusions, such as equal lines that appear to be of unequal length; a stationary balloon that when inflated and then deflated seems to advance and then recede; and a specially constructed Distorted Room, in which a man looks smaller than a boy. Diseases or drugs, including alcohol, may produce other illusions, such as double images or the unearthly colors and multiple shapes an object may assume for one who has taken mescaline. Other examples are mirages, mirror effects, and conjurers' tricks. The perception of motion introduces many more: At the cinema a rapid succession of slightly different stills on a flat screen makes us see a scene with a three-dimensional perspective in which people move about; the wheels of a coach may seem to be

going backward when really they are moving rapidly forward (stroboscopic effect).

RELATIVITY OF PERCEPTIONS. A round plate that looks elliptical when seen from an angle and a square table that looks diamond shaped illustrate the relativity of perception. The same water may feel cool to one person and warm to another; the same wine may taste sweet or dry, depending on what one has just been eating; green hills may look blue in the distance; and as a train rushes past, the pitch of its whistle may seem to vary. Further examples are color blindness, shortsightedness, and other physical defects that alter the appearance of things. In all these cases the apparent properties of an object vary relative to the position of the percipient, the distance and media between him and the object, the lighting, the state of his health, body, or sense organs, etc. These are not strictly illusions (they usually do not deceive), and they vary around a norm in which the objects are perceived accurately.

HALLUCINATIONS. In pure hallucinations—for example, the pink elephant a drunkard sees, the apparitions of delirium, Macbeth's dagger—some physical object is "perceived" when neither it nor anything at all like it is present. In contrast are illusions where the mistake is about the properties, position, or identity of some object actually in view.

Some, perhaps even most, hallucinations are triggered by some perceived feature of a very different character; for instance, a beam of light may be taken to be a person. Many hallucinations are integrated; they fit well with the real background, cast shadows, and vary in size and perspective as they move. One may also class phantom limbs as hallucinations. Pain or other sensations are felt "in the toes," for example, of a leg that has been amputated—the victim still feels he possesses the missing limb.

ARGUMENT FROM ILLUSION

The main aim of the argument from illusion is to show by means of illusions that the senses are not to be trusted and that perception is not direct and certain awareness of the real properties of material objects but awareness of appearances only. In fact, this argument involves three subarguments.

(A) A SKEPTICAL CLAIM. However sure we are about our perceiving, it is always possible that we are being deceived by one of the many kinds of illusion or hallucination, since it is characteristic of such states that we cannot tell that we are suffering from them. This may in practice be a negligible possibility, but philosophy is concerned with the highest standard of exactitude, and from this strict position perceiving is not absolutely certain because there is always some theoretical possibility of error. Various conclusions can then be drawn. One is that for certain knowledge we must rely not on the senses but on some other faculty, such as intellectual intuition (as in René Descartes); another is that we must abandon commonsense realism.

(B) NATURE OF APPEARANCES. In all these illusions there is some thing or quality that does not coincide with the object or object-properties that are in fact present— for example, the apparitions of hallucinations, the elliptical appearance we see when we look at a round plate, the black shape the color-blind person sees when looking at a red box, the oasis of a mirage, and the second bottle in double vision. All these are merely appearances and cannot be identified with real objects or properties. What then are these appearances? In some cases, and probably in all, they must be *sensa*, private, probably mental, objects of awareness quite distinct from external material objects, although no doubt they are caused by or resemble material objects.

(C) SIGNIFICANCE OF CONTINUITY. If one were to change from seeing an appearance, a private and transitory sensum, to seeing a public, enduring physical object ("public" meaning observable by several persons at one time), one would expect a sudden change in the character of one's sensory experience. But no such jump occurs: There is normally an unbroken continuity between situations where we cannot actually be seeing the material object but are aware only of appearances and situations where we think we see the material object. As we move from where the plate looks elliptical to where it looks round, or as the drunkard looks first at the pink rat and then at the real bed on which it sits, there is a smooth transition. Consequently, even in these seemingly genuine or veridical perceptions we must also be aware of appearances or sensa and not directly of the object itself.

We may note three things concerning our subarguments: (1) Argument (*b*), unlike (*a*), does not depend on there being error; even if one is not deceived by perspectival distortion, double vision, and so on, the argument that what is really perceived must be sensa is unaffected. (2) The claim in (*b*), that the appearances are private and mental existents, depends to some extent on considerations of continuity. Almost all hallucinations, the dark

shapes a color-blind person sees or the results of diseases and drugs, are plausibly private to the percipient. But simple perspectival distortions will be private only to the viewpoint. For instance, the elliptical appearance of the plate is as public as the round one in that many may see it at once; this holds similarly for mirages and reflections. Unless causal considerations are introduced, the supposition that each person is then seeing a numerically different but qualitatively similar elliptical appearance or sensum must rely partly on similarity with cases where the content of illusion is undeniably private and partly on the assumption that if the plate is round, then the elliptical appearance must be something other than the plate; but these are hardly compelling grounds. (3) The charge may be made, How do we know that the plate is round or what its real color is? These points would normally be settled by measurement or by reference to standard lighting conditions, but the argument does not rely on this. To take the plate example, it may be put thus: The plate looks elliptical to *A* and round to *B*; it cannot be both round and elliptical, for that would be a self-contradiction; therefore, one of these appearances at least must be quite distinct from the plate—and perhaps (by continuity) both are.

CRITICISM OF THE ARGUMENT FROM ILLUSION

The argument from illusion can be countered in various ways.

CERTAINTY. The skeptical claim is often met by stressing the comparative rarity of illusion and the efficacy of the various tests that can be made to remove doubt. We can use one sense to help another. For example, wax fruit may look like real fruit, but touch and taste reveal it; sight, memory, and testimony can show that a phantom limb does not exist; measurement can settle the real shape of an object; confirmation from others can show up many hallucinations, though there are some group hallucinations; we soon learn to discount alcohol and drugs and may generally argue from known causal factors present. But although these tests reduce the possibility of error in a tested perception to extremely slight and in practice negligible proportions, the critic will still say that it is not absolutely certain and that only absolute certainty will satisfy the philosopher. To this there are two replies. (1) It is logically impossible that we suffer from hallucinations all the time; if no perception were ever certain, then there would be no way of distinguishing hallucinations and illusions from normal perception. (2) The skeptic is mis-

using the word *certain*; well-tested perceptions are just the things we refer to as certain. If we say they are only probable we destroy the normal useful distinction between *certain* and *probable*. If nothing is certain, the word has no meaning, and we shall just have to invent a new term for that ordinary distinction.

We may comment on these replies. Reply (1) is of no help in deciding whether any particular perception is certain or not—which is one of the main points—and anyhow, a merely approximate certainty would serve to distinguish perceptions from hallucinations. Reply (2) seems to depend on confusing meaning and reference. It is true that perceptions are things we refer to as certain, but that may only be due to our ignorance of the possibility of illusions. The normal meaning of "certain"—without any possibility of doubt—is correctly adopted by the skeptic; he merely argues that it may only be used of the results of intuition or of mathematical demonstration, not of perception; that is he differs only as to the referents of the word. Also, he can still distinguish between "probable" and "practically certain" in perceptual statements. However, a modified reply to the skeptic may be made (3) that he is in fact limiting the word *certain* to cases of logical necessity, to those that it is self-contradictory to deny. This limitation not only has the practical disadvantage of destroying the ordinary certainty-probability distinction but also rules out a priori the possibility of any perceptual statement's being certain; thus the lack of certainty in perception is due not to any defect in perceiving but simply to its not being something quite different from what it is, namely intuition or entailment. It would therefore be much more appropriate to use a relaxed standard in dealing with perception and to allow a perceptual statement to be regarded as certain if it has passed all conceivable or all recognized tests. At any rate, there is no reason to suppose that ordinary perceptions are uncertain in the way that the result of a horse race or the nature of next year's weather is uncertain.

HALLUCINATIONS. The argument from the significance of continuity claims (1) that hallucinations are private sensa, not public material objects, and (2) that since they are indistinguishable from the objects of perceptual consciousness, especially when integrated with them, the latter must also be groups of sensa—representations, perhaps of external objects.

(*a*) One answer, based on the usual psychological account of hallucinations, would be that they are not sensa but mental images of an unusually vivid type that are confused with normal perception. To

meet point (2), the unusual vividness and the lack of normal discrimination may be stressed and explained by the special circumstances in which almost all hallucinations occur, as when the victim is suffering from fever, drunkenness, drugs, starvation, religious ecstasy, or madness or is influenced by lesser factors, such as fear, acute anxiety, or drowsiness. (In the hallucinations of mescaline the person's mental powers are unimpaired, but he usually recognizes the hallucinations as such and is not deceived into thinking they are real.) It is questionable whether these factors, especially the lesser ones, can account for the integration and triggering of hallucinations—cases in which the continuity argument is strong and imagery would seem to merge with genuine perceptions. Also, to be complete this answer would need to offer an explanation of the nature of mental imagery and of why it resembles perceiving. Probably imagery depends on reactivation of the kinds of brain and nervous activity that occur in perception (or in action, if it is motor imagery), and the occurrence of such activity can be detected during the imagery. However, this involves the causal processes, study of which leads by a different route to the abandonment of commonsense theories.

(b) It has been pointed out, by J. L. Austin, for example, that the argument from illusion as applied to hallucinations relies on certain dubious assumptions, namely, that if two things (i.e., an object of genuine perception and an object of hallucination) are not generically the same they cannot look alike, and that they cannot be distinguishable if we in fact fail to distinguish them. The special circumstances cited in point (a) may come in here as providing reasons for the victim's failing to distinguish what are in fact distinguishable and quite different experiences. This criticism certainly undermines the argument from illusion as a demonstration; for it to be that, these assumptions would have to be accepted as universally true. But it can be replied that an explanation is still required for the general similarity between the two things (sufficiently close a similarity for people suffering only from anxiety to confuse them); also, we need some general theory of the nature of hallucinations and of their integration and triggering.

Phantom limbs are not covered by these points: One can hardly say that the pains and sensations involved are images of genuine ones—they are genuine enough—nor are the victims suffering from drugs or delirium. The usual physiological explanation is that the nerves from the toes, for example, remain in the untouched part of the limb and, being irritated at the stump, send impulses to the brain similar to those they would send if the toes were being crushed or the pain and other receptors in the toes were being otherwise stimulated. This seems to confirm that pain and somatic sensations are private sensa and accords with the general causal theory of representative realism. But it is still arguable that such sensations are very different from sight and hearing, so that nothing follows about the nature of the latter.

ILLUSIONS AND RELATIVITY. The argument from the nature of appearances relies on the odd assumption that things cannot look other than they are, that when one apparently sees as elliptical a plate that is actually round, then one cannot really be seeing the plate; one is seeing something, an appearance or sensum, which, being elliptical, cannot be the round plate. But one can simply deny the assumption and say that one is in fact seeing a round plate from such a position that it looks elliptical; its elliptical appearance is not some entity different from it. To treat appearances as entities, as though they were things, is a quite unjustified reification; when we speak of the appearance of something we speak of how it, the original object, appears, not of some other object distinct from it. One may confirm this point by noting that the elliptical shape will appear on a photograph too, so that it cannot be subjective or mental.

The same answer may be applied to the various examples of relativity and illusion. The distant green mountains are actually seen but look blue and may be so photographed; in the Doppler effect we still hear the whistle (a "public" noise), and its apparent variation in pitch may be recorded on tape. In the optical illusions we are still seeing lines on paper, balloons, or a man and a boy, and cameras will photograph them with their deceptive appearances. Again, as Austin has shown in detail, in refraction and reflection we still see the object—the face in the mirror or the stick in the water; even in a mirage we see a real oasis, though it appears many miles nearer than it actually is. It may also be claimed that the color-blind man sees the red box, even if it looks black to him, and that the man with double vision sees the one bottle, but it looks double to him. (This last point is more dubious: It may be said that looking double is not like looking blue for it involves an extra apparent object and not a dif-

fering quality of the one object. On the other hand, the percipient is not seeing two bottles in the same way normal people see one: The bottle and the background have a doubled, slightly defocused appearance that perhaps makes it reasonable to say they look double.)

For some people this general answer is immediately convincing, and it seems incredible that the argument from illusion was ever taken seriously. But others protest that it is inadequate and neglects the immediacy of perception; in the various situations mentioned they seem clearly and directly to be aware of an elliptical shape or a blue expanse of mountain, an advancing balloon, two bottles, or, if color-blind, a black box-shaped expanse. Thus to be told that they are aware only of a round plate, green mountain, stationary balloon, one bottle, and so on, is to them unconvincing and fails to do justice to the facts of experience. This feeling for the immediacy of sensory awareness, and the belief that confrontation is so direct that its apparent object must exist as perceived, is at the bottom of the sense-datum theory. The alternative is to dismiss as illusory this apparent direct and mistake-proof confrontation in perception; perceiving is variable in quality, is affected in its accuracy by position, distance, and many other factors, and may thus be inefficient. It is more plausible to suppose that position, distance, and media distort perception of a round or green object or that color blindness and shortsightedness prevent one from seeing it properly than to suppose that these factors give one excellent and perfect awareness of some elliptical or blue sensum different from the object.

But this is not a final answer, for if one then seeks to discover how these factors affect the quality of perception, one has to go into scientific details. Angle of sight varies the pattern of light striking the eye, refraction or reflection bends the light rays, dust scatters them or absorbs some frequencies rather than others, drugs affect the activity of the nervous system, lack of certain retinal pigments alters the eye's response to light, the Distorted Room and other optical illusions rely in their effects on misleading cues. In short, the effects of illusion point beyond themselves to the causal and psychological processes that underlie perception and constitute its most serious theoretical problem.

Bibliography

The argument from illusion is a stock feature of introductions to philosophy and is dealt with in most of the books in the bibliographies for the entries Sensa, Realism, and Perception. The books listed below give a fuller treatment of the subject.

Henry Habberley Price's *Perception* (London: Methuen, 1932) and Charlie Dunbar Broad's *Scientific Thought* (London: K. Paul, Trench, Trubner, 1923) and *The Mind and Its Place in Nature* (London: Kegan Paul, 1923) develop the argument to support sense data. Alfred Jules Ayer's *Foundations of Empirical Knowledge* (London: Macmillan, 1940) develops it to support the introduction of a "sense-datum language." Price has some second thoughts on perspectival distortion in his article "Illusions," in Volume III of *Contemporary British Philosophy*, edited by Hywel David Lewis (London, 1956), and Ayer's views are presented in his clear introductory work *The Problem of Knowledge* (London: Macmillan, 1956).

John Langshaw Austin, *Sense and Sensibilia* (London: Oxford University Press, 1962), D. M. Armstrong, *Perception and the Physical World* (London: Routledge and Kegan Paul, 1961), and Rodney Julian Hirst, *The Problems of Perception* (London: Allen and Unwin, 1959), are critical of the argument from illusion. See also George McCreath Wyburn, Ralph William Pickford, and R. J. Hirst, *Human Senses and Perception* (Toronto: University of Toronto Press, 1964), which, besides criticism, gives some physiological and psychological details. For other attempts to meet the facts of illusion without postulating sensa, see the works listed under "Perspective Realism and the Like" in the bibliography for Realism and under "Sense Data" in the bibliography for Sensa.

The neurologists John Raymond Smythies, in *Analysis of Perception* (London: Routledge and Paul, 1956), and Russell Brain, in *The Nature of Experience* (London: Oxford University Press, 1959), give some useful references and nontechnical information on hallucinations. The psychological details of illusion in general can be found in any good introductory textbook on psychology, such as David Krech and Richard S. Crutchfield, *Elements of Psychology* (New York: Knopf, 1958).

IMAGERY, MENTAL

In many ways, mental imagery has been a fundamental issue in the history of philosophy. At least since Aristotle, philosophers have argued that knowledge is often represented in the form of mental images, taken to be inner pictures of some sort. However, questions have frequently been raised about the capacity of such images to play roles in thinking, remembering, and imagining; for instance, in George Berkeley's well-known doubts about the possibility of general or abstract images. Debates about mental imagery have been important in the history of psychology as well. Because the images in question are the bearers of conscious experience, claims about them have often been made on the basis of introspection, and the rejection of introspection in favor of behavioral studies was central to the emergence of psychology as a science. However, with the rise of cognitive science, quantified behavioral research has put mental images back on the map.

For example, Roger Shepard and his colleagues (1982) asked subjects to determine whether one geometrical figure matched another, the overall orientation of which was tilted relative to that of the original figure. Reaction times were a linear function of the angle of the tilt: The greater the displacement between the two otherwise identical figures, the longer it took subjects to respond. The implication is that reaction time depends on an operation such as rotating one of the perceived figures through space. Assuming a constant rotation rate, time to respond will depend on the distance through which the figure is rotated. One conclusion that can be drawn is that imaging is like perceiving, because matching rotating objects or figures in perception is similarly governed by a time-to-distance law.

This *perceptual similitude* thesis is an important part of pictorialist theories, according to which images are like mental pictures. It is particularly important on Stephen Kosslyn's account, the most fully developed version of pictorialism. In one well-known experiment, Kosslyn asked subjects to visualize a map they had previously studied and to focus on one of several items represented on the map (e.g. a hut, a pond, a tree). Subjects were then asked to say whether various items were located on the map. Reaction times were a linear function of the distance between the original focal point and the identified item. This suggests that they were scanning a mental map and not simply accessing a description or list. While reaction times might be due to the position of terms on a list, given the initial conditions of free study, there is no reason to think that the locations would be listed systematically by their proximity to the focal point, with the nearest first, the farthest last, and so on.

In Kosslyn's *Image and Mind* (1980), scanning and other operations, such as panning and zooming, are defined as functions that could be performed by a digital computer. This use of a computer model illustrates why theories of mental imagery do not need to treat the mind as an immaterial substance or entail a homunculus to view the inner pictures. Forming and accessing images can be explained in terms of more basic level operations, which can themselves be further decomposed into fundamental processes that a machine could perform.

The same is true for the mental sentences posited by descriptionalist theories of imagery, which constitute the opposing camp. The best-known of these has been developed by Zenon Pylyshyn in *Computation and Cognition* (1984). His argument has two parts. First, he claims that evidence shows that imaging is cognitively penetrable. It is influenced by background knowledge and belief. Therefore, he argues, there cannot be perception-like processes of the sort that pictorialism requires; that is, generic operations such as scanning or rotating at a standard rate that are part of a fixed functional architecture employed similarly across imaging tasks. Second, he maintains that what is a vice for the pictorialist is a virtue on the descriptionalist account. The data on reaction times can be explained, he argues, precisely in terms of the effects of tacit knowledge in the face of experimental task demands. This tacit knowledge is expressed in language-like representations and operates through the production of the descriptions in which imaging consists.

For instance, when four-year-old children were shown an inclined beaker containing colored liquid and then later asked to draw it, they typically drew the fluid level as perpendicular to the sides of the beaker. The implication is that the children's memory images, upon which the drawings are based, are not simply pictures that reproduce the perceived object, and the images reflect that young children do not possess an understanding of geocentric level. Extending this analysis to rotation and scanning studies, Pylyshyn argues that the results can be explained in terms of task demands: Subjects are led to

believe that, in visualizing objects, they are to replicate the process of perceiving the objects. Knowing that perceived object rotations must obey a time-to-distance law, they reproduce the relevant reaction times, although not necessarily with conscious intent.

However, a number of objections have been made to these claims. First, it is sometimes argued that Pylyshyn's descriptionalist view makes images epiphenomenal, giving them no role in causal explanations of behavior. Of course, if such images can be identified with the underlying data structures that take a descriptive form, the charge is not strictly correct. Nonetheless, such a construal will not explain the phenomenal properties of conscious imagery, which are thus excluded from scientific accounts.

Second, not all reaction time studies can be explained in terms of task demands, a point that Pylyshyn now concedes. Moreover, because imaging is affected by background knowledge, it need not be taken to undercut explanations in terms of a basic set of perceptual operations. Kosslyn agrees that imaging is cognitively penetrable. He notes, for example, that the rate of scanning may vary across individuals or tasks. However, that does not mean that scanning cannot be defined in terms of standard operations—such as shifting attention incrementally—or that the employment of those operations is not governed by law-like generalizations. Scanning might be one of a fixed set of operations available to everyone—even if it is not always used—and it can exhibit regularities, despite the effects of knowledge and belief. For example, it can be assumed to occur at a constant rate within individual subjects on a given task.

Nonetheless, a positive account must be given of the knowledge effects that imaging does display, and this requires more than an appeal to perceptual similitude. Thus Kosslyn argues that imaging occurs in a *visual buffer*, a distinctively spatial medium analogous to an internal computer monitor. Although the representations on such a screen will be composed of distinct elements—such as cells in a matrix that can be labeled—the images are said to be pictorial, in the sense that spatial properties of objects are represented by the spatial properties of the medium.

Originally posited as part of Kosslyn's computational model, this visual buffer is identified in his *Image and Brain* (1994) with topographically organized areas of visual cortex. In topographic representations, the features of an object can be distorted. Nonetheless, spatiallydefined regions of the medium will correspond systematically to spatial regions of the object. Moreover, unlike

descriptions, such images have the property that the farther apart two points appear to be on an object, the more representational elements there will be between representations of the points. Although these elements need not be closely contiguous, they cannot be just anywhere. If two points appear to be adjacent in a represented object, then the elements that represent them must be—at least in an extended sense—adjacent as well. Several types of evidence from brain research can now be cited in support of the pictorialist view; for instance, lesions to the visual system cause subjects to be unaware of one side of the visual field in imaging, just as they do in perception.

One objection often made to pictorialism is that mental pictures lack the syntactical regularities that would allow them to express thoughts precisely. Sentences can be used to single out certain types of information while ignoring others, but pictures will inevitably represent features that are irrelevant to the task at hand. Thus Daniel Dennett (1981) has argued that imagining cannot be mental picturing, because the former can be more indeterminate than the latter. On the one hand, it is possible to imagine a striped tiger without envisioning it as having a definite number of stripes. On the other hand, it is impossible to depict a striped tiger without showing the number of stripes that it has. However, this line of argument commits what Ned Block (1983) has called the "photographic fallacy." It assumes that pictures cannot employ selective devices; there are actually several ways in which pictures can omit details, Block argues (e.g., by virtue of viewpoint, occlusion, atmospheric blurriness, or schematization). Moreover, the argument from indeterminacy can be turned around. In *The Imagery Debate* (1991), Michael Tye has argued that there are certain kinds of corollary or implicit information that both pictures and images inevitably carry. For instance, any perceptual or imagistic representation of two objects, A and B, will necessarily represent an apparent direction of one to the other. Descriptions of A and B need not contain information of that sort. Thus, Tye argues, images cannot be construed as descriptions alone.

However, one way to capture picture-like properties in descriptionist terms has been proposed by Geoffrey Hinton (1979). According to him, imagery does not occur in a special medium, a visual buffer of the sort that Kosslyn describes. However, neither does it depend on the same format and processes as higher-order thought— that is, descriptions in Pylyshyn's sense. Rather, it involves a distinctive format and set of operations, albeit defined over descriptions of a more elaborate kind. Attached to object-centered descriptions of shapes are egocentric

coordinates for objects in a scene, which add spatial information and allow for operations of a special sort (e.g., a gradual alteration of the coordinates, in terms of which rotation and scanning can be described). This account explains why subjects find it hard to identify figures embedded in complex geometrical shapes (a triangle in a star of David) or to reinterpret ambiguous figures, once an original interpretation has been made (e.g., to see the rabbit in the duck-rabbit image if it was initially seen as a duck). Interpretations not included in or derivable from the original descriptions will be hard to come by, and this may be particularly so if they require a revision of the coordinate reference frame. The problem is that Kosslyn's evidence shows that subjects are able to reinterpret images even when the new interpretation is incompatible with the original reference frame. This would not be predicted on Hinton's account.

Tye has proposed a hybrid theory, according to which an image consists in an array and an interpretive description combined. The descriptive components are limited, consisting primarily of part descriptions that are produced whenever the part is scrutinized. Thus the array is not rendered irrelevant by a complex description that could simply take its place. However, it is unclear exactly how arrays and interpretations are combined on this account; that is, why certain descriptions are generated for an array on certain tasks and precisely how the properties of the array are used to perform the task. The question is why, on the one hand, basic part descriptions are not simply activated directly on a visual memory task, thus making the array unnecessary. On the other hand, if the array functions to support the discovery of previously unnoticed features, then there is no guarantee that ambiguities will not appear in descriptions of basic shapes themselves.

One promising avenue for research is suggested by Tye's argument that part descriptions are generated only as needed. That claim is consistent with Kosslyn's current view that imagery and perception are governed by a principle of *opportunistic processing*: Representational resources can be deployed in diverse and sometimes limited ways, as required by a task. In his 1994 book and subsequent research, Kosslyn argues that imaging is not a single capacity, but comprises a set of subsystems that are distributed in the brain. Although these subsystems are functionally specialized, they can interact, and they can be employed strategically in various combinations. This approach implies that the interpretation of images in the visual buffer need not always consist in inferences over language-like representations. Instead, assignment of content in an image is constrained by the particular operations and strategies in which aspects of the image are incorporated. For instance, image scanning consists in enhancing activity in various parts of the visual buffer, thus priming specific features, making them easier to encode. In that sense, scanning patterns constitute interpretations, because they bias the content that can be ascribed to the image by the visual system. This account has the potential to explain individual differences in image interpretation in terms of variations in perception-like strategies. Born out of Kosslyn's turn to neural networks and connectionist modeling, this emphasis on imaging strategies tracks the ongoing development of cognitive science and philosophy of mind.

IMAGES

Aristotle's claim that "it is impossible even to think without a mental picture" (*On Memory and Recollection* 450a) has frequently been echoed by subsequent philosophers. David Hume equated thinking with having mental

images, since he appears to have considered ideas and images to be the same; for of any sense impression "there is a copy taken by the mind, which remains after the impression ceases; and this we call an idea" (*Treatise of Human Nature,* Book I, Part I, Sec. ii). The sole contents of the human mind are original impressions and these copies of them. Thomas Hobbes was stating much the same view when he said, "Imagination therefore is nothing but *decaying sense*" (*Leviathan,* Ch. 2).

Many other philosophers have also accepted the existence of such mental contents without examining their nature; they had assumed that images are things whose nature or existence is obvious to all human beings and that can most simply be described as "copies" or "pictures" of the external world. Views denying the existence of such objects have been rare; the chapter in Gilbert Ryle's *Concept of Mind* that seems to attack the commonly held view of the imagination as the power of producing mental images is felt by many to be contrary to normal experience. The images that Hobbes and Hume were talking of, and that Ryle attacks, are mental existents, depending on our prior experience of the physical world, though they may have objective counterparts in the brain. In this they differ from the Epicurean *eidola* or *simulacra,* which Lucretius defined as "images of things, a sort of outer skin perpetually peeled off the surfaces of objects and flying about this way and that through the air" (*De Rerum Natura,* Book IV, 11. 29ff.). These images Lucretius thought of as physical objects, albeit rather ethereal ones, whose function is to explain perception as well as images and dreams. When actual existence is attributed to them they are made to resemble the physicists' "real images," which are the representations of objects formed on screens or in space by lenses, or on the retina of the eye by the same mechanism. Physicists also talk of a "virtual image," a visual appearance that cannot be detected by physical means in the place in which it seems to be (for example, the appearance of objects behind the mirror's surface). This usage, which implies that there is something unreal about the image, is nearer to the normal philosophical or psychological use than is that of the term *real image.* The connection between "image" and "imaginary" is preserved in ordinary usage.

IMAGES AS THE MEANINGS OF WORDS

Undoubtedly the strongest desire to maintain the existence of mental images has come from the need to provide something to serve as the bearer of meaning for words of our language. George Berkeley's attack on John

Locke in the introduction to *The Principles of Human Knowledge* is mainly concerned with this question. Against what he took to be Locke's view of the existence of "abstract general ideas," or the meanings of general terms, Berkeley argued that images must be particular. It is, he claimed, impossible for anyone to form a general idea (by which he clearly meant "image") of a triangle, for it would have to be "neither oblique nor rectangle, neither equilateral, equicrural, nor scalenon, but all and none of these at once." Whether Locke had meant this by his argument for abstract general ideas will not be discussed here; the important point is that Berkeley may be said to have shown that in some cases thought may proceed without images, because there could be no image or "mental picture" to correspond with some terms of our vocabulary.

Nevertheless, it may still be claimed that imagery is an important part of our mental life; this is argued by H. H. Price in his *Thinking and Experience* and elsewhere. Empirical evidence would appear to show that there is considerable divergence in the amount of mental imagery experienced by different individuals; Sir Francis Galton (in *Inquiries into Human Faculty and Its Development*) stated that imagery tended to be lacking in "scientific" minds and to be common in those of artistic bent. The Würzburg school of psychologists in the early twentieth century maintained that their experiments proved the existence of "imageless" thought. The difficulty here lies at least partially in determining what is to be called a "mental image." Although most people, as has been said, understand the instruction "Picture to yourself a familiar building" and claim to be able to do so, it is obvious that what they do in such a case is not the same thing as looking at a picture or photograph of the object, and it is not clear what connection this ability has with that of using the words of a language.

WITTGENSTEIN'S CRITICISM

Ludwig Wittgenstein argued that if some form of mental picture is needed to "give meaning" to a word, then an actual picture can be used instead; for example, asked to get a red apple, a man could use a color chart that gave a specimen of red opposite the word *red.* He could then compare apples with this sample until he found one that matched. Those who think of images as being essential to the use of language are talking as if each person carried such charts "in his head" and proceeded in the same way in the absence of an actual sample. The difficulty with this view, in Wittgenstein's opinion, is that the command "Imagine a red patch" can be given and obeyed; here it is obvious that the "mental sample" will be of no use or will

lead to an infinite regress. The image can itself be recognized as red without the use of any intermediary, so there is no reason why a specimen of red should not also be recognized. Most people do, in fact, immediately recognize specimens of the common colors, though they may need a chart for the rarer ones. Wittgenstein summarized his attack on the false picture of recognition as follows:

> It is as if I carried a picture of an object with me and used it to perform an identification of an object as the one represented by the picture. Our memory seems to us to be the agent of such a comparison, by preserving a picture of what has been seen before, or by allowing us to look into the past (as if down a spy-glass). (*Philosophical Investigations,* Sec. 604)

There are two further difficulties about this view of the image as the bearer of meaning. First, it is not clear how an actual picture functions, and second, the comparison of the image with a picture itself gives rise to difficulties.

FUNCTIONING OF ACTUAL PICTURES

Price has stated that "both words and images are used as symbols. They symbolise in quite different ways, and neither sort of symbolisation is reducible to or dependent on the other. Images symbolise by resemblance" (*Thinking and Experience,* p. 299). Price's arguments for his weakened version of the imagist theory rest, as the quotation shows, on the assumption that images, like other pictures, are related to their objects by resemblance. Such a view assumes that there is no problem in recognizing a picture of, say, a man as a man. Just as anyone who could pick out a real man could identify a mirror image of a man, so, it is thought, could he pick out a pictorial representation of a man.

But what is to count as a picture of a man here? A child's matchstick man consisting of five lines and a circle? A rough sketch? A "lifelike" portrait by a Royal Academician? A life-size photograph? As the art historian E. H. Gombrich has shown in his *Art and Illusion,* the representation and the recognition of three-dimensional objects on a two-dimensional surface is a sophisticated activity. Our children are taught something of the appropriate techniques at about the same time as they learn their native language. There is no basis for feeling that the procedure of representing objects in these ways is more "natural" than describing them by means of words. It has been said that some primitive peoples find it impossible to recognize a photograph of one of their number because they have not learned to interpret the pattern of black and white in the appropriate way. Yet it would seem that a photograph is the most "natural" representation because it is the product of a purely objective projection of the object; drawings and paintings depend on a variety of learned techniques of representation.

It is necessary to distinguish between the way in which a picture is produced and the use that is made of it. There may be a method of projection, but it is not because of that method that we accept the picture as a likeness. Furthermore, it is not clear from the picture itself, though it may be from the title, what it is meant to be the likeness of. A picture of an oak may be that of a particular historic tree (King Charles's Oak, for example), an example of an oak tree for purposes of identifying the species, an illustration for a general article on trees, a sign for a forest, or a composition to hang on the wall for its "artistic" quality. Without some rule it is impossible to tell what the picture is for and hence what its subject is; its meaning, what it symbolizes, lies in the use we make of it. In the context of a botany class it may be quite clear that the picture of an oak is being shown to enable students to identify specimens of that tree; here the rule is given by the situation in which the picture is used. Similarly, it is clear that the man who carries a photograph of his sweetheart does it to remind himself of her, uses it as a kind of substitute for her presence. Real pictures have a variety of uses.

IMAGES AS PICTURES: OBJECTIONS

A picture may be used to give information; from a picture of the Pantheon it is possible to discover the number of columns in the facade. But as Jean-Paul Sartre points out in *L'imaginaire* (p. 117), an image of the Pantheon may not be sufficiently detailed to enable this, even though before the question was asked the agent thought his image was perfectly clear. If he does not already know the number, then he cannot count the columns in his image. In this the image differs radically from the picture. Furthermore, it is usually known what the image is an image of without the need to inspect it for clues. Even when an image arises in the mind and cannot be recognized, no closer examination will provide clues to its identity; we have to wait until the name comes to us. In the extreme case of dreaming, we may "recognize" a person even though his characteristics are entirely different from those possessed in real life. A picture, on the other hand, may be identified gradually by the collection of clues. Thus, "having an image" of an object differs from contemplating either the object or a picture of it. The image

is not a picture in a special private gallery (cf. Ryle, op. cit., p. 247).

Part of the difficulty, as Ryle stresses, is due to an excessive concentration on the sense of sight; we naturally talk of "picturing" or of "visualizing," but there are also aural, tactual, and olfactory imagery. (A blind man's imagery, presumably, would be entirely of these kinds.) But in these cases there is no recognized means of representing the sound, touch, or smell—what would such a process be like?—and hence no temptation to talk of such images in terms that are drawn from the inspection of physical representations.

We do find it very natural to talk of mental images, and because external objects are normally described in visual terms, these terms are also applied to images.

Images are not always under our control; a person may find he is "haunted" by the image of a street accident or by the cries of the victim. Images do occur and must be accounted for. But to say this need not lead us to think of them as "decaying sense." Such a description would apply to afterimages, caused by staring at a bright light and then looking away. But these are actually perceived and can be physically located, on or just in front of whatever is looked at. Mental images have no location and are not related to public visual space; it is useless to ask a subject, as some psychologists have done, to project his mental image onto a screen, for it is impossible to look at the physical world and contemplate an image at the same time. But the "seeing" of a visual image or the "hearing" of an auditory one is only, in Sartre's terminology, a "quasi observation"; as Ryle puts it, "an imagined shriek is neither louder nor fainter than a heard murmur. It neither drowns it nor is drowned by it" (op. cit., p. 250; despite differences in terminology, there is a measure of agreement between Ryle and Sartre on this topic). The "quasi-observational" nature of our apprehension of images is marked by the device, naturally adopted, of putting quotation marks around "see" and "hear" in this context.

Nevertheless, the question "What is a mental image?" is wrongly posed, for it implies that there is some definite mental content to which the words can be applied. As has been shown above, the similar question "What is a picture?" equally has no definite answer. A picture may be regarded as a pattern of pigment on a piece of canvas, and much can be said about it in this respect. But such a description leaves out of account its function *as a picture,* which may be to recall the face of an absent friend. When it is being used for this purpose its characteristics as a physical object are ignored; the person is seen "through" the painted representation. It is he in whom we are inter-

ested. Similarly, when a mental image is being used it is the object that is of interest to us, not the image itself. "When we are thinking, although we must know what our images are of, it is not necessary for us to know what our images are like—even whether they are clear and distinct, or fuzzy and shifting" (D. W. Hamlyn, "The Stream of Thought," 71). Indeed, it is hard to see how it is possible to know "what they are like," for they are described only in terms of their objects. In the case of the portrait there is a public object that can be described in physical terms and serves as the "analogue" of the absent friend.

It has been suggested that there are similar analogues in the case of mental imagery—for example, movements of the eyeballs. These may well occur, but their occurrence is not part of what is meant by having an image. In the case both of the picture and of such movements it is the way in which an existing but absent object is indicated or referred to that constitutes the essence of the representation. Sartre has suggested that we can set up a series of representations, starting with a photograph, continuing with a full portrait, a drawing, a caricature (which may be a few lines on paper or a piece of behavior on the part of an actor). All these are ways of indicating a particular person. The series can be continued with a mental image, and finally with the person's name. These different ways of thinking of him depend on a relation of meaning. "For the contents (images for instance) which accompany or illustrate them are not the meaning or intending. … If God had looked into our minds He would not have been able to see there whom we were speaking of" (Wittgenstein, op. cit., p. 217). Or whom we were thinking of. So far from being the vehicles of meaning, images are dependent on a prior ability to mean or intend particular objects for their very existence. In this they are like pictures, but this fact must not lead us into talking of our apprehension of images as if it were the inspection of private pictures.

IMAGINATION

Imagination is generally held to be the power of forming mental images or other concepts not directly derived from sensation. In spite of the popular usage of the term, the majority of philosophers from Aristotle to Immanuel Kant considered it in relation to knowledge or opinion. They conceived it either as an element in knowledge or as an obstacle to it—as in Plato's attack on art—or as both an obstacle and an element. David Hume is a representative of the last view: "Nothing is more dangerous to reason than flights of the imagination, and nothing has been the occasion of more mistakes among philosophers." Yet in the same place he wrote of the understanding as "the general and more established properties of the imagination" (*Treatise of Human Nature,* Book I, Part IV, Sec. vii). The fancy, the power of the imagination to combine ideas in fantastical ways, is to be avoided, but nevertheless imagination is vital to knowledge.

This latter element in Hume's view had its greatest development in Kant's *Critique of Pure Reason,* where the imagination is described as a "blind but indispensable function of the soul, without which we should have no knowledge whatsoever, but of which we are scarcely ever

conscious." Kant thought that the imagination has two tasks to perform in giving rise to knowledge, though it is not always easy to separate them. First, it completes the necessarily fragmentary data of the senses: it is impossible to perceive the *whole* of an object at once, yet we are seldom aware of the partial nature of our perception. For example, we cannot see more than three sides of a cube at one time, but we think of it as having all six sides. This completion of perception is the work of the "reproductive" imagination (called reproductive because it depends on prior experience for its operation). Kant contrasted this with the "productive" imagination, which has an even more important role to play.

The two names mark different functions of the imagination, rather than imply that it is twofold. The productive imagination gives rise to the transcendental synthesis of imagination, which combines our experience into a single connected whole. Kant called this operation "transcendental" because it is prior to experience, not subsequent to it; without such a synthesis no coherent experience of a world would be possible. So central is the work of the imagination to the first *Critique* that it is sometimes hard to separate from the understanding; Kant even said in one passage: "*The unity of apperception in relation to the synthesis of the imagination* is the *understanding*; and this same unity, with reference to the *transcendental synthesis* of the imagination, the *pure understanding*" (A 119).

ARTISTIC IMAGINATION

In spite of Kant's emphasis on the productive nature of the imagination and the importance he gave to it, his view of it in the first *Critique* is still as a faculty for forming images, images that are at the service of the cognitive powers of the mind. It is our normal apprehension of the world that is mainly at issue in that work. Consequently, it is hard to see how this use of the term is related to that by which we talk of writers and artists as "imaginative." Many critics and philosophers have written as if the artist or writer were a person especially good at imagining, in the sense of visualizing, scenes or events that had not occurred, which he then transmitted to the public by means of his art. The mental operations were of the "fancy" in Hume's sense of the term, the imagination recombining materials it had previously received from the senses into new forms that were not reproductions of previous experiences. The degree to which an artist could do this was the measure of his imaginative powers, while the reader or viewer reproduced in his own mind what

the artist had had in his. Two contemporary literary critics have attacked this view:

> But much great literature does not evoke sensuous images, or, if it does, it does so only incidentally, occasionally and intermittently. In the depiction even of a fictional character the writer may not suggest visual images at all. … If we had to visualise every metaphor in poetry we would become completely bewildered and confused. (Wellek and Warren, *Theory of Literature,* pp. 26–27)

It has even been suggested that the term *imaginative* has now come to fill the place in the critical vocabulary left by the general abandonment of the term *beautiful* in aesthetics; a "work of imaginative power" would previously have been called "beautiful." Clearly it is inadequate to equate "imagination" with the power of the mind to produce images. Interestingly enough, the germ of a better theory of the imagination might be seen in Kant's discussion of teleological judgment in his *Critique of Judgment*: to think of nature *as if* it had a purpose is an imaginative activity, though there do not seem to be any actual images involved in the process.

COLERIDGE. One of the most important contributions to the theory of the imagination in the nineteenth century was that of Samuel Taylor Coleridge, put forward in *Biographia Literaria* and elsewhere. He strongly contrasted the Fancy and the Imagination; the former he defined as "no other than a mode of Memory emancipated from the order of time and place." It operates almost mechanically and is responsible for the production of verse, whereas the Imagination is the source of true poetry. This he divided into two: the Primary Imagination, which is the equivalent of Kant's productive imagination and is responsible for all human perception, and the Secondary Imagination, which is the source of art. Coleridge described the operation of the Secondary Imagination as follows: "It dissolves, diffuses, dissipates, in order to re-create … it struggles to idealise and to unify. It is essentially *vital,* even as all objects (*as* objects) are essentially fixed and dead." This vital nature of the imagination meant for Coleridge that it is a way of discovering a deeper truth about the world; he would have agreed with John Keats's "What the imagination seizes as beauty must be Truth," and thus he went beyond the Kantian original of this theory. In this he sided with the romantics, for whom art and science were alternative ways of reaching the real world; previous writers had tended to think of science and philosophy as superior to art in this respect.

RYLE ON IMAGINATION

Coleridge and those who followed him, including both Benedetto Croce and R. G. Collingwood, still thought of the Imagination as a single faculty or power of the mind. Gilbert Ryle, in his chapter on imagination in *The Concept of Mind,* stresses that there is no one thing that can be called "imagination" but rather a variety of activities that are imaginative, among which are pretending, acting, impersonating, fancying, and so-called imaging. His arguments clearly establish his central thesis, though his subsidiary denial of mental images, which is not essential to the main point, is open to doubt. A child shows his imaginative ability, Ryle maintains, not by what goes on in his head but rather by the way in which he plays—for instance, the manner in which he pretends to be a bear. An actor, again, demonstrates his ability by the way he performs on the stage, his public appearance, to which mental accompaniments are largely, if not entirely, irrelevant.

Many of the activities called "imaginative," Ryle says, are "mock-performances"; he talks of boxers sparring as "making these movements in a hypothetical and not a categorical manner" (p. 261). This is closely connected with supposal, the running over in the mind of a future possibility. Indeed, in ordinary speech the word *imagine* is often synonymous with "suppose" or "think"; the instruction "imagine what it would be like if" is equivalent to "think what it would be like if." In both cases the evidence that the instruction had been carried out would be a report in words; even the operation itself might have been purely verbal, without any "images" passing through the mind. Hence, Ryle can argue that there is no need for an artist or writer—or, indeed, for anybody at all—to have "mental imagery."

IMAGINATION AND TRUTH

Because there is such a close connection between "imagining" and "supposing" or "fancying," it is easy to see why what is imagined is often thought to be unreal or false. In fact, "I must have imagined it" is a common form for the admission of a mistake of some kind. Hence, it is natural for epistemologically minded philosophers to assume that all imaginative activity is false or unreal. Ryle, in spite of the overall excellence of his account, may be criticized on this score: Such forms of expression as "mock-performance" and the use of quotation marks stress this element. However, the falsity of the imagination may, by philosophers of other persuasions and interests, be welcomed as a sign of the mind's freedom. Jean-Paul Sartre would appear to be of this number. E. J. Furlong, in his

book *Imagination,* agrees with Sartre on this point: "to act 'with imagination' is to act with freedom, with spontaneity; it is to break with the trammels of the orthodox, of the accepted; it is to be original, constructive" (p. 25). But, as has already been mentioned, artists and writers about art often want to go further than this, to stress the "truth" of imaginative works. Collingwood, for example, in a section of *The Principles of Art* titled "Imagination and Truth," has said, "Art is not indifferent to truth; it is essentially the pursuit of truth" (p. 288). It is clear that the truth in question is one somehow connected with the imagination rather than with the ordinary cognitive powers of the mind.

The difficulty of assessing this claim is increased by the fact that the idealist theory of art, of which Collingwood and Croce are the chief representatives, places the locus of the work of art not in its physical manifestation, the painting or poem, but in the imagination of the artist and spectator. The real work of art is an experience in the mind of the artist, and the spectator is moved to re-create the experience of the artist in his own imagination when he contemplates the picture. The picture is thus connected with the work of art but is not the work itself. The main difficulty here lies in the fact that it is an imaginative experience, not a statement, which is said to be true. A subsidiary problem is that such a view leads to the undervaluing of the actual product of the artist, the picture, novel, or poem. But the stress on the part played by the imagination in appreciating art is shared by some writers not normally thought of as idealists. For instance, Sartre says, "In a word, reading is directed creation" (*Situations II,* p. 96). The writer, he argues, has only provided a series of clues that the reader has to "solve" and complete by his own activity. Sartre even goes so far as to talk of reading as a "dream under our own control" (ibid., p. 100), which assimilates the appreciation of art even more closely with activities normally thought of as imaginative—for example, daydreaming.

One aspect of the idealist account of art clearly fits in with our normal thinking on the subject, for a person said to be "imaginative" is frequently one who is capable of appreciating works of art or of fiction. A man who could not read novels because "they are not factual" would be unimaginative. But the antithesis imaginative-factual that is here employed would seem to contradict the idealist claim that art is connected with truth. In ordinary conversation a novel may be described as "true to life" or "realistic." A child pretending to be a bear may also be praised for the realism of his performance, as may a young actor playing the part of an old man. In these and similar instances no one need be deceived by the novel or the performance; the readers or spectators can be fully aware that they are not reading a factual account or seeing a genuinely old man. Indeed, if they were not so aware their reactions would be different. The spectator who responds to the stage performance as to an actual event has made a serious mistake; many events on the stage would be too painful to contemplate if they took place in real life. This kind of awareness has sometimes been described as "aesthetic distance," but it is the same feature that was above described as the "unreality" of the imagination. Sartre expresses this fact by saying that the image "contains a certain nothingness." He continues: "However lively, however affecting or strong an image may be, it is clear that its object is non-existent" (*L'imaginaire,* p. 26). For Sartre, when someone imagines the face of an absent friend he is supposing that the friend is present to him, which ex hypothesi he is not. A person who forgets that he is imagining, that his thought is supposal, not fact, has made the same mistake as the spectator who thinks a real murder has been committed on the stage. The sense in which imagination may provide, in works of fiction, for example, a "truth" that is not conformity to actual fact can thus only be that the world which is supposed is a possible one, in the sense that it is self-consistent. Those who claim that the imagination gives another "truth" must be extending the meaning of the word in a way that requires justification, or at least explanation.

What has just been said also serves to point to a solution of the difficulty of the idealist account, that of the actual mode of existence of the work of art, whether it is in the mind or is the physical object it is ordinarily taken to be. Against the idealist view it is normally asserted that what is criticized in a work of art is the work itself, not its effects on the imagination, which would be private to each person; the critic thinks he is talking about a public object. The solution lies in the ambiguous nature of the work of art, as Sartre stresses, in that a picture, for example, can be viewed either as paint on canvas or as a picture of an absent friend. The picture does not produce an image of the absent person, but, as Sartre says, we respond to the picture in some of the ways in which we would respond to the friend himself, albeit we are aware that he is not present. The ability to respond in this way is the imagination, but the response does not require a flow of imagery in the mind. To have established this is one of the merits of Ryle's account.

MIMESIS

It is now possible to see the connection between many of the various, apparently disparate uses of "imagination." The man who is thoroughly immersed in reading a story, who is almost dreaming it, is very like the child who is fully occupied with pretending to be a bear. These are in a position similar to that of the man who is taking the behavior of a young actor on the stage for that of an old man. There is a common element in the behavior of all three, which is shared by the man who is supposing that something is the case, though his activity is less full. This man, again, is not dissimilar to the person having a mental image, who is fancying or supposing that he is seeing or hearing something he is not seeing or hearing, although aware that he is not.

All of these notions are related to an earlier account of art, the Greek *mimesis,* or imitation, although it has often been thought that there was a radical difference between them. Aristotle's idea of an "instinct of imitation" in the *Poetics* (IV, 1) is not entirely unlike Ryle's account of the imagination. In both cases there is something unreal about the activity, as Sartre has tried to indicate by his talk of "nothingness" as a feature of imagination; in these areas the implications of normal life do not hold. Thus, in spite of the apparent diversity of usage, there is a "family likeness," in Ludwig Wittgenstein's phrase, between the various terms, which makes talk of "the Imagination" legitimate.

A. R. Manser (1967)

IMAGINATION [ADDENDUM]

Late-twentieth-century discussions of imagination have tended to focus on three sorts of issues. Discussions in the philosophy of mind have focused on the cognitive architecture underlying imagination, and on the ways that imagination differs from and resembles belief, perception, and supposition. Discussions in modal epistemology have focused on the extent to which imaginability—and its cousin conceivability—can serve as guides to possibility. And discussions in aesthetics have focused on a cluster of issues concerning our imaginative engagement with fictional characters and events.

PHILOSOPHY OF MIND

Within the philosophy of mind, three distinct notions of imagination have been discussed: sensory imagination (quasi-perceptual experience in the absence of appropriate stimuli); recreative imagination (mental simulation); and creative imagination (combining ideas in unexpected and unconventional ways), with the great bulk of discussion devoted to the former two.

SENSORY IMAGINATION. Drawing on work by cognitive psychologists (e.g., Shepard 1982, Farah 1999), philosophers have explored the extent to which sensory imagination in general, and visual mental imagery in particular, employs the same systems as those involved in corresponding perceptual experience, and the related question of whether mental images are encoded in analogue form (as mental pictures) or propositionally (as descriptions). While the mainstream view holds that entertaining a visual mental image involves inspecting some sort of picture-like object (Kosslyn 1994), critics—most notably Zenon Pylyshyn (2003)—maintain that reasoning with mental images need not involve any sort of quasi-sensory representation. (A selection of early philosophical papers on the topic of visual imagery can be found in Block 1981; an overview of the debate is presented in Tye [1991/2000]; discussion of related issues in the phenomenological tradition can be found in Casey 2000; these themes are also examined in McGinn [2004] and Williams [1973].) Discussions of other sensory modalities have been explored less thoroughly, though some philosophical attention has been paid to the question of how motor imagery ought to be understood—whether as imagined action or imagined perception of action (Jeannerod 1997, Currie and Ravenscroft 2002); and there is a small literature on auditory imagery (primarily in the phenomenological tradition; cf. also Reisberg 1992).

A related discussion concerns the intentional status of mental images: do they derive their content through resemblance alone (an image of a maple leaf resembles and thus represents a maple leaf), or through some other mode of representation (an image of a maple leaf represents a maple leaf only as a result of being "labeled" as such)? Many analytic philosophers, following Jerry Fodor (1975) and Hilary Putnam (1981) have endorsed the latter view, though there has been some dissent.

RECREATIVE AND CREATIVE IMAGINATION. The other main area of exploration in the philosophy of mind has concerned what Gregory Currie and Ian Ravenscroft

(2003) have dubbed recreative imagination: the capacity that underpins one's ability to take perspectives other than one's own. This capacity, sometimes called off-line simulation, seems to play a central role in the understanding of other minds, in the contemplation of counterfactual scenarios, in the planning of behavior, and in engaging in explicit games of pretense. (Autistic children, for example, show marked deficits both in pretend play, and in understanding the mental states of others.) Beginning in the early 1990s—prompted in part by work of philosophers Alvin Goldman, Robert Gordon, and Jane Heal, and by empirical work by psychologists such as Simon Baron-Cohen, Paul Harris, Alan Leslie, and Uta Frith—investigation of these connections began in earnest, resulting in a number of important anthologies (Carruthers and Smith 1996, Davies and Stone 1995a, 1995b), collections (Currie 2004, Heal 2003) and book-length treatments (Currie and Ravenscroft 2003, Nichols and Stich 2003).

In a related vein, philosophers concerned with simulation and pretense have offered hypotheses concerning the cognitive architecture that supports such a capacity (Nichols and Stich 2003) and offered discussions of the features which it shares with and which distinguish it from related attitudes such as belief and supposition (Currie and Ravenscroft 2002, Velleman 2001; essays in Lopes and Kieran 2003; Nichols 2006).

Work on the creative imagination has been primarily in the context of empirical psychology (Boden 2003, Csikszentmihalyi 1996, Sternberg 1998; see also Gaut and Livingston 2003.)

MODAL EPISTEMOLOGY AND AESTHETICS

Within the context of modal epistemology, a great deal of scholarly attention has been focused on the question of whether there is some representational capacity, imagining or conceiving, that can serve as a reliable guide to possibility, and, if so, whether particular conclusions about, for example, mind-body dualism can be established by exploring what one can or cannot conceive or imagine. Advocates of conceivability-possibility theses, most notably David Chalmers, have contended that under certain conditions, conceivability is a fully reliable guide to certain sorts of possibility (Chalmers 1996); critics have maintained that the relevant notions of conceivability or possibility are of doubtful philosophical utility (Gendler and Hawthorne 2002.)

Within the general purview of aesthetics, philosophers interested in the imagination have discussed both

general questions about the nature of the imagination as well as a number of specific and general puzzles, among them the Paradox of Fictional Emotions (how and why one feels apparent emotional reactions toward characters and events that one explicitly recognizes as fictional), the Paradox of Tragedy (how and why one enjoys artworks that induce feelings such as sadness and fear) and the Puzzle of Imaginative Resistance (why one is reluctant to imagine fictional worlds that differ morally from the actual world). (Influential anthologies on these topics include Bermúdez and Gardner 2003, Hjort and Laver 1997, Lopes and Kieran 2003, Nichols 2006; collections of essays include Currie 2004, Levinson 2002; book-length treatments include Carroll 1990, Currie 1990, 1995, Feagin 1996, Robinson 2005, Scruton 1997, Walton 1990; see also Brann 1992.)

Tamar Szabó Gendler (2005)

IMMORTALITY

The literature on the philosophical problems involved in the question of a future life begins with Plato. We cannot therefore do better than start with a quotation from *Phaedo,* the dialogue in which Plato deployed what is put forward as a demonstration of the immortality of the soul. Having heard and apparently accepted the supposed proof put into the mouth of Socrates, Crito asks:

> "But how shall we bury you?" "However you please," Socrates replied, "if you can catch me and I do not get away from you." And he laughed gently, and looking towards us, said: "I cannot persuade Crito, my friends, that the Socrates who is now conversing and arranging the details of his argument is really I: he thinks I am the one whom he will presently see as a corpse, and he asks how to bury me. And though I have been saying at great length that after I drink the poison I shall no longer be with you, but shall go away to the joys of the blessed, he seems to think that was idle talk uttered to encourage you and myself."

(115CD)

This passage can be employed to fix two fundamental points by reference to which the main problems can be mapped.

The first point is that the essence of doctrines of personal survival (or immortality)—and precisely this and this only is what gives them their great human interest—is that they should assert that after our deaths we shall continue to exist (forever). Only in this way can they provide the basis for what John Wisdom has called "these logically unique expectations"—that we shall, to put it as noncommittally as possible, have "experiences" after death, that death will be not our terminus but the beginning of a new journey. This has to be underlined both because there have been some famous philosophical doctrines of immortality which have not been of this sort and because there have been other doctrines which either were from the beginning substitutes for, or have been so hedged and interpreted that they have now ceased to be,

the genuine article, personal immortality. Thus, whatever one makes of Aristotle on the immortality of the intellect (*De Anima* 429a–431a) or of Benedict Spinoza on the eternal element in the mind (*Ethics,* V, xxiii ff.), it is certain that these views do not, nor were they intended to, provide any ground for such "logically unique expectations." Again, the man who urges that we all of us live forever because the ill (and sometimes even the good) men do lives after them indicates by the very irrelevance of his supporting reason that this sort of immortality is not the authentic personal brand.

The second basic reference point is that any doctrine of survival or immortality has one enormous and immediate obstacle to surmount before it can begin to qualify for any further consideration. This obstacle consists simply in our manifest universal human mortality. It is due to this ineluctably familiar fact that "All men are mortal" has become a trite truistic example in logic and that we so use the word *survive* that it is logically impossible for one and the same passenger to be both dead and a survivor after a crash. One can recognize and respect the longing that may lie behind the epitaph "Not dead, but sleeping," yet no one can deny that, literally interpreted, it is false. Indeed, even to consider the contrary possibility would be to enter the ghoulish world of Edgar Allan Poe. This second reference point is, of course, as obvious as the first though the inducement to disregard it is perhaps greater. And both points have to be kept constantly in view.

THREE DOCTRINES OF IMMORTALITY

There seem to be three ways of trying to circumvent the massive initial difficulty confronting any doctrine of personal immortality. If once the initial obstacle could be overcome, the remaining problems would turn out to be not philosophical but factual and practical.

IMMORTAL-SOUL DOCTRINE. The first of the three doctrines is the Platonic attempt to demonstrate two points. One point is that we are essentially composite beings. Besides the more familiar corporeal element, the body, there is also something else, different in kind—the incorporeal soul. For the duration of a life the soul is somehow attached to—incorporated into or imprisoned in—its body. Although the soul is incorporeal, it is nevertheless a substance, something that could significantly be said to exist independently of anything else. This is precisely the point of Plato's arguments to the conclusion that the soul is not a harmony, for it would not even make sense to suggest that a harmony might survive or, for that matter, precede the elements of which it is a harmony.

This is no more possible than that there could be a grin without a face to grin it (*Phaedo* 85E–86D and 91C–95A).

The other point is that the soul must be the person or, at any rate, the real, true, or essential person. This, though it is sometimes neglected, is crucial. Unless it is established that I am my soul, the demonstration of the survival of my soul will not demonstrate my survival, and the news that my soul will last forever could provide me with no more justification for harboring "these logically unique expectations" than the rather less elevated assurance that my appendix is to be preserved eternally in a bottle.

RECONSTITUTION DOCTRINE. The second doctrine is, in its purest form, extremely simple and direct. It consists in urging the resurrection of the body or, more accurately, the reconstitution of the person. Whereas the first doctrine insists that I am the sort of thing that could perfectly well escape unharmed and unnoticed at death ("if you can catch me and I do not get away"); the second recognizes that to be truly a human person, I have to have the corporeal human form. It then relies on an act of sheer omnipotence to produce the immortal me.

SHADOW-MAN DOCTRINE. Considering that the reconstitution doctrine or something approaching it has been part of traditional Christianity, it is surprising to find that Thomas Aquinas seems to be the only philosopher of the first rank to have discussed a version of it at any length. (See especially "Treatise of the Resurrection" in the supplement to Part III of the *Summa Theologiae*.) But the shadow-man doctrine seems to have received even less attention. It can perhaps best be regarded as an attempt to combine the strong points of the other two doctrines. It is the claim that a person is a kind of shadow man, sufficiently human and corporeal to overcome the problem of identification with the familiar flesh and blood person and at the same time sufficiently ethereal and elusive to have no difficulty in escaping unnoticed from the ordinary earthy body which is destined to be burned or buried. This view is found in some of the Christian Fathers (for instance, Tertullian in *De Anima*). A similar view is also held by some modern spiritualists—"the astral body" detaches itself at death to proceed on its "journey to the summerland." Perhaps the best way of conveying the idea to the modern reader unfamiliar with either patristic or spiritualist literature is to refer to the many films in which a "spirit" is shown as a tenuous shadowy replica of a man that detaches itself from him at death and is thereafter visible to the entire audience but only to favored characters in the film.

DIFFICULTIES IN THESE DOCTRINES. At first sight the third doctrine might appear to be the most promising way to avoid the initial difficulty. However, the doctrine is bold precisely where the other two are discreet. By insisting upon the essential incorporeality of the soul, the first neutralizes all the ordinary weapons of empirical inquiry; the second, by deferring the corporeal resurrection to an unspecified time and place, indefinitely postpones any occasion for their deployment. But astral bodies, detaching themselves at death from the other sort, should be empirically detectable here and now. The crucial and probably insoluble dilemma for the shadow-man doctrine is to provide a specification of the nature of an astral body in which an astral body remains sufficiently like an ordinary flesh and blood person to avoid difficulties of identification and at the same time to ensure that the claim that there are such things would be verified or, at least, not immediately falsified by the appropriate factual investigation.

In the time of Tertullian and even in the early days of modern psychical research there may have been some slight basis for believing that this might possibly be done. Tertullian himself appealed not only to purely theological considerations but also to such cases as that of the woman who claimed to have seen "a transparent and lucid figure in the perfect form of a man." The systematic investigation of such phantasms has shown, however, that though they do undoubtedly occur, they belong to the category of purely subjective and hallucinatory experience. (See, for instance, G. N. M. Tyrrell, *Apparitions,* London, 1953.) The third way must therefore be dismissed as a blind alley.

Any reconstitution doctrine confronted with the question "How is the reconstituted person on the last day to be identified as the original me, as opposed to a mere replica, an appropriately brilliant forgery?" There seems to be no satisfactory answer to this question, at least for a pure reconstitution theory. This question is, however, logically prior to all questions about the reasons, if any, that might be brought forward in support of such a doctrine.

This decisive objection seems rarely to have been raised, and when it has been, its force has not usually been felt. No doubt, the explanation lies largely in the fact that the doctrine is scarcely ever found in the pure form, unalloyed with any Platonic elements. There are two defenses that might be offered. It could be urged that God will infallibly ensure that the unending torments and the eternal ecstasies are allocated to the right people—that is, in the one case to the very same people who had incurred his disapproval and in the other case to precisely those who had won his favor. It might also be suggested that

though there might indeed be cases in which all other merely human observers must be entirely at a loss, the person himself could not fail to know whether he was the original person rather than a changeling or a replica. These are, in substance, the arguments presented by John Locke in developing and defending his own analysis of personal identity; however, that analysis itself was intended to meet difficulties about the identification of the future victims of divine judgment with people now living on Earth.

Both these arguments, though they possess a strong appeal, seem to miss the point. Notwithstanding the form of the original question, the difficulty is not one of "How do you know?" but of "What do you know?" The objection is that the reconstituted people could only be mere replicas of and surrogates for their earthly predecessors. Neither the appeal to the cognitive and executive resources of Omnipotence nor the appeal to the supposed special status of the person in question does anything at all to meet this contention.

The point can be brought out better in the case of the argument that the person cannot fail to know who he is. This argument depends on the premises that if I remember doing something, I must have done it and that normal people in normal situations are usually able to remember the most important features of their lives. Both premises are true, but it does not follow from them that if someone on the last day or any other day claims in all honesty to remember doing something, he must in fact have done it. From "He remembers doing that" it follows necessarily that "He did that," just as from "He knows that that is true" it follows necessarily that "That is true." But from "He claims to remember doing that, and he is not lying" it does not follow that "He did that," any more than from "He claims to know that that is true, and he is not lying" it follows that "That is true."

The crux in both cases is the possibility of honest error. However honest and however convinced, claims that you did something do not guarantee that you actually did it. In normal circumstances most such claims are no doubt entirely reliable, and the memories involved can properly be said to constitute knowledge. But the circumstances envisaged by the reconstitutionists are conspicuously not normal. In these circumstances the question of whether any of the ostensible memories enjoyed by the reconstituted people can properly be counted as memories at all must wait on the resolution of the logically prior issue of whether they have any past to remember, of whether, in particular, they are indeed the people they apparently think they are.

Thomas Aquinas seems to have appreciated that the immediate objection to any pure reconstitutionist view is decisive. This insight is no doubt one of the reasons that his own view incorporated important Platonic elements. In answer to the objection "that it will not be identically the same man that shall rise again. … After the change wrought by death the selfsame man cannot be repeated," Thomas replied:

> The form of other things subject to generation and corruption is not subsistent of itself, so as to be able to remain after the corruption of the composite, as it is with the rational soul. For the soul, even after separation from the body, retains the being which accrues to it when in the body. … Consequently there has been no interruption in the substantial being of a man, as would make it impossible for the selfsame man to return on account of an interruption in his being. (Op. cit., IIIa, Supp. 79, 2, *ad* 1)

IMMORTAL-SOUL DOCTRINE

It thus seems that if any headway is to be made toward overcoming the first gigantic obstacle in the way of doctrines of survival or immortality, it will have to be, at least in its first stages, Platonic in an extremely broad sense. In this sense René Descartes's views on the nature of the soul and its relations to the bodily machine can be characterized as Platonic (see, for instance, *The Passions of the Soul* I, xxx ff.), and even Thomas must count as at least Platonizing. For everyone who maintains that the mind or the soul is a substance, in the sense that it could significantly be said to exist alone and disembodied, is thereby Platonizing, and everyone who identifies this putative substantial mind or soul as the real or true person is adopting a fully Platonic position.

Platonizing concerning the nature of the soul seems to be the essential condition of the possibility of any defensible doctrine of personal immortality or even survival. Philosophy that is Platonizing or Platonic in this sense constitutes an enormous field, so this article will concentrate on the views of Plato, Aristotle, and Descartes, making their positions serve as focuses. All three are well suited to serve in this way both because their work has been and is enormously influential and because they can each be seen as representative of a different approach to the problem. Since all three believed in some sort of immortality and since it is scarcely possible to treat their arguments about the nature of the soul without touching on their ideas of immortality, it will be convenient to consider the two together.

DIFFICULTIES IN THE NOTION OF THE SOUL. One great and rather peculiar difficulty of our present subject is that it is very hard and, hence, very uncommon for anyone really to begin from the beginning. The key terms such as *body, mind,* and *soul* and their equivalents or near equivalents in other languages are all in a way familiar to all those acquainted with the languages concerned. Though there may be much unclarity about their meanings and perhaps even a certain indeterminacy in their usage, they are not the recognizably fresh coinages that both demand definitions and enable meanings to be prescribed with some confidence that the appropriate usage can be followed consistently by the prescriber and by others. (The point here is simply that speech habits, like other habits, can be very hard to break.)

Again, in the air there always are and always have been vulgar or not so vulgar theories about bodies, minds, and souls and their several natures, destinies, and relations, with no guarantee that these theories can be harmonized with the meanings of such terms as *mind* or *soul* as actually determined by whatever is the accepted correct usage of the culture concerned. For instance, correct usage—and this surely is and must be the only possible standard of meaning—may very well determine that the soul, in the relevant sense of *soul,* is not a substance, even though the people concerned entertain fantasies which presuppose that it is. This thesis has been fully developed in this connection by Gilbert Ryle, chiefly in *The Concept of Mind.* The consequence of this is that the issues tend to be presented not as a matter of first giving some suitable sense to the word *soul* or *mind* and then asking whether in that sense the term would in fact have any application but, rather, as an inquiry which presupposing that we have or are souls or minds, asks what is the nature of the soul or the mind. Such a presentation is bound to constitute a temptation to prejudge the question whether, in the sense eventually chosen, we have or are such things. By itself this might give rise to no more and no less trouble than the insistence of the modern analytic philosopher that he is not concerned with the reality of matter, time, or whatever but is merely searching for an adequate analysis of the notions of matter, time, and so on. In the present case, however, there are also the various theories in the background, and these theories happen to be of very different sorts and suited to answering very different questions.

The fundamental distinction needed is that between theories that might serve as answers to philosophical questions about the meanings of the terms *mind, soul,* and the like and theories that offer some sort of explana-tion of why the creatures that are said to have minds, souls, and the like behave and suffer as they do. Thus, for instance, in reading Aristotle's criticisms of his predecessors (*De Anima* I), we must distinguish—even if they, or he, did not—between those thinkers who said that the soul was a vapor, blood, or something of that order and must to that extent be interpreted as embryonic scientists and those thinkers who urged that the essence of the soul is motion, sensation, or some combination of the two and are therefore to be counted as philosophers.

Another crucial distinction must be made between explanatory and descriptive concepts. Suppose that for some person the meaning of the words *mind* and *soul* is to be given entirely in terms of certain capacities or incapacities and that in his use having a first-class mind is just being able to compass certain sorts of achievement. In his sense of *mind,* then, it can be no explanation to say that someone can do these things because he is endowed with a first-class mind, for to say this is, for him, only to redescribe the phenomenon. If his concept of mind is to be explanatory, he must give the word *mind* a meaning such that minds would be, in the terminology already explained, substances.

PLATO. There seems to be only one, very brief passage in Plato (*Alcibiades* I 129B–130C) where the argument is explicitly directed toward the justification of the Platonic presupposition that the soul is the person. Even in this passage the first presupposition, that we are composite beings, is very much taken for granted.

Soul as the person. Socrates is talking with Alcibiades, and the question is raised, "What are we, and what is talking with what?" The conclusion is that we are our souls. The argument runs in this way. In speaking, we use words. The user and the thing used are always different. We use our hands, our eyes, our whole bodies. Thus, I cannot be my body. Yet it is agreed that I must be my soul, my body, or a combination of both. However, because the user and the thing used are always different and because I use my body, I cannot be either my body or my body and soul combined. Thus, I must be my soul.

Considering how vital the conclusion is, Plato's argument may seem inadequate. But if, sympathetically, we call in the rest of Plato's writings to provide supplementary evidence, it becomes clear that it has to be taken as the epitome of many arguments. For Plato constantly talked of the phenomenon of self-control and the lack of it and of all those times when we are inclined to speak of being let down or dragged down by the weaknesses or by the excessive strength of the body or some part of it. Few

concepts are, in the ordinary narrow sense, more typically Platonic.

In all the innumerable cases of bodily control or lack of it, it is possible to produce arguments of basically the same form, and it is not at all necessary to appeal to the assumption, which may not seem as obvious to everyone today as it did to Plato's Alcibiades, that I must be my soul, my body, or both. Thus, starting from the known fact that our eyes sometimes play tricks on us, we may go on to argue that this shows that we see not with, but through, them, that they are, as it were, built-in optical instruments (compare *Theaetetus* 184C ff.). Or, again, noting how natural and entirely proper it is to describe someone on some desperate occasion as "flogging on his protesting body," we may infer that we drive our bodies as we drive our cars. In every case the Platonic conclusion, expressed in a more modern idiom, would be that the personal pronouns, personal names, and all other person words, words which clearly must refer to something and which, it seems, equally clearly cannot refer to bodies, the only available corporeal objects, must therefore refer to some incorporeal objects, the conclusion is that these are the objects to which we apply the term *souls.*

This conclusion is wrong, however, and all arguments of this kind are misguided. It is not true that person words are words for any sort of incorporeal objects. People are what you meet. We do not meet only the sinewy containers in which other people are kept, and they do not encounter only the fleshy houses that we ourselves inhabit. It is therefore wrong to suggest that the word *person* is equivalent to the word *soul* in this sense of *soul* and, hence, to imply that it is contradictory to deny that people are incorporeal objects and that it is absurd to say that you can see a person. This basic fact about the meanings of person words is central and fundamental to the entire problem.

To deal in detail here with all the variations on the present argument would be impossible. The mistake involved in all such arguments seems to be that of insisting that because expressions such as "that person" are, for one reason or another, not synonymous with "that human body" and because we use all sorts of idioms in which I and my body are spoken of as if they were two substances, there must therefore be a special class of incorporeal objects for person words to refer to. This false conclusion seems to be one more product of the perennially disastrous *unum nomen, unum nominatum* theory of meaning—the misconception that every different class of word must refer to a different class of object. The truth seems to be that in this area we have a vastly rich and idiomatic vocabulary that provides us with all manner of subtle linguistic instruments, all of which we employ to say things about one sort of inordinately complicated but essentially corporeal creature, ourselves.

Argument from reminiscence. Plato's second argument to the conclusion that we are incorporeal souls was his doctrine of reminiscence. This has two forms, each proceeding to the same conclusion from rather different premises. In one form the premise is that we can all be shown to possess some knowledge, which we have not acquired in this life, of a priori truths (*Meno* 81B–86B). In the other it is that we all have certain ideal concepts, such as the ideal of perfect equality, which we cannot have acquired in our lives because they are never fully instantiated in this world (*Phaedo* 73A–77A). In both forms the conclusion is that these facts can be accounted for only in terms of memory. We, or "our souls," must have acquired our knowledge of the conclusion of the theorem of Pythagoras or have been acquainted with the Platonic Idea of equality before this life began.

This argument has never been very popular, partly because of a well-grounded mistrust of both premises and partly because of the fact that the notion of preexistence involved in the conclusion does not square with the demands of Western orthodoxy. For its force the argument depends on the existence of an important logical link between (true) memory and personal identity. If I really do remember certain truths or being acquainted with certain objects, then it follows that at some time in the past I must have learned them or made that acquaintance. Plato's argument is sound, but he draws the wrong conclusion. The correct conclusion is not that we must be remembering from a former existence but that memory cannot be involved. It cannot be memory for the simple and basic reason that we were not available to acquire knowledge or anything else before we existed, because we are not, what this argument in fact assumes that we are, the sort of incorporeal things which could preexist our conception and growth.

It is worth remarking that although to products of Western cultural conditioning preexistence appears much less credible than immortality, Plato, in insisting on both, was adopting a much less arbitrary position than that of those who assert immortality alone. It was not without reason that in the ancient world Lucretius and other spokesmen for human mortality made much of the comparison between our nothingness before birth and our annihilation in death (see, for instance, Lucretius, *De Rerum Natura* III. 11. 830–842 and 973–977). As George

Santayana once remarked, "The fact of being born is a poor augur of immortality."

Argument from rationality. Another argument was developed from distinctions embedded in Plato's account of Socrates' intellectual history (*Phaedo* 96A ff.). The Platonic Socrates here tells of his dissatisfaction with Anaxagoras, who apparently wanted to explain how the universe works rather than justify why everything is for the best. Socrates then goes on to contrast the physiological conditions of human behavior with the reasons the agent has for acting as he does. These categorial distinctions could serve as the foundations of an argument to the conclusion that since there are no necessary connections between the concepts of physiology, on the one hand, and the concepts that are peculiar to the distinctively human business of giving reasons for actions, on the other, it must therefore follow that rational agents are of their very nature incorporeal.

It would probably be going too far to attribute the argument in this form to Plato, although the conclusion and all the ideas involved are thoroughly Platonic. It is nevertheless one that needs to be noted here. C. S. Lewis and other contemporary apologists have tried to use these ideas to show that rationality is somehow essentially supernatural and that the bodily occurrences involved in rational behavior cannot be completely compassed in any scientific explanation.

There are two crucial points to be made in reply to this argument. The first is that precisely because the justification and appraisal of actions is so totally different from the causal explanation of physiological events, questions and answers belonging to the one universe of discourse cannot rival those belonging to the other. It is thus entirely possible to be confronted by a series of corporeal events—those, for instance, involved in what would normally be described as the oral development of an argument—and to ask and to answer both logical questions about the rationality of the whole performance considered as an argument and physiological questions about the causes of all the various glottal, oral, and nervous happenings considered as subject matter for the physiologist.

The second point is that to show that the concepts involved in the rational assessment of conduct are not logically reducible to purely physiological terms is not the same as to establish that agents must be essentially incorporeal. It would be equally impossible by purely logical analysis to translate the statement "Italy declared war" into a series of assertions about individual Italians, but this is no reason for thinking that "Italy" is the word for

some incorporeal substance. Nor is the impossibility of a logical reduction any reason for thinking that it could even make sense to talk of incorporeal rational agents' or of Italy's taking part in international affairs if there were no individual Italians.

Life as a substantial soul. The Platonic approaches thus far considered have all involved thinking of the soul as the person; at the same time the person was wrongly thought of as an incorporeal substance. Another approach starts from the notion of a soul as a principle of life. It helps to note some peculiarities of the Greek language. The word ψυχὴ, translated "soul," is etymologically related to such words as ἔμψυχος, meaning "alive" (literally, "ensouled"), and λιποψυχία, meaning "swooning" or "death" (literally, "abandonment" by the soul). A popular idea to which Plato makes gently contemptuous reference was that death was a matter of the soul's permanently leaving its body; the soul was thought of as a puff of air, an invisible vapor, that would be dispersed in the breeze (see *Phaedo* 77D; compare, for instance, Euripides, *Supplices* 553–554). In this connection we might therefore distinguish two senses of "soul." In the first "to have a soul" means merely "to be alive"; in the second "soul" is the word for a class of supposititious entities, corporeal but elusive.

In the first sense one might speak, rather pretentiously, of the soul as the principle of life. In this sense we do have souls, for to say that a creature possesses a soul in this sense is just a misleadingly substantival way of describing it as alive. At this point Plato took another step, apparently without recognizing that any step was involved and, therefore, without providing the slightest warrant for taking it. He simply assumed what is manifestly false—that the word *soul* in this sense is equivalent to the term *soul* construed as a synonym for *person* (albeit for persons recognized to be incorporeal objects). He unjustifiably equated this "soul as the principle of life" with what the older commentators call "the soul as the bearer of moral values" (see, for instance, *Republic* 353D, a passage that is no less revealing for being found in an argument a little removed from our present concern).

Incompatibility of life and death. The false equation of two senses of "soul" is crucial in the most considerable of Plato's arguments for immortality (*Phaedo* 100B–107A). Of his other arguments the only one that retains more than antiquarian interest is the contention that the soul is something that moves itself and that whatever moves itself must be ingenerable and incorruptible (*Phaedrus* 245C–246A). And the interest of this argument lies mainly in its later theological development. It was the

germ of some of the theology of Plato's *Laws.* This theology led to Aristotle's notions of God as the Unmoved Mover. And Thomas later quarried Aristotelian materials for the first of his five ways—the argument to the First Mover.

This most interesting of the Platonic arguments presupposes Plato's general theory of Ideas, or Forms, especially as expounded in *Phaedo,* in the *Republic,* and elsewhere; in fact, Plato's other arguments derive what plausibility they may have from the theory of Ideas as a background assumption. Plato believed that for every significant word, such as *justice* or *equality,* there is a corresponding abstract Idea, or Form. These Ideas are eternal and incorporeal substances, intelligible to the intellect as material things are sensible to the senses. All the many particular instances of some general class of things "participate" in the appropriate unique Idea, and this Idea serves as an ideal standard, itself apparently preeminently possessing the characteristic concerned. These Ideas are thought of as providing answers both to questions about criteria—What makes an *X* count as an *X*?—and to questions of a more causal character—What is ultimately responsible for the existence of *X*'s?

The argument to show that life is incompatible with death starts from the notion of the soul as the principle of life, and this is equated, in terms of the theory of Ideas, with the Form of Life. Now, life in the abstract is as incompatible with death as equality is with inequality. Life can never be overcome by Death. Thus, the conclusion is that the soul as the very Idea of Life is essentially deathless and eternal and, hence, "the immortal part" of us is not destroyed by death, for "our souls will exist somewhere in another world" (*Phaedo* 106E and 107A).

The answer to this argument is that since Life and Soul are convertible terms in this context, there is as much or as little reason for saying that the Idea of Soul is eternal as there is for maintaining the eternal reality of any other Form. But, as Plato himself always insisted, the abstract Form is entirely different from the particular individual, whereas the nerve of the entire argument lies precisely in the equation of the Form of Soul with the particular soul. This identification is impossible not merely because, as we have seen, there is no reason to equate souls in the present sense with the souls that are people but, more fundamentally, because in the present sense no meaning has been given to the expression "an individual soul." This vital fact is one of the many that are obscured by the confusion of explanatory and descriptive concepts and by the failure to separate philosophical questions about criteria from factual questions about

causes. Once these distinctions are made, it becomes clear that to say that someone has a soul (is alive) is not to say that he is alive only thanks to the presence of some mysterious extra substance, whether corporeal or incorporeal.

ARISTOTLE. Aristotle's *De Anima* is perhaps best approached as a philosophical treatise on life. *Anima* is Latin for "soul" and is the word from which our *animate* and *inanimate* are ultimately derived; the declared aim of *De Anima* is "to ascertain the nature and essence of soul" as "the principle of life" (402a–403b). The fundamental thesis is that life or the soul is "the form of the particular living body." The Aristotelian notion of form is complex and is to be distinguished from the Platonic. R. D. Hicks, the editor of the classic English language edition, stated that by the thesis that the soul is the form of the body Aristotle "so far from favouring materialism, secures once and for all the soul's absolute immateriality" (R. D. Hicks, ed., *Aristotle: De Anima,* Cambridge, U.K., 1907, p. xliii). Aristotle does dispose of all ideas that the soul is a lump of stuff. However, Aristotle's basic thesis is quite un-Platonic and leaves no room at all for any doctrine of immortality. An Aristotelian form is no more a corporeal thing than a Platonic Form would be, but it is not an incorporeal one either. In our sense it is not a substance at all. The soul as the form stands to the stuff of the particular body—and the examples are all Aristotle's—as the configuration of the statue to the materials of which it is made, as vision to the eye capable of seeing, as cutting power to the serviceable ax. Whatever else may be obscure, here it is obvious, as Aristotle himself said, that in this view the soul is not separable from the body (413a) and, furthermore, that this inseparability is a matter not of physical but of logical impossibility.

Had this been all that Aristotle said, Aristotle's views could not have been used in support of immortality. He also maintained, however, certain Platonic views that have given rise to much discussion and development, particularly among the Scholastics and others committed to a belief in personal immortality. These views concern the intellectual aspects of man and the corresponding intellectual (functions of the) soul. Despite the enormous labors of the commentators, precisely what Aristotle thought on these points is far from clear, possibly because Aristotle was not very clear in his own mind. There are nevertheless some relevant points that may usefully be made.

Immortal Abstract Intellect. The tradition descending from Alexander of Aphrodisias through Averroes

attributes to Aristotle a belief in some sort of Eternal Intellect. This is, however, a doctrine of personal immortality offering "prospect of rewards and punishments," a point emphasized by St. Thomas (*De Unitate Intellectus Contra Averroistes*). Furthermore, since the Abstract Intellect as opposed to the intellects of particular men is necessarily unique, it is not at all the right material to serve Thomas's own vital theoretical need for bridges between us and our successors in the next life.

Two senses of "eternal." The one kind of reason that might be proffered for saying that the Abstract Intellect (or any other putative Abstract Reality) is essentially eternal is really no reason for saying that anything at all actually goes on forever. In a way it is correct to say that such things as necessary truths and the logical relations between abstract mathematical concepts are somehow timeless and eternal. Yet this is not a matter of the existence of anything imperishable but, rather, of its not making sense to ask temporal questions about the periods during which any of these truths and these relations obtain. From *eternity* in this sense we can have nothing either to hope or to fear.

This distinction between two senses of *eternity* is fundamental in discussing personal immortality. We are concerned only with a life that would live on forever; the eternity of mere abstractions is not to the point. In the light of this distinction we can better appreciate the significance and the error of Plato's contention that the soul belongs to the same category as the abstract Ideas and, hence, that it is the sort of thing that may be presumed immortal (*Phaedo* 78B–80B).

The presumption that an incorporeal substance would be naturally incorruptible has always been the philosophers' favorite argument for the immortality of the soul. Thomas appealed to it, for instance, although he, of course, would not have included Platonic abstract Ideas in this category and although he was also careful to insist that souls, like everything else, are sustained by God and would be at once annihilated if he chose to withdraw his support (*Summa Theologiae* Ia, 75, 6; *ad* 2). It was perhaps with the same idea in mind that in the *Republic* Plato offered, as if it were a proof, the following unconvincing argument: Because every sort of thing has its one congenital evil, because nothing can be destroyed by anything but its own congenital evil, because the congenital evil of the soul is wickedness, and because wickedness as such is never directly lethal to the wicked man, our souls must be immortal (*Republic* 608E–611A).

Reason not localized. Assuming that Aristotle had really wanted to suggest that it could make sense to talk of an individual intellect's existing separately, then, presumably, a large part of his reason would have lain in his belief that ratiocination, unlike sight or hearing, is not localized in any organ (*De Anima* 402a, 408a, 429a). This belief has, of course, turned out to be erroneous. But even if it had not, the absence of any special corporeal organ provides no justification for assuming that our intellectual attributes must, or even might, be those of special incorporeal substances. The lack of special organs of melancholy or of volition is surely not to be construed as grounds for seeking invisible subjects to which to attribute Eric's feeling glum or Katrina's wanting to go to sleep. These are simply and obviously attributes of the people concerned.

Aristotle himself never employed any argument of this sort. On the contrary, he urged that the intellect, "since it thinks all things must needs, in the words of Anaxagoras, be unmixed with any, if it is to rule, that is, to know" (429a). This dark saying has been construed as an expression of a belief that our intellects are both incorporeal and substances, a belief that might seem to mesh well with the conviction, which Aristotle undoubtedly did have, that pure intellectual activity, abstract cognition, is something rather grand, almost divine, an occupation only for the highest sort of person (see, for instance, *Nicomachean Ethics* 1177a–1179b). Aristotle immediately went on to insist, however, that this pure intellect "has no other nature than this, that it is a capacity," and a capacity is not at all the sort of thing that can significantly be said to exist separately. Again, he seems elsewhere to have dismissed the idea of individual immortality with contempt (ibid., 1111b). And in the whole range of his works there is neither a positive treatment of the subject of a future life nor any promise of such treatment. The most plausible interpretation of Aristotle's view is surely that defended by Pietro Pomponazzi in Chapter 9 of his great polemic *De Immortalite Animae.* He concluded that the soul, including the intellect, "is in no way truly itself an individual. And so it is truly a form beginning with, and ceasing to be with, the body; nor can it in any way operate or exist without the body."

THOMAS AQUINAS. Thomas, as was mentioned, had urgent theoretical reasons for wanting to show that the soul is a substance, that it is, as he put it, "something subsistent." He was therefore inclined as far as possible to read Aristotle as holding the same view. In his *Commentary on Aristotle's De Anima* he explained the passage considered above (429a) in this way:

> But our intellect … must itself lack all those things which of its nature it understands. Since then it naturally understands all sensible and

bodily things, it must be lacking in every bodily nature; just as the sense of sight, being able to know colour, lacks all colour. If sight itself had any particular colour, this colour would prevent it from seeing other colours, just as the tongue of a feverish man, being coated with a bitter moisture, cannot taste anything sweet.

If this were indeed what Aristotle meant, he really was confused. For if intellect is, reasonably enough, to be compared with the sense of sight, it is because they are both (cognitive) capacities. But we need no particular argument to show why a capacity, as opposed to the subject that may possess that capacity, cannot itself have any material characteristics. The reason that the sense of sight is not yellow is not that being yellow must render it or its possessor incapable of seeing yellow things but that, generally, it is nonsense to attribute sensible characteristics to a capacity. (It is hard not to regard all this as the product, at least in part, of the bad habit of making nouns out of verbs and then succumbing to the temptation to presume that a substantive must be a word for a substance.)

It might seem that it is upon precisely this argument that Thomas himself relied in the *Summa Theologiae* to establish "that the principle of intellectual operation which we call the soul is … both incorporeal and subsistent." He even employed the same example of "a sick man's tongue being vitiated by a feverish and bitter humour," but here he was comparing the soul as "the principle of intellectual operation" with the organ, not the sense, of sight. Having thus supposedly established that "it is impossible for the intellectual principle to be a body," he proceeded:

> It is likewise impossible for it to understand by means of a bodily organ; since the particular nature of the organ would prevent its knowing all bodies; compare the way in which liquid put into a glass vase seems to be of the same colour, not only when some particular colour is in the pupil of the eye but even when it is in the vase. (Ia, 75, 2)

In this version the argument escapes the previous criticism. But it escapes only at the price of removing what was in the commentary on *De Anima* offered as the proof of its major premise, here formulated as the proposition that "whatever knows certain things cannot have any of them in its own nature; because that which is in it naturally would impede the knowledge of anything else." The question arises, "How is this premise known?" The answer seems to be that it is not known, perhaps even that it is known to be false. Take Thomas's own example

of the eye as the organ of sight. The eyes are admittedly material, yet that does not prevent us from using them for seeing material things, including other people's eyes and even—in mirrors—our own. Furthermore, even if the Thomist proposition did fit all the facts about our present sense organs, this would at most suggest that it was a contingent truth about them. But to serve Thomas's purpose, it must be known to be, if not actually necessary, at least sufficiently universal to apply not only to sense organs but also to "that principle of intellectual operation which we call the soul"—something which he himself is here trying to show to be radically different from anything corporeal.

DESCARTES. Plato and Aristotle can be regarded as the archetypical protagonists of two opposing views of man. Plato is the original spokesman for a dualistic view, and it seems that it is upon dualism that a doctrine of personal immortality must be grounded if it is to possess any initial plausibility. As a defender of a monistic view, Aristotle was neither so consistent nor so wholehearted. Yet it is still fair to see him at his most characteristic as the philosophical founding father of the view that the person is the living human organism, a view that apparently leaves no room whatsoever for belief in personal immortality. Thomas, who generally followed Aristotle on this point, characteristically attempted a synthesis that would have opened, had it been successful, the doors to heaven and to hell. In the present perspective Descartes must be placed squarely in the Platonic tradition. Thus, in the final paragraph of Part V of the *Discourse on Method,* after remarking that "next to the error of those who deny God … there is none which is more effectual in leading feeble spirits from the straight path of virtue, than to imagine that … after this life we have nothing to fear or to hope for, any more than the flies or the ants," Descartes concluded that "our soul is in its nature entirely independent of the body, and in consequence that it is not liable to die with it. And then, inasmuch as we observe no other causes capable of destroying it, we are naturally inclined to judge that it is immortal."

Soul as a thinking substance. Although his conclusions were thoroughly traditional, Descartes was nevertheless a revolutionary thinker. Unlike Plato, his chief intellectual interests were science, in particular physiology. Like Thomas Hobbes, the other great metaphysician of his period, Descartes quickly grasped the wider significance of the work of William Harvey and Galileo Galilei. Harvey's discovery of the circulation of the blood suggested to Descartes that both animals and human bodies might be regarded as machines. Descartes then asked

himself how the creatures that we know might be distinguished from living machines. His answer was that with respect to animals there simply was no distinction in principle but that an automaton in human shape, however brilliantly constructed, could always be distinguished from a true human being in two ways. There were two sorts of test which were bound to reveal the absence of the vital rational soul: without a rational soul such an automaton would not be able "to reply appropriately to everything … said in its presence, as even the lowest type of man can do," and their lack of versatility would always reveal that the automata "did not act from knowledge, but only from the disposition of their organs" (*Discourse on Method,* Part V).

One fundamental distinction, often overlooked in discussing these questions, is that between logical and technical impossibility. In Part V of the *Discourse,* his first published treatment, Descartes seems to have been making a purely factual claim "that it is morally impossible that there should be sufficient diversity in any machine to allow it to act in all the events of life in the same way as our reason causes us to act." To make any such would-be factual claim must be both rashly premature and scientifically defeatist. Elsewhere and later, it becomes clear that what Descartes, like so many successors, really wanted to say is that it is inconceivable that any material mechanism could be responsible for certain sorts of things. Thus, in the *Passions of the Soul* he laid down the principle "that all that which is in us and which we cannot in any way conceive as possibly pertaining to a body, must be attributed to our soul" (I, iv). And in his view what has to be thus attributed is thought, in his own rather broad sense of "thought," which seems to include all actions and passions considered to involve consciousness (ibid., I, xvii ff.). "By the word thought I understand all that of which we are conscious as operating in us. And that is why not only understanding, willing, imaging, but feeling also here count as thought" (*Principles of Philosophy,* I, ix).

Descartes was thus insisting that it is inconceivable that matter, however disposed, could in this sense think. This is a notion of the same sort as the idea that purposive and rational beings could not, without benefit of control by some Higher Purpose, have evolved first from creatures of a lower order and, ultimately, from inanimate matter, an idea found in both some objections to evolutionary theory and some versions of the Argument to Design. Presumably, Descartes would have accepted both contentions and many others like them because they fall under the generic principle, which he formulated as the fourth of his "axioms or common notions"; "All the real-

ity of perfection which is in a thing is found formally or eminently in its first and total cause" (Addendum to the Replies to the Second Set of Objections to the *Meditations*).

It has since Immanuel Kant become the custom to dignify such principles with the title "synthetic a priori propositions." But the one with which we are here concerned, though certainly synthetic, can be described as a priori only in the quite artificial sense that it is wholly arbitrary and unwarranted. Descartes's more specific idea had been forcibly challenged long before by the Epicureans (see, for instance, Lucretius, *De Rerum Natura* II. 865–870 and 875–882). The challenge was later repeated by both Spinoza and Locke even before David Hume launched his decisive onslaught on the generic notion that it is possible to know a priori that some thing or sort of thing must be or cannot be the cause of some other thing or sort of thing. The points made, in their different ways, by both Spinoza and Locke were that there is no contradiction in the idea of something material being endowed with thought and that we are in no position to deny dogmatically that there are material creatures so endowed.

Subjectivism. Thus far, Descartes's originality, as against the Platonic tradition, has chiefly been in his positive scientific interests and in his mechanistic ideas about the body. His achievement was to form a new framework of discussion and to provide a metaphysical foundation for the further development of physiology. He was also revolutionary on a second count, for it was he who developed with compelling dramatic power a new approach to questions of mind and matter. For three full centuries this remained part of the accepted philosophical orthodoxy, an orthodoxy that even Hume seems never to have thought to question. This approach can be characterized, though with no intended moral overtones, as self-centered.

Whereas Plato generally—and Descartes, too, when he suggested tests of humanity—approached people from our common public world, Descartes at his most characteristic tried to approach the world from inside the closed circle of his logically private consciousness. Thus, in Part IV of the *Discourse,* having reached his rock-bottom certainty in the proposition *cogito ergo sum,* he asked what he was. "I saw that I could conceive that I had no body, and that there was no world nor place where I might be; but yet that I could not for all that conceive that I was not." He concluded that he "was a substance the whole essence or nature of which is to think, and that for its existence there is no need of any place, nor does it depend

on any material thing; so that this 'me,' that is to say, the soul by which I am what I am, is entirely distinct from body, … and even if the body were not, the soul would not cease to be what it is" (compare, especially, *Meditations,* II).

Much of the power of the Cartesian argument lies in the use of the first-person personal pronoun and in the idiosyncratic choice of tenses and moods. For there is surely no difficulty at all, even for Descartes, in supposing that Descartes may one day be annihilated or that Descartes might never have been born. The most fundamental objections are founded upon a rejection of his unstated general assumption that (his) words obtain their meaning by reference to (his) logically private experiences. In particular, Descartes mistakenly assumed that all the words for all the things that he comprehended under the term *thinking* are words for such private experiences. Only on this assumption is it possible to assert that there could be—much less that we are—essentially incorporeal beings and, as such, fully capable of every sort of thinking. To insist that this assumption is wrong is not necessarily to adopt either a complete logical behaviorism—saying that all terms of this type refer only to public performances—or Ludwig Wittgenstein's extreme later position—apparently denying the very possibility of a language's containing words defined in terms of one man's logically private experience. It is sufficient to commit oneself only to the more modest claim that most thinking words refer wholly or partly to various actual or possible proceedings that are necessarily corporeal. To recognize that this is true and could scarcely be otherwise, it is sufficient to reflect for a moment upon the whole context in which we learn to use these terms; consider how we should teach the meaning of "He argued with her" or "She drew her own conclusions." In this perspective it becomes no wonder that, as Wittgenstein said, "The human face is the best picture of the human soul."

Personal identity and parapsychology. The appeal of the Cartesian approach and its influence can be appreciated by considering two examples, both relevant to the question of immortality—first, the discussion of personal identity initiated by Locke and continued by Joseph Butler, Hume, and Thomas Reid and, second, the investigation of the question of human survival by modern parapsychologists through the study of the possible relevance of the evidence furnished by all types of mediumistic performances.

Both investigations have started from the self-centered Cartesian standpoint and have taken for granted that, essentially, people are bodiless. Thus, the problem of

personal identity was generally taken to be one of the identity of an incorporeal thinking thing. Locke tried to provide an analysis of personal identity, so construed, in terms of consciousness (memory). The decisive objection to any such analysis was sharply put by Butler: "And one should really think it self-evident that consciousness of personal identity presupposes, and therefore cannot constitute, personal identity" (Dissertation I, "Personal Identity," appended to the *Analogy of Religion*).

But most of Locke's critics, Butler included, seem to have failed to appreciate just how difficult—even, perhaps, impossible—the problems of the nature of the identity and of the principle of the individuation of such putative incorporeal beings must be. If people are thought of as incorporeal substances having sorts of thinking, in the wide Cartesian sense, as their qualities (the substance, or "pure ego," theory of the self), then the question is how such substances are to be identified, what sense can be given to the expression "pure ego." If, with Hume, one is unable to provide any satisfactory answer to this question, the only alternative seems to be thinking of people as collections of experiences (the serial, or "bundle," theory of the self). Theories of this sort face two difficulties. First, it does not seem to make sense to speak of thoughts or experiences as "loose and separate" without anyone's having them, and, second, there seems to be no string capable of tying the bundles of experiences together while keeping one bundle distinct from another. The first difficulty may or may not be merely grammatical. The second, once the impossibility of using memory as the string is fully realized, appears very formidable. It was the second difficulty in a slightly different form that Hume had to confess to be "too hard for my understanding" (Appendix to *Treatise of Human Nature*).

In parapsychology it seems to have been almost universally assumed that mediumistic material, insofar as it cannot be either satisfactorily explained away in terms of fraud and delusion or conveniently redescribed in terms of telepathic and clairvoyant transactions among the living, can and must be interpreted as evidence for human survival. Yet to interpret such material in this way is not to provide support for, but rather to presuppose, a Platonic-Cartesian view of man. For it is only insofar as a person is essentially incorporeal that it can even make sense to suggest that someone years ago dead, buried, and dissolved is even now communicating with us through a medium.

OTHER ARGUMENTS CONCERNING IMMORTALITY

This article has thus far concentrated on philosophers who have adopted, more or less consciously, a Platonic or Platonizing view of man and who, if they have argued philosophically for any sort of immortality, have urged that the nature of the soul is such that it must be or must be presumed to be imperishable. None of these arguments requires any reference to a deity, and none appeals to any moral premises. This may perhaps be surprising, for most people—at least those in the European cultural tradition—are likely to think that beliefs in God and in immortality must go together. They are inclined to take it for granted that the main if not the only point of immortality—and sometimes perhaps of God, too—is to provide inordinate rewards and punishments. Yet there is no obvious inconsistency in believing in a Creator while denying that he has established a new world in a future life to redress the moral unbalances of the old. Nor does it appear that to assert our immortality is logically either to presuppose or to imply the existence of any sort of god. It may seem odd, but it is not manifestly inconsistent, for such avowedly atheist philosophers as J. M. E. McTaggart and C. J. Ducasse to affirm immortality, McTaggart offering exclusively metaphysical reasons and Ducasse appealing mainly to the evidence of parapsychology.

MORAL ARGUMENTS. The most considerable philosopher to rest his case for immortality on morality was Kant. Unfortunately, this is one of the many cases in which it is difficult to give an account of Kant's position and reasons that is clear, consistent, persuasive, precise, and acceptable to Kant scholars. Kant himself may be at fault here not merely, as usual, because he obscured his thought with cumbrous and idiosyncratic expression but also because he presented imprecise and uncompelling arguments.

But with these warnings it can be said that in the *Critique of Practical Reason* and in the *Critique of Judgment* Kant offered freedom, immortality, and God as the three postulates of practical reason. Practical reason is for Kant the source of the universal imperatives of morality. A "postulate of pure practical reason" is defined in the *Critique of Practical Reason* as "a theoretical proposition which is not as such demonstrable, but which is an inseparable corollary of an a priori unconditionally valid moral law" (translated by L. W. Beck, Chicago, 1949, pp. 225–228). The form of the argument, in the cases of immortality and God, appears to be that something is said to be commanded by the moral law but could be obeyed only on a certain condition; therefore, the conclusion is drawn not that that condition must obtain but that it must be a postulate of practical reason. The first difficulty is to see how Kant, who in and after the *Critique of Pure Reason* regularly denied the possibility of proofs of immortality or of the existence of God, proposed to reconcile this denial with insistence on the validity of the present deductions. The most promising response to this is to suggest that they cannot be rated as proofs of the doctrines that Kant maintained to be unprovable because it has not been and cannot be shown that the moral ideas are indeed soundly based but that they do prove that to act in accordance with moral ideas is to act as if, or to act on the assumption that, these doctrines are true.

The second difficulty lies in the supposed derivations themselves. In the case of the postulate of immortality the conclusion is to be drawn from the premise that the moral law commands us to achieve a perfect correspondence between our will and that law. This is taken to be out of the question in this life. Thus, what the law really requires is an endless progress toward the ideal, which is possible "only under the presupposition of an infinitely enduring existence and personality of the same rational being." If this is what Kant meant—as it certainly is what he said—then the moral law includes one very strange command. For to reach the proposed conclusion, we have to construe that law not as stating that we should approach as near to perfection as is humanly possible, or, as Kant seemed at first inclined to say, that we must actually achieve perfection, but, rather, that we must forever approach asymptotically this eternally unattainable ideal.

In the case of the third postulate of God the moral premise is that the law requires us to promote the highest good, which involves a perfect correspondence between the morality and the happiness of every individual. But the only guarantee of the possibility of this correspondence would be the existence of God, presumably because God alone would possess the power necessary to achieve it. Consequently, practical reason demands this postulate.

There seems to be a crucial disharmony between the premises of the second and the third arguments. Only at first in the second but throughout the third, Kant apparently wanted to insist that the ideals prescribed by practical reason must be practically and not just theoretically possible. Surely, it is merely the contingent weakness of the flesh that makes holiness something "of which no rational being in the world of sense is at any time capable," whereas if the theoretical possibility of achieving the necessary correspondence was all that was at stake, there would be no call "to assume the actual existence of God."

Yet Kant had urged in the second argument that the true imperative is to press ever closer to an ideal which is, it seems, not even theoretically attainable. This is fatal. If it is once allowed that an imperative can be to get as near as is humanly possible to an ideal that may be practically—even theoretically—unattainable, then the whole foundation of both arguments collapses. For such more modest demands could be satisfied in an earthly lifetime and without benefit of God.

Three general points about the Kantian arguments should be particularly noted. First, that the cases for the second and for the third postulate are separate. Second, Kant scrupulously avoided any suggestion that the authority of the moral law is at all dependent on the availability, here or hereafter, of rewards and punishments. Third, Kant was careful not to make the mistake of trying to deduce what is the case from premises affirming only what ought to be. It is not often that any of these things can be said for some more popular arguments for immortality.

For instance, it is often urged—most commonly, perhaps, in Roman Catholic textbook apologetic but elsewhere, too—that the lack of appropriate rewards and punishments would make nonsense of the claims of morality. Thus, the Jesuit M. Maher wrote:

> But in the judgement that conduct entailing a sacrifice *ought* to be pursued, there is implied a further judgement that it cannot be ultimately *worse for the agent himself* to do that which is right. … The supposition that virtue can finally result in … misery for the agent; or that wickedness may effect an increase in the total quantity of his personal happiness is seen to be in conflict with reason, and to be destructive of all morality. (*Rational Psychology,* London, 1940, p. 530)

Maher proceeded to argue that God could not permit this and, therefore, that there must be immortality, with penalties and compensations. He himself believed that the existence of God is independently established by natural theology (p. 533), but "some of the proofs of Immortality are amongst the most forcible arguments for the existence of a Deity" (ibid., pp. 525–526). It is interesting to compare the distress of Henry Sidgwick, who saw the moral situation similarly but was unable to share the supposedly saving religious convictions (*Methods of Ethics,* London, 1874, especially Part IV, Ch. 7).

Even if it were to be allowed that some such view is correct, it certainly does not warrant the suggested conclusions. Suppose we allow that rewards and penalties are indeed morally necessary; at most, this could support a demand not for immortality but for a temporary survival. Nothing has been said in the premises to explain why these necessary rewards and penalties have to be eternal. Indeed, to the secular moralist, to whom no revelation has been vouchsafed, it might seem that to provide eternal penalties for temporal offenses would be to make the universe infinitely worse. More generally, it is essential to insist that no argument from purely gerundive premises—stating only what ought to be or what is in some other way desirable—can by itself either establish or make probable any conclusion about what is actually the case. (Compare J. S. Mill, *Three Essays on Religion,* London, 1874, especially the essay "Theism.")

In any case it is certainly no part of the meaning of moral obligation that the obligation must always accord with the eventual self-interest or the person obliged. The sense in which categorical imperatives can be characterized as essentially rational refers to their universality and impartiality rather than to any implication that obedience must always be ultimately the best-paying policy. If anything, surely, it is part of the very idea of morality that sacrifices are sometimes required.

ARGUMENT FROM DESIRE. Many other arguments have been and are put forward. It is urged, for instance, that the allegedly almost universal belief in survival is somehow evidence of its own truth, a contention rejected by J. S. Mill for the decisive reason that to urge this is not to offer a good ground but, rather, if anything, to concede tacitly that there is none. Again, attempts have been made (by Dugald Stewart, for instance) to make something of the allegedly almost universal desire for immortality or of the existence of human potentialities that cannot be realized in a mere three score years and ten. If the existence of a desire really were a reason for affirming not merely, as perhaps it is, that this desire has some describable object but also, as it manifestly is not, that this object must actually be realized, then the argument could still be refuted by the consideration—pressed by Hume in his essay "Immortality"—that the certainly no less nearly universal fear of annihilation equally demands its real object. Of course, the existence of a desire for immortality, where it is found, does call for—and can easily be given—a naturalistic explanation. Such a desire, however, begins to be useful to the advocate of immortality only insofar as it can be used in conjunction with some idea of a God who may be relied on to arrange for the ultimate fulfillment of (some of?) the desires and (some more of?) the potentialities that he has arranged for us to have. (The qualification "some of" has, presumably, to be put in to allow for

the existence of ambivalent and evil desires; the "some more of" is needed if we are to have an argument that even appears to hold.)

To consider the possibility of establishing the existence of such a God is beyond the scope of this article. Yet it is perhaps worth suggesting that the existence of these ostensibly frustrated wholesome desires and these apparently unfulfilled splendid potentialities must, by itself, count as evidence against, rather than for, the existence of this kind of God. It is, as Hume insisted both in his *Dialogues* and in the first *Enquiry,* very odd—notwithstanding that it is very common—to argue from what in themselves would have to be rated as defects of the familiar world to the conclusion that this world is the work of a being without defect, who will in the future make good all present deficiencies.

ARGUMENTS AGAINST IMMORTALITY

Philosophers opposed to the belief in immortality have generally confined their case to attacking weaknesses in the arguments thought up by immortalists. But some have also advanced arguments intended to show that human beings do not survive the death of their bodies. Thus, in the essay mentioned above Hume was not satisfied with pointing out the flaws in the metaphysical and the moral arguments for immortality but urged a number of considerations "from the analogy of nature" in favor of "the mortality of the soul." Similarly, many other writers who are not materialists and who are not committed to the view about the meaning of person words presented in this article maintain that there are powerful empirical grounds supporting a negative position on immortality. The most popular and impressive of these is what may be called the "body-mind dependence argument," an argument that, according to its more recent exponents, has received powerful confirmation from modern brain research. Bertrand Russell wrote,

> We know that the brain is not immortal, and that the organized energy of a living body becomes, as it were, demobilized at death and therefore not available for collective action. All the evidence goes to show that what we regard as our mental life is bound up with brain structure and organized bodily energy. Therefore it is rational to suppose that mental life ceases when bodily life ceases. The argument is only one of probability, but it is as strong as those upon which most scientific conclusions are based. (*Why I Am Not a Christian,* New York, 1957, p. 51)

Philosophers in the Hume-Russell tradition have also generally insisted that in the case of immortality the onus of proof must lie entirely with the believers. In their view it is quite wrong that we start with an open question. As this article urged at the beginning, the familiar facts of life and death establish an overwhelming presumption of mortality. Given these facts and the fact that person words mean what they do mean, there are massive philosophical obstacles to be overcome before the question of a future life can be shown to be sufficiently open to leave any room at all for appeals to evidence or even to faith.

Of course, there is nothing to stop anyone from giving what sense he likes to the expression "disembodied person." The difficulty is to attach enough sense to the expression so that some discovery about disembodied people could provide us with grounds for believing that we survive death. In their present senses person words have logical liaisons of the very greatest human importance. Personal identity in the present sense is the necessary condition of both accountability and expectation. This is only to say that it is unjust to reward or punish someone for something unless, as a minimum condition, he is the same person who did the deed and that it is absurd to expect things to happen to me in 2014 unless, as a minimum condition, there is going to be a person in existence in 2014 who will be the same person as I. The difficulty is to change the use of person words so radically that it becomes significant to talk of people's surviving dissolution without changing it in such a way that these crucial logical liaisons must be broken.

If this difficulty cannot be overcome—and there seems little reason to think that it can—then the apocalyptic words of the early Wittgenstein are to the point: "Our life is endless as the visual field is without limit. Death is not an event in life. Death is not lived through" (*Tractatus Logico-philosophicus,* London and New York, 1922, Secs. 6.431 and 6.1411).

Bibliography

For a massive survey of the history of the doctrine of immortality, see W. R. Alger, *A Critical History of the Doctrine of the Future Life* (New York, 1871). For surveys of particular aspects of the doctrine, consult the bibliography of Antony Flew, ed., *Body, Mind, and Death* (New York: Macmillan, 1964), an anthology that includes a number of important pieces on immortality. The sources for the views given in the text are cited there.

St. Augustine's *De Immortalite Animae* has been translated by George G. Leckie in St. Aurelius Augustine, *Concerning the Teacher and On the Immortality of the Soul* (New York and London: Appleton-Century, 1938). Pietro Pomponazzi's *De Immortalite Animae* is available in an English translation by W. H. Hay II, revised by John H. Randall Jr., in *The Renaissance Philosophy of Man,* edited by Ernst Cassirer, Paul Oskar Kristeller, and John H. Randall Jr. (Chicago: University of Chicago Press, 1948).

Moses Mendelssohn's *Phaedon* (Berlin, 1767) is a famous dialogue on immortality that consciously imitates Plato's *Phaedo.* Hume's "Of the Immortality of the Soul" first appeared in *Two Essays* (London, 1777); it is reprinted in *A Modern Introduction to Philosophy,* 2nd ed., edited by Paul Edwards and Arthur Pap (New York: Free Press, 1965). The translation of Immanuel Kant's *Critique of Practical Reason* quoted in the text is that of L. W. Beck (Chicago: University of Chicago Press, 1949). Dugald Stewart's *Philosophy of the Active and Moral Powers of Man* is contained in *The Works of Dugald Stewart,* Vol. V (Cambridge, MA: Hilliard and Brown, 1829), pp. 366–423. J. M. E. McTaggart's views can be found in *Some Dogmas of Religion* (London: Arnold, 1906). For C. J. Ducasse's views see *Nature, Mind, and Death* (La Salle, IL: Open Court, 1951) and *The Belief in a Life after Death* (Springfield, IL, 1960). Joseph Butler, *The Analogy of Religion* (London, 1736), Part I, Ch. 1, is a detailed argument for immortality with replies to objections. John Fiske, *The Destiny of Man* (Boston and New York: Houghton Mifflin, 1884) and *Life Everlasting* (Boston: Houghton Mifflin, 1901); William James, *Human Immortality* (Boston: Houghton Mifflin, 1898; 2nd ed., with reply to critics, 1917); Harry Emerson Fosdick, *The Assurance of Immortality* (New York, 1926); John Baillie, *And the Life Everlasting* (London, 1934); A. E. Taylor, *The Christian Hope of Immortality* (London: Unicorn Press, 1938); and Jacques Maritain, *The Range of Reason* (New York: Scribners, 1952) all present arguments for immortality, as does "Ten Reasons for Believing in Immortality," a sermon by John Haynes Holmes, published in *The Community Pulpit* (1929–1930) and reprinted in Edwards and Pap, op. cit. G. T. Fechner, *Büchlein vom Leben nach dem Tode,* translated by John Erskine as *Life after Death* (Chicago, 1906), is a panpsychist defense of immortality. A. S. Pringle-Pattison, *The Idea of Immortality* (Oxford: Clarendon Press, 1922), holds that if there is personal immortality, it is not the inherent possession of every human soul but must be won by continual effort. E. S. P. Haynes, *The Belief in Personal Immortality* (Londo: Watts, 1913); Chapman Cohen, *The Other Side of Death* (London, 1922); Clarence Darrow, *The Story of My Life* (New York: Scribners, 1932); and Corliss Lamont, *The Illusion of Immortality* (London and New York, 1932) argue against immortality. Bertrand Russell, *Why I Am Not a Christian and Other Essays* (London: Allen and Unwin, 1957), should be consulted for a representative sample of Russell's arguments against immortality. A negative position similar to that presented in this article is found in C. B. Martin, *Religious Belief* (Ithaca, NY: Cornell University Press, 1959).

C. D. Broad's *The Mind and Its Place in Nature* (London: Kegan Paul, 1925), though somewhat dated, is perhaps the most valuable work on the problem of mind and body so crucial to the question of immortality. In Section D, Broad argues against the moral argument for immortality.

The source of the discussion of personal identity is Locke's *Essay concerning Human Understanding,* edited by A. C. Frazer, 2 vols. (Oxford: Clarendon Press, 1894), Vol. II, Ch. 27. For the contributions of Butler, Hume, and Reid and for later works on this topic, see the bibliography of the Personal Identity entry.

The classic parapsychological study of immortality is F. W. H. Myers, *Human Personality and Its Survival of Bodily Death* (London and New York: Longmans, Green, 1903). See also Ducasse, op. cit.; C. D. Broad, op. cit., *Religion, Philosophy, and Psychical Research* (London: Routledge, 1953), and *Lectures on Psychical Research* (London: Routledge, 1962); Antony Flew, *A New Approach to Psychical Research* (London: Watts, 1953); and the bibliography of the Parapsychology entry. For the investigations of psychical researchers into the nature of the experiences of spirits, see, for instance, G. N. M. Tyrrell, *Apparitions* (London: Society for Psychical Research by G. Duckworth, 1953). J. R. Hick, "Theology and Verification IV," in *Theology Today,* 17 (April 1960), reprinted in *The Existence of God,* edited by J. R. Hick (New York: Macmillan, 1964), presents a view opposite to the thesis of this article on the difficulty of identifying the reconstituted person with the original person.

F. C. Copleston, *Aquinas* (Harmondsworth, U.K.: Penguin, 1955), gives a sympathetic and illuminating account of Thomas's views on immortality.

For the most important recent criticism of the Cartesian doctrine of the soul, see Gilbert Ryle, *The Concept of Mind* (London and New York: Hutchinson, 1949). For a Wittgensteinian criticism see P. T. Geach, *Mental Acts* (London: Routledge & Paul; New York: Humanities, 1957).

For the view that the bodily occurrences involved in rational behavior can be completely explained only supernaturally, see, for example, C. S. Lewis, *Miracles* (London and New York, 1957), especially Ch. 2. For a fuller development of the view that such occurrences can be the subject matter of the physiologist while logical questions as to the rationality of the performance considered as an argument can be raised and answered, see Antony Flew, *Hume's Philosophy of Belief* (New York: Humanities Press, 1961), Ch. 5.

Antony Flew (1967)

IMMORTALITY [ADDENDUM]

The arguments against immortality on offer at the beginning of the twenty-first century are essentially those dis-

cussed by Professor Flew in the first edition of this reference work and will only be summarized here, following which we will consider non-traditional conceptions of immortality, and arguments in support of immortality. Four principal arguments have been presented against immortality: (1) The notion of a disembodied person is incoherent: to be a person just is to be embodied. (2) Advances in neuroscience have led to increased understanding of the brain and support physicalist theories in philosophy of mind. Physicalism (and *a fortiori* philosophical naturalism) denies the existence of an immaterial soul. The dependence of the mind on the functioning brain then grounds a formidable argument against the possibility of surviving the dissolution of the brain. (3) Determining identity conditions that would enable us meaningfully to assert that a particular disembodied soul was identical to a particular deceased person is a problem with no clear answers. Plausibly, souls would be individuated by mental contents. But it is logically possible for two minds to have identical contents, and in the absence of some bodily criterion of identity, it is not possible to tell which one has the genuine contents. Hence even if Smith somehow survived death, there would be no way to know that a particular soul was Smith. (4) The theory of evolution challenges the belief that there is anything special about humans in virtue of which we, and not other living things, would have immortal immaterial souls. But the conclusion that all living things are immortal—bacteria to baboons, barnacles to bananas—is absurd.

NONTRADITIONAL CONCEPTIONS OF IMMORTALITY

The difficulties inherent in the traditional concept of immortality, coupled with a pervasive human fear of death, have led to nontraditional conceptions that affirm immortality even while denying the survival of the person after death.

(1) CURING DEATH. Advances in biomedical technologies suggest that death is a disease to be cured. Immortality thus is conceived as prolongation of human life. Whereas it may be theoretically possible to postpone death indefinitely (through technologies such as cryogenics or genetic engineering), the desirability of prolonging life indefinitely is a significant ethical question that raises troubling questions about human nature and the purpose of life. Leon R. Kass (2001) argues that deferring death would radically change social institutions and undercut the universal human drive to procreation and protection of offspring, even to sacrifice on their behalf. Kass urges

us to "resist the siren song of the conquest of aging and death" (p. 24). Regardless of the merits of Kass's argument, it is doubtful that many of us would embrace immortality if it were just "more of the same." Would this not be what Bernard Williams called "the tedium of immortality"?

(2) CYBERNETIC IMMORALITY. Assuming that the mind—thoughts, memories, feelings, dispositions—is not an immaterial substance but is reducible to patterns of neural activity, advances in computer science (nanotechnology, quantum computing) offer the prospect of transferring the entire contents of one's brain to a computer chip—far less likely to wear out than an organic body, and easily transferred again if chip failure becomes imminent. In *The Age of Spiritual Machines* (1999), Ray Kurzweil predicts such immortality will be achieved by uploading the contents of our brains into ever-better computers. Frank J. Tipler (1994) proposes a similar cybernetic immortality.

Granting for sake of argument that a computer program could instantiate Jones's mind, would the software offer immortality to Jones? Not only do familiar problems of personal identity plague this scenario, but it seems that (at least normally) humans are relational creatures who interact with their environment and with other persons by means of their bodies. In what sense then would the silicone-chip Jones be human? And if not human, how could it be Jones?

(3) ANTIREALISM. An antirealist view of immortality sees "eternal life" as a matter of quality, not quantity, of life. There seems to be a rather widespread sense that death is somehow transcended through one's projects or progeny. But this surely is not immortality traditionally conceived. Nor is the antirealist theological view of D. Z. Phillips (1970), according to which eternal life is participation in the life of God—that is, personal transformation in this temporal life.

(4) REINCARNATION. John Hick melds Christian and Eastern ideas to reinterpret immortality, resurrection, and reincarnation as "the divine creation in another space of an exact psycho-physical 'replica' of the deceased person" (1976, p. 279). Hick sees such divine recreations as occurring multiple times and in different "spaces" within a multiverse. Critics of Hick's view grant that God would have the power to create an exact replica, but deny that the replica would in fact be the person who died. The right sorts of connections that would preserve identity through recreation do not obtain. Further, the possibility

of multiple replicas raises both metaphysical and episte-mological reasons to deny that the replica is identical to the original in any interesting sense.

DEFENSES OF IMMORTALITY

Clearly, if God exists, the prospects for an afterlife increase dramatically. A remarkable development in ana-lytical philosophy in the last four decades has been the resurgence of philosophy of religion and natural theolog-ical arguments for God's existence. Indeed, Professor Flew (2004) himself, while still denying the possibility of immortality, recently acknowledged a significant change in his beliefs prompted by the Argument from Design. It is no surprise then that arguments for immortality, gen-erally in the form of bodily resurrection, have also seen a renewal. Defenses of the immortality of the disembodied soul have been largely absent from recent literature.

CHRISTIAN VIEWS. Christian analytic philosophers have offered a variety of philosophical arguments defend-ing the possibility of immortality through resurrection. There are two views on the nature of such immortality. Dualists affirm that the mind/soul is an immaterial sub-stance distinct from the body, whereas monists adopt a physicalist philosophy of mind that denies the existence of an immaterial soul.

Christian dualists generally reject a strong Cartesian form of dualism. John W. Cooper (2000) argues that "holistic dualism" is the proper Christian view. Richard Swinburne (1997) offers a modal argument in defense of substance dualism, and William Hasker (1999) presents an argument from the unity of consciousness in defense of his emergent substance dualism.

J. P. Moreland and Scott B. Rae (2000) argue that free will and agency entail an immaterial mind. Moreland, with Gary R. Habermas (1992), also considers the empir-ical support offered by near-death experiences. A signifi-cant body of recent literature, beginning with Raymond A. Moody's *Life After Life* (1975), documents perimortem experiences. Habermas and Moreland point to features such as perceptions of physical facts that the clinically dead patient would have been physically unable to per-ceive which, if veridical, strongly support the possibility of conscious existence apart from the body.

Stephen T. Davis (1989) defends the traditional Christian understanding of the soul existing temporarily in a disembodied state, followed by the reunion of the soul with a resurrected body. Because personal identity is grounded in the soul rather than in the physical body, whether any or all of the atoms constituting the body of a person at death are incorporated in the resurrected body is not a significant issue. Davis further argues that the problems concerning individuating disembodied souls confuse criteria of identity with evidence for identity; epistemological uncertainty about identity does not undercut the possibility of genuine metaphysical individ-uation.

Christian monists reject the possibility of disembod-ied existence, yet hold to immortality gained through a resurrected body. Because the resurrection is eschatolog-ical, monists generally hold that personal identity is com-patible with a temporal gap. Peter van Inwagen (1978) suggests that at death God miraculously preserves the essential core physical component(s) of the body, from which God reconstructs the resurrection body, thus pre-serving personal identity by means of the right sort of causal connections. Nancey Murphy (2002) accepts a physicalist anthropology, and contends that all the per-sonal attributes that constitute personal identity super-vene on the body, so if God creates a perfect replica of the body, that body will subserve all the necessary attributes constituting identity.

JEWISH VIEWS. Two poles of Jewish thought are seen as early as the Middle Ages. Maimonides (1135–1204) believed that the soul is immortal only because God sus-tains it. Although he wrote his *Essay on the Resurrection* to silence critics' claims that he denied the doctrine, he believed that the resurrected dead will eventually die again. Nachmanides (1194–1270) defended resurrection as the teaching of the Torah, while speculating on the ethereal nature of the resurrection body.

The tension in Jewish philosophy between immortal-ity and resurrection may be traced into the present. Moses Mendelssohn (1729–1786), the first modern Jew-ish philosopher, was also the last to argue that the exis-tence of the afterlife was rationally demonstrable (because the soul is by nature indestructible). The exis-tentialist thinkers Martin Buber (1878–1965) and Franz Rosenzweig (1886–1929) tended to place discussion of the afterlife in a mythical category. Neil Gillman (1997) moves from the theological argument that God is more powerful than death, to philosophical arguments that a person is both body and soul, a psychophysical unity, and concludes that body and soul will be resurrected. In gen-eral, contemporary Reformed and Conservative Jewish thinkers reject bodily resurrection in favor of spiritual immortality, whereas Orthodox Jews retain belief in res-urrection.

MUSLIM VIEWS. The nature of the soul occupies a prominent place in classical Islamic philosophy. Both the Neoplatonist Al-Kindī (d. 870) and the great Aristotelian Avicenna (Ibn Sīnā, 980–1037) asserted that the rational soul, being simple, is naturally indestructible. Al-Fārābī (875–950) held that only the rational soul that has knowledge of universals—eternal aspects of the universe—is indestructible. Averroes (Ibn Rushd, 1126–1198), departing from Aristotle, argued that the acquired intellect was indestructible because it was one with the divine mind; for this he was condemned by fellow Muslims as well as Christians and Jews.

Contemporary Islamic philosophers familiar in Europe and North America tend to focus on politico-ethical thinking (e.g., Rachid Ghannoushi, Mohamed Arkoun) rather than metaphysics or philosophy of religion. However, belief in immortality, and more particularly in resurrection, the Day of Judgment, and heaven and hell (the specific characters of which vary widely among different Islamic sects), is deeply embedded in all branches of Islam.

Garrett J. DeWeese (2005)

IMPARTIALITY

Impartiality is a more complex concept than is generally recognized. Judging a person to be impartial is not as straightforward as judging a person to have some moral virtue such as kindness or trustworthiness. People do not even understand what it means to claim that one is impartial unless they know both the group toward which that person is impartial and the respect in which one is impartial with regard to that group. The impartiality required by morality also requires a specification of the group toward which morality requires impartiality and the respect in which it requires impartiality with regard to that group.

The most common characterization of general impartiality is that it requires that like cases be treated alike. Almost all philosophers take this characterization as trivially true, but it is mistaken. Consider a baseball umpire who is upset because he believes that umpires are not appreciated. While staying within the accepted interpretations of the rule, he changes the strike zone every three innings; he starts with a widest zone, goes to the narrowest one, and then returns to a widest one. If he changes without regard to which team benefits or is harmed by this change, then he is impartial with regard to the two teams in calling balls and strikes. Because he does not treat like cases alike—that is, he calls balls and strikes differently in the first and fifth innings—he is a bad umpire, but he is still completely impartial with regard to the two teams with respect to calling balls and strikes. He is inconsistent, but inconsistency should not be confused with impartiality. A good umpire must be consistent as well as impartial. An inconsistent umpire will be sus-

pected of not being impartial, but when the disgruntled umpire is not influenced at all by who is benefited or harmed, he remains impartial with respect to calling balls and strikes with regard to the two teams.

A person is impartial with regard to a group in a specified respect insofar as that person acts impartially in that respect with regard to that group. The basic concept of impartiality is defined as follows:

A is impartial in respect R with regard to group G if and only if A's actions in respect R are not influenced at all by which member(s) of G are benefited or harmed by these actions.

A teacher can be impartial with regard to a group G—for example, the students in her class in respect R; or, for example, grading their exams—but not impartial in a different respect, such as calling on them in class, for she may favor boys over girls in this respect. Two umpires, both consistent and impartial with regard to two teams, need not be impartial with regard to pitchers and batters. If one prefers a higher scoring game and the other a lower scoring one, they may, within the accepted interpretations, call some pitches differently. Both show partiality toward pitchers or toward batters, but both are still impartial with regard to the two teams.

Some contemporary consequentialists claim that morality requires impartiality whenever any sentient being's interests are involved. However, not only is there disagreement about whether all sentient beings are included in the group toward which morality requires impartiality, it is generally recognized that even with agreement about the group, morality does not require impartiality with respect to all actions affecting people's interests. It is generally agreed that morality does not even require impartiality when following moral ideals—for example, relieving or preventing pain, or helping the needy. Unless one does not act on these ideals at all, it is impossible to act on them impartially even with regard to all moral agents; no one can relieve or prevent pain impartially with regard to all moral agents. The only respect in which morality requires impartiality is with respect to violating moral rules—for example, those rules prohibiting killing, causing pain, deceiving, and breaking promises. It is only with regard to these kinds of moral rules—those that can be formulated as prohibitions—that it is humanly possible to act impartially with regard to a group large enough to be an appropriate group.

The examples of the teacher and umpire show that the group with regard toward which impartiality is usually required is often small and usually does not include the agent. The impartiality required by morality differs from this kind of impartiality in that it requires impartiality with respect to violating a moral rule toward a group composed of at least all moral agents, including the person violating the rule. Morality requires impartiality with regard to those moral agents affected by a violation of a moral rule—for example, being partial toward friends is not morally allowed. It also requires impartiality with respect to whether one can violate a moral rule; that is, it is not morally allowed to violate a rule in circumstances if it would be irrational to be willing for everyone to know that they are allowed to violate the rule in those same circumstances.

Sometimes all impartial rational persons favor violating a moral rule—for example, deceiving a hired killer in order to save an innocent person's life. Because morality always requires impartiality with respect to violating moral rules, it must be possible to violate a moral rule and still be acting impartially in this respect. This kind of impartiality can be achieved by violating a moral rule only when one would be willing for everyone to know that they are allowed to break the rule in the same circumstances. This achieves Kant's point about morality not allowing a person to make special exceptions for herself without creating the kinds of problems caused by the claim that morality requires acting on the categorical imperative.

Kant claims that morality requires that the group with regard to which one must be impartial with respect to violating a moral rule include only moral agents, that is, those persons who are required to act morally. Jeremy Bentham claims that the group includes all sentient beings. Most people, including most philosophers, do not agree with either Kant or Bentham; almost all want to include infants and children in the group toward which morality requires impartiality, but there is considerable disagreement about whether morality requires impartiality with regard to fetuses or to nonhuman animals. However, many who think that morality does not require impartiality with regard to nonhuman animals hold that morality does provide some protection to sentient nonhuman animals.

Because the concept of impartiality presupposes that there be some group with regard to which one is impartial, it does not make sense to claim that there is an impartial method for picking the group with regard to which morality requires impartiality. Recognizing that rational persons can differ about the composition of the group with regard to which morality requires them to be impartial helps explain the moral disputes concerning abortion and the treatment of animals. Morality limits the freedom of moral agents, so that the larger the group

with regard toward which morality requires impartiality with respect to violating a moral rule, the greater the limitation on the freedom of moral agents. A rational person can rank this freedom of moral agents higher than the welfare of nonmoral agents or vice versa. The former is more likely to hold that morality does not require impartiality with regard to nonmoral agents, whereas the latter may hold that it does.

Even when there is agreement about the composition of the group with regard to which morality requires impartiality with respect to violating a moral rule, rational persons who are impartial with regard to all members of this group can still disagree. Because rational persons can rank the various evils—for example, death, pain, and disability—differently, one impartial rational person can favor everyone knowing that they are allowed to break a rule in circumstances in which another impartial rational person would not favor this. Impartiality does not require unanimity, as some philosophers such as Kant and Rawls seem to claim. If it did, then assuming that all Supreme Court justices know all of the relevant information, and do not suffer from any other mental dysfunction, one would be forced to hold that whenever the United States Supreme Court issues a split decision, at least one justice is not impartial.

IMPETUS

Aristotle distinguished between two sorts of motion: natural and unnatural. Natural motions were those induced by the elemental constituents of things to seek their natural places—the earth at the center of the cosmos, fire under the periphery, water and air in their intermediate locations. Anything not in its natural place (i.e., not at that point in the stratification of things appropriate to its elemental composition) has an internal inclination to reach its natural place that will be exercised so long as nothing impedes it. Moreover, the speed of any body in natural motion (i.e., approaching its natural place) is a function of its heaviness in the case of downward motion, lightness in the case of upward, and an inverse function of the resistance of the medium through which it moves.

Not all motions, however, are natural; heavy objects can be hurled upwards, buoyant ones forcibly submerged. These unnatural motions are the result of force, yet Aristotle also notoriously held that in any change (including change of position) there must be a continuously acting agent of change; in the case of projectile motion, he supposed that the original action of the thrower endowed successive enveloping portions of the medium (air or water) with the ability both to receive and to transmit motive force; and so the projectile continues to move after it leaves the thrower's arm as a result of the continuing—albeit diminishing—power successively induced in the surrounding elastic medium. This explanation was often felt to be less than adequate; John Philoponus explicitly rejected it, supposing rather that the thrower imparted a certain quantum of force into the projectile, which it gradually exhausted in the course of its flight until it fell to earth.

Thus Philoponus crucially rejects the Aristotelian assumption that there must be continuous contact between a thing in motion and some external mover of it, speaking of an "induced power" (*endotheisa dunamis*) possessed—albeit temporarily and in this sense nonnaturally—by the moving body. This was to become the *vis impressa* of medieval theorists such as Jean Buridan, who attacked the reemerging Aristotelian orthodoxy with vigor (although perhaps without fully understanding it).

Impetus theory (the term is owed to Pierre Maruice Marie Duhem) thus maintains that all motion relies ultimately on the transmission of force from a mover, although not necessarily simultaneously with that motion, as Aristotle required. The theory also maintained that force gradually diminishes, although different versions of the impetus theory disagreed as to whether it

does so simply because all movement requires force, and that force is like a fuel to be consumed, or (as some writers in the Arabic tradition such as Avicenna apparently held), only as a result of contact with a retarding medium (and hence that in a vacuum the impetus would continue for ever). Whereas both versions retain the ancient commitment to the view that all action requires a continuous active cause, the latter was a step in the direction of the inertial notions that would revolutionize physics. Galileo Galilei, in his early *De Motu* (1590) is still an impetus theorist, and gratefully acknowledges Philoponus and other predecessors for showing the way beyond Aristotle. By the time of the mature physics of the *Discorsi* (1638), impetus theory itself has been left decisively behind.

INDETERMINISM

See *Chance; Determinism, A Historical Survey; Determinism and Freedom; Determinism and Indeterminism*

INDEXICALS

Suppose that Natasha says "I am right and you are wrong" to Joey. Natasha's utterance of "I" designates Natasha and her utterance of "you" designates Joey. The truth-conditions of her statement are that Natasha is right and Joey is wrong.

Now suppose that Joey responds by uttering the exact same words back to Natasha: "I am right and you are wrong." He has said the same words, with the same meaning, but he has not said the same thing. Joey's utterance of "I" designates Joey and his utterance of "you" designates Natasha. The truth-conditions of his statement are that Joey is right and Natasha is wrong. Joey has directly disagreed with Natasha.

In this article, "meaning" refers to the rules or conventions that are associated by a language with the expressions in it, the rules that one learns when one learns the language. Given this, the meanings of Natasha's words and of Joey's are the same. What differs is the

objects the particular expressions designate and the truth conditions of the statements. This aspect of utterances will be called "content."

The crucial differences between the first and second utterances were the speakers and the addressees. Such facts about an utterance can be called its "context." Differences in the contexts of the utterances account for the differences in their contents.

(The role of context in this case differs from that in a case of homonymity or ambiguity. With homonymity the context helps us determine which word is being used; with ambiguity, which meaning of a word or phrase is being used. But in this case context still has a role to play after questions of words and meanings have been settled. The meanings of "I" and "you" direct us to features of the context, to determine who is designated.)

The content of an utterance using "I" or "you" is determined by contextual facts about the utterance in accord with their meaning. Such expressions we call "indexicals."

In addition to "I" and "you," the standard list of indexicals includes the personal pronouns "my," "he," "his," "she," "it," the demonstrative pronouns "that" and "this," the adverbs "here," "now," "today," "yesterday," and "tomorrow," and the adjectives "actual" and "present" (Kaplan 1989). The words and aspects of words that indicate tense are also indexicals. And many other words—for instance, "local"—seem to have an indexical element.

According to David Kaplan's account, each indexical, and each sentence containing an indexical, has a meaning or character that is a function from contexts to content. The character of "I" is a function whose value, for each context, is the speaker or agent of that context. The character of "now" is a function whose value, for each context, is the time of that context. The character of "you" is a function whose value, for each context, is the person addressed by the speaker in that context. The character of the sentence spoken by Natasha and Joey is a function whose value, for a context with a speaker x and an addressee y, is the proposition that x is right and y is wrong. Natasha and Joey's words have the same characters, but their utterances have different contents.

In the formal development of his theory, Kaplan equates content with the intensions of intensional semantics. He criticizes earlier attempts to provide a formal theory within this framework for treating contexts on a par with "circumstances of evaluation" (Kaplan 1989, pp. 507ff.). The context determines which proposition is expressed by Joey's utterance of "I am right and you are

wrong"; the circumstance of evaluation determines whether or not the proposition is true. The necessity for such a distinction was seen by Hans Kamp (1971).

(Kaplan notes that at the level of character it makes sense to talk about the logic of indexicals. "I am here now" is a truth in the logic of indexicals, because, given its character, this sentence will have a true content at each context. The content will be contingent and can be expressed by a sentence that is not a logical truth.)

Kaplan's concept of content corresponds to "what is said" by an utterance (let us call this "official" content). This is what someone who knows the meaning and the context grasps. Other philosophers have thought it important also to bring in the concept of token-reflexive or diagonal content. This is what someone who knows the meaning but does not know the context grasps (Burks 1949, Perry 1993, Stalnaker 1981).

Consider an utterance *u* of "Je ne comprends pas l'anglais" made by Erin during a cocktail party. Suppose that Natasha hears the words and understands French but does not see who said them. Joey hears the words, understands French, and also sees that Erin said them. Based on her knowledge of French, Natasha can assign utterance-reflexive truth conditions to *u:* Natasha knows that *u* is true iff (if and only if) (1) the speaker of *u* does not understand English. Joey, since he knows who is talking, can assign nonreflexive truth conditions to *u:* Joey knows that *u* is true iff (2) Erin does not understand English. Natasha knows what the world has to be like for *u* to be true, given the meaning of the words in *u.* Joey knows what the world has to be like, given the meaning of the words in *u* and the relevant facts about context. What Joey knows, (2), is the official content of Erin's remark. It is what we would ordinarily say Erin said. Erin did not say (1): She did not make a remark about her own utterance. Nevertheless, (1) corresponds to an important level of understanding that we must take account of to explain the cognitive significance of sentences containing indexicals. (When Erin said what she did, she probably wanted her listeners to grasp that the person in front of them, at whom they were looking and with whom perhaps trying to converse in English, did not understand that language. This would be an easy inference from the proposition expressed by (1)—that the person who was producing the utterance they were hearing did not understand English. To understand Erin's plan, we seem to need the reflexive content of Erin's remark, and not only its official content.)

INDIAN PHILOSOPHY

The "India" in question is the Indian subcontinent—the land constituting present-day India, Pakistan, Bangladesh, and surrounding countries such as Srī Lanka to the south and Bhutan, Sikkim, Afghanistan, and Nepal to the north. And although *philosophy* in the sense in question covers much of what is covered by the term *philosophy* in its contemporary usage in English-speaking countries, it also has a specific use in the Indian context, in which it refers to the thoughts expressed in the literature relating to liberation (*mokṣa; nirvāṇa*). In this usage, philosophy, and the philosophical literature of India, is contrasted in Indian thinking with the literature pertaining to other matters, notably the literature concerned with political and social concerns (*arthaśāstra*), with interpersonal relations such as the sexual and aesthetic dimensions of love (*kāmaśāstra*), and with morals (*dharmaśāstra*), each of which has a pertinent literature of its own. The "philosophical" literature of India, then, relates to ultimate concerns, especially how to achieve liberation from rebirths and the nature of a universe in which liberation is possible and available. It is a literature that does not primarily include such Western fields of philosophy as political and social philosophy (for that is *artha*), aesthetics (for that is *kāma*) and ethics (for that is *dharma*). It also does not include the literature concerning the natural and social sciences (although it is arguable that parts

of Indian philosophy are offshoots of aspects of early Indian protoscience) or the applied sciences (agriculture, astronomy, and so on); nor does it include the domain of poetry and prose literature.

Whether Indian philosophy overlaps religion or not is a matter of how one thinks of "religion." The majority of the early Indian philosophical systems (*darśana*) do not acknowledge, and in some cases explicitly deny, the existence of a supreme being or lord (*īśvara*). All classical Indian thinking accepts gods (*deva*). They are viewed as unliberated, like humans; they are beings who inhabit other realms and occasionally visit ours. They eventually live out their lengthy period as gods and are reborn into lower realms as humans or even animals. This process is part of the Indian theory of karma—accepted until modern times—according to which selves are beginningless and are caused by their past actions to inhabit a series of bodies ranging from insects (or even plants) up to gods, depending on the particular portion of the stored-up results of past actions (*karman*) that becomes activated (*prārabdha*) as one enters the next birth.

In what has been dubbed the "*bhakti* period"—the period beginning around the turn of the second millennium CE, many philosophical viewpoints became inspired by and wedded into one or another religious movement. These movements typically recognize and worship one or more of the Hindu deities such as Śiva or Viṣṇu, and their literature is a mixture of devotional and philosophical concerns. However, the systems that originated in the previous centuries—Sāṃkhya and Yoga, Nyāya and Vaiśeṣika, Pūrvamīmāṃsā and Advaita Vedānta, Buddhism and Jainism—have persisted up to the present. Their literature continues to expand, and for most of them (except Buddhist systems) there are still *maṭha*s and *āśrama*s in India where followers devote their lives to the study of one of these systems.

In the "modern" period—from the nineteenth century to the present—the application of the term "Indian philosophy" has become more complex because the British-founded system of higher education has bred a group of philosophers (in the Western sense) who are native South Asians. Because of the broad Western connotation of the terms *philosophy* and *philosophers*, among modern Indian philosophers one finds not only academic philosophers but also profound and influential political and social thinkers such as Ramakrishna, Vivekananda, Aurobindo, and even Gandhi.

THE INDIAN PHILOSOPHICAL LITERATURE

This article covers, under a variety of topical headings, the philosophical views (*darśana*) discussed in the classical literature. The writers focus chiefly on the path that can lead to liberation from karmic bondage. These writers also defend the very possibility of gaining liberation against doubts. In mounting this defense, they explore the nature of the kind of universe that would allow for the working out of karma. They examine the very possibility of liberation and what it takes to confront and overcome the causes of bondage. These writings have yielded a rich variety of profound metaphysical, logical, and epistemic theories.

The language of this Indian philosophical literature is mainly Sanskritic. The broad designation "Sanskritic" includes not only Sanskrit itself but also vernaculars such as Pāli (the language of early Buddhist philosophical treatises) and Prakrit, the language of some early Jain works. In the case of a few of the "*bhakti*-period" movements, some of the philosophical literature comes to us in Tamil and occasionally other modern Indian languages. But for the most part, classical Sanskrit is the language of Indian philosophy.

Great foundational works of Sanskrit literature are frequently included within the literature of Indian philosophy, specifically works such as the Vedas, the Upaniṣads, the epics, the *Bhagavadgītā*, the Pāli canon, the canonical Jain works, and the *Bhāgavatapurāṇa*. These works certainly include matters that pertain to "Indian philosophy" as characterized above, but it is commentaries on these foundational works that are the locus of a significant portion of India's philosophical literature.

Of the many philosophical systems that have grown up in India, there is one basic text that has come to be viewed as the basic scripture for each system. Sometimes such works have a title that ends in "-*sūtra*s." Thus the *Nyāyasūtras, Vaiśeṣikasūtras, Mīmāṃsāsūtras*, and *Brahmasūtra*s play this basic role, respectively, for the Nyāya, Vaiśeṣika, Pūrva-mīmāṃsā, and Vedāntic schools of thought. For other systems a basic text (if there is one) has a different kind of title. From these basic texts—whether called "*sūtra*" or not—an interpretive literature grew up over the centuries that is a significant part of the Indian philosophical corpus. For example, in the case of Nyāya, there is a series of commentaries upon commentaries stemming from the basic *Nyāyasūtra*s. The number of commentaries and subcommentaries on the *Brahmasūtra*s is vast, because there are many Vedānta systems,

and each has its own interpretive literature based on that text.

THE SYSTEMS OF INDIAN PHILOSOPHY

Indian scholars traditionally speak of "six systems of Indian philosophy." But there are many more than six. A "system" or "school" (*darśana*, literally a "view") in this context constitutes a set of theories about liberation and the means to it based on a certain ontology, logic, and epistemology. This definition has to be understood in a loose way. The system known as Cārvāka has a theory about liberation—it denies that it is possible to be liberated—so its position is largely an extended polemic against the rest of the systems, whose theories are adopted specifically to account for and illuminate the possibility of liberation. Some of the Vedāntic systems place limitations on who is and who is not capable of liberation, and some of them elevate devotion to God to a position that equals or even surpasses liberation itself. The later Buddhist notion of the Bodhisattva who declines his own liberation until all beings have been liberated implies another exception to the general view that it is one's own liberation from karmic bondage that is the defining concern of Indian philosophy.

It is, indeed, impossible to give a finite list of Indian systems of philosophy. For one thing, new schools are being founded even now; their durability might be far from certain, but some recent ones have their adherents. For another thing, it is not always clear how to differentiate one system from another—it is not obvious, for example, whether those called "Buddhist logicians" are to be counted as a separate school of Buddhist thought or not; and there are clearly several disparate branches of Mīmāṃsā; there are an indefinite number of schools that call themselves "Vedānta."

ASSUMPTIONS COMMON TO ALL SYSTEMS (EXCEPT CĀRVĀKA)

As noted earlier, the Cārvākas do not accept liberation as a feasible goal. Their outlook has been culled from references in polemical passages by others attempting to refute their views and a limited number of literary works such as Jayarāśi's *Tattvopaplavasiṁha* and Kṛṣṇa Miśra's *Prabodhacandrodaya*.

All the other systems in this survey accept at least two relevant theses: The first is that there was no absolute beginning of things, that the series of lives each of us has lived is without beginning. This doctrine of beginning-lessness (*anāditva*) entails, of course, that there can be no God who created us *ab initio* or who functions as the first cause of the universe. As we shall see, this does not necessarily stop Indian philosophers talking about God (*īśvara*); various roles are assigned to Him aside from that of ultimate creator.

The other thesis generally accepted by all systems except Cārvāka is what is often referred to as the "karma theory" or the "law of karma." Although many details about how karma works can be gleaned from the pages of the Indian philosophical literature, karma remains an assumption underlying all philosophical theories rather than a theory itself. It is infrequently defended, merely assumed.

What is this "karma theory"? First, given the assumption of the beginninglessness of selves, each person has always existed; each is always performing actions ("action" being the basic meaning of *karman*), at least some of which lay down "karmic traces" (*saṃskāra; vāsanā*) that are stored up in the agent until each is eventually "worked off" through performance of another action at some later date. These traces, which constitute each self's "karmic baggage," are carried through life and over into the next birth, where a certain portion of that baggage is identified or "ticketed" as requiring working off during that coming lifetime. In working off the ticketed portion, one performs more actions that in turn breed more traces, so that one must be born again and again in order to work off both stored-up karma from previous lives and un-worked-off karma from one's present life.

A commonly cited passage in the *Yogasūtra*s specifies three aspects of one's life that are determined by the traces stored up from previous lives. One is the kind of life one gets at each birth. Some part of one's karmic store, perhaps the traces of the latest or perhaps of the most virtuous or vicious actions, results in the coming birth's occurring at an appropriate place in the great chain of being—perhaps as an animal if the aspects are vicious, perhaps as a god if they are virtuous. A second aspect of one's life said to be governed by one's activated karma is the length of the life one is about to lead. And a third is the kind of experiences one is likely to have as one goes through this coming lifetime—relatively pleasant if good karma predominates, relatively unpleasant if bad karma predominates.

The philosophical literature often denies that karma implies fatalism. Although karmic traces are powerful, they are not indestructible. It is possible, although not easy, to resist the force of one's karma. That is why phi-

losophy has an important role to play in indicating the modes of thought and action that can avoid laying down new traces and thereby destroy the power of one's ticketed karma. Traveling the path to liberation usually requires the personal attention and advice of a teacher (*guru*) who can give advice about how to meditate and behave so as to bring the powers of past actions to heel.

EIGHT TYPES OF PHILOSOPHICAL SYSTEMS

Indian philosophical systems are divided into eight groups (nine if one includes the Cārvākas). It is traditional to distinguish a basic three systems: Jain, Buddhist, and Hindu. The Hindu systems are here distinguished into six groups: (1) Sāṃkhya and Yoga, which share a common metaphysics; (2) Nyāya and Vaiśeṣika, which share an ontology; (3) "Mīmāṃsā," more properly "Pūrvamīmāṃsā," whose members share a common approach to the interpretation of the authority of the Vedas, which they view mainly as a source of prescriptions about behavior; (4) "Vedānta," which treats the "closing sections of the Vedas" (*vedānta*)—the Upaniṣads—as authoritative; (5) a group of philosophical systems whose common ground is that their proponents are worshipers of Śiva; and (6) the Grammarians (*vaiyākaraṇa*), who view the study of language as providing the key to liberation. Many of these approaches claim ancient authority for their standpoints.

SĀṂKHYA AND YOGA

The characteristic terminology of these two systems, featuring terms such as *prakṛti* and *puruṣa*, is found in the earliest Indian literature, the Vedas, which date roughly from the end of the second millennium BCE. Sāṃkhya terms are also prominent in the great Indian epics, especially the *Mahābhārata*, for example in the portion that constitutes the *Bhagavadgītā*. There is reason to believe that several Sāṃkhya authors lived prior to the fourth century CE, at which time the basic Sāṃkhya text, the *Sāṃkhyakārikās*, ascribed to one Īśvarakṛṣṇa, appears to have been composed. This work plays the role of the system's basic *sūtra*s. A much later work by Kapila (1375) is named the *Sāṃkhyasūtra*s, but its claims to antiquity are usually disputed (though the name "Kapila" is ascribed to one of the otherwise unknown earlier sages cited in the later literature). One or two commentaries on the *Sāṃkhyakārikās* are regularly studied to elucidate that text. The most frequently cited is by Vācaspati Miśra (940), the *Tattvakaumudī*, but there are numerous others. And a few independent works on Sāṃkhya were written

over the centuries: the *Yuktidīpikā*, of unknown authorship and date; and several works by a relatively late writer, Vijñānabhikṣu (1575), an interpreter.

The fundamental text of Yoga philosophy is the very popular, widely studied and quoted *Yogasūtra*s of Patañjali (300). An ancient (475) commentary, the *Yogabhāṣya*, is ascribed to someone named Vyāsa, and Vācaspati Miśra (940) has written a commentary on that named *Tattvavaiśāradī*. The term *yoga* is of course now standard throughout the world and no longer merely a Sanskrit term. In general usage it connotes techniques of breath control, bodily postures, and meditation, among the topics addressed in the texts just cited. The underlying metaphysics of Yoga, however, is the same as that of the Sāṃkhya ontology; in effect, Yoga provides the account of how to go about achieving liberation through meditation, whereas Sāṃkhya lays out the account of the ontological, logical, epistemogical, and psychological truths that form the basis of what is to be meditated upon.

Sāṃkhya (and thus Yoga as well) postulates two fundamental kinds of real entities: *puruṣa*s and *prakṛti*. Each self in the universe is termed a *puruṣa* in this system, and there are as many *puruṣa*s in the world as there are embodied minds, perhaps even more if bugs and plants are included. However, a peculiarity of the system is that a self has only one function: to be a seat of consciousness. All other features ascribed to humans belong to *prakṛti*.

One might think that *prakṛti* thus corresponds to the "body" side of the mind/body dichotomy. But this is not true for Sāṃkhya. The consciousness that is *puruṣa* is merely "pure" consciousness, not any particular awareness or mental state. Particular modes of awarenesses, such as sensations, emotions, and mental events of all sorts, along with particular physical features such as the particular bodies, sense-organs, and activities of what is ordinarily called a "self," are features of a being's *prakṛti*. (Remember that selves are not limited to human beings—each center of consciousness from gods down to insects and perhaps plants are selves.)

Karmic bondage pertains only to one's *prakṛti*, since it is that being's *prakṛti* alone that changes from time to time, birth to birth. The true self, *puruṣa*, remains unaffected in reality; it appears to be affected only by karma. To use an analogy that is constantly appealed to, a *puruṣa* is like a lamp that lights up things that are themselves inert; some of those things—thoughts and modes of awareness, for example—may seem to us to be conscious, others in turn to be objects of those modes of awareness, but for Sāṃkhya fundamentally all *prakṛti*—whether psy-

chological activity or physical objects—is unconscious, inactive.

One must not, however, misunderstand Sāṁkhya as contending that all *prakṛti* is unreal. Unmanifest (*avyakta*) *prakṛti* is real, permanent, and is the real cause of real effects. Appealing to language of great antiquity we are told that *prakṛti* is made up of three *guṇa*s, called *sattva, rajas* and *tamas*. Every actual element in manifest *prakṛti*, that is, in the world that we experience, is different from every other, and the difference is due to which *guṇa*s are dominant in each thing and to what extent.

So for Sāṁkhya both causes and effects are real. Unmanifest *prakṛti*, made up of the three *guṇa*s, actually causes real effects (the term used is *pariṇāma*, usually translated as "evolves" or "transforms"), just as milk really produces real curds. And so there is no question about the reality of bondage either, since a state of bondage is the real product of causal forces that are themselves constituted by the balance of the three *guṇa*s that constitute that state.

For this system bondage is due to a failure to discriminate between what is permanent—the pure self and unmanifest *prakṛti*—and what is temporary—all the evolutionary states of *prakṛti* that we normally construe as our nature and the nature of the world and the universe. To learn to discriminate the permanent from the temporary is the purpose of meditation, of yoga. When properly discriminated, the self will no longer be subject to the limitations of *prakṛti* and will have achieved liberation.

NYĀYA AND VAIŚEṢIKA

These two systems merged by the end of the first millennium CE. At the start, though, there were two distinct sets of *sūtra*s, the *Vaiśeṣikasūtra*s ascribed to Kaṇāda (whose date is unknown but who lived probably during the first couple of centuries CE) and the *Nyāyasūtra*s ascribed to some Gautama (not the Buddha), who most likely flourished in the second century CE.

The *Vaiśeṣikasūtra*s lay out six categories of actual entities that the aspirant needs to thoroughly understand and that are intended to cover all the things that exist in the world. These six are substances (*dravya*), qualities (*guṇa*), motions (*kriyā*), univeral properties (*sāmānya*), individuators (*viśeṣa*), and inherence (*samavāya*). The *Vaiśeṣikasūtra*s, like most *sūtra*s, are extremely laconic and require a commentary to be understood. The earliest extant commentary is by Praśtapāda (530) entitled *Padārthadharmasaṁgraha*. Commentaries on Praśastapāda's work by Vyomaśiva (950), Śrīdhara (991),

and Udayana (1054) develop accounts of the six categories and add a seventh, the category of negative entities or "absences" (*abhāva*). Most commentaries on the *Vaiśeṣikasūtra*s prior to the fifteenth century are known only from references by others, but there is a full commentary by Śaṁkara Miśra (1440).

The author of the *Nyāyasūtra*s works from a broad conceptual base that suggests its origins in a worldview with an approach broadly similar to that of Kaṇāda. Gautama starts from a list of sixteen topics, some epistemic, some ontological, but most of them harking back to the ancient practice of holding debates. The metaphysics, though not identical with Vaiśeṣika's categories, clearly presupposes them. The epistemology proposes four ways of gaining knowledge: through perception (*pratyakṣa*), inference (*anumāna*), comparison (*upamāna*), and authoritative language (*śabda*). The sixteen categories are as follows: instruments of knowledge, objects of knowledge, doubt, purpose, example, tenets, members of an inference, reductio ad absurdum, ascertainment, discussion, sophistry, cavil, fallacies, quibble, futile rejoinder, and ways of losing a debate. The last two "debate categories" by themselves take up the the entire fifth and last book of the *Nyāyasūtra*s.

A series of commentaries on commentaries is developed through the ages stemming from these *Nyāyasūtra*s, each commentary explaining the previous one in the list. This list comprises the *Bhāṣya* by Vātsyāyana (450), the *Vārttika* by Uddyotakara (610), the *Tātparyaṭīkā* of Vācaspati Miśra (960), and the *Pariśuddhi* by Udayana (1054). Important independent expositions of the Nyāya system are found in the *Nyāyamañjarī* by Jayanta Bhaṭṭa (870) and in several works by Udayana (1054).

Udayana is likewise the author of a widely studied book that has become the standard work concerning arguments for the existence of God: *Nyāyakusumāñjali*. In Nyāya-Vaiśeṣika God is another self, though one unlike us in never having been involved in the round of transmigration and rebirth. At the beginning of each era (*kalpa*) His function, according to Nyāya, is to cause the atoms, which were unmoving during the period (*pralaya*) between creations, to come into contact, thus starting the production of physical bodies that the selves (who have persisted throughout *pralaya*) inhabit through their karma. Since the *Vaiśeṣikasūtra*s themselves make no mention of God, and the *Nyāyasūtra*s mention Him only in reporting the opinion of an objector, it appears that the development of the role of God in Nyāya-Vaiśeṣika may have been influenced by the growing tendency toward

devotionalism in India toward the close of the first millennium CE.

The method of gaining liberation as described by Nyāya-Vaiśeṣika appears to be mainly intellectual, requiring study of the tenets of the system, which eventually removes the ignorance (*avidyā*) that occasions defects (*doṣa*) defects that occasion the desires and other mental attitudes that conduce to bondage.

With Gaṅgeśa (1320) an important new phase of Nyāya-Vaiśeṣika begins, known appropriately enough as *Navyanyāya*, "new Nyāya." Gaṅgeśa's sole work was the seminal *Tattvacintāmaṇi*, which takes up the four ways of gaining knowledge in a fresh way and employs a style of explanation that involves a host of new technical terms to indicate the various relations among the things contained in the Nyāya categories. These new relations make it possible for Navyanyāya to develop an "artificial" or "ideal" language in a way that resembles the methods of the logical positivists in modern analytic philosophy in the West. It also, not surprisingly, makes reading Navyanyāya texts especially difficult for the reader uninitiated into the technical terminology.

Gaṅgeśa's text is the basis for a flowering of hundreds of commentaries composed over the following centuries down to the present. The best known of these is the *Dīdhiti* by Raghunātha Śiromaṇi (1510), the subject, in turn, of myriads of commentaries, the most influential of which are those by Jagadīśa Tarkālaṁkāra (1620), Mathurānātha Tarkavāgīśa (1650), and Gadādhara (1660). Also during this post-Gaṅgeśa period two works were composed that introduce the student to the terminology, categories, and logic of Nyāya-Vaiśeṣika: the widely studied introductory work by Annambhaṭṭa (1500) (*Tarkasaṁgraha)* and that by Viśvanātha Nyāyācārya Bhaṭṭācārya (1640) (*Bhāṣāparicccheda*, with its autocommentary *Siddhāntamuktāvalī*).

PŪRVAMĪMĀṀSĀ

The term *mīmāṁsā* connotes a method of textual interpretation, especially of the Vedas. Rules determining the proper way to read and interpret the passages of the Vedic corpus developed early. The earlier portions of the Vedas did not speak of liberation; the subject discussed was taken to be *dharma*, featuring prescriptions on sacrifice, how to live, and what actions to perform and not to perform.

These Mīmāṁsakas viewed the Vedas as without any author—not even the gods were the authors of scripture. The authority of the Vedas is based on their being begin-

ningless and thus authorless and so not subject to the foils of any human or even divine creator. However, because the Upaniṣads, the later part of Vedic scripture, allude to liberation, later Mīmāṁsā philosophers beginning with Kumārila and Prabhākara recognized the possibility of attaining liberation.

While the Vedas themselves constitute the basic literature of Mīmāṁsā, a particular set of aphorisms—the *Mīmāṁsāsūtra*s ascribed to Jaimini (25 CE?)—is regularly cited as Mīmāṁsā's basic text, with the commentary (*Bhāṣya*) by Śabara (400) on it appealed to for explanations. These two works are largely devoted to matters that concern the proper interpretation of Vedic maxims about how to sacrifice and act in appropriate ways. But the literature of the Mīmāṁsā philosophical systems about to be discussed include interpretive and other works that, although largely concerned with Vedic interpretation, develop categorial frameworks that are comparable to those found in the other systems of Indian thought, and attempt to controvert the views of those other schools.

The Bhāṭṭa school of Mīmāṁsā looks to the interpretation of Kumārila (660) as found in that writer's commentary on Śabara's *Bhāṣya*, particularly in that portion of it titled *Ślokavārttika*, in which Kumārila makes a trenchant attack on other views known to him and provides reasons for preferring his own interpretation. The Bhāṭṭa literature develops through the works of Maṇḍana Miśra (690) (*Brahmaviveka, Vidhiviveka*), Pārthasārathi Miśra (1075) (*Nyāyaratnamālā, Śāstradīpikā, Nyāyaratnākara*), Āpadeva (1610) (*Mīmāṁsānyāyaprakāśa*), Laugākṣi Bhāskara (1660) (*Arthasaṁgraha*), and Kṛṣṇa Yajvan (1750) (*Mīmāṁsāparibhāṣā*).

The Prābhākara school is named after Prabhākara (700), author of the commentary *Bṛhati* on Śabara's *Mīmāṁsābhāṣya*. Among later Prābhākara Mīmāṁsakas, far fewer in number to the Bhāṭṭas, one may note Śālikānātha Miśra (825), author of the *Prakaraṇapañcikā*.

There is also said to be a third Mīmāṁsaka school known as the "Miśras" after Murāri Miśra, reputed author of several works most of that are now lost.

ADVAITA VEDĀNTA

The term *vedānta* literally means "the end or final portions of the Vedas." Those final portions are the Upaniṣads. The various systems that are called "Vedānta" take at least the older Upaniṣads as authoritative, bolstered by the *Bhagavadgītā* and the *Brahmasūtra*s. Vedānta commentaries and independent works expressing the views of these schools claim to represent the cor-

rect interpretations of these scriptural materials. But the philosophical positions they take vary widely.

The best-known Vedānta system is Advaita, "nondualism." It takes the position that there is only one real entity: the Brahman identified in the Upaniṣads as the true Self (*ātman*). Perhaps the oldest completely extant text expounding Advaita views is a commentary on the Māṇḍūkya Upaniṣad by Gauḍapāda (600). But the writer acknowledged as the authoritative source of Advaita is Śaṁkarācārya (710), who wrote a number of works and who is assumed to be the author of many others of later origin. The most important of Śaṁkara's works is his commentary (*Bhāṣya*) on Bādarāyaṇa's (50 CE) *Brahmasūtra*s. Śaṁkara is also probably the author of commentaries on several of the oldest Upaniṣads and on the *Bhagavadgītā*, and of at least part of an independent work titled *Upadeśasāhasrī*.

Śaṁkara refers to at least two other Vedānta systems. One is regularly termed "Bhedābhedavāda." In contrast to Śaṁkara's austere nondualistic position that there is only one real entity, Brahman, and that all difference and thus all plurality is illusory, the Bhedābheda view is that Brahman is both different (*bhedā*) and nondifferent (*abheda*) from the world. Śaṁkara also clearly has in mind for refutation a contemporary named Maṇḍana Miśra, who, in a work entitled *Brahmasiddhi*, defends an interpretation of Advaita according to which one does not (contrary to Śaṁkara's interpretation) achieve complete liberation prior to death. Maṇḍana holds that an enlightened person must still continue to practice meditation after achieving emancipation.

Śaṁkara's own position is that the Upaniṣadic texts are of one or the other of two types, in effect comprising two distinct portions of scripture referred to as the *karmakāṇḍa* and the *jñānakāṇḍa*. The *karmakāṇḍa*, as its name implies, consists of those portions of scripture that are governed by injunctions about how one should act. Because it prescribes actions, proper attention to it should lead one to perform appropriate kinds of action, as the Pūrvamīmāṁsakas correctly suppose. The viewpoint required by one who appeals to the *karmakāṇḍa* for advice is a view that assumes differences (*bheda*) between things. One could hardly act if one did not assume differences—between what is and what should be, between what is done and what ought to be done, between action and agent, between you and me.

In contrast, Śaṁkara claims that the other part of the Upaniṣadic texts, the *jñānakāṇḍa*, deals not with what is to be done but with what one should know. Instead of injunctions to act, the contents of this part refer solely to

what is actually the case. Instead of enjoining us to act, this part provides us with knowledge; instead of dealing with differences among the many things and beings of the world, including ourselves, the *jñānakāṇḍa* speaks merely to the one Reality in which no distinctions or differences can ACTUALLY abide. That Reality is called Brahman, and the "great sentences" (*mahāvākya*) of the Upaniṣads—sentences such as "that art thou" (*tattvamasi*)—can provide us with enlightenment concerning the ultimate unity of Brahman and one's true Self if and when we are ready to appreciate it.

Once realization has dawned, one is completely liberated from bondage to actions, for that bondage requires recognition of differences and the liberated person no longer recognizes any differences as real. True, one remains alive and appears to act because of the *prārabdhakarman* that constituted the rationale for his present life, but there will be no future lives for such a one, no rebirth. The contrary view of the Bhedābhedavādins and of Maṇḍana Miśra, that one must still meditate even after liberation, is claimed by Śaṁkara to be incorrect, for meditation is an act, and the liberated self is incapable of performing any action because that would require recognition of that reality of differences among things and people that, in his liberated state, he no longer recognizes.

Important Advaita treatises are ascribed to Śaṁkara's pupils Padmapāda (740) (*Pañcapādikā*) and Sureśvara (740) (*Naiṣkarmyasiddhi* and commentaries on at least two of Śaṁkara's commentaries on the Upaniṣads). The standard account of post-Śaṁkara Advaita, which has been subjected to serious dispute, distinguishes two or three schools of Advaita, one stemming from Padmapāda, though named after a commentary on that work, the *Vivaraṇa* by Prakāśātman (975); another from Vācaspati Miśra's (940) commentary *Bhāmatī* on Śaṁkara's *Brahmasūtrabhāṣya*; and (sometimes) a third, unnamed, school stemming from Sureśvara. The vast majority of interpretations of Advaita defend the Vivaraṇa position. Among the writers who represent this school are Jñānaghana (975), author of *Tattvaśuddhi*, Vimuktātman (975) (*Iṣṭasiddhi*), Sarvajñātman (1027) (*Saṁkṣepaśārīraka*), Citsukha (1200) (*Citsukhī*), Vidyāraṇya or Mādhava (1350) (*Pañcadaśī*), Sadānanda (1500) (*Vedāntasāra*), Prakāśānanda (1505) (*Vedāntasiddhāntamuktāvalī*), Madhusūdana Sarasvatī (1570) (*Advaitasiddhi*), and Dharmarājadhvarīndra (1615) (*Vedāntaparibhāṣā*). The *Khaṇḍanakhaṇḍakhādya* of Śrīharṣa (1180) is a polemical treatise attacking the Nyāya-Vaiśeṣikas on behalf of Advaita. The far less numerous Bhāmatī-school authors include Amalānanda (1255)

(*Vedāntakalpataru*) and Akhaṇḍānanda Sarasvatī (1670) (*Ṛjuprakāśikā*).

VIŚIṢṬĀDVAITA VEDĀNTA

In contrast to Advaita's monistic interpretation of the relation of Brahman to the world, which says that only Brahman is real and that the world is illusory, the system of Viśiṣṭādvaita views Brahman and the world as real and takes Brahman and the world to be the same thing. The earliest author of this persuasion whose works are available is Yāmuna (1010), the author of *Āgamaprāmāṇya, Bhagavadgītārthasaṁgraha* and *Siddhitraya*. The real founder of Viśiṣṭādvaita is, however, Rāmānuja (1120), the author of a *Bhagavadgītābhāṣya*, the *Śrībhāṣya* on the *Brahmasūtra*s, and several independent works (*Vedāntadīpa, Vedāntasāra,*and *Vedārthasaṁgraha*). The most important writers in the ensuing centuries include Lokācārya Pillai (1300), who wrote in Tamil; Vedānta Deśika (1330), who is believed to have written more than thirty Sanskrit works; and Śrīnivāsa (1625), whose *Yatīndramatadīpikā* provides a useful summary of the major tenets of the school.

Viśiṣṭādvaita, frequently rendered as "qualified nondualism," is a kind of pantheism in which the unity of Brahman is gained not (as in Advaita) by denying Brahman's relation to anything else but rather by construing Brahman's unity as an "organic" unity of everything. Rāmānuja postulates three distinct real types of entities—selves, matter, and God—and construes "Brahman" as referring to the organic whole that they constitute. That is, Brahman for Viśiṣṭādvaita is *saguṇa*—it really has qualities—whereas for Śaṁkara it is *nirguṇa*, without any qualities whatsoever.

DVAITA PHILOSOPHY

Taking a straightforwardly pluralistic attitude toward the relations between Brahman, God, humans, and the things in the world was Madhva or Ānandatīrtha (1250), who wrote commentaries on the usual body of Vedānta texts (the *Brahmasūtra*s, *Bhagavadgītā*, and Upaniṣads) along with a number (usually reckoned as ten) of independent treatises. His system is known as Dvaita or "dualistic," or, in this case, more aptly, "pluralistic." Jayatīrtha (1370) comments on most of Madhva's works. The *Nyāyāmṛta* of Vyāsatīrtha (or Vyāsarāya) is a polemical treatise in which the author uses Navyanyāya methods to defend Dvaita and to criticize the views of others. Where Rāmānuja divided reality into three aspects of the organic unity of Brahman, Madhva's position features a basic distinction between Brahman, the Lord, who is deemed independ-

ently Real (*svatantra*), and the other Reals (including selves and things in the world), which are classed as real but dependent (*paratantra*) on God—dependent not for their being, which is beginningless, but for their being allowed to live, act, and gain release.

OTHER VEDĀNTIC SYSTEMS

The Bhedābhedavāda position, mentioned previously, which Śaṁkara criticizes, was apparently propounded in works, now lost, by writers who preceded Śaṁkara, notably Bhartṛprapañca (550). Later, Bhāskara (750) wrote a *Brahmasūtrabhāṣya* defending the position. A similar standpoint, called "Dvaitādvaita," is defended by Nimbārka (1250) in his commentary on the *Brahmasūtra*s, *Vedāntaparijātasaurabha*, and in other works.

A position known as Acintyabhedābheda has achieved some importance outside of India through the influence of the Hare Krishna movement. The founder of this school is Caitanya (1520), who wrote no works but whose views are capably expounded and defended by Sanātana Gosvāmin, Rūpa Gosvāmin, and Jīva Gosvāmin, all of whom seem to have lived in the sixteenth century. The writings of these and other exponents of this religious philosophy construe liberation as devotion to God culminating, according to A. C. Bhaktivedanta Swami (*The Nectar of Devotion*, p. 38), in "five liberated stages, which are 1) to be one with Me, 2) to achieve residence on My planet, 3) to have My opulences, 4) to possess bodily features similar to Me, and 5) to gain personal association with Me."

The Śuddhādvaita Vedānta school's literature starts with the numerous works of Vallabha (1525), which include an *Anubhāṣya* on the *Brahmasūtra*s and a commentary on the *Bhagavata Purāṇa*, along with more than thirty independent treatises. A series of commentators during the sixteenth and seventeenth centuries is capped by the prolific Puruṣottama Pītamabara Sarasvatī, who is credited with more than eighty works. The term *Śuddhādvaita*, "pure monism," is based on this school's theory that Brahman (called the highest Self [*puruṣottama*] or Śrī Kṛṣṇa) by nature emanates existence, intelligence, and joy like sparks from a fire. A spark where the joy portion becomes concealed by the existence portion constitutes an individual self. When, through devotion generated by God's grace (*puṣṭibhakti*), the lost joy is regained, one rejects liberation and chooses eternal service of Lord Kṛṣṇa, enjoying the boundless joy experienced in eternal play.

ŚAIVA SYSTEMS

Of the philosophical systems devoted to Śiva, perhaps the oldest literature is that of Kashmir Śaivism. Vasugupta (840) is the reputed author of *Śivasūtra*s and the *Spandakārikās*, and Somānanda (850) of *Śivadṛṣṭi*. Utpala's (925) *Īśvarapratyabhijñā* is another important work. Abhinavagupta (1014) contributes copiously and significantly to this tradition in a variety of works of which the *Tantrāloka* is the most enterprising. Kṣemarāja (1040) is the author of a popular exposition of the system in his *Pratyabhijñāhṛdaya*.

Kashmir Śaiva philosophy is also called the Pratyabhijñā system because it considers the ultimate aim to be self-realization (*pratyabhijñā*). Ontologically it teaches that the world is made to appear by Śiva's power (*śakti*) of consciousness. An individual self (*paśu*) is a center of consciousness, which is different from Śiva's in that a self's consciousness is limited by impurities (*mala*). Through following the spiritual path, one removes the impurities and gains realization. Three basic kinds of means (*upāya*) constituting the spiritual path are distinguished: external (*āṇava*), consisting of yogic postures, control of breathing, and so on; mental (*śākta*), voluntary meditation involving conceptual construction (*vikalpa*); and spontaneously viewing the entire world including oneself as a reflection of Śiva, a view that is effortless or construction-free (*nirvikalpaka*). In this final state the mind is dissolved into consciousness because of the removal of obstructions.

Śaiva Siddhānta has its home in the South of India. Its literature was written entirely in Tamil. Among the important authors and works in this tradition are those by Sadyojyoti (890), Meykanta Tevar (1221) (*Śivajñānabodha*), Aruṇanti Śivacariyār (1253) (*Śivajñānasiddhiyār*), Umāpati Śivacariyār (1310) (*Tiruvaruṭpayan*), and Śivāgra Yogi (1600) (*Śaivaparibhāṣā*).

Other Śaiva systems that have a literature in Sanskrit include those of Vīraśaiva and Śivādvaita. The most widely known work of the latter system is Śrīkaṇṭha's (1400) *Śrīkāra-bhāṣya* on the *Brahmasūtra*s, along with Appayya Dīkṣita's (1585) *Śivakaraṇidīpikā.* Appayya Dīkṣita has also written two independent treatises on this system.

GRAMMARIAN PHILOSOPHY

One of the remarkable achievements of early Indian science was in linguistics or grammar. Pāṇini (perhaps fifth century BCE) anticipates the linguistic analysts of the twentieth century in having managed, in his *Aṣṭādhyāyī*, to have shown how to generate the entire Sanskrit language from a series of rules, including rules about how to apply the rules. Grammar (*vyākaraṇa*), which formed a distinct science with a sizable literature, also caught the attention of philosophers of several of the systems discussed previously. But Grammarian philosophy is largely a product of Bhartṛhari (450) who, in his work *Vākyapadīya*, wedded grammar, epistemology, and ontology into a full-fledged philosophical system.

Bhartṛhari's innovations pertain to the proper account of language, of epistemology and ontology. The characteristic and unique idea of Bhartṛhari's view of language is the notion of the *sphoṭa*, which is conceived to be a unitary and permanent entity underlying the significance found in syllables, words, and sentences. A cognition is likewise construed as a unitary mental event that appears as having distinctions of subject and object, of time and space. But ultimately such distinctions are transcended: only language itself existse—even physical objects are no longer discriminated.

Maṇḍana Miśra (see above) has contributed an important work on Grammarian philosophy, the *Sphoṭasiddhi*. Several of the best grammatical works contain considerable philosophical material: for example, Kauṇḍa Bhaṭṭa's (1650) *Vaiyākaraṇa-bhūṣaṇa* and several works by Nāgeśa (or Nāgojī) Bhaṭṭa (1700).

Jain Philosophy. Jainism and Buddhism (along with Cārvāka) are sometimes referred to as "heterodox" schools in that they, unlike the systems listed above, do not view the Vedas as authoritative. (In fact, among the foregoing schools Nyāya-Vaiśeṣika and Sāṃkhya-Yoga do not cite the Vedas as authority either, although some texts of those schools very occasionally appeal to Vedic passages when suitably supportive.)

The Jain *sūtra*s represent early (the precise dating is unclear) representations of a variety of concerns only occasionally philosophical. They are written in Prakrit, a Sanskritic vernacular. Some of the Jain interpretive literature is also in Prakrit, though for the most part it exists in Sanskrit.

Perhaps the most notable feature of Jain thought is its refusal to accept a single account of reality. This is reflected in the Jain theory of *anekāntavāda*, that there are several equally true aspects of any given thing or topic. This is spelled out in their theories of *syādvāda* and *saptabhaṅgī*, which emphasize that everything we cognize can be viewed in several different ways each of which is acceptable given its particular orientation. The earliest writers of texts on Jain philosophy appear to have been

Kundakunda (200?) (*Pañcāstikāyasāra, Pravacanasāra, Samayasāra*) and Umāsvāti (200?) (*Tattvārthasūtra*). The interpretive literature on the latter work is voluminous, starting with Pujyapāda (500) (*Sarvārthasiddhi*), who also wrote the *Samādhitantra*. Bhadrabāhu (550) is the author of authoritative commentaries on the Jain *sūtra*s. Bhaṭṭa Akalaṅka (680) contributed a number of important works to the extensive literature on logic, along with Vidyānanda (850). A Siddhasena Divākara, whose date is not entirely certain, is the author of a small work, *Nyāyā-vatāra*, which is perhaps the usual beginning point for students beginning the study of Jain philosophy. Other important contributors to the Jain philosophical litera-ture are Haribhadra Sūri (750) (at least twenty-five works), Maṇikyanandin (950) (*Parīkṣāmukha*), Nem-icandra Siddhāntacakravartin (1080) (*Gomatasāra, Dravyaviveka*), Vādideva or Devasūri (1143) (*Pra-māṇanayatattvāloka*), Hemacandra (1150) (*Pramāṇa-mīmāṁsā, Anuyogavyavacchedadvātriṁśikā*) and Yaśovijaya (1680), to whom over thirty works are attributed.

BUDDHIST PHILOSOPHY

Although the number of Buddhist philosophical schools is still unsettled six distinct positions will here be distin-guished. The standard division into Hīnayāna and Mahāyāna is not really relevant to these distinctions, although Theravāda, Sarvāstivāda and Sautrāntika are usually classed as Abhidharma (an expression we prefer instead of the pejorative "Hīnayāna"), the other three dis-cussed here as Mahāyāna. Since Buddhism is discussed extensively elsewhere the most important authors and Indian texts on Buddhist philosophy are here merely listed.

Both the Theravāda and Sarvāstivāda acknowledge a list of seven Abhidharma texts, but a different seven for each of the two. The chronology of this literature is unclear, although we may conjecture that the seven texts in both lists existed prior to the beginning of the Christian era. The seven Sarvāstivāda or "northern" Abhidharma texts are *Dharmaskandha, Saṅgītiparyāya, Prajñaptibhāṣya, Dhātukāya, Vijñānakāya, Prakaraṇapāda* and *Jñānaprasthāna*, ascribed to various authors. The Sar-vāstivāda reached its maturity, however, in the (*Mahā*)*Vibhāṣā*, compiled by committee in the first half of the second century CE, in which are recorded the opin-ions of many Abhidharma teachers concerning the proper understanding of Sarvāstivāda tenets. The names of a large number of Buddhist schools are also given in this and in various later works; the relations of some of these schools to the ones discussed in our brief overview are still being determined. In any case, the term "Vaib-hāṣika" is used synonymously with "Sarvāstivāda" in recognition of the importance of the *Vibhāṣā*.

The fourth-century (?) author Vasubandhu (the dat-ing is still controversial) is the author of the best-known exposition of Vaibhāṣika theses, entitled *Abhidharmakoṣa*, together with his own commentary (*Bhāṣya*) in which Vasubandhu criticizes those very Vaibhāṣika views from the standpoint of the interpretation labelled "Sautrān-tika" (derived from "*sūtra*"). The Sautrāntikas urged going back to the Buddha's own words as found in the Buddhist canon. Vasubandhu provides us with a detailed acount of the Sautrāntika's opinions, and perhaps goes on to criticize both Vaibhāṣika and Sautrāntika from a Yogācāra (see below) perspective. This defection from Vaibhāṣika tenets produced a violent reaction by Vasubandhu's contemporary Saṁghabhadra in his *Nyāyānusāra*.

Turning to the Theravāda, their list of seven Abhid-harma works comprises the *Dhammasaṅgaṇī, Vibhaṅga, Dhātukathā, Puggalapaññatti, Kathāvatthu, Yamaka* and *Paṭṭhāna*. The place of the *Kathāvatthu* is somewhat sim-ilar to that of the *Vibhāṣā* in the Sarvāstivāda tradition, in that it records many different opinions about a variety of Buddhist concerns, some doctrinal, others practical, which appear to have caught the notice of the author, who wrote in about the third century BCE A noncanoni-cal work that appears to date from the pre-Christian era as well is the popular *Milindapañha*, a literary treatise presenting itself as recording a discussion between King Milinda (Menander?) and the monk Nāgasena.

Buddhism appears to have moved to what is now Śrī Laṅka several centuries after the Buddha, although the earliest literary remnants of Buddhism there are now lost. Around 425 two Indians, BuddhagHosa and Buddha-datta, appear to have visited Śrī Laṅka—there is a tradi-tion about their meeting on the seas between island and mainland—and each wrote works in Pāli (a vernacular of Sanskrit) recording the philosophical position of the Theravādins. Buddhadatta's work, titled *Abhidham-māvatāra*, is not studied frequently nowadays, but the works of Buddhaghosa (who remained in Lanka), espe-cially the mammoth *Visuddhimagga*, are seminal to the philosophical theses of the Buddhism that has flourished since, initially in Ceylon and eventually throughout Southeast Asia. Buddhaghosa is said to have also written commentaries on all seven of the works of the Theravāda or "Pāli canon" Abhidharma.

Beginning at least by the first century CE a type of lit-erary production began to appear, the importance of

which for understanding the subsequent development of Buddhism both in India as well as throughout Asia is very apparent from the vast interpretive literature that has grown up around it. The texts in question are often referred to as "Mahāyāna *sūtra*s." While the exact connection between these works and the coming of Mahāyāna Buddhism (not to mention the use of the self-laudatory word "Mahāyāna") is not well understood, some of these works are among those most familiar and dear to the heart of millions of Buddhists throughout the world under names such as the "Lotus Sutra," "Heart Sutra," "Diamond Sutra," etc.

It is still being argued by scholars what is the correct account of the rise of what has come to be called "Mahāyāna." Some accounts connect it with Nāgārjuna (150 CE), author of a number of philosophical works such as the *(Mūla)Madhyamaka-kārikās* and *Vigrahavyāvartanī*. The connection between that Nāgārjuna and Mahāyāna is not at all clear, however. It is other Nāgārjunas, the apparent authors of works of probably later vintage, that show affinities with what are taken to be particularly Mahāyānic topics and theories.

In any case, the Madhyamaka tradition persists in India, and eventually in Tibet and East Asia, in a literature of which we mention here only the Indian portion. The works attributed to the second-century Nāgārjuna show their author to be a masterly critic of all philosophical positions, so much so as to have earned him the charge of being merely a skeptic or—worse still—a nihilist. A vast secondary as well as a lively interpretive literature concerns itself with the proper interpretation of his position. Although it is still somewhat controversial to say so, the major lines of interpretation seem to be two, terms for which have been borrowed from subsequent Tibetan commentators. One line insists that when Nāgārjuna says that everything is "empty" or "void" (*śūnya*) he means what he says, i.e., that (as he himself says) he has no thesis whatsoever, that he uses language solely to refute those who do take positions. This interpretation is known as "Prāsaṅgika," and its earliest Indian protagonists are Buddhapālita (480) and Candrakīrti (600). An alternative, "Svātantrika" line of thinking is particularly defended by Bhavya (or Bhāvaviveka) (550), who wishes to allow for the positive use of inferential arguments to establish the interdependence of all things, termed "emptiness" in Madhyamaka. All these writers composed commentaries on Nāgārjuna's *Mādhyamikasūtra*s.

Madhyamaka is one of the philosophical positions regularly identified as Mahāyāna. The other is known as Yogācāra or Vijñānavāda Buddhism. Whereas Madhya-

maka's position (if it has one) is that nothing is real (not even emptiness), the Yogācāras exempt consciousness itself from this denial. What exist are many streams of consciousness (or perhaps only one stream); what appears as an independent world is merely a construction based on our karma. The earliest proponents of this position are regularly held to be the brothers Asaṅga and Vasubandhu (fourth century), although scholars are fairly certain that these two did not found the system, that it was already in place and expounded in works slightly earlier, e.g., in the *Saṃdhinirmocanasūtra* and *Laṅkāvatārasūtra* (both about 325 CE). Furthermore, there is some reason to believe that at least parts of the works ascribed to Asaṅga are of an earlier vintage and that the Vasubandhu who wrote the influential Yogācāra works titled *Triṃśikā* and *Viṃśkā* as well as the *Karmasiddhiprakaraṇa* was not the same person as the one who wrote the *Abhidharmakośa*. In any case, a healthy literature soon grew up around these works, eventually leading to attempts to find *rapprochement* between Yogācāra and Madhyamaka, as in Śāntarakṣita (750) (*Tattvasaṃgraha*) and his commentator Kamalaśīla (770), and perhaps to the development of the Buddhist Logic tradition (see below) which is itself viewed by East Asian interpreters as merely a branch of Yogācāra. Eventually Yogācāra becomes very important in Tibet, expounded there by the influential monk Atīśa (or Dīpaṃkara Śrījñāna, 1035) and others.

Attention is given to the theory of inference or logic by Vasubandhu and others prior to Dignāga (510) (*Pramāṇasa-muccaya*), but it has become customary (influenced by Th. Stcherbatsky's book *Buddhist Logic*, available in a popular publication in English early in the twentieth century) to refer to Dignāga's philosophical position as that of the "Buddhist Logicians." The works by Dignāga and others that constitute the literature of this school concentrate on the methodology of inferential reasoning, but also speculate on many of the same metaphysical and epistemological questions that other Buddhist systems were addressing, for example, whether consciousness alone is real or whether nothing at all is real, and whether it is even possible to speak or think truly. Dignāga is ambiguous on those questions, but nevertheless he develops an identifiable position stemming from an epistemic distinction between "perception"—which grasps what Westerners might call "sense-data," which are taken to be actual entities—and inference which, since it deals with universal properties, is deemed unreal since it can only concern conceptual constructions. Dignāga's approach is taken up and critically clarified with zeal in subsequent periods, notably by Dharmakīrti (610), Dhar-

mottara (770), Jitāri (990), Jñānaśrīmitra (1015), Ratnakīrti (1070), and eventually elegantly summarized by Mokṣākara Gupta (1100) in his *Tarkabhāṣā.*

INDUCTION

The name "induction," derived from the Latin translation of Aristotle's *epagoge*, will be used here to cover all cases of nondemonstrative argument, in which the truth of the premises, while not entailing the truth of the conclusion, purports to be a good reason for belief in it. Such arguments may also be called "ampliative," as C. S. Peirce called them, because the conclusion may presuppose the existence of individuals whose existence is not presupposed by the premises.

Thus, the conclusion "All *A* are *B*" of an induction by simple enumeration may apply to *A*'s not already mentioned in the finite number of premises having the form "*A_i* is *B*." Similarly, in eduction (or arguments from particulars to particulars) the conclusion "Any *A* is *B*" is intended to apply to any *A* not yet observed as being a *B*.

It would be convenient to have some such term as *adduction* to refer to the sense of induction here adopted, which is broader than the classical conception of induction as generalization from particular instances. Most philosophical issues concerning induction in the classical sense arise in connection with the more general case of nondemonstrative argument.

In what follows it will be convenient to use Jean Nicod's expression "primary inductions" to refer to those nondemonstrative arguments "whose premises do not derive their certainty or probability from any induction." Problems of philosophical justification are most acute in connection with such primary inductions.

It may be added that "mathematical induction" is a misnomer because the useful types of reasoning so labeled are rigorously demonstrative. Given that the first integer has a certain property and also that if any integer *n* has that property then so does *n* + 1, the next, it follows demonstratively that all the integers have the property in question. Inductive arguments, as here conceived, do not constitute mathematical or logical proofs; by definition induction is not a species of deduction.

TYPES OF INDUCTIVE ARGUMENTS

In addition to the types of arguments already mentioned, the following are most frequently discussed:

(1) Elaborated induction (as it might be called) consists of more or less sophisticated variations of induction by simple enumeration, typically including supplementary information concerning the mode of selection of the individuals named in the premises and perhaps including reference to negative instances.

(2) Proportional induction is inference from the frequency of occurrence of some character in a sample to the frequency of occurrence of the same character in the parent population—that is, from "m_1/n_1 *A*'s selected by a stated procedure *P* are *B*" to "m_2/n_2 *A*'s are *B*." Here the ratio stated in the conclusion may be other than the one stated in the premise; it is often advantageous to locate the final ratio within a certain designated interval.

(3) Proportional eduction is argument from sample to sample. From the same premises as in proportional induction a conclusion is drawn concerning approximate frequency of occurrence in a further sample obtained by the same procedure or by another one.

(4) Proportional deduction (commonly called "statistical syllogism") is inference from "*m/n C*'s are *B*" (where *m/n* is greater than 1/2) and "*A* is a *C*" to "*A* is a *B*."

In all the above cases modern writers usually insist upon inserting some more or less precise indication of probability or likelihood, either within the conclusion itself or as an index of reliability attached to the mark of inference ("therefore," "hence," or the like). Careful attention to the probability or likelihood attributed to a given inductive conclusion is a distinct merit of modern treatments of the subject.

The foregoing list cannot claim to be exhaustive, nor are its items to be regarded as mutually irreducible. There is no general agreement concerning the basic forms of inductive argument, although many writers regard simple enumeration as in some sense the most fundamental.

HISTORY OF INDUCTIVE METHODS

Interest in the philosophy and methodology of induction was excited by the extraordinary successes of natural science, which tended to discredit the rationalistic conception of knowledge about matters of fact. The classical writers on the subject, from Francis Bacon on, have lamented the powerlessness of deduction to do more than render explicit the logical consequences of generalizations derived from some external source. If recourse to intellectual intuition or to self-evidence is repudiated as a source of factual knowledge, nothing better seems to remain than reliance upon the empiricist principle that all knowledge concerning matters of fact ultimately derives from experience. However, experience, whether conceived as sporadic and undirected observation or as the systematic search for specific answers extorted by planned experiment, seems to supply knowledge only of particular truths. Empiricists are therefore faced with the problem of accounting for the crucial step from knowledge of experiential particulars to reasoned acceptance of empirical generalizations sufficiently powerful to serve as the major premises of subsequent logical and mathematical deduction.

The aspiration of early writers was, characteristically, to demonstrate the conclusions of acceptable inductive arguments as true; not until the end of the nineteenth century did a more modest conception of inductive argument and scientific method, directed toward acquiring probability rather than certainty, begin to prevail.

PROBLEM OF INDUCTION

The celebrated problem of induction, which still lacks any generally accepted solution, includes under a single heading a variety of distinct, if related, problems. It is useful to distinguish the following:

(1) The general problem of justification: Why, if at all, is it reasonable to accept the conclusions of certain inductive arguments as true—or at least probably true? Why, if at all, is it reasonable to employ certain rules of inductive inference?

(2) The comparative problem: Why is one inductive conclusion preferable to another as better supported? Why is one rule of inductive inference preferable to another as more reliable or more deserving of rational trust?

(3) The analytical problem: What is it that renders some inductive arguments rationally acceptable? What are the criteria for deciding that one rule of inductive inference is superior to another?

These problems may be briefly labeled "justification," "differential appraisal," and "analysis." Many writers on induction have also occupied themselves with the task of codification, the formulation of a coherent, consistent, and comprehensive set of canons for the proper conduct of inductive inference. Important as it is, this task is not distinctively philosophical, except insofar as it requires in advance answers to the questions listed above.

In practice the three problems here distinguished cannot be pursued separately; a comprehensive general defense of inductive procedures involves specification, inter alia, of legitimate forms of inductive argument, and selection between alternative inductive rules or methods must rely, explicitly or not, upon determination of what, if anything, makes an inductive argument "sound." The *why* of inductive argument cannot profitably be isolated from the *how*.

It is characteristic of much recent investigation of the subject to concentrate on the last two of the problems listed, often in the hope of formulating precise canons of inductive inference (an inductive logic). These comparative and analytical versions of the problem of induction are thought worth pursuing even by writers who reject the general problem of justification as insoluble.

HUME'S VIEW OF CAUSATION. For better or worse, all modern discussion of the philosophy of induction takes off from David Hume's celebrated analysis of causation, whose connection with the philosophical problems of induction (a word that Hume never used) arises from his view that all reasoning concerning matters of fact is founded on the relation between cause and effect. Although Hume may be held to have given undue prominence to causation (his skeptical conclusions do, in fact, challenge every kind of nondemonstrative argument, whether or not grounded in causal imputation), it is easy to overlook and to be misled by the special form in which he conceived the problem of justification.

Hume, unlike such later writers as J. S. Mill, was not satisfied to analyze the notion of cause and effect into the notions of spatial contiguity, temporal succession, and joint occurrence; he fatefully added to these the criterion of "necessary connexion." That objects of certain kinds have been conjoined or associated in past experience might be no more than an extended coincidence. Something more is needed before one event can properly be recognized as the cause of the other; we must be able to pass from *post hoc* to *propter hoc*. In predicting a putative effect of a given event we can ensure contiguity and succession by choosing to look only for a spatiotemporally

proximate event, and memory (if that can be relied on) will furnish knowledge of constant conjunction in the past. Whether we are truly justified in predicting the occurrence of the putative effect will therefore turn entirely upon whether there is good reason to assert that it is necessarily connected with its neighbor. Hume, in effect, challenged his reader to find anything in the observation of a single case of supposed causal action (for instance, in the favorite example of a collision between two billiard balls) that answers to the required "necessary connexion" between two events. No observation, however attentive, will discover more than contiguity and an internal habit of expecting association. Nor will examination of a series of cases, all exactly alike, help at all: A sum of zeroes is still zero.

But what did Hume mean by "necessary connexion"? Although he did not tell us in so many words, his main proof that we can "never demonstrate the necessity of a cause" rests simply upon the conceivability, and hence the logical possibility, of an event's being bereft of its putative cause. He seems, therefore, to have implied that our notion of a cause and its effect requires the existence of the one to be entailed by the existence of the other. If so, it does not need much argument to show that we can have no impression (direct sensory experience) of such entailment. Hume concluded that necessity cannot reside in the external world but must arise, as an idea, from an internal impression of the mind, a "determination to carry our thoughts from one object to another."

Repeated observation of the association of events leads us to the habit of expecting the association to continue "by means of an operation of the soul … as unavoidable as to feel the passion of love, when we receive the benefits" (*Enquiry concerning the Human Understanding*, Sec. 5, Part 1). Our idea of necessary connection is nothing more than an internal response to the habit of expecting effects: "Upon the whole, necessity is something in the mind, not in objects." At this point skepticism is just around the corner; we are on the verge of such famous conclusions as that "all probable reasoning is nothing but a species of sensation" (*Treatise*, Book I, Part 3, Sec. 8).

The reference to habit or custom explains nothing, of course, and is at best only a concise reference to the truism, which according to Hume's view simply has to be accepted, that men do in fact expect events to be accompanied by effects. Without such habits of causal expectation men could hardly have survived—but this reflection, itself based on induction, cannot be a reason for belief in causation. For a philosopher so critical of such allegedly occult entities as power and energy, Hume was strangely carefree in his reliance upon habit or custom as a *vera causa*. In keeping with his own principles he ought to have turned as skeptical an eye on habit as on cause and ought to have concluded that our idea of habit is derived from nothing more than a habit of expecting that a man who acts in a certain way will continue to do so. But now the account looks circular. Have we any better reason to believe in the existence of habits—even if construed, in as reductionist a fashion as possible, as mere constant conjunctions—than we have to believe in causes? And would not everything that tended to show we have no sufficient basis in external experience for belief in the objective reality of causal connection also tend to show, by parity of reasoning, that we have no basis for believing in the existence of those habits that are invoked at least to explain, if not to justify, our ordinary causal beliefs?

It has seemed to nearly all of Hume's readers that his method must lead to a skepticism more sweeping than he himself was perhaps willing to recognize or to accept. If Hume had been correct about the origin of the idea of necessity, he would have been committed to a totally skeptical answer to the general problem of justification. Whether or not we can escape from the bondage of causal expectation, we are at any rate free to see that such a habit can provide no reason, in Hume's sense, for the belief in causal connection. And once we see this, wholesale skepticism concerning inductive inference seems inescapable.

Hume's skeptical conclusions cannot be dismissed on the ground that they originated in an oversimplified psychology of ideas and impressions, for his argument can, with little difficulty, be made independent of any psychological assumptions. Cause and effect are logically independent, not because repeated search fails to find any logical connection, as Hume's own account misleadingly suggests, but because it is a part of what we mean by cause and effect that the two shall be logically separable. It is tempting to say, then, that there is no reason why the separable consequent should follow its antecedent in any particular instance. We can very well imagine or conceive the cause's occurring without its usual consequent, and, in Hume's words, "nothing of which we can form a clear and distinct idea is absurd or impossible" (*A Treatise of Human Nature*, Book I, Part 1, Sec. 7).

NEO-HUMEAN ARGUMENTS. Even if Hume was wrong in including logical necessity in the idea of causal connection, a neo-Humean can correct his argument without weakening its skeptical force. It is reasonable to say that what distinguishes a causal connection from a

merely accidental association is that empirical rather than logical necessity obtains between the two events. This, in turn, may be rephrased by saying that the observed conjunction is a case of lawful and not merely accidental association. But then Hume's challenge to discover such lawfulness in experience remains as formidable as ever; no matter how many instances of joint occurrence we encounter, we will never observe more than the de facto association and will never have ultimate, noninductive grounds for believing in a de jure connection.

Thus, Hume's problem can be put into modern dress, without restriction to causal inference, as follows: An inductive inference from an observed association of attributes (A_n—B_n) can justify inference to another case (A_{n+1}—B_{n+1}) or inference to the corresponding generalization ("All A are B") only if the association is somehow known to be lawlike, not merely accidental. Yet how can this be known in primary inductions that do not themselves rest upon the assumed truth of other laws? Certainly not by immediate experience, nor a priori, nor, without begging the question, by appeal to induction.

The sharpest form of this version of the problem (called by its author the "new riddle of induction") is that of Nelson Goodman. Suppose all emeralds examined before a certain time t have been green; use the label "grue" for the property of being green up to the time t and being blue thereafter. Then all the evidence supports equally well the competing laws "All emeralds are green" and "All emeralds are grue." Here an instance of the comparative problem is raised in a particularly pointed and instructive way.

Goodman's challenge awaits an answer. Some writers have hoped to defend the received or standard modes of inductive argument by invoking criteria of relative simplicity. But apart from the yet unsolved problem of clarifying what simplicity is to mean in this connection, there seems no good reason why nature should obligingly make correct inference simple; often enough the best-confirmed law is less simple than others that would accord with the given evidence. Goodman's own suggestion to restrict defensible inductions to "entrenched" predicates (roughly speaking, those that have been frequently employed in previous inductive judgments) seems less than satisfying.

From the standpoint of the philosophy of induction the chief significance of Hume's memorable discussion (apart from its tonic effect in disturbing "dogmatic slumber") is that it brought into full daylight the problem of distinguishing between a merely accidental series of associations and the genuine laws that we seek by means of inductions.

DEDUCTIVE STANDARD OF JUSTIFICATION. A demand that induction be justified arises, of course, from some supposed deficiency or imperfection. If all were obviously well with inductive argument, there would be no point in asking for any defense or justification. It is therefore of the first importance to be clear about the alleged weakness or precariousness of induction and the corresponding standard of justification to which appeal is covertly made. We need to know what is supposed to be the trouble with induction, for only when the disease is understood will the search for a remedy have much prospect of success.

The root of the trouble is plain enough in the writings of a hundred writers who have trodden in Hume's footsteps. All have been haunted by the supposedly superior certainty of demonstrative reasoning. If valid deduction from premises known to be true transmits certainty to the conclusion, even the best induction will seem inferior by comparison. (John Locke said that induction from experience "may provide us convenience, not science"— *Essay concerning Human Understanding*, Book IV, Ch. 12, Sec. 10.) The nagging conviction that induction somehow falls short of the ideals of rationality perfectly exemplified in valid deductive argument has made the problem of induction needlessly intractable.

If Hume, for instance, did not require that induction be shown as somehow satisfying the criteria of valid deduction, an answer to his question about how "children and peasants" learn from experience would be easy. The method employed, as he himself stated, is that of arguing from similarity of causes to similarity of effects. However, such an answer would obviously not have satisfied him, because this method will not guarantee the truth of the conclusion drawn; that is, it is not the kind of method that would be acceptable as justifying a valid deduction. Hume would have liked an inductive conclusion to follow from (be entailed by) premises known to be true, for anything less would not have seemed genuinely reasonable. Having shown, in effect, that no reason of this kind can be produced for primary inductions, he was forced to regard the question of justification as demonstrably insoluble. This conclusion has the notable inconvenience of leaving the comparative problem also insoluble (while the analytical task vanishes for lack of an object).

Hume's conclusion must be granted if his is the only sense of "reason" in point. If we never have a reason for an inductive conclusion unless we know the conclusion to

follow strictly from premises known to be true, then we can have no reason for believing in primary inductive conclusions; it is as reasonable to expect that thistles will bear figs, or something equally absurd, as it is to expect anything else extending beyond past experience. (Whether we can in fact bring ourselves to believe anything so absurd is beside the point.) Only in recent times have serious efforts been made to escape from the spell of the deductive model, used by Hume and his innumerable followers, by inquiring whether there may not be other proper and relevant senses of "reasonable." It will be argued later that belief in induction is reasonable in principle and that belief in one kind of inductive conclusion is more reasonable than belief in another.

The lasting attraction of the deductive model is not hard to understand. The raison d'être of deductive argument seems enticingly plain: Valid deductions are truth-transmitting and truth-preserving—which, given an interest in obtaining novel truth, seems enough to show the point of deductive reasoning. (That this cannot be the whole story is obvious from the uses of deductive reasoning in exhibiting the consequences of propositions hypothetically entertained—not to mention *reductio* arguments and other uses.) By contrast the raison d'être of induction seems unclear and mysterious. It would be easy, although unsatisfying to the genuinely perplexed, to say that sound inductive arguments are "likelihood-transmitting," for likelihood is as unclear a concept as inductive correctness. Thus, it is natural to ask for and to expect a detailed answer to the question "Why should a reasonable man rely upon likelihood in default of truth?" Even if the power of sound induction to confer likelihood upon conclusions is regarded as sufficient to make inductive argument reasonable beyond further cavil, the question how such likelihood is conferred will remain. Attention thus shifts to the analytical task.

It may be added that an enduring source of disquiet concerning inductive argument is its disorderliness and formlessness by contrast with deductive argument. In deductive argument we flatter ourselves upon readily perceiving the underlying principles and their necessary connection with logical form. By contrast with such classic simplicity, and order the realm of inductive argument seems disconcertingly complex, confused, and debatable: An inductive argument accepted by one judge may be rejected, on good grounds, by another, equally competent judge; supposedly sound arguments from different sets of true premises may yield opposed conclusions; the very soundness of induction seems not to be clear-cut but to admit of gradations of relative strength and reliability.

Given all this, it is not surprising that although many students have labored to introduce order into the field, others, abandoning any hope of so doing, have turned away from induction as a tissue of confusions.

TYPES OF SOLUTION

The answers given in the literature to Hume's problem can be briefly summarized as follows:

(1) Hume's challenge cannot be met; consequently, induction is indefensible and ought to be expunged from any reasoning purporting to be rational.

(2) In the light of Hume's criticisms, inductive arguments as normally presented need improvement, either (*a*) by adding further premises or (*b*) by changing the conclusions into statements of probability. In either case a conclusion's validity is expected to follow demonstratively from the premises, and inductive logic will be reconstructed as a branch of applied deductive logic.

(3) Although inductive argument cannot be justified as satisfying deductive standards of correctness, it may be proved that inductive policies (rather than rules or principles) are, in a novel sense to be explained later, reasonable. Induction can be vindicated if not validated.

(4) Hume's problem is generated by conceptual and linguistic confusions; it must therefore be dissolved, rather than solved, by exposing these confusions and their roots.

These approaches are not all mutually exclusive. Thus (3), the pragmatic approach, is usually combined with (1), repudiation of induction as an acceptable mode of reasoning. Apart from (4) all the approaches accept or make substantial concessions to Hume's major assumption—namely, that the only wholly acceptable mode of reasoning is deductive. This is true even of those who hold (3), the "practicalists," who might be supposed, at first glance, to be relaxing the criteria of rationality.

REJECTION OF INDUCTION. The rejection of induction as a proper mode of scientific reasoning is sometimes found in the guise of advocacy of the so-called hypothetico-deductive method. According to such a view, the essence of genuinely scientific reasoning about matters of fact is the framing of hypotheses not established by given empirical data but merely suggested by them. Inference enters only in the control of hypotheses by the verification of their observable consequences: Negative

instances strictly falsify a hypothesis, whereas positive instances permit its use, pending further experimental tests, as a plausible, if unproved, conjecture. Science, as well as all reasoning about matters of fact aspiring to the reliability of scientific method, needs only the kind of reasoning to be found in deductive logic and in mathematics. Some such position was already adumbrated in the writings of William Whewell. It has at least the merit of drawing attention to the role of hypotheses in scientific method, a welcome corrective to the excessive claims of early partisans of inductive logic.

The most influential, and possibly the most extreme, of contemporary writers following this line is Karl Popper, who often maintained that what is called induction is a myth, inasmuch as what passes under that title "is always invalid and therefore clearly not justifiable." In his own conception of scientific method such repudiation of induction is linked with the thesis that the purpose of scientific theorizing is falsification (demonstration of error) rather than verification or confirmation (provisional support of an approximation to the truth). Those who agree would rewrite putatively inductive inferences to make them appear explicitly as hypothetical explanations of given facts. (Thus, instead of inferring "All A are B" from premises of the form "A_n is B," the first statement is offered as a more or less plausible explanation of why all the A_n should have been found to be B.)

In spite of its enthusiastic advocacy, it is hard to see where this proposal accomplishes more than a superficial change in the form in which inductive arguments are written and a corresponding alteration in the metalanguage in which they are appraised. Any hypothetical explanation of given empirical data is intended to reach beyond them by having empirical consequences amenable to subsequent tests. If all explanations consonant with the known facts (always an infinite set) were treated as equally unjustified by the evidence, Hume's problem would certainly be set aside, but only at the cost of ignoring what provoked it—namely, the apparent existence of rationally acceptable nondemonstrative arguments. It can hardly be denied that there are nondemonstrative arguments lending reasonable support to their conclusions; otherwise it would be as reasonable to expect manna from heaven as rain from a cloud. Anti-inductivists have seldom been hardy enough to brand all inductive arguments as equally invalid, but as soon as they discriminate between alternative hypotheses as more or less corroborated, more or less in accord with available facts, they are faced, in a new terminology, with substan-tially the original problems of justification and differential appraisal.

INDUCTIVE SUPPORT FOR INDUCTION. To the layperson the most natural way of defending belief in induction is that it has worked in the past. Concealed in this reply, of course, is the assumption that what has already worked will continue to do so, an assumption that has seemed objectionably circular to nearly all philosophers of induction. A stubborn minority (including R. B. Braithwaite and Max Black), however, insists that the appearance of circularity arises only from overhasty application of criteria applicable to deduction. Even in the limiting case, where the rule governing the supporting argument from previous efficacy is the very rule that is to be defended, it can be plausibly argued that no formal circularity is present. Nor is there the more subtle circularity that would obtain if knowledge of the conclusion's truth were needed to justify use of the self-supporting argument. In spite of spirited objections, this line of reasoning has not yet, in the writer's opinion, been shown to be mistaken.

The point that inductive support of induction is not necessarily circular has some importance as illustrating the interesting self-applying and self-correcting features of inductive rules; in virtue of these features, scrutiny of the consequences of the adoption of such rules can, in favorable cases, be used to refine the proper scope of inductive rules and the appropriate judgments of their strength.

A more serious weakness of this kind of defense, if it deserves to be called that, is lack of clarity about what counts as success in using the rule, which is connected in turn with the insufficiently discussed question of the raison d'être of induction considered as an autonomous mode of reasoning.

But even if this controversial type of inductive support of inductive rules ultimately survives criticism, it will not dispose of the metaphysical problems of induction. Those satisfied with Hume's conception of the problem are at bottom objecting to any use of inductive concepts and of the language in which they are expressed unless there is deductive justification for such use. They will therefore reject any reliance upon induction by way of defense, however free from formal defect, as essentially irrelevant to the primary task of philosophical justification. It must be admitted that inductive support of induction, however congenial to the layman, does not go to the roots of the philosophical perplexity.

A PRIORI DEFENSES. A few twentieth-century writers (notably D. C. Williams and R. F. Harrod) maintained that certain inductive arguments, unimproved by the addition of supplementary premises or by modification of the form of the conclusion, can be proved to be valid. Williams argued, with surprising plausibility, that the probable truth of the conclusion of a statistical syllogism can be shown to be necessitated by the truth of the premises, solely by reference to accredited principles of the mathematical theory of chances. While admiring the ingenuity displayed in this approach, critics have generally agreed in finding it fallacious. That some modes of inductive argument are certified as sound or acceptable on broadly a priori (perhaps ultimately linguistic) grounds is, however, a contention of some versions of the linguistic approach.

DEDUCTIVE RECONSTRUCTION. The effort to provide justification for induction through a reconstruction of inductive arguments so as to make them deductively valid has chiefly taken two forms.

Search for supreme inductive principles. If a given nondemonstrative argument, say from the amalgamated premise *P* to a conclusion *K* (where *K*, for the present, is regarded as a categorical statement of fact containing no reference to probability), is looked at through deductive spectacles, it is bound to seem invalid and so to be regarded as at best an enthymeme, needing extra premises to become respectable. It is easy, of course, to render the original argument deductively valid by supplying the additional premise "If *P* then *K*" (this premise will be called *Q*). In order for induction to be defended in the classical way, however, the premises have to be true and known to be true. Since *P* was supposed not to entail *K*, the new premise, *Q*, will be a contingent statement of fact, knowledge of whose truth is presumably to be derived either by deduction from more general principles or by induction from empirical data. In either case, if the deductive standard of justification is to be respected, the process must continue until we obtain general factual principles, neither capable of further empirical support nor needing such support.

The line of thought is the following: Since *K* does not follow strictly from *P*, the fact that the truth of propositions resembling *P* in assignable ways is regularly associated with the truth of propositions resembling *K* is a contingent fact about the actual universe. Looked at in another way, if events occurred purely at random, it would be impossible to make successful inductions; conversely, if inductions of a certain sort do systematically produce true conclusions, there must be a contingent regularity in the universe that should be capable of expression in the form of supreme principles or postulates of induction. Only if such postulates are true can inductions be sound; they must therefore be the assumed but unexpressed premises of all sound inductive arguments.

Favored candidates for the role of such enabling postulates have been the principle that the future resembles the past (Hume), a general principle of causation to the effect that every event has a sufficient cause (Mill), a principle of spatiotemporal homogeneity, which makes locations and dates causally irrelevant (Mill again), and a principle of limited independent variety ensuring that the attributes of individuals cluster together in a finite number of groups (J. M. Keynes, C. D. Broad; Keynes's principle, however, was intended to ensure only the probability of inductive conclusions). Any of these, if true, records the presence in the universe of a certain global regularity or order that permits inductive procedures to produce the desired true conclusions. For example, if we somehow knew in advance that a given attribute *C* of an observed event must have some other attribute invariably associated with it, and if we further knew that the associated attribute must be included in a finite list of known attributes, say E_1, E_2, …, E_n, then there would be a good prospect that repeated observations of similar events would eliminate all but one of the possible associations, E_1—E_i. Refinements aside, this is how Mill, for instance, conceived of inductive method; his celebrated "methods" (which have received attention out of all proportion to their merits) reduce, in the end, to deductive procedures for eliminating unfit candidates for the title of necessary or sufficient conditions. (Later attempts to develop eliminative induction follow substantially the same path.)

It is clear that the whole interest of this program rests upon the considerations that can be advanced in favor of the supreme premises. If the supreme premises can be known to be true, the remaining processes of inference become trivial (so that there is no need for an autonomous logic of induction); if not, the entire project floats in the void.

The task of formulating plausible principles of the sort envisaged by this program has proved harder than Mill supposed. However, it may be argued that the search for them is pointless and misguided. For one thing, they would accomplish too much: If known to be true, they would allow the conclusions of selected primary inductions to be demonstrated as true, which is too much to expect. It is generally agreed (and rightly so) that the conclusion of even the best inductive argument may without

contradiction turn out to be false—if only through bad luck.

Still more serious is the problem of how, from the standpoint of this program, the desired supreme premises could ever be known to be true. Since appeal to induction is excluded at this point on the score of circularity, and since the principles themselves cannot be analytic if they are to serve their desired purpose, there seems no recourse at all. At this point those who search for supreme inductive principles find themselves with empty hands. Mill, for instance, was compelled to let his whole program rest upon the supposed reliability of simple enumeration (the method he regarded as the weakest), in whose defense he had nothing better to say than that it is "universally applicable" (which, on his principles, delightfully begs the question); Keynes, forsaking his empiricist principles for a half-hearted flirtation with Immanuel Kant, could do no better than to suggest that the ultimate principles rest upon "some direct synthetic knowledge" of the general regularity of the universe. Induction may indeed beg to be spared such defenders as these; better the robust skepticism of Hume or Popper than the lame evasions of Mill or Keynes. The conclusion seems inescapable that any attempt to show (as Bacon and many others have hoped) that there are general ontological guarantees for induction is doomed to failure from the outset.

Recourse to probability. A more promising way, at least at first sight, of hewing to the deductive line is to modify the conclusion of an inductive argument by including some explicit reference to probability. This approach, influential since Keynes's spirited exposition of it, still has many adherents. If there is no prospect of plugging the deductive gap between P and K by adding further premises known to be true, then perhaps the same end can be achieved by weakening the conclusion. If K does not follow from P, why not be satisfied with a more modest conclusion of the form "Probably, K" or perhaps "K has such and such a probability relative to P"?

The most impressive projects of this sort so far available have encountered severe technical difficulties. It is essential to Keynes's program, for instance, that the probability of a generalization relative to an unbroken series of confirmatory instances steadily approach unity. The conditions necessary for this to be possible in his program are at least that the generalization have an initial nonzero probability and that infinitely many of the confirmatory instances be independent, in the sense of having less than maximal probability of occurrence given the already accumulated evidence. The supreme ontological principles to which Keynes was ultimately driven to appeal (see the preceding section) hardly suffice to satisfy these conditions; subsequent criticism—for example, by Nicod and G. H. von Wright—has shown that even more rigorous conditions are needed. (Von Wright has argued that the desired asymptotic convergence will result only if in the long run every instance of the generalization is scrutinized—which would certainly render the theory somewhat less than useful in practical applications.) For all his importance as a founder of confirmation theory, the theory advocated by Keynes must be judged a failure.

Carnap's construction. The merits of Rudolf Carnap's impressively sustained construction of inductive logic, following in the tradition of Laplace and Keynes but surpassing the work of both in elaboration and sophistication, are still in dispute. Taking probability to express a logical relation between propositions, Carnap has shown how, in certain simplified languages, it is possible to define the breadth or logical width of a given proposition. (Roughly speaking, the degree of confirmation given by a proposition x to a proposition y is the ratio of the width of $x \cdot y$ to the width of x.) The definition of logical width depends on the class of possible universes expressible in the language in question. In order to assign a definite measure of logical width it is necessary to adopt some method of weighting the various possible universes ("state descriptions," in Carnap's terminology) compatible with a given proposition.

One of the merits of Carnap's analysis is to have shown that there is an entire continuum of alternative weighting procedures and associated inductive methods, each of which is internally coherent. The arbitrariness thereby recognized in inductive procedure has worried even the most sympathetic of Carnap's readers; still more disturbing is the emergence of what might be called the paradox of the unconfirmable generalization—the impossibility of ensuring, by Carnap's principles, that an unbroken series of positive instances will raise the probability of a generalization above zero. (Carnap retorts that an instance confirmation—that is, the conclusion of an eduction—does acquire progressively increasing probability, but this is insufficient to satisfy those critics who still hope to find a place for authentic generalization within inductive method.) It is too soon to decide whether such problems as these are more than the teething pains of a new subject. The ingenious modifications of Carnap's program suggested by, among others, J. G. Kemeny and Jaakko Hintikka offer some hope for their elimination.

More serious is the fundamental difficulty that flows from Carnap's conception of confirmation statements as

analytic. If it is a truth of logic (broadly speaking) that given the selected definition of confirmation, presented evidence confirms a given hypothesis to such-and-such a degree, then how could such an a priori truth justify any rational belief in the hypothesis? Or, again, if someone were to adopt a different definition of confirmation and thereby be led to a contrary belief, then how could he be shown to be in error?

Carnap's answer is based on the notion that the bridge between confirmation, as defined by him, and rational belief is to be found in some principle for the maximization of expected utility (due allowance being made, however—in his sophisticated rendering of that principle—for subjective estimates of probabilities and utilities). Yet it seems that because considerations of probability also enter into the calculation of probabilities and expected utilities, a logical circle is involved here. Since Carnap's discussions of this fundamental point are still comparatively rough and provisional, it would be premature to reach any final judgment on the success that he and those who agree with him are likely to achieve in coping with this basic difficulty. (It might be said that difficulty with the connection between probability judgments and practice is not peculiar to Carnap's work, since it arises in one form or another for all theorists of induction who take the trouble to work out in detail the consequences of their principles and assumptions.) It may be held, however, that Carnap's relatively cursory judgments about the justification of induction belong to the least satisfactory parts of his work on inductive logic.

How much the recourse to probability will accomplish depends, of course, upon how the reference to probability is construed. With empirical interpretations of probability, such as those favored by "frequentists," the probability conclusion still extends beyond the premises by covert reference to finite or infinite sets of events not covered by the given premises. The inductive leap remaining in the reconstructed argument will thus still leave the problem of induction unsolved. If, however, probability is construed in some logical way (as by Keynes or Carnap), the amended conclusion will say less than the premises and will therefore be untouched by subsequent empirical test; the deductive validity of the reconstructed argument will be saved only at the cost of rendering problematic its relevance to prediction and empirical control. In converting a purportedly inductive argument into a valid deductive one, the very point of the original argument—that is, to risk a prediction concerning the yet unknown—seems to be destroyed.

PRAGMATIC DEFENSES. Answers of the pragmatic type, originally offered by Peirce but independently elaborated with great resourcefulness by Hans Reichenbach, are among the most original modern contributions to the subject. To many they still offer the best hope of avoiding what seems to be the inevitable failure of the attempts so far discussed. The germ of the pragmatic strategy is the reflection that in ordinary life, situations sometimes arise where, in default of reliable knowledge of consequences, problematic choices can still be justified by a "nothing to lose" argument. Faced with a choice between an operation for cancer and a sure death, a patient may choose surgery, not because of any assurance of cure but on the rational ground that nothing is lost by taking the chance.

Reichenbach's "vindication." According to Reichenbach, the case is similar in what he takes to be the paradigmatic inductive situation. Given an antecedent interest in determining the probability of occurrence of a designated character (construed, by him, as the limit, in an infinitely long run of events, of the relative frequency of occurrence of that character), Reichenbach argues that the only rationally defensible policy is to use the already ascertained relative frequency of occurrence as a provisional estimate of the ultimate limiting value. A man who proceeds in this way can have no guarantee or assurance that his estimates, constantly revised as information about the series gradually accumulates, will bring him into the neighborhood of a limiting value of the frequency, for the provisional values of the relative frequencies may, in fact, diverge. In that case no predictive policy at all will work, and successful induction is impossible.

However, if this should not be the case and the series really does have a limiting value for the relative frequency in question, we can know in advance, and with certainty, that the policy is bound eventually to lead the reasoner to estimates that will remain as close to the limit as desired. There is therefore nothing to lose by adopting the inductive policy: If the series of events under scrutiny is sufficiently regular to make induction possible, the recommended policy is bound to yield the desired result ultimately (and we know before we start that it will do so), whereas if the series is irregular enough to defeat the standard inductive policy, nothing will avail, and we are no worse off than if a contrary decision had been made.

This type of justification is often called "vindication," as Herbert Feigl termed it. It is claimed that in a sense the type of vindication sketched above resolves Hume's problem by bypassing it. We know for certain that what Hume desired—namely, certification of the soundness of inductive argument by the standard of demonstrative reason-

ing—cannot be supplied. But it would be fainthearted to leave the matter there. By conceiving the practice of induction as the adoption of certain policies, applied in stoic-acceptance of the impossibility of assured success in obtaining reliable knowledge concerning matters of fact, we are able to see that such policies are, in a clear sense, preferable to any of their competitors. Standard induction is preferable to soothsaying because we know that it will work (will approach limiting values in the long run) if anything will.

To these plausible claims it has been objected that the analogy with genuinely practical decisions to act upon insufficient evidence is misconceived, for in the state of perfect ignorance postulated by defenders of the pragmatic approach no method at all can be regarded as superior to any other. Vindicationists have been relatively undisturbed by such general criticism; they have, however, felt obliged to seek remedies for a grave technical flaw that threatens to wreck their entire program. Given the assumption that the best to be achieved by an inductive policy is asymptotic convergence to a limiting relative frequency, it is obvious that no policy for inductive estimation in the short run is excluded as unreasonable. Thus, from the standpoint of pragmatic vindication an unbroken run of *A*'s found to be *B* would not make it unreasonable to predict the subsequent occurrence *in the short run* of *A*'s that are not *B*, provided only that the adopted estimates are chosen so as to converge eventually to the limit (if it exists). But since the long run is in fact never attained, even by immortal beings, it follows that the pragmatic defense yields no criteria for inductive decisions in short-run cases, to which inductive prediction is confined, and offers no differential reasons for preferring one inductive policy to another.

In spite of strenuous attempts (notably by Wesley Salmon) to improve Reichenbach's original conception by providing supplementary reasons for rejecting unwanted nonstandard policies, the prospects for vindicationism remain dubious. Even if some plausible way could be found of assigning, on vindicationist principles, a special status to the standard policy of induction, the approach would be vulnerable to the objection that it conceives inductive method in an eccentrically restricted fashion. The determination of limiting values of relative frequencies is at best a special problem of inductive method and by no means the most fundamental.

Peirce's views. Peirce, whose views on induction have exerted a lasting influence on the subject since the posthumous appearance of his *Collected Papers*, had a more complex conception of scientific method than latter-day vindicationists. Induction, conceived by him as a process of testing statistical hypotheses by examining random samples, has to be understood in its relations to two other procedures, statistical deduction and abduction.

Statistical deduction consists of inference from the frequency of occurrence of an attribute in a population to the probable and approximate occurrence of that attribute in a sample randomly drawn from it. Given Peirce's definition of probability as limiting frequency and his conception of randomness, it follows demonstratively that most of the samples drawn will have nearly the same composition as the parent population; statistical deduction is thus "valid" in the sense that it generates conclusions that are true most of the time.

Abduction, the creative formulation of statistical hypotheses and the only mode of scientific inference introducing new ideas, is a kind of inversion of statistical deduction. It has almost no probative force, its value being rather that it provides new generalizations needing independent verification and having "some chance of being true."

When the three procedures are used in combination, induction is seen to be a self-correcting method that if indefinitely followed must in the long run lead the scientific community, although not the individual reasoner, indefinitely close to the truth. In such asymptotic convergence to the truth lies the peculiar validity of induction.

Peirce cannot be held to have succeeded in his effort to defend the rationality of inductive policies in terms of long-range efficacy in generating conclusions approximately and for the most part true. Since the intended justification of induction depends essentially upon the randomness of the samples used, it must be objected that there is normally no way of guaranteeing in advance the presence of such randomness. (To this objection Peirce had only the lame and unsupported rejoinder that inductive inference retains some probative force even in the absence of the desired randomness.) The following are among the most obvious weaknesses of Peirce's views about induction.

The self-corrective tendency of induction, which Peirce, in his last writings on the subject, came to view as the heart and essence of inductive method, remains obscure, in spite of his eulogies. That inductive estimates will need, on Peirce's principles, repeated adjustments as further evidence accumulates is clear enough, but that this process will show any convergence toward a limiting value cannot be guaranteed a priori. If the samples to be

examined were random in Peirce's severe sense of that term, we could at least count upon an overall predominance of approximately correct estimates, but even then we should have no reason, in the absence of additional guarantees, to expect the better estimates to come near the end of the testing process. In any case, supposing realistic conditions for the testing of hypotheses (such as our necessary reliance on cases that we are in a position to examine), it seems clear that the conditions for the kind of sampling demanded by Peirce cannot be fulfilled.

Peirce's references to the long run seem on the whole incoherent. Much of the time he seems to have been thinking of what would prove to be the case in an actual but infinitely extended series of trials. Toward the end of his life, however, he appears to have recognized that his definitions of probability and of the validity of induction needed to be construed more broadly, by reference to the "would be" of events, conceived as real general characters or habits. How such general features of events can in fact be disclosed, even by very lengthy series of trials, Peirce never made plain. Yet the need for clarification is great for anybody attracted by his approach. The infinitely long run is a chimera, and to be told that a certain method, if consistently pursued, would in such a long run eventually lead as close as we pleased to the truth is to be told nothing that can be useful for the actual process of verification. All verification is necessarily performed in the finite run, however extended in length, and what would happen if *per impossibile* the "run" were infinite is not relevant to the relative appraisal of given hypotheses. We need a method for adjudicating between rival hypotheses, if not now then in the foreseeable future, and this Peirce's conception cannot provide. Because of his reliance upon the infinitely long run Peirce's pragmaticism, which initially seems so hardheaded in its emphasis upon success and practical consequences, ends by being as utopian as any of the metaphysical conceptions that he derided.

JUSTIFICATION AS A PSEUDO PROBLEM. In view of the quandaries that beset all known attempts to answer Hume's challenge, it is reasonable to consider whether the problem itself may not have been misconceived. Indeed, it appears upon examination that the task of logical justification of induction, as classically conceived, is framed so as to be a priori impossible of solution. If induction is by definition nondeductive and if the demand for justification is, at bottom, that induction be shown to satisfy conditions of correctness appropriate only to deduction, then the task is certainly hopeless. But to conclude, for this reason, that induction is basically invalid or that a belief based upon inductive grounds can never be rea-

sonable is to transfer, in a manner all too enticing, criteria of evaluation from one domain to another domain, in which they are inappropriate. Sound inductive conclusions do not follow (in the deductive sense of "follow") from even the best and strongest set of premises (in the inductive sense of "strongest"); there is no good reason why they should. Those who still seek a classical defense of induction may be challenged to show why deductive standards of justification should be appropriate. Perhaps the retort will be that there is no clear sense in which assertion of a conclusion is justified except the sense in which it is known to follow strictly from premises known to be true, so the burden of argument rests upon anybody who claims the existence of some other sense.

Linguistic approach to the problem. The challenge to the claim that inductive arguments cannot be said to be justified might be met in the following way: Suppose a man has learned, partly from his own experience and partly from the testimony of others, that in a vast variety of circumstances, when stones are released they fall toward the ground. Let him consider the proposition *K*, that any stone chosen at random and released will do likewise. This is, in the writer's opinion, a paradigm case for saying that the man in question (any of us) has a good reason for asserting *K* and is therefore justified in asserting *K* rather than not-*K*. Similarly, this is a paradigm case for saying that the man in question is reasonable in asserting *K* and would be unreasonable in asserting not-*K*, on the evidence at hand. Anybody who claimed otherwise would not be extraordinarily and admirably scrupulous but would be abusing language by violating some of the implicit criteria for the uses of "good reason," "justified," and "reasonable," to which he, like the interlocutor with whom he succeeds in communicating, is in fact committed.

Any man—say, one from Mars—who used these words according to criteria that would really make it improper for him to apply them in the kind of situation envisaged would not, in the end, be understood by us. Worse still, he would be trying, if he were consistent, to change our actual concepts of reason and reasonableness so that it would be logically impossible to have reasons for assertions concerning the unknown or to be reasonable in expecting one matter of fact rather than another on the basis of empirical evidence. (He would be behaving like a man who insisted that only stallions deserved to be called horses.) Nor would such distortion achieve anything significant, for the man who proposed to make "empirical reason" as impossible of application as "being in two places at once" would find himself forced to rein-

troduce essentially the same concept under some such label as "generally accepted as a reason" or "what commonly passes for a reason." The distinction between what ordinary men and what scientists call "good reasons" and "bad reasons" is made for a good purpose, has practical consequences, and is indispensable in practice. Thus, the dispute between the advocate of the linguistic approach and his opponent seems to reduce to a verbal one, ripe for oblivion.

Given the intertwined complexity of the concepts entering into alternative formulations of the problem of induction and the seductive plausibility of the distortions to which such concepts are subject, no brief reply such as the above can be expected to clarify and to expose the conceptual confusions upon which traditional formulations of the problem rest. A full discussion would at least also have to consider the relevant senses of "knowledge" and "possibility" and related epistemological notions. The outline of the strategy is perhaps sufficiently plain; the line to be taken is that close and detailed examination of how the key words in the statement of the problem occur will show that criteria for the correct uses of such terms are violated in subtle and plausible ways. If this can be established, the celebrated problem of justifying induction will dissolve, and the confused supposition that induction needs philosophical justification or remains precarious in its absence will disappear.

The comparative problem and the analytical problem do not dissolve under this attack. Advocates of the linguistic approach can be fairly reproached for having been too often content to show to their own satisfaction that the general problem of justification is rooted in confusion, while neglecting the constructive tasks of rendering clearer the criteria for preferential appraisal of inductive arguments.

To those unsympathetic with the linguistic approach such an attack upon the traditional problem has sometimes seemed to be operating with dubious and insufficiently elaborated theories of meaning or use and to be altogether too glib in its attribution of semantic confusions. Moreover, a number of critics have thought that an appeal to ordinary language cannot be ultimately decisive from a philosophical standpoint. Even if it were established that it is a violation of ordinary language to describe the conclusion of some inductive arguments as supported by less than good reasons, the critics ask, what is there in the nature of things that requires us to continue talking in the ordinary way or to be bound by the encapsulated metaphysical prejudices of those originally responsible for establishing the rules of use to which

appeal is now made? The linguistic philosopher necessarily uses such key words as *reasonable* in his polemic against the traditional approaches to the problem. But to use the crucial terms in a discussion of the nature of the inductive problem, it might be urged, is to beg the very question at issue. A lunatic or an eccentric philosopher might well use the expression "good reason" in a way that would be blatantly improper, yet he might be able to prove, by appeal to his own criteria, that he had "good reasons" to use the phrase in the way he did. But are we ourselves in any better position? Are we not obligated to break through the linguistic barrier and at least to show why the alleged criteria for good reasons to which appeal is made should continue to receive our allegiance?

There is no short way of dealing with this type of objection. It may be helpful, however, to sketch the general view upon which the present writer, as a defender of the linguistic approach, would rely.

Defense of the linguistic approach. All normal adult human beings follow the same broad and systematic patterns for drawing inferences concerning the unobserved and apply the same general principles for appraising such nondemonstrative inferences. For instance, all normal persons expect observed cases of association of attributes to be confirmed in further experience unless there are countervailing factors (the principle of simple enumeration), all count increase in the number of independent confirmatory instances of a law as strengthening (or at least not weakening) the probability of the law's truth, and all alike share the inductive beliefs that underpin causal notions. It is, therefore, not fanciful to conceive of all sane adult human beings as participating in a complex system of ways of learning from experience that might be called the inductive institution. Like other institutions (warfare, the law, and so on), it has a relatively fixed, though not immutable, structure, transmitted from one generation to the next and crystallized in the form of prohibitions and licenses, maxims of conduct, and informal precepts of performance. Like other institutions, the inductive institution requires that its participants have mastered a system of distinctive concepts (among them the concepts of good reason, sound argument, and relative likelihood) having both descriptive and normative aspects.

Such mastery is shown in capacity to use the corresponding language correctly—which, in turn, implies recognition of, though not invariable obedience to, associated rules for assertion, for evaluation, and for the appraisal of actions. Understanding what people mean by reasons for empirical conclusions requires acceptance of

certain types of situations as paradigmatic of empirical evidence; to call given facts sound reasons for some conclusion is to imply the acceptability of certain criteria for judging one reason to be better than another; asserting that some belief about the hitherto unobserved is reasonable commits the speaker to holding that other things being equal, action based on such belief should be approved.

The philosophical problem of justifying induction can arise only for somebody who is a member of the inductive institution and is therefore already bound by its constitutive rules. A spectator can understand bridge without being a player, but all of us are necessarily players of the "inductive game" before we achieve the reflective self-consciousness characteristic of philosophical criticism.

The constitutive rules of the inductive institution (whose precise delineation remains a still unfinished task for philosophers of induction) are highly abstract, schematic, and limited in their practical usefulness. Indeed, the general principles of inductive inference are about as relevant to practice as the abstract principles of justice are to decisions on concrete legal issues. In particular situations concerning the soundness of empirical hypotheses the reasoner is compelled to fall back upon his specific knowledge of relevant facts and theories. In this way the conduct of concrete inductive inference resembles the exercise of a craft or skill more than it does the automatic application of a decision procedure. Yet the constitutive rules provide important general constraints that cannot be violated without generating nonsense. To be in command of inductive language, whether as a master of advanced techniques of statistical inference or as a layperson constantly and more or less skillfully anticipating future experience, is necessarily to be subject to the implicit norms of belief and conduct imposed by the institution.

The inductive concepts that we acquire by example and formal education and modify through our own experiences are not exempt even from drastic revision. The norms may be usefully thought of as formal crystallizations into linguistic rules of general modes of response to the universe that our ancestors have, on the whole, found advantageous to survival, but the earlier experience of the race never has absolute authority. Piecemeal reform of the inductive institution can be observed in the history of modern science.

What is clearly impossible, however, is the sort of wholesale revolution that would be involved in wiping the inductive slate clean and trying to revert to the condition of some hypothetical Adam setting out to learn from experience without previous indoctrination in relevant rules of inductive procedure. This would be tantamount to attempting to destroy the language we now use to talk about the world and about ourselves and thereby to destroy the concepts embodied in that language. The idea of ceasing to be an inductive reasoner is a monstrosity. The task is not impossibly difficult; rather, its very formulation fails to make sense. Yet it remains important to insist that the inductive institution, precisely because its raison d'être is learning from experience, is intrinsically self-critical. Induction, like the Sabbath, was made for humankind, not vice versa. Thus, constantly renewed experience of the successes and failures of the specific inductive procedures permitted within the general framework of the inductive institution provides a sound basis for gradual reform of the institution itself, without objectionable circularity.

Yet even if no feature of the institution is exempt, in principle, from criticism and reconstruction, the entire institution cannot be called into question all at once without destroying the very meaning of the words in which the philosophical problems of induction are stated. Wholesale philosophical skepticism about matters of fact is senseless and must be shown to be so. If this is the "linguocentric predicament," we must make the best of it.

The view here outlined must be carefully distinguished from what is commonly called conventionalism. The argument is not that the constitutive inductive rules hold by convention but rather that the sweeping question "Why should we accept *any* inductive rules?" can be shown to make no sense.

Our sketch may be usefully compared with Hume's view of induction as a habit or custom. Both views agree in regarding inductive practices as being, on the whole, social and contingent facts obtaining at given periods in human history. It is, after all, a contingent fact that there have existed animals sufficiently rational to be able to speak and hence to have inductive concepts. The present conception differs significantly from Hume's, however, in regarding the inductive institution as partly constituted by normative inductive rules to which the philosopher, like every reasoning individual, finds himself already committed. Thus, the encompassing social fact of the existence of the inductive institution includes within itself the means for appraisal and criticism of inductive procedures; we cannot regard inductive inference as something merely "given," as a natural fact, like the Milky Way, that it would be absurd to criticize. To understand induction is necessarily to accept its authority. However

(to repeat), questions about the general or ultimate justification of induction *as such*, questions of the form "Why should any induction be trusted?" must be recognized as senseless. If we persist in trying to raise them, we come, as Wittgenstein expressed it, to the "limits of language," and we can see that we have done so by perceiving that what we had hoped were important and fundamental questions are no better than nonsense masquerading as sense. The foregoing will undoubtedly strike critics of the linguistic approach as too facile, for the tangle of philosophical problems that have been dubbed "the problem of induction" constitute, in their depth, their importance, their elusiveness, and their capacity to bewilder and confuse, a very paradigm of philosophical perplexity.

The preceding survey indicates that no wholly satisfactory philosophy of induction is yet available. The work still to be done may be summarized as follows: For those who recognize the crucial role of probability in inductive inference, to develop a consistent, systematic, and relevant reconstruction of the concept of probability; for those who reject induction as an outmoded myth, to elaborate a detailed and comprehensive account of scientific practice that will be reasonably close to the best actual procedures used in reasoning about matters of fact; for those who pin their hopes on the construction of an inductive logic, to remove the constraints imposed by the study of artificially simplified languages and to show in detail how analytical statements of probability can be relevant to the practice of inductive prediction; for vindicationists, to solve the comparative problem of selecting competing hypotheses and to show how eventual convergence in the long run can bear upon short-run judgment; for those who regard induction as a pseudo problem, to articulate the theory of language presupposed and to demonstrate in convincing detail the origins and the character of the stubborn confusions that have infested the subject.

See also Laws of Nature; Probability and Chance.

Bibliography

COMPREHENSIVE STUDIES

The best introduction to the whole subject of induction is still William Kneale, *Probability and Induction* (Oxford: Clarendon Press, 1949). See especially Part II, "The Traditional Problem of Induction." A shorter and more up-to-date discussion is Stephen F. Barker, *Induction and Hypothesis* (Ithaca, NY: Cornell University Press, 1957), which is especially good on the role of simplicity in inductive inference. Georg Henrik von Wright, *The Logical Problem of Induction* (Oxford, 1941; 2nd ed., 1957), is invaluable for its ample discussion of the history of the subject and also contains penetrating criticism. John Patrick Day, *Inductive Probability* (London: Routledge and Paul, 1961), uses somewhat opaque symbolism but is very comprehensive. *Induction: Some Current Issues*, edited by Henry E. Kyburg Jr. and Ernest Nagel (Middletown, CT: Wesleyan University Press, 1963), is a conference report containing edited versions of discussions by Black, Braithwaite, Nagel, Salmon, and others.

TERMINOLOGY

For a good brief treatment of terminology, see Kneale, op. cit., pp. 24–48, which includes discussion of Aristotle's uses of *epagoge*. Kneale is good also in his treatment of intuitive induction and mathematical induction.

S. F. Barker, "Must Every Inference Be Either Deductive or Inductive?," in *Philosophy in America*, edited by Max Black (Ithaca, NY: Cornell University Press, 1965), pp. 58–73, answers in the negative; it is an illuminating effort to distinguish criteria for nondemonstrative inference.

HISTORY OF INDUCTIVE METHODS

André Lalande, *Les théories de l'induction et de l'expérimentation* (Paris: Boivin, 1929), contains brief discussions of Isaac Newton, John Herschel, Claude Bernard, and other scientists, as well as of Bacon and Mill. There is no satisfactory general history of inductive methods.

Most students of Bacon confine themselves to Book I of the *Novum Organum* (available in many editions). The best philosophical commentary on Bacon remains R. L. Ellis's general preface to *The Works of Francis Bacon*, edited by James Spedding, R. L. Ellis, and D. D. Heath (London: Longman, 1857–1854). For a lucid and sympathetic appreciation of Bacon's general program—but with comparatively little discussion of Bacon's views on induction—see the commemorative address by C. D. Broad, *The Philosophy of Francis Bacon* (Cambridge, U.K.: Cambridge University Press, 1926).

For Mill, see *A System of Logic*, 8th ed. (London, 1872), especially Book III, Ch. 3, "On the Ground of Induction," and Ch. 21, "Of the Evidence of the Law of Universal Causation." Ernest Nagel, ed., *John Stuart Mill's Philosophy of Scientific Method* (New York: Hafner, 1950), is a useful selection from the *Logic*, including part of Mill's *Examination of Sir William Hamilton's Philosophy*. The editor's introduction is helpful.

A serious student of Mill will wish to consult his unjustly neglected critic, William Whewell, whose *The Philosophy of the Inductive Sciences* (London: J.W. Parker, 1847)— especially Part II, titled "Novum Organum Renovatum"—is still instructive. A useful summary of Whewell's views is C. J. Ducasse's "William Whewell's Philosophy of Scientific Discovery," pp. 183–217 in *Theories of Scientific Method: The Renaissance through the Nineteenth Century*, edited by Edward H. Madden (Seattle: University of Washington Press, 1960).

For Peirce's views, see the *Collected Papers of Charles Sanders Peirce*, edited by Charles Hartshorne, Paul Weiss, and Arthur Burks (8 vols., Cambridge, MA: Harvard University Press, 1931–1958), especially "Ampliative Reasoning," Vol. II, pp. 272–607. Unfortunately, Peirce's writings on induction are scattered throughout the volumes, out of chronological

order. A concise critical examination is Thomas A. Goudge, "Peirce's Treatment of Induction," in *Philosophy of Science* 7 (1940): 56–68. Part VI of the same author's *The Thought of C. S. Peirce* (Toronto: University of Toronto Press, 1950) has a fuller treatment, for which the rest of the book provides good background.

For Keynes, see *A Treatise on Probability* (London: Macmillan, 1921). Chs. 18–22 are the most relevant; they include, inter alia, Keynes's original ideas concerning analogy. Jean Nicod, "The Logical Problem of Induction," Part II of *Foundations of Geometry and Induction* (London: K. Paul, Trench, Trubner, 1930), contains lucid and trenchant criticisms of Keynes's position. For more recent appraisal, see von Wright, op. cit., pp. 127–132.

Rudolf Carnap, *Logical Foundations of Probability* (Chicago: University of Chicago Press, 1950), is an elaborate treatise that, although still unfinished and in part superseded by Carnap's later studies, remains the most important original source for his views.

The Philosophy of Rudolf Carnap, edited by P. A. Schilpp (La Salle, IL: Open Court, 1963), is now indispensable to the serious student because of its important essays by Carnap's defenders and critics and the detailed comments and replies by Carnap. John G. Kemeny, "Carnap's Theory of Probability and Induction," pp. 711–738, is an outstandingly successful effort to convey the gist of Carnap's position sympathetically; Ernest Nagel, "Carnap's Theory of Induction," pp. 785–825 (vigorously attacked in Carnap's rejoinder, pp. 989–995), expresses at length the misgivings of those who see in Carnap's view a retreat from empiricism; Hilary Putnam, "'Degree of Confirmation' and Inductive Logic," pp. 761–783, is a highly ingenious attempt to demonstrate that a logic based on confirmation must violate accepted canons of scientific method.

Carnap's "The Aim of Inductive Logic," pp. 303–318 in *Logic, Methodology, and Philosophy of Science*, edited by Ernest Nagel, Patrick Suppes, and Alfred Tarski (Stanford, CA: Stanford University Press, 1962), is an important pioneering discussion of the application of inductive logic. Carnap concludes, "Induction, if properly reformulated, can be shown to be valid by rational criteria."

PROBLEM OF JUSTIFICATION

There is no substitute for reading Hume. His own summary, *An Abstract of a Treatise of Human Nature* (London, 1740; reprinted, with introduction by J. M. Keynes and Piero Sraffa, Cambridge, U.K.: Cambridge University Press, 1938), should not be overlooked. Pp. 11–20 express the essence of Hume's position. The serious student must, of course, read *A Treatise of Human Nature*, edited by L. A. Selby-Bigge (Oxford: Clarendon Press, 1896). See especially Book I, Part 3. Sec. 6 contains the famous skeptical attack on the objectivity of causal connection.

See also Hume's *Enquiry Concerning the Human Understanding*, edited by L. A. Selby-Bigge, 2nd ed. (Oxford: Clarendon Press, 1902), especially Sec. 4, "Sceptical Doubts concerning the Operations of the Understanding."

Bertrand Russell, "On Induction," Ch. 6 of *The Problems of Philosophy* (London: Williams and Norgate, 1912), is a lucid and concise version of what is basically Hume's skeptical position.

The best statement of the "new riddle of induction" is in Nelson Goodman, *Fact, Fiction and Forecast* (Cambridge, MA: Harvard University Press, 1955), Chs. 3 and 4. Goodman's position, with some unpublished improvements, is sympathetically discussed in Israel Scheffler, *The Anatomy of Inquiry* (New York: Knopf, 1963), pp. 291–326. The same book is valuable for its lucid appraisal of various theories of inductive confirmation.

REJECTION OF INDUCTION

See Karl Popper, *The Logic of Scientific Discovery* (London: Hutchinson, 1959), especially Ch. 1. John Oulton Wisdom, *Foundations of Inference in Natural Science* (London: Methuen, 1952), is written from a Popperian standpoint; Parts II–IV, pp. 85–232, deal with induction. For criticism of Popper's general position, see John Arthur Passmore, "Popper's Account of Scientific Method," in *Philosophy* 35 (1960): 326–331.

A PRIORI DEFENSES

Donald C. Williams, *The Ground of Induction* (Cambridge, MA: Harvard University Press, 1947), claims to have answered Hume on a priori grounds. For a dissenting verdict, see the extended review by Max Black in *Journal of Symbolic Logic* 12 (1947): 141–144.

Roy F. Harrod, *Foundations of Inductive Logic* (London: Macmillan, 1956), is still another ingenious attempt to show that induction must be successful. For criticism, see Popper's review in *British Journal for the Philosophy of Science* 9 (1958–1959): 221–224; Harrod's reply appears in 10 (1959–1960): 309–312.

INDUCTIVE SUPPORT FOR INDUCTION

Consult Richard B. Braithwaite, *Scientific Explanation* (Cambridge, U.K.: Cambridge University Press, 1953), Ch. 8, "The Justification of Induction," pp. 255–292.

Abner Shimony's severely critical "Braithwaite on Scientific Method," in *Review of Metaphysics* 7 (1953–1954): 644–660, has not been rebutted. On this topic see also H. E. Kyburg Jr., "R. B. Braithwaite on Probability and Induction," in *British Journal for the Philosophy of Science* 9 (1958–1959): 203–220.

A defense of the soundness of self-supporting inductions can be found in Max Black, "Inductive Support of Inductive Rules," pp. 191–208 in *Problems of Analysis* (Ithaca, NY: Cornell University Press, 1954), and "Self-Supporting Inductive Arguments," pp. 209–218 in *Models and Metaphors* (Ithaca, NY: Cornell University Press, 1962). For criticism of Black's views, see Peter Achinstein, "The Circularity of a Self-Supporting Argument," in *Analysis* 22 (1961–1962): 138–141. See also Black's reply in the same journal, 23 (1962–1963): 43–44, and Achinstein's rejoinder, ibid., 123–127.

DEDUCTIVE RECONSTRUCTION

See Bertrand Russell, *Human Knowledge: Its Scope and Limits* (New York: Simon and Schuster, 1948). Russell states and defends postulates of scientific inference in the concluding part, pp. 421–507. Arthur W. Burks, "On the Presuppositions of Induction," in *Review of Metaphysics* 8 (1955): 574–611, is a persuasive exposition by the ablest contemporary defender of deductive reconstruction. See also Burks's article in *The Philosophy of Rudolf Carnap*,

edited by Schilpp (above), and his *Chance, Cause, Reason: An Inquiry into the Nature of Scientific Evidence* (Chicago: University of Chicago Press, 1977). Deductive reconstruction is criticized in most of the articles listed below in the section on induction as pseudo problem.

C. D. Broad, "On the Relation between Induction and Probability," in *Mind* 27 (1918): 389–404, and 29 (1920): 11–45, is an early and unjustly neglected discussion whose second part is a suggestive development of Keynes's ideas.

PRAGMATIC DEFENSES

Herbert Feigl's views are contained in two of his articles, "De Principiis Non Est Disputandum …?," in *Philosophical Analysis*, edited by Max Black (Ithaca, NY: Cornell University Press, 1950), and "Validation and Vindication," in *Readings in Ethical Theory*, edited by Wilfrid Sellars and John Hospers (New York: Appleton-Century-Crofts, 1952), pp. 667–680. The first paper argues the case for vindication as a special mode of justification, and the second enlarges upon the idea.

Hans Reichenbach, *The Theory of Probability* (Berkeley: University of California Press, 1949), is the locus classicus of recent pragmatic defenses; see especially "The Justification of Induction," pp. 469–482. The same author's *Experience and Prediction* (Chicago, 1938) contains a more popular presentation.

Isabel P. Creed, "The Justification of the Habit of Induction," in *Journal of Philosophy* 37 (1940): 85–97, and Everett J. Nelson, "Professor Reichenbach on Induction," in *Journal of Philosophy* 33 (1936): 577–580, are two thorough appraisals and criticisms of Reichenbach's position.

Max Black, "'Pragmatic' Justifications of Induction," in his *Problems of Analysis* (Ithaca, NY: Cornell University Press, 1954), pp. 157–190, is a full-scale attack upon "pragmatic vindication."

Wesley C. Salmon, "The Short Run," in *Philosophy of Science* 22 (1955): 214–221, is an admirable, if ultimately unsuccessful, attempt to avoid reliance upon the infinitely long run. In "Should We Attempt to Justify Induction?," *Philosophical Studies* 8 (1957): 33–48, Salmon elaborately defends the pragmatic approach; Black's "Can Induction Be Vindicated?," in his *Models and Metaphors* (Ithaca, NY: Cornell University Press, 1962), pp. 194–208, is a detailed reply to Salmon.

Salmon's "Vindication of Induction," in *Current Issues in the Philosophy of Science*, edited by H. Feigl and G. E. Maxwell (New York: Holt, Rinehart and Winston, 1961), pp. 245–256, is the latest version of Reichenbach's approach by its ablest contemporary advocate. See also Salmon's contributions to Nagel and Kyburg, eds., *Induction*, above.

INDUCTION AS A PSEUDO PROBLEM

For an introduction to the growing number of studies written from this standpoint, see Alice Ambrose, "The Problem of Justifying Inductive Inference," in *Journal of Philosophy* 44 (1947): 253–272; Max Black, "The Justification of Induction," in his *Language and Philosophy* (Ithaca, NY: Cornell University Press, 1949), pp. 59–88; Frederick L. Will, "Will the Future Be Like the Past?," in *Mind* 56 (1947): 332–347; and Paul Edwards, "Russell's Doubts about Induction," in *Mind* 58 (1949): 141–163. Perhaps the most accessible brief account is Peter F. Strawson, "The

'Justification' of Induction," in *Introduction to Logical Theory* (London: Methuen, 1952), pp. 248–263. Brief criticism of the "linguistic approach is to be found in many of the works listed above. No satisfactorily broad statement of the position of the "linguists" or their critics is yet available.

BIBLIOGRAPHIES AND SURVEYS

Lengthy bibliographies are supplied in the above-mentioned books by Keynes (to 1921), Carnap (to 1951), and von Wright (to 1955).

Black's "Induction and Probability," in *Philosophy in the Mid-century*, edited by Raymond Klibansky (Florence: Nuova Italia, 1958), pp. 154–163, is a critical survey of the work of the decade prior to its publication.

H. E. Kyburg Jr., "Recent Work in Inductive Logic," in *American Philosophical Quarterly* 1 (1964): 249–287, is a highly useful analysis of the main trends, with criticism and an extensive bibliography.

INFERENCE TO THE BEST EXPLANATION

In an inductive inference, we acquire a belief on the basis of evidence that is less than conclusive. The new belief is compatible with the evidence, but so are (possibly many) competing hypotheses that we are unwilling to infer. Such is the situation for a great number of the inferences we make, and this raises a question of description and a question of justification. What principles lead us to infer one hypothesis rather than another? And do we have any reason to believe that these principles are good ones, leading us to accept hypotheses that are true and to reject those that are false? Inference to the Best Explanation offers partial answers to both questions.

According to this model, explanatory considerations are a guide to inductive inference. We decide which of the competing hypotheses the evidence best supports by determining how well each of the competitors would explain that evidence. Many inferences are naturally described in this way. Seeing the ball next to the broken vase, I infer that my children have been playing catch in the house because this is the best explanation of what I see. Charles Darwin inferred the hypothesis of natural selection because, although it was not entailed by his diverse biological evidence, natural selection would provide the best explanation of it. When astronomers infer that a galaxy is receding from the Earth with a specified velocity, they do this because the supposition of such a recession would provide the best explanation of the observed red-shift of the galaxy's characteristic spectrum. When the detectives infer that it was Moriarty who committed the crime, they does so because this hypothesis would best explain the fingerprints, blood stains, and other forensic evidence. Sherlock Holmes to the contrary, this is not a matter of *de*duction. The evidence will not *entail* that Moriarty is to blame, since

it always remains possible that someone else was the perpetrator. Nevertheless, Holmes is right to make his inference, since the supposition of Moriarty's guilt provides a better explanation of the evidence than does the supposition of anyone else's guilt.

Inference to the Best Explanation can be seen as an extension of the idea of "self-evidencing" explanations, where the phenomenon that is explained in turn provides an essential part of the reason for believing the explanation is correct. In the example above, the speed of recession explains the red-shift, but the observed red-shift may at the same time be an essential part of the reason astronomers have for believing that the galaxy is receding at that speed. Self-evidencing explanations exhibit a curious circularity, but this circularity is apparently benign. The recession is used to explain the red-shift and the red-shift is used to determine the recession, yet the recession hypothesis may be both explanatory and well supported. According to Inference to the Best Explanation, this is a common situation: Hypotheses are supported by the very observations they are supposed to explain. Moreover, on this model, the observations support the hypothesis precisely because it would explain them.

Inference to the Best Explanation thus partially inverts an otherwise natural view of the relationship between inference and explanation. According to that natural view, inference is prior to explanation. First we must decide which hypotheses to accept; then, when called upon to explain some observation, we will draw from our pool of accepted hypotheses. According to Inference to the Best Explanation, by contrast, it is only by asking how well various hypotheses would explain the available evidence that we can determine which hypotheses merit acceptance. In this sense, Inference to the Best Explanation has it that explanation is prior to inference.

Although it gives a natural account of many inferences in both science and ordinary life, the model needs further development. What, for example, do we mean by "best?" It is sometimes taken to mean "likeliest" or "most plausible," but Inference to the Likeliest Explanation would be a disappointingly uninformative model, since the main point of an account of inference is to say what leads one hypothesis to be judged likelier than another, that is, to give the symptoms of likeliness. A more promising approach construes *best* as "loveliest." In this view, we infer the hypothesis that would, if correct, provide the greatest understanding.

The model should thus be construed as "Inference to the Loveliest Explanation." Its central claim is that loveliness is a guide to likeliness, that the explanation that

would, if correct, provide the most understanding, is the explanation that is judged likeliest to be correct. This at least is not a trivial claim, but it faces at least three challenges. The first is to identify the explanatory virtues, the features of explanations that contribute to the degree of understanding they provide. There are a number of plausible candidates for these virtues, including scope, precision, mechanism, unification, and simplicity. Better explanations explain more types of phenomena, explain them with greater precision, provide more information about underlying mechanisms, unify apparently disparate phenomena, or simplify our overall picture of the world. But analyzing these and other explanatory virtues is not easy, and it also leaves the other two challenges. One of these is to show that these aspects of loveliness do indeed match judgments of likeliness, that the loveliest explanations tend also to be those that are judged likeliest to be correct. The remaining challenge is to show that, granting the match between loveliness and judgments of likeliness, the former is in fact our guide to the latter.

In addition to offering a description of our inductive practices, Inference to the Best Explanation has been used to justify them, to show that those hypotheses we judge likely to be correct really are so. For example, it has been argued that we have good reason to believe that our best scientific theories are true, since the truth of those theories is the best explanation of their wide-ranging predictive success. Indeed, it has been claimed that the successes of a theory would be inexplicable unless it were at least approximately true. This argument has considerable plausibility, but it faces serious objections. If scientific theories are themselves accepted on the basis of Inferences to the Best Explanation, then to appeal to an argument of the same form to show that those inferences lead to the truth seems to beg the question. Moreover, it is not clear that the truth of a theory really is the best explanation of its predictive success. For one thing, it seems no better an explanation than would be the truth of any other competing theory that happens to share those particular predictions. For another, to explain why our current theories have so far been successful may not require an appeal to truth if scientists have a policy of weeding out unsuccessful theories.

INFINITESIMALS

The ubiquitous use of infinitely small quantities in mathematics dates back at least to the seventeenth century. Despite continuing qualms as to their legitimacy and their supposed elimination as a result of the thoroughgoing reform movement of the nineteenth century, "infinitesimals" have continued to be used, especially in applied mathematics. The logician Adolf Fraenkel gave what was no doubt the widely accepted view when he stated, "The infinitely small is only to be understood as a manner of speaking based on the limit concept, hence a *potential* infinite; it is a matter of variable … [positive] numbers or quantities that can ultimately decrease below any arbitrarily small positive value. A fixed [positive] number different from zero that can serve as a lower bound to all finite positive values is not possible" (1928, p. 114, my translation, emphasis in original). In 1960 Fraenkel's one-time student Abraham Robinson showed how to obtain just such a "fixed number" and thereby vindicated the discredited infinitesimal methods.

The benefits of the free use of infinitesimal methods were amply demonstrated by the success of Gottfried Wilhelm Leibniz's version of the differential and integral calculus and the continued use of these methods by the Bernoulis and especially by Leonhard Euler. Working mathematicians had no difficulty in knowing just which properties of ordinary numbers infinitesimals could be assumed to possess and just when it was legitimate to equate such quantities to zero. But the lack of any clear justification for these methods provided an opening for scathing attacks such as that of George Berkeley. The need for rigorous methods was felt by mathematicians them-

selves and eventually supplied (Edwards 1979, Robinson 1974).

Robinson's key insight was that the methods of model theory could be used to construct a powerful rigorous theory of infinitesimals. Thus, for example, we may consider a first-order language in which a constant symbol is provided as a "name" for each real number, a function symbol is provided as a "name" for each real-valued function defined on the real numbers, and the only relation symbols are = and <. Let T be the set of all true sentences of this language when each symbol is understood to have its intended interpretation. Let δ be a new constant symbol, and let W consist of the sentences of T together with the infinite set of sentences:

$$\delta > 0$$

$$\delta < 1, \delta < \tfrac{1}{2}, \delta < \tfrac{1}{3}, \delta < \tfrac{1}{4},\ldots$$

Since any finite subset of W can be satisfied in the ordinary real numbers by interpreting δ as a sufficiently small positive number, the compactness theorem for first-order logic guarantees that W has a model. But in that model, the element serving to interpret δ must be positive and less than every positive real number (i.e., infinitesimal). The structure with which we began of real numbers and real-valued functions can readily be embedded in the new model. Thus if r is a real number and c_r is the constant of the language that names r, we may regard the element of the new model that serves to interpret c_r as simply r itself. Functions can be embedded in the same way. One speaks of the new model as an enlargement.

Moreover, because $T \subseteq W$, all true statements about the real numbers that can be expressed in our language are also true in this enlargement. A false statement about the real numbers is likewise false in the enlargement: If the statement S is false, then $\neg S$ is a true statement about the reals and hence is also true in the enlargement. It is this transfer principle, the fact that statements are true about the real numbers if and only if they are true in the new enlarged structure, that makes precise just when an assertion about ordinary numbers can be extended to apply to infinitesimals as well.

The enlargement will contain infinitely large as well as infinitesimal elements. This is readily seen by applying the transfer principle to the statement that every nonzero real number has a reciprocal. One may even speak of infinite integers; their existence follows on applying the transfer principle to the statement that for any given real number there is a positive integer that exceeds it.

The basic facts of real analysis can be established on this basis using modes of argument that would earlier have been quite correctly regarded as illegitimate. For example, the basic theorem that a continuous function on a closed interval assumes a maximum value can be proved by dividing the interval into infinitely many subintervals, each of infinitesimal length, and selecting an endpoint of such a subinterval at which the function's value is greatest (Davis 1977, Robinson 1974). By beginning with a more extensive language, it is possible to apply infinitesimal methods to branches of mathematics requiring a more substantial set-theoretic basis (e.g., topology, functional analysis, probability theory). It has even proved possible to use these "nonstandard" methods to settle certain open questions in mathematics.

For those with qualms concerning nonconstructive methods in mathematics, these infinitesimal methods are bound to seem unsatisfactory. Because the underlying language is built on an uncountable "alphabet," the use of the compactness theorem hides an application of some form of the axiom of choice. This in turn is reflected in a basic indeterminacy; we can establish the existence of enlargements but cannot specify any particular enlargement. Robinson himself has emphasized that although nonstandard analysis "appears to affirm the existence of all sorts of infinitary entities," one always has the option of taking the "formalist point of view" from which "we may consider that what we have done is to introduce *new deductive procedures* rather than new mathematical entities" (1974, p. 282, emphasis in original).

INFINITY, AXIOM OF

INFINITY IN MATHEMATICS AND LOGIC

The notion of infinity, and the problems, both philosophical and mathematical, that arise from it have been a central concern for over two millennia. Any serious thought about the nature of space, time, God (or gods), mathematics, and motion quickly leads to more general concerns regarding the notion, or notions, of infinity intimately tied up with such issues. As a result, it is unsurprising that philosophers throughout history have thought deeply about what infinity is, whether the notion is coherent, whether there are infinite entities (or infinitely many entities), and how we can know about such entities if they exist.

This entry focuses on two aspects of the infinite. The first is infinite divisibility, the idea that an object can, in some sense (and perhaps only ideally), be divided into an infinite collection of smaller and smaller parts. The puzzles that arise from such division are central both to philosophical thinking about notions such as part and whole and to the mathematical analysis of lines, surfaces, and other continuous objects. The second aspect to be addressed is already implicit in the first—the idea that there can be infinitely large collections at all. Much of the history of mathematics and philosophy can be seen as an (often indirect) inquiry into the coherence of such collections and how they differ from finite collections.

As a result, this entry will for the most part ignore other interesting, but less central, issues within the literature on infinity, including infinitesimals, mereological theories containing gunk, unrestrictedly general quantification, nonstandard set theories, and nonmathematical uses of the term "infinite" (e.g., theological understandings of the infinite). The discussion below, then, is not meant to be a comprehensive survey of all aspects of infinity (or even all aspects of this notion as it appears within mathematics, logic, and metaphysics), but is instead intended to provide a basic understanding of two important themes underlying hundreds of years of thought on the topic.

INFINITE DIVISIBILITY: ARISTOTLE AND ZENO

Given the long pedigree of thought regarding infinity, it seems apropos to begin at (or near) the beginning, with the ancient Greeks. While mathematics in general, and geometry in particular, was central to Plato's philosophy,

he has little to say regarding the nature of the infinite. His few comments on the topic occur in the *Philebus*, where he equates the infinite with the unlimited, unbounded, excessive, and indefinite.

Identifying the infinite with such notions is, in hindsight, less helpful than one might hope: The surface of a sphere, which in a certain sense has no boundaries or limits, nevertheless has finite area. Extremely large collections can be thought of as excessive yet finite. Indefiniteness has, recently, been associated more with vague phenomenon (such as the boundary between colors) than with the infinite. Thus, Plato's discussion, while interesting, fails to provide clear criteria for distinguishing between finite and infinite collections, relying rather on the idea that we can tell the difference when we see it.

Plato's star pupil, Aristotle, follows his teacher in neglecting to provide a clear definition of the infinite (and in equating it with suspect notions such as unboundedness). Even so, he made an influential contribution by distinguishing between two different types of infinity, or two different ways of conceiving infinite collections. This contribution was due to Aristotle's need to respond to Zeno of Elea's paradoxes.

Zeno presented four paradoxes that, through clever uses of infinity, demonstrated (so it was claimed) that motion was impossible. Here we consider only two: the paradox of Achilles and the paradox of the runner (an adequate response to either can likely be generalized to the others).

The paradox of Achilles is perhaps the best known of Zeno's puzzles. Swift Achilles is to run a race against a tortoise, and the tortoise is given a head start. Zeno argues that, no matter how fast Achilles runs, he can never overtake the tortoise. First Achilles must reach the point at which the tortoise started, call it P_1. By the time he does so, however, the tortoise will have traveled some short distance further, to a point we can call P_2. So Achilles's next task is to run from P_1 to P_2. By the time he achieves this, the tortoise will have traveled a bit further, to P_3. So Achilles's next task is to run to P_3. But by then the tortoise will have reached P_4, and so on.

Thus, according to Zeno, Achilles can never pass the tortoise and win the race, because, no matter how fast he runs, each time he reaches a point where the tortoise was, the tortoise will have moved a bit farther on. Stating the conclusion more carefully, Zeno's argument does not (and was most likely not intended to) show that Achilles cannot overtake the tortoise; rather, it demonstrates that there is a conceptual puzzle regarding how he does so.

Zeno's paradox of the runner is similar, slightly less well known, but mathematically a bit more elegant. Imagine a runner who must run from point 0 to point 1. Before reaching 1, he must reach the midpoint between 0 and 1 (i.e., point 1/2). Once he has reached 1/2, however he must, before he can reach 1, run to the midpoint between 1/2 and 1, (i.e., 3/4). Then he must run to the midpoint between 3/4 and 1 (i.e., 7/8), and then run to 15/16, and 31/32, and so on.

| 0 | 1/2 | 3/4 | 7/8 ... | 1 |

Zeno concluded that, in traveling from 0 to 1, the runner traverses an infinite number of distinct distances.

It is worth noting that this paradox depends on a by now well-known mathematical fact: Some infinitely long lists of numbers (or *infinite series*) have a finite sum. In particular, the construction of the paradox demonstrates an at least implicit awareness that:

$$1 = 1/2 + 1/4 + 1/8 + 1/16 + 1/32 + \dots$$

or, in more modern notation:

$$\sum_{i=1}^{\infty} 1/2^n = 1$$

We can provide an intuitively compelling (although not mathematically rigorous) argument demonstrating this as follows. Set the infinite sum equal to x:

$$x = 1/2 + 1/4 + 1/8 + 1/16 + 1/32 + \dots$$

Multiply both sides by 2:

$$2x = 1 + 1/2 + 1/4 + 1/8 + 1/16 + 1/32 + \dots$$

Subtract the first line from the second, and we obtain the desired result:

$$x = 1$$

As Aristotle realized, there are two puzzles lurking within Zeno's paradoxes, and only one of them is difficult. First, the worry might be that Zeno's arguments suggest that we can accomplish infinitely many tasks in a finite amount of time (for example, traveling through the infinite sequence of distances 0 to 1/2, 1/2 to 1/4, 1/4 to 1/8 … or inhabiting the infinite sequence of points 1/2, 1/4, 1/8 …). This, however, as Aristotle noted, is a misleading way of characterizing the situation, because if we can divide distances in the way envisioned by Zeno, then we can divide time in the same way (so our minute of time can be divided into the first half of a minute, then the next quarter of a minute, then the next eighth of a

minute, …). Rather, according to Aristotle, the puzzle concerns the idea that we can ever complete infinitely many tasks (no matter how they are described). In other words, is the infinite division of either space or time that Zeno envisioned legitimate?

The answer for Aristotle had to be "no," because, as already noted, he equated the infinite with the unbounded or unlimited. As a result it should be impossible to complete infinitely many tasks, because it is impossible to reach the bound or limit of something that, by its nature, is unlimited. Aristotle had little choice but to conclude that there is a mistake lurking within Zeno's argument, and it is in his explanation of this mistake that his potentially/actually infinite distinction makes its appearance.

Zeno's paradoxes result from the fact that line segments are (or at least seem to be) infinitely divisible. Consider an arbitrary (finite) line segment. We can easily divide the line into two halves, producing two parts. Additional divisions, of course, are also possible. The crucial question now arises: How many distinct parts does the line segment contain? In some sense, at least, the correct answer is infinitely many, since for any part we can further subdivide it into two halves, obtaining two more parts. Thus, for any finite number of parts we divide the line into, we can further subdivide those segments to obtain more parts.

Aristotle distinguished this sort of unboundedness—the potentially infinite—from actually infinite collections. On the one hand, a collection is potentially infinite if we can continue to add to it without limit. On the other hand, the actual infinite is, for Aristotle, a completed totality, that is, an unbounded collection that is nevertheless present all at once. In considering the division of a line segment Aristotle writes that "It is always possible to think of a larger number: for the number of times a magnitude can be bisected is infinite. Hence the infinite is potential, never actual; the number of parts that can be taken always surpasses any assigned number" (Physics 207b8).

In understanding Aristotle's potential/actual distinction it is useful to distinguish between three distinct theses:

(1) Any part of a line can be divided into distinct subparts.

(2) A line contains infinitely many distinct parts.

(3) A line contains infinitely small parts.

The first claim, according to Aristotle (and most thinkers since) is undeniable. The third, which asserts the existence of so-called infinitesimals, would be of great importance in the development of the calculus during the seventeenth century. The second claim is, for our purposes, the crucial one. According to Aristotle, claim (2) is ambiguous, having both a true and a false reading.

Aristotle understood the first of these three claims as something such as: given a time t_1, any part of a line that exists at t_1 can be divided into distinct subparts at some future time t_2. Once we recognize the temporal ingredient of claim (1), two distinct readings of (2) are then apparent:

(2a) For any number n, there is a time t such that a line has been (or can be) divided into (at least) n parts at t.

(2b) There is a time t such that a line has infinitely many parts at time t.

Although (2b) implies (2a), Aristotle argued, in effect, that (2a) does not imply (2b): Imagine that we have a line segment in front of us, and each hour we divide up each of its parts into two subparts. Then (2a) is true (assuming we live forever and never forget to carry out the divisions) yet (2b) fails, because there is never a particular time at which we have finished dividing. The collection of parts of a line segment is potentially infinite if (2a) is true, and is actually infinite if (2b) holds.

It is important to note that Aristotle's distinction contains both a constructive aspect and a temporal aspect. First, lines (and other objects) are not presented to us already divided into their parts, rather, the division of an object into its components is somehow a construction that we perform on it. Second, these constructions cannot be carried out all at once, but must be carried out one by one in time. This aspect of Aristotle's view is what prevents the potential infinite from collapsing into the actual infinite, because it allows us to distinguish between a series of ever increasing finite collections spread out through time and an infinite collection existing at a particular time.

Aristotle applied the potential versus actual distinction, not just to parts of line segments, but to the natural (counting) numbers 0, 1, 2, 3, … as well (we include 0 and 1 here because they are now considered to be the first two natural numbers, although Aristotle would not have recognized 0, and perhaps not even 1, as a number at all). The natural numbers, for Aristotle, are potentially infinite, because for any number we have counted to, we can always count one (or ten, or one hundred) numbers fur-

ther. Nevertheless, we will never reach a time when we will have counted out all the numbers.

Aristotle's final contribution lies in his insistence that not only some but all infinities are potential, not actual. Thus, there are no infinitely long line segments, only a potential series of ever longer finite line segments, and no infinitely large collections, only series of larger and larger finite ones.

The denial of absolute infinity provided Aristotle with a solution to Zeno's puzzles: If space and time are only potentially infinite, then the sort of division of space and time necessary for Zeno's construction is illicit. In the paradox of the runner, the runner does not pass through infinitely many different distances (nor does he occupy infinitely many different points, because Aristotle thought that points only exist if a line has in fact been divided into two parts that meet at that point). Rather, given any particular time, there are only finitely many parts into which the distance between 0 and 1 will have been divided into. Of course, at a later time we might further subdivide the distance into a larger (but still finite) collection of parts. It does not follow, however, that we have therefore traveled over infinitely many distances, because the parts of the path from 0 to 1 are merely potentially infinite.

For approximately two thousand years Aristotle's view remained unchallenged—philosophers and mathematicians both (for the most part) denied the existence of actual, completed infinities, arguing that the notion of potential infinity could, within both philosophy and mathematics, fulfill any role that the infinite might need to play.

RIGOR AT LAST: DEDEKIND INFINITY

During the development and rigorization of the calculus (a long, torturous period stretching from the beginning of the seventeenth century to the end of the nineteenth century) it became evident that the further development of classical mathematics required actual infinities. (The details need not detain us here. Suffice it to say at least some infinite collections needed to be viewed as complete, because it became necessary to study arbitrary subcollections of these infinite structures). If Aristotle and his followers were correct, however, and the only viable understanding of the infinite was the potential one, then classical mathematics was facing a crisis.

Fortunately, a number of philosophers and mathematicians stepped into the breach. They were faced with two main mathematical tasks and one philosophical one:

first, to provide a rigorous definition of "infinite"; second, to provide a mathematical theory of the infinite that clarified how the behavior of infinite collections differed from the well-known behavior of finite collections; and third, and perhaps most importantly, to provide a philosophical account of the actual infinite that defended its intelligibility. The first two tasks were successfully carried out during the nineteenth century, by Richard Dedekind (1901) and Georg Cantor (1955) respectively.

Before considering definitions of infinity, it is useful to introduce some terminology. The existence of an actually infinite collection involves the idea that such a collection can be presented all at once, as a completed totality—that is, in some sense, as a single thing. Such totalities, considered as single objects, are called *sets*. The central idea behind *set theory* is that, given any collection of objects (or almost any, see the discussion of *Russell's paradox* below), there exists another object—the set containing exactly the original objects. Thus, if we start out with three distinct persons, Alan, Bob, and Carl, we obtain the following sets:

{Alan}, {Bob}, {Carl}, {Alan, Bob}, {Alan, Carl}, {Bob, Carl}, {Alan, Bob, Carl}

Note that the one-membered set {Alan}, called the *singleton* of Alan, is not the same thing as Alan himself, because {Alan} is a set, yet Alan, who is a person, is not. At this point it should be noted, as well, that the collection containing no objects, the so-called *empty set* { } or ∅, although somewhat puzzling (how can there exist a collection formed out of nothing?) is nevertheless accepted as a set, and thus an object, in most accounts of set theory.

Sets are objects, so there is nothing to prevent us from forming collections of these (i.e., sets of sets), obtaining, for example:

{∅, {Alan}, {Bob}, {Alan, Bob}}

This expression names a single object, a set collecting together four other sets.

There are two important relations that can hold between sets and other objects: *membership* and *subsethood*. The members of a set are those objects that were collected together to form the set. Using "$x \in y$" to express the claim that x is a member of y (and "$\notin$" for nonmembership), we have:

Alan ∈ {Alan}

{Alan}∈ {∅, {Alan}, {Bob}, {Alan, Bob}}

and:

{Alan} ∉ {Alan}

Alan ∉ {∅, {Alan}, {Bob}, {Alan, Bob}}

Our second notion, subsethood, can be defined in terms of membership. Given two sets A and B, A is a subset of B if and only if every member of A is a member of B. This implies that every set is a subset of itself, and, using "$x \subseteq y$" to express the claim that x is a subset of y, we have:

{Alan, Bob} ⊆ {Alan, Bob, Carl}

{Alan, Bob} ⊄ {∅, {Alan}, {Bob}, {Alan, Bob}}

Finally, a *function f* from a set A to a set B, symbolized by:

$f: A \rightarrow B$

is a mapping that assigns to each member of A exactly one member of B. For example, there is a function:

f_1: {Alan, Bob} → {Alan, Bob, Carl}

which maps Alan to Bob and Bob to Carl (f_1 does not map anyone to Alan). We can express this symbolically as:

$f_1(\text{Alan}) = \text{Bob}$

$f_1(\text{Bob}) = \text{Carl}$

Another example is:

f_2: {Alan, Bob, Carl} → {Alan, Bob}

mapping Alan to Bob, Bob to Alan, and Carl to Bob:

f_2 (Alan)   = Bob

f_2 (Bob)   = Alan

f_2 (Carl)   = Bob

There are two conditions on functions that will be crucial in what follows. First, a function is from A to B is *injective* (or *one-to-one*) if and only if no two distinct members of A get mapped onto the same member of B. In the examples above, f_1 is injective, but f_2 is not, because both Alan and Carl both get mapped onto Bob. Second, a function from A to B is *surjective* (or *onto*) if and only if every member of B gets mapped onto by some member of A. f_2 above is surjective, whereas f_1 is not, because neither of Alan or Bob gets mapped onto Alan. A function that is both one-to-one and onto is *bijective*.

We can now consider possible definitions of infinite. One obvious approach suggests itself: To define finite in terms of counting, that is, a set is finite if and only if we can assign 0 the first member of the set, 1 to the second, 2 to the third, … and at some point we reach the last member of the set, to which we assign some natural number. Using the terminology introduced above:

A set A is finite if, and only if, there is a natural number n and a bijective function:

$$f: A \rightarrow \{0, 1, 2, \ldots, n-1\}$$

Thus, on this definition a set is finite if there is a number n and a bijective function from A to the set of natural numbers less than n. A set is infinite if there is no such function.

For example, the set {Alan, Bob, Carl} is finite because:

$$f_3: \{\text{Alan, Bob, Carl}\} \rightarrow \{0, 1, 2\}$$

$$f_3 \,(\text{Alan}) \quad = 0$$

$$f_3 \,(\text{Bob}) \quad = 1$$

$$f_3 \,(\text{Carl}) \quad = 2$$

is bijective, whereas the set of natural numbers {0, 1, 2, 3, …} is, on this definition, infinite.

While this definition provides the desired results, there is a problem. The definition works by determining whether a set is finite or infinite in terms of whether it can be mapped bijectively onto the natural numbers less than n, for some n. The reason this works is that we know, for any number n, that the set of numbers less than n is finite. What could be more obvious? The problem, however, is that the definition lacks the sort of generality required in both mathematics and philosophy. What we want is a criterion that tells us which sets are infinite and which sets are finite. What we have is a criterion that tells us this, assuming that we already know that certain sets of natural numbers are finite.

An appropriately general definition of infinite set was produced by Richard Dedekind in 1888. The definition is based on an insight into infinite collections that traces back to Galileo Galilei (and probably to the ancient Greeks). Galileo noticed that there is a bijective mapping between the natural numbers and the even natural numbers:

$$f_4: \{0, 1, 2, 3, \ldots\} \rightarrow \{0, 2, 4, 6, \ldots\}$$

provided by mapping each number onto its double:

$$f_4(0) = 0$$

$$f_4(1) = 2$$

$$f_4(2) = 4$$

$$f_4(3) = 6$$

etc.

Galileo argued that this provided further evidence against the notion of actual infinity, because if both the natural numbers and the even numbers were completed infinities, then the latter would be a part of the former. The existence of the bijective mapping, however, seemed to imply that there was just as much "stuff" in each infinite collection, violating the (at the time sacrosanct) dictum that the part must be less than the whole.

Dedekind, however, embraced the puzzling nature of this discovery, and proposed an alternative definition that does not rely on prior knowledge that certain sets of natural numbers are finite. Instead, a set is infinite, according to Dedekind, if it can be mapped bijectively onto a proper subset of itself (a subset of a set A is *proper* if it is not identical to A itself):

A set A is *Dedekind infinite* if, and only if, there is a function:

$$f: A \rightarrow A$$

(i.e., a function from a set A to itself) that is injective but not surjective.

A set is (*Dedekind-*) *finite* if there is no such mapping. With this definition in place, actual, completed infinities are at least partially vindicated, insofar as mathematicians and philosophers now have a general, formal criterion for distinguishing between finite and infinite sets.

At roughly the same time Bernard Bolzano (2004) produced a competing definition of infinite set: A set A is infinite if there is a nonterminating series of sets B_1, B_2, B_3, … such that each set in the series is a subset of A, each set in the series is a subset of all sets that follow it in the series, and no set in the series is a subset of any set in the series that precedes it. In other words, a set is infinite if it contains a series of subsets that get "bigger" and "bigger" without end. While Bolzano's definition is especially interesting in light of its obvious connection to Aristotle's ideas regarding the infinite, there are legitimate worries regarding whether the definition is of any help, since "nonterminating series" seems synonymous with "infinite series." Thus, this definition, like the one we began with (but unlike Dedekind's), assumes an understanding of the concept that we are trying to define.

With a rigorous definition of infinite set in hand, the next step in securing the notion of actually infinite from Aristotelian worries would be a well worked out theory of the existence and "behavior" of infinite sets. Much of this theory was worked out by Cantor, and will be the subject of the next section. Before examining Cantor's work, however, it should be noted that, even after the work of

Dedekind and Cantor, not everyone accepted that infinite totalities existed. A number of influential thinkers denied that Dedekind's definition, interesting or not, applied to any complete collections, returning to Aristotle's distinction between potential and actual infinity (although most took Aristotle's idea of the potentially infinite as being potentially extendable in time to be little more than a metaphor). Post-Dedekind/Cantor views of this sort include Kronecker's finitism, Brouwer's intuitionism, Weyl's constructivism, and the later Wittgenstein.

SIZES OF INFINITY: CANTOR'S INFINITE NUMBERS

Georg Cantor began with the idea that infinite sets, like finite sets, have a corresponding number. Such numbers, which measure how many things are contained in a set, are called *cardinal numbers* (or *cardinalities*). We represent the cardinal number of a set A as Card(A).

The idea that infinite collections have cardinal numbers, or, equivalently, that there are "infinite" numbers coming after the natural numbers 0, 1, 2, 3 … , was rejected prior to the nineteenth century on the grounds that infinite numbers required actual infinite totalities, and this in turn (so the story went) implied a contradiction. For example, the great seventeenth-century philosopher, logician, and mathematician Gottfried Leibniz wrote that "I proved beyond any doubt that the number or multitude of all numbers implies a contradiction, if taken as a unitary whole. I think that the same is true of the largest number" (1849, p. 535). One notable aspect of this line of thought is the assumption that the existence of infinite numbers implies the existence of a largest infinite number, or a number of all numbers.

This assumption traces to a rather basic intuition: won't any two "unbounded" or "unlimited" collections, whether complete or potential, contain the same number of elements (or members), because both just keep going and going? Cantor's great contribution to both mathematics and philosophy was his discovery that the answer to this question is "no."

Cantor begins, not by asking which number should be attached to a particular set, but by asking what criteria can be given for deciding when two sets have the same number (independently of which particular number or numbers are involved). To illustrate the difference between the two approaches, consider the following situation: you have two baskets of fruit, one containing apples, the other containing oranges, and you need to determine whether the number of apples in the first bas-

ket is the same as the number of oranges in the second basket.

There are two strategies. First, you could count the apples, count the oranges, and then determine if the two numbers are the same. This strategy corresponds to the first approach, where we first assign particular numbers to sets and then compare them. On the second approach, you repeatedly remove one apple from the first basket and one orange from the second, until you run out of either apples or oranges. When you reach a stage where you cannot remove a pair consisting of one apple and one orange, there are three options: Either there are apples left in the first basket, in which case there are more apples than oranges; or there are oranges left in the second basket, in which case there are more oranges than apples; or both baskets are empty, in which case the number of apples is the same as the number of oranges. (The second strategy, while perhaps more efficient, is less informative, because you do not, in the end, know how many apples or oranges were in the baskets, but only whether or not there was more of one than the other. A similar difficulty arises with regard to the *continuum hypothesis*, which will be discussed below.) The second "pairing" strategy amounts to nothing more or less than attempting to construct a bijective mapping between the set of apples and the set of oranges.

Cantor's insight was in noticing that, although extending the first strategy (counting and comparing numbers obtained) to infinite sets is not viable until we have a well-worked-out theory of infinite cardinal number (which was exactly what he was attempting to formulate), the second strategy can be applied to infinite sets (almost) as easily as to finite ones.

The following principle, a version of what has come to be called *Hume's Principle* and which we can call *Hume's Principle for Sets*, sums up Cantor's approach:

HPS: For any sets A and B:

Card(A) = Card(B)

if, and only if, there is a bijective function $f: A \rightarrow B$.

We supplement this with the following definition of "less than" for cardinal numbers:

Def$_<$: For any sets A and B:

Card(A) < Card(B)

if, and only if, there is an injective function $f: A \rightarrow B$ but no surjective function $g: A \rightarrow B$.

This definition agrees with the intuitive one for finite sets. For example, we can verify that Card({Alan, Bob}) <

Card({Alan, Bob, Carl}) (i.e., two is less than three) by noting that there is an injective mapping from the first to the second (f_1 above provides one of the six possible injective mappings) but there is no surjective mapping, because one of the three members of the latter set will always be "missed."

Consider Galileo's puzzle again. Galileo showed that there was a bijective mapping between the set of natural numbers {0, 1, 2, 3 …} and the set of even natural numbers {0, 2, 4, 6 …}. Thus, Card({0, 1, 2, 3 …}) = Card({0, 2, 4, 6 …}). More surprisingly, Cantor also proved that the set of rational numbers (i.e., all numbers that can be written as a fraction a/b where a and b are both natural numbers) has the same cardinal number as the set of natural numbers. Cantor called this number $\aleph_0$, and a set is *countable* if, and only if, it is either finite or its cardinal number is $\aleph_0$ (reflecting the fact that such sets are the same size as some set of natural, or "counting" numbers). Dedekind's definition of infinite set implies that $\aleph_0$ is the smallest infinite cardinal number; in other words, there is no infinite set that cannot be mapped surjectively onto the natural numbers.

Cantor used $\aleph_1$, $\aleph_2$, $\aleph_3$ … as names for the second, third, fourth … infinite numbers, and sets with these cardinal numbers are called *uncountable*. Providing names for infinite cardinal numbers is one thing, however; showing that there are sets that have those numbers is something else. Thus, Cantor's next task was to demonstrate that there were infinite sets that do not receive $\aleph_0$ as their number, that is, that there are infinite sets "bigger than" the set of natural numbers. He did this in two ways.

The first strategy depends on a second species of number, the *ordinal numbers*. Whereas cardinal numbers measure how many members a set has, ordinal numbers are a measure of particular orderings on that set (compare one, two, three … with first, second, third …). In other words, ordinal numbers attach, not to sets by themselves, but to a set plus an ordering on that set, and the same (infinite) set can correspond to different ordinal numbers if we consider different orderings on it.

More carefully, an ordinal number attaches to a pair consisting of a set A and an ordering ≤ on A. If a set/ordering pair ⟨A, ≤⟩ is to receive an ordinal number, then the relation ≤ must be a well-ordering (we call such pairs well-ordered sets, and represent the ordinal number of a well-ordered set ⟨A, ≤⟩ as Ord(A, ≤)).

We begin with the notion of a *totally ordered set*. An ordering ≤ is a total ordering on A (i.e., ⟨A, ≤⟩ is a totally ordered set) if, and only if, it satisfies the following three conditions (here and below I assume familiarity with the notation of first-order logic):

Antisymmetry: $(\forall x)(\forall y)((x \leq y \wedge y \leq x) \rightarrow x = y)$

Transitivity: $(\forall x)(\forall y)(\forall z)((x \leq y \wedge y \leq z) \rightarrow x \leq z)$

Comparability: $(\forall x)(\forall y)(x \leq y \vee y \leq x)$

More intuitively, a relation on a set A is a total ordering if, and only if: (i) given two distinct objects in A, it cannot be the case that the first is less than or equal to the second and the second is less than or equal to the first (if so, then they would be the same object); (ii) for any three objects in A, if the first is less than or equal to the second, and the second is less than or equal to the third, then the first is less than or equal to the third; and (iii) given any two objects in A, either the first is less than or equal to the second, or the second is less than or equal to the first (this implies that any object in the ordering is less than or equal to itself). Two examples of total orderings are the natural numbers {0, 1, 2, 3 …} on their standard ordering (i.e., $0 \leq 1 \leq 2 \leq 3 \leq …$), and the integers {… −3, −2, −1, 0, 1, 2, 3 …} on their standard ordering (i.e., $… \leq −3 \leq −2 \leq −1 \leq 0 \leq 1 \leq 2 \leq 3 \leq …$).

A totally ordered set ⟨A, ≤⟩ is a *well-ordered set* if and only if the following additional condition holds:

Well-foundedness: $(\forall B \subseteq A)(\exists x \in B)(\forall y \in B)$
$(x \leq y)$

Loosely put, if ≤ is a well ordering on a set A, then there is no "infinitely descending chain" in ⟨A, ≤⟩, that is, there is no infinite sequence $x_1 \geq x_2 \geq x_3 \geq x_4 \geq …$ (although there can be infinitely ascending chains $x_1 \leq x_2 \leq x_3 \leq x_4 \leq …$). The standard ordering on the natural numbers is a well ordering, whereas the standard ordering on the integers is not, because the negative integers form an infinitely descending chain.

Finally, we need the notion of an *order-preserving* function from one ordered set to another:

Given two ordered sets ⟨A, $\leq_1$⟩ and ⟨B, $\leq_2$⟩, and a function *f*: A → B, *f* is *order preserving* if and only if, for any two members *x* and *y* of A, $x \leq_1 y$ if, and only if $f(x) \leq_2 f(y)$.

In other words, if we take two members of A, where the first is, according to the ordering on A, less than or equal to the second, then an order preserving function will map the first object onto a member of B that is, according to the ordering on B, less than or equal to the member of B onto which the second object is mapped.

We can now provide an analogue of *Hume's Principle* for ordinals, which we can call the *Order Type Principle For Sets* (OTP):

OTP: For any well-ordered sets $\langle A, \leq_1 \rangle$ and $\langle B, \leq_2 \rangle$:

$$\mathrm{Ord}(A, \leq_1) = \mathrm{Ord}(B, \leq_2)$$

if, and only if, there is an order preserving bijective function f: A → B.

and provide an analogous definition of *less than* for ordinal numbers:

Def: For any well-ordered sets $\langle A, \leq_1 \rangle$ and $\langle B, \leq_2 \rangle$:

$$\mathrm{Ord}(A, \leq_1) < \mathrm{Ord}(B, \leq_2)$$

if, and only if, there is an order preserving injective function *f*: A → B, but no order preserving surjective function *f*: A → B.

Given this definition, Cantor was able to prove that the ordinal numbers, ordered by < as defined above, are themselves well-ordered.

Cantor also proved that the ordinal number of the natural numbers on their standard ordering is the smallest infinite ordinal number, which he called ω (An ordinal is infinite if it is the ordinal of some well-ordered set $\langle A, \leq \rangle$ where A is infinite, an ordinal is countable if it is the ordinal of some well-ordered set $\langle A, \leq \rangle$ where A is countable, and so on).

The standard ordering on the natural numbers, however, is not the only way to order them. Instead, we might move zero from the beginning to the end, so that (on this ordering) 1 is the least natural number, and zero is greater than any other natural number (i.e., 1, 2, 3, 4, 5 … 0). The ordinal corresponding to this ordering is greater than ω, and there is no ordinal less than this one but greater than ω. Thus, this ordinal, called ω + 1 (because it consists of a "copy" of ω followed by a single element) is the second infinite ordinal. Continuing in this way, we can then move 1 from the beginning to the end (i.e., 2, 3, 4, 5 … 0, 1) obtaining ω + 2, and then ω + 3, ω + 4, … We can then consider the ordering consisting of all of the even natural numbers followed by all of the odd natural numbers (i.e., 0, 2, 4, 6, … 1, 3, 5, 7 …), whose ordinal number is ω + ω, and so on.

Because there are many different ways of well-ordering the natural numbers, resulting in different countable ordinals, a natural question to ask is how many different countable ordinals there are (or, equivalently, how many different types of well-ordering can be constructed from the natural numbers). Cantor proved that

the cardinal number of the set of natural numbers (what Cantor called the *first number class*) is less than the cardinal number of the set of countable ordinals (the *second number class*), and that there is no set whose cardinal number is greater than the former and less than the latter. In other words, $\aleph_1$, the second infinite cardinal number, is the cardinal number of the set of countable ordinals.

We can then go on to ask about the cardinal number of the set of ordinals of well-ordered sets of size $\aleph_1$ (i.e., how many different types of well-ordering are there on a set of objects of size $\aleph_1$?). The answer is $\aleph_2$. How many ordinals of size $\aleph_2$? Surprise, its $\aleph_3$! And so on. In this way, Cantor managed to use ordinal numbers to prove the existence of a series of sets of cardinality $\aleph_1$, $\aleph_2$, $\aleph_3$, and even $\aleph_\omega$ (the first infinite cardinal number that is larger than infinitely many other infinite cardinal numbers). In fact, for any ordinal number α, there is a set whose cardinal number is $\aleph_\alpha$.

Cantor had a second means by which to prove that there are uncountably infinite sets, a method that relies on the notion of *powerset*. The powerset of a set A (or $\wp(A)$) is the set that contains exactly the subsets of A. For example:

$\wp(\{\text{Alan, Bob}\}) = \{\emptyset, \{\text{Alan}\}, \{\text{Bob}\}, \{\text{Alan, Bob}\}\}.$

Notice that whereas {Alan, Bob} has two members, its powerset has $2^2 = 4$ members. This holds more generally: if κ is the cardinal number of a set A, then 2^κ is the cardinal number of $\wp(A)$ (even for infinite sets).

Cantor proved that, for any set A, Card(A) < Card($\wp(A)$). The method of proof is known as the method of *diagonalization*, and generalizations of it have become immensely important in mathematics. For more technically interested readers, a proof follows (readers not interested in purely mathematical matters may skip the next paragraph).

We can provide an injective function from A to $\wp(A)$ by mapping each member of A onto its singleton (because, for each member of A, its singleton is a subset of A and thus a member of $\wp(A)$). No mapping from A to $\wp(A)$ can be surjective, however. Let f: A → $\wp(A)$ be an arbitrary function from A to its powerset. Define the set B as follows: for any object *x*, $x \in B$ if, and only if, $x \in A$ and $x \notin f(x)$. Assume, for *reductio*, that there is $c \in A$ such that $f(c) = B$. By the definition of B, we have $c \in B$ if, and only if, $c \in A$ and $c \notin f(c)$, which implies that $c \in B$ if, and only if, $c \notin B$. Contradiction, so *f* cannot be surjective.

Thus, the cardinality of any set is less than the cardinality of its powerset, and, as a result, for any cardinal number $\aleph_\kappa$, $\aleph_\kappa < 2^{\aleph_\kappa}$. We might wonder why anyone would make all this fuss over powersets, however. Haven't we already seen that we can construct larger and larger sets, and thus obtain larger and larger cardinal numbers, using the ordinal numbers?

There are two aspects of Cantor's diagonalization result that are noteworthy. The first concerns the import of cardinality results for ordinary mathematics. We might wonder why everyday mathematicians (and ordinary nonmathematicians) should worry about different "sizes" of infinity, because neither ordinary folk nor most professional mathematicians run across infinite sets of ordinal numbers in their everyday business. Cantor's result, however, connects the theory of cardinal numbers to more intuitive, everyday mathematical concerns, because the cardinal number of the set of real numbers (i.e., the cardinal number of the set containing all the numbers on the continuous number line) is $2^{\aleph_0}$. As a result, there are more points on a continuous line than there are natural numbers! Because real numbers and lines are commonly used within basic mathematics, this result provides a direct connection between Cantor's theory and the practice of everyday measurement and mathematics.

The second reason that Cantor's result regarding powersets is interesting is that it introduced one of the great unsolved problems of mathematics. One might wonder, because we have the notation $\aleph_0$, $\aleph_1$, $\aleph_2$, … $\aleph_\omega$ … for the series of cardinal numbers, why we use a different notation ($2^{\aleph_0}$) for the cardinal number of the powerset of the natural numbers. The reason is simple: Although we know that $2^{\aleph_0}$ is larger than $\aleph_0$, we do not know how much larger. In particular, we do not know whether Cantor's *continuum hypothesis*:

$$2^{\aleph_0} = \aleph_1$$

is true or false. The truth of the continuum hypothesis amounts to the claim that there are no sets that are strictly larger than the set of natural numbers yet smaller than the set of real numbers. (Our account of cardinal numbers failed to settle this problem because our bijection strategy tells us whether one number is larger without necessarily telling us how much larger.)

More generally, for any ordinal number α, we can ask whether:

$$2^{\aleph_\alpha} = \aleph_{\alpha+1}$$

is true. The claim that the above is true for all ordinals α is know as the *generalized continuum hypothesis*.

Despite great effort, Cantor (and others that followed him) failed to settle the issue one way or another. In retrospect, this is not surprising. During the 1940s Kurt Gödel (1986, 1989) proved that if the standard principles of set theory are consistent, then they do not allow one to refute the continuum hypothesis, in other words, adding the continuum hypothesis to standard set theory does not lead to inconsistency. Roughly two decades later Paul Cohen (1963, 1964) proved that the same basic axioms fail to prove the continuum hypothesis as well (again, assuming that standard set theory is consistent). As a result, we can add either the continuum hypothesis or its negation to standard set theory, and either way no contradiction results.

THE INFINITELY LARGE TODAY: ZERMELO FRAENKEL SET THEORY

Of course, the Gödel/Cohen result is not all that interesting until one knows what the standard axioms of set theory are. The theory in question is called *Zermelo Fraenkel set theory* (or ZFC) and consists of the following axioms and axioms schemes (assume here that the quantifiers range only over sets).

First, we have the *axiom of extensionality*:
Extensionality: $(\forall x)(\forall y)(x = y \leftrightarrow (\forall z)(z \in x \leftrightarrow z \in y))$

which says that there cannot be two distinct sets with exactly the same members (i.e., sets are individuated by their members). Next, we have two purely existential axioms, that is, axioms that assert outright the existence of objects. The *empty set axiom*:
Empty Set: $(\exists x)(\forall y)(\neg\, y \in x)$

states that there is a set that contains no members (i.e., $\emptyset$). The *axiom of (Zermelo) infinity*:
Infinity: $(\exists x)(\emptyset \in x \wedge (\forall y)(y \in x \to \{y\} \in x))$

states that there is a set that contains the empty set and the singleton of every set which it contains (i.e., the set contains $\emptyset$, $\{\emptyset\}$, $\{\{\emptyset\}\}$, $\{\{\{\emptyset\}\}\}$ …).

Following these we have what we can call conditional existence axioms, which tell us which sets can be "built up" from previously existing objects. The first of these is the *pairing axiom*:
Pairing: $(\forall x)(\forall y)(\exists z)(\forall w)(w \in z \leftrightarrow (w = x \vee w = y))$

The pairing axiom asserts that, given any two objects, there is a set that contains exactly those two objects and nothing else. The pairing axiom guarantees that the sin-

gleton of any object exists (because we can just take the pair of an object and itself). Next we have the *union axiom*:

Union: $(\forall x)(\exists y)(\forall z)(z \in y \leftrightarrow (\exists w)(w \in x \wedge z \in w))$

which states that, given any set, there is second set that contains exactly the members of the members of the first. Unsurprisingly, we also have an axiom asserting the existence of the powerset of any set:

Powerset: $(\forall x)(\exists y)(\forall z)(z \in y \leftrightarrow (\forall w)(w \in z \rightarrow w \in y))$

Our next principle, the *axiom of choice*, states that, given any set of nonempty pairwise disjoint sets, there exists a second set that contains exactly one member from each of the sets contained in the original set. The axiom of choice is often replaced with a more easily understood, but provably equivalent, principle called the *well-ordering principle*:

Well-Order: $(\forall x)(\exists R)(<x, R> \text{ is a well-ordering})$

The well-ordering principle guarantees that for any set, no matter how large, there is a relation that well-orders its members. During the first half of the twentieth century the status of the axiom of choice was highly controversial; since then it has become a standard part of the everyday mathematician's toolkit.

Our final two conditional existential principles take the form, not of single axioms, but axiom schemes, which have infinitely many instances. The first is the *axiom(s) of separation*. Given any condition Φ expressible in the language of set theory:

Separation: $(\forall x)(\exists y)(\forall z)(z \in y \leftrightarrow (z \in x \wedge \Phi z))$

This axiom states that, given any set and any condition on objects, there exists a set that contains exactly the members of the original set that satisfy the condition in question. The second schematic principle is the *axiom(s) of replacement*, which consists of all instances of:

Replacement: $(\forall x)(\exists y)(\forall z)(z \in y \leftrightarrow (\exists w)(w \in x \wedge f(w) = z))$

where *f* is any function definable in the language of set theory. Put loosely, given any set and any function, replacement insures that there is a set containing exactly the objects obtained by applying the function to the members of the original set.

The final axiom of *Zermelo Fraenkel set theory* does not assert the existence of any sets, but instead imposes a restriction on what sorts of sets exist. The *axiom of foundation*:

Foundation: $(\forall x)((\exists y)(y \in x) \rightarrow (\exists z)(z \in x \leftrightarrow \neg (\exists w)(w \in x \leftrightarrow w \in z)))$

asserts that any nonempty set (i.e., any set other than $\emptyset$) contains as a member some second set that has no members in common with the original set. Although it is difficult to sum up the consequences of this axiom in simple terms, its main purpose it to rule out the existence of sets that contain themselves, such as the (potential) set that has itself as its only member, that is, $\Omega = \{\Omega\}$.

When confronted with such a list, a number of questions naturally arise, including: (1) Might there be a simpler set of principles that does the same job?; (2) Why have we chosen these principles?; (3) Might there be additional principles that we have overlooked? Complete answers to all of these questions are beyond the scope of the present article, but partial answers can at least be given.

Regarding the first question, we can rule out one initially promising simplified theory, *Naive Set Theory*, which has one axiom schema. The principle in question is the *naive comprehension principle*:

Naive Comp: $(\exists y)(\forall z)(z \in y \leftrightarrow \Phi(z))$

which states that, for any condition whatsoever (as long as we can express it in our set theoretic language), there is a set containing exactly the objects that satisfy that condition (note the similarity to separation above). The naive comprehension principle entails all of the axioms given above. Unfortunately, however, it also entails a contradiction, as was famously proved by Bertrand Russell (1996).

The reasoning, which has come to be known as Russell's paradox, proceeds as follows. Given naive comprehension, some sets will be members of themselves (such as the set of all sets) and some will not (such as the empty set). Because a set's not being a member of itself is a condition expressible in the language of set theory (i.e., $x \notin x$), if the following instance of naive comprehension:

$$(\exists y)(\forall z)(z \in y \leftrightarrow x \notin x)$$

were true then there would be a set that contains exactly those sets that are not members of themselves. Call this (supposed) set the *Russell Class*, or R (collections too ill-behaved to form a set are called *proper classes*, although this terminology obscures the fact that such "classes" cannot be objects at all). To obtain the contradiction, we need only ask whether R is a member of itself. By the criteria just stated, we can conclude that R is a member of itself if, and only if, it is not a member of itself. The contradiction is evident. (Similar arguments demonstrate

that there cannot be a set of all ordinals, a set of all cardinals, or a set of all sets.)

Thus, we must reject naive comprehension, and with it any conception of set that allows for the existence of the Russell Class. ZFC provides us with one means to achieve this. The next question, however, is why we have chosen these axioms, because presumably there are other collections of principles that would do the same job. The answer is that the axioms were not chosen at random, nor was their selection based merely on their individual plausibility. Instead, these axioms were selected because they correspond to natural thoughts regarding how one should separate the legitimate sets from those "collections," such as the Russell Class, that are not well-behaved enough to correspond to sets.

There are, roughly speaking, two intuitive pictures of the universe of sets that have motivated the formulation of ZFC. The first, and more influential, is founded on the idea that each set is built up from other sets or objects that are simpler, or at least prior to, the set in question. This notion of set is known as the *iterative conception of set*, and is summarized by George Boolos:

> According to the iterative, or cumulative, conception of sets, sets are formed at stages; indeed, every set is formed at some stage of the following "process": at stage 0 all possible collections of individuals are formed … The sets formed at stage 1 are all possible collections of sets formed at stage 0, … The sets formed at stage 2 are all possible collections of sets formed at stages 0 and 1. The sets formed at stage 3 are all possible collections of sets formed at stages 0, 1, and 2 … The sets formed at stage 4 … In general, for any natural number n, the sets formed at stage n are all possible collections of sets formed at stages earlier than n, i.e. stages $0, 1, … , n-1$. Immediately after all stages 0, 1, 2, … there is a stage, stage ω. The sets formed at stage ω are, similarly, all possible collections of collections of sets formed at stages earlier ω, i.e., stages $0, 1, 2, …$ After stage ω comes stage $\omega+1$: at which … In general, for each α, the sets formed at stage α are all possible collections of sets formed at stages earlier than α. There is no last stage: each stage is immediately followed by another. Thus there are stages $\omega+2, \omega+3, …$ and so it goes. (1989, p. 88)

Another notion that has been used to justify the particular choice of axioms constituting ZFC (and which is closer to what Cantor originally had in mind) is the *limitation of size conception of set*. The underlying thought is

that problematic collections, such as the Russell Class, are not sets because they are, in some sense, too big. Boolos sums up the limitation of size conception as the view that "objects form a set if and only if they are not in one-one correspondence with all the objects there are" (1989, p. 90), in other words, a collection forms a set if, and only if, it is smaller than the universe of all sets or all objects.

The exact role that such conceptions of set can, and should, play within the philosophy and practice of set theory is something of an open question. One particular worry surrounding such intuitive pictures is that the axioms of *ZFC* do not all seem to follow from a single conception. For example, the powerset axiom seems basic on the iterative conception of set but less obvious on a limitation of size understanding, whereas the axiom of replacement seems straightforward on the latter approach but somewhat questionable on the iterative conception. Nevertheless, we can at least recognize that these conceptions played a significant role in the actual choice of axioms included within ZFC.

The final question to ask is whether there might be additional axioms that can be added to the basic theory. The answer, of course, is "yes." We have already seen one such principle, the continuum hypothesis. As we noted, we can add either the continuum hypothesis or its negation to ZFC, and in either case we obtain a consistent theory. If one thinks there is a unique universe of sets (and debate rages over this question) then at most one of these theories can be correct. Even so, the Gödel/Cohen results are enough to guarantee that ZFC alone leaves at least some set theoretic questions unanswered.

There is another type of question to which ZFC provides only a partial answer, namely determining how many sets there are. The axioms of ZFC imply that the universe of sets is larger than any particular set, otherwise the axiom(s) of replacement would provide us with a set of all sets that, using the axiom(s) of separation, would provide us with the Russell Class and a contradiction. Thus, we can ask: How big must the universe be in order to satisfy the axioms of ZFC?

Before providing the answer, we need a few more definitions. First, the *supremum* of a set of cardinal numbers A (i.e., sup(A)) is the smallest cardinal greater than or equal to each of the cardinal numbers in the set. Second, a cardinal number κ is *regular* if and only if, given any set of cardinals A, if card(A) $< \kappa$ and, for every cardinal $\gamma \in$ A, $\gamma < \kappa$, then sup(A) $< \kappa$ (intuitively, a cardinal κ is regular if we cannot reach it by summing up smaller cardinals unless we add up at least κ-many smaller cardinals). Finally, a cardinal κ is *strongly inaccessible* if and

only if it is uncountable, it is regular and, for each cardinal γ less than κ, 2^{γ} is also less than κ.

We can now answer the question just raised: any collection of objects that satisfies the axioms of ZFC has a cardinal number at least as big as the first strongly inaccessible cardinal number. (We are fudging here a bit, because we have assumed that only sets have cardinal numbers. One should consult a good textbook to see the formal details.)

If there must be (according to the axioms of set theory) at least strongly inaccessibly many objects, our next question might be: Why should there not be a set that is that big? The answer, according to set theorists, is that there is (or at least, it is worth exploring the assumption that there is). Thus, one of the most common axioms added to ZFC is the *strong inaccessible cardinal axiom*, which is equivalent to the claim that there is a set whose cardinal number is strongly inaccessible.

We need not stop here. Once we have determined how big the universe needs to be in order to satisfy all of the axioms of ZFC plus the strong inaccessible cardinal axiom, we can add axioms that assert the existence of even larger sets (and thus larger cardinal numbers). This process can continue indefinitely.

Thus, recognition of the fact that there is no set of all sets and no largest set leads us to posit the existence of larger and larger sets, resulting in stronger and stronger theories. Principles that assert the existence of extremely large sets are called *large cardinal axioms* (technically, a *large cardinal* is any cardinal number whose existence cannot be proved from the axioms of ZFC alone). Surprisingly, large cardinal axioms often have consequences for less esoteric areas of mathematics, such as the theory of the real numbers, although for the most part they fail to impact the status of the continuum hypothesis. In addition, adopting stronger theories including large cardinal axioms allows us to prove the consistency of weaker theories. As a result, the study of large cardinal axioms is one of the most fruitful areas of research within set theory.

The introduction of large cardinal axioms is one instance of a more general method for generating new set theoretic principles. The method, known as *reflection*, assumes that, for any sentence true of the entire set theoretic universe, there will be a set such that the sentence will also be true when restricted to that set. Thus, letting *SI* be the claim that the universe contains strongly inaccessibly many sets, reflection tells us that, because *SI* is true, *SI* must be true when restricted to some set (i.e.,

there is a set that contains inaccessible many other sets as members, or, equivalently, there is a set whose cardinal number is a strong inaccessible cardinal).

Interestingly, reflection principles imply (and in some cases are equivalent to) strong versions of the axiom of choice. For example, let Φ be the claim that there is no well-ordering on the entire universe of sets. Reflection implies that if Φ is true, then there is some set whose contents cannot be well ordered. The axiom of choice is equivalent to the claim that every set can be well-ordered, however, so, if we accept both the axiom of choice and reflection, then Φ must be false; in other words, there must be a relation that well-orders the entire universe of sets. This thesis, known as *global choice*, is stronger than the axiom of choice.

We can now observe the great irony of the theory of the infinite. The revolution in the mathematics and philosophy of the infinite occurred in late nineteenth century when mathematicians such as Cantor and Dedekind abandoned the Aristotelian view that infinite collections could not, and should not, be thought of as completed totalities (i.e., sets). Their account of infinite totalities, however, and subsequent work on large cardinals, suggests a universe of sets that in some sense is ever expanding, with no upper limit to the size or variety of sets themselves. As a result, Aristotle was at least partially right, because there are collections (such as the collection of all objects, or all sets) that cannot, and should not, be thought of as completed, definite totalities.

Instead, the universe of sets, considered as a whole, is what has come to be called *indefinitely extensible*. Russell, reflecting on the paradoxes that arise when some intuitive "collections" are treated as sets (such as the paradox that bears his name) described the situation as follows:

> A concept is indefinitely extensible if, for any definite characterization of it, there is a natural extension of this characterization, which yields a more inclusive concept; this extension will be made according to some general principle for generating such extensions, and, typically, the extended characterization will be formulated by reference to the previous, unextended characterization. (1963, pp. 195–196)

Understanding Russell's "definite characterization" as the contents of a set, any time we think we have collected together all the objects, or all of the sets, together into a single set, there will turn out to be more objects, or sets, which we somehow missed. To put the point loosely, Cantor's embrace of the actually infinite has led us, in the

end, to the recognition that the set theoretic hierarchy itself is (or is something very much like) potentially infinite.

ACTUAL INFINITY AND INFINITE DIVISIBILITY

As we saw at the beginning of this entry, Aristotle's solution to Zeno's paradoxes relied on the fact that we do not accomplish infinitely many things when we run from point 0 to point 1, because it is never the case that all of the parts of this journey (including the infinite sequence of distances 0 to 1/2, 1/2 to 1/4, 1/4 to 1/8, …) are present at one time. This solution relied, in turn, on the distinction between potential and actual infinity and on Aristotle's insistence that the actual infinite is illusory. If, however, our post-Cantorian mathematical view allows, and even embraces, actually infinite collections, then we are left with the possibility that the problematic parts of the runner's path from 0 to 1 are actually present as a completed totality. If so, then, assuming that motion is possible, it follows that we can accomplish infinitely many tasks (and we do so every time we wiggle our little finger!)

The most tempting response to this line of thought is "So what?" We might be surprised to learn that any action (no matter how slight) involves infinitely many tasks, but this astonishing fact is little more than the result of a clever (and perhaps misleading) description of the event. The movement from 0 to 1 might be, on one description, composed of infinitely many smaller motions, but it can also be viewed as a single continuous action, that of moving from 0 to 1. It is this latter fact that explains how we can accomplish the movement, and furthermore do so in a finite amount of time.

A task that consists of infinitely many subtasks carried out in a finite amount of time (such as Zeno's description of the runner traveling from 0 to 1) is called a *supertask*. Once we admit that Zeno was right, and we can sometimes carry out supertasks, problems emerge. There are other easily describable supertasks that seem to lead to paradoxes. Two of the most famous are *Thompson's Lamp* and *Bernardete's Paradox*.

Imagine an ideal lamp (indestructible, and able to be switched on or off instantaneously) that, at exactly 12:00, is turned on. 1/2 minute later, it is switched off, then 1/4 minute later it is switched back on, then 1/8 minute later it is switched off, and then 1/16th minute later it is switched on, … The infinite series of switchings will be completed at exactly 12:01. The puzzling question that arises is: Will the lamp be on or off once the supertask is completed? There seems to be no good reason to answer one way rather than another. Nevertheless, a lamp, even an ideal one, must be either on or off.

Thompson's Lamp is similar to Zeno's paradox of the runner in that it divides a unit of time into the first half, the first half of the second half, the first half of the last fourth, the first half of the last eighth, … Bernardete's paradox, however, forces us to bizarre (if not outright contradictory) conclusions using the mirror image of this division, namely dividing a unit of time into the last half, the last half of the first half, the last half of the first fourth, the last half of the first eighth, … (more intuitively, we can see it as having the structure … $+ 1/32 + 1/16 + 1/8 + 1/4 + 1/2$ instead of $1/2 + 1/4 + 1/8 + 1/16 + 1/32 + …$).

José Bernardete constructs a number of different versions of his paradox, here we will consider a particularly striking formulation. Imagine an object that exists up until 12:00, when an infinite series of gods take notice of it. The gods are omnipotent and, additionally, they always carry out the actions they decide upon. The first god decides that if the object still exists at 1/2 minute after 12:00 then he will annihilate it (he will do nothing otherwise). The second god decides to annihilate the object if it still exists at 1/4 minute past 12:00 (and again, do nothing otherwise). The third god decides to annihilate the object at 1/8 minute after 12:00 if it still exists, and so on. There is no threat to the existence of the object other than the intentions of each of the infinite series of gods. We can conclude that the object will suddenly cease to exist at exactly 12:00, yet nothing (and in particular, no god) will have caused its destruction.

First of all, assume that the object exists past 12:00. The there must be some fraction of a minute $1/x$ such that the object existed for (at least) that long after 12:00. If so, however, then one of the gods failed to live up to his intentions, because there will be some god in the list who decided to destroy the object if it still existed at $1/y$ minutes past 12:00 where $1/y$ is less than $1/x$ (because the series 1/2, 1/4, 1/8 1/16… tends to zero). But this contradicts the fact that the gods always carry out their intentions. Thus, the object will cease to exist at 12:00.

The natural assumption to make is that one or more of the gods must have destroyed it, but we can see this is incorrect as well. Each of the gods decided to destroy the object at a time after 12:00 (and to do nothing otherwise). Because the object did not survive past 12:00, the gods did nothing. Thus, the object blinks out of existence at exactly 12:00 yet nothing acted in such a way as to cause its disappearance. Even if not exactly paradoxical, Bernardete's paradox is deeply puzzling.

Of course, unlike Zeno's runner, both of these puzzles begin with an absurd situation. On the one hand we have a lamp that can be turned on and off arbitrarily fast and infinitely many times without malfunction, on the other we have an infinite collection of gods (most of us nowadays still puzzle over whether or not there is even one god!). It is tempting to conclude that the proper reaction to these puzzles should be mere amusement but not worry, because they concern situations that are at such a distance from our everyday experience of the world.

This would be a mistake. Both Thomson's Lamp and Bernardete's paradox are intended to challenge our understanding of the infinite and infinite divisibility. To dodge such challenges by noting that they require physically impossible situations or events is to miss the point. Surely neither an indestructible lamp nor an infinite pantheon of gods is logically impossible, and if they are logically possible then their behavior is relevant to our understanding of the infinite (which is, after all, a logical, or at least mathematical, concept). Thus, these puzzles, and others like them, are not mere curiosities but instead represent important unsolved problems confronting the coherence of, and our understanding of, the notion of infinity at the heart of mathematics and philosophy.

This entry ends in roughly the same way in which it began, with a discussion of infinite divisibility. This is the topic Aristotle focused on, and where his notion of the potentially infinite gained its greatest (albeit temporary) success. Even as we abandoned Aristotle's proscription on the actually infinite and embraced modern set theory, puzzles such as Russell's paradox and the nonexistence of a set of all sets prevented us from rejecting the potentially but not actually infinite altogether. Finally, given our acceptance of at least some actually infinite collections, paradoxes similar in structure to those that Aristotle first considered continue to plague our understanding of collections that keep going and going and going and going …

INFINITY IN THEOLOGY AND METAPHYSICS

It would be profitless (even if it were possible) to catalog every nuance that the word *infinity* possesses in minor, as well as major, thinkers. Fortunately, the dominant strands are clear. Among these the theistic one is the most important both historically and in terms of contemporary debate.

GREEK PHILOSOPHY

ANAXIMANDER. The first Western philosopher to speculate on infinity was the pre-Socratic Anaximander. By the infinite (*to apeiron*) he meant a limitless substance from which the limited things that constitute the world have come. This substance is limitless in three respects: It is eternal, not having a beginning or an end; it is inexhaustible; and it lacks internal boundaries and distinctions. But it is not spatially unlimited, for Anaximander (almost certainly) conceived it as a sphere. Also, it is not qualitatively indeterminate, like Aristotle's unformed matter, for it contains nature's basic elements in a fused, nonseparated state.

PYTHAGORAS. The Pythagoreans adopted Anaximander's concept. Some of them identified it with air (which Anaximenes considered to be the basic constituent of the universe). But their main contribution was to posit a limit (*peras*) as a principle that gives structure to the limitless or infinite. This limit was mathematical; the limitless once limited gives the point, twice limited the line, thrice limited the plane, and four times limited the solid. Later writers interpreted Pythagoras theologically. Thus in the *Placita* we are told that he believed in two principles—the monad (God, the Good, the essential nature of the One, *Nous* alone and by itself) and the indefinite dyad (or evil, which is bound up with materiality and multitude).

PLATO. Plato's speculations on infinity are contained in his *Philebus.* He gives a fourfold classification of "all that now exists in the universe." The whole world can be viewed in terms of the unlimited, limit, mixture, and the cause of the mixture. This theory is an application of the axiom that the nature (and therefore the good) of anything consists in an intelligible order or proportion. The cosmic cause mixes limit with the unlimited and so imposes structure on the world. In 15D–17A Plato interprets the *peras-apeiron* contrast logically. The unlimited stands for particulars, and the limited for the species into which they can be put. But in 23C–26D the contrast has an ontological significance of a Pythagorean kind. The limitless consists in a collection of opposites (for example, hot and cold, dry and moist). Limit consists in "all that puts an end to the conflict of opposites with one another, making them well proportioned and harmonious by the introduction of number" (25E). This principle of limitation is essential also in the moral realm. Plato affirms that human pleasures (which, in themselves, tend to unlimited excess) ought to be rationally controlled by a law and order that are marked by limit.

Thus, in classical Greek philosophy *infinity* represents a substratum that is formless, characterless, indeterminate. It is a pejorative word. An entity is good to the extent that it is limited by form. The Pythagoreans identified this form with numerical ratios. But, as the *Philebus* shows, it can be nonnumerical (such as a universal essence or the personal activity of reason).

An important fact emerges from this survey. Plato could not envisage God (or the divine) as infinite. If God is perfect, he must represent the principle of limit. The cause of cosmic mixture in the *Philebus* is equivalent to the Demiurge in the *Timaeus.* The latter's task is to impose intelligible form on preexistent matter and thereby make an ordered whole. Otherwise the world would be a vast *apeiron*—a formless, unintelligible chaos. Hence, to say that he is *apeiros,* or that the Forms that he copies are *apeira,* would have seemed self-contradictory.

PLOTINUS. Plotinus occupies a place between Plato and Christian theologians who, if they are orthodox, regard infinity as the first among God's attributes. Plotinus applied the concept of the infinite, or unbounded (*apeiron* or *aoriston*), to two categories of being. First, he applied it to matter, which is evil because it tends intrinsically to formlessness. In this he developed philosophical tradition. But second, he applied it to the divine hypostasis. Thus, he called Mind infinite because of its endless power, its complete unity, and its self-sufficiency. Yet while he says that the One is formless, he does not say that it is infinite. The history of *apeiron* prevented him from predicating it of the Absolute. He expressed the infinite nature of the One by denying that any positive idea abstracted from finite experience is applicable to it.

MEDIEVAL AND MODERN PHILOSOPHY AND THEOLOGY

Throughout the postclassical period of Western thought it has been widely assumed that God, or the Absolute, is infinite, or limitless. The division lies between those philosophers (such as Giordano Bruno, Benedict de Spin-

oza, and G. W. F. Hegel) who interpret God pantheistically and those (especially Christian theists) who hold that he wholly transcends the world. According to the first group of thinkers, the world, being divine, is also infinite (even if particular things and persons reflect its infinity in limited degrees). According to the second group, the whole world is finite (as created), and only God (as the Creator) is infinite.

PANTHEISM. The clearest example of the pantheistic group is Spinoza. Having posited one substance (God or nature), he affirmed that it must be infinite both in its essence and in the number of its attributes. God must be infinite in his essence because if he were finite, we could suppose the existence of something else by which he is limited, so that he would not be the sole reality. His attributes must be infinite because if his essence is infinite, there must be an infinite number of ways in which it can be conceived.

Hegel's theory is more dynamic and complex. It was based on the conviction that finite and infinite are correlative terms within a single system of thought and reality. The Absolute Spirit (God) is infinite. But it does not exist outside the finite spirits through whom it manifests itself. Since the world is the manifestation of the Absolute, and since the Absolute requires the world for its development, we can predicate infinity either of the Absolute (considered as an identity-in-differences) or of the world (considered as a rational totality). Hegel considered Christianity to be the highest form of religion because it represents a perfect reconciliation between man and God, the finite and the infinite.

Any theory that views the finite as, in some sense, the self-expression of the infinite is exposed to two basic objections.

(1) The world (so the theist claims) is not limitless. It is limited in two main ways. First, it is morally imperfect. The premise of Immanuel Kant's moral argument for immortality is irrefutable. We cannot in this life bring our wills into complete accordance with the moral law, and even if we could do so, the spatiotemporal order could not fulfill our deepest longings (as A. E. Taylor argued in his Gifford Lectures). Second (and this is the core of theism), the world in all its aspects bears the marks of radical contingency, so that its existence cannot be explained unless we suppose it to be derived from a transcendent being who is infinite or absolute.

(2) In any case, the world is full of differences and discordances. How can these be reconciled within a unitary Absolute? How can a set of finite (that is, limited and mutually exclusive) entities constitute a nonlimited and all-inclusive whole? In particular, how can this whole, if it is complete and perfect (as it must be if it is infinite), contain within itself both good and evil? There is no satisfactory answer to these questions. Nicholas of Cusa, in his pantheistic moments, affirmed that in God there is a "synthesis of opposites" (*coincidentia oppositorum*). Similarly, Friedrich von Schelling affirmed that the Absolute is a self-identity in which all differences vanish. But these affirmations are metaphysically vacuous, as Nicholas admitted when, using mystical terminology to conceal a contradiction, he called our knowledge of the all-inclusive Maximum a *docta ignorantia*.

THEISM. Theists do not have to face the above problems. Certainly they hold that all perfections preexist in God eminently. But they also hold that the mode of this existence is determined by the infinity that God does not share with any creature. God's infinity means that he is "not-finite." He is free from the limitations that affect every other being. There are two fundamental limitations.

First, every other being is a mode of existence (or existing). A man exists in one way, a dog in another. But God is existence *simpliciter*. He does not suffer from the determinations that are reflected in genera and species. We can express this (with deliberate paradox) by saying that he is his own genus.

Second, if God is existence "in itself," he must be self-existent in the sense that he does not derive his being from any other source. Every other being is dependent or derived. It does not contain within itself the cause of its existence. It depends continuously on the creative act of God who alone exists *a se* (that is, by his own intrinsic power).

Both these aspects of God's infinity are affirmed by the Scholastic dictum that in him essence and existence are identical. The finitude of any being consists in the lack of this identity at both the points mentioned above. Its essence limits its existential act (or pattern of activity), and this limitation follows from its dependent character. It exists as "this" or "that" by its derivation from a being who is existence in a necessary and perfect form.

This view of God's infinity must be safeguarded by the following assertions.

(1) God's infinity is not to be interpreted as formlessness (as if it were equivalent to Plato's *apeiron*). It is the nature of finite being (at any rate in the subangelic realm) to be a *compositum* of form and matter. The form limits matter. Without some degree of limitation there would be no difference (either generically or individually) between one finite being and another. But since God's essence and existence are identical, his form cannot be a principle of limitation. "Matter," Thomas Aquinas wrote, "is perfected and made definite by form. Infiniteness attributable to matter is imperfect and amorphous. On the other hand, form as such is not perfected by matter, but contracted rather; hence infiniteness attributable to form is perfection" (*Summa Theologiae* I, 7, 1).

(2) God's infinity is incomprehensible. We cannot imagine or conceive it. We can know that God is self-existent. But how he is self-existent is utterly unknowable by us in our present state. As soon as we try to represent his infinity through a univocal use of concepts, we commit three errors. We fall into anthropomorphism; we confuse infinity with formlessness; and, finally, we reach a self-contradiction, for the essence of a finite entity (however high it may be on the scale of being) is to possess a form that acts as a limit that excludes other forms.

However, the various attributes that constitute God's character are all deducible from his self-existence. He must be absolutely simple, for if in him essence and existence are identical, his qualities must be coinherent through the whole range of his activity. He must be spiritual and nontemporal, for corporeality entails spatial limitation and temporal successiveness implies divisibility. He must be omniscient and omnipotent, for there cannot be any externally imposed limit to his knowledge or his power. Finally, he must be absolutely good.

Two of these characteristics, spirituality and eternity, call for comment. Since God is nonspatial and nontemporal, the concept of his infinity is unaffected by the views we hold concerning space and time. Whether space and time are limited or unlimited makes no difference to the claims of the theist concerning God's infinity and his relation to the world. Thus, even if the world has existed for an endless length of time, it would still (according to the Cosmological Argument) be endlessly incomplete, so that we should still have grounds for positing a nontemporal act of divine creativity.

Yet the theistic view of God's infinity raises problems of its own. Four are especially urgent. First, if God is infinite and we are finite, how can we speak of him positively (as the biblical writers and doctrinal theologians do)? Second, Christians affirm that God is personal. But does not the idea of personality conflict with the idea of infinity? (This objection was first urged by Carneades and later elaborated by David Hume.) Third, is it not contradictory to say that all God's attributes (for example, justice and mercy) can coexist in a limitless degree? Are not even theists forced to posit a *coincidentia oppositorum* in the Godhead? Fourth, if God is infinite both in goodness and in power, how can we explain the presence of evil in the world?

The answers that theists normally give to these objections are as follows.

(1) While we cannot speak of God univocally, we can do so analogically. But in applying any analogue to God, we must distinguish between the manner of predication and the object signified. The only positive meaning that we can attach to a term we predicate of God is the one which it has when predicated of finite beings. Yet since God and the creature are ontologically related by an analogy of attribution, we can *affirm that* (although we cannot *know how*) the divine analogate possesses the analogue, according to the analogy of proportionality, in a manner appropriate to his infinite existence.

(2) The basic answer to the second question is that we need not equate the essence, or norm, of personality with its human mode. On the contrary, the latter (according to the Bible) is a created image of an infinite archetype. The theist would claim that while we cannot *see how* God can be both infinite and personal, we can *understand that* an infinite existence, so far from being incompatible with personality, would represent it in its most perfect form. At any rate (so the theist would maintain), it is not contradictory to assert that individuality can exist without individuation and that God therefore can have a positive character without possessing characteristics of the kind that differentiate a member of one created genus from a member of another.

(3) If God's attributes were essentially incompatible, they could not be predicated of him infinitely and simultaneously without a logical contradiction that could be solved (as Nicholas and Schelling found) only by an *asylum ignorantiae*. But theists

claim that any contradiction is only apparent. Everything depends on how we define our terms. Thus, if we take justice to mean retribution, it is bound to be incompatible with mercy, if both are infinitely conceived. But if we take it to mean the vindication of the moral order, mercy becomes (as St. Paul saw) the primary form of its expression.

(4) Most Christian theists would admit that the fact of evil seems to be incompatible with belief in a God who is infinite both in goodness and in power. But they would also claim that the apparent incompatibility disappears once we recognize first, that since God's power and goodness are inconceivable, his purposes are bound to be largely inscrutable and second, that in Christ he has shown that he not only can but also does bring the greatest good out of the greatest evil.

INFORMATION THEORY

Among the more interesting trends of the past half-century has been the consolidation of probability, statistics, combinatorial optimization, information theory, and computer science into a single imposing discipline of *infomatics*.

MINIMAL BELIEF CHANGE

Of special philosophical interest is the enrichment of Bayesian inference by a rule of belief change that goes by minimizing the distance between two probability distributions, $P = (p_1, \ldots, p_k$ and $Q = (q_1, \ldots, q_2)$, as measured by the expected log-likelihood ratio:

$$(1) \qquad H(P,Q) = \sum_{i=1}^{k} p_i \ln(p_i / q_i)$$

The likelihood ratio, $P(e|h):P(e|k)$, is a fundamental index of the support that e accords h over k (see the entry "Foundations of Statistics").

Using the visually transparent Gibbs inequality,

$$(2) \qquad \ln x \leq x - 1$$

with equality if and only if (iff) $x = 1$, in the equivalent form $\ln x \geq 1 - 1/x$, it follows that $H(P, Q) \geq 0$ with equality iff $P = Q$. Notice, however, that $H(P, Q) \neq H(Q, P)$.

Alan Turing and his wartime assistant, Irving John Good, used $H(P, Q)$ in their code-breaking work, but it

was not until 1959 that another wartime code breaker, Solomon Kullback, developed its properties systematically in his book *Information Theory and Statistics* (1959), unleashing a floodtide of applications to classification, contingency tables, pattern recognition, and other topics.

A second line of development began with Claude Shannon's creation of information and coding theory (Shannon and Weaver 1949), whose central concept is a measure of uncertainty,

$$(3) \qquad H(P) = -\sum_{i=1}^{k} p_i \ln p_i$$

that Shannon dubbed the entropy function. One sees that minimizing $H(P, U)$ against a uniform distribution, $U = (k^{-1}, \dots, k^{-1})$, namely,

$$H(P,U) = \sum_{i=1}^{k} p_i \ln(p_i / k^{-1}) = \sum_{i=1}^{k} p_i \ln p_i + \ln k$$

is equivalent to maximizing the entropy (MAXENT). In view of this relation $H(P, Q)$ is often called the cross (or relative) entropy of P with respect to Q, and the rule of minimizing it MINXENT.

Shannon characterized $H(P)$ axiomatically as continuous, strictly increasing in k when $P = (k^{-1}, \dots, k^{-1})$ is uniform, and by the general form of a consistency requirement exemplified by:

$$A(9) = \frac{3}{9} A(3) + \frac{4}{9} A(4) + \frac{2}{9} A(2) + H\left(\frac{3}{9}, \frac{4}{9}, \frac{2}{9}\right)$$

where $A(3) = H(\frac{1}{3}, \frac{1}{3}, \frac{1}{3})$, and so on. Roughly speaking, one's uncertainty about a lottery is the same for an equivalent two-stage form of it, where in the example $H(\frac{3}{6}, \frac{1}{6}, \frac{2}{6})$, is one's uncertainty about the first stage.

Exploiting the conceptual link Ludwig Boltzmann established between thermodynamic entropy and Shannon entropy through his celebrated formula, $S = k \ln W$, Edwin T. Jaynes showed how to derive the probability distributions (over microstates) of statistical mechanics by maximizing the (Shannon) entropy subject to mean value constraints given by measured values of macro variables like pressure, volume, or internal energy. Intuitively, the maxent distribution is the most spread out of all those satisfying the constraints, the one that is maximally noncommittal with regard to missing information. Statistical mechanics could thus be seen as a branch of statistical inference operating on physically given constraints. Jaynes quickly realized that MAXENT admits of much

TABLE 1

k	1	2	3	4	5	6	entropy
n_k	3246	3449	2897	2841	3635	3932	
g_k	0.16230	0.17245	0.14485	0.14205	0.18175	0.19660	1.784 990
p_k	0.15294	0.15818	0.16361	0.16922	0.17502	0.18103	1.790 103
q_k	0.16433	0.16963	0.14117	0.14573	0.18656	0.19258	1.785 225
r_k	0.16139	0.17361	0.14434	0.14256	0.18215	0.19594	1.784 993

wider application. A collection of his papers (Jaynes 1983) sparked an explosion of applications whose subsequent progress can be followed in the published proceedings of workshops on maximum entropy and Bayesian methods held annually since 1981 (e.g., see Erickson and Smith 1988). Brian Buck and Vincent A. Macaulay's *Maximum Entropy in Action* (1991) is a sampler of physical applications to such fields as spectroscopy, X-ray crystallography, the structure of macromolecules, magnetic resonance, thermodynamics, and plasma physics. The method is universal, however, and applies equally well to image reconstruction or time series.

INFERRING HIDDEN CAUSES

Irving John Good (1983) viewed $H(P, Q)$ as a natural measure of deviation suitable for testing multinomial hypotheses, and like Karl Pearson's better-known chi-squared measure of deviation

$$X^2 = \sum_{i=1}^{k} \frac{(n_i - np_i)^2}{np_i} = n \sum_{i=1}^{k} \frac{(f_i - p_i)^2}{p_i}$$

the analogous informational measure

$$\psi = 2nH(F,P) = 2n \sum_{i=1}^{k} f_i \ln(f_i / p_i)$$

is asymptotically distributed as χ^2_{k-1}, the chi-square distribution with $k - 1$ degrees of freedom. By comparing the current model to the ideally best-fitting model, the resulting psi test sets limits to how much room there is for improving support by moving to a new (possibly more complicated) model (Jaynes 2003). When such a move is indicated, MINXENT helps guide one to plausible better-fitting models, as the following example illustrates:

Seen in the first row of Table 1 are the frequencies with which the six faces of a white die turned up in $N =$

20,000 tosses recorded by the Swiss astronomer Rudolf Wolf. One sees at a glance that Wolf's die was biased; the question of interest is how to find physically plausible hypotheses that best account for these data. The distributions shown in rows 3 to 5 of the table afford successively better approximations to the empirical distribution, $\{g_j\}$, of row 2. Jaynes (1983) found them by moving the initial uniform distribution just enough to satisfy mean value constraints given by the data that correspond to physical imperfections of a die. Among the most plausible are:

(1) A shift in the center-of-mass due to the different amounts of ivory removed from opposite faces

(2) Oblateness, due to the difficulty of machining a perfect cube (Jaynes 1983)

The first implies a mean higher than the 3.5 of an "honest" die. Maximizing the entropy subject to the observed mean, $\langle i \rangle = 3.5983$, yields the distribution P of row 3. Notice that it assigns higher probability to the 6 spot than the 1 spot, the 5 spot than the 2 spot, and the 4 spot than the 3 spot, with decreasing margins, which is just what the posited physical cause would lead one to expect. But while P improves on the uniform distribution, its fit to the data is still poor, with $X^2 = 33.4$. This points to the existence of another constraint. The lower than expected frequencies of faces 3 and 4 are best explained by oblateness of the die, the 3-4 dimension being longer than the other two. This is reflected in the nonzero mean value, $\bar{f}_2 = 0.1393$, of the oblateness function, $f_2(j) = 1$ for j = 1, 2, 5, 6 and $f_2(j) = -2$ for j = 3, 4. Adding this constraint to the first leads to the maxent distribution Q for both constraints (row 4). The fit to Wolf's data is now fairly good, but there is some slight evidence for a third constraint, a slightly chipped 2-3-5 corner. Maximizing entropy subject to all three constraints then yields the distribution of the last row, whose fit to the data is preternaturally good. Note: It makes no difference in which order the constraints are applied, provided each one is retained in applying the next one.

If Wolf's die still exists, one could actually put the posited physical imperfections to the test of careful measurements. In any case, one would expect other dice to exhibit the first two imperfections. As it happens, Wolf also tossed a red die 20,000 times, and this expectation is realized (Jaynes 1983). To permit such inferences to physical causes, one must assume, of course, that Wolf tossed his dice in a manner that precludes skill.

MAXENT first enters, then, as a technique of mathematical modeling, as a means of generating plausible hypotheses for explaining old data or testing against new data (Good 1983, pp. xvi–xvii, 41, 99–100). Indeed, most of the probability distributions that figure prominently in pure and applied probability are maxent distributions for a suitable set of constraints. For example, the exponential distribution is maxent for a positive random variable whose (finite) first moment is given. (This result depends on extending the cross entropy function to continuous distributions, sums giving way to integrals.) Jaynes (2003, §7.6) even makes a case for thinking the ubiquitous use of the normal law of errors is owing to the fact that it is the maxent distribution having specified values of the first two moments.

When predictions based on MAXENT are verified, one's belief in the completeness of the given constraints is borne out, but one learns most when one's predictions fail. For then one infers the existence of a previously unsuspected cause to which the observed deviations point one. However, for this kind of "learning from error" to be effective requires that those inferences be one's best inferences (Jaynes 2003, p. 326). In what sense, then, are MINXENT or MAXENT inferences best possible?

One can look, first, at how MAXENT operates on a mean value constraint:

$$\sum_{i=1}^{n} p_i f(x_i) = \bar{f}$$

With $\sum p_i = 1$, the method of Lagrange for constrained extrema yields a solution,

(4) $\qquad p_i = Z(\lambda)^{-1} \exp(\lambda f(x_i)) \qquad i = 1, 2, \ldots, n$

with $Z(\lambda) = \sum_{i=1}^{n} \exp(\lambda f(x_1))$. More generally, given $m < n$ such constraints, $\sum_{i=1}^{n} p_i f_k(x_i) = \bar{f}_k$, a solution is

(5) $\quad p_i = Z(\lambda_1, \ldots, \lambda_m)^{-1} \exp[\lambda_1 f_1(x_i) + \ldots + \lambda_m f_m(x_i)]$

for $i = 1, \ldots, n$, where the partition function, Z, is defined by:

(5a) $Z(\lambda, \ldots, \lambda_m) = \sum_{i=1}^{n} \exp[\lambda_1 f_1(x_i) + \ldots + \lambda_m f_m(x_i)]$

Moreover, the moments of the resulting maxent distribution are given by the derivatives of $\ln Z$, so that, in particular, the mean values are:

(5b) $\qquad \dfrac{\partial}{\partial \lambda_i} \ln Z = \bar{f}_i$

as one can verify. Thus, Z is a kind of (exponential) generating function and is called the partition function for reasons given by Jaynes (2003, pp. 280–282). The parallel minxent distribution is given by:

$$(6) \qquad p_i = \frac{p_i^0 \exp[\lambda_1 f_1(x_i) + \dots + \lambda_m f_m(x_i)]}{\sum\limits_{i=1}^{n} p_i^0 \exp[\lambda_1 f_1(x_i) + \dots + \lambda_m f_m(x_i)]}$$

where $P^0 = (p_z^0, \dots, p_n^0)$ is the initial "pre-distribution." (6) reduces to (5) when $p_i^0 = n^{-1}$ is constant.

For a simple discrete example, let the mean for a die be $\langle i \rangle = 4$. Here, $x_i = i$ and $f(x) = x$, so the partition function becomes (with $x = e^\lambda$):

$$Z(\lambda) = \sum_{i=1}^{6} e^{\lambda i} = x(1 + x \dots + x^5) = x\frac{1 - x^6}{1 - x}$$

Then since $dx/d\lambda = e^\lambda = x$, the chain rule yields:

$$\frac{d \ln Z}{d\lambda} = x\frac{d\ln Z(x)}{dx} = x\left[\frac{1}{x} - \frac{6x^5}{1 - x^6} + \frac{x}{1 - x}\right]$$

$$= \frac{(1 - x)(1 - x^6) - 6x^6(1 - x) + x(1 - x^6)}{(1 - x)(1 - x^6)}$$

whereupon, setting $d \ln Z/d\lambda = 4$, $3(1 - x)(1 - x^6) = 5x^7 - 6x^6 + x$, which is solved numerically for x to yield, $x = 1.190804264$, or $\lambda = \ln x = 0.1746289309$. Hence, the maxent distribution of mean 4 is:

$$(p_1, \dots, p_6) = (.103, .123, .146, .174, .207, .247)$$

The general formula for mean $\bar{f}$ works out to $(6 - \bar{f})x^7 - (7 - \bar{f})x^6 + \bar{f}x - \bar{f} + 1 = 0$, and one seeks a root other than $x = 1$. Verify that for mean 3.5, the only root is $x = 1$, so the maxent distribution is uniform. Thus, MINXENT gives back the pre-distribution if it already satisfies the constraint—a redundancy property that should hold generally. Computer programs are available for finding maxent distributions subject to mean value constraints.

The method of Lagrange for constrained extrema is not guaranteed to yield a global maximum, and so to settle this point, one invokes the Gibbs inequality (2) to obtain:

$$\sum p_i \ln(u_i / p_i) \leq \sum p_i\left(\frac{u_i}{p_i} - 1\right) = 0$$

when $\sum u_i = \sum p_i = 1$, whence

$$-\sum p_i \ln p_i \leq -\sum p_i \ln u_i$$

with equality iff $p_i = u_i$. Knowing the form (5) of the maxent distribution, one sets

$$u_i = Z(\lambda_1, \dots, \lambda_m)^{-1} \exp[\lambda_1 f_1(x_i) + \dots + \lambda_m f_m(x_i)]$$

and the last inequality then specializes to:

$$H(p_1, \dots, p_n) \leq \sum_{i=1}^{n} p_i\left[\ln Z - \sum_{k=1}^{m} \lambda_k f_k(x_i)\right]$$

$$= \ln Z - \sum_{j=1}^{m} \lambda_j \bar{f_j}$$

with equality iff the p_i are given by (5). This not only shows that (5) is the (one and only) distribution of maximum entropy satisfying the given constraints, but that the right side,

$$(7) \qquad H_{max} = \ln Z(\lambda_1, \dots, \lambda_m) - \sum_{j=1}^{m} \lambda_j \bar{f_j}$$

is the maximum entropy permitted by those constraints. Any distribution of lower entropy must be importing additional information. Or, as in the example of Wolf's die, if the data distribution is of lower entropy than a hypothesized distribution, an additional condition must be constraining those data to lie in a proper subset of those allowed by the hypothesis in question.

AXIOMATIC CHARACTERIZATION

Every property of MINXENT (MAXENT) rules out potential rivals. Write $P = P^0 \circ C$ for the distribution, P, nearest the pre-distribution, P^0, among all those satisfying a constraint, C (of class C), where for equality or inequality linear constraints the class C is closed and convex and there is a nearest P to P^0. The following properties of MINXENT are then easily proved (Shore and Johnson 1980, §4; Williams 1980):

Uniqueness: The minxent distribution is unique

Redundancy $P \circ C = P$ when P satisfies the constraint C [since $H(Q, P) = 0$ only if $Q = P$]

Chain consistency: The order in which constraints are applied is immaterial, provided each is retained in applying the next one

System independence: The "post-distribution" should not import a dependence between two vari-

ates that is neither implied by the constraints nor the pre-distribution

Invariance: $P = P^0 \circ C$ should not depend on one's choice of a coordinate system

Subset independence: It should not matter whether one obtains a conditional distribution for disjoint subsets of outcomes by finding the post-distribution nearest the conditional prior for each subset or by obtaining the post-distribution for the whole outcome space and conditioning it on each subset

To illustrate the last property, the even and odd faces in tossing a die may be reported separately. Let the prior be uniform and the mean for both the odd and even faces be 4. By redundancy, the post-distribution, Q, is also uniform on the even faces: $Q(2) = Q(4) = Q(6) = \frac{1}{3}$, while for the odd faces, one finds (as above) that $Q(1) = 0.1162$, $Q(3) = 0.2676$, and $Q(5) = 0.6162$. One can also solve the problem by finding the post-distribution for all six states by applying the mean value constraints conjointly obtaining:

$Q'(1) = 0.0524$	$Q'(2) = 0.1831$
$Q'(3) = 0.1206$	$Q'(4) = 0.1831$
$Q'(5) = 0.2778$	$Q'(6) = 0.1831$

To condition on the subsets of odd and even faces, divide each column by its sum and obtain the same conditional distributions found earlier. If these two ways of solving the problem did not agree, MINXENT could be justly deemed inconsistent.

In 1980 John E. Shore and Rodney W. Johnson vindicated Jaynes's conjecture that "deductions made from any other information measure … will eventually lead to contradictions" (1983, p. 9) by deriving MINXENT for mean value constraints from uniqueness and the last three mentioned properties. All these ring changes on the consistency requirement that two ways of doing a calculation must agree, the very condition from which Richard T. Cox derived the basic rules of probability (see the entry "Foundations of Statistics"). Rather than attempt a sketch of their proof, one can illustrate how rival rules violate the Shore-Johnson axioms and lead to contradictions.

INCONSISTENCY OF OTHER RULES

An alternative measure of the spread of a distribution, $\sum p_i^2$, dubbed the repeat rate by Turing, is, like entropy, continuous and assumes its extreme values of $1/n$ and 1 at the extremes of uniformity and concentration. The closely related Gini diversity, $1 - \sum_{i=1}^{n} p_i^2$, has a well-established place in statistics as a measure of the qualita-

tive diversity of a population, with widespread applications to such fields as genetics, ecology, and linguistics. Table 2 shows how closely the distribution of a die of mean 4 obtained by minimizing $\sum p_i^2$, approximates the maxent distribution for this constraint found earlier.

On a superficial examination, one might easily suppose that the repeat rate (RR) rule performs about as well as MAXENT. Still, one knows it must violate one of Shore and Johnson's (1980) consistency postulates, and inconsistency always brings a degradation of performance in its train.

In casting a red and a white die with mean values, $E(R) = 4$ and $E(W) = 3$, and a uniform prior, the method of Lagrange for the RR-rule leads in this case to three linear equations in three unknowns (the Lagrange multipliers), which are easily solved to yield the joint post-distribution:

$$P(R = i, W = j) = \pi_{ij} = \frac{1}{36} + \frac{i - j}{210}$$

from which the marginal distributions for R and W are computed to be:

$$P(R = i) = p_i = \sum_j \pi_{ij} = \frac{3i + 7}{105}$$

and

$$P(W = j) = q_j = \sum_i \pi_{ij} = \frac{-3j + 28}{105}$$

One easily checks that $p_i q_i \neq \frac{1}{36} = \pi(i,i)$. Hence, the RR-rule violates system independence. Its inconsistency shows up even more clearly when one enlarges the problem to the case of symmetric mean values, $E(R) = 3.5 + \Delta$ and $E(W) = 3.5 - \Delta$. From the joint post-distribution, one can compute a value of Δ, namely, $\Delta = \frac{7}{12}$ at which the RR-rule makes the smallest of the joint probabilities zero, even though no outcome is excluded by the pre-distribution or the constraints. For values of Δ greater than $\frac{7}{12}$, the RR-rule breaks down completely, making some of the joint probabilities negative.

Consider the more general family of rules that minimize a Csiszar divergence:

$$H_f(P, Q) = \sum q_i f(p_i q_i)$$

with f a convex function. This family includes MINXENT as the special case $f(x) = x \ln x$, as well as the chi-squared

rule that minimizes $\sum_{i=1}^{k} \frac{(pi-qi)^2}{qi}$, given by $f(x) = (x - 1)^2$. Applied to a uniform prior, $q_i = 1/n$, this is minimized by minimizing $\sum p_i^2$, hence, it inherits the inconsistencies of the RR-rule.

RELATION TO BAYESIAN CONDITIONING

The upshot of Shore and Johnson's (1980) axiomatic derivation of MINXENT is to place it on a par with Bayes's rule for revising a probability assignment—the most basic rule of belief change. Hence, it is of interest to see what MINXENT delivers in this case (Williams 1980). For any distribution P satisfying $P(B) = 1$:

(8) $\qquad H(P, P^0) = H(P_B, P_B^0) - \ln P^0(B)$

writing $P_B(A) = P(AB)/P(B)$ for the conditional measure. For then using $\sum_{xi \in B} P(x_i) = P(B) = 1$,

$$H(P_B, P_B^0) = \sum_{x_i \in B} P(x_i) \ln[P(x_i)/\frac{P^0(x_i)}{P^0(B)}]$$

$$= \sum_{x_i \in B} P(x_i) \ln[P(x_i)/P^0(x_i)] + \ln P^0(B)$$

since $P_B(x_i) = P(x_i)/P(B) = P(x_i)$, which proves (8). Since (8) is clearly a minimum when $H(P_B, P_B^0) = 0$, hence, when $(P_B = P_B^0)$, one sees that the distribution P nearest P^0 among those for which $P(B) = 1$ is the Bayesian posterior distribution, P_B^0.

What if the constraint $P(B) = 1$ is weakened to $P(B) = q$, $0 < q < 1$? For any such P one has the following straightforward generalization of (8):

(8a) $\qquad H(P, P^0) = qH(P_B, P_B^0) + \bar{q}H(P_{\bar{B}}, P_{\bar{B}}^0)$

$$- q \ln\left[\frac{P^0(B)}{q}\right] - \bar{q} \ln\left[\frac{P^0(\bar{B})}{\bar{q}}\right]$$

with $\bar{q} = 1 - q$. The right side is minimized by making both $H(P_B, P_B^0)$ and $H(P_{\bar{B}}, P_B^0)$ zero, which means that the nearest P to P^0 is given by:

$$P = qP_B^0 + \bar{q}P_{\bar{B}}^0$$

a q-weighted average of the conditional distributions for B and its negation. There is an obvious generalization to a partition $B_1, \ldots, B_n$ and the constraint $P(B_i) = q_i$, with $\sum q_i = 1$. This special case of MINXENT is known as Jeffrey conditioning. Indeed, Williams (1980) generalizes

TABLE 2

i	1	2	3	4	5	6
Maxent	.103	.123	.146	.174	.207	.247
RR-rule	.095	.124	.152	.181	.209	.238

further to the case where the B's need not be mutually exclusive. The validity of this rule requires that the sole affect of the datum or sensory input is to raise the probability of B to a value $q < 1$. For conditions under which Jeffrey conditioning is not valid, see Jaynes (2003, §5.6).

FREQUENCY CONNECTIONS

MAXENT also has frequency connections (Jaynes 1983). Of the k^N outcomes (i.e., outcome sequences) of N trials, the number that yields category counts $(n_1, \ldots, n_k)$ with $\sum n_i = N$ is given by the multinomial coefficient:

$$W = \frac{N!}{n_1! \ldots n_k!}$$

Using Stirling's approximation to the factorial function, one easily proves that

(9) $\qquad N^{-1} \ln W \to H(f_1, \ldots, f_k)$

Hence, the maxent distribution is W-maximizing, hence realized by the most outcomes. Moreover, given two sets of relative frequencies, $\{f_i\}$ and $\{f_i'\}$,

(10) $\qquad \frac{W}{W'} \sim Ae^{N(H-H')}\left[1 + \frac{B}{12N} + O(N^{-2})\right]$

gives the ratio of the number of ways each can be realized, where $H = H(f_1, \ldots, f_k)$ and $H' = H(f_1', \ldots, f_k')$, $A = \prod_{i=1}^{k}(f_i / f_i')$ and $B = \sum_{i=1}^{k} \frac{(f_i - f_i')}{f_i f_i'}$. For example, for the two distributions of Table 2, $H = 1.7485056$ and $H' = 1.7470082$, and so at $N = 20,000$ trials, the maxent distribution is realized by $W/W' = 9.86 \times 10^{12}$ more outcomes than the similar looking distribution of the RR-rule. The peak is thus enormously sharp. Just how sharp is quantified by Jaynes's concentration theorem (1983), which allows one to compute the fraction of possible outcome sequences whose category counts, f_i, have entropy in the range $H_{max} - \Delta H \le H(f_1, \ldots, f_k) \le H_{max}$. This gives, in effect, a new kind of significance test for detecting when additional constraints are hidden in one's data.

Not unrelated results concern typical outcomes of a stationary Markov process (Khinchin 1957). Namely, if H is the entropy of a regular Markov chain and s sufficiently large, then almost all s-step outcomes C satisfy:

$$\left| \frac{\log \frac{1}{c}}{s} - H \right| < \eta$$

with η arbitrarily small. That is, almost all s-step sequences of the process deliver information arbitrarily close to the average, $H^{(s)} = sH$. The entropy is defined in the obvious way as the expectation of

$$H_i = -\sum p_{ik} \log p_{ik}$$

the one-step uncertainty, so that $H = \sum_i P_i H_i$ where $P = (P_1, \dots, P_k)$ is the stationary distribution and (p_{ik}) is the one-step transition matrix.

Aleksandr Khinchin's prophetic remark, that "the study of entropy will become a permanent part of probability theory" (1957, p. 2), has been borne out not only by the flowering of the maxent method but also by D. S. Ornstein's proof that entropy is a complete invariant of an ergodic Markov chain (for an informal treatment and references to the mathematical literature, see Suppes 2002, §4.5). That is, two ergodic chains (in which any state is reachable from any other) are isomorphic iff they have the same period and the same entropy.

INFORMATION THEORY AND STATISTICAL MECHANICS

The frequency implications of MAXENT play their most important role, however, in statistical mechanics. Thus, Ludwig Boltzmann found the famous Maxwell-Boltzmann energy distribution for molecules in a conservative force field by partitioning the 6n-dimensional phase space of position and velocity (or momentum) coordinates into cells, R_k, small enough for the energy to be a constant, E_k, and large enough to contain a sizeable number, N_k, of molecules. Then the total number, N, and the total energy, E, are constants of the molecular motion. Boltzmann argues that the most probable distribution, $(N_1, \dots, N_s)$, is the one that is realized by the most microstates among those compatible with the constraints:

$$\sum N_i = N \text{ and } \sum N_i E_i = E$$

By virtue of (5), this most probable distribution,

(11) $$\hat{N}_i = \frac{N}{Z(\beta)} \exp(-\beta E_i)$$

is none other than the maxent distribution for the given constraints.

In this derivation, Boltzmann may be said to have launched MAXENT and the information theoretical approach to statistical mechanics. All the canonical distributions J. Willard Gibbs (1902) later derived are simply maxent distributions for other sets of constraints, for example, that for fixed values of the total energy and angular momentum is Gibbs's rotational ensemble. Unfortunately, Gibbs slipped in the logical basis of his derivation so unobtrusively that most readers missed it. Moreover, he provided no clear or compelling rationale, so that in their famous review article of statistical mechanics published a decade later, Paul Ehrenfest and Tatiana Ehrenfest (1912) dismissed Gibbs's method of derivation as "a mere analytic trick" (for the relevant history, see Jaynes 1983, pp. 98ff). Thus began a long siege of confusion and controversy over the justification of Gibbs's formalism that continues to this day, notwithstanding Jaynes's rediscovery of the MAXENT method of Gibbs in 1957 and his clear rationale for using it (1983, chapter 1). In particular, the information theoretical approach dispenses with the ergodic hypothesis.

Jaynes's second great contribution was to extend the Gibbsian (MAXENT) formalism to irreversible processes and nonequilibrium thermodynamics (1983, chapter 10, §D). He writes:

> The final breakthrough came in the Christmas vacation period of 1962 when, after all else had failed, I finally had the courage to sit down and work out all the details of the calculations that result from using the Maximum Entropy Principle; *and nothing else*. Within three days the new formalism was in hand, masses of the known correct results of Onsager, Wiener, Kirkwood, Callen, Kubo, Mori, MacLennon, were pouring out as special cases, just as fast as I could write them down; and it was clear that this was it. (p. 239)

The unbelievably short derivation of (11) as the equilibrium distribution of the energies has seemed too short to many physicists and philosophers. This initial impression is only reinforced when it is seen that (11) implies the familiar barometric formula,

(11a) $$\rho(z) = \rho(0) \exp(-\beta mgz)$$

for the density of the atmosphere at height z, as well as Maxwell's velocity distribution in the form:

(12) $\qquad f(v_b) = B(\beta)\exp(-\beta m v_b^2/2)$

where $f(v_b)dv_b$ is now the probability that a molecule has a velocity in a tiny neighborhood of v_b. Indeed, even more follows, for (12) does not depend on the position of the molecule (an assumption Boltzmann was forced to make in his derivation of the Maxwell distribution from his collision equation). This implies, in turn, the dynamic stability of the distribution. However, the MAXENT derivation seems to ignore the dynamics altogether.

Jaynes responded in several ways. First, the derivation does not ignore the dynamics; it uses conservation of energy as well as the preservation of the volumes of the cells, R_k, under evolution of the system (Liouville's theorem). Jaynes emphasizes that, in addition, one is trying to predict reproducible macrostates. These are *ipso facto* under the experimenter's control, and so the myriads of details concerning microstates not under his control must needs be irrelevant for prediction. Moreover, reproducible macroscopic properties must be characteristic of the overwhelming preponderance of microstates in the allowed region of the phase space. Given the large number of degrees of freedom entailed, the maxent distribution will be enormously peaked. Hence, predictions of other macro quantities based on their mean values will be correct (within experimental error) with probability close to one (Jaynes 1983). As far as Jaynes is concerned, these considerations fully explain the predictive success of equilibrium thermodynamics as "inferences from the available information."

In particular, there is no need to appeal, as Maxwell and Boltzmann did (but Gibbs did not) to the equality of infinite time averages and averages with respect to the canonical distribution. Even if this could be established from some other easily verified assumption—the program of ergodic theory—it would be nothing to the purpose. For one would have to show, in addition, that the averages over finite time intervals involved in measuring macro quantities closely approximate their infinite time averages, and there are positive reasons to doubt this (Jaynes 1983).

Apart from the clarity, unity, and simplicity the information theoretical approach brings to the foundation of statistical mechanics, David Hestenes (1993) considers Jaynes's greatest merit to lie in his recognition that "in the evolution of statistical mechanics the principles of physics had gotten confused with principles of statistical inference" (1993, p. 153).

Jaynes regards the formalism of quantum mechanics as a similar "nasty omelet" scrambling together properties of physical systems and our information about them in ways that are difficult to unscramble. See the cited article by David Hestenes for one noteworthy attempt to disentangle subjective and objective aspects of the electron wave function, namely, a probability factor and a kinematic factor, using a powerful "universal geometric calculus" based on Hermann Grassmann's Ausdehnumgslehre. Hestenes purports to show, in particular, that the complex "probability amplitudes" of the formalism have nothing to do with probability per se but have, instead, a physical origin in the "Zitterbewegung", or circular dance, of the electrons generating their spin and magnetic moment.

Jaynes's views on quantum mechanics are outlined (with references) in the same volume—a festschrift in his honor—in which the article by Hestenes appears. For other views, see Philosophy of Statistical Mechanics and Quantum Mechanics.

INFORMED CONSENT

A fundamental requirement of both ethics and the law is that medical treatment cannot be given to competent patients without their "informed consent." This represents a rejection of more traditional authoritarian or paternalistic accounts of the physician/patient relationship in which the physician had decision-making authority in favor of a process of shared decision making between physicians and patients. In this respect informed consent helps shape the nature of nearly all health-care treatment decision making. Informed consent also has special importance in a narrower class of cases in which patients and their physicians are unable to agree on a course of treatment. In these cases a competent patient is given the right to refuse any recommended treatment, even including life-sustaining treatment, no matter how strongly the physician or others believe that the treatment should be undertaken.

There are two principal moral values that are served by and justify the informed-consent requirement in health care. The first is patient well-being—arguably the fundamental goal of all health care. The concept of patient well-being, as opposed to the apparently more objective goals of protecting and promoting patients' health and lives, signals the important respect in which what will best serve a particular patient's well-being is often to a significant degree a subjective determination that depends on the particular aims and values of the patient in question. Increasingly, there are medically

acceptable alternative treatments (including the alternative of no treatment), no one of which is best for all patients with a particular medical condition. The patient's participation in decision making is therefore necessary in order to select the treatment that best fits his or her aims and values. The other fundamental moral value that undergirds the informed-consent requirement is individual self-determination or autonomy. Self-determination in this context is the moral right of ordinary persons to make significant decisions about their lives for themselves and according to their own aims and values. Requiring that health care not be rendered without a competent patient's informed consent respects this right of self-determination. The informed-consent requirement reflects the fundamental moral point that it is the patient and the patient's body that undergo the treatment, and so it should be the patient who is morally entitled to authorize or refuse the treatment.

Three conditions are necessary for ethically valid informed consent—that the patient's decision be informed, voluntary, and competent. The requirement that the decision be informed places a responsibility on the patient's physician to provide the patient with information, in an understandable form, about the patient's condition or diagnosis and the prognosis if no treatment is provided, together with the alternative treatments that would improve that prognosis, along with their risks and benefits. This typically does not require that the physician provide, or that the patient understand, complex medical and scientific information, but rather information about how the various alternatives would likely affect the patient's pursuit of his or her plan of life. Legal requirements regarding how much and which information must be provided vary, but the ethical ideal is to provide the information that the particular patient would reasonably want to know in order to make his or her decision.

The requirement that the consent be voluntary means that treatment must not be rendered against the patient's will, either by force or by coercing the patient's choice. More important, it also forbids physicians from manipulating the patient's choice through selective provision of information, playing on the patient's fears, and other means. Ethically objectionable manipulation, as opposed to appropriate informing and persuasion, aims to produce a different choice from what a competent patient would have made if fully informed and freely choosing.

The third requirement of competence is the most complex. Usually, patients are either clearly competent, with their normal decision-making capacities intact, or

clearly incompetent, unable to make any decision. In borderline cases in which there is significant, but not total, impairment of the patient's decision-making capacities, the competence determination is often controversial. The competence evaluation should address the process of the patient's decision making in order to determine whether there are significant impairments, limitations, or mistakes in that process that have resulted in a choice different from what the patient would have wanted in the absence of those impairments, limitations, or mistakes. The proper standard of competence in borderline cases is controversial but increasingly understood to be a variable standard, requiring a higher level of understanding and reasoning when the patient's well-being would be seriously affected by the decision in question and a lower level when there would be only limited impact on the patient's well-being. While treatment refusal may reasonably trigger an evaluation of the patient's competence, it should not serve as any evidence of the patient's incompetence—that evidence must come from impairments or limitations that cannot be remedied in the process of the patient's reasoning. When the requirements for ethically valid informed consent (that is, informed, voluntary, and competent) are met, the patient's choice should be reasonably in accord with his or her well-being, and his or her self-determination will have been respected.

When the patient has been determined to be incompetent to make his or her own treatment choices, a surrogate or proxy, typically a close family member, should substitute for the patient in the decision-making and consent process. The patient's informed consent is also not required in emergency conditions, when taking time to obtain consent would involve serious risks to the patient's well-being, or when the patient has waived his or her right to give consent and has authorized another to make the treatment decision.

INFORMED CONSENT IN THE PRACTICE OF LAW

The doctrine of informed consent has deeper historical roots in the practice of law than in the practice of medicine. The modern rule that medical treatment cannot be given without the informed consent of competent patients did not arise until the late twentieth century, whereas a century earlier, courts already recognized that, like other agents, lawyers may breach their fiduciary duty to client-principals when they fail to provide them with sufficient information. In some respects, however, the legal profession may have lagged behind the medical profession. Thus lawyers, who played a critical role in developing the informed consent model in medicine, have been criticized for failing to adequately develop such a model for their own practice.

The legal profession has long recognized that lawyers may not reveal confidential information or represent conflicting interests unless the client consents after full disclosure. Because it has not always been clear precisely what information the lawyer must disclose to the client before acting, the American Bar Association (ABA) amended its Model Rules of Professional Conduct in 2002 to require the lawyer to obtain the client's *informed consent*, taking advantage of lawyers' familiarity with that term in the context of medical practice. The Model Rules also draw on language familiar in the medical context in defining informed consent to require the communication of "adequate information and explanation about the material risks of and reasonably available alternatives to the proposed course of conduct" (ABA *Model Rules*, Rule 1.0[e]).

Aside from confidentiality and conflicts of interest, the use of informed consent doctrine in legal practice is unclear. The difficulty lies in determining which decisions are for the client (in which case lawyers are required to provide sufficient explanation for the client to make informed decisions) and which decisions are for the lawyer (with or without consulting the client). Certain decisions are clearly reserved for the client—whether to accept a settlement offer and, in criminal cases, what plea to enter, whether to waive a jury trial, and whether the client will testify. In addition, there is agreement that the client defines the objectives of the representation. What remains unclear is how to distinguish between a client's objectives and the means of achieving those objectives (for example, when the client wants to win a lawsuit by asserting a particular right), how properly to allocate decision-making as to the means of the representation

(for example, when the client does not want to pay for additional depositions), and whether there are some decisions lawyers may make without first consulting the client (for example, deciding what questions to ask a witness on direct or cross-examination).

As initially promulgated, the ABA *Model Rules* appeared to suggest that all means decisions were for the lawyer to make after consultation with the client. Aside from the difficulty of distinguishing between objectives and means, many believe that there are some means decisions that ought to be for the client to decide, particularly when they involve expenses or concern for third persons, as opposed to technical, legal and tactical matters. On the other hand, it would be inefficient to require the lawyer to consult the client prior to taking any action, especially when the matter is in trial. Case law has not resolved these issues; some courts state that a lawyer must obey all lawful instructions of a client, while others adhere to the traditional distinction between ends and means.

The amended *Model Rules* provide that lawyers may act without prior consultation when the action is "impliedly authorized" to carry out the representation (Rule 1.2[a]), as when the lawyer reasonably assumes that the client would not want to be consulted because the matter is highly technical and does not involve significant risk to the client. As to other means decisions, the *Model Rules* require the lawyer to reasonably consult the client, but do not prescribe how to resolve disagreements between lawyer and client, other than suggesting that the lawyer may withdraw from the representation when the lawyer has a fundamental disagreement with the client and that, conversely, the client may resolve the disagreement by discharging the lawyer.

A similar problem exists in medical practice. Historically, the failure to obtain the patient's informed consent to surgery or some other invasive procedure was treated in law as a battery. In the 2000s, most courts agree that the cause of action is better understood as deriving from the patient's right to self-determination rather than the right to reject a nonconsensual touching; therefore, they base the informed consent action in negligence rather than battery. The question arises, however, whether the physician must obtain the patient's consent to all treatment (and perhaps diagnostic) options, even when the proposed treatment is noninvasive, such as bed rest, and one or more of the options is not one that the physician would recommend. Some courts hold that a physician may not subject a patient to a course of treatment, whether invasive or noninvasive, without disclosing information that will enable the patient to intelligibly evaluate the available options and risks of each.

These courts also recognize, however, that it would be unduly burdensome to require physicians to explain in detail all treatment options in every case, such as when a physician proscribes one of several potentially appropriate antibiotics in treating a respiratory infection. Other courts refuse to apply informed consent doctrine to procedures or diagnostic options not recommended by the physician or to situations where the patient refuses the recommended treatment, fearing that recognizing such a duty would in effect require physicians to give a mini-course in medical science and would further suggest that physicians should defer their medical judgment to the patient's wishes.

The difficulty of determining when to use informed consent doctrine stems from the need to balance the individual's right to self-determination with other concerns. Like physicians, lawyers resist being forced to give detailed explanations of every exercise of professional judgment, because some explanations entail either excessive costs or unwarranted invasions of professional autonomy. Obviously there must be some limits to the reach of informed consent doctrine. One approach is to draw admittedly arbitrary lines between the objectives and means of a representation, or between invasive and noninvasive procedures (or recommended and nonrecommended treatment or diagnostic options). Another approach is to reject arbitrary line-drawing in favor of fact-intensive, case-by-case determinations of the proper allocation of decision-making between professionals and consumers, guided by the decisions reasonable consumers would presumably want to make. In any event, the precise boundaries of informed consent doctrine, whether in legal or medical practice, continue to be debated.

INGARDEN, ROMAN
(1893–1970)

Roman Ingarden, the Polish phenomenologist, was born in Kraków. He studied philosophy under Kazimierz Twardowski at Lvov and under Edmund Husserl at Göttingen. At Göttingen he also studied mathematics under David Hilbert and psychology under G. E. Müller. Ingarden followed Husserl to Freiburg, where he received his PhD in 1918 with the dissertation "Intuition und Intellekt bei Henri Bergson." The same year Ingarden returned to Poland, where he taught mathematics in high schools. After his habilitation in 1921 he was named Privatdozent in philosophy at the University of Lvov. During the German occupation Ingarden was basically preoccupied with writing "Controversy over the Existence of the World"; universities in Poland were closed at that time. In 1945 he accepted the chair of philosophy at the Jagellonian University at Kraków. During the early 1950s the Polish government barred him from teaching philosophy because of his adherence to "idealism"; during this period he translated Immanuel Kant's *Critique of Pure Reason* into Polish. Ingarden regained his chair in 1956 and retired in 1963, but he continued to be philosophically active.

Ingarden was one of the ablest pupils of Husserl. He accepted Husserl's main analytical results and the phenomenological method, but he rejected Husserl's transcendental idealism, showing instead how phenomenology could lead to realism. Max Scheler, Jean Hering, and, in her earlier works, Hedwig Conrad Martius, also exerted some influence on Ingarden. Traces of Ingarden's ideas can be found in the work of Nicolai Hartmann, Herbert Spiegelberg, and Michel Dufrennes, as well as in that of such American aestheticians as René Wellek.

Ingarden's philosophy is a fusion of two traditions: the variety of German speculative metaphysics as represented by Franz Brentano and the restrained and painstaking Polish analytical philosophy. Ingarden wove grand philosophical designs, but he wove them with great care and clarity. He opposed what he regarded as the narrowness and one-sidedness of the analytical trend, and he was probably the first to argue (in 1934) that the logical positivist verification principle of meaning, since it is a metalanguage statement, is itself unverifiable; and since it is not analytic, it is therefore meaningless. Ingarden followed this criticism with many others, but he nevertheless acquired and used the skills and techniques of the analytical philosophers. His phenomenology is therefore marked by an intelligibility and clarity rare among metaphysicians and ontologists.

AESTHETICS

Ingarden's earliest work was in epistemology, which he conceived of as an independent discipline able to show the certainty of its own conclusions. The center of his investigations later shifted to ontology, which he regarded as a science of pure possibilities. Ontology determines and describes these possibilities in order to provide us with conceptual apparatuses by which we can express various existential situations.

Ingarden also conducted significant work in aesthetics. His fully elaborated and original theory of art is perhaps the best-known part of his philosophy. He arrived at this theory through the ontological investigations that were central to his thought, and the theory itself was a preparation for his realistic ontology. One of the possible ways of settling the controversy between idealism and realism is through examining the nature of objects that exist. There seems to be a necessary connection between a mode of being and its formal structure. Ingarden first attempted to investigate this problem through examining works of art, which, in contrast with spatiotemporal objects, are dependent for their existence on the conscious act of the creator but which nevertheless transcend this act and continue to exist in their material shape afterward. What makes them works of art is the intention of the creator to endow them with significance, and it requires another intentional act on the part of the receiver to decipher this significance expressed by physically perceptible signs. Thus, the work of art possesses many strata. In a literary work of art, for example, the following can be distinguished: (1) the visual or phonic stratum; (2) the stratum of the meanings of words and sentences; (3) the stratum of objects described; (4) the stratum of the appearances of these objects. All these strata are polyphonically orchestrated to compose one work of art. In a poem it is not the printed marks in the shape of letters, nor even the actual meanings of particular words, that matter; rather, it is the "poetic significance" achieved through these printed marks and through the meanings of particular words. The inten-

tional act of the creator and another intentional act of the receiver are indispensable for the existence of the work of art. And because of this, works of art are called purely intentional objects.

ONTOLOGY

It is customary to link phenomenology with existentialism, as if Husserl, Martin Heidegger, and Jean-Paul Sartre were three links in the development of one trend and as if existentialism were an inevitable development of phenomenology. But the linking of phenomenology and existentialism in this manner blurs the fact that for Husserl phenomenology was primarily a cognitive philosophy, seeking to acquire knowledge, whereas for Sartre the main function of philosophy was consolatory, to explain the mystery of man and justify his tragic existence. Ingarden's philosophy was a continuation, development, and restatement of the cognitive core of Husserl's philosophy, and perhaps was closer to its cognitive spirit than any other development of Husserl's doctrine by his numerous pupils. Ingarden perhaps succeeded better than Husserl himself in making his phenomenological inquiries consistent and coherent. Husserl, as Ingarden observed, was entangled in a vicious circle of phenomenology: In order to conduct the phenomenological reductions that are to yield self-evident knowledge, Husserl had to assume that our consciousness is transcendental, whereas it is precisely through application of the phenomenological reductions that consciousness is revealed to be transcendental.

Ingarden attempted to break away from this circle by what he called eidetic analyses, the penetration of the nature of essences in an "objective" way, as opposed to the transcendental approach Husserl used in his later work. Ingarden's objective approach was to clear the ground for philosophy as an independent and self-sufficient discipline. He contended that any reconstruction of our knowledge must start from thorough analyses of the nature of the objects of our knowledge, both existing and possible. Ontology is basic to other philosophical endeavors because the manner of our cognizing is determined by the objects of cognition. It follows that there are as many types of immediate experience as there are types of objects and types of relationships occurring among objects.

Ingarden devoted his principal work, *Spór o Istnienie Świata* (The controversy over the existence of the world), to the analysis of these various objects and relationships. According to Ingarden, existence is not that which exists but that by means of which something exists. Not every-

thing that can be distinguished in an object belongs to its attributes: Existence is not an attribute of an object. Ingarden attempted to account for the specific role of existence in whatever is, by distinguishing between modes of being (*modus existentiae*) and existential moments (*momentum existentiale*). The real existence (reality) of something, the possibility of something, and the ideal existence of something are examples of modes of being (modes of existence). Nonexistence, however, is not a mode but the absence of any being. An existing object can never be experienced by us without its mode of being. In every mode of being we can distinguish existential moments. The existential moments are the elemental units of the modes and thus are the key to understanding them. Many different existential moments can be distinguished intuitively in each mode of being of something. What we grasp in the object is not existence as such, which is a certain universal idea, but particular existential moments.

Ingarden divided moments of being into mutually exclusive pairs. There are four basic pairs. The first pair comprises existential autonomy and existential heteronomy. "Something is self-existent (is existentially autonomous) if it has its existential foundation *in itself*. It has such a foundation if it is *immanently determined* in itself" (*Time and Modes of Being*, p. 43). Otherwise it is existentially heteronomous. "An object is *existentially original* if, in its essence, it cannot be produced by any other object" (ibid., p. 52). If it can be so produced, it is existentially derivative. "An object is existentially separate if, *for its existence, it does not in its essence require the existence of any other object with which it would have to coexist, because of its essence, within the compass of one and the same whole*" (ibid., p. 82). If it does require such another object, it is "inseparate." The fourth pair of existential moments are existential self-dependence and existential contingency. Existential contingency involves separate objects that, in spite of being separate, require for their existence some other existentially separate object. An existentially self-dependent object, which is also an existentially separate object, does not require such another object.

Ingarden discussed at length both time and causality. In the analysis of time he distinguished further pairs of existential moments, including actuality and nonactuality, persistence and fragility, fissuration and nonfissuration. His original interpretation of the causal relation arose out of his analysis of the moments of existential originality and existential derivation. For Ingarden a causal relation occurs between *C* and *E* if: (1) *C* and *E* are

diverse; (2) *C* actually conditions *E* but *E* does not condition *C* in the same way; (3) both *C* and *E* are events or processes (as far as their form is concerned); (4) the occurrence of *E* is simultaneous with that of *C*; (5) both *C* and *E* are real actual).

Modes of being consist of noncontradictory combinations of existential moments. Ingarden distinguished four basic modes, or regions, of being: absolute being, temporal (or real) being, ideal (or extratemporal) being, and purely intentional being. Absolute being is characterized by the existential moments of autonomy, originality, separateness, and self-dependence. The other modes have many subtypes, each of which is characterized by a number of existential moments.

Each of Ingarden's analyses of pairs of existential moments is a small monograph on traditional ontological problems usually rooted in Aristotle and scholastic philosophy. On one level they may appear to be analyses of language, as one linguistic philosopher has pointed out, but they are of a scope not generally undertaken by linguistic philosophers, and Ingarden regarded linguistic analysis as an inadequate tool for the systematic analysis of philosophical problems. The analyses contained in this work were to pave the way for the eventual solution of the controversy between idealism and realism over the nature of the world and our relation to it. They follow in many instances the spirit of Aristotle's analysis of categories, but to be fully comprehended they presuppose familiarity with medieval discussion of pure possibilities.

INGE, WILLIAM RALPH
(1860–1954)

William Ralph Inge, the English ecclesiastic and religious thinker, was born at Crayke, Yorkshire. Educated at Eton and Cambridge, he was fellow of Hertford College, Oxford, from 1889 to 1905, vicar of All Saints Church, Knightsbridge, from 1905 to 1907, and professor at Cambridge from 1907 to 1911, when he was appointed dean of St. Paul's Cathedral, London. During his long tenure of this high office, he became one of the best-known Englishmen of his generation. He continued his lifelong studies in philosophy and mysticism, and his penetrating comments on the events of his time, especially on the foibles of contemporary civilization, earned him the sobriquet of "the gloomy dean." He retired in 1934 to Brightwell Manor, Berkshire, where he spent twenty years more of thought and activity before his death.

What provoked Inge's criticism of contemporary culture was its preoccupation with material progress; against this, he pleaded for an end to the separation of fact and value. He maintained that Plato taught an abiding truth when he instructed us to seek reality beyond what is present to the senses; and only a culture that is based on the invisible but eternal values of truth, beauty, and goodness is securely founded. These values are in turn grounded in God, the ultimate spiritual reality, so that Inge's plea was for a religious attitude toward life. The model for such an attitude is provided by the mystic, who penetrates the phenomena of the sensible world to the realm of values and whose soul ascends toward union with God. However, this advocacy of mysticism is not to be understood as escapism or as a denial of the reality of the world of the senses. Inge considered himself in some ways more of a realist than an idealist, and he insisted that any adequate philosophy must take account of the findings of the natural sciences. Mysticism, as he understood it, does not imply emotionalism or irrationalism. Mysticism is itself a kind of spiritual philosophy, a quest for knowledge of the real. If today there is a conflict between the rational and the religious approaches to reality, this is because modern rationalism has become too narrow in its understanding of reason. A genuine rationalism takes account of values as well as of facts; this is the kind of rationalism that flourished in the earlier tradition of Western philosophy, and such a broadly based rational philosophy conduces to the same results as the mystical insights of religion. Both lead, Inge claimed, to "perfect knowledge of the Perfect."

Inge steeped himself in the history of mystical and religious thought, but there was one particular school that seemed to him to approach his ideal of combining genuine rationalism with mystical insight and that therefore strongly attracted him: the Neoplatonism of Plotinus. Inge spoke of Plotinus in terms of almost exaggerated respect as not merely an intellectual teacher but also a spiritual director, and he studied his philosophy not just as a historical phenomenon but also as the classic statement of the insights that have guided Western culture—and thus as a message for our time. Platonism, Christianity, and Western civilization, Inge believed, are inseparable and interdependent; and a restatement of the philosophy of Plotinus can provide an intellectual basis that, when combined with the spirit of Christianity, can lead to the rejuvenation of the West.

INGENIEROS, JOSÉ
(1877–1925)

José Ingenieros, the Argentine positivist metaphysician and ethical philosopher, was born in Buenos Aires. He studied, successively, medicine, psychiatry, axiology, and metaphysics and held appointments on the faculties of medicine and of philosophy and letters in Buenos Aires; he also founded the *Revista de Filosofía.* Ingenieros lived for some years in Germany and Switzerland. He had great influence in Latin America, and some of his works were translated into several European languages.

In *Proposiciones relativas al porvenir de la filosofía* (Buenos Aires, 1918), Ingenieros set forth a prospectus for a metaphysics of the "inexperiential." By the "inexperiential" he did not mean a transcendent object but those parts of the natural world that the limitations of the senses and instruments exclude from present experience. He rejected the "classical" problems of the existence and nature of God, immortality, and freedom, finding them to be not so much meaningless as falsely stated under the influence of theological and ethical orthodoxy. The legitimate problems of metaphysics are those of metacosmology, metabiology, and metapsychology; in metabiology, for example, some legitimate problems are the origin of life, the possibility of life beyond this planet, and the final purpose of life. Because its objects lie beyond experience, metaphysics cannot achieve certainty. Its statements are hypotheses, which must be logically consistent and compatible with experience. Like the sciences, the metaphysics of the future will be antidogmatic, tentative and indefinitely perfectible, and impersonal in the sense that it will be the work of many collaborators.

The ethics of Ingenieros, discussed with visionary enthusiasm in *El hombre mediocre* (Madrid, 1913), is naturalistic, evolutionary, and deterministic. Values or ideals are hypotheses for the perfecting of human life. They arise out of experience, are formulated by the imagina-

tion, are tested in the evolutionary process, and are at once relative and a challenge to strenuous philosophy. They are created by exceptional men, or idealists, and are often thwarted, at best conserved, by the mass of mediocre men. For these reasons *El hombre mediocre* is critical of democracy, although it calls for equality under law while asserting an aristocracy of merit.

INNATE IDEAS

The theory of "innate ideas," in any of its philosophically significant forms, claims that all morally right judgment or all science, or both, rest upon or consist in a knowledge a priori either of (*a*) universal principles governing reality or (*b*) objects transcending sensory experience. Representative of such universal principles are "From nothing, nothing comes" (*Ex nihilo, nihil fit*); "Equals added to equals give equals"; "It is wrong to murder." Illustrations of transcendent objects are Platonic Forms and God. Concomitantly, the theory attempts to explain the genesis and epistemological status of the conception of such principles and objects. For this purpose it introduces the notion of innate ideas.

Proponents of the theory of innate ideas (henceforth "innatists") would typically agree with empiricists that sensory experience consists of particulars. They would claim, however, that scientific knowledge is knowledge that holds good everywhere and at every time, that such knowledge in fact exists, and that the abstracting and compounding of sensory particulars in empiricist inductions cannot possibly provide us with such knowledge, but at most only with opinion. Innatists would also maintain, in agreement with some empiricists, that the

abstractions and compoundings of sensory particulars described by empiricism as the basis of conception cannot possibly provide us with the conception of such universal principles or transcendent objects as are referred to above. At the same time, innatists would typically disagree with those realists who claim that such conceptions and knowledge are attained through direct perceptions or intuitions of nonsensory reality, or if they did join the theory of innate ideas with a theory of such intuitions, as Plato seems to have done, they would hold that scientific knowledge, though it may conclude in such intuitions, does not commence with them. (To maintain that scientific knowledge commences with such intuitions would be to make the notion of innate ideas methodologically and epistemologically superfluous.) The notion of innate ideas rests, for its philosophical significance, on the assumption that knowledge of reality is not given directly—at least, not in its chronologically first premises—but through representations. Where reality is viewed as something distinct from sensory particulars, innatists are thus representative realists.

Since proponents of the theory of innate ideas deny that such conceptions of universal principles or of transcendent objects as are described above are derived either from sensory experience or from intuitions of nonsensory reality, they are left with the problem of explaining their genesis. This they solve by holding these conceptions to be innate or inborn—to be, in short, innate ideas. But in speaking of innate ideas, proponents of the theory seem to mean two things. By "idea" they sometimes mean an object of awareness, like a mental image. When speaking in this way, innatists must maintain that conceptions of universal principles or of transcendent objects are present in the mind from birth or even prior to it. Innatists then typically explain why children and savages do not seem to be cognizant of the principles or objects in question by holding that these conceptions or representations, though present in the mind, are obscured by the presence of other conceptions or ideas—in particular, sensory ideas or percepts—much as the sound of a flute might be present in the air but be inaudible because of other sounds or noises. Again, innatists sometimes mean by "idea" not an object of awareness but, rather, a disposition of the mind or reason to form a determinate conception under certain conditions or stimuli. In René Descartes, for instance, whenever consciousness occurs, there also occurs the conception that something is conscious—namely, oneself—and this is innate in the dispositional sense.

An equally crucial problem for proponents of the theory of innate ideas is to explain the epistemological status of innate conceptions. Since these conceptions are held to constitute the foundation for all science and since science is conceived of as depicting reality, the question arises: How can we know that these conceptions apply to reality?

Again, two answers are traditionally given to this question. One answer, originating in Plato, holds that innate ideas are actually memories. These memories are the representations of direct intuitions of reality experienced before birth. Innate ideas express knowledge, then, in the way that memories do. A second answer, exemplified in Descartes, holds that the truth of innate ideas can be internally validated. Thus, in Descartes we find upon reflection that two innate ideas, the idea that I am and the idea that from nothing nothing comes, possess a special property—they not only involve the immediate assent of reason (their denial being a contradiction of sorts) but they cannot be subjected to doubt, since any possible argument of doubt, as, for instance, appeal to an evil demon as the source of these ideas, must implicitly affirm the ideas in question. Thus, in arguing that an evil demon might be deceiving me, I at the same time affirm that I am and employ the principle that from nothing nothing comes. Taking a stand on these two innate ideas, Descartes then purports to prove the existence of God and God's goodness; by so doing, he thinks to establish clarity and distinctness as both the necessary and the sufficient condition of an idea's being true and thus validate all other innate ideas.

In summary, then, the theory of innate ideas states that certain conceptions of universal principles and nonsensory objects are innate, in the sense of being either images present in the mind at or before birth or inborn dispositions of the mind to form conceptions under certain circumstances. Since these conceptions, taken as either images or dispositions, exist chronologically before sensory experience, they are a priori in the literal, temporal sense of the term. Since they are not composed from or testable in sensory experience but since they provide the basis for all scientific knowledge, they are also a priori in the logical and epistemological senses.

HISTORY OF THE THEORY

The notion of innate ideas patently lends itself to theological speculation and to systems of metaphysics that locate reality in realms transcending sensory experience. Plato employed the notion as the bridge to the realm of Forms, and similar metaphysical and theological uses of

the doctrine occur in the works of the Neoplatonists (Plotinus, for example), as well as in the works of later philosophers and theologians belonging to the Platonic and the Neoplatonic tradition, including St. Augustine in the early period of Christianity, and Marsilio Ficino in the Italian Renaissance. Outside the strictly Platonic and Neoplatonic line, Descartes, as already noted, employed the doctrine in his proof of God's existence, and it was used in a similar fashion by the ancient Stoics, Herbert of Cherbury, and many other philosophers.

The doctrine of innate ideas also has an intimate relationship with the philosophy of science. Historically, this relationship has minifested itself in the fact that philosophical controversy over the doctrine has been greatest just when philosophers have been most concerned to establish foundations and methods for science. Thus, the existence of innate ideas was especially debated in the fourth century BCE by the philosophers of the Academy and the Lyceum and in the seventeenth century by the Continental rationalists and the British empiricists.

The question of whether innate ideas exist is not without consequences in the establishment of science. The doctrine of innate ideas favors certain scientific procedures and discourages others. In particular, it favors meditation as opposed to laboratory experimentation and mathematical methods as opposed to inductive methods. It might seem, however, that philosophical theories concerning the origins and foundations of scientific knowledge could have had, and therefore have had, no actual influence on the establishment of science, just as it has seemed to many philosophers that philosophical theories concerning ethics could have had and have had no actual influence on men's moral behavior. But this view overlooks the failures of would-be science in the seventeenth and eighteenth centuries: On the one hand, the imposing but vacuous systems spun out of the doctrine of innate ideas, and, on the other, the aimless experimentation and observation that Jonathan Swift, for example, caricatures in parts of *Gulliver's Travels*. The truth would appear to be, not that the doctrine of innate ideas could have had no real influence upon the development of science, but that if it had been strictly and universally adhered to in the seventeenth century and afterward, science would not have been established; but, then, universal adherence to the stricter forms of empiricism would also have been a sterile cause, and so, too, it would seem, would have been an intellectual climate in which neither philosophical empiricism or philosophical rationalism played any part in men's thinking.

EVALUATION

The classic attack upon the doctrine of innate ideas is made by John Locke in the first book of *An Essay concerning Human Understanding*. Locke argues that if the doctrine of innate ideas were true, one would expect to find certain ideas, such as the idea of God or the idea that whatever is, is, possessed by everyone and consciously employed in all their reasonings. This is not the case, however. Small children and savages do not possess these ideas, nor do persons consciously employ them in all their reasonings.

Commentators on the theory of innate ideas have sometimes complained that Locke's criticism of the theory sets up a straw man that no responsible innatist has ever cared to defend. In particular it has been claimed that responsible innatists have not held, and have not pretended to hold, that universal recognition and acceptance are corollaries to the existence of innate ideas. But this complaint is beside Locke's point. It is clear, for instance, that if small children everywhere, at the commencement of their discourse with others, appealed explicitly to the idea that whatever is, is, or to the idea of God, there would be good empirical grounds for supposing that innate ideas existed. For these would be at least some of the crucial empirical consequences one would want to deduce from the theory. Since these crucial consequences are not observed but might theoretically be observed, the theory is an empirical theory and, as such, it stands refuted by experience.

It has been argued against the theory of innate ideas that whatever transcendent principles or conceptions the theory pretends to account for can be accounted for more plausibly by supposing them to be constructed from givens of experience or acquired through transcendent intuitions. This argument, however, is not very convincing. It is, for example, impossible to conceive how the concept of infinity could be constructed from givens of experience or acquired through the contemplation of some transcendent realm of entities. But it is not clear, either, how possession of the concept can be accounted for through the theory of innate ideas.

Bibliography

PRIMARY SOURCES

Plato connects the theory of innate ideas with the doctrines of reminiscence and metempsychosis in *Meno* and *Phaedo*. (See *Dialogues*, edited by B. Jowett, 2 vols., 4th rev. ed., Oxford, 1953). He supports this by the case of the slave boy who carries out geometrical demonstrations in a manner suggesting recollection.

Herbert of Cherbury bases his doctrine of natural religion upon a theory of innate ideas. In his *De Veritate*, translated as *On Truth* by M. H. Carré (Bristol, U.K., 1937), universal recognition and acceptance are treated as criteria distinguishing innate ideas from other ideas. Pragmatic overtones are introduced: Our common or innate notions are also those that conduce to our preservation, and conversely.

Descartes lays the foundation for most subsequent discussion, pro and con, of the theory of innate ideas in his account of the wax tablet and our judgments of other minds in the "Second Meditation" and in his threefold division of ideas in the "Third Meditation." See *Meditations*, in *The Philosophical Works of Descartes*, translated by E. S. Haldane and C. T. Ross. 2 vols. (Cambridge, U.K.: Cambridge University Press, 1911, 1931; New York, 1955).

Locke's classic attack upon the theory of innate ideas is given in Book I of the *Essay concerning Human Understanding* (edited by J. W. Yolton, 2 vols., London, 1961). Locke argues that the theory that all knowledge is acquired from experience can be substantiated in experience; the doctrine of innate ideas is disconfirmed by experience.

Gottfried Wilhelm Leibniz's *New Essays concerning Human Understanding* contains an exhaustive examination and critique of Locke's attack upon the theory of innate ideas. See "Specimens of Thoughts upon the First Book of the Essay on Human Understanding, 1698," the preface, and "Book I" in the *New Essays* as translated by A. G. Langley. 3rd ed. (La Salle, IL, 1949). In opposition to Locke, Leibniz argues that insensible perceptions exist and that thus Locke's arguments concerning children and savages being unaware of the concept of God or such principles as whatever is, is, do not refute the theory of innate ideas. Contains Leibniz's own version of the theory of innate ideas.

David Hume in his *Enquiry concerning Human Understanding* offers a very brief but penetrating and informative discussion of the theory of innate ideas and its relation to his principle that every simple idea is the copy of a precedent simple impression. See Sec. 2, footnote 1, in the *Enquiry* edited by C. W. Hendel (New York, 1955).

N. O. Losskii connects the historical appearance of the doctrine of innate ideas in the seventeenth century with the failure of empiricists of that era to account for transcendent knowledge, necessary truths, and knowledge of an external world. See Ch. 2 of his *The Intuitive Basis of Knowledge*, translated by N. A. Duddington (London: Macmillan, 1919), where he argues that although the pre-Kantian rationalists seemed able to resolve the difficulties in question by the doctrine of innate ideas, the cost of this resolution was prohibitive. They "had to assume that *the whole of knowledge is innate*."

R. I. Aaron in *The Nature of Knowing* (London: Williams and Norgate, 1930) discusses innate ideas in connection with his intuitionist theory of knowledge. Although he maintains that all discursive knowledge rests upon a priori knowledge of indubitable or self-evident principles, he denies that the latter are innate ideas.

H. H. Price maintains in *Perception* (London: Methuen, 1932) that there are a priori innate ideas, but that "we only come to clear consciousness of such concepts … when we have already applied them many times."

Lewis E. Hahn's *A Contextualistic Theory of Perception* (Berkeley and Los Angeles: University of California Press, 1942) contains a detailed discussion of the interrelationship of strict sense-data theories of perception, pragmatic theories of perception, and the doctrine of innate ideas. Hahn argues that a strict sense-data theory of perception forces one to accept the doctrine of innate ideas in order to account for one's knowledge and conception of material things, whereas a pragmatic theory of perception does not. He takes this consequence to count in favor of pragmatic theories of perception and against sense-data theories.

John Wild maintains in his *Introduction to Realistic Philosophy* (New York: Harper, 1948) that what evidence we possess strongly indicates that rational knowledge does not rest upon innate ideas, but is acquired. This evidence consists in the fact that "first we do not know. Then we know."

INNATE IDEAS, NATIVISM

Nativism, or the doctrine of innate ideas, is the thesis that human beings possess at least some substantive knowledge innately. The doctrine has long been the subject of intense controversy among philosophers, and since the late 1950s, among cognitive scientists as well. It is generally understood in opposition to the doctrine of empiricism, according to which all substantive human knowledge derives from sense experience.

Proponents of nativism argue that experience alone cannot account, either *de facto*, or in principle, for the extent and specific content of human knowledge. Arguments of the first type focus on the type and amount of information actually available to a human being during a given period of empirical experience, and purport to show that the information contained in that experience is insufficient to account for a person's manifest cognitive achievements at that point. Such arguments have become known by the term introduced by linguist Noam Chomsky as "poverty-of-the-stimulus" (POS) arguments, and constitute the most common way of defending nativist hypotheses (Chomsky 1957, 1965, 1975). Arguments of the second type are transcendental in character. They purport to show that certain kinds of knowledge are preconditions of empirical learning, and could not, therefore, be the products of such learning. Philosopher Jerry Fodor, who posits an innate system of representation, is probably the most well-known contemporary author of an argument of this type (Fodor 1975). In both kinds of argument, nativists tend to focus on the particular mechanisms of knowledge acquisition presumed or posited by their opponents.

Opponents of nativism also employ a variety of strategies. Some attempt to rebut POS arguments, by showing that the relevant body of empirical experience does, in fact, contain the right types and amount of information to account for human knowledge, and that actual human learning mechanisms can, in fact, extract it. Others critics attack the doctrine directly, arguing either that the notion of innate knowledge is hopelessly obscure, or that it cannot be made scientifically respectable. Still other opponents contend that the doctrine properly understood is trivial—that it posits nothing an empiricist need reject.

Indeed, philosophical discussion of nativism has tended to focus on the meaning of the doctrine, and in particular, the operative terms, "knowledge" and "innate." Philosophers have traditionally made a provisional distinction between declarative, or theoretical knowledge—

"knowing-*that*"—and practical knowledge—"knowing-*how*." It is one thing to attribute to someone practical knowledge of, for example, logic, and quite a different thing to attribute to her declarative knowledge of logic. Normal human beings all have the ability to reason in accordance with the laws of logic, whereas few of us can articulate those laws, or even recognize them if they were laid out explicitly before us. Accordingly, the claim that some practical ability is innate is, on its face, different from the claim that some bit of declarative knowledge is.

The term "innate" has both a categorical and a dispositional sense. In the categorical sense, a trait is innate only if it is manifestly present at the creature's beginning; in the dispositional sense, a trait can be innate if the creature is disposed to manifest it under normal conditions. Now it may well be that a newborn human infant lacks the ability to reason—the relevant neuronal connections may not yet have formed—so that practical knowledge of logic is not innate in the categorical sense. Still, a normal infant is disposed to acquire the ability to reason, in normal circumstances. That is, the infant is so constituted that the necessary neurological connections will be formed, provided the infant gets enough to eat, suffers no head injuries. Practical knowledge of logic should therefore be counted as innate in the dispositional sense. The same point can be made with respect to declarative knowledge: It could be innate in the dispositional sense even if it is not innate in the categorical sense.

There are further complications. Knowledge can be either explicit or implicit. While it could be argued that few individuals have explicit declarative knowledge of the laws of logic, it is clear that everyone has—in virtue of being a competent reasoner—implicit knowledge of those laws. Contemporary cognitive science introduces another wrinkle: Knowledge can reside at the "personal" or at the "sub-personal" level. Personal-level knowledge is knowledge that can be consciously accessed, and that can play a role in conscious deliberation. Sub-personal knowledge is posited to reside in cognitive "modules"—subsystems that perform cognitive operations that are inaccessible to consciousness, and that are isolated from personal-level beliefs and desires. Many philosophers find the notion of sub-personal "knowledge" oxymoronic, and yet the notion has come to play an increasingly important role in contemporary cognitive science.

Contemporary cognitive science and cognitive ethology (the study of nonhuman animal cognition and behavior) have generated a great deal of support for the view that much apparently intelligent animal behavior is to be explained by natively structured cognitive "mod-

ules" containing domain-specific information and algorithms. Explanations of this sort have been posited for phenomena as diverse as bird navigation systems and bee foraging strategies (Gallistel et al. 1991). Psychologist Steven Pinker suggests that this conception of "instinct" provides the best way to understand the species-specific human capacity for language (Pinker 1994).

Nativism as it is understood in philosophy and contemporary cognitive science is a theory of human universals, of species-wide characteristics. It should therefore be sharply distinguished from "biological determinist" theories—theories that purport to explain individual human differences with respect to such traits as intelligence and criminality in terms of innate and supposedly immutable genotypic differences.

HISTORY OF THE DEBATE

The basic outlines of the debate were set in ancient Greece, and were further elaborated in the early modern period. Plato employed a POS argument for a version of nativism, his doctrine of "recollection" (*anamnesis*). In *Meno*, Plato's character Socrates elicits from an uneducated slave boy the solutions to a series of problems in geometry, culminating in the identification of an irrational number, the square root of two. Since the boy could not have learned it, Socrates argues, the relevant information must have already been present within his soul, needing only the stimulus of Socrates's questioning for it to be "recollected." Socrates goes on to argue that the origins of this knowledge, which every human being could "find … within himself" (Plato 1981, p. 75), are prenatal, the result of the soul's early encounter in a previous life with the objects of eternal truths.

Aristotle rejected Plato's doctrine of innate ideas, averring that the mind is initially blank. Universals, or "intelligible forms" can only be grasped through experience, by abstraction from the "sensible forms" delivered to the mind through sense perception (*Posterior Analytics*, Bk. II). This Aristotelian empiricism was embraced and elaborated by the Scholastics in the Middle Ages. According to Aquinas, apparently *a priori* knowledge such as that of Plato's slave boy could be accounted for in terms of the mind's detection of its own operations. Although the mind natively has the propensity to perform these operations, it is not until the mind is stimulated by the provision of the sensible forms imparted through perception that such operations actually occur. In this sense, then, even the apprehension of one's own inner mental life is indirectly dependent upon sensory experience (Adams 1975).

René Descartes revived nativism. He rejected the Aristotelian/Scholastic doctrine that our ideas of perceptual qualities resemble or share a form with the qualities of the bodies that occasioned them. On Descartes's view, perception, like all causal processes, involved the movement of tiny bodies or corpuscles, the properties of which bore no resemblance to the ideas of sensory qualities in which the process culminated. In that case, Descartes argued, our ideas of color, shape, movement could not have been imparted by sensation, but must rather be innate, and merely occasioned by sensation. In calling such ideas innate, Descartes was not claiming that they were manifestly present in the mind since birth. Rather, he meant that our minds are innately constituted in such a way that sensory experiences of certain sorts reliably give rise to ideas of certain sorts (Descartes 1648/1969).

Although Descartes did not believe that ideas must share forms with the objects they represented, he did accept a principle that constrained the relation between the two. This principle, sometimes called the "principle of proportionate reality," formed the basis of a type of POS argument, albeit an a priori one. The principle states that a cause must contain at least as much reality as its effect. Applied to the special case of the relation between ideas and their causes, Descartes claimed that the principle entails that the cause of an idea must possess at least as much "formal" reality as the "objective" (or representative) reality contained in the idea.

There are three possibilities, Descartes says, as to the causes of those of our ideas that are involved in judgments, that is, that admit of truth or falsity: they can be (a) caused by something outside of ourselves ("adventitious" ideas), (b) fabricated by ourselves ("factitious"), or (c) innate. Now our idea of God is an idea of an infinite, eternal, omniscient, omnipotent and perfectly benevolent being. Since the amount of objective reality in such an idea is infinite, the cause of this idea itself must be something infinite and perfect. No finite substance could be the cause, and hence it could not have been caused by a substance exeeeee e external to myself, nor could I have caused it myself. Only an infinite, perfect being could have caused it, i.e., only God Himself. Furthermore, since this idea does not come upon me "unexpectedly" as do ideas that come through the senses, and since it is not within my power to change it as is the case with ideas that I originate, my idea of God, Descartes concludes, must be innate, implanted by God at the beginning of my existence (Descartes 1641/1969).

Descartes also made two empirical arguments for the domain-specificity of the human language capacity, argu-

ments explicitly cited by Noam Chomsky in his twenti-eth-century defense of the same conclusion. In *Discourse on Method* (1637/1969) Descartes sought to establish the existence of a "special faculty" in human beings that accounted for our capacity, distinctive within the animal kingdom, for creative language use. He considers the objection, offered by a hypothetical interlocutor, that human linguistic competence might be due to a merely quantitative difference in some general ability between human beings and other animals, rather than, as Descartes's view had it, a difference in kind.

Descartes's first response is to point out that even the "stupidest" human children acquire language without difficulty, whereas not even the most intelligent infrahu-man animals are able to acquire it at all. (It is noteworthy that Descartes's judgment about the linguistic incapacity of infrahuman animals was confirmed during the 1970s, when a variety of researchers attempted, without success, to teach American Sign Language to apes and chimpanzees. Despite assiduous training, not one of the otherwise highly intelligent and creative animals even approached the linguistic achievements of the average deaf human three-year-old (Pinker 1995). This response, however, is vulnerable to the following rejoinder: It may be that there simply is no overlap between humans and other animals in the ranges of variation in the relevant ability, that the "stupidest" human has a far greater amount of this hypothetical general ability than does the "most perfect parrot or monkey." Descartes's second argument speaks to that possibility: if human linguistic ability is a manifestation of a more general ability, then we'd expect that human beings would excel above animals in all activities to the same extent we exceed them in the practice of communication. But this is not what is observed (Descartes 1637/1969).

John Locke, like Aristotle, held that the mind is initially only a "white paper void of all characters, without any ideas" (1689/1979, p. 2). He explicitly rejected Descartes's doctrine of innate ideas. It was unnecessary, he argued, to posit "innate principles" in order to account for any feature of human knowledge, when the humanly "natural faculties" of sensation and reflection could be shown to be quite sufficient. He particularly objected to the view that ideas of sense were innate, arguing that "it would be impertinent to suppose the ideas of colors innate in a creature to whom God hath given sight, and a power to receive them by the eyes from external objects" (1689/1979, p. 1). But he was equally adamant that truths of reason became known only through experience. The *faculty* of reflection was sufficient to ensure that we rec-

ognize such propositions as true as soon as we apprehend them.

Locke's *Essay* was meant to provide a systematic explanation of the origins of all human knowledge from these raw materials of human faculties and simple ideas of sense, and thus was addressed to Descartes's POS arguments. But Locke also had principled reasons for rejecting the doctrine of innate ideas, reasons that echo today in contemporary empiricists' objections to empirical nativist theories. To begin with, he argued, these allegedly innate principles are not in fact universally known—"children and idiots have not the least apprehension … of them" (p. 4)—and so could not have been imprinted upon the human soul at birth. If it is replied that the principles could have been imprinted without the subjects' being aware of them, Locke argues, then the doctrine of innate ideas is trivialized. If we can make sense of the notion of an unperceived idea, Locke argues, it can only be as an idea that we have the *capability* of acquiring. If the doctrine is understood in this way, however, it becomes trivial, because *any* truth a person can come to know in the course of a lifetime would count as "innate" in this sense. And in any case, even if "universal consent" were established, nativism would not provide the only explanation.

Locke's positive account of the acquisition of ideas and the formation of knowledge relied on posited mechanisms of association and abstraction for the accumulation and manipulation of sensory impressions into general ideas, abstract ideas, and judgments. Subsequent empiricist models of concept acquisition and learning have followed Locke's model in essentials.

Gottfried Leibniz, in his *New Essays*, attempted a systematic rebuttal of Locke's critique of the doctrine of innate ideas. Leibniz first addressed Locke's in-principle objection to the notion of an innate, but unperceived idea. Leibniz argues that Locke is operating with too restrictive a notion of "knowledge" if he does not acknowledge the existence of implicit or unconscious knowledge. And to Locke's objection that allowing implicit knowledge would trivialize the doctrine of innate ideas, Leibniz responds that a distinction can and must be made between sciences like arithmetic and geometry, that we can "construct for ourselves … in our private room … without learning through sight or even touch the truths which we need," and those which require sensory experience (Leibniz 1704/1975). Furthermore, Leibniz argues, there is a difference between the mind's actually possessing structure, of a sort that permits the generation, *a priori*, of knowledge, and the mind's simply having the

potential for acquiring truths. This disagreement between Locke and Leibniz about the nature and significance of innate mental structure has echoes in contemporary philosophical debates.

Leibniz then turned his attention to Locke's positive account of the development of knowledge, and here makes an argument of the type this entry has termed "transcendental." Leibniz focuses on two concepts repeatedly cited by Locke as examples of ideas that could not possibly have been innate, but must be acquired through experience, namely impossibility and identity. According to Locke, these ideas can only be the product of the comparison of various specific sensory experiences, such as the taste of a normal nipple, versus one rubbed with wormwood. But this, according to Leibniz makes no sense: abstraction cannot explain the acquisition of these concepts, because abstraction presupposes the ability in the subject to classify experiences as similar or different, and thus as possessing the concepts same and different. Possession of such concepts is a precondition of, and thus cannot be the result of empirical learning (Leibniz 1704/1975). Ironically, a similar argument was made by the empiricist David Hume for the innateness of the principle of induction. The notion that the future tends to resemble the past is not one, Hume argued, that could be acquired through experience, because we need to presume that principle in order to take experience as evidence for anything at all (Hume 1748/1977).

Immanuel Kant, from whom my use of the term "transcendental" is borrowed, argued similarly that empirical experience as we know it—"intuitions"—are only possible because of innate forms and structures that characterize our perceptual and intellectual capacities. Space and time, he argued, are not features of reality considered "in itself" but are rather the "a priori" forms of perception. Perceptual experiences are only cognitively available to us because of the "pure categories of the understanding," highly general concepts like object and cause, that allow us to utilize experience to form judgments (Kant 1781/1787/1929).

CURRENT CONTROVERSIES

At the beginning of the twentieth century, under the influence of logical positivism, many philosophers rejected not only the doctrine of innate ideas, but the very notion of the mind. Hypotheses about mental structures and processes were held to be at best unverifiable, and at worst, unintelligible; the only possible "science of the mind" would be, ironically, a science of behavior. J. B. Watson and B. F. Skinner developed what they claimed

was a fully general account of learning, applicable to all behavior, whether "intelligent" or reflexive, human or infrahuman. The basic mechanisms posited by behaviorists—classical and operant conditioning—involved the evocation, shaping and reinforcement of patterns of behavior. Although behaviorists eschewed any reference to the mental, they did tacitly accept Leibniz's point against Locke. Accordingly, they posited what philosopher W. v. O. Quine called an "innate similarity space"— a disposition to treat stimuli as falling into similarity classes, manifested by "stimulus generalization," the transfer of a reinforced response to similar but novel circumstances, a precondition of the learning of complex behavior (Skinner 1953).

Skinner thought that behaviorist principles could and would account for even the most complex behaviors acquired by human beings in their lifetimes, including the mastery of language. His book *Verbal Behavior* was the first, and to date, the last, effort by an anti-nativist, anti-mentalist to provide a systematic and relatively detailed explanation of the acquisition of human language (Skinner 1957). But in 1959, Noam Chomsky published a devastating review of the book in which he showed that the theory faced a fatal flaw: It was either grossly empirically inadequate or else devoid of empirical content (Chomsky 1959).

Chomsky had outlined his own positive account of language acquisition in 1957, an account that was iconoclastic at the time in reviving not only mentalism, but nativism. Unlike Skinner, who derived his model of language learning top-down, Chomsky urged a naturalistic approach to the study of language, one that focused on the actual conditions in which children acquired their linguistic competence. This focus quickly revealed several important points: (1) children attain language without any explicit instruction; (2) language is almost universally acquired, even for blind children (and deaf children if they are given access to signed language) within the first five years of life; and (3) the body of evidence available to children during acquisition—the body of "primary linguistic data"—is badly "impoverished" relative to the body of information eventually mastered. In particular, the data do not contain "negative evidence"—information that certain constructions are *not* licensed. This is highly significant, as there seem to be certain kinds of ungrammatical constructions that never appear among children's early mistakes. Given all this, Chomsky concluded that language acquisition was not the result of some general learning mechanism operating on sensory data, but that it rather involved, a domain-specific cogni-

tive mechanism that embodied constraints on the forms human linguistic systems can take—the "language acquisition device" (LAD). This natively specified set of constraints, "universal grammar" (UG), greatly simplifies the acquisition task by sharply constraining the set of candidate grammars a child must consider in response to data and by filling in gaps left by experience.

The POS paradigm has since been applied in many other ways within cognitive science. Psychologists Barbara Landau and Lila Gleitman have shown that blind children acquire verbs of sight (for example, "look" "see") in much the same way as sighted children, though, obviously, in the absence of any visual experience (Landau and Gleitman 1985). Gleitman has argued that children's mastery of semantics (as opposed to syntax, which is Chomsky's focus) cannot be explained on the basis of experience, showing that the most common verbs in human language have no distinctive profiles of contingency of usage from which the child could infer their meanings (Gleitman 1990). These findings directly contradict the empiricist accounts of meaning acquisition found in Skinner and Quine (Skinner 1957, Quine 1973).

Elizabeth Spelke, pioneering an experimental paradigm for studying infant cognition, has provided empirical support for the views of Leibniz and Kant that our basic conceptual organization of the external world is natively specified, as a precondition of all other empirical learning (Spelke 1995). Evidence from the study of autistic persons has led many researchers to posit an innate "theory of mind" that enables non-autistic persons to interpret the facial expressions, gestures, intonation patterns of their fellow human beings in a reflexive way, and to effortlessly generate appropriate hypotheses about their likely intentions, desires, and reactions (Frith 1992, Baron-Cohen 1995). Empiricist critics of this so-called "theory-theory" approach to our capacity for psychological understanding argue that we do not need innate psychological knowledge; that rather, we utilize our capacity to mimic our conspecifics to run "simulations" of other individuals' psychologies, and thus to learn empirically what is going on in their heads (Gordon 1986, Heal 1994, Goldman 2006).

Philosophical critics of Chomsky have challenged the intelligibility of his model of mind and his conception of innate knowledge, raising many of the points raised by Locke and other empiricists. Gilbert Harman and Hilary Putnam each have argued that Chomsky's arguments demonstrate, at best, the existence of native principles of induction governing the learning of language, a thesis any empiricist could accept. Putnam also argued that

nativism is not the only or the best explanation for the existence of linguistic universals, or the ubiquity of acquisition (Putnam1967, Harman 1967). Chomsky replies that the real issue is whether there are specialized mechanisms that in some sense embody domain-specific information, not how that information is embodied (See also Katz 1966). He insists that the notion of "innate knowledge" should be understood as an abductive posit in a scientific theory, with the details to be worked out as part of the relevant scientific investigation, as is usual in other branches of science (Chomsky 1969). Pinker and others have stressed, in response to Putnam's second point, that it is the poverty of the stimulus, rather than universality, that provides the strongest support for nativism. Alvin Goldman considers and responds to the objection, first found in Locke, that mere innateness cannot secure the justification required for knowledge, arguing that an externalist epistemological framework that takes account of selectional processes that account for native beliefs or biases can provide the systematic warrant needed for knowledge (Goldman 2006).

On the empirical side, critics have focused, appropriately, on the POS argument. Some have attacked the logic of the POS argument, contending that many cognitive achievements are made in the absence of apparently needed evidence, with there being no reason to think the relevant knowledge is innate. Fiona Cowie, for example, argues that she acquired the concept "curry" without explicit instruction, without negative evidence, but that that is no reason to think the concept is innate (Cowie 1998). Others contend that the primary linguistic data are richer than Chomsky has supposed. For example, it has been widely documented that parents and other speakers interacting with infants tend to produce a simplified and pedagogically friendly version of human language, dubbed "Motherese," that may provide the child with a salutarily biased sample of the language (Snow 1972). Other critics argue that our cognitive resources for extracting information from the environment are more powerful than Chomsky supposed. These latter critics include advocates of a new empiricist model of mind called "connectionism." Connectionists reject the view that cognition involves the manipulation of structured representations, arguing instead that the mind is a vast network of neural nodes, capable, given suitable "training," of detecting and responding, at levels not accessible to consciousness, to very subtle regularities in the data stream (Elman et al. 1996).

Chomsky's theory is computationalist—that is, it presupposes that the mind is, *inter alia*, an information

processing device. In 1975, philosopher Jerry Fodor argued that not only Chomsky's, but all successful and fruitful psychological theories were tacitly committed to this model, and that the model itself carried a heavy ontological commitment. Computations, Fodor argues, require a *medium of computation*. Since the acquisition of natural language is one of the processes that is, *ex hypothesi*, computational, natural language cannot itself be the medium in which the relevant computations take place. There must be an antecedently existing medium, an innate "language of thought" (LOT), with at least as much syntactic complexity and expressive power as needed to fully represent natural languages (Fodor 1975).

Fodor's view on the latter point has developed. Initially, he claimed that the argument showed that all concepts were innate, but he has recently modified this to the claim that no concept is *learned*, leaving open the possibility that there are non-computational, and hence non-psychological means for acquiring concepts (Fodor 1997). The argument that no concepts are learned is transcendental in character, and simple to state: (1) Concept learning (if there is such a thing) would involve the formulation, projection and confirmation of hypotheses as to the extension of the concept to be learned; (2) Such processes presuppose the means to represent the extension of the concept to be learned; (3) But any system that has the means to represent the extension of a concept *ipso facto* possesses the concept. Therefore, (4), one cannot learn a concept without already possessing that concept; hence (5) concept *learning* is impossible.

Fodor's critics include many of the philosophers who have challenged Chomsky. Critics have charged that the LOT leads to an infinite regress of languages and interpreters (Dennett 1975, Harman 1975). Connectionists have argued that Fodor's fundamental assumption—that mental operations involve the manipulation of structured symbols—is mistaken, and that there is therefore no need to posit an innate medium of computation (Clark 1993). Other critics have argued that Fodor has constructed a false dilemma about concept learning: that there are plausible models that do involve a rational extraction of information, and that should thus count as learning, but that do not employ the hypothesis-confirmation model that Fodor presumes to be the only alternative to non-psychological triggering (Margolis 1998, Cowie 1998).

Fodor is also responsible for revitalizing the theory of mental modularity (Fodor 1983). According to Fodor, processing in each sensory modality, as well as linguistic processing, takes place in specialized functional regions of the brain, equipped with proprietary algorithms, memory, and computational vocabulary. Such processing is characteristically fast, automatic, and "informationally encapsulated"—insensitive to information from outside the module, typically information stored in central systems. The character of these modules is specified in the genome, although their development may require experiential inputs at crucial stages. Contemporary anthropologists and social psychologists, along with some cognitive psychologists, have become increasingly interested in developing modular explanations for a wide variety of human cognitive and psychological traits, from reasoning about social contracts to men's alleged aesthetic preference for firm breasts in women (Barkow et al. 1992; see Pinker 1997, 2002 for an overview). Ironically, Fodor has emerged as the most vocal critic of this line of thought, objecting both to the strict adaptationist presumptions of the modularists' methodology, and to what he regards as the emptiness of the conception of modularity they employ (Fodor 2000). The debate beginning with Plato will no doubt continue as philosophers, psychologists, and cognitive scientists try to bring fresh insight to the issue of innate ideas.

INNER SENSES

The scholastic theory of the inner senses can be viewed as an attempt to explain and classify cognitive abilities shared by human beings and nonrational animals, abilities that go beyond pure sensation and require a certain level of abstraction. Given that capacities such as reason or belief were generally denied to animals beginning in the classical period of Greek philosophy, these powers or faculties of the sensible soul were thought to account for goal-directed or intentional animal behavior as well as memory and dreaming in humans and animals.

Historically, the concept of the inner senses is rooted in Aristotle's (384–322 BCE) remarks on postsensory faculties of the soul in the second and third books of *De Anima* and in *De memoria et reminiscentia*. A model list-

ing three "inner" psychic faculties, assigned to three cerebral ventricles (imagination/front ventricle, intellective faculty/middle ventricle, memory/rear ventricle), stems from the writings of Galen (129–c. 199) and was handed down to medieval thinkers via Nemesius's (fourth century AD) *De natura hominis* (chapter 5) and John Damascene's (c. 675–749) *De fide orthodoxa* (chapters 32–34). St. Augustine (354–430) was the first to use the Latin term *sensus interior*, meaning Aristotle's common sense (*Confessions*, book 1, chapter 17; *vis interior* in book 7, chapter 27).

However, the notion of the inner sense only appears there in its singular form. The tendency to posit a plurality of inner senses was probably most influenced by Avicenna's (980–1037) *Liber de anima sextus de naturalibus* (part 1, chapter 5). The Islamic philosopher lists five inner senses as powers of the apprehensive part of the sensible soul: (1) the common sense (*sensus communis*) combines the forms it receives from the five external senses; (2) the imagination (*imaginatio*) keeps these forms stored; (3) the imaginative power (*vis imaginativa*) combines and separates forms kept in the imagination; (4) the estimative power (*vis aestimativa*) judges perceived salient or of interest (e.g., the sheep that apprehends the perceived wolf as something it should flee from); and (5) the memory (*vis memorialis et reminisci-bilis*) keeps these prerational estimations. Although Avicenna gives three- and fourfold classifications as well, this fivefold classification came to be frequently cited in medieval texts.

Albert the Great (Albertus Magnus, c. 1200–1280) uses Avicenna's classification and combines it with a description of the brain and the functions of animal spirits taken from Costa ben Luca's (c. 864–923) *De differentia animae et spiritus* to localize the inner senses. According to Albert the classification reflects different levels of abstraction and corresponds to the grades of subtlety of the animal spirits (*Summa de homine*). The common sense belongs to the same level of abstraction as the five external senses because its function depends on the immediate presence of a perceived object. Nonetheless, it is not counted as an external sense because it does not receive its forms directly from the external object, but from the external senses.

St. Thomas Aquinas (1225–1274) calls the common sense the "root and principle" of the external senses because it joins the different impressions of the external senses and thus combines the raw sense-data to form a unified episode of perceiving an object. Besides the common sense Aquinas's fourfold list of inner senses (*Summa*

Theologiae, pars Ia, quaestio 78, articulus 4) includes the imagination (*imaginatio sive phantasia*), the functioning as storage for sensible forms, the estimative power (*vis aestimativa*), and the memory (*vis memorativa*, *memoria sive reminiscentia*). In contrast to Albert and Avicenna, Aquinas—following Averroes (1126–1198)—stresses that in human beings the animal estimative power is replaced by the cogitative power (*vis cogitativa sive ratio particularis*) that accounts for quasi-propositional perception. In modern philosophy the term *inner sense* is used to signify the mind's ability to reflect on its own operations (Locke 1975, Kant 1998).

INSTRUMENTALISM

See *Dewey, John; Pragmatism*

INTENSIONAL TRANSITIVE VERBS

A verb is transitive if it takes a direct object and intensional if it exhibits one or more intensionality effects in its direct object. The three main such effects are (i) resistance to interchange of coextensive expressions, such as coreferential names or common nouns that happen to apply to exactly the same objects; (ii) lack of existence entailments even when the direct object is existentially

quantified; and (iii) a relational-notional ambiguity if the direct object is quantified.

Verbs of search, desire, and expectation, exhibit all three intensionality effects. Thus, for (i), "Lois seeks Superman" and "Lois seeks Clark" might differ in truth-value even though Superman is Clark. For (ii), "Perseus seeks a gorgon" can be true even if there are no gorgons (contrast the extensional transitive *found*). For (iii), "Richard III seeks a horse" is normally understood to mean that his search may be concluded successfully by finding any one of a range of horses: There need be no particular horse he must find. This is the notional reading. The relational reading is that there is some horse such that he is looking for that horse: Finding other horses will not do. Extensional transitives only allow relational readings: If Richard III rode a horse, there is a particular horse he rode. The relational/notional distinction was named and explored in Quine (1956).

Other groups of verbs exhibit various effects in various ways, providing much for an account of intensional transitives to explain. For example, depiction verbs generate a relational-notional ambiguity only with certain quantifiers in the direct object. "Guercino drew a dog" has both the relational reading—some specific dog—and the notional reading—no specific dog. But "Guercino drew every dog" seems to advert to some antecedent domain on which "every dog" is interpreted, requiring him to have drawn particular dogs (similarly with "most dogs" and "the dog"). By contrast, "Aldrovandi seeks every dog on his property" has a notional reading, according to which he simply has a general intention to find all the dogs there may be in the area. So depiction verbs are a special case.

Verbs of evaluation, such as *despise, fear, respect* and *admire*, resist interchange of coreferential expressions (for example, "Lex Luthor fears Superman but not Clark") but it is not so clear that they give rise to relational/notional ambiguities, at least with existential direct objects. The sentence "Churchill scorned a pedant" (pedantry was something up with which he was not prepared to put) can be understood in two ways: There is a relational reading, according to which there was a particular pedant who was the object of his scorn, and there is a generic reading, which attributes a ceteris paribus response-disposition to him and allows for exceptions. Generic readings are not notional ones, since they are just as common with extensional verbs—for instance, "Corporations overcompensate their CEO's" (see Ariel 1999 for more on generics). So "scorned a pedant" lacks a notional reading.

The verb *need* (and transaction verbs such as *wager* and *owe*) displays the opposite behavior: notional readings are unproblematically available, but substitutions are permitted that fail with evaluation verbs and desire verbs. For example, if Richard III is dehydrated and therefore needs some water, it follows, since water is H_2O, that he needs some H_2O, whether or not he has such concepts as hydrogen and regardless of his other beliefs. But if he thinks H_2O is a kind of rat poison, he may want some water without wanting some H_2O and fear H_2O without fearing water.

An obvious question is whether the three types of intensionality effect have a common ground or whether two or even three distinct mechanisms are involved. The contrast between *need* and *scorn* suggests that one mechanism is involved in substitution resistance and another in generating notional readings: The former is not available to *needs*, the latter not to *scorn*. And since one may need more flu vaccine even if there is no more left, existence neutrality apparently goes with the availability of notional readings.

It might be objected that we get existence neutrality with evaluation verbs as well: The Ancient Greeks worshipped Zeus even though there is no such entity. However, serious use of names for fictional or mythical items requires an ontology of abstract fictional or mythical entities that exist contingently (they would not have existed if the corresponding fictions or myths had not been created; see Salmon [2002]). We should also note that *worship* is peculiar among evaluative verbs as regards notional readings. For instance, if a priest sacrifices with the words "To whichever god is out there," this is, arguably, a case of worshipping a god, but no particular one.

The next step is to describe the mechanisms accounting for the intensionality effects. One possibility is that in all three cases, the problems with intensional transitive verbs simply duplicate those encountered with propositional attitude verbs. This position seems quite plausible for substitution-resistance. If we have a good account of why substitution fails in "Lex Luthor fears that Superman is nearby" we would surely expect it to transfer straightforwardly to "Lex Luthor fears Superman"—unless, that is, the account for propositional attitude verbs depends on the presence of a clausal complement, as appears to be the case with Davidson's "paratactic" analysis of propositional attitude ascriptions (Davidson 1969). However, other accounts of substitution-failure in propositional attitude ascriptions transfer more smoothly—for instance, any account on which a name is associated with

a way of thinking of the referent and that way of thinking somehow enters into the truth conditions of the ascription. (See, for example, the "hidden indexical" mechanisms explored in Crimmins [1992] and Forbes [2000]).

There is also the view that substitution resistance is an illusion (locus classicus Salmon [1986]), which, if correct for propositional attitude verbs, should be equally correct for intensional transitives. On this view a name contributes only its referent to the meaning of a sentence, so no semantic distinction is to be drawn between "Lex fears Superman" and "Lex fears Clark."

The idea that no new problem is presented by intensional transitives runs into trouble, however, when we consider the relational-notional distinction. With propositional attitude verbs, the difference between (a) ascribing some cognitive relation between a subject and a specific item that the attitude is about and (b) not making such an ascription is captured by a scope distinction: "Lex fears that an extraterrestrial is nearby" gets the relational meaning when the quantifier "an extraterrestrial" is moved out of the attitude-content specification so that it has scope over "fears," as in "An extraterrestrial is such that Lex fears it is nearby"; the notional reading corresponds to unambiguous restriction of the quantifier to the attitude-content specification, as in "Lex fears-true the proposition that an extraterrestrial is nearby." But when we turn to intensional transitives, we find that, at least within a first-order framework, notional readings cannot be represented as ones in which the intensional verb has scope over the quantifier. For the verb to have wide scope, the quantifier must be one of its arguments: "seeks (Lois, an extraterrestrial)." But in first-order language a quantifier cannot be an argument to a relation: it must take scope over a sentence, open or closed, hence "without an inner sentential context, distinctions of scope disappear" (Kaplan 1986, p. 266).

According to propositionalism, the inner sentential context is there but partly hidden. Quine (1956) advances this view in the thesis that search-verb sentences can be paraphrased in terms of trying to find. So "Perseus seeks a gorgon" would be paraphrased as "Perseus is trying to find a gorgon." Partee (1974, p. 97) notes that search verbs cannot all be paraphrased using "trying to find," since they are not all synonymous (*cf.* "hunt" and "rummage about"), but in defense of propositionalism, both Parsons (1977) and Larson (2001) suggest using the search verb itself along with "to find." So we get "Perseus seeks to find a gorgon," or, in a more explicitly propositionalist formulation, "Perseus seeks (in order) to make it true that he himself finds a gorgon."

Evidence for an implicit inner sentential context varies with different kinds of verbs. For example, "Richard III needs a horse quickly" barely makes sense if *quickly* is understood to modify "needs" or any other explicit material. It seems instead to modify an implicit *get*. Along with other evidence (see Den Dikken et al. [1996] for more) this makes it quite plausible that desire verbs and *needs* are not really transitive but take infinitival *to get* clauses as their true complements. However, comparable evidence for search verbs is hard to find, and whether converting the direct object into a purpose clause is meaning-preserving can be doubted. Depiction verbs and evaluative verbs present even more of a challenge. For instance, to fear x is not to fear encountering x, since one may not fear x but may fear encountering x because x has a dangerous communicable disease. Nor is fearing x the same as fearing that x will hurt you, since you may fear that your accident-prone dentist will hurt you without fearing your dentist. It is therefore conceivable that intensional transitives are not a unified semantic group: for some, such as desire verbs, *need*, and maybe verbs of expectation, propositionalism is workable, but not for others.

The main alternative to propositionalism is developed in Montague (1973) as part of a higher-order, type-theoretic semantics for natural language. In this framework, quantifiers can be arguments to verbs, so "seeks (Lois, an extraterrestrial)" is allowed as the semantics of the notional reading of "Lois seeks an extraterrestrial." Montague's ideas are refined, revised, and developed in Zimmerman (1993), Moltmann (1997), and Richard (2001), although in all these accounts, notional readings of search-verb sentences still put the searcher into a search relation to an abstract entity, the meaning of the quantifier (in standard Montague grammar, this is something rather complicated, a function from possible worlds to sets of intensional entities; see Dowty et al. [1981] for an accessible account). It is unclear that such a semantics is compatible with the evident univocality of *seeks* in "seeks an extraterrestrial, but no particular one" and "seeks a particular extraterrestrial."

The approach of Forbes (2000) avoids this problem by employing a Davidsonian event-semantics (Davidson 1967) in which verbs are treated as predicates of events and the same predicate *search* appears in both relational and notional readings. In relational readings, the syntactic object signals a theme of the event, but in notional readings, it simply classifies the search as being one of a certain kind, for instance, as being a search of the at-least-one-extraterrestrial kind.

Intensional transitives raise interesting logical problems. It may be argued that propositional attitude ascriptions have no logic at all: even "x believes that p and q" does not logically entail that "x believes that p": at best we may endorse a psychological principle that persons aware that they accept a conjunction will also accept each conjunct individually. But for intensional transitives, there are substantial questions about the validity of certain inference-patterns. For example, if Richard III needs a warhorse, does it follow that he needs a horse? If notional readings are glossed in terms of indifference ("any would do," as in Lewis [1972, p. 199]) it does not follow: Even if Richard III needs a warhorse, and any one will do, it does not follow that he needs a horse, and any one will do—in the mayhem of the Battle of Bosworth, a cart horse would not do. On the other hand, the standard glossing of notional readings using "no particular one" seems to leave open the logical status of the inference rather than settling it one way or the other. These and other issues about the validity of specific inference patterns are pursued in Richard (2000) and Forbes (2003).

INTENTION

Philosophical work on intention is motivated by three general concerns. First, philosophers of action want to understand what it is for an event to be an intentional action and how intentional actions are produced by their agents. They have good reason to think hard about what intentions are and how they may be involved in the production of intentional actions, because, even if it is unclear exactly how intentional actions and intentions are related to each other, it is clear that they are intimately related. Second, moral philosophers and others in the business of developing theories of the evaluation of actions and their agents need an account of intentional action, and such an account is likely to involve intention in an important way. Moral evaluations of actions have intentional actions as their primary subject matter, even if people sometimes are proper targets of moral blame for some unintentional actions (e.g., when a drunk driver accidentally injures or kills someone). Third, some philosophers have the goal of crafting analyses of philo-

sophically interesting concepts as they are reflected in ordinary language.

INTENTIONS AND RELATED STATES OF MIND

It is generally agreed that intentions are closely linked to desires—especially *action-desires*, desires to do things—and beliefs. An intention to do something *A* has a motivational dimension, as does a desire to *A*. Having an intention also is widely regarded as requiring the satisfaction of a belief condition of some sort. Few philosophers of action would maintain that people who believe that their chance of winning today's lottery is about one in a million intend to win the lottery, no matter how strongly they desire to win. A relatively popular claim is that having an intention to *A* requires believing that one (probably) will *A*. The proposal is designed to capture, among other things, the confidence in one's success that intending allegedly involves. A less demanding claim is that having an intention to *A* requires that one lack the belief that one (probably) will not *A*. (The agent may have no belief on the matter.) Other alternatives include the requirement that the agent believe to some nonzero degree (even a degree associated with a subjective probability well below 0.5) that he or she will *A* and the requirement that the agent believe that there is a chance that he or she can *A*.

Philosophers are divided on how tight the connection is between intentions, on the one hand, and desires and beliefs, on the other. In particular, they disagree about whether intentions are reducible to combinations of action-desires and beliefs. The central point of contention is whether the settledness that intention encompasses can be captured in terms of beliefs and desires. One who desires to *A*—even someone who desires this more strongly than he or she desires not to *A* and who believes on inductive grounds that he or she probably will *A*—may still be deliberating about whether to *A*, in which case the person is not settled on *A*-ing. Ed wants more strongly to respond in kind to a recent insult than to refrain from doing so, but, owing to moral qualms, he is deliberating about whether to do so. He is unsettled about whether to retaliate, despite the relative strength of his desires and despite his inference from his past behavior in similar situations that he is more likely to retaliate than not to do so (Mele 1992). In acquiring an intention to retaliate—or an intention to refrain from retaliating—Ed becomes settled (but not necessarily irrevocably) on a course of action.

Two ways of coming to intend to *A* should be distinguished. Many philosophers claim or argue that to decide to *A* is to perform a mental action of a certain kind—an action of forming an intention to *A*. According to one version of this view, deciding to *A* is a momentary mental action of intention formation, and it resolves uncertainty about what to do (Mele 2003). The assertion that deciding to *A* is momentary is meant to distinguish it from, for example, a combination of deliberating and deciding. Students who are speaking loosely may say, "I was up all night deciding to major in English," when what they mean is that they were deliberating or fretting all night about what major to declare and eventually decided to major in English. Not all intentions are actively formed. For example, "When I intentionally unlocked my office door this morning, I intended to unlock it. But since I am in the habit of unlocking my door in the morning and conditions … were normal, nothing called for a *decision* to unlock it" (Mele 1992, p. 231). If I had heard a fight in my office, I may have paused to consider whether to unlock the door or walk away, and I may have decided to unlock it. But given the routine nature of my conduct, there is no need to posit an act of intention formation in this case. My intention to unlock the door may have been acquired without having been actively formed.

Some intentions are for the nonimmediate future and others are not. Ann may decide on Tuesday to attend a meeting on Friday, and she may decide now to phone her mother now. The intention formed in the former decision is aimed at action three days in the future. The intention Ann forms when she decides to phone her mother now is about what to do now. Intentions of these kinds are, respectively, *distal* and *proximal* intentions. Proximal intentions also include intentions to continue doing something that one is doing and intentions to start *A*-ing (e.g., start running a mile) straightaway. *Temporally mixed* intentions have both proximal and distal aspects. Consider an intention to watch the movie *Dangerous Intentions* in one sitting, beginning now. Executing it requires doing something now and continued activity for some time.

INTENTION'S FUNCTIONS AND CONSTITUTION

What work do intentions do? And how are they likely to be constituted given that they do this work? Functions plausibly attributed to intentions include initiating and motivationally sustaining intentional actions, guiding intentional action, helping to coordinate agents' behavior over time and their interaction with other agents, and

prompting and appropriately terminating practical reasoning (see Brand 1984, Bratman 1987, McCann 1998, Mele 1992, and Searle 1983).

Intentions, like many psychological states, have both a representational and an attitudinal dimension. The representational content of an intention may be understood as a *plan*. The intending attitude toward plans may be termed an *executive* attitude. Plans, on one conception, are purely representational and have no motivational power of their own. People have many different attitudes toward plans, in this sense. They may believe that a plan is too complicated, admire it, hope that it is never executed, and so on. To understand the executive dimension of intention—something at work in the initiation of action—recall that intending to *A*, unlike desiring to *A*, is partially constituted by being settled on *A*-ing. To have the intending attitude toward a plan is to be settled (but not necessarily irrevocably) on executing it. In virtue of this motivational feature of intentions, acquisitions of proximal intentions are well suited to the task of initiating actions and the persistence of intentions that initiate actions is well suited to sustain them. (In the case of an intention for a not-doing—for example, an intention not to vote in tomorrow's election—the agent may instead be settled on not violating the simple plan embedded in it, the plan not to vote.)

Why do acquisitions of proximal intentions initiate and sustain the actions that they do? Why, for example, does acquiring a proximal intention to order a hamburger and fries initiate and sustain one's ordering a hamburger and fries rather than one's ordering a salad or one's singing a song? Attention to the representational side of intentions provides an answer. An intention to *A* incorporates a plan for *A*-ing, and which intentional action(s) an intention generates is a partial function of the intention-embedded plan. In the limiting case, the plan in an intention has a single node. It is, for example, a prospective representation of one's pushing a window closed. Often, intention-embedded plans are more complex. The proximal intention to check his bank account online that Bob is executing incorporates a plan that includes clicking on his bank's link, then typing his ID and password in a certain pair of boxes, and so on. Agents who successfully execute an intention are guided by the intention-embedded plan. The guidance depends on agents monitoring progress toward their goals. The information (or misinformation) that Bob has entered his ID, for example, helps to produce his continued execution of his plan.

Although the content of an intention is a plan, such expressions as "Bob's intention to check his bank account now" and "Ann intends to shoot pool tonight" are common. It should not be inferred from such expressions that the agent's intention-embedded plan is structurally simple. Often, ordinary expressions of an agent's motivational attitudes do not identify the full content of the attitude and are not meant to. Bob says, without intending to mislead, "Ann wants to shoot pool tonight," even though he knows that what she wants is to play eight-ball with him at Pockets tonight for a dollar a game until the place closes, as they normally do.

Intention's coordinative capacities lie both in its executive aspect, which includes settledness, and in its plan component. Comprehensive plans for extended activity can be constructed out of plans embedded in less inclusive intentions, and developments in plans will be influenced and constrained by what one is already settled on doing. (This is not to deny the possibility of revising earlier intentions.) Moreover, knowledge of what others are settled on doing assists one in forming intentions and plans for cooperative ventures. To the extent to which coordination depends on practical reasoning, intention promotes coordination by providing motivation for required reasoning—motivation deriving from the settledness intention encompasses. Michael Bratman argues that the coordinating roles of distal intentions rest on several features of these intentions: they have the capacity to control behavior, they "resist (to some extent) revision and reconsideration," and they involve dispositions to reason with a view to intention-satisfaction and "to constrain one's intentions in the direction of consistency" (1987, pp. 108–109). All of these features are tied to the settledness intentions encompass.

Intention is an appropriate terminator of practical reasoning precisely because in forming or acquiring an intention one becomes settled on a course of action. Practical reasoning is aimed at action; and, if all goes well, one does what one has become settled on doing on the basis of one's practical reasoning. Intention's capacity to prompt such reasoning, as just noted, also derives from the settledness it involves.

INTENTIONS AND REASONS

Are people's reasons for intending to *A* limited to their reasons for *A*-ing? Gregory Kavka's (1983) "toxin puzzle" suggests that they are not. In this puzzle, a trustworthy billionaire offers you a million dollars for intending tonight to drink a certain toxin tomorrow afternoon. You are convinced that he can tell what you intend independ-

ently of what you do. Although drinking the toxin would make you ill for a day, you do not need to drink it to get the money. Constraints on prize-winning intentions include prohibitions against creating special incentives for yourself to drink the toxin, various tricks, and forgetting relevant details of the offer. For example, you will not receive the money if you hire a hit man to kill you should you not drink the toxin or persuade a hypnotist to implant the intention in you. If, by midnight tonight, without violating any rules, you intend to drink the toxin tomorrow afternoon, you will find a million dollars in your bank account when you awake tomorrow morning. Because you are well aware of this point and would love to be a millionaire, you seemingly have a great reason to form the intention. Now, you probably would drink the toxin for a million dollars. But can you, without violating the rules of the offer, intend tonight to drink it tomorrow? Apparently, you have no reason to drink the toxin and an excellent reason not to drink it. Seemingly, you will infer from this that you will not drink the toxin. Indeed, it seems that you will be confident that you will not drink it, and your confidence in that seems inconsistent with your having an intention to drink it.

Kavka draws the moral that intentions are "dispositions to act that are based on *reasons to act*—features of the act itself or its (possible) consequences that are valued by the agent" (1983, p. 35). However, because not all the work in Kavka's puzzle is done by truths about intention, reasons, and the like, his perfectly general claim about intentions cannot be established by reflection on the puzzle. Were it not for the rule against forgetting, for example, you could become a millionaire. If, tonight, you can so arrange things that at midnight you will be confident that the toxin will be in your favorite afternoon drink tomorrow and confident, as well, that by tomorrow you will have forgotten about the toxin, then at midnight you can intend to drink the toxin tomorrow. The content of your intention may be described roughly as follows: "Tomorrow afternoon, I drink the toxin unintentionally while sipping my customary afternoon tea." Even though you will have a reason tomorrow to drink tea, you will have no reason at all to drink the toxin; and that is clear to you at midnight. This scenario falsifies the idea that all possible intentions to *A* are based on reasons to *A*. A more cautious diagnosis of your apparent inability to intend to drink the toxin given the constraints Kavka imposes is that having an intention to *A* is inconsistent with being convinced that one will not *A*.

The preceding scenario leaves open a more modest version of Kavka's moral. Perhaps all possible intentions to *A* such that in executing them one would *intentionally A* are based on reasons to *A*. Although one cannot find in reasons for *A*-ing a necessary basis for all possible intentions to *A*, one may find in them a necessary basis for all intentions of the sort just identified—*orthodox intentions*. The relatively cautious diagnosis previously mentioned provides a hint about how to test this hypothesis. Might there be agents who know that they have no reason to drink the toxin, have not forgotten anything relevant, and nevertheless believe that they will drink it?

Consider the following story. An evil genius tricks Ted into drinking nonlethal liquid toxins whenever such toxins happen to be nearby, and Ted is well aware of this. Ted also has—as he knows—a condition called *intention perseverance*: once he forms an intention, he will not abandon it unless he has a good reason to abandon it. Finally, Ted is indifferent between drinking toxins unintentionally and drinking them intentionally: only the subsequent illness bothers him.

Seemingly, Ted can get the big prize in Kavka's scenario. Although normal folks are confident that they will not drink the toxin, Ted is confident that he will drink it. He also has an excellent reason to decide to drink it: in so deciding he would form an intention that will make him a millionaire. And he can count on the intention formed in his decision to persist and to result in intentional toxin drinking, given that he lacks a good reason to abandon the intention after he forms it. Ted's intention to drink the toxin is such that, in executing it, he intentionally drinks the toxin. So he undermines even the more modest version of Kavka's moral. His intention to drink the toxin is based on his reasons for forming that intention, and it is not based at all on reasons for drinking the toxin. This leads back, then, to the relatively cautious diagnosis of one's apparent inability to intend to drink the toxin. The diagnosis is about a completely general connection between intention and belief, not a completely general connection between intention and reasons: having an intention to *A* is inconsistent with being convinced that one will not *A*.

Sometimes people consider reasons for and against taking a prospective course of action. Gilbert Harman (1986) and Michael Bratman (1987) argue that the concept of intentional action is sensitive to reasons agents have for not doing what they do in a way in which the concept of intention is not. The upshot is that agents sometimes intentionally do things that they lack an intention to do. For example, Bill knows that his vacuuming his carpets today will cause Beth to sneeze, and he counts that as a reason not to vacuum them today. Even so,

because he believes that it is important to vacuum today, he does so, and he notices Beth sneezing as he works. Harman and Bratman would say that even though making Beth sneeze is no part of what Bill intends, he intentionally makes her sneeze. This judgment may be in line with ordinary usage of the terms at issue, and it may be a judgment that a majority of nonspecialists would make. However, granting the existence of intentionally produced side effects that the agent does not intend to produce would complicate the task of philosophers of action who say that they are in the business of explaining how intentional actions are produced by their agents. They would need a theory that explains intentional actions of two different kinds: actions the agent is trying to perform and actions the agent is not trying to perform. Such philosophers may do well to seek—and to set up as the target of their explanatory efforts—a more circumscribed notion of intentional action that is no more sensitive to reasons against doing what one does than Harman and Bratman say the concept of intention is.

INTENTIONALITY

The term "intentionality" was used by Jeremy Bentham to distinguish between actions that are intentional and those that are not. It was reintroduced by Edmund Husserl in connection with certain doctrines set forth in Franz Brentano's *Psychologie vom empirischen Standpunkt* (1874). The word is now used primarily in this second sense.

> Brentano wrote:

> Every mental phenomenon is characterized by what the scholastics of the Middle Ages called the intentional (and also mental) inexistence of an object, and what we would call, although not in entirely unambiguous terms, the reference to a content, a direction upon an object (by which we are not to understand a reality …), or an immanent objectivity. Each one includes something as an object within itself, although not always in the same way. In presentation something is presented, in judgment something is affirmed or denied, in love [something is] loved, in hate [something] is hated, in desire something is desired, etc.

> This intentional inexistence is exclusively characteristic of mental phenomena. No physical phenomenon manifests anything similar. Consequently, we can define mental phenomena by saying that they are such phenomena as include an object intentionally within themselves. (*Op. cit.,* Vol. I, Book II, Ch. 1)

This passage contains two different theses: one, an ontological thesis about the nature of certain objects of thought and of other psychological attitudes; the other, a psychological thesis, implying that reference to an object is what distinguishes the mental or psychological from the physical. These two theses are the subject matter of the present article. It should be noted, however, that "intentionality" is also used in connection with certain other related theses of phenomenology and existentialism.

INTENTIONAL INEXISTENCE

The problem that gave rise to the ontological thesis of intentional inexistence may be suggested by asking what is involved in having thoughts, beliefs, desires, purposes, or other intentional attitudes, which are directed upon objects that do not exist. There is a distinction between a man who is thinking about a unicorn and a man who is thinking about nothing; in the former case, the man is

intentionally related to an object, but in the latter case he is not. What, then, is the status of this object? It cannot be an actual unicorn, since there are no unicorns. According to the doctrine of intentional inexistence, the object of the thought about a unicorn *is* a unicorn, but a unicorn with a mode of being (intentional inexistence, immanent objectivity, or existence in the understanding) that is short of actuality but more than nothingness and that, according to most versions of the doctrine, lasts for just the length of time that the unicorn is thought about.

EARLY THEORIES. St. Anselm's ontological argument was thus based upon the assumption that, if God is thought about, he thereby "exists in the understanding." Anselm then proceeded to contrast the perfections of that which "exists in the understanding alone" with that which "exists in reality." Peter Aureol and William of Ockham contrasted the intentional existence of the objects of thought with the subjective existence of the thoughts themselves. The term "objective existence," referring to the existence of something *as* an object of thought, was used by medieval philosophers and by René Descartes as a synonym for "intentional existence"; Descartes thus contrasted the formal, or subjective, existence of actual objects with the objective existence in the mind of objects that are merely thought about. The terms *objective* and *subjective,* in these uses, had connotations quite different from those that they have now; that which was said to have objective existence (for instance, a unicorn as an object of thought), unlike that which had subjective existence (the idea of a unicorn, for instance), need not exist in fact.

Advantage of the doctrine. The doctrine of intentional existence, or, as Brentano called it, intentional inexistence, had at least the advantage of providing a literal interpretation for the dictum that truth consists in a kind of correspondence between mind and thing: an affirmative judgment is true if the properties of the intentional object are the same as those of the actual object. The very statement of this advantage, however, betrays the fact that the judgment is directed, not upon the intentional object, but upon the actual object, in which case, as Pierre Gassendi pointed out, the intentional object would seem to be superfluous.

Intentional reference. The difficulty of the apparent superfluity of the intentional object may be traced, in part, to the fact that the phenomenon of intentionality has two sides. Our intentional attitudes may be directed upon objects that do not exist (Diogenes looked for an honest man), but they may also be directed upon objects

that do exist (there is a certain dishonest man whom the police happen to be looking for). The object of the latter quest, obviously, is not a thing having only immanent or intentional existence. But this is also true, as Brentano was later to point out, of the object of the former quest: Diogenes was not looking for an immanent object (for, if the doctrine of intentional inexistence were true, he already had one in his mind); he was looking for an actual, existing honest man, despite the fact that, as we may suppose, no such man exists. Thus, Brentano said, "If we think about a horse, the object of our contemplation is a horse and not a contemplated horse."

In the expression of the ontological thesis of intentionality, "intentional" may be said to refer to a mode of being *within* the mind; but in the expression of the psychological thesis of intentionality, "intentional" is used to describe the direction upon objects that may exist *outside* the mind. It is not inaccurate to say that intentional entities were posited in the attempt to account for intentional reference, but precisely because they were intentional, the attempt did not succeed. Husserl said, in the fifth of his *Logische Untersuchungen,* that the objects of our intentional experiences are never immanent—never intentional objects—but are always transcendent.

BRENTANO'S LATER VIEWS. Thus, for various reasons Brentano abandoned the ontological part of his doctrine of intentionality. In his later writings, he said that "unicorn" in the sentence "John is thinking about a unicorn" has no referential function; a contemplated unicorn is not a type of unicorn. "Unicorn," in such sentences, is used syncate-gorematically to contribute to the description of the person who is said to have a unicorn as the object of his thought. But this conclusion seems to leave us with our problem. The statement "John is thinking about a unicorn" does not describe *John* as a unicorn; how, then, does "unicorn" serve to contribute to his description?

The ontological problem, therefore, may be said to survive in the question, "How are we using 'unicorn' in 'John believes that there are unicorns'?" There is a temptation to say that the use of "unicorn" in such sentences has no connection at all with the use it would have in "There are unicorns." That this would be false, however, may be seen by noting that "John believes that there are unicorns" and "All of John's beliefs are true" together imply "There are unicorns." Thus, Ludwig Wittgenstein remarked:

One may have the feeling that in the sentence "I expect he is coming" one is using the words "he is coming" in a different sense from the one they

have in the assertion "He is coming." But if it were so, how could I say that my expectation had been fulfilled? If I wanted to explain the words "he" and "is coming," say by means of ostensive definitions, the same definitions of these words would go for both sentences. (*Philosophical Investigations,* p. 130e)

CARNAP'S THEORY. In the *Logical Syntax of Language* (London, 1937), Rudolf Carnap suggested that linguistic entities are the objects of our intentional attitudes. "Charles thinks (asserts, believes, wonders about) *A,*" he said, might be translated as "Charles thinks '*A.*'" Taken literally, this suggestion would imply, falsely, that a man who wonders whether there are unicorns is a man who wonders whether there is the word *unicorns.*

INSCRIPTIONAL THEORY. A closely related view has been developed by W. V. Quine and Israel Scheffler. These authors, however, instead of saying that our intentional attitudes have linguistic entities as their objects, suggest instead that certain sentences, which relate people to words or to other linguistic entities, might be used to perform all of the functions of intentional sentences; if this view were adequate, the problem of the status of the intentional object might be avoided. Thus, "John believes-true a Socrates-is-mortal inscription" may be interpreted as a sentence affirming a certain relation to hold between John and a linguistic entity or "inscription," but a relation that is true only under the conditions under which "John believes that Socrates is mortal" is true; hence, if we use the former sentence instead of the latter, we relate John only to inscriptions.

However, it may be held (1) that the plausibility of this approach depends upon the assumption that there are certain semantic sentences (for instance, "The German sentence '*Sokrates ist sterblich*' means that Socrates is mortal") that are true of certain inscriptions and (2) that these semantic sentences are abbreviations for intentional sentences that leave us with our original problem (for instance, "German-speaking people use '*Sokrates ist sterblich*' to express and convey the belief that Socrates is mortal").

This inscriptional approach, moreover, fails to distinguish between such sentences as "Someone is looking for a horse" and "There is a horse that someone is looking for"; these two types of sentence, as noted above, reflect the two different sides of the phenomenon of intentionality. It has been suggested that sentences of the latter sort may be illegitimate, on the ground that they

quantify, in effect, into contexts that are referentially opaque, in a sense explained below. To say that such intentional sentences are illegitimate is to imply that the mind is incapable of referring to objects that exist and, hence, that we cannot "get outside the circle of our own ideas."

RESPONSE THEORY. There have been still other approaches to the problem of the intentional object. Some of the American New Realists proposed, behavioristically, that to think about a unicorn might merely be to "put one's unicorn responses in readiness." The thinker, instead of relating himself to unicorns, disposes himself to behave in just those ways in which he would behave if there *were* unicorns. Other psychological attitudes were treated analogously. It would seem, however, that "unicorn responses" cannot be adequately specified except by reference to beliefs and desires that are directed upon unicorns, since the ways in which a man would respond to a unicorn would be, in part, a function of what he otherwise perceives, desires, and believes. More recent revivals of the specific-response theory seem to be subject to similar difficulties.

CHURCH'S VIEW. Alonzo Church, in his *Introduction to Mathematical Logic* (Princeton, NJ, 1956), proposed that the sentence "Schliemann sought the site of Troy" asserts that a certain relation holds between Schliemann and the *concept* of the site of Troy; Church said, negatively, that the relation is "not quite like that of having sought," but he did not say more positively what it is. This view suggests a return to the medieval doctrine, at least to the extent of viewing the objects of our intentional attitudes as beings of reason.

ANALOGICAL THEORY. Thomas Aquinas seems to have held that "unicorn," in such sentences as "John is thinking about a unicorn," is used *analogically* (*De Potentia* 7c; *Summa Theologiae* 1, 13, 10). There is ground for questioning whether the doctrine of analogical predication is itself sufficiently illuminating to throw light upon the problem of intentionality, but the fact that we can understand the use of "unicorn" and cannot say just what function the word there performs may, on the other hand, throw some light upon the doctrine.

The most plausible defense of the doctrine of intentional inexistence, therefore, would seem to be that this doctrine, unlike most of its alternatives, *does* provide us with a straightforward account of the use of "unicorn" in "John is thinking about a unicorn": The word is being used simply to designate a unicorn.

PSYCHOLOGICAL THESIS OF INTENTIONALITY

According to Brentano's second thesis, intentionality is peculiar to psychological phenomena and thus provides a criterion by means of which the mental may be distinguished from the nonmental. The problem for the proponent of this second thesis is not so much that of showing that mental phenomena *are* intentional as it is that of showing that physical phenomena are *not* intentional. Some now believe that the thesis can be defended by reference to the language we use in describing psychological phenomena—that the sentences we must use in describing psychological phenomena have certain logical properties that are not shared by any of the sentences we must use in describing nonpsychological phenomena, and that these properties are correctly called intentional. If this view is true, then the basic thesis of physicalism and the unity of science is false. Can we find, then, a logical criterion of the intentional, one that we may then use to distinguish the mental from the physical?

UNSATISFACTORY CRITERIA OF INTENTIONALITY. It has been suggested that failure of existential generalization yields a logical criterion of the intentional. The intentional "John is thinking about a horse," unlike the nonintentional "John is riding on a horse," does not imply that there are horses. However, existential generalization also fails in application to some of the terms in the following statements that describe physical phenomena: "New Zealand is devoid of unicorns," "That lady resembles a mermaid," and "The dam is high enough to prevent any future floods."

Nonextensional occurrence has also been proposed as a possible criterion of the intentional. A phrase, *p,* may be said to occur nonextensionally in a sentence, *s,* provided that the result of replacing *p* in *s* by any phrase having the same truth value as *p* will be a sentence having the same truth value as *s.* Thus, "Johnson is Kennedy's successor" may replace "Socrates was a philosopher" in "Either Socrates was a god or Socrates was a philosopher," without altering the truth value of the whole, whereas similar replacement is not possible in "Plato believed that Socrates was a philosopher." Nonextensional occurrence, however, is not peculiar to sentences that are intentional; compare "It is necessarily true that if Socrates was a member of the class of philosophers, then Socrates was a philosopher."

Referential opacity has also been proposed as a criterion of the intentional. The occurrence of a substantival expression in a sentence, *s* (for instance, "Truman's suc-

cessor" in "Joe Martin believed that Dewey would be Truman's successor"), is referentially opaque if its replacement in *s* by another substantival expression (such as "Eisenhower") designating the same individual may result in a sentence having a truth value different from that of *s.* However, referential opacity is not peculiar to the intentional; we may assert "It is necessarily true that if Dewey was Truman's successor, then Dewey was Truman's successor," but not "It is necessarily true that if Dewey was Truman's successor, then Dewey was Eisenhower."

SATISFACTORY CRITERIA. The failure of nonextensional occurrence and referential opacity has led some to believe that there are no logical characteristics peculiar to intentional statements. However, there are other criteria that do seem to be satisfied only by intentional statements. We may mention two.

Let us refine upon ordinary English in the following way: instead of writing propositional clauses as "that" clauses, we will eliminate the "that" and put the remainder of the clause in parentheses; for example, instead of writing "John believes that there are men," we will write "John believes (there are men)." A simple sentence prefix may be said to be an expression that contains no proper part that is logically equivalent to a sentence or to a sentence function and that is such that the result of prefixing it to a sentence in parentheses is another sentence. We may say that a simple sentence prefix, *M,* is *intentional* if, for every sentence p, $M(p)$ is logically contingent. Thus, "it is impossible" is not intentional, since when prefixed to "(some squares are circles)," it yields a sentence that is necessary and therefore not contingent; "it is right" is not intentional since, when prefixed to "(there is not anything of which it can be truly said that it is right)," it yields a sentence that is contradictory and therefore not logically contingent.

However, *every* sentence, whether it is itself contingent or not, is such that the result of thus prefixing it by "John believes" is contingent. Similar observations apply to "John questions," "John desires," and to other prefixes referring to intentional attitudes. Thus, we might say that the psychological differs from the nonpsychological in this respect: an adequate description of the psychological requires the use of intentional prefixes.

It may also be argued that some intentional prefixes (for instance, "John believes") are such that the possible ways of inserting them into a universally quantified sentence (for instance, into "For every x, x is material") and into the corresponding existentially quantified sentence

("There exists an *x* such that *x* is material") yield four statements ("John believes that, for every *x*, *x* is material"; "For every *x,* John believes that *x* is material"; "John believes that there exists an *x* such that *x* is material"; and "There exists an *x* such that John believes that *x* is material") that are logically related in ways in which no corresponding sentences with nonintentional prefixes are related. Thus, it may be said of the four sentences just cited: Neither the first nor the third implies any of the others; the second implies all but the first; the fourth implies the third but does not imply either the first or the second; and there is no nonintentional prefix that will yield four sentences that are similarly related. This contention, to the extent that it applies to "John believes," is based upon the assumptions that in believing a thing to have certain properties, one thereby believes that the thing exists; that one may believe falsely, of some nonuniversal set of things (some set comprising less than everything there is), that it comprises everything there is; and that one may believe falsely, of a universal set of things, that it does not comprise everything there is.

There are other psychological sentences—for instance, "He is in pain" and "He is thinking about Jupiter"—that may not satisfy the above criteria of intentionality. The first of these sentences, however, might be said to be intentional if, as some believe, one cannot be in pain if one is not *aware* that one is in pain; or if one does not *believe* that one is in pain; or if, at any one instant, one does not *remember* the pain of previous instants; and analogously for the second quoted sentence. Another possible view, however, is to say that intentionality is at least a sufficient if not a necessary condition of the psychological.

INTENTIONALITY [ADDENDUM]

The medieval word *intentionality* was reintroduced into late nineteenth-century philosophy by Franz Clemens Brentano. Intentionality is the power of minds to represent, stand for, or be about things, properties, and states of affairs. The English word *intentionality* stems from the Latin verb *intendere*, which can be used to denote the act of stretching a bow string with the aim of propelling an arrow into its target. In Brentano's sense intentionality is the mental tension whereby the human mind aims at objects. The nature of intentionality has been a central topic in the philosophy of mind and language in the twentieth century in both the phenomenological tradition (founded by Edmund Husserl, a student of Brentano) and the analytic tradition.

In several well-known paragraphs from his 1874 classical work, *Psychology from an Empirical Standpoint*, quoted by Roderick M. Chisholm at the beginning of his entry, Brentano did two things: he provided a puzzling definition of intentionality and he put forward the thesis

that intentionality is the mark of the mental. This entry briefly considers some of the logical and ontological puzzles raised by Brentano's definition of intentionality. It then turns toward issues raised by Brentano's thesis that intentionality is the mark of the mental, considering whether only mental (or psychological) phenomena exhibit intentionality and whether all do, in this order.

LOGICAL AND ONTOLOGICAL PUZZLES

WHAT INTENTIONALITY DOES NOT MEAN. To grasp the philosophical significance of the concept expressed by the word *intentionality* for contemporary philosophy, it is important not to confuse it with two of its cognates: *intention* and *intension*. *Intention* and *intending* refer to specific mental states, events, or processes that, unlike others (e.g., beliefs, judgments, expectations, perceptions, fears, desires, and hopes), play a distinctive role in the etiology, the preparation, and the execution of actions. By contrast, in Brentano's philosophical tradition, intentionality is a property of many—if not all—such mental states and events as beliefs, judgments, desires, and perceptions. Nor should *intentionality* be confused with *intensionality* (with an *s*). *Intensional* and *intensionality*, which mean respectively "nonextensional" and "nonextensionality," refer to logical features of words and sentences. To take Willard Van Orman Quine's famous example, "creature with a heart" and "creature with a kidney" have the same extension because they apply to the same things: all the creatures with a heart have a kidney and conversely. But the two expressions have different intensions because *heart* and *kidney* have different meanings and extensions.

THE IMPACT OF BRENTANO'S DEFINITION. Brentano defined *intentionality* as what enables a psychological state or act to be directed on what he called an intentional object. He further ascribed to intentional objects the puzzling property that he called intentional inexistence or immanent objectivity. Finally, Brentano's quote suggests that a satisfactory explanation of intentionality must be able to account for the inferences illustrated by the following sentences, which contain a psychological verb that refers to a mental intentional state (e.g., "to watch," "to admire," or "to fear"), in which (b) is a conclusion that follows from premise (a), and (c) represents the logical form of (b):

(1a) George W. Bush watches Laura Bush.

(1b) George W. Bush watches something.

(1c) ($\exists$x) (George W. Bush watches x).

(2a) George W. Bush admires Sherlock Holmes.

(2b) George W. Bush admires something.

(2c) ($\exists$x) (George W. Bush admires x).

(3a) George W. Bush fears God.

(3b) George W. Bush fears something.

(3c) ($\exists$x) (George W. Bush fears x).

As illustrated by sentences (1) to (3), all sorts of things can be the target of intentionality and, therefore, qualify as intentional objects: concrete physical objects in space and time (e.g., stars, stones, plants, animals, and persons), abstract objects (e.g., numbers), and objects of fiction (e.g., Sherlock Holmes) that are neither in space nor in time, and even objects whose properties are inconsistent with known natural or geometrical laws (e.g., unicorns and squared circles). As Chisholm elegantly puts it in his entry, although unicorns do not exist, thinking about a unicorn is not the same thing as thinking about nothing. Arguably, by ascribing to intentional objects the property he called intentional inexistence or immanent objectivity, what Brentano presumably meant was that intentional objects need not exist in space and time: it is enough that they exist within the mind.

ARE THERE THINGS THAT FAIL TO EXIST? Brentano's definition gave rise to a fundamental gap in twentieth-century philosophical logic between intentional objects theorists, who claimed that there are things that do not exist, and their opponents, who denied it. On the one hand, Alexius Meinong (who was Brentano's student) and his followers took it as a genuine condition of adequacy on an account of intentionality that it ought to provide a uniform account for the validity of all inferences from premises of type (a) to conclusions of type (b), in sentences of type (1) to (3), notwithstanding the fundamental ontological differences between the kinds of entities over which the bound variable ranges in the logical form of conclusions of type (c).

For example, Meinong (1904/1960) supposes that for any set of properties, there is an intentional object that instantiates them, but only some, not all, such objects exist. On his view, it is one thing to say that there are unicorns. It is another thing to say that unicorns exist. On the contrary, following Bertrand Arthur William Russell, Quine (1960) and most twentieth-century analytic philosophers denied that there are things that do not exist, on the threefold grounds that (1) existence is not a property (or the English verb "to exist" should be treated as a quantifier, not as a predicate); (2) the theory of inten-

tional objects incurs intolerably heavy ontological commitments; and (3) an ontology of nonexistent objects can hardly be reconciled with the ontology of the contemporary natural sciences. The rest of this entry is devoted to issues that arise only if one denies that there are things that do not exist.

PSYCHOLOGICAL AND LINGUISTIC INTENTIONALITY

What Quine (1960) calls semantic ascent (and others the linguistic turn) enables one to rise from talk about things to talk about talk about things (i.e., words and sentences). As Chisholm explains in the second half of his entry, the ascent from talk about intentionality to talk about talk about intentionality raised the prospect of a linguistic doctrine of intentionality and it also gave rise to an objection to Brentano's thesis that only mental phenomena exhibit intentionality.

IS INTENSIONALITY A CRITERION OF INTENTIONALITY? Sentences about intentionality exhibit the two logical features of intensionality (or referential opacity). First, sentences about intentionality do not always license substitution of coreferential terms *salva veritate*. Thus, even though sentence (4a) expresses a true proposition, it does not automatically follow that sentence (4b) does, even though "Cicero" and "Tully" name one and the same individual:

(4a) George W. Bush believes that Cicero was bald.

(4b) George W. Bush believes that Tully was bald.

If George W. Bush fails to know that "Cicero" and "Tully" are coreferential, then the truth of (4a) does not entail the truth of (4b). Second, sentences about intentionality do not always license the rule of existential generalization. A speaker may truly believe that Bush holds the belief ascribed by (5a) without committing him- or herself to the truth of (5b):

(5a) George W. Bush believes that Zeus transformed himself into a bull.

(5b) (∃x) (George W. Bush believes that x transformed himself into a bull).

On this basis, Chisholm (1957) argues, on the one hand, that linguistic descriptions of intentional phenomena, which fail the criteria of extensionality, cannot be replaced by descriptions of observable behavior (or bodily movements), which satisfy the criteria of extensionality. On the other hand, he contemplates the prospect that the intensionality of sentences describing intentional

phenomena might constitute a logical criterion for the intentionality of the described phenomenon. This criterion fails for two reasons. First, reports of visual perception may be extensional. For example, if "Ralph saw Laura" is true, then "Ralph saw something" is true. Furthermore, if "Laura" and "the president's wife" are coreferential and if "Ralph saw Laura" is true, then "Ralph saw the president's wife" cannot fail to be true. So if "Ralph saw Laura" truly reports an intentional phenomenon, then the intensionality of a report cannot be a necessary condition for the intentionality of the reported phenomenon. Second, many sentences that do not describe intentionality (e.g., sentences about natural laws) exhibit intensionality. So, the intensionality of a report cannot be a sufficient condition for the intentionality of the reported phenomenon.

DERIVED VERSUS UNDERIVED INTENTIONALITY. Brentano's thesis that only mental phenomena exhibit intentionality can be questioned on the grounds that the utterances of sentences, which have meaning but are nonmental things, exhibit intentionality. Most contemporary philosophers of mind, such as Jerry A. Fodor (1987), John Haugeland (1981), and John R. Searle (1983), would respond to this objection to Brentano's thesis by offering a distinction between the underived (or primitive) intentionality of a speaker's mental states and the derived intentionality of the utterances of the sentences whereby he or she expresses his or her mental states. On their view, sentences of natural languages have no intrinsic meaning and would be deprived of meaning if humans did not use them for the purpose of making their private thoughts known to others. Thus, according to the revised version of Brentano's thesis, only mental phenomena have underived intentionality. Daniel C. Dennett (1987), however, disagrees because, according to him, the distinction between derived and underived intentionality is just an illusion.

HOW TO NATURALIZE INTENTIONALITY

QUINE'S DILEMMA. The thesis that only mental phenomena possess underived intentionality lead both Chisholm and Brentano to embrace a version of the ontological dualist distinction between mental and physical things. Quine (1960) agrees with Chisholm's thesis that sentences describing an agent's intentional phenomena cannot be successfully paraphrased into sentences about the agent's behavior or bodily movements: intentionality, therefore, cannot be naturalized. He does not, however,

endorse ontological dualism. Instead, he embraces a physicalist ontology according to which everything, including allegedly mental things, are physical, and he puts forward an influential dilemma: since intentionality cannot be naturalized, one must choose between a physicalist ontology and intentional realism (i.e., the view that intentionality is real). Some of the physicalists who accept Quine's dilemma (e.g., Churchland 1989) embrace eliminative materialism and deny purely and simply the reality of beliefs and desires. It is, however, difficult to make sense of the belief that there are no beliefs. Others (such as Dennett 1987) take the instrumentalist view that although the intentional idiom is a useful stance for predicting a complex physical system's behavior, it lacks an explanatory value. But the question arises how the intentional idiom could make useful predictions if it fails to describe and explain anything.

As a result of the difficulties inherent to both eliminative materialism and interpretive instrumentalism, several physicalists choose to deny both Quine's challenge and Brentano's thesis that only nonphysical things can exhibit intentionality. Their project is to naturalize intentionality. Since they are physicalists, they assume that all so-called mental things are physical things, and their goal is to show that uncontroversially physical things exemplify, if not full-blown intentionality, at least the seeds of intentionality.

INFORMATIONAL SEMANTICS. One influential strategy for doing so has been Fred I. Dretske's (1981) proposal that a device that carries information exhibits some degree of intentionality. According to Paul Grice's (1957/1989) distinction between natural and nonnatural meaning, whereas the English word *fire* nonnaturally means fire, *smoke* naturally means fire. Dretske extends the Gricean notion of natural meaning into an information-theoretic approach according to which the informational relation is the converse of a nomic relation. If the length of a metal bar is nomically correlated with variations in temperature, then the former carries information about the latter. The direction of the needle of a compass carries information about the location of the North Pole because it nomically co-varies with the location of the North Pole. If it is not a law that polar bears live at the North Pole, then a compass will fail to indicate where polar bears live even though it indicates the location of the North Pole and this is where polar bears happen to live. If so, then the linguistic report of the information carried by a signal exhibits some of the intensionality (with an *s*) of reports of intentionality.

It is widely recognized, however, that pure informational semantics fails to generate the full intentionality of human mental representations. It is part and parcel of human mental representations that they can misrepresent what they are about. Since the informational relation is the converse of a nomic correlation, it cannot account either for misrepresentation or for the normativity of the contents of representations.

TELEOSEMANTICS. A second major proposal for naturalizing intentionality is the teleosemantic approach championed by Ruth Garrett Millikan (1984). It starts by offering a direct solution to the problems that plague informational semantics, namely the problems of misrepresentation and the normativity of mental content. Its basic insight is that what Brentano calls intentional inexistence is exemplified by biological (so-called teleological) functions and is, therefore, a particular case of a more general biological phenomenon. For example, if it is the function of a mammal's heart to pump blood, then a mammal's heart ought to pump blood even though it might fail to do so: it may fail to fulfill its function. Of course, a heart has no semantic properties: it represents nothing and does not exhibit intentionality in Brentano's sense. Millikan's teleosemantic claim is not that having a function is a sufficient condition for semantic aboutness, but that it is necessary. Something cannot be a representation unless it can misrepresent what it is about. It could not misrepresent anything unless it could malfunction and it could not malfunction unless it had a function. Arguably, nothing can have a function unless it results from some historical selection process. Selection processes are design processes. According to teleosemantic theories, design is the main source of function, which in turn generates intentionality.

Such theories are called teleosemantic in virtue of the intimate connection between design or teleology and content (or intentionality). Selection processes can be intentional or nonintentional. The fundamental goal of the teleosemantic approach is to derive the intentionality of human mental states from the nonintentional process of natural selection that gave rise to human cognition in the course of human phylogeny.

IS INTENTIONALITY CONSTITUTIVE OF MENTALITY?

THE SEVERAL DIMENSIONS OF INTENTIONALITY. Ever since Brentano put forward his thesis that intentionality is constitutive of the mental, philosophers have identified two major dimensions along which intentional

phenomena vary. The first psychological distinction arises from the ontological distinction between objects and states of affairs (such that the former are constituents of the latter). Some mental states are intentional in virtue of being directed toward an object under a particular psychological mode. Thus, perceiving, remembering, loving, or hating someone or something may be instances of such object-directed psychological states. Other (arguably more complex) psychological states are intentional in virtue of the fact that they represent full states of affairs. True beliefs and judgments represent actual states of affairs (or facts). False beliefs, false judgments, desires, intentions, and hopes represent possible or even impossible states of affairs.

One important issue in the philosophy of mind has been whether object-directedness can be reduced to propositional content. Philosophers of perception, in particular, sharply disagree about the intentionality of visual perception: does visual perception always represent full states of affairs, as David Malet Armstrong (1968) and Dennett (1991) argue? Or can visual perception be merely object-directed or nonepistemic, as Dretske (1969) argues? These questions are closely linked to the question whether perceptual experiences have nonconceptual content, as argued by, for example, Gareth Evans (1982) and Christopher Peacocke (1992), and as denied by John McDowell (1994).

The second distinction is internal to the category of psychological states that represent full states of affairs. Russell calls them propositional attitudes, because they are ascribed by complex sentences containing a singular term standing for a person, a main verb expressing his or her attitude (e.g., believing, judging, desiring, and hoping) followed by a that clause expressing the propositional content that is the object of the attitude (as in "John believes that Pegasus flies"). Following Gertrude Elizabeth Margaret Anscombe (1957) and Searle (1983), beliefs and judgments are said to have a "mind-to-world direction of fit" because their function is to record facts. Intentions and desires are said to have a "world-to-mind direction of fit" because their function is not to represent facts but nonactual states of affairs that are goals for actions.

THE VARIETIES OF CONSCIOUS AWARENESS. What do a pain, a visual experience of blue, the taste of a glass of burgundy, the smell of a rose, an intention to act, a thrust of anger, a feeling of depression, and the belief that 2 is a prime number have in common? If they have nothing in common, then presumably the English word *men-*

tal fails to express any well-defined property. If so, then as Richard Rorty (1979) argues, the word *mental* may just be part of an academic language game with no realistic explanatory, let alone scientific, import. According to Brentano's thesis, all these psychological phenomena have something in common: they exhibit intentionality (in the form of either object-directedness or propositional content). Is Brentano's thesis true? Much twentieth-century philosophy of mind has addressed this issue by asking the question: Can one be consciously aware without being aware of something or other?

As many philosophers would recognize, however, the concept expressed by conscious awareness needs some clarification. A first clarification is provided by David M. Rosenthal's (1991) distinction between creature consciousness and state consciousness. A creature can be said to be conscious and a creature's mental state (e.g., one of his or her beliefs) can be said to be conscious. Second, as Rosenthal also points out, if conscious, a creature can either be intransitively conscious or transitively conscious of something. A creature is intransitively conscious if he or she is not unconscious (e.g., as in a coma). He or she can be transitively conscious of things, properties, and states of affairs by either perceiving them or thinking of them. Whereas a creature can be either intransitively conscious or transitively conscious of something, a creature's mental state (or representation) can only be intransitively conscious. Third, one of the things a creature can be transitively conscious of is him- or herself. Arguably, a creature could not be self-conscious or self-aware unless he or she had some concept of him- or herself. But it does not follow that a creature could not be transitively conscious of things in his or her environment unless he or she was self-conscious and unless he or she had a concept of the self. Finally, as Ned Block (1997) argues, there are two distinct ways a mental state can be conscious: It is access conscious if it is poised for free use in reasoning and for the direct rational control of action and speech. It is phenomenally conscious if, as Thomas Nagel (1974) famously puts it, "there is something it is like" to be in that state, that is, if the state has a phenomenal character.

THE DISPUTES BETWEEN INTENTIONALISTS AND NONINTENTIONALISTS. Philosophers who accept Brentano's thesis that all psychological phenomena exhibit intentionality are intentionalists. Philosophers who do not are nonintentionalists. The nonintentionalists argue that the phenomenal character (phenomenal consciousness) of qualitative mental states (*qualia*) such as pains cannot be accounted by its intentionality if it has any. Radical nonintentionalists, such as Searle (1992) and

Galen Strawson (1994), reject Brentano's view that intentionality is the mark of the mental and argue that either accessibility to consciousness or phenomenal consciousness is the true criterion of the mental. If accessibility to consciousness were the criterion of the mental, then psychological states and processes investigated by cognitive science that are unavailable to consciousness would fail to qualify as mental (or psychological). If phenomenal consciousness were the criterion of the mental and if the belief that 5 is a prime number lacks phenomenal consciousness, then this belief would fail to be mental. Many nonintentionalists, such as Block (1997), David J. Chalmers (1996), and Charles P. Siewert (1998) hold a more moderate dual view according to which many, if not all, mental states have both intentional and phenomenal properties.

If a psychological state has some phenomenal character, then it is incumbent on an intentionalist either to show that its phenomenal character is derivable from its intentionality or to argue that its having a phenomenal character is merely an illusion. Radical intentionalists, such as Dennett (1991), who are *qualophobes*, choose the last option and argue that the mysteries of phenomenal consciousness should be explained away or dissolved. Philosophers who subscribe to moderate forms of intentionalism take the former option, which in turn can be divided into two distinct strategies. According to the higher-order thought (HOT) theory of conscious states (defended by Rosenthal [1991]), what makes a person's mental state phenomenally conscious is that the person is transitively conscious of it by virtue of forming a HOT about it. If, however, a creature (e.g., a human baby) lacks the ability to form a HOT about his or her own perceptions, then his or her perceptions will lack phenomenal consciousness—a consequence that many will find implausible. Finally, pure intentionalists, such as Michael Tye (1995) and Tim Crane (2001), argue that *qualia* are mental representations with nonconceptual content. Tye, for example, argues that pains are mental representations of damaged bodily parts and that the phenomenal features of pains arise from the nonconceptual content of the bodily representation. Arguably, the intentionalist account of pain may derive some empirical support from the phenomenon of phantom pains, whereby people who have had limbs amputated may still experience pain in their phantom limb. A bodily part need not exist for someone to feel pain in it: it is enough that the bodily part be mentally represented.

INTERNAL RELATIONS

See *Relations, Internal and External*

INTERNALISM AND EXTERNALISM IN ETHICS

Among the various uses of the term *internalism* in ethics, there are two that are central and importantly different. In the following entry, these two uses will be distinguished as judgment internalism and reason internalism.

JUDGMENT INTERNALISM

Judgment internalism is the view that moral judgments can be sufficient to motivate actions. Motivation is internal to morality. Externalists, by contrast, hold that the motivation to act morally is supplied by motives that are only contingently related to moral judgments. Internalism is thus opposed to the view that we need to appeal to special motives in order to explain compliance with moral demands, such as sympathy, as well as to a Hobbesian outlook claiming that the motivation to act is always self-interested, and that the motivation to act morally must therefore be self-interested, too. Internalism in this sense has been defended by Thomas Nagel (1970), John McDowell (1978), Christine Korsgaard (1986), and possibly by Immanuel Kant (1785).

One of the first to introduce the term in this sense was William Frankena (1958) who is critical of internalism. Externalism—the view that moral judgments as such

cannot motivate moral actions—has few explicit defenders. However, John Stuart Mill (1861) claimed that we should distinguish sharply between the 'proof' of the moral principle (the principle of utility, as he sees it) and its 'sanctions.' While it can be demonstrated to anyone that an action is morally wrong if it violates the principle of utility, the motivation to act in accordance with the principle will be present only in those who received an appropriate education.

One response to judgment internalism is error theory (Mackie 1977). On the level of semantics, internalists have it right: Moral judgments involve an attempt to refer to properties that exist independently of a person's desires, but that are capable of motivating him or her. Thus, on the one hand, those properties must be features of the world as it is independently of our responses to it. But, on the other hand, we necessarily respond to them in certain ways. This combination of claims is, according to Mackie, ontologically speaking, 'queer:' It requires that moral properties be primary and secondary properties at the same time. But there can be no such properties. Therefore, all our moral judgments are false (for a critical discussion of J.L. Mackie's argument, see McDowell [1985]).

REASON INTERNALISM

Yet there is a different use of the terms *internalism* and *externalism* that in effect reverses the one sketched above. Bernard Williams in his influential essay *Internal and External Reasons* (1980) defends the view that all practical reasons are internal reasons. By *internal* he means that they are related to a person's given desires—to the elements of his or her subjective motivational set. This Hume-inspired view is based on an explanation of motivation in terms of desires as a distinct kind of psychological state.

Practical reasons are potentially both explanatory and justificatory: They determine what a person should do, but also explain his or her actions (if he or she acts for those reasons). But as explanation must appeal to an agent's motives (or desires), reasons have to be suitably linked to those. Desires, in turn, are not (ultimately) the product of reasons. Therefore, in order to be explanatorily relevant, a person's reasons must be based on his or her given desires. A person has a reason to ϕ, if he or she can reach the conclusion to ϕ by a sound deliberative route starting from his or her given desires (Williams 1989).

Desires, Williams explains, need not be conceived narrowly. The term applies to a whole array of states of a

very different kind comprising a person's projects, commitments, and loyalties. Desire is simply a term of art that can be used to refer to all motivationally relevant attitudes. It follows that a person has reason to act in a certain way only if he or she happens to have an appropriate desire: a desire that will be satisfied if he or she acts accordingly, provided the desire is not based on false belief and formed on the basis of correct information about the relevant facts. Therefore a person's reasons do not exist independently of his or her psychological states.

This view is at odds with the normal understanding of moral reasons, and of practical reasons more generally. We tend to interpret at least some reason statements as referring to how things are in the world (independently of the agent's attitude toward them). They are thus external reasons, according to Williams's terminology: reasons that are independent of a person's psychological states. In interpreting reason statements as referring to external reasons, Williams claims, we are mistaken because external reasons are incapable of explaining a person's actions (for an earlier, yet different defense of a similar view, see Davidson [1963]).

Williams's defense of internalism led to an intense and continuing debate (see Hooker [1987], Smith [1995], Millgram [1996], FitzPatrick [2004]). McDowell (1995) replied that Williams may well be right thinking that if reasons can be external, then not everyone is capable of being motivated by practical reasons that apply to him or her. But the externalist is not committed to thinking that they can. The externalist's crucial claim is that reasons exist independently of motives—not that they can motivate anyone independently of what his or her motives happen to be. Is the externalist committed to denying Williams's claim that practical reasons are both justificatory and explanatory then? According to McDowell, he or she is not. Those who are motivated by reasons may not be so motivated by a desire whose existence is independent of the reason.

McDowell suggests an Aristotelian alternative to Williams's Humean view: The capacity of being motivated in the right way is a matter of moral upbringing. But moral upbringing is (in part) the ability to be motivated by moral reasons. The moral person is one who responds to his or her perception of the morally salient features of the his or her situation. Thus McDowell can agree with Williams that practical reasons are both justificatory and explanatory, but denies that explanation must appeal to desires that exist independently of reasons. Reasons exist independently of desires, and they can

motivate independently of them—at least those who have been brought up in the right way.

Various versions of reason externalism have been proposed in recent years (see Dancy [2000], Parfit [1997], Raz [1999], Scanlon [1998]). Korsgaard (1986 and 1996) defends a version that is stronger than the one proposed by McDowell: She claims that a reason can motivate a person insofar as he or she is rational (independently of given motives). According to her, being rational is the ability to respond to reason, and we all have that ability (perhaps to a lesser or higher degree). Thus there is no emphasis on moral upbringing in Korsgaard's account of motivation.

Against this, Michael Smith (1987) provides an a priori argument for internalism, or—as he puts it—the Humean theory of motivation. Smith develops Hume's view that beliefs and desires are distinct psychological states, distinguishing them by their different direction of fit. Beliefs aim to represent the world as it is, whereas desires are an agent's dispositions to change the world in such a way that it fits with the desire. Beliefs have a mind-to-world and desires a world-to-mind direction of fit. Only states with the right direction of fit (i.e., desires) can motivate. Beliefs as such cannot. If we are to understand value judgments as beliefs (as Smith thinks we should) they will not be sufficient to explain actions (Smith 1994). This argument gave rise to an ongoing discussion (Wallace 1990; Velleman 1992).

The two uses of internalism can be seen as related: The older tradition of judgment internalism identifies internalism with the claim that moral judgments as such are capable of explaining actions. This claim, however, bears some similarity to Williams's claim that practical reasons are both justificatory and motivating. The main difference is that judgment internalism is confined to moral judgments, whereas Williams is concerned with practical reasons more generally (a further difference is that reason internalists are not committed to accepting that practical reasons are, at least in part, judgments; for the significance of this difference see Dancy [2000]).

Yet, according to Williams, put together with some version of the Humean theory of motivation, the claim that practical reasons are both explanatory and justificatory leads to the conclusion that reasons must be based on desires, which is the view that he calls internalism: reason internalism. Thus, roughly, judgment internalism labels one of the premises of Williams's argument internalism, whereas Williams himself uses the term to refer to its conclusion. The focus of disagreement is then on the

Humean theory of motivation, which divides the two approaches.

Ulrike Heuer (2005)

INTERNALISM VERSUS EXTERNALISM

Internalism in epistemology is a thesis about the nature of epistemic normativity, or the sort of normativity that is involved in the evaluation of cognition. Specifically, internalists claim that the (epistemically) normative status of a belief is entirely determined by factors that are relevantly "internal" to the believer's perspective on things. By contrast, externalists in epistemology deny this. The externalist says that the epistemic status of a belief is not entirely determined by factors that are internal to the believer's perspective.

When internalism and externalism are characterized in this way, several things become apparent. First, internalism is a rather strong thesis, in the sense that it says that epistemic status is entirely a function of internal factors. By contrast, the denial of internalism is a relatively weak thesis. Externalism in epistemology holds that some factors that are relevant to epistemic status are not internal to the believer's perspective. A second point to note is that there are several kinds of epistemically normative status, corresponding to several kinds of epistemic evaluation. We can say that a belief is justified, rational, reasonable, or intellectually responsible, and these need not

mean the same thing. It is possible, then, to be an internalist about some kinds of epistemic status and an externalist about others. Hence, there are a variety of internalisms and a corresponding variety of externalisms.

Third, we get different understandings of internalism (and externalism) depending on different ways that we may understand the phrase "internal to the believer's perspective." The most common way to understand the phrase is that something is internal to a believer's perspective just in case the person has some sort of privileged access to the thing in question. For example, some fact F is relevantly internal to some person S's perspective if S can know by reflection alone whether F obtains. A related, though not equivalent, understanding of "internal to S's perspective" is as follows: Some factor F is internal to S's perspective just in case F constitutes part of S's mental life. For example, a person's perceptual experience counts as internal on this understanding, since how things appear perceptually to S is part of S's mental life in the relevant sense. Also, any belief or representation that S has about how things are would be internal on this understanding, since one's beliefs and other representations are also part of one's mental life. These two understandings are related because it is plausible to think that one has privileged access to what goes on in one's mental life, and perhaps only to what goes on in one's mental life. In that case the two understandings would amount to the same thing for practical purposes. Internalism would then be the thesis that epistemic status (of some specified sort) is entirely a function of factors that are part of one's mental life, and to which one therefore has privileged access.

Finally, it is apparent that some varieties of internalism are initially more plausible than others. That is, some sorts of epistemic evaluation are obviously externalist on the previous understandings. Most importantly, and perhaps most obviously, whether a belief counts as knowledge is an external matter, if only because a belief counts as knowledge only if it is true, and whether a belief is true is typically an external matter.

OBJECTIVE VERSUS SUBJECTIVE EVALUATIONS

There is another reason knowledge and many other sorts of epistemic evaluation must be understood as externalist, however. Consider that we can evaluate both persons and their beliefs in two different ways. Broadly speaking, we can evaluate them either from an objective point of view or from a subjective point of view. From the objective point of view we can ask whether there is a good fit between the person's cognitive powers and the world. For example, we can ask whether the person has a good memory or an accurate vision. Also from this point of view we can ask whether a person's methods of investigation are reliable, in the sense that they are likely to produce accurate results. By contrast, there is a second broad category of epistemic evaluation. This sort does not concern whether a belief is objectively well formed, but whether it is subjectively well formed. It asks not about objective fitness, but about subjective appropriateness. Internalism is pretty much a nonstarter with respect to evaluations of the first category. Evaluations from an objective point of view involve factors such as accuracy, reliability, and appropriate causal relations to one's environment, and these are paradigmatically external factors. Therefore, internalism is best understood as a thesis about the second broad category of epistemic evaluation: It is a thesis about what factors determine subjective appropriateness. Let us use the term *epistemic justification* to signify this second sort of epistemic status. In that case internalism is the thesis that epistemic justification is entirely a function of factors that are within the believer's perspective.

THREE CONSIDERATIONS IN FAVOR OF INTERNALISM

Why would someone be an internalist? Three considerations have been stressed in the literature. The first begins with an assumption about the nature of epistemic justification (where *epistemic justification* refers to the sort of subjective appropriateness required for knowledge or some other important epistemic status). The assumption is this: A belief is epistemically justified just in case it is epistemically responsible. However, the argument continues, epistemic responsibility is entirely a matter of factors that are internal to S's perspective. Therefore, epistemic justification is entirely a matter of factors that are internal to S's perspective.

A second consideration put forward in favor of internalism invokes a strong intuition about epistemic justification. Namely, in many cases it seems that believers who are alike in terms of internal perspective must also be alike in terms of epistemic justification. The point is often illustrated by considering René Descartes's victim of an evil deceiver. Suppose that the victim is exactly like you in terms of internal perspective. Even if the victim lacks knowledge, the argument goes, surely his beliefs are as well justified as yours are. If you are justified in believing that there is a table before you, and if the victim's perspective is exactly as yours, then he must be justified in believing that there is a table before him.

A third consideration invoked in favor of internalism is that externalism makes an answer to skepticism too easy. Philosophical problems are supposed to be difficult. If the externalist has an easy answer to the problem of skepticism, this argument goes, then that is good reason to think that externalism is false. At the least it is good reason to think that the externalist has changed the subject—that he is no longer talking about our traditional notions of justification and knowledge.

How does externalism make an answer to skepticism too easy? The idea is roughly as follows: According to the skeptic one can know via sense perception only if one knows that sense perception is reliable. Similarly, one can know by inductive reasoning only if one knows that inductive reasoning is reliable. This creates problems for the internalist, because it is hard to understand how one can mount a noncircular argument to the desired conclusions about the reliability of one's cognitive powers. There is, however, no such problem for the externalist since the externalist can deny the initial assumption of the skeptical argument. For example, an externalist can insist that sense perception gives rise to knowledge so long as sense perception is in fact reliable. There need be no requirement, on an externalist account, that one know that one's perception is reliable. What is more, on an externalist account one seemingly can know that one's cognitive powers are reliable, and easily so. For example, one can use reliable perception to check up on perception, and then reason from there that perception is reliable. Similarly, one can use reliable induction to check up on induction, and then reason from there that induction is reliable.

EXTERNALIST REPLIES

Externalists reply that none of these considerations adequately motivate internalism. First, externalists argue, even if epistemic justification is to be understood in terms of epistemic responsibility, it is false that epistemic responsibility is entirely a matter of factors that are internal to S's perspective. This is because whether a belief is epistemically responsible is partly a function of the belief's etiology, or how S came to have the belief in the first place. For example, whether a person is epistemically responsible in holding some belief is partly a function of the person's prior behavior: If S's reasons for believing b are the result of prior negligence, then S is not now blameless in believing b. Similarly, we can make a distinction between (1) merely having good reasons for a belief, and (2) believing on the basis of those reasons. Plausibly, a belief is epistemically praiseworthy only if it is believed

on the basis of good reasons—merely having good reasons, if one does not use them, is not enough. But etiological considerations such as these involve external factors; that is, factors that are not typically internal to S's perspective.

The same line of argument has been used to counter the second consideration in favor of internalism. The problem is that two believers might be alike internally, and yet different regarding the causal genesis of their beliefs. Suppose that two persons arrive at the same internal perspective, but that one does so in a way that is epistemically responsible, whereas the other does so in a way that is careless and thick-headed. The two persons will not be alike in epistemic justification, although they share the same internal perspective.

Finally, externalists argue that the third consideration in favor of internalism is self-defeating. In effect, internalists claim that only they can give a satisfactory answer to traditional skeptical concerns. On the contrary, externalists argue, internalism makes it impossible to answer the skeptic. This is because traditional skeptical arguments assume internalism about epistemic justification. Moreover, if one concedes that assumption, externalists argue, then the skeptic has all he or she needs to construct skeptical arguments that are otherwise sound. Therefore, externalists conclude, internalism about epistemic justification guarantees skepticism about epistemic justification.

John Greco (1996, 2005)

INTRINSIC VALUE

A thing's intrinsic value is the value it has in itself as opposed to the instrumental value it derives from causally producing something else. Such value is important for the theory of the right, since on most views at least one moral duty is to promote intrinsic goods and prevent intrinsic evils. But it also matters in itself. If an earthquake causes suffering no one could have prevented, the suffering is still intrinsically bad. In fact, it is distinctive of the concept of value that, unlike that of ought or right, it is not restricted to what is under our voluntary control. And intrinsic value is the central kind of value. Something is instrumentally good if it produces something else good, but on pain of infinite regress, what it produces must eventually be intrinsically good.

There are two types of questions about intrinsic value: conceptual questions about what it is and substantive questions about what things have it. One conceptual issue is whether judgments of intrinsic value are objectively true or false or merely express emotions, but this question arises equally for all normative concepts. A more distinctive question is how intrinsic goodness relates to other normative concepts. One view, defended by G. E. Moore (1903), says the concept of goodness is simple and unanalyzable, even in normative terms; a rival view analyzes the good as what one ought to desire (Sidgwick 1907) or as the desire for which is correct or appropriate (Brentano 1969, Ewing 1948). Like the first view, the second allows judgments of goodness to extend beyond ones about right action, since one can desire what one cannot produce. But it cannot say, as the first can, that one ought to desire something *because* it is good, and it faces the further difficulty that, since one often cannot produce desires at will, its *ought* cannot be the simple deontic one and is therefore not clearly distinguishable from *good*.

A second conceptual question is what type of entities have intrinsic value. The most common view is that they are states of affairs, so to say that pleasure is good is really to say that the state of affairs in which someone enjoys pleasure is good. But some attach value primarily to objects. Thus, Immanuel Kant (1998) held that the prime bearers of intrinsic value are persons (and not the states of affairs in which persons exist) while others find such value in, say, beautiful works of art. A related question is what the morally required response to intrinsic value is. Many who locate such value in states of affairs say this response is only to desire and promote the good; others say there is a separate and stronger requirement to respect good states by not directly destroying them. In fact the Kantian view centers on respect. Since one cannot promote values that already exist, as the Kantian value of persons does, the required response is not to treat them in a way that disregards their value.

A final conceptual question is what kind of properties intrinsic value can depend on. Moore held the strict view that a thing's intrinsic value can depend only on its intrinsic properties, those it has independently of relations to other things. He therefore tested for intrinsic value by a *method of isolation*, which involves imagining a world where only a given thing exists and asking whether that world is good. Others hold, more liberally, that intrinsic value can depend on relations, so a belief can be intrinsically better if it corresponds to reality and therefore is true, or a pleasure can be better if it is that of a virtuous person and so deserved. (Some restrict the term *intrinsic value* to value that depends only on intrinsic properties and use *final value* for what can vary with relations; they still differ from Moore in holding that some value worth promoting for itself depends on relations.)

The substantive issues about intrinsic value arise most clearly if it is located in states of affairs; the question then is which states are worth desiring and promoting for their own sakes. Here, the simplest view is hedonism, which holds that only pleasure is intrinsically good and only pain intrinsically evil. Though defended by Jeremy Bentham, Sidgwick, and other utilitarians, hedonism faces numerous objections. It implies that a world of intense mindless pleasures like those of *Brave New World*, where people are systematically deluded and exercise no serious skills, can be supremely good; it makes morally vicious pleasures, such as pleasure in another's pain, purely good; and it also makes undeserved pleasure good.

In response, many philosophers develop pluralistic views according to which the intrinsic goods include not just pleasure but also, for example, other states of persons such as knowledge, the achievement of difficult goals, and moral virtue; patterns of distribution of goods across persons, such as equal distributions or ones proportioned

to people's deserts; and even states outside persons, such as the flourishing of complex ecosystems. These pluralistic views require comparisons between their different goods whereby some may be higher or greater than others. Thus, scientific knowledge may be better than the pleasure of eating chocolate and the virtue of compassion better than both. But in so far as there is a duty to promote intrinsic value, one should pursue the best overall outcome, weighing all goods appropriately against each other.

Many nonhedonic goods involve what Moore called the "principle of organic unities (1903, p. 27-36) according to which the intrinsic value of a whole need not equal the sum of the values its parts would have on their own, so states with little value when apart can make for significant value when combined. The exact formulation of this principle depends on whether intrinsic value can depend only on intrinsic or also on relational properties. Either way, the greatest value can be found not in simple states such as pleasures but in complexes combining several elements in a specified way.

A final substantive question is whether all intrinsic values are agent-neutral, so everyone has equal reason to pursue them, or some are agent-relative, with greater value from some people's point of view than from others'. Given Moore's view that goodness is an unanalyzable property, agent-relativity is impossible: A state either has the simple property, in which case everyone has a duty to promote it, or it does not. But analyses of good in terms of ought allow relativity: We can say that each person's pleasure is something only that person ought to desire, or that parents should care more about their children's pleasure than about that of strangers. On the agent-neutral view, intrinsic value specifies a common goal that everyone is to pursue together; given agent-relativity, there can be different goods and different required goals for different people.

INTROSPECTION

The term *introspection* might be defined as the direct, conscious examination or observation by a subject of his or her own mental processes. The term is derived from two Latin words, *spicere* ("to look") and *intra* ("within").

From at least the time of René Descartes up to the early twentieth century, it would have been considered unproblematic that the mind can reflect (or bend its attention back) upon itself. In the eighteenth and nineteenth centuries, if not earlier, self-reflection began to be interpreted, in the main, as introspection. In turn, to introspect one's own mental processes was explained in terms of the capacities (1) to focus the full glare of one's conscious attention upon the task of observing some particular, first-level, conscious process (or mental act), which was an item in one's stream of consciousness, and (2) to report in a privileged and incorrigible way upon the results of such observation. This introspective act was considered to be a form of inner, though nonsensuous, perception, and deliberate parallels were frequently drawn between it and ordinary outer perception by means of our senses, such as those of vision or hearing.

In the nineteenth century, Franz Brentano and other philosophical psychologists were at pains to distinguish introspection (sometimes called inner observation) from its close relative, self-consciousness (sometimes called inner perception). Introspection was a deliberate act of focusing a subject's attention on some inhabitant in his stream of consciousness. Self-consciousness was an indeliberate but inescapable, though partial, concomitant awareness on the part of a subject of at least some features of some of his first-level conscious mental acts. To put it metaphorically, introspection was a deliberate ogling with the inner mental eye; self-consciousness was

unavoidably catching sight of something out of the corner of one's mental eye.

However, even as this canonical version of introspection was being formulated, doubts were being voiced about the possibility of splitting consciousness into two processes that operated at two different levels at the same time. Pushing aside these doubts, the early psychological introspectionists—such as Wilhelm Wundt, Edward B. Titchener, Narziss Ach, Karl Bühler, and William James—believed that either introspection proper or some version of self-consciousness was nevertheless the only possible method for inaugurating a truly empirical, that is, scientific, psychology. For only the subject of mental acts or processes can have "eye witness," knowledge by acquaintance of the denizens of his or her stream of consciousness. So, the very first psychological laboratories were devoted to introspection (for this term came to be used for both introspection proper and for scientific versions of self-consciousness). In carefully designed laboratories bristling with chronograph and tachistocope, subjects were asked to produce detailed introspective reports on various aspects of the inner conscious effects of carefully controlled stimuli applied to their senses.

These experiments resulted in some of the most tedious literature that psychology has ever produced. Also, there could be found little or no agreement about results across schools or from one laboratory to the next. Yet another consequence, which Wundt, for example, readily admitted, was that introspection experiments seemed confined to a study of comparatively trivial mental episodes.

Surprisingly, the failure of introspectionism did not lead many people to question the inherent model of introspection. As psychology and philosophy wound their way through behaviorism and versions of the mind-brain identity theory to contemporary forms of physicalism, such as functionalism, both were faithful to the original, classical model of introspection. They abandoned the Cartesianism of the psychological introspectionists and questioned the privileged status of introspection reports, but they did not question the basic two-level picture—that introspection was a second-level monitoring, observing, registering, or tracking of some first-level process or processes.

Thus, classical psychological behaviorists such as John Broadus Watson or B. F. Skinner gave, as at least one account of one employment of introspection, that it was a literal monitoring by the subject of his thinking (which for a classical behaviorist was to be analyzed as inner truncated movements in the muscles of speech, or

"stopped short" speech). Only the repeated failure of experiments seeking to verify this theory led to the abandonment of that particular, and now notorious, explanation.

The philosophers, or most of them, also championed some version of the two-level account of introspection, and still do. Even the most tough-minded of the physicalists, such as David M. Armstrong or Daniel Dennett, stick resolutely to a two-level monitoring account of introspection. Thus, in *A Materialist Theory of the Mind* Armstrong describes introspection as one part of the brain scanning another part of the brain such that the subject, whose brain it is, generates (in entirely causal fashion) a belief about the nature of the first-level, scanned, brain process. In *Content and Consciousness* and again in *Brainstorms* and *Consciousness Explained*, in an uncompromising functionalist account of mind, Dennett describes introspection in terms of one part of the brain "accessing" another (like one part of a computer accessing another) and then, via the speech center, "printing out" the results.

In philosophy and psychology since the 1950s, there has been a minority view that this two-level account of introspection is simply mistaken. Humans have no such second-level inspecting or scanning or monitoring capacity. Earlier, Gilbert Ryle (1949) argued convincingly that this two-level account did not make theoretical sense. Unfortunately, he substituted for it an unconvincing behaviorist account (in terms of the ordinary perceptual "retrospection" of ordinary behavior). More recently, psychologists and philosophers (such as Wilson and Nisbett 1977 and Lyons 1986) have suggested that, besides those theoretical grounds for rejecting the two-level account of introspection, there are also empirical grounds for rejection drawn from contemporary experimental psychology, anthropology, and the brain sciences. In contemporary introspective experiments subjects produced reports that were more like stereotyped and predictable "folk" interpretations than detailed eyewitness accounts of inner events. Besides, it seems that in cultures more or less uninfluenced by European culture people do not claim to have powers of introspection. More important, there does not seem to be any part of the brain that functions as a monitor of those neurophysiological states that maintain and control conscious states. Finally, it seems both possible and more plausible to give an account of what humans are doing, when they claim to be introspecting, in terms of the exercise of the internal but quite ordinary capacities of memory and imagination. This opposition of views has not yet been resolved, and,

because of this, introspection (like consciousness itself) is likely to receive more direct and sustained treatment in the future.

INTUITION

The broadest definition of the term *intuition* is "immediate apprehension." *Apprehension* is used to cover such disparate states as sensation, knowledge, and mystical rapport. *Immediate* has as many senses as there are kinds of mediation: It may be used to signify the absence of inference, the absence of causes, the absence of the ability to define a term, the absence of justification, the absence of symbols, or the absence of thought. Given this range of uses, nothing can be said about intuition in general. Instead, it is necessary to pick out those principal meanings of the term that have played the most important roles in philosophical controversy and to discuss each of these individually.

Four principal meanings of *intuition* may be distinguished: (1) Intuition as unjustified true belief not preceded by inference; in this (the commonest) sense "an intuition" means "a hunch." The existence of hunches is uncontroversial and not of philosophical interest. (2) Intuition as immediate knowledge of the truth of a proposition, where *immediate* means "not preceded by inference." This is a philosophically important sense, since philosophers have found it puzzling that one can have knowledge, and thus justified belief, without having made oneself aware through the process of inference of any justification for this belief. (3) Intuition as immediate knowledge of a concept. "Immediate knowledge" here means, roughly, "knowledge that does not entail ability to define the concept." (4) Intuition as nonpropositional knowledge of an entity—knowledge that may be a necessary condition for, but is not identical with, intuitive knowledge of the truth of propositions about the entity. This sense of *intuition* is exemplified by (*a*) sense percep-

tions, considered as products of a cognitive faculty distinct from the faculty of forming judgments concerning the entity sensed; (*b*) intuitions of universals, or (as in Immanuel Kant) of such insensible particulars as time and space—intuitions that are necessary conditions of our intuitive knowledge of a priori truths; (*c*) mystical or inexpressible intuitions that, unlike sense perceptions and intuitions of universals, do not make possible knowledge of the truth of propositions about the entities intuited—such intuitions as Henri Bergson's inexpressible intuition of duration, Johann Gottlieb Fichte's intuition of the Transcendental Ego, and the mystic's intuition of God.

FACULTY AND LINGUISTIC EXPLANATIONS OF INTUITIVE KNOWLEDGE

INTUITIVE AND NONINFERENTIAL KNOWLEDGE. There is both a strong and a weak sense of "intuitive knowledge that *p*." In the weak sense of this term, *S* knows that *p* intuitively if (*a*) *p* is true, (*b*) he is justified in believing that *p*, and (*c*) his knowledge that *p* is not based upon his inferring *p* from other propositions. The criterion for its not being so based is simply that *S* would deny, for any set of propositions *p** from which *p* follows, that he believes that *p because* he believes that *p** (although he might in fact believe *p** and be willing to adduce *p** to satisfy someone else's doubts about *p*). In this sense of "intuitive," we may know intuitively that we have two legs or two children, but we cannot know intuitively that the Civil War was caused by slavery, or that nothing can move faster than the speed of light. In this sense, the existence of intuitive knowledge is unquestionable; and "intuitive" in this sense is synonymous with "noninferential."

In the stronger sense of *intuition*, however, only a certain species of noninferential knowledge is intuitive: *S* knows that *p* intuitively only if (*a*) *p* is true, (*b*) he is justified in believing that *p*, and (*c*) there are no accepted procedures for resolving doubts about the truth of *p*, given *S*'s belief that *p*. Thus we may be justified in believing without inference that we have two legs, but if we have doubts we can undertake such tests as looking and seeing, asking others, and checking the possibility of collective hallucination. Given these tests, so much evidence may appear to show that one leg is missing that it would be irrational to maintain our previous belief. But in certain cases—for example, our belief that we are in pain, or that every event has a cause—there are (at present) no procedures available for resolving doubt. It is never irrational to continue to believe that *S* has a pain once one knows

that he believes he does, despite, for instance, the failure of physiologists to find a concomitant neural process. Again, if someone thinks that some events are uncaused, we have no way of testing his hypothesis. Yet we are not willing to give up our claim to know that he is wrong. In both sets of cases—so-called rock-bottom data of perception and introspection, and so-called unquestionable first principles—justified belief is accompanied by the lack of procedures to settle doubt. These are the two paradigm cases of "intuitive knowledge," in the strong sense of the term—first-person statements about those psychological states to which one has "privileged access" and underived a priori truths.

In this stronger sense, too, the existence of intuitive knowledge is unquestionable. Two points should, however, be noted. First, if in formulating the conditions for the application of this sense of intuitive knowledge we had simply said "*p* is indubitable" rather than "there are no accepted procedures for resolving doubts about *p*," then it would have been questionable whether any such knowledge existed. It can plausibly be argued that, under sufficiently peculiar circumstances, it may be rational to doubt one's belief that one is in pain, or that every event has a cause. In general, it can plausibly be argued that there are no intrinsically indubitable propositions, for rational doubt may outstrip the possibility of rationally settling doubt. Second, it is possible for procedures to come into existence for settling doubt in areas where none existed before. Thus we now take *S*'s belief that he was in pain as the best possible evidence for his having been in pain, but advances in physiology may bring about a practice of withdrawing claims to have been in pain when the relevant neural processes have failed to occur. Under these conditions, *S*'s belief that he was in pain would be intuitive in the weak sense, but no longer in the strong sense. Again, some philosophers would argue that, with the rise of quantum theory, we are now in a position to treat "every event has a cause" as an empirical hypothesis, even though it was once the paradigm of an unquestionable first principle. In general, whether a proposition can count as the object of intuitive knowledge (in the strong sense) is a function of the availability of accepted procedures for settling doubt, and it is doubtful that we can know a priori in what areas such procedures will and will not be developed.

Noninferential will here be used in place of the weak sense of intuitive, and *intuitive* in place of the strong sense. Both noninferential and intuitive knowledge seemed to philosophers to require explanation because the paradigm of knowledge has, since Aristotle, fre-

quently been taken to be inferential knowledge—the case in which one knows not only that *p* is true but also why *p* is true, and believes that *p* is true because one believes certain other propositions from which *p* may validly be inferred (see Aristotle's *Posterior Analytics* I, 2). Noninferential knowledge has often been explained by being assimilated to this paradigm through the use of the notion of implicit or unconscious inference. Cases of nonintuitive knowledge have been treated as cases in which an inference from intuitively known premises was performed, and cases of nonintuitive, noninferential knowledge as cases in which the knower is not aware of having performed the appropriate inference.

FACULTY THEORY. Various explanations have been given of the existence of intuitive knowledge. As was noted, the objects of intuitive knowledge seem to fall into two quite different groups—such very particular facts as "This looks white" or "This hurts," and such very general facts as "Every event has a cause" or "If *p* implies *q*, and *p*, then *q*." Our knowledge of the particular has often been referred to as sensory intuition, and of the very general as nonsensory intuition. The simplest, most familiar, and least helpful explanation of our possession of these two sorts of intuition is that we possess faculties which produce such knowledge. Accepting this explanation amounts to granting that the presence in our mind of the original starting points of knowledge is inexplicable and must be accepted as a brute fact. Aristotle was content with this solution, and so was René Descartes. In Cartesianism this inexplicability was woven into the fabric of a metaphysical dualism, according to which no mental event (such as a coming-to-know) could be caused by any sequence of physical events, and in which the only mental relation that could bring about a coming-to-know was the relation of being inferred from. This picture of the mind required that comings-to-know which were not preceded by inference be treated as uncaused causes, incapable of explanation.

Descartes's extreme rationalism led him to insist that sensory intuitions are not really cases of knowledge at all, and this in turn led him to hold that they are not really mental events but merely physical ones. Thus he did not recognize two intuitive faculties (one sensory and one nonsensory) but only one, the nonsensory. In his view, sense perception is in principle nonessential to attaining complete knowledge, although it is mysteriously necessary in practice. This paradoxical position was criticized by John Locke and others. Under the impact of such criticisms, a more moderate rationalistic position was developed, according to which both sense perception and the

intellect are sources of genuine knowledge and enjoy equal status as intuitive faculties.

LINGUISTIC THEORY. The new moderate rationalism was attacked by the immoderate empiricism of David Hume, according to which our only intuitive faculty is that of sensory intuition. Hume, however, and such later empiricists as Bertrand Russell, continued to accept the Cartesian metaphysical framework, thus admitting that no explanation can be given of the fact that a physical event *p* (the modification of one of *S*'s sense organs) is frequently followed by the mental event *M* (*S*'s coming-to-know that *p*). They insisted, however, that an explanation can be given of the acquisition of our nonsensory intuitive knowledge and that consequently it is not necessary to postulate a special faculty that provides us with knowledge of first principles. The alternative explanation (in the form it was given by the logical positivists) was that all such knowledge is knowledge of analytic truths and that the process of acquiring such knowledge is identical with the process of learning the conventions of one's language. This view—sometimes called the linguistic theory of a priori knowledge—held that to know, for example, that all events are caused is simply to know something about the meanings of the words *event* and *cause*, and that this knowledge is acquired by easily understandable processes of psychological conditioning. To this suggestion, rationalists objected, first, that the process of learning the meaning of *cause* cannot be accounted for except by invoking a special faculty of intuitive acquaintance with universals; and, second, that the linguistic theory represents a confusion of acquiring knowledge with acquiring the ability to express this knowledge.

PRELINGUISTIC KNOWLEDGE. The rationalists held, concerning the linguistic theory, that even granted that it would be a violation of linguistic conventions to speak of "uncaused events," the real question is: How do we know that this is the right convention to adopt? Is not this latter piece of knowledge, knowledge of nonlinguistic fact? Are not linguistic conventions adopted on the basis of such prelinguistic knowledge? Such questions, many philosophers thought, show that the linguistic theory does not enable us to dispense with a faculty of nonsensory intuition. As long as the central presupposition of these questions—that *S* can properly be said to know that *p* prior to his ability to express *p* in language—was granted, this rationalist rebuttal created a new deadlock.

The influence of Cartesianism, and particularly of the Cartesian notion of sense perception as a special,

unanalyzable mental act correlated with certain modifications of sense organs, made it difficult to question this presupposition. Sense perception was, it seemed to most philosophers, a clear example of our ability to know facts without having the ability to express them. If a child, by virtue of his faculty of sensory intuition, can see that a physical object O has the sensory quality Q by a simple, uncaused act, prior to acquiring the ability to express this fact in language, then why cannot the same child see with his mind's eye that every event has a cause and, on the basis of this prelinguistic intuitive knowledge, check the correctness of conventions concerning the words *cause* and *event*?

BEHAVIORIST ANALYSIS. The notion of prelinguistic knowledge, and with it the whole Cartesian conception of comings-to-know as mental occurrences, was questioned by Gilbert Ryle, Ludwig Wittgenstein, and their followers. Under the influence of these writers, many philosophers have come to treat "S knows that p" not as a statement about S's mind but as a statement that, besides presupposing the truth of p, asserts that S is disposed to assert p on appropriate occasions, and also either that S is prepared to give good reasons for believing that p or that S is justified in believing p even though he is unable to give reasons for believing that p. The last case covers all noninferential knowledge, both intuitive and nonintuitive. In the case of S's nonintuitive, noninferential knowledge—that, for example, he has two children, or that there is a house in front of him—the criteria that establish that S is entitled to assert these propositions are of two sorts: those that determine whether he knows the meanings of the terms he uses and those that determine whether his situation and abilities are normal (where *normal* means, roughly, that the sincere reports of persons with these abilities in these situations are usually confirmed when checked by independent means). For example, S would be justified in believing that there is a house in front of him if he knew what a house is (that is, knew what *house* means), had his eyes open, and had normal vision. He would be justified in believing this even if, when asked, "How do you know that that's a house?" he was too unsophisticated to make any reply except "I just know." Whether S satisfies these criteria can be determined by public procedures—testing his grasp of the language, his vision, and his position vis-à-vis the house in straightforward and unmysterious ways.

According to the Cartesian view, what justifies S in believing p in the absence of an ability to produce good reasons for believing p is a special, private, introspectable mental state. S introspects to see whether or not he knows

that p, and thus he knows intuitively that he knows that p and has better ground for the belief that he knows that p than anyone else can have. The behaviorist alternative asserts, on the contrary, that the fulfillment of public criteria is not just an external symptom of the presence of an occult mental state called knowledge, but that the statement of such criteria gives a full account of the meaning of "to know." This treatment of such cases of nonintuitive, noninferential knowledge as "I see that O is Q" is designed to replace the Cartesian notion of sense perception as a simple, unanalyzable act with the view that to see that O is Q cannot happen prior to the ability to use correctly the terms O and Q (or some equivalent expressions). Infants and animals, confronted by O, have sensations but do not have perceptions. They begin to perceive that O is Q when these sensations, and only these sensations, are accompanied by a disposition to assert or assent to "O is Q." Thus, they begin to perceive that O is Q only when their belief that O is Q becomes a reliable indicator of the truth of "O is Q."

This behaviorist analysis of nonintuitive, noninferential knowledge can be used to explain the difference between this case and the case of intuitive knowledge. The difference is that in the case of intuitive knowledge the only criterion that S must satisfy in order to be entitled to believe p without being able to offer good reasons for p is that he knows his language. The paradigms of intuitive knowledge—knowledge of "private" psychological states and knowledge of underived a priori truths—are such that if a person claims knowledge of this sort, the only way in which his claim can be refuted is to show that he does not know his language. For example, if someone sincerely believes that he is in pain, we cannot show that his belief is mistaken unless (as in the case of a young child) we can show that his use of *pain* is idiosyncratic. Again, if someone claims to know that every event has (or does not have) a cause, we cannot show that his belief is unjustified unless we discover that he does not understand what he is saying (and we discover this by discovering that his use of *event* or of *cause* is idiosyncratic). To know what one is saying is, in certain cases, to know that what one says is true.

Behaviorist analysis also permits an explanation of our possession of intuitive knowledge that dispenses with the notion of intuitive faculties. In the case of sensory intuition, the process of acquiring intuitive knowledge is simply the occurrence of certain sensations in a person who knows a language that contains ways of describing these sensations (that is, contains expressions whose utterance speakers of the language are conditioned to

correlate with occurrences of these sensations). In the case of nonsensory intuition, we acquire intuitive knowledge simply by reflecting upon our own linguistic behavior (where *reflecting* means, roughly, "asking ourselves questions about what we would say if …"). In both cases, the crucial precondition is knowledge of a language, and the process of acquiring this knowledge is taken to be a matter of psychological conditioning—conditioning whose operations are explicable entirely in terms of a stimulus-response model. Whereas according to the traditional Cartesian faculty view the difference between men and animals is a matter of man's possession of a special sui generis power (variously called awareness, consciousness, spirit, reason, and the like), this difference is regarded by many contemporary philosophers as a matter of the ability (due, presumably, to a more complex central nervous system) to respond in more diverse ways to a wider variety of stimuli—as a matter of degree rather than of kind.

CARTESIAN AND WITTGENSTEINIAN ATTITUDES. The difference between Cartesian and Wittgensteinian attitudes toward the fact that intuitive knowledge that *p*, such that belief in *p* is justified yet there is no way to settle doubt about *p*, exists may be summed up by saying that for a Cartesian the claim that belief in *p* is justified must reflect a natural fact—for example, some intrinsic feature of that belief (considered as a mental state), such as self-evidence. For the Wittgensteinian, this claim need reflect only a social convention. On the Cartesian view, it is only contingently true that we possess intuitive knowledge, a fact that is to be explained (if at all) by reference to the makeup of our minds. On the Wittgensteinian view, our possession of intuitive knowledge is a necessary truth, built into the use of the word *know*. The Cartesian reasons that since there cannot be an infinite regress—and thus justification of beliefs must stop somewhere—there must be certain kinds of belief that are intrinsically of a special sort, such that to have them is to know that they do not require justification. Followers of Wittgenstein reason that since there can be no infinite regress—and thus justification of belief must stop somewhere—one would expect, given our use of the word *know* to mean "justified belief," that there would be certain conventions dictating that certain beliefs are justified even in the absence of good reasons. For the Cartesian, these conventions reflect introspectable facts about the mind or about entities (such as universals) visible to the eye of the mind; for the Wittgensteinian, they do not reflect anything. To ask why we have procedures for settling doubt about *S*'s claim that he sees a house, although

we do not have procedures for settling doubt about his claim that he has a pain, is, according to Wittgensteinians, to ask why we use the words *pain, house*, and *see* as we do. To such questions there is no answer. Nor is there any answer to the question why we use *event* or *cause* in such a way that it does not make sense to ask whether or not a given event was uncaused. We just do. That in certain cases it does not make sense to ask certain questions—for example, the question "How do you know?"—is, on this view, as much a matter of convention as the fact that one normally says "I am in pain" when being tortured but not when being caressed.

OBJECTIONS TO THE LINGUISTIC EXPLANATION. Much contemporary epistemological controversy consists of arguments for and against the behaviorist analysis of knowledge and the linguistic explanation of intuitive knowledge. The principal objections to the linguistic explanation are three: (1) It has been claimed that no behavioristic analysis of *believes* (and thus a fortiori of *knows*) can be achieved without recourse to terms that, like *believes* itself, exhibit intentionality. (2) It has been argued that the view that there is no awareness, perception, consciousness, or knowledge prior to the acquisition of linguistic ability makes it impossible to understand how we can learn language in the first place. (In rebuttal, it has been argued that to suppose that we learn how words are used by associating certain awarenesses with certain utterances is a misleading backward projection of the way in which an adult learns new words into the original learning of language by the child.) (3) It has been argued that the stimulus-response model is inadequate for explaining the learning of languages, on the ground that one who knows a language is able to produce grammatical sentences he has never heard. This fact has suggested to some theorists that we must postulate innate knowledge in order to explain language-learning.

This entry will not attempt to resolve these issues, but will only describe how the linguistic explanation has been brought to bear upon (*a*) the notion of unconscious inference, (*b*) the notion of intuitive awareness of universals, and (*c*) the notion of nonpropositional knowledge.

NONINFERENTIAL KNOWLEDGE AND UNCONSCIOUS INFERENCE

It has traditionally been held that all knowledge that is not intuitive is inferential, and thus that the cases of nonintuitive, noninferential knowledge should properly be regarded as the products of unconscious inference. This view is most familiar in the form of the phenomenalist

claim that *S*'s knowledge that, for instance, there is a white house before him is always the result of an inference from propositions concerning the sense data that *S* is currently having or concerning the appearances that the house is presenting to him. Proponents of this view regard *S*'s denial that he made such an inference or believed such propositions simply as evidence of a lack of philosophical sophistication. Such a view results from the assumption that only certain special propositions are suited, by virtue of their intrinsic properties, to be objects of noninferential knowledge. Thus, phenomenalists hold that "That is a white house" is inherently unsuited to be noninferentially known, whereas "I am now having a white sense datum" or "There now seems to me to be something white in my visual field" is inherently suited to be so known. The occurrence of an unconscious inference in *S*, they hold, is guaranteed by the fact that his belief is unsuited to be an expression of direct sensory awareness. No empirical evidence is allowed to disconfirm that such an unconscious inference was performed.

The criterion for being an expression of direct sensory awareness used by sense-datum theorists usually takes one or the other of the following forms:

(1) *p* expresses *S*'s direct sensory awareness if and only if *S* has intuitive knowledge that *p* (if, in other words, there are no procedures available that would provide better evidence against *p* than the fact of *S*'s belief that *p* provides for *p*), and if *S*'s coming to know that *p* is correlated with *S*'s having a certain sensation.

(2) *p* expresses *S*'s direct sensory awareness if and only if a sufficient condition of the acquisition of knowledge that *p* by *S* is that *S* has a certain sensation (so that none of *S*'s antecedent knowledge interferes to provide an interpretation of what his senses give).

These two criteria are often taken as interchangeable by philosophers who have gone in quest of the "given" elements in experience—for, at first blush, such intuitively knowable propositions as "I am in pain" or "I seem to be seeing something white" seem the most promising candidates for satisfying the second form.

The linguistic explanation of sensory intuition attempts to dispense with both the given and unconscious inference. According to the linguistic theory nothing could possibly satisfy the second form, since a sensation is never a sufficient condition for the acquisition of a bit of knowledge. Also, there is nothing paradoxical in saying that a man may simultaneously come to know, without performing any inferences, that this is an airplane, a Boeing airplane, and a B-29 as a result of a single modification of the eyes—the same modification that, in a child, would produce only the knowledge that this is something silver. According to this theory, the man's belief in all these propositions is justified because, roughly speaking, he has been conditioned to utter statements expressing each of them when certain sensory stimuli are received. Some men, as we say, just know a B-29 when they see one, and others do not. An aircraft spotter trained to respond to the appearance of a B-29 by saying "There is a B-29" would have a justified belief in this proposition even if he were unable to list any criteria for B-29-hood (and thus were unable to provide any reasons for his believing the plane to be a B-29).

For those who accept a linguistic explanation of intuitive knowledge, the traditional attempt to identify noninferential and intuitive knowledge by means of the notion of unconscious inference results from a confusion of the context of *S*'s acquisition of the knowledge that *p* with the context of his justifying his belief that *p* to one who doubts *p*. If an argument between *S* and a doubter of an empirical proposition *p* were carried to its ideal limit, *S* might eventually have to retreat to such intuitively known statements as "It seems to me that I remember that *q*" and the like. The ideal empiricist would be the man who never believes an empirical proposition *p* unless he has previously performed an inference embodying the argument that he would give in defense of *p* when challenged by a die-hard doubter. (The ideal empiricist, in other words, is the ideal Cartesian doubter; he always doubts every proposition he knows how to doubt.) The notion that we are all unconsciously ideal empiricists is a confusion of "*S* would not be able to justify his belief that *p* to a die-hard doubter without appealing to certain propositions that he knows intuitively to be true" with "*S* is not justified in believing *p* if he has not previously so justified his belief to himself."

Once we adopt the linguistic explanation of intuitive knowledge, its defenders argue, we see that whereas noninferential knowledge is a matter of one's disposition to make certain statements being a sufficient ground for one's belief that they are true, intuitive knowledge is a matter of that disposition serving as the best possible evidence for their truth. The propositions that can be noninferentially known by *S*, like those that can be intuitively known by him, are determined by *S*'s training, circumstances, and abilities, together with the conventions in force within his linguistic community. The fact that certain propositions are usually known noninferentially, and

others usually known intuitively, by normal adults has misled philosophers into thinking that certain special intrinsic properties belong to all those propositions, and only to those propositions, properties detectable by our mental eye. The linguistic theory, freeing us from the "mental eye" model, directs our attention to the factual criteria that we use in deciding whether a certain belief, held by a certain person, is justified.

INTUITIVE ACQUAINTANCE WITH CONCEPTS

A person is said to have intuitive acquaintance with a concept if he is able to understand a large range of propositions that employ a term signifying this concept and is unable to explain the significance of this term. Thus (confining ourselves, for the sake of simplicity, to descriptive concepts) we may say that *S* grasps F-ness intuitively if and only if he can use the expression "F" correctly, and he does not know any noncircular definition of "F," where a "definition of 'F'" is any true statement of the form "*X* is called 'F' (or 'an F') if and only if it is _____," and "noncircular" means that the blank is filled by some expression that neither contains "F" nor contains any word whose definition itself contains "F," nor any word whose definition contains words whose definition contains "F," and so on.

ACT OF ABSTRACTION THEORIES. As in the case of intuitive knowledge that *p*, there is no dispute among philosophers about the existence of intuitive acquaintance with concepts. Rather, as in the former case, controversy arises concerning the explanation of this fact. In this case also, philosophers working within a Cartesian tradition accept a "simple act" theory. On this traditional view, we possess a faculty called abstraction that, for example, peels the whiteness of white objects from these objects and holds the whiteness up before our mental eye; once we have whiteness clearly in focus, we can label it with the term *white* and thus can acquire a knowledge of how to use this term. This act of abstraction, like the act of intuiting that *p*, is specifically mental, simple, and unanalyzable. Within this Cartesian framework, the principal issue is that between rationalists and empiricists: Whether such a simple act of abstraction must be postulated to explain only our knowledge of apparently indefinable sensory concepts (like "white"), or whether it is also needed to explain our knowledge of apparently indefinable nonsensory concepts, such as "being," "cause," "necessity," or "good." Empiricists have traditionally held that these latter concepts are not grasped intuitively. They have claimed either that our knowledge of how to use

terms signifying them is a result of our implicitly or unconsciously possessing noncircular definitions of them, or that these terms do not refer to concepts at all but are without meaning. Consequently, they have devoted themselves to proposing such definitions, or to developing theories of meaningfulness that would permit the conclusion that these terms have no meaning. Rationalists, on the other hand, have insisted that certain terms signify a priori concepts, and that none of the definitions of these terms proposed by empiricists (such as Hume's definition of *causation* as "constant conjunction") are adequate.

LINGUISTIC THEORY OF CONCEPTUAL INTUITION. The traditional account of our intuitive grasp of concepts contains many of the same elements as the traditional view of intuitive knowledge that *p*. It is again assumed that we need to account for a difference between humans and animals (the fact that we can use concepts, whereas animals can merely respond to stimuli) by postulating a simple sui generis mental act and that this simple act does not occur in all the cases that, prima facie, are cases of immediate knowledge, but that some such cases are cases of unconscious mediation. Just as recent philosophical thought has turned away from the notion that intuitive knowledge that *p* is to be regarded as such a simple act, and has offered an account of the acquisition of such knowledge in terms of a theory according to which the use of language is a necessary condition of the possession of any piece of knowledge, recent thought has likewise asserted that the ability to use "F" correctly is all that is signified by the phrase "acquaintance with F-ness," and thus that the notion of a prelinguistic grasp of F-ness is incoherent. According to this newer view, no object of acquaintance (such as a concept, conceived of as a sort of mental particular) need be postulated as that with which language learners correlate utterances of general terms. We learn such terms as *white* not by correlating utterances of them with anything but by being subjected to a conditioning process that leads us, after some trial and error, to utter these words in appropriate contexts in appropriate situations. This process need not, at any stage, involve our knowing the truth of any proposition of the form "*X* is called 'F' only when it is an instance of F-ness."

The older view, in insisting on the necessity of such knowledge, assumes that the process of learning the use of an indefinable word such as *white* must parallel the process of learning the use of a word by learning its definition. Just as we might correlate utterances of "bachelor" with situations in which we would be inclined to say

"unmarried male," and thus learn the meaning of "bachelor," so (the older theory holds) we correlate utterances of "white" with situations in which we are aware of whiteness. But, proponents of the newer view object, the only test we have for knowing whether we are aware of whiteness is whether or not we are inclined to utter "white." Nothing is added to an explanation of learning words ostensively by a reference to acquaintance with concepts, save the unverifiable claim to possess a piece of prelinguistic knowledge. If this newer view (largely due to Wittgenstein and his followers) is accepted, then what distinguishes us from the animals is not that they cannot perform the mysterious operation of intuiting concepts but simply that we can respond in much more various ways to a much greater variety of stimuli than they can (and, specifically, we can develop patterns of linguistic behavior). Once again, the difference between humans and animals reduces to the possession of language.

One advantage claimed by defenders of this newer view is that, if it is accepted, the old controversy about the existence of a priori concepts that divided rationalists from empiricists is rendered moot. The question of whether we must postulate a sort of nonsensory ostention of such concepts as causality, or an innate grasp of them, no longer arises if the same sort of process that enables us to learn the use of *white* enables us to learn the use of *cause*. To acquire the concept of causality is, on this view, to learn the use of the word *cause*; this can be done without correlating utterances of *cause* with anything, but simply by trial and error: Sometimes when we say "This caused that," we are rebuked, and sometimes praised, until gradually we get it right. (Before we got it right, we were said not to know the meaning of *cause*, just as we were said not to know the meaning of *white* as long as we called "white" what our parents called "gray.") The question of whether *cause* (and other terms that have been held to signify a priori concepts) is definable without circularity now loses its philosophical interest.

INTUITION AS NONPROPOSITIONAL KNOWLEDGE

The final sense of intuition comes primarily from Kant, who defined "intuition" as "knowledge that is in immediate relation to objects" (see *Critique of Pure Reason*, A19–B34, A320–B377). By *immediate* he here meant "without the mediation of concepts," and he took sense perception as the paradigm of intuition (although he also argued for the existence of pure intuitions of space and time). Kant sharply distinguished immediate knowledge from knowledge of the truth of judgments concerning the objects sensed, since he held that the formation of judgments requires the addition of concepts to intuitions. The former sort of knowledge is a necessary condition of the latter. The knowledge gained in sense perception is expressed by judgments concerning the objects sensed but exists prior to the formation of these judgments. Perceptual knowledge of *O* is, on this view, not reducible to knowledge that *O* has certain properties.

This distinction between immediate knowledge of objects and mediate knowledge of facts about these objects was formulated by Russell, in *The Problems of Philosophy*, as the distinction between "knowledge by acquaintance" and "knowledge by description." He proceeded to explain a priori knowledge by postulating a faculty, analogous to sensation, that acquaints us with universals and with the relations between universals. The assertion of the existence of universals has, traditionally, gone hand in hand with the faculty explanation of our intuitive knowledge of a priori truths and of our grasp of nonsensory concepts. It is still current among contemporary philosophers who resist the linguistic explanation of this knowledge. These philosophers include both such traditional rationalists as Brand Blanshard and phenomenologists who adopt Edmund Husserl's notion of intuition of essences.

The Kantian notion of sense perception as a kind of nonjudgmental knowledge has had the effect of opening the door to the suggestion that we possess a certain sort of knowledge that is like sense perception, or Russellian acquaintance with universals, in being immediate but unlike either in being inexpressible. In other words, it is suggested that we have an intuition of a certain object *O* even though we do not know the truth of *any* proposition of the form "*O* is *Q*." The reason usually given for our failure to have the latter sort of knowledge is that conceptual thought (or language) is inadequate to capture the essence of *X*. For example, Bergson argued that duration cannot be captured by concepts (nor, a fortiori, expressed in language) because concepts (and thus language) are designed precisely to freeze and stabilize (and thus to distort) the flux of experience, whose essence is duration. Again, God's perfect simplicity—his identity with his own attributes—is held to make it impossible truly to apply any predicate to him, and thus to know any true propositions about him.

Philosophers who adopt the view that there is no knowledge prior to the possession of language, and who construe knowledge in the behavioristic manner, naturally object to the notion of nonpropositional knowledge. On their view, the original Kantian notion of sense per-

ception as a kind of knowledge is based upon a confusion. Once this confusion is dissipated, the analogy to sense perception that is the basis of Russellian accounts of a priori knowledge and of theories of inexpressible intuition will no longer be available, and the notion of knowledge of *O* that is irreducible to the knowledge that *O* has certain features will appear as paradoxical as it really is. The original confusion, these philosophers argue, is that of the cause of the belief that some sensed object *O* has the feature *Q* with the justification of this belief. Specifically, the fact that knowledge that *O* is *Q* is caused by a sensation of *O* is combined with the assumption that nothing can serve to justify *S*'s claim to know about *O* except another piece of knowledge about *O* by *S*. This produces the conclusion that the mere sensing of *O* is itself a case of knowing—distinct from, because giving a ground for, the knowledge that *O* is *Q*. Since sensing *O* is construed as a direct relation between the knower and *O*, whereas knowing that *O* is *Q* is construed as a relation between the knower and something distinct from *O* (a fact or a proposition), it is inferred that there are two sorts of knowing, one of which is primitive and direct and the other derivative and indirect. A causal condition for knowledge is thus confused with a special type of knowledge—knowledge by acquaintance.

Philosophers who deny the existence of such nonpropositional knowledge by acquaintance argue that the notion of knowledge of *O* that is not knowledge that *O* has some feature is neither present in ordinary usage nor part of a useful explanatory theory. On their view, all knowledge of objects is knowledge of the truth of propositions about these objects. This anti-Kantian position is supported by, and supports, the anti-Cartesian behaviorist position, according to which knowledge cannot occur prior to the ability to learn language. Although it is logically possible to hold both that there can be prelinguistic knowledge of facts and that there is no such thing as knowledge of particulars as distinct from knowledge of facts, this position is not popular. Contemporary epistemological thought is, by and large, split between those who adopt both a Cartesian "simple act" explanation of the intuitive knowledge that *p* and a Kantian notion of nonpropositional knowledge as a necessary condition for intuitive propositional knowledge, and those who reject both of these views in favor of a radically behavioristic approach.

INTUITION OF THE INEXPRESSIBLE

Even philosophers who have remained faithful to the traditional Cartesian and Kantian positions tend to criticize the use of the notion of intuition as nonpropositional awareness made by such philosophers as Fichte, Bergson, and contemporary Thomists. Their criticism is based on the view that the only criterion for knowing whether *S* has nonpropositional knowledge of *O* is his knowledge of the truth of propositions about *O*. Thus both groups reject claims to have knowledge that one is unable to express (except, perhaps, in analogies and metaphors). Anti-Cartesian philosophers, however, argue that it is precisely the Kantian view that sensing is a kind of knowing that opens the gates to claims to intuit the inexpressible. This view leads naturally to the conclusion that even the objects of ordinary sensory acquaintance are incommunicable and inexpressible. No amount of talk by Jones (who has seen *O*) will suffice to reproduce in Smith (who has not) the sensation Jones had when he was in the presence of *O*. This failure to reproduce an experience is, given the view that sensing is a kind of knowing, taken as a failure to convey knowledge of *O*, even though Smith may learn, from Jones's reports, every fact about *O* that Jones knows. We thus find ourselves adopting a novel, and peculiarly philosophical, sense of "express"—a sense in which an experience would be expressed only if it were reproduced. Whereas in the normal sense of the term, my seeing a white house is completely and adequately expressed by some finite set of such propositions as "That's a white house," in this new sense such propositions are inherently unsatisfactory surrogates. This line of thought, opponents of nonpropositional knowledge argue, plays into the hands of those who, like Bergson, hold that language is inadequate to reality.

The claim that language is inadequate to express one's intuitive knowledge of reality would, in itself, be harmless. However, the danger of adopting this new meaning of "inexpressible" is that we may find ourselves claiming private justification for our moral, philosophical, religious, aesthetic, or other beliefs by saying, "Although I cannot, of course, express (or communicate or put into words) the experience that I had, and hence cannot supply you with reasons for believing that *p*, I am nevertheless entitled to believe that *p* solely on the strength of that experience." The plausibility of this sort of reasoning stems from the fact that, in the case of noninferential belief about physical objects, we sometimes say things like "Since you haven't seen a flying saucer, you have no reason to believe that there are flying saucers; but I have seen one, and so I do believe in them." Here we seem to be justifying a belief solely on the basis of private experience. The difference is that "I saw a flying saucer" is a complete and adequate expression of this experience, in the ordinary sense of "express." The justification is sufficient because the state-

ment that an experience *E* was had analytically implies *p*. (If *S* saw a flying saucer, then there are flying saucers to be seen.) In the former case, however, the statement that an experience *E* was had cannot entail any statement about the object of the experience because the nature of the experience is, ex hypothesi, inexpressible.

This obvious disanalogy is veiled by the fact that in the second, philosophical sense of "inexpressible," our experiences of seeing houses or flying saucers are just as inexpressible as the Thomists' intuition of Being, or Bergson's intuition of duration. In other words, a tacit shift to a new sense of "express" creates the sophistical argument "Since your sensory experiences are inexpressible, and yet sufficient to justify your beliefs, it is unfair of you not to let my inexpressible nonsensory experiences justify my beliefs." Of course, in the ordinary sense of "express," sensory experiences are as expressible as experiences can be.

In addition to this criticism of the ambiguity contained in the philosophers' use of "inexpressible," a further criticism of such claims to private justification is available if the behaviorist view of the nature of justification of claims to noninferential knowledge is adopted. If this justification is viewed not as a matter of an intrinsic, introspectable property (self-evidence) of certain beliefs but rather as a matter of social convention, then one will hold that we know which of our noninferential beliefs are justified only by knowing which ones our peers would agree are justified. In the flying saucer example, we rightly think that our belief in flying saucers is justified if we think we have seen flying saucers, because we are confident that anyone who had had the sensations we have had would have been disposed to utter "I see a flying saucer." We know that our belief is justified because our peers admit that if they should ever have an experience of the sort we claim to have had, they would share our belief. The only element of privacy lies in the fact that they can have doubts about, for example, whether we are being truthful in claiming that we had this experience, or whether we were sober, or attentive, whereas we cannot.

In the "inexpressible intuition" case, however, we cannot tell whether our peers would share our belief if they shared our experience, for we do not know what our experience was. Here we could speak of a private justification only if we had a private language in which we could express to ourselves, although to no one else, what we experienced, and private criteria of justification formulated (in part, at least) in this private language. But, aside from the general difficulties in the notion of a private language pointed out by Wittgenstein, "private criteria of justification" is an intrinsically paradoxical notion. One can

no more have private rules for justifying beliefs than one can have private rules for justifying actions. A criminal has no greater claim on our sympathy if he proclaims that his private ethical code differs from ours, and a believer in untestable beliefs has no greater claim on our attention when he says that his epistemological code is not ours.

Bibliography

The medievals used "intuitive cognition" as we would use "sensory intuition" to refer to knowledge about objects present to the senses. The term was opposed to "abstractive cognition," which included memory and imagination. They also, however, used "intuition" to refer to a vision of God. This use of "intuition" for any sort of knowledge that has the same noninferential character as knowledge of the apparent features of an object present to the senses was continued by Descartes (*Regulae* XII), Benedict de Spinoza (*Ethics* II, Prop. 40, Note 2), and Locke (*Essay concerning Human Understanding*, Book II, Ch. 2, Sec. 1). These philosophers used the term as we would use "nonsensory intuition"—to refer to our noninferential knowledge of, for instance, mathematical axioms and analytic truths, and of the validity of valid inferences. Between Descartes and Kant, "intuition" was rarely used in reference to perceptual knowledge, nor was a clear distinction made between propositional and nonpropositional knowledge. Since Kant, however, it has been usual to speak of both nonpropositional perceptual knowledge of a particular, and of the propositional knowledge derived from this nonpropositional knowledge, as cases of intuition.

Whereas Kant had denied the existence of intellectual intuition (nonpropositional knowledge of insensible objects), Fichte asserted it in his *Werke*, edited by I. H. Fichte (Berlin, 1845), Vol. I, pp. 463ff. However, Fichte argued that he did not really disagree with Kant because the object of this intuition, the Transcendental Ego, was an act rather than a thing. The same strategy is adopted by contemporary neo-Thomists, who speak of an intuition of Being; what is intuited, they say, is an act rather than a thing or an essence. See Jacques Maritain, *Existence and the Existent* (New York: Pantheon, 1948), Ch. 1, and Étienne Gilson, *Being and Some Philosophers* (Toronto: Pontifical Institute of Mediaeval Studies, 1949), Ch. 6. The most influential recent proponent of a faculty of nonpropositional knowledge other than sense perception is Henri Bergson; see his *Introduction to Metaphysics* (New York: Putnam, 1913). For a criticism of Bergson's notion of intuition, consult G. Watts Cunningham, *A Study in the Philosophy of Bergson* (New York: Longmans Green, 1916), Ch. 3. For a discussion of the philosophical importance of the ineffable intuitions claimed by mystics, see W. T. Stace, *Mysticism and Philosophy* (New York, 1960), Chs. 1 and 3.

W. H. Walsh, *Reason and Experience* (Oxford: Clarendon Press, 1947), contains an account of traditional controversies between rationalists and empiricists concerning intuitive knowledge. For the traditional view that intuitive knowledge of facts about objects sensed is based on a nonpropositional

acquaintance with these objects, see Bertrand Russell, *The Problems of Philosophy* (London: Williams and Norgate, 1912), Ch. 5. Criticism of the notion of knowledge by acquaintance, which Russell develops in *The Problems of Philosophy*, is found in H. L. A. Hart, "Is There Knowledge by Acquaintance?" in *PAS*, Supp. 23 (1949): 69–90; also see the essays by G. E. Hughes and J. N. Findlay on the same topic in the same volume, 91–128, and Wilfrid Sellars, *Science, Perception, and Reality* (London, 1963), pp. 127–196. Additional criticisms of the view that sensing is a form of knowing occur in H. A. Prichard, "The Sense-Datum Fallacy," in *PAS*, Supp. 17 (1938): 1–18; Wilfrid Sellars, "Physical Realism," in *Philosophy and Phenomenological Research* 15 (1954–1955): 13–32; and Gilbert Ryle, *The Concept of Mind* (London: Hutchinson, 1949), Ch. 7.

The notion of unconscious inference is presented in Bertrand Russell, *The Problems of Philosophy*, Ch. 13, and a defense of this notion in Gilbert Harman, "How Belief Is Based on Inference," in *Journal of Philosophy* 61 (1964): 353–359. For the criteria of direct sensory awareness, see Bertrand Russell, "On Verification," in *PAS* 38 (1937–1938): 1–20. Russell's *Analysis of Mind* (London: Macmillan, 1921), Ch. 12, states the view that beliefs are introspectable mental occurrences. For criticism of this view, see Gilbert Ryle, *The Concept of Mind*, Chs. 2 and 5. The view that we can introspectively differentiate knowledge from mere belief is found in H. A. Prichard, *Knowledge and Perception* (Oxford, 1950), p. 88. Prichard is criticized on this point by Norman Malcolm in his *Knowledge and Certainty* (Englewood Cliffs, NJ: Prentice-Hall, 1963), p. 58.

For the contemporary reaction to Cartesianism, see Gilbert Ryle, *The Concept of Mind*, and Ludwig Wittgenstein, *Philosophical Investigations* (Oxford: Blackwell, 1953). An earlier reaction against the Cartesian account of intuitive knowledge is C. S. Peirce's *Collected Papers* (Cambridge, MA: Harvard University Press, 1933–1958), Vol. V, pp. 135–189. For the linguistic account of intuitive knowledge of the truth of propositions, see Wilfrid Sellars, *Science, Perception, and Reality*, pp. 164–170. The view that intuitive knowledge of a priori truths is founded upon a nonpropositional knowledge of universals or essences is found in Bertrand Russell, *Problems of Philosophy*, Ch. 10; Brand Blanshard, *Reason and Analysis* (La Salle, IL: Open Court, 1962), Chs. 6, 9, 10; and Edmund Husserl, *Ideas* (New York: Macmillan, 1931). For critical discussion of this view and of the linguistic account of a priori knowledge, see Arthur Pap, *Semantics and Necessary Truth* (New Haven, CT: Yale University Press, 1958).

INTUITION [ADDENDUM]

In the history of philosophy "intuition" has been used primarily as a term for an intellectual, or rational, episode intimately tied to a priori knowledge. The term has sometimes been used in a broader way to include certain sensory episodes (appearances) and certain introspective episodes (e.g., inner awareness of the passage of time). In contemporary philosophy this broader use has fallen out of fashion (except among Kantians), and the narrower use prevails.

An intuition in this sense is simply a certain kind of seeming: For one to have an intuition that *P* is just for it to seem to one that *P*. This kind of seeming is intellectual, not sensory or introspective, in the following sense: Typically, if it is possible for someone to have the intuition that *P*, then it is possible for someone to have the intuition that *P* in the absence of any particular sensory or introspective experiences relevant to the truth or falsity of the proposition that *P*. For this reason, intuitions are counted as "data of reason" not "data of experience." In this connection, intuitions are sometimes called "a priori intuitions" or "rational intuitions."

Intuition must be distinguished from belief: Belief is not a seeming; intuition is. For example, I have an intuition—it still seems to me—that the naive set-abstraction axiom from set theory is true despite the fact that I do not believe that it is true (because I know of the set-theoretical paradoxes). There is a rather similar phenomenon in sense perception. In the Müller-Lyer illusion, it still seems to me that one of the two arrows is longer than the other, despite the fact that I do not believe that one of the two arrows is longer (because I have measured them). In each case, the seeming persists in spite of the countervailing belief. Similar considerations show that intuitions must likewise be distinguished from guesses, hunches, and common sense.

Many philosophers identify intuitions with linguistic intuitions. But this is mistaken if by "linguistic intuition" they mean intuitions about words, for most of our intuitions simply do not have any linguistic content. Other philosophers think of intuitions as conceptual intuitions. Nothing is wrong with this if "conceptual intuition" is understood broadly enough. But there is a common construal—originating in David Hume's notion of relations of ideas and popular with logical positivists—according to which conceptual intuitions are all analytic. The problem is that countless intuitions are not analytic on the traditional construal of that term (convertibility into a logical truth by substitution of synonyms). For example, the intu-

ition that, if region r_1 is part of region r_2 and r_2 is part of region r_3, then r_1 is part of r_3. Possibility intuitions are also not analytic (e.g., in epistemology the intuition that the Gettier situations are possible). In response, some philosophers have countered that possibility intuitions are just intuitions of consistency, but this view is mistaken on several counts. For example, it is consistent to hold that region r_1 is part of r_2, r_2 is part of r_3, but that r_1 is not part of r_3, despite the fact that such a thing is not possible.

Standard practice in logic, mathematics, linguistics, and philosophy is to use intuitions as evidence. (For example, in epistemology Roderick Chisholm uses intuitions to show that traditional phenomenalism is mistaken, and Edmund Gettier uses intuitions to show that the traditional identification of knowledge with justified true belief is mistaken. In metaphysics Saul Kripke uses intuitions to show that, if water is H_2O, then it is necessary that water is H_2O. In philosophy of mind, Hilary Putnam uses intuitions to show that logical behaviorism is mistaken, and so forth.) A great many philosophers believe that use of intuitions is essential to the indicated disciplines.

Radical empiricists, who doubt that intuitions have evidential weight, usually defend their view by pointing to the fact that intuitions can be unreliable. They cite, for example, the fact that our intuitions about naive set theory are in conflict with our intuitions about classical logic. But this shows only that traditional infallibilism is mistaken, not that intuitions lack evidential weight. After all, sense perceptions have evidential weight even though they can be unreliable. (Incidentally, although various cognitive psychologists—Peter C. Wason, Philip Johnson-Laird, Eleanor Rosch, Richard E. Nisbett, D. Kahneman, A. Tversky, and others—have examined human rationality with a critical eye, their studies have not attempted to test empirically the reliability of intuitions, and it will be quite difficult to do so.)

Why should intuitions have evidential weight? A plausible answer is that intuitions have an appropriate tie to the truth: As a noncontingent fact, if a subject's cognitive conditions (intelligence, attentiveness, and so forth) were suitably close to ideal, the subject's intuitions would be sufficiently reliable to permit the subject to arrive at a mostly true theory regarding the subject matter of those intuitions. This is a consequence of an analysis of what it is to possess concepts determinately: A necessary and sufficient condition for determinately possessing one's concepts is that one's intuitions have this kind of tie to the truth; if the subject's intuitions lacked this sort of tie to the truth, that would only show that the subject did not determinately possess those concepts (or that the sub-

ject's cognitive conditions were not sufficiently good). In contemporary philosophy, many have come to accept (some form of) this moderate rationalist theory of intuitions and concept possession.

INTUITION [ADDENDUM 2]

An intuition is a noninferential awareness of something: a concept, a proposition, space or time, a physical object, our own existence, or God. While sometimes people talk of sensory intuitions of perceptual objects, by which they mean an immediate awareness of how they appear, this use of "intuition" is becoming more rare. Nowadays philosophers use the term primarily to mean a nonsensory and nonintrospective awareness of a proposition or concept. Some philosophers hold that an intuition must be of a proposition that seems necessarily, or possibly, true. But people who lack the concepts of necessity and possibility are able to have something very like what philosophers call intuitions. So a more plausible view is that a person has an intuition that P if and only if P seems true, or possibly or necessarily true, where that appearance is intellectual—that is, based on the understanding, not on perception or introspection. George Bealer thinks that intuitions are not beliefs because we can disbelieve something that still appears true. Perhaps some argument has convinced us that in a lottery with seventy-six million tickets we know before the drawing that we hold a losing ticket if the ticket is in fact a loser, but it may still seem that at that time we do not know that it will lose.

Thus, by "intuition" most philosophers mean a rational intuition—or a rational insight—that is based solely on understanding the proposition that is its object. The intu-

ition that a person who commits suicide kills himself, that nothing can be red and green all over at the same time and in the same respects, and that it is prima facie wrong to flog or torture an infant to death are based solely on understanding the relevant propositions. These examples show that the propositions that are the objects of intuitions can be either analytic or synthetic, where analytic propositions are ones that can be reduced to logical truths by the substitution of relevant synonyms, and synthetic ones are nonlogical truths that cannot be so reduced. The first proposition about suicide is analytic but the other two are not.

The propositions that are the objects of intuitions need not be true, though they must at least seem true. People often have the intuition that an unmarried male of marriageable age is a bachelor but come to see that this is false once they consider the example of the pope, who is such an unmarried male of marriageable age but not a bachelor. This shows that intuitions are fallible.

It is also possible to distinguish between immediate and mediate intuitions. For some propositions, such as "bachelors are unmarried," the proposition immediately seems true upon considering it. For others, such as "knowledge requires true belief," or "personal identity requires continuity of memory," reflection may be required before a sufficient understanding of the concepts involved develops and enables one to "see" that these things are true. A person might have to consider examples where it is intuitively obvious that a person lacks knowledge because he has a false belief before the general claim that knowledge requires true belief seems true to him. Similarly, a person might have to consider a case where someone has completely and irretrievably lost her memory in an auto accident to see that personal identity requires continuity of memory.

Intuitions are mental events that occur and then end, and so are unlike beliefs that are dispositions that endure even when nothing is presently before the mind (as happens when one is in a dreamless sleep). However, it is the understanding, which is the basis of rational intuitions, that provides a priori justification and sometimes knowledge. We are justified in believing that if A is greater than B, and B is greater than C, then A is greater than C solely on the basis of understanding what that proposition asserts. We will know that proposition, and not simply be justified in believing it true, provided that it is true and we believe it on the basis of the corresponding intuition.

There are some necessary truths that we cannot know, or even be justified in believing, on the basis of intuition. No one can be justified in believing that water

is H_2O solely on the basis of understanding that proposition. Empirical investigation is needed. However, we can know on the basis of intuition that some clear, odorless, colorless, drinkable liquid that does not have the same underlying physical structure as water is not water.

One challenge to the justificatory force of intuitions is that they lack such force when directed to propositions that are expressed by sentences that contain natural kind terms, terms such as water, aluminum, horse, topaz, and ruby. Further, some argue that the concepts that philosophers are interested in are natural kind concepts. Some hold, for instance, that causation, knowledge, and justice are natural kind concepts whose essence can only be discovered empirically. Note that some terms such as "ruby" might express what might be called hybrid concepts because we can know via intuition that a ruby must be red, but can learn only through empirical investigation what chemical structure rubies must have. Rubies differ from topaz in this respect because topaz can be any color, and the essence of topaz can be discovered only by empirical investigation. If concepts of interest to philosophers are either not natural kind concepts at all or hybrid concepts such as the concept of a ruby, then intuitions can be used to discover, and justify, conceptual truths involving those concepts.

Another challenge to the justificatory force of intuitions is that people with different backgrounds have conflicting intuitions about, say, the nature of knowledge. Gettier examples show that having a justified true belief is not sufficient for knowledge. For instance, if you are driving down a road where ninety-nine out of a hundred structures that look like barns are really indistinguishable facades, you do not know, though you are justified in believing, that you are looking at a barn if you happen to stop in front of the one barn on that road. Here it seems intuitively obvious to many that you have a justified true belief but lack knowledge. However, it is reported that people from other cultures do not have this intuition. So how can intuitions provide justification if there is this sort of disagreement? Surely no one would think that, say, clairvoyance had justificatory force if people "saw" events happening at a distance but did not agree on what they "saw."

A third challenge says that if intuitions provide justification then there must be a faculty of intuition similar to one of our five senses or to memory. But because there is no such faculty, intuitions cannot provide justification. One response to this objection is to maintain that intuition is a faculty, similar to the language faculty and similar to what Jerry Fodor calls a module, and then ask why

that is a problem. Another response denies that intuitions must come from some faculty if they are to provide justification.

A fourth challenge says that we can never be justified in believing that intuitions sometimes provide justification because we would have to rely on intuitions that say they do, and such a circular argument could never provide real justification. Of course, this is a problem for all basic sources of evidence. For instance, to be justified in believing that memory provides justification, we would have to remember instances where our memories have been correct. But then we would be relying on memory to justify reliance on memory.

A plausible view to hold is that intuitions can provide a priori justification when their objects are certain sorts of propositions, say, mathematical, logical, or what at least appear to be conceptual truths, though this justification is fallible and can be defeated by widespread disagreement among people who understand the relevant propositions equally well. An argument for the view that intuitions sometimes justify can be constructed from the notion of what it is to possess a concept: To possess the concept, C, we must be able to apply C and not-C correctly to most hypothetical situations. Hence our possession of the concept guarantees reliability in its application, though reliability does not require infallibility.

INTUITIONISM, ETHICAL

Philosophers thought of as intuitionists include Henry Sidgwick, H. A. Prichard, W. D. Ross, C. D. Broad, and A. C. Ewing. More recent intuitionists include Derek Parfit, John McDowell, and Thomas Scanlon. Though all but one of these philosophers are British, the expression "British intuitionism" standardly refers only to work done in the first half of the twentieth century by Prichard, Ross, Broad, and Ewing.

WHAT IS INTUITIONISM?

To be an ethical intuitionist is to hold a combination of five views in metaethics, only one of which says anything about intuitions. The first view is the pluralist view that there are many different ways in which an action can get to be right or wrong, good or bad. This is opposed to monism, the view that all moral requirements can be captured in one basic principle. The classic example of monism is John Stuart Mill's utilitarianism, which holds that an action is right if and only if, of all available alternatives, it has the best (or least bad) effect on the general happiness.

Note, however, that there are two sorts of monism: monism about the right and monism about the good. Mill's position combines both. He held that there is only one way for an action to get to be right, and only one sort of thing that is good; the only sort of thing that is good is happiness, and the only way for an action to be right is to produce as much of that good as possible. G. E. Moore, by contrast, was a monist about the right and a pluralist about the good; he agreed that a right action is one that produces the most good, but held that there are several different goods, mainly social intercourse and aesthetic appreciation, which cannot be reduced to one. So Moore is not an intuitionist, because he is a monist about the right, though he agreed with the intuitionists on everything else. Intuitionists, by contrast, combine both forms of pluralism. W. D. Ross, for instance, provided a list of goods, as Moore did, but also argued that there are many different moral duties and that they cannot all be reduced to the duty to produce the most good.

The second view is the realist (or "objectivist") view that some ethical or moral judgments are true and others are false; there is truth and there are facts of the matter in ethics. This is opposed to the noncognitivist claim that moral assertions are expressions of attitude (pro or con) rather than of belief; in saying that an action is wrong, one is not trying to characterize correctly some slice of moral reality, but expressing one's opposition to the action, the stance one takes toward it.

The third view is the nonnaturalist view that moral facts are not natural facts; the opposite view is naturalism. A natural fact is one that can be discovered using the methods of the natural sciences. (At least, this is one way

of trying to say what it is for a fact to be natural.) There are naturalist and nonnaturalist forms of utilitarianism. The naturalist form holds that rightness *is* the natural property of increasing general happiness; sociologists are presumably the people best equipped to tell us which actions have that property. Mill, however, held that actions that increase the general happiness have the *further* property of being right, and he showed no signs of thinking that this further property is natural. (One could however think that to show a moral property to be natural we do not need to find a second, "natural" way of picking it out.) Intuitionists, anyway, think that moral properties and moral facts are irreducibly nonnatural. They tend to argue for this position by pointing out that moral properties and facts are *normative*, and insisting that nothing normative can also be natural. The most famous way of making this point is Moore's "open question argument": since the question "Is increasing the general happiness being right?" is not the same question as "Is increasing the general happiness increasing the general happiness?", to increase the general happiness cannot be the same thing as to be right.

The fourth view is that the normative status of moral or ethical facts cannot be explained, but also requires no explanation. Normativity is not a mystery. When we say that it matters whether people are free or oppressed, we are saying that something is morally important, or makes a moral difference. Intuitionists think that this "making a moral difference" is a feature that some things have and others do not, but they do not think that the special nature of such features is one that calls for elaborate explanations. In this they are opposed to those nonnaturalists who feel called on to provide such explanations— in particular, they oppose Kantians, whose explanations of the morally important run in terms of some relation to the will of a rational being. Compared to the Kantians, intuitionists are quietists; they do not feel the need to say any more.

The fifth view is the one that talks about intuitions. If there are these distinct, nonnatural, normative facts and features, how do we find out about them? By which aspect of our intellectual or sensory equipment are we rendered capable of discerning when an action is right and when it is not? Intuitionists maintain that we are capable of coming to know *basic* moral facts directly, in ways that involve no inference from other nonmoral facts. They have to say this, since it seems impossible simply to move by inference from a natural belief to a normative one, given the great difference intuitionists discern between the two. And they have to say that there

are basic moral facts, since even if some of our moral beliefs are defended by appeal to others, this process has to stop somewhere. There must, then, be some basic moral beliefs, which if true are beliefs in basic moral facts. How then do we come to recognize those basic moral facts? The intuitionist answer is (supposedly): by a special faculty of moral intuition. Hence the name.

COMMENTS ON THESE VIEWS

The form of monism that intuitionists targeted most eagerly would now be called consequentialism: the view that actions are made right or wrong by the value of their consequences. Intuitionists tended to argue against this view by appeal to example. Ross (1930, 1939), for instance, said that when I keep my promises, my thoughts are not normally on the future, on the good that I will achieve by doing what I once promised to do, but on the past, on the fact that I did promise to do it. That is my reason for doing it, and it is my having promised to do it that makes the action my duty. More generally, Ross thought that actions can become duties in various ways, only some of which have anything to do with consequences. One can have duties that derive from one's role as a neighbor, or as a teacher, or as a friend, and these duties are not necessarily related to making things go better. In fact, they are not grounded in thoughts about what is better or worse, in considerations of value, at all. At this point Ross is expressing a deontological stance; and indeed intuitionists are standardly deontologists.

Historically speaking, intuitionists tended not to argue for the view that there is truth in ethics; they more or less assumed it. They were familiar with the idea that to express a moral opinion involves expressing an attitude or feeling, but Ross wrote, "What we *express* when we call an object good is our attitude towards it, but what we *mean* is something about the object itself and not about our attitude towards it" (1939, p. 255).

Nonnaturalism arouses extreme passions in some quarters. The real pressure behind naturalism is the sense that there cannot be two distinct realms: the familiar natural realm investigated by physics and a much less familiar normative realm learned about in quite other ways. If there really are such properties as right and wrong, good and bad, they must be properties that natural objects such as people and actions can have (and of course physical objects too can be good or bad, of course, though not morally so). But surely natural objects can have only natural properties, and so the normative properties must somehow be natural. To claim anything else is to commit oneself to the existence of some most peculiar features,

quite unlike, and utterly unconnectable to, any natural features. To this the intuitionists reply that there is a connection; it is *because of* their natural features that objects come to have, or to lack, normative ones. This "because of" is not a causal "because," of course. Actions are not caused to be wrong by their natural features; they are made wrong by them. Put another way, the natural features are the reasons why an action is wrong, the reasons for not doing it. The question then focuses on this notion of a reason, which is itself not a natural notion but a normative one. Intuitionists would say that nobody can do without this notion, and that it is not possible to think of "being a reason for" as a natural relation.

This focus on what it is for one thing to be a reason for an action gives the intuitionists something to say against the Kantians. Is it possible to think that the relation of "being a reason for" is one that can be, and needs to be explained (whether in natural terms or, as the Kantians would urge, in nonnatural terms)? Intuitionists have more recently tended to say that the basic notion here is that of favoring; a fact is a reason for an action if it favors doing that action. But there is, they say, very little that can be said about this notion of favoring, even though it is one with which we are all familiar.

Finally, with respect to intuitions, we need first to decide what sorts of facts are basic moral facts. Henry Sidgwick (1874) thought that the utilitarian principle was a basic moral fact. For him, a basic moral fact is a universal principle, then, and he held that such principles are self-evident, meaning that one has only to consider them in order to recognize their truth. W. D. Ross held that what we know first is that a certain feature counts in favor of (or is a reason for doing) a particular action, and that we work from this to the recognition of a general "prima facie" duty by a process of "intuitive induction." In Ross's view, then, what we are capable of directly recognizing is that one thing is a reason for another, and that is not a matter of drawing inferences. This seems to commit him to the view that we know these things by intuition (though he never explicitly said as much). The question is, What else could one say about our ability to recognize reasons?

INTUITIONISM AND INTUITIONISTIC LOGIC

Logic, in the modern preponderantly mathematical sense, deals with concepts like truth and consequence. The main task of logic is to discover the properties of these concepts. Ever since Aristotle it had been assumed that there is one ultimate logic for the case of descriptive statements, which lent logic a sort of immutable, eternal appearance. Only in the beginning of the twentieth century were certain principles of traditional logic submitted to a critical revision. It was L. E. J. Brouwer, who, in a radical constructive framework of mathematics, discovered that traditional logic could not be upheld in its full extent.

This entry sketches the basic ideas of Brouwer's constructivism, which goes by the name of intuitionism, and then discusses the fundamental principles. Next, an exposition of the familiar notions, such as proof system, semantics, and the like, is provided. In particular, this entry will show how the Brouwerian mathematical universe takes a special place in terms of its logical properties.

INTUITIONISTIC TRUTH

For all practical purposes it suffices to consider in mathematical logic only a few logical constants, or connectives. The traditional conjunction (*and*, $\wedge$), disjunction (*or*, $\vee$, and *not*, $\neg$), and implication (*if* …, *then* … , $\rightarrow$) will do for propositional logic. By adding the two quantifiers, the universal quantifier (*for all*, $\forall$) and the existential quantifier (*there is*, $\exists$), one gets the required connectives for predicate logic. The notion of intuitionistic truth is laid down for composite statements by an inductive procedure. Hence, one has to start by explaining the truth of the basic statements, the so-called atomic ones.

In intuitionism the objects and relations of mathematics are mental creations of the individual, called sub-

ject here. And logic has its domain of action in the self-constructed universe. The fundamental construction is that of the natural numbers. The move of time causes the subject to experience a sensation, which is succeeded by another sensation, while the first one is stored in memory. Brouwer called this the ur-intuition. Through a process of abstraction (identification of experienced two-ities), the empty two-ity, that is, the number 2 is obtained. A process of iteration then yields the natural numbers, and reflection on the process yields the principle of complete induction. Now, one can establish simple identities like 2 + 3 = 5. This is done by a construction of the following kind: (1) construct 2, (2) construct 3, (3) construct the sum of 2 and 3, (4) construct 5, (5) carry out the comparison construction for the outcome of (3) and (4). The success of (5) tells one that "2 + 3 = 5." The basic statements are thus verified, or proved, by constructions. One can denote "the construction a proves φ" by "a:φ." It is easy to see how a conjunction is proved; one has a proof of $\varphi \wedge \psi$ if one has a proof of φ and a proof of ψ. So the proof of $\varphi \wedge \psi$ is an ordered pair (a, b), such that a:φ and b:ψ.

The disjunction is slightly more problematic; $\varphi \vee \psi$ is a statement that contains two possibilities φ and ψ, and at least one of these is to be the case. Constructively, one wants therefore to select one of the two and provide a proof for it. We put this as (a, b):$\varphi \vee \psi$ if $a = 0$ and b:φ, or $a = 1$ and b:ψ. So a distinguishes between φ and ψ and b is the required proof. The classical notion of disjunction (the word *classical* is used here for "nonintuitionistic") is more liberal, something like "it is φ or ψ but I don't know which." This notion is not constructively acceptable. The implication is by far the most interesting; p is a proof of $\varphi \rightarrow \psi$ means that p is an operation that carries proofs into proofs such that for a proof a of φ, $p(a)$ is a proof of ψ. In symbols: $p : \varphi \rightarrow \psi \Leftrightarrow$ for any a a:$\varphi \Rightarrow p$(a):ψ. This notion is in fact the natural interpretation of implication. The interpretation of negation has also to be rendered constructively, that is, we have to explain what a:$\neg \varphi$ means, a mere "not" will not do. Brouwer's solution was: $\neg \varphi$ is true if φ can be reduced to a contradiction (absurdity); in terms of constructions: p:$\neg \varphi$ if for any proof a:φ, $p(a)$:$\perp$, where $\perp$ stands for a contradiction. That is, $\perp$ is a statement that has no proof. As a consequence, φ cannot have a proof. In Brouwer's conception the paradigm of a contradiction is $0 = 1$.

For the quantifiers, one has the following proof clauses, where one considers some fixed domains D of objects d:

$$a:\forall x \; \varphi(x) \text{ if for each } d \in D \; a(d):\varphi(d).$$

$$(a, b):\exists x \; \varphi(x) \text{ if } b:\varphi(a).$$

The constructive character of existence is thus made explicit in the sense that the proof contains a witness a and a proof of $\varphi(a)$.

The above proof interpretation defines *truth* as "having a proof," where a proof is a construction of an open-ended, unspecified nature. Hence, there is no preferred class of constructions specified—one recognizes a construction when one sees one. The precise form was published by Arend Heyting in 1934, and a similar interpretation was provided by Kolmogorov in his "problem-interpretation" (1932). In an informal manner the proof interpretation was conceived and used by Brouwer. He demonstrated the use of the interpretation, for example, in his proof of the historically first theorem of intuitionistic logic: $\neg \varphi \leftrightarrow \neg \neg \neg \varphi$. On the proof interpretation the principle of the excluded middle (PEM), $\varphi \vee \neg \varphi$, is not always provable (i.e., true). For it would demand that one can give for each proposition φ in advance either a proof of φ, or a construction that reduces any proof of φ into a proof of $\perp$. This is not a matter of abstract logic, but a matter of a general superalgorithm that decides any φ, a so-called omniscience principle. Hence, on the proof interpretation, PEM is equivalent to Hilbert's dogma, which states that all mathematical problems are solvable (1900). However, on the same interpretation, there are no absolutely unsolvable problems, for if $\varphi \vee \neg \varphi$ has no proof, φ cannot have a proof, and this is equivalent to "$\neg \varphi$ has a proof." So in this respect, David Hilbert was right, "there is no ignorabimus."

FORMAL SYSTEMS

The first formalization of (a fragment of) intuitionistic logic was presented by Kolmogorov (1925), and Heyting followed in 1930 with a full system. Both used Hilbert-type formalizations. The axioms were chosen in such a way that the classical system is obtained by adding just one extra axiom (schema): the principle of the excluded middle. The following is an axiom system:

$\varphi \rightarrow (\psi \rightarrow \varphi)$	$(\varphi \rightarrow \psi) \rightarrow ((\varphi \rightarrow (\psi \rightarrow \sigma)) \rightarrow (\varphi \rightarrow \sigma))$
$\varphi \rightarrow (\psi \rightarrow (\varphi \wedge \psi))$	$(\varphi \rightarrow \sigma) \rightarrow ((\psi \rightarrow \sigma) \rightarrow ((\varphi \vee \psi) \rightarrow \sigma))$
$(\varphi \wedge \psi) \rightarrow \varphi$	$\varphi \rightarrow (\varphi \vee \psi)$
$(\varphi \wedge \psi) \rightarrow \psi$	$\psi \rightarrow (\varphi \vee \psi)$
$(\varphi \rightarrow \psi) \rightarrow ((\varphi \rightarrow \neg \psi) \rightarrow \neg \varphi)$	$\neg \varphi \rightarrow (\varphi \rightarrow \psi)$
$\varphi(t) \rightarrow \exists \; x \varphi(x)$	$\forall x \varphi(x) \rightarrow \varphi(t)$

There are three derivation rules:

From φ and φ→ψ derive ψ, in symbols φ, φ→ψ / ψ (modus ponens); σ→φ(x) / σ→∀xφ(x); φ(x)→σ / ∃xφ(x)→σ.

An alternative formalization was presented by Gerhard Gentzen (1909–1945); his system of natural deduction differed from the Hilbert-type formalization in having no axioms and only rules. The rules are particularly perspicuous, in the sense that they tell one how to introduce a connective and how to eliminate it. In other words, what one has to assume to conclude a composite statement, and what are the consequences of a composite statement. For example, from φ and ψ infer φ∧ψ; from φ∧ψ infer φ and likewise ψ. In Gentzen's notation:

$$\frac{\varphi\ \psi}{\varphi\wedge\psi} \qquad \frac{\varphi\wedge\psi}{\varphi} \qquad \frac{\varphi\wedge\psi}{\psi}$$

Thus, the rules appear in the form of *introduction rules* and *elimination rules*. Some rules are purely local in the sense that they only concern the immediate premises and the consequence, and some are more complicated in that they concern the whole history of the derivation. The remaining rules can be found in the literature.

The Gentzen rules can be viewed as a means of providing the meaning of the connectives. This was the underlying idea of Per Martin-Löf's (1984) type theory, and it also played a role in Michael A. E. Dummett's (2000) meaning theory.

A question of immediate interest concerns the relation between intuitionistic and classical logic. The first is a subsystem of the second, that is, every intuitionistic theorem is a classical one. There is also a natural way of interpreting classical logic in intuitionistic logic. Kolmogorov (1925), Kurt Gödel (1934) and Gentzen (1934) translated classical logic so that derivability was preserved. If one denotes classical derivability by $\vdash_c$ and intuitionistic derivability by $\vdash$, then $\Gamma \vdash_c \varphi \Leftrightarrow \Gamma^\circ \vdash \varphi^\circ$ where φ° is the translation of φ. One can see here the Gödel translation:

$\varphi^\circ = \neg\neg\varphi$ for atomic φ $\qquad (\varphi\wedge\psi)^\circ = \varphi^\circ\wedge\psi^\circ$

$(\varphi\vee\psi)^\circ = \neg\varphi^\circ\wedge\neg\psi^\circ \qquad (\varphi\rightarrow\psi)^\circ = \varphi^\circ\rightarrow\psi^\circ$

$(\forall x\varphi(x))^\circ = \forall x\varphi^\circ(x) \qquad (\exists x\varphi(x))^\circ = \neg\forall x\neg\varphi^\circ(x)$

The translation clearly indicates from an intuitionistic point of view a weakening of the meaning of the connectives. The translation also works for concrete theories, for example, arithmetic. Let **PA** be the standard formalization of Peano's arithmetic, and HA the same for Heyting's arithmetic, where **PA** = **HA** + PEM. Now **PA** $\vdash_c$ A $\Leftrightarrow$ **HA** $\vdash$ A$^\circ$. This immediately shows that **PA** and **HA** are equally consistent. Historically, this came as a surprise. **HA** was supposed to be more consistent on the ground of its constructive nature. Translations, such as Gödel's, can also be carried out for certain higher order systems.

Gödel (1934) also observed that the extra strength of intuitionistic logic (from a constructive point of view) had an implicit modal character. He translated propositional logic into a modal logic, where □φ had the heuristic meaning "I know φ" or "I have established φ." The translation is given by:

$\varphi^m = \Box\varphi$ for atomic φ $\qquad (\varphi\wedge\psi)^m = \varphi^m \wedge \psi^m$

$(\varphi \vee \psi)^m = \neg(\neg\varphi^m \wedge \neg\psi^m) \qquad (\varphi \rightarrow \psi)^m = \Box(\varphi^m \rightarrow \psi^m)$

Intuitionistic logic thus translates into modal logic, and derivability is preserved in the sense that $\vdash \varphi \Rightarrow S4 \vdash \varphi\psi)^m$. Gödel's idea was recently adopted and vigorously extended by Artemov (2002), who combined the proof interpretation and the modal interpretation for arithmetic and extensions.

There are many classically derivable propositions that are not derivable in intuitionistic logic, the best known being PEM and the double negation principle ¬¬φ→φ. The latter obviously follows from the first, but conversely the schema ¬¬φ→φ implies the schema φ∨¬φ (Bernays). One simply applies the double negation principle to φ∨¬φ (and uses some intuitionistic logic).

It is convenient to remember the following rule: ∃ and ∨ are strong connectives. So, as to be expected, for example, ¬(φ∧ψ)→(¬φ∨¬ψ), (φ→ψ)→(¬φ∨ψ), ¬∀xφ(x)→∃x¬φ(x), ∀x(φ∨ψ(x))→(φ∨∀xψ(x)) are not derivable.

In an obvious way intuitionistic logic is weaker than classical logic, that is to say, as a subsystem. However, it is stronger on the ground of certain metalogical properties. For example, if $\vdash\varphi\vee\psi$, then $\vdash\varphi$ or $\vdash\psi$ (disjunction property). This testifies to the strength of the disjunction in intuitionistic logic. Similarly, one has $\vdash\exists x\varphi(x) \Rightarrow \vdash\varphi(c)$ for a constant c (in a language without function symbols) (existence property).

SEMANTICS

Where classical logic basically has one natural semantics, the truth table semantics of true, false, intuitionistic logic has many semantics, each with its specific features. The intended intuitionistic semantics is the proof interpretation, but for model theoretic applications it is rather too open ended. There are semantic interpretations of intuitionistic logic that have the flexibility one needs for

uncovering logical properties. There are roughly two classes of semantics: those based on (classical) set theory and those of an algorithmic nature. The set-theoretical ones will be considered first.

THE TOPOLOGICAL INTERPRETATION (TARSKI). In classical logic one can interpret propositional logic by means of Venn diagrams (or rather interpret monadic logic), that is, one assigns subsets of a set to propositions and interprets $\wedge$, $\vee$, $\neg$ as $\cap$, $\cup$, ^{c}. The topological interpretation refines this by considering open sets in a topological space and reinterpreting $\neg$ by the interior of the complement (where the interior of a set is the largest open subset of that set). More precisely, given a topological space X and a domain D, assign an open set $[\![\varphi]\!]$ in X to each atom φ (and $\emptyset$ to $\bot$) then

$[\![\varphi \wedge \psi]\!] = [\![\varphi]\!] \cap [\![\psi]\!]$, $[\![\varphi \vee \psi]\!] = [\![\varphi]\!] \cup [\![\psi]\!]$

$[\![\varphi \to \psi]\!] = \text{Int}([\![\varphi]\!]^c \cup [\![\psi]\!])$, $[\![\neg\varphi]\!] = \text{Int}([\![\varphi]\!]^c)$

$[\![\exists x\varphi(x)]\!] = \cup\{[\![\varphi(d)]\!] \mid d\in D\}$, $[\![\forall x\varphi(x)]\!] = \text{Int}(\cap\{[\![\varphi(d)]\!] \mid d\in D\})$

Under this interpretation one obtains completeness:

$\vdash\varphi \Leftrightarrow [\![\varphi]\!] = X$ for all topological spaces X.

Brouwer's theorem, $\neg\neg\neg\varphi \to \neg\varphi$, is topologically explained by the fact that the interior of the interior is the interior (also "the closure of the closure if the closure"). One can easily see that $\varphi\vee\neg\varphi$ and $\neg\neg\varphi\to\varphi$ are not valid, and hence not derivable: consider the real line R and put $\varphi = R-\{0\}$, then $[\![\neg\varphi]\!] = \emptyset$ and $[\![\neg\neg\varphi]\!] = R$.

HEYTING VALUED INTERPRETATIONS (TARSKI AND MCKINSEY). Classical propositional logic, from an algebraic point of view, is a Boolean algebra if one identifies provably equivalent propositions. A similar fact holds for intuitionistic logic, only the algebra fails to be Boolean, for in general $\varphi \leftrightarrow \neg\neg\varphi$ is not valid. The algebras for intuitionistic logic are called Heyting algebras. Since Heyting (and Boolean) algebras have a partial ordering (given by $[\![\varphi]\!] \leq [\![\psi]\!] \Rightarrow \vdash\varphi\to\psi$) with suitable properties, they turn out to be lattices. The algebraic and lattice theoretic approach are closely related. Jaskowski (1936), in his pioneering work, constructed certain lattices that in a specific sense capture intuitionistic propositional logic. The applications of Heyting algebras and Heyting valued models can be found in Peter T. Johnstone's book, *Stone Spaces* (1982).

BETH AND KRIPKE MODELS. Where the previous interpretations are more technical than foundational in char-

acter, Beth and Saul Kripke formulated in the 1950s and 1960s interpretations that intended to do justice to Brouwer's philosophical motivations, in particular his conception of mathematics, and thus logic, as a creation of the subject. Beth introduced his models in 1956 and Kripke in 1963. Kripke showed how the two interpretations are in a precise sense equivalent. The underlying idea is to take the notions "*the subject knows* (or 'has established') φ *at time t*" seriously. So Beth and Kripke consider stages of research (or knowledge) in time for the subject. These states are partially ordered, as the subject has at each stage a number of options of how to pursue his or her research further. The subject is assumed to have perfect memory, so what is known at a certain stage is preserved in future stages. The subject directly becomes aware of and establishes basic facts, so at each stage k a number of atomic statements are accepted; one can denote "φ is known at stage k" by k $\Vdash$ φ, and we can say "φ is forced at stage k." The interpretation for composite statements is defined inductively. Some decisions are made on the spot, for example, $\varphi \wedge \psi$ is forced at k if both φ and ψ are forced at k; some, however, involve the future. The paradigmatic case is the implication: $\varphi \to \psi$ may be accepted as correct although no information is available about the correctness of φ and ψ. Here is a Brouwerian example: Let φ stand for "there are 100 consecutive zeros in the decimal expansion of π," and ψ for "there are 99 such decimals." Obviously $\varphi \to \psi$ is correct, even for an intuitionist. So what does $k \Vdash \varphi\to\psi$ mean? The natural solution is: If at a future stage k' one has $k' \Vdash \varphi$, then $k' \Vdash \psi$. In fact, this is the natural interpretation of implication, which is only obscured by the truth table definition.

The universal quantifier also involves the future. The subject not only establishes atomic facts but also constructs objects of the domain. So at a later stage, in general, more objects will be available (exist) than at an earlier one. So the universal quantifier has also to take future elements into account; one can denote the domain at stage k by $D(k)$. One can now give Kripke's definition of $\Vdash$:

$k \Vdash \varphi \wedge \psi \Leftrightarrow k \Vdash \varphi$ and $k \Vdash \psi$; $k \Vdash \varphi\vee\psi \Leftrightarrow k \Vdash \varphi$ or $k \Vdash \psi$;

$k \Vdash \varphi \to \psi \Leftrightarrow \forall k' \geq k(k' \Vdash \varphi \Rightarrow k' \Vdash \psi)$;

$k \Vdash \exists x\varphi(x) \Leftrightarrow \exists d\in D(k)(k \Vdash \varphi(d))$;

$k \Vdash \forall x\varphi(x) \Leftrightarrow \forall k' \geq k \forall d\in D(k')(k' \Vdash \varphi(d))$.

Furthermore $\bot$ is never forced. So for negation one has $k \Vdash \neg\varphi \Leftrightarrow \forall k' \geq k$ not $k' \Vdash \varphi$. This semantics is sound, and even complete for intuitionistic logic. A particular partially ordered set with prescribed forcing for atoms, and a given domain assignment $D(k)$ for all k, is called a Kripke model. It is a simple exercise to construct coun-

termodels for nonderivable statements. For example, the model with two stages, k_o and k_1, such that $k_o < k_1$ and k_o forces no atoms, and

$k_1 \Vdash \varphi$, has the property that not $k_o \Vdash \varphi \vee \neg\varphi$.

The completeness theorem (Kripke 1963) states that

$\vdash\varphi \Leftrightarrow$ for all Kripke models K and all stages $k \in K\ k \Vdash \varphi$.

For propositional intuitionistic logic it even suffices to consider only finite Kripke models. In that case the so-called finite model property holds: if not $\vdash \varphi$, then there is a finite Kripke model that refutes φ.

Kripke models have been extensively used in metalogical research. Unfortunately, the proofs of the completeness theorem use a classical metatheory and are based on PEM. Hence, not all the applications of Kripke semantics are intuitionistically correct. W. Veldman (1976) generalized the notion of the Kripke model, so that the use of PEM can be avoided.

Beth models are similar to Kripke models, be it that the clauses rely strongly on the future. For example, $\varphi \vee \psi$ is forced at stage k if any (infinite) sequence of future stages $k \leq k_o \leq k_1 \leq \ldots$ eventually leads to a stage in which φ or ψ is forced.

Beth models are less flexible than Kripke models, but they have their advantages for metalogical applications and for modeling second-order theories.

ALGORITHMIC INTERPRETATIONS. In 1945 Stephen Cole Kleene introduced an algorithmic interpretation of intuitionistic arithmetic called realizability. One may think of the constructions in the proof interpretation as partial recursive functions, so that the proof evidence can be given as the index n of such a function. We can say that "n realizes φ" ($n\ \mathbf{r}\ \varphi$). For closed atoms the correctness can immediately be verified, so one defines $n\ \mathbf{r}\ t_1 = t_2$ if $t_1 = t_2$ is true. The interesting case is, again, the implication: $n\ \mathbf{r}$ $\varphi \rightarrow \sigma$ if $\forall m(m\ \mathbf{r}\ \varphi \Rightarrow \{n\}m\ \mathbf{r}\ \sigma)$, where $\{n\}m$ is assumed to converge. The class of all realizable sentences is a theory that extends **HA**; it is axiomatized by some natural axioms. The interesting and surprising fact is that Church's thesis, $CT_0\ \forall x\exists y\varphi(x,y) \rightarrow \exists e\forall x\ \varphi(x\{e\}x)$, is realized. Church's thesis claims that all algorithms (on natural numbers) are recursive functions. Hence, in this extended arithmetic (which is inconsistent with PA) all functions are given by Turing machines.

Gödel introduced an interpretation of arithmetic by means of (effective) functionals of higher types, the so-called Dialectica interpretation (1958). Another such interpretation was introduced by Georg Kreisel (b. 1923):

modified realizability. For a survey of the previously discussed text and more, see the bibliography.

SECOND-ORDER SYSTEMS

On Brouwer's view, there are two basic kind of objects, given by the first and second act of intuitionism. The first act gives one the discrete objects, and the second infinite sequences. These sequences, say of natural numbers, need not be given by a law; they are chosen more or less arbitrarily by the subject, hence the name choice sequences. The codification takes place in second-order logic with variables for natural numbers $x, y, z, \ldots$ and variables for infinite sequences of natural numbers, $\alpha, \beta, \gamma, \ldots$ (see Troelstra and Dalen 1988). There are a number of systems treating this intuitionistic analysis. Besides the obvious axioms they usually contain an axiom of countable choice, $\forall x\exists y\varphi(x,y) \rightarrow \exists\alpha\forall x\varphi(x,\ \alpha(x))$, and continuity axioms of various strengths. The motivation for the continuity principle that comes to mind first runs as follows: suppose one has a function F from choice sequences to natural numbers; since the output has to be computed in a finite time, only a finite part of the input choice function α can be used. Hence F is a continuous function from Baire space to N. This argument is an oversimplification (see Atten and Dalen 2002). A formulation of the (weak) principle of continuity, WC, runs as follows: $\forall\alpha\exists x\varphi(\alpha,x)$ $\rightarrow \forall\alpha\exists xy\forall\beta\ [\alpha(0)=\beta(0)\wedge \ldots \wedge \alpha(y-1) = \beta(y-1) \rightarrow \varphi(\beta,x)]$. For functions F one gets the $\forall\exists!$ prefix.

This continuity principle evidently fails for the following $\varphi(\alpha,x)$: $[\forall z(\alpha(z)=0\wedge x=0)\ \vee\exists z(\alpha(z)>0\wedge x=1)]$. Hence, intuitionistic systems with continuity principles are inconsistent with PEM. Furthermore, Brouwer introduced a certain principle of transfinite induction, the principle of bar induction, which lends the system a considerable proof theoretic strength (enough to prove consistency of **HA** and **PA**). A corollary is the so-called fan theorem, which basically says that the intuitionistic Cantor space is compact. A consequence of the fan theorem is the following: "every real function on a closed interval is uniformly continuous" (Brouwer 1975–1976); Brouwer also showed that the continuum is indecomposable, that is, R cannot be split into two nonempty parts.

In the 1920s Brouwer started to exploit the idealized choice activity of the subject. This was formalized and further analyzed by Kreisel, Kripke, and John Myhill in the 1960s. Kreisel laid down axioms for the theory of the creating subject in a kind of modal formulation. Let $\square_n\ \varphi$ stand for "the subject knows (has evidence for) φ at time n." The axioms are $\square_n\ \varphi \rightarrow \square_{n+m}\ \varphi$; $\square_n\ \varphi \vee \neg\square_n\ \varphi$; $\exists x$ $\square_x\varphi \leftrightarrow \varphi$.

Kripke simplified the theory by condensing the total action of the creating subject in one schema, $\exists\alpha(\varphi\leftrightarrow\exists(\alpha(x)\neq 0))$, Kripke's schema (KS). This schema allowed a formal reconstruction of Brouwer's later results. A recent application of KS showed that, for example, the set of irrationals is indecomposable.

Of course, there is also a second-order arithmetic with set variables, HAS. In general, sets are less palpable then functions. In constructive mathematics one cannot reduce sets to characteristic functions, since only decidable sets have characteristic functions.

METAMATHEMATICAL ASPECTS

There are striking similarities between function spaces and logic, which were first observed by Haskell Curry (1900–1982), who indicated the relation between certain combinators and propositional axioms. In the Curry-Howard isomorphism, this is extended to full logic. The present typed lambda calculus is based on these ideas. Henk Barendregt (b. 1947) systematized the various logical- and typed λ-calculus systems and arranged them in Barendregt's cube. Martin-Löf had already in the early 1970s introduced type systems that treat in a uniform way intuitionistic logic and higher-order type systems. These systems yield a most perspicuous presentation of mathematics in a constructive setting and also allow a thorough proof theoretical analysis. It may be remarked that in Martin-Löf's systems (suitable forms of) the axiom of choice became provable, thus confirming the strength of a constructive approach to mathematics. The type theoretic approach to mathematics has born fruit in computer science; there are, for example, implementations of type theory that allow automatic theorem proving. Nicolaas Govert de Bruijn (b. 1918) was the first to develop modern type systems in his AUTOMATH system.

The various semantics that were introduced over the years have found a generalized formulation in category theory. There is a special class of categories, called toposes, that in a most flexible way yields the existing older semantics. A topos can be viewed as a higher-order intuitionistic universe. Hyland (1982) introduced the effective topos, in which Church's thesis holds. Thus nowadays there are many models of all kinds of constructive universes around that allow metamathematical analysis. In particular, there are generalizations of the topological interpretation, the so-called sheaf interpretations, that perfectly model intuitionistic analysis and topology.

One particular line of research by McCarthy shows that in a universe with Church's thesis, intuitionistic truth

(for predicate logic) is not arithmetical (hence, the logic is incomplete), and moreover that HA has up to isomorphism, only the standard models. This extends earlier work by Kreisel and refines insights into incompleteness of intuitionistic logic.

A great deal of metamathematical research deals with basic principles, such as transfinite inductions, axioms of choice, and continuity principles. Some of these principles are far from neutral with respect to logic, for example, the full axiom of choice implies PEM.

IONESCU, NAE
(1890–1940)

Nae Ionescu, the Romanian logician, metaphysician, and religious philosopher, studied at the University of Bucharest and received his doctorate from the University of Munich in 1919 with the thesis *Die Logistik als Versuch einer neuen Begründung der Mathematik.* From 1920 on he was professor of logic, history of logic, and metaphysics at the University of Bucharest. He was also the editor in chief (1924–1928) and director (1928–1934) of the newspaper *Cuvântul*, in which he published more than 1,000 articles on religious, political, and economic problems.

Ionescu's scholarly publications were few—some articles on logic, a few prefaces, and a series of articles in the theological journal *Predania* (1937–1938). Nevertheless, his influence from 1922 to 1940 was enormous. His teachings and writings inspired a new interest in metaphysics and religious philosophy in Romania. Although he was primarily a logician, he strove to understand all forms of human activity. According to Ionescu, the philosopher must take into consideration not only the theoretical expression of historical life—from religion to logic and science—but also its meaningful creations: crafts, arts, biographies, political events, and all others. He approached the history of logic, as well as the history of metaphysics and of religion, as a typology of the human spirit. Such a typology he regarded as always a creation of history and ultimately of life. This seems to imply a radical historicization of the mind's activities, but God, for Nae Ionescu, is present in history through the Incarnation. On the other hand, man's mode of being is completely fulfilled only through death, and death is above all transcendent.

WORKS ON IONESCU

A complete posthumous edition of Ionescu's philosophical works in twelve volumes was announced during World War II, but only three volumes were published: *Istoria Logicei* (Bucharest, 1941) and *Metafisica*, 2 vols. (Bucharest, 1942–1943). New editions of many of Ionescu's works appeared during the 1990s, all edited by Marin Diaconu and published by Humanitas Press, Bucharest, most notably: *Curs de metafizica* (2 vols., 1991 and 1995; Lectures in metaphysics), *Curs de istorie a logicii* (1993; Lectures in the history of logic), and *Curs de logica* (1993; Lectures in logic).

IQBAL, MUHAMMAD
(1877–1938)

Muhammad Iqbal, an Islamic poet and metaphysician, was born in Sialkot, Pakistan. He studied philosophy at Cambridge for three years under J. M. E. McTaggart and James Ward. He received his Ph.D. from Munich University in 1908 for his thesis *The Development of Metaphysics in Persia.*

Inheriting the classical tradition of Muslim mystic poets, both Persian and Urdu, Iqbal was for a long time an admirer of the Spanish Sufi philosopher Ibn al-Arabi (1165–1240), the most consistent advocate of pantheism among Muslim thinkers. Very soon, however, he realized that this philosophy was foreign to the simple and invigorating message of Islam as embodied in the Qur'an and as represented in the dynamic life of Muḥammad and his

early followers. Under the influence of Jalāl al-Din Rūmī (1207–1273), the great mystic poet, whose philosophical outlook was allied in several important respects with post-Kantian voluntaristic thought in the West, as represented by Friedrich Nietzsche and Henri Bergson, he evolved a new system of thought that was meant to revitalize the faith of the Muslims of the Indo-Pakistan subcontinent. At first his message, written in verse in the *Secret of the Self* (1915), raised a storm of opposition, but very soon this opposition died its natural death, and the whole subcontinent reverberated with his inspiring melodies. He exerted great influence in molding the pattern of political, social, and intellectual life of the Muslims in the early decades of the twentieth century, an influence that is visible everywhere even now. In 1930, as president of the Muslim League, he proposed the creation of a "Muslim India within India." Pakistan, Iqbal's dream, came into being in 1947, nine years after his death. As a tribute to his memory, the government of Pakistan established in 1951 a statutory body known as Iqbal Academy, in order "to promote the study and understanding of the works of Iqbal."

The system of thought that he evolved may be called theistic pluralism in contradistinction to Ibn al-Arabi's pantheistic doctrine of the unity of being, which denied not only the unique personality of the Divine Being and his existence as distinct from the universe but also the existence of human individuals and their partnership with God in constituting the commonwealth of ends.

Immanuel Kant's negative answer to the possibility of metaphysics provided Iqbal with a basis on which to construct his thought. Human thought, Kant asserted, is circumscribed by the categories of space and time; therefore, the Ultimate Reality, which, by definition, is beyond these categories, cannot be comprehended by pure thought, which is intimately related to and based on the normal level of experience. According to Iqbal, however, time and space are not fixed and unvarying modes, as Kant had thought; their significance may vary with the beings of higher or lower grade, the degree of being determined by greater or lesser psychic powers. Moreover, this normal level is not the only level of knowledge-yielding experience. The level above spatiotemporal experience is revealed by intuition, a form of perception that is allied to ordinary experience in giving objective knowledge but which is quite distinct from it in not being solely dependent upon sense perception; intuitive experience is individual and incommunicable. It is not simple Bergsonian "intellectual sympathy," which implies negation of the perceiver; intuition, according to Iqbal, by bringing the

perceiver into contact with the Most Real, has the power to vitally transform his character and to endow him with a new personality, which reveals to him the higher consciousness of his manifold relations with God and the universe. Through his contact with Reality, the individual discovers his uniqueness, his metaphysical status, and the possibility of improvement in that status. The experience of intuition not only serves to confirm his reality and deepen his whole being but also sharpens his will with the creative assurance that the universe is not something to be really seen and known through concepts but rather something to be made and remade by continuous action, by interpreting the intuition of reality as a stimulus to ideal ends and purposes. Conceptual knowledge gives us knowledge of relations, not of reality; it is only through intuition that we can grasp the Real and give a fresh direction to the course of human history.

To Iqbal, ego is the basic reality revealed by intuition as the center of all efforts—a revelation that is vouchsafed not in the barren contemplation of the recluse but in moments of great decision and action, which are expressive of a firm faith in the ultimate purposiveness of the universe. The life of the ego consists in meeting obstruction in its contact with matter and overcoming it. This gives the ego the power to act freely. It is partly determined and partly free, and it reaches fuller freedom by approaching the individual who is most free—God. In other words, the ego is continually moving from a state of lesser freedom to that of greater freedom.

The ego is also immortal. According to Averroes immortality means transindividual eternity of intellect; according to Nietzsche immortality is synonymous with what he calls eternal recurrence, a most "intolerable" conception, as Iqbal put it. Immortality, according to Iqbal, must be individual and personal. He repudiated the pantheistic belief that the self, as a differentiation of the Absolute, will in the end be submerged and lose its identity in the Whole. It was to save man from this fate that Iqbal advocated that immortality is not a gift that every ego will enjoy; rather, it is a hope, an aspiration, depending, of course, upon a particular philosophy of life and a particular ethic that tends to maintain the state of tension in the ego and develop self-reliance, self-respect, self-confidence, self-preservation—even self-assertion, when such a thing is necessary in the interest of life—and the power to stick to the cause of truth, justice, and duty, even in the face of death. Such behavior helps in the integration of the forces of ego, thus hardening it against the forces of disintegration and dissolution. Because the ego, which exists only in the state of tension, is the most valu-

able achievement of man, he should exert all efforts not to revert to a state of relaxation. We are mortal insofar as we keep ourselves fettered to spatialized time; as soon as we rise above it and immerse ourselves in what Bergson called duration, we become timeless. It is possible, Iqbal held, to realize this timelessness even in this life, although it be but for a moment. It is the moral duty of man to keep the state of tension intact by repudiating life-negating philosophies and to attain immortality by his ego-sustaining behavior. It is in this sense that attaining immortality, according to Iqbal, becomes a moral duty.

How is the ego related to the world of matter? Iqbal viewed matter, as did Albert Einstein, as "a system of interrelated events" and the universe as an "organism," as did Alfred North Whitehead. Every atom, however low in the scale of being, is an ego. Mind, with its capacity for self-consciousness, is a higher ego, and body is a combination of subegos. Thus, on this principle the universe is of the nature of life—free, creative, and original. The universe is constantly growing and progressing toward an end—a rationally directed creative life.

How is the Ultimate Ego (God) related to the universe and to the human ego? To the Absolute Self the universe is not a reality confronting him as an "other"; it is only a passing phase of his consciousness, a fleeting moment of its infinite life. Iqbal began with Einstein's view that the universe is finite but boundless and added that it is finite because it is a passing phase of God's extensively infinite consciousness and boundless because the creative power of God is intensively infinite. But the human self is the exception; it is not a mere passing phase in God's consciousness, for it is self-centered and exclusive. It is distinct but not isolated from God. The Ultimate Ego is characterized by the most beautiful names and attributes; he is transcendent and yet immanent, and above all he is a Person who responds to man's inner yearning in "the awful silence of the universe."

IRIGARAY, LUCE
(1930–)

Luce Irigaray is a Belgian-born French feminist philosopher whose work draws on her multiple doctorates in the areas of linguistics, philosophy, and psychoanalysis. Her main contributions are her concept of sexual difference and the methodology she developed for a feminist interpretation of the history of philosophy. Like many feminist philosophers, Irigaray argues that women have always been defined in relation to men. She would agree with the mid-twentieth century French feminist philosopher Simone de Beauvoir, who argued that "the relation between the sexes is not quite like that of two electrical poles, for man represents both the positive and the neutral … whereas woman represents only the negative, defined by limiting criteria." Irigaray agrees that the feminine tends to be described "in terms of deficiency or atrophy, as the other side of the sex that alone holds a monopoly on value: the male sex" (1985b, p. 69). Irigaray demonstrates this idea with examples from literature, philosophy, everyday life, and economic and social history.

Irigaray stresses that texts from the history of philosophy have been inconsistent in their discussions of women. They have included conflicting, often overlooked hypotheses about the sexes. These may be explicit contradictions in canonical literature or implicit alternatives. In this sense, the most sex-biased historical text may be a rich resource for a feminist rereading. Rather than dismissing sex-biased caricatures of women as false or irrelevant, Irigaray recommends critiques of their their incoherence as part of a project of imaginative literary elaboration. She therefore argues that feminists should not forgo the close study of historical texts about the

sexes, particularly those of the history of philosophy, and her interpretations have focused on such figures as Plato, Aristotle, Plotinus, Hegel, Nietzsche, Heidegger, Sartre, Levinas, Marx, Lévi-Strauss, Freud, and Lacan.

Irigaray's methodology involves extensive citation, parody, and whimsical or ironic diagnoses of what a thinker does not "want" to say about women. Such diagnoses are often accompanied by writing experiments in which Irigaray attempts to describe women or write as a woman in ways that she claims would be deemed undesirable by the authors of the texts she is analyzing.

"Sexual difference," as an Irigarayan concept, does not refer to historical depictions of men and women counterposed in terms of such unsatisfactory hierarchies as reason/sensibility, wisdom/ignorance, culture/nature, and public/private. Instead, Irigarayan "sexual difference" refers to a hypothetical, alternative means of envisaging the sexes, according to which they would be considered neither like men nor their opposites or complements, but genuinely different. The concept is not generated through empirical description nor utopian imagination. Instead, it is primarily grounded in Irigaray's notion that such a prospect seems to have been "excluded" historically.

Irigaray has argued, controversially, that equality often means "equal *to*" a default individual (for example, male or white or able-bodied). She has proposed the alternative notion of equivalent rights for men and women and has devised a short bill of "sexuate" rights (1993). Such initiatives embody her view that legal reform should include a concern with the quality of representation of sexual identity. She has also directed collective research on empirical differences in the speech habits of contemporary European men and women, and she has formulated linguistic reforms corresponding to a hypothetical culture that would affirm sexual difference.

IRRATIONALISM

Like other words in current philosophical use, such as *historicism* and *subjectivism, irrationalism* is an exceedingly imprecise term that is employed with a wide variety of meanings and implications. Consequently, any attempt to elucidate its sense within the confines of a clear-cut and tidy formula quickly runs into difficulties. It might be said, for instance, that to describe a writer as an irrationalist is to speak of him as denying the authority of reason. But how is the notion of "reason" itself to be understood, and in what respects is its authority supposed to be flouted? It would scarcely be sufficient to reply that denial of reason consists in illogicality or confusion of thought, or that it manifests itself in a tendency to arrive at unacceptable conclusions; for this would apply to the work of many thinkers to whom the label "irrationalist" is clearly inapplicable. In addition, the suggestion fails to identify the primary point of calling a writer an irrationalist. A man may be accused of irrationality if he is prone to make mistakes of a particular kind or to indulge in invalid reasoning; but it is only insofar as he maintains some specific doctrine concerning such things as the status and role of reason or the relevance of rational standards within various domains of experience or inquiry that he can be called an irrationalist. In other words, attention is focused not on an unwitting failure to conform to norms of generally recognized validity, but on the explicit repudiation, or putting into question, of such norms in the light of certain considerations or in relation to certain contexts.

ENLIGHTENMENT RATIONALISM

A more promising approach to the understanding of irrationalism is the historical. One might try to understand irrationalism by contrasting it with that "belief in reason," that faith in the application of mathematical and scientific procedures, which was so prominent in the thought and speculation of seventeenth-century and eighteenth-century Europe and which provided the inspiration for the Enlightenment. Such a proposal, however, runs the risk of invoking generalities as vague as they are misleading. Seventeenth-century and eighteenth-century theorists interpreted the ideal of rationality in widely differing ways, and they assumed it or sought to realize it at various levels of inquiry—metaphysical, epistemological, ethical, and political. René Descartes, John Locke, Thomas Hobbes, Gottfried Wilhelm Leibniz, Benedict de Spinoza, and David Hume shared the conviction that in their speculations concerning the nature of the world and our knowledge of it they were conforming

to a course acceptable to reason and were applying methods that reason prescribed. But they differed fundamentally concerning both what constituted rational procedure and what types of discovery such procedure was capable of achieving. Similar disagreements may also be discerned at the other levels of investigation mentioned.

NINETEENTH-CENTURY IRRATIONALISM

The diversity of opinion attributable to thinkers who all held a general belief in rationality puts in doubt the notion that irrationalism can be neatly and unambiguously identified by reference to its rejection of a single set of assumptions allegedly shared by philosophers associated with the Enlightenment. Nevertheless, the ideas of those thinkers most typically classified as irrationalists did develop to a large extent in reaction to the ambitious claims made on behalf of reason by Enlightenment theorists and their nineteenth-century successors, however widely such claims may have varied in actual content and formulation. That the world is in some sense a rational or harmonious whole, that the human mind is capable of comprehending it, and that there exist certain communicable and teachable methods by means of which its inner workings can be revealed; that this knowledge can be systematically utilized in a manner that will insure the continuous improvement of human society in the foreseeable future; that man is by nature a reasonable and progressive being whose potentialities can be realized through the removal of ignorance and the creation of institutions based upon principles of justice—it has been against views like these that irrationalist philosophies have, in different ways, characteristically protested. Vociferous insistence upon the limitations and weaknesses of reason followed an equally vociferous insistence upon its possibilities and powers.

ONTOLOGICAL IRRATIONALISM

The belief that reality, at least in its innermost nature, represents an intelligible, ordered system whose fundamental character is accessible to the human intellect, is an ancient one; in philosophy, it dates at least from Plato. During its long history it has admittedly been subjected to a number of widely differing interpretations, ranging from the animistic or religious to the mathematical or scientific. Yet the notion of some kind of comprehensible pattern or rational structure to which all that exists or happens can finally be shown to conform retained its hold. From this point of view the world we belong to is not an alien world; on the contrary, it is one in which, by virtue of our own rationality, we can feel at home.

PASCAL'S SKEPTICISM. There have, however, been thinkers to whom the consoling idea of an intelligible world has seemed less acceptable. Thus even in the seventeenth century, the heyday of Cartesian rationalism, Blaise Pascal was questioning the conception of reality as a logically coherent whole, transparent to human reason and in which everything, including man himself, can be seen to have its necessary place: "Too much clarity darkens," he wrote with reference to Descartes's famous "clear and distinct ideas." Forcibly impressed both by the contingent character of human existence in an unfathomable universe and by the inadequacies of human reason, Pascal had little use for rational theology with its pretended proofs of God; he eschewed all such forms of ratiocination in favor of an inward religious faith that transcended ordinary methods of argument and justification and that was beyond demonstration.

THE WORLD AS WILL. The intense dissatisfaction and disquiet Pascal experienced when he contemplated the world and our situation within it has been echoed in the works of many subsequent writers, although they have not always shared the religious convictions that ultimately sustained him. For some it has appeared necessary simply to acquiesce in the realization that reality, far from representing an intellectually satisfying or morally acceptable system, is in truth devoid of all rational meaning or purpose and that salvation can only be reached through a complete liberation from its trammels. Such an attitude found perhaps its most eloquent and forceful exponent in Arthur Schopenhauer. In Schopenhauer's conception of existence there was an explicit and uncompromising reversal of the traditional approach. He made it his object to show, not that the world is governed according to some beneficent teleological principle or that it is the embodiment of certain fundamental rational categories, but that, on the contrary, what lies at its center is something antithetical to all reason and value, namely, a blind unconscious force or striving he termed "will." It is this that constitutes the metaphysical essence of the world, and not (as G. W. F. Hegel and his followers had taught) Absolute Spirit or Mind manifesting itself according to the inner laws of its own rational development. For Schopenhauer, in fact, all forms of rationalism—metaphysical and scientific alike—involve an illicit projection into the ultimate nature of reality of principles whose actual source and spring is the human intellect alone.

THE DOCTRINE OF ABSURDITY. Schopenhauer's theory rested, in the last analysis, upon a professed knowledge of what "really" lies beneath the phenomenal (and finally illusory) surface of things. Yet there have also been thinkers whose skepticism, although quite as profound as Schopenhauer's, did not derive from claims of this kind but instead took as its point of departure the concrete facts of ordinary experience. Such is the doctrine of *absurdité* in the work of twentieth-century French existentialists like Jean-Paul Sartre and Albert Camus. In some respects Sartre remained firmly within the Cartesian tradition, founding his epistemology upon the conception of man as a thinking consciousness confronted by an external world of unthinking substance. But the world that we are aware of is not, for Sartre, an intrinsically intelligible world whose nature conforms to a determinate logical order and whose existence is guaranteed by a benevolent deity. Sartre's view of material existence is perhaps most succinctly expressed in his first novel, *La nausée*, a book that contains in embryo many of the cardinal themes that later figure in his impressive philosophical treatise *L'être et le néant*. The hero of *La nausée*, Roquentin, is described as experiencing in a peculiarly vivid and horrifying way the brute "contingency" of things, their palpable failure to measure up to the standards of logical rigor and necessity, of clarity and distinctness, that reason of its nature seeks to impose upon or find realized within the world. Roquentin is impressed by the loose and arbitrary character of our modes of classifying objects and by the manner in which existence, in all its rich and pointless superfluity, seems inevitably to elude the network of interpretative concepts and schemes that we try to throw over it. When so perceived, the world can strike us as divested of all significance or value. "The world of explanations and reasons," Roquentin remarks, "is not the world of existence."

The impossibility of trying to reduce experienced reality to a system, whether Cartesian, Hegelian, or some other, had already been accepted by Søren Kierkegaard, who is often regarded as the originator of modern existentialism. But in Sartre's work one is conscious of a more positive and explicit insistence upon the opacity and ultimate unintelligibility of the world and its resistance to the abstract categories of thought. For Kierkegaard there was something eccentric, some element of radical misunderstanding, in the entire project of attempting to explain or justify existence as a whole in rational terms. By contrast, both Sartre in his philosophical works and Camus in *Le mythe de Sisyphe* are plainly sympathetic to those who demand intellectually or morally satisfying systematic accounts of existence; it is felt to be in some sense an imperfection of our condition as human beings in the world that such demands are necessarily incapable of being satisfied. The essence of what they call *absurdité* lies precisely in the contrast between the contingent amorphous character of reality, on the one hand, and the understandable requirements of reason that reality so patently fails to meet, on the other.

EPISTEMOLOGICAL IRRATIONALISM

Irrationalism sometimes finds expression, not in the claim that reality itself is devoid of ultimate senses or purpose, but in the distinguishable idea that the customary or scientific methods by means of which we are accustomed to explore its nature and to which we accord the honorific title of "rational," are inherently defective or suspect. There are clearly close connections between this view and the conceptions of ontological irrationalism. For if the world really is irrational in the ways it is sometimes declared to be, this presumably implies that, at some level at least, it is not amenable to those modes of investigation typically regarded as rational. But some philosophers, while agreeing that such methods are incapable of leading us to any finally acceptable and satisfying explanation of the nature of things, have not supposed themselves to be thereby committed to holding that all comprehension of the desired kind is in principle impossible. They have suggested, in other words, that alternative modes of apprehending and understanding the world, free from the limitations that beset standard procedures, remain open. The object of their strictures has been the distortions inherent in these procedures, rather than the world itself.

THE LIMITS OF RATIONAL INQUIRY. The belief that there exist determinate limits to what we can discover by the resources of ordinary sense and understanding received precise and systematic exposition in the works of Immanuel Kant. To prescribe limits to what rational inquiry can accomplish is not, as such, to impugn such inquiry, and much of the argument in the *Critique of Pure Reason* is, in fact, expressly concerned with establishing and explaining the validity of mathematical and scientific forms of reasoning within the empirical realm. But there were, nevertheless, two strands in Kant's philosophy that led to doctrines far removed in spirit from those Kant himself propounded. One of these was the claim that the fundamental principles in terms of which phenomenal reality is intelligible derive from the human mind and understanding; the other was the claim that there is a "noumenal" realm of things-in-themselves that is necessarily inaccessible to rational investigation.

SUBJECTIVITY OF CRITERIA OF RATIONAL INQUIRY. Kant's description of the means by which phenomenal reality is intelligible gave rise to the suggestion that the criteria of rational judgment and inference we normally accept are not the stable, objectively grounded things we take them to be but are, on the contrary, essentially subjective and even susceptible to change and variation. Thus Johann Gottlieb Fichte, at any rate in his earlier writings, often gave the impression of having thought that the basic principles in terms of which human beings interpret their experience ultimately fall within the sphere of individual choice or commitment; as prerational posits they cannot be themselves subject to rational assessment and must, instead, be evaluated by reference to the needs and demands of human beings conceived as volitional agents in the world. Fichte ended by taking refuge in the notion of an Absolute Spirit or rational ego that transcended all particular human selves.

Other nineteenth-century thinkers, however, reinterpreted Fichte's initial postulates in a fashion that implied a definite skepticism regarding the claims of rationality. This was true above all of Friedrich Nietzsche, who—at least in certain aspects of his complex and not always consistent thinking—exhibited a profound suspicion of accredited concepts and procedures. Possibly more sensitive than any previous philosopher to the emotional drives and attitudes that operate beneath the surface of human life and unconsciously influence thought and behavior, he was at times prepared to speak as if the entire manner in which we approach the world were founded upon pervasive myths and fictions. The "lies and frauds" that permeate our cherished forms of scientific investigation and description are not devoid of all value; on the contrary, from a "life-furthering, life-preserving, species-preserving" point of view they are actually indispensable. But insofar as we take them to embody or reveal the truth, we are the victims of deception.

NONRATIONAL COGNITION. Although his own confident affirmations concerning the limitations of common sense and science might seem to have required it, Nietzsche did not, in fact, postulate a superior form of cognition capable of circumventing the delusive schemes of ordinary thought and experience and of arriving at some clear, unsullied understanding of the world as it is in itself: in the last analysis there could be no escape from particular interpretations and perspectives. But to other thinkers this has not seemed so evident. Friedrich von Schelling, the contemporary of Fichte and Hegel, evolved an elaborate system in which intuition of a mystical or quasi-religious character was accorded a central place and

was held to provide access to the ultimate nature of reality. "The nature of the Absolute *itself*," Schelling wrote, "which as ideal is also immediately real, cannot be known through explanations, but only through intuition" (*Philosophie und Religion*, p. 15). Later Henri Bergson also drew a sharp distinction between the intellect, regarded as having a basically practical function and as rationalizing experience through the construction of mechanistic models and hypotheses, and intuition, whereby an inner sympathetic consciousness of the creative flow that underlies and pervades the universe was attainable.

The division between rational and nonrational or suprarational modes of apprehending the world, which these and other writers have stressed, often merges into further, related contrasts; for example, between conventional perception and artistic perception, between scientific and historical understanding, or between technical know-how, which is communicable in words, and a sense of, or feel for, the inward direction and meaning of things, which is not. Rationalists have tended to point out in return that such contentions are open to serious objections. Emphasis is laid upon the "privacy" of the alleged "insight" or "intuition"; but how can such insight aspire to the status of knowledge if no public criteria are available whereby its findings may be tested or confirmed? Again, in what sense can one speak of knowledge or understanding if—as often seems to be assumed—the intuition is of a kind that precludes conceptualization? Nevertheless, whatever difficulties irrationalist epistemology may present, these have not prevented its adherents from claiming that there are modes of awareness of the deepest significance to which rationalistic theorists have remained perennially blind.

ETHICAL IRRATIONALISM

Questions have also been raised with regard to our claims to moral knowledge and certainty. For instance, a number of writers of an empiricist persuasion (including Rudolf Carnap, A. J. Ayer, and C. L. Stevenson) adopted views concerning the meaning and function of moral judgments that would seem to deny, or at least put in doubt, the possibility of treating these as the proper subjects of rational argument. Yet such writers would certainly reject the suggestion that they are irrationalists in any of the senses so far distinguished. If they owe a historical debt, it is to David Hume (himself a skeptic concerning the rationality of morals) rather than to Continental sources, and they would in any case claim that their theories are grounded upon purely logical considerations related to the analysis of moral concepts and terms rather than

upon alleged discoveries about the nature of the world or the status of human beings within it. Nor would they be likely to admit that what they say entails any dramatic consequences so far as the realm of practical choice and action is concerned; on the contrary, they have tended to contend that their theories, being of a wholly conceptual character, are neutral between particular moral standpoints and outlooks.

ABSENCE OF A MORAL ORDER IN THE WORLD. Not every challenge to the rationality of morals has, however, been characterized by a comparable detachment. One of the strongest motives in recent times for belief that moral convictions are without basis or justification has been precisely the decay of all-encompassing theological and philosophical interpretations of reality; for these were thought of as providing the moral consciousness with the kind of backing it logically required. Along with the religious beliefs to which it was sometimes allied, the conception of a moral order at the heart of existence, either revealing itself directly to the eye of reason or manifesting itself empirically in the course of human life and history, was already in decline during the nineteenth century. Schopenhauer's theory of all-pervasive metaphysical will was directly expressive of this development, but it was Nietzsche, not Schopenhauer, who drew the radical consequences. According to Nietzsche, it was necessary to recognize, once and for all, that there is no moral order, no system of ready-made values, objectively subsisting "out there" in the world—"there are no moral phenomena, only moralistic interpretations of phenomena," he wrote in *Beyond Good and Evil*. The notion of moral facts is a philosopher's delusion. With such ideas in mind Nietzsche, in effect, did two things. First, he embarked upon a devastating analysis intended to show how traditional moral codes, far from resulting from the operations of contemplative reason, derive instead from deep-lying nonrational forces in the human psyche, from motives like resentment and sadism and fear. Second, he urged that it is now possible for us—since, in his famous phrase, "God is dead"—to create new values, more fitted to preserving the dignity of humanity and to realizing those human energies and capacities that still await their true fulfillment.

ALTERNATIVE THEORIES. The claim that it is now possible to determine new values along these lines drew attention to a difficulty that has beset theorists who have denied the possibility of appealing to rational canons within the moral sphere. Nietzsche was a moralist who wished to insist that certain forms of character and behavior were evidently superior to others; at the same time, he was committed to the opinion that, objectively considered, there was nothing to justify preference for one way of life, one system of values, rather than another—*nichts ist wahr, alles ist erlaubt* ("nothing is true, everything permitted"). If traditional Christian morality is without foundation in fact or reason, then so, likewise, is any alternative ethics with which we may seek to replace it.

Similar tensions and ambiguities underlie other varieties of individualist or existentialist teaching, from Max Stirner and Kierkegaard on. Sometimes it seems to be maintained that sheer intensity and sincerity of commitment is all that ultimately counts from a moral point of view. What is chosen is not a matter for argument, since in the last resort there is no yardstick, no privileged set of criteria, against which rival possibilities may be assessed and evaluated. The vital thing is for a man to assert his essential freedom by refusing to conform his will to forces and agencies external to himself, including the falsely substantialized standards of conventional religion and ethics.

Sometimes, on the other hand, an attempt is made to give the notion of an acceptable mode of living more positive content, the implication being that certain forms of behavior are more appropriate to our situation in the world than others. For beings who find themselves in an alien and meaningless world, which is bereft of purpose or value, there may be virtue, or at any rate fittingness, in conduct that reflects the inescapable absurdity of their condition. Suggestions as to how conduct might be said to do so have for the most part been as vague as they have been various. Living in the present or for the moment, giving spontaneous vent to instincts or passions (as opposed to trying to heed the reasonable dictates of conscience or prudence), indulging in anarchical or incongruous behavior for its own sake, undertaking certain types of useless artistic activity—these are among the proposals that may be extracted from works purporting to show what is meant. Such works often seem to be inspired by a curious form of inverted rationalism; the rational response to an irrational world is to act irrationally. Yet it would be incorrect to imply that this is the only consideration that has been used to justify such behavior. Instead, the recommendation appears to be held by some proponents to follow from a realization of what constitutes our true innermost nature as human beings; and this claim introduces a further dimension of irrationalist thought.

PSYCHOLOGICAL AND SOCIAL IRRATIONALISM

The claim that it is not the human situation that is intrinsically absurd, but that human nature itself is in some fundamental sense irrational, is not confined to philosophers of a metaphysical or speculative persuasion; its adherents also include psychologists, political scientists, social theorists, historians, literary artists, and even statesmen. In this area, above all others, a pervasive departure from certain dominant Enlightenment conceptions may be discerned, involving a shift of outlook that has led to drastic changes in the approach adopted by many writers to problems concerning man and society.

It is difficult neatly to summarize the complex and sometimes conflicting ideas involved here. One underlying theme, however, has been that the *idéologues* of the eighteenth century, together with the utilitarians and progressive radicals who followed them in the nineteenth century, grossly exaggerated the extent to which human behavior is motivated, or is capable of being modified, by rational consideration. It has further been suggested that such overvaluation of reason or intellect caused liberal and democratic thinkers to adopt absurdly optimistic, unrealistic, and naive views concerning the capacity of men to improve themselves and the conditions under which they live.

INDIVIDUAL PSYCHOLOGY. At the level of individual psychology it is held to be false that people usually or consistently are activated by calculations regarding their best interests or that they can confidently be expected to respond to considerations of abstract moral principle or general advantage once these are clearly apprehended and understood. Such doctrines are the fictions of philosophical theory and ignore three essential points. First, vast areas of human behavior are, in fact, governed by overriding antisocial passions like pride and cruelty. The indulgence of these is in general detrimental to the agent's long-term advantage, frequently causing as much harm to him as to those against whom his actions may be directed. Second, it is a mistake to write off as mere eradicable superstition the various myths, religious and otherwise, in terms of which men are prone to conduct their lives. These are often attuned to powerful nonrational forces in the psyche that demand expression and that, if frustrated, are likely to seek outlet in other, possibly more dangerous forms. Third, it is important to appreciate how often people are totally unaware of the true motives and drives that determine their actions; human beings are adept at rationalization and self-deception, and their conduct may appear to be guided by reason when, in reality, it is directed by quite different factors. Intimations of these notions occurred in the writings of the Marquis de Sade and Joseph de Maistre at the close of the eighteenth century; and they were subsequently given forceful expression in the works of romantic and postromantic thinkers like Schopenhauer and Nietzsche. More recently, they have been regarded as receiving impressive and detailed corroboration from the advances in psychoanalysis initiated by Sigmund Freud and C. G. Jung.

POLITICAL AND SOCIAL THOUGHT. In the sphere of political and social theory, insistence upon the irrationality of human nature has tended to be combined with traditionalist, authoritarian, or reactionary conceptions of government. To some, it has seemed obvious that the only enduring way of preserving the integrity of society against the disruptive forces of violence and passion lurking beneath the thin surface of civilized life consists in the use of coercion and suppression. De Maistre, for instance, considered the executioner to be the most significant figure in the state. Stress is laid on the importance of instilling habits of obedience to authority by appeals to supernatural or providential powers and by safeguarding the atmosphere of reverence and awe that surrounds the person of the ruler in established societies—a principal objection to proposals for the reorganization of social life according to egalitarian or consciously utilitarian general principles has been the belief that they can only lead to a loosening of the mysterious ties that hold a political community together. Likewise, attempts to displace unreasoned acceptance of the existing order of things by the propagation of scientifically inspired ideas and policies strike at the root of all that makes for social cohesion.

Edmund Burke was, for these reasons, deeply distrustful of revolutionary theories and plans. He thought that the true sources of political harmony lay below the level of rational reflection and showed considerable prescience concerning the consequences likely to ensue if the checks upon men's passions provided by traditional arrangements were challenged or removed. He did not, however, share the curiously ambivalent attitude toward violent or sadistic human propensities discernible in certain later social thinkers, who saw these as something to be systematically exploited rather than inhibited and for whom the ideas of force and brutality seem to have possessed a powerful emotional appeal. In the case of Vilfredo Pareto, for instance, the approach adopted toward the role of the irrational in human life was not as detached or objective as he tried to present it. Such writers did not merely dismiss humanitarian schemes for

social amelioration and improvement as ultimately unrealistic, impracticable, or utopian; it was also strongly suggested in their works that if these schemes were to be realized, this would constitute an intrinsically undesirable state of affairs. It is for pressing the second claim, as well as the first, that fascism is often described as an irrationalist ideology.

Major currents of thought do not originate in a vacuum, and the various components of modern irrationalism have many diverse sources. Among them are the void left by the decay of institutionalized religion, the recurrent failure of large-scale reformist movements (like the French and Russian revolutions) to fulfill the hopes that originally inspired them, and the inability of contemporary industrial society to provide scope for individual self-expression. But it would be a mistake to regard irrationalist trends as purely pathological symptoms or to suppose that they have contributed nothing of value to the development of thought. It is common for Anglo-Saxon critics to denounce some irrationalist claims as having played a pernicious role in the formation of extremist political ideologies and to dismiss others as representing no more than inflated or misleading formulations of familiar logical doctrines—for instance, it has been suggested that the existentialist conception of the world as irrational is (partly at least) a bombastic restatement of the Humean insight that there exist no necessary connections between matters of fact. Up to a point such objections may be justified. However, it is worth remembering that there are important areas of human consciousness and behavior that theorists of a rationalistic temper have been characteristically prone to overlook and that it has been largely left to theorists of a different outlook to explore and define these areas. To say that the task has sometimes been perversely performed is not to say that it should not have been undertaken at all.

ISAAC OF STELLA
(c. 1100–c. 1169)

Isaac of Stella, one of the great monastic thinkers of the Middle Ages, was born in England about 1100. He apparently studied in both England and France before entering the monastery of Citeaux. After several years at Stella (L'Étoile) in Poitou, where he became abbot, Isaac attempted to found a monastery on the lonely island of Ré, near La Rochelle, but soon returned to Stella, where he died about 1169. His writings include a treatise on human nature (*De Anima*), an exposition of the liturgy (*De Officio Missae*), and fifty-four sermons, preached either at Ré or at Stella. Through the *De Spiritu et Anima* of Alcher of Clairvaux his psychological theories became widely influential, notably in the Franciscan school of the thirteenth century.

Isaac's mind, schooled in the biblical spirituality of the Cistercians, was steeped in Scripture, and his writings are full of biblical allusions. In contrast to many of his contemporaries, however, he was careful and systematic in his use of Scripture. Moreover, although most monastic interpreters were content with the moral lessons derivable from the biblical text, Isaac was deeply interested in its doctrinal content. Thus, his biblical exegesis reflects his metaphysical concerns.

As a philosophical theologian, Isaac stood in the tradition of Christian Neoplatonism at the point where it first felt the impact of the Aristotelian renaissance. Both the Greek Fathers and Augustine were extensively studied by the Cistercians, but Isaac's grasp of their teaching was exceptional. Indeed, apart from Erigena no earlier medieval thinker could equal his knowledge of Eastern and Western Neoplatonism. On the one hand, as both his doctrinal tendencies and his extensive use of a Dionysian vocabulary, including at least a dozen Greek terms, indicate, he was well acquainted with the works of the pseudo-Dionysius. On the other hand, he was thoroughly familiar with the philosophical, theological, and mystical thought of Augustine.

Isaac's ambition to reconcile Neoplatonism and Aristotelianism is apparent in his account of human knowledge, which combines the Augustinian doctrine of illumination with the theory of abstraction. In his synthesis reason forms universal concepts by abstraction from sense experience of corporeal objects. Intelligence, however, must be aided by divine illumination in its effort to apprehend incorporeal beings.

The influence of the pseudo-Dionysius can be seen in Isaac's insistence on the negative approach (*via nega-*

tiva) to the knowledge of God. It appears also in his emphasis on the hierarchical structure of reality, in his exemplarist doctrine of creaturely participation in the divine perfections, and in his strong interest in liturgical symbolism.

The influence of Augustine's theology is most conspicuous in Isaac's discussion of predestination. With frequent echoes of Augustine's own style, he fully develops the theme of God's initiative in the process of human salvation. Augustinian influences are obvious also in Isaac's teaching on many points, including the Trinity, the virtue of charity, and the church as Christ's mystical body.

ISLAMIC PHILOSOPHY

In Islam the development of philosophical thought, properly speaking, succeeded earlier schools of dialectical theology (*kalām*) that began to arise in the eighth century (second century AH in the Islamic calendar) through the action of foreign ideas—particularly Greco-Christian—on certain fundamental moral issues raised within the Islamic community. These moral issues clustered particularly around the problems of the freedom of the human will, God's omnipotence and justice, and God's relationship to the world. Although these early schools do not properly belong within the scope of this article, since they are theological rather than philosophical, a very brief characterization of the main groups and their tenets will serve to elucidate the content of the philosophical movement itself. Broadly speaking, there were two theological schools. The so-called rationalist, or Muʿtazila, school maintained the freedom of the will; insisted that right and wrong are knowable through reason independently of, but confirmed by, revelation; and claimed that God's attributes are identical with his essence and that God cannot do what is unreasonable or unjust. However, the Muʿtazilites posed and solved all these problems theologically, not philosophically; their entire thought was theo-

centric. For example, they did not pose the problem of the will absolutely but discussed it mainly insofar as it is relevant to the concept of a just God. However, their opponents (the Ahl al-Sunnah wa'l-Jamāʿah), who came to constitute the orthodoxy, accused them of stark humanism and opposed them on all these major questions. The orthodoxy, after a long, hard struggle, completely routed the Muʿtazilites as a theological school, but the spark of the Muʿtazilites kindled the purely rationalist movement in philosophic thought.

The work of the original philosophers in Islam was preceded by feverish translation that began around 800 and lasted for about two hundred years; its climax was reached in the time of Caliph al-Maʾmūn al-Rashid (reigned 813–833). Al-Maʾmūn set up the first official seat of liberal learning in Islam, called the House of Wisdom, whose main function was to translate the works of the Greek masters of science and philosophy. The translations, however, were mostly from Syriac versions and not directly from the Greek. These translations, which were made almost invariably by Arab Christians, covered the entire range of Greek civilization—that is, its thought content—but excluded such specifically cultural aspects as mythology, drama, and literature, which were foreign to the Arabs and to Islam. The Arabs were able to develop a highly technical philosophical diction with astonishing rapidity and to integrate it into the Arabic language so successfully that a philosopher like al-Fārābī (c. 873–950), who was a Turk and not an Arab, was able to express himself philosophically in Arabic with remarkable facility. All this happened within a span of about 150 years in a language that had previously known no technical philosophical literature whatsoever.

The main character of Islamic philosophy was set by the combination of Aristotle and Neoplatonism that had constituted an important tradition in the late stages of Hellenistic philosophy and that was represented particularly by the Neoplatonic commentators on Aristotle in Athens and Alexandria, such as Simplicius and John Philoponus (sixth century). The Muslim philosophers introduced into this tradition other fundamental concepts in order to adapt it to an Islamic milieu; the most important were the ideas of contingent and necessary being and of prophethood. Despite these fundamental changes, the Muslim philosophers accepted the general cosmological scheme they had inherited from the Greek traditions. Thus, an important place in their cosmology and metaphysics is occupied by the role of the stars and the heavenly bodies, a role that has no place in the scheme of reality of the Qur'an. This must be attributed to the

Greek beliefs about the status of stars and the heavenly bodies and their creative influence on the sublunary sphere, although such a picture of the universe was also quite in harmony with other traditions existing in the Middle East, for instance, Sabaeans and Babylonians.

AL-KINDĪ

The first important Muslim philosopher was the Arab prince Abū-Yūsuf Yaʿqūb ibn Isḥāq al-Kindī (d. after 870). Al-Kindī's philosophic thought is directly connected with, on the one hand, Greek philosophical doctrines transmitted to him through translations and, on the other, with the rationalist theological movement of the Muʿtazilites. He seems to have espoused the Muʿtazilite doctrines in toto and to have sought to create a philosophical substructure for them. Thus, the Muʿtazilite dogma of the attributeless transcendence of God must have led him to the somewhat parallel idea of God as absolute and transcendent being, a combination of the Aristotelian concept of God and the Neoplatonic concept of the One. It is this affinity that must have led him further to formulate the doctrine, common to all the great Muslim philosophers, that philosophy and religion, or the rational truth and the revealed truth, not only do not conflict with each other but, in fact, lend support to each other and are basically identical. This recalls the Muʿtazilite doctrine that the source of our knowledge of values is reason confirmed by revelation.

In his philosophy, al-Kindī was more of a Neoplatonist than an Aristotelian. (The Arabs attributed certain Neoplatonic works, such as *De Causis* and *Theologia Aristotelis,* to Aristotle.) He adopted the Neoplatonic doctrine of emanation in his metaphysics and cosmology. Also, in his theory of intellectual knowledge he adopted the doctrine of the active intellect and the passive intellect, originally formulated by Aristotle, later elaborated by the commentator Alexander of Aphrodisias, and subsequently reworked and essentially modified by Neoplatonists. Al-Kindī introduced into the Greek framework of ideas some fundamental doctrines of Islam. Thus, although he accepted the theory of emanation, he asserted that the first being was created by the sheer act of God's will and out of nothing, an antithesis to the general Greek doctrine that nothing comes out of nothing. Aristotle had postulated two ultimates—one was God, the form of forms; the other, the prime matter—each of which had "existed" independently of the other. Similarly, although the Neoplatonic doctrine of emanation differs vitally from Aristotle's theory of the cosmic movement, it still seeks to avoid having to accept creation ex nihilo by

postulating the emanatory process. However, it is difficult to see how, in the last analysis, the emanation theory can overcome the difficulties of creation ex nihilo. Al-Kindī, however, simply asserted emanationism and creationism side by side without reconciling the contradiction between the two. It was Avicenna (Ibn Sīnā) who later attempted the reconciliation, but it was important to the development of Islamic philosophy that al-Kindī, far from giving up the Islamic requirements of the relationship of God and the world, juxtaposed both the Islamic and the Greek doctrines. In his theory of intellection, al-Kindī was attracted by the ideal of a form of knowledge that would do justice to the demands of reason and revelation, although in his extant works we do not find an elaborated theory of prophethood. This, again, was taken up later by al-Farabi and Avicenna, but it was al-Kindī who initiated development of the theory of intellection in Islamic philosophy.

AL-FĀRĀBĪ

With al-Fārābī, philosophy reached maturity in Islam. Not many of his works have come down to us, but his writings that we do possess reveal an unusually incisive and clear mind. In his cosmology, as well as in his psychology, al-Fārābī was almost entirely Aristotelian, except for the doctrine of emanation. In political theory, which seems to have preoccupied him considerably more than it did other Muslim philosophers, he based himself on Plato's *Republic* and *Laws,* but he adapted the Platonic system to his contemporary political situation with a remarkable ingenuity. He developed the doctrine of the intellect from the point at which al-Kindī had left off, and he constructed a theory of divine inspiration that was to serve as a model for Avicenna. But apart from his original theories, the importance of al-Fārābī lies in his attempt to elevate philosophy to the place of highest value and to subordinate the revelation and the *sharīʿa,* or religious law, to it. In this also he served as a model for both Avicenna and Averroes (Ibn Rushd), but it was precisely this doctrine, in which the *sharīʿa* took an inferior place as a symbolic expression of a higher intellectual truth, that was also ultimately responsible for the fatal attacks on the philosophical movement by representatives of the orthodoxy.

In his religious attitudes, al-Fārābī was a genuinely universalistic spirit who believed that the entire world should have one religion, of which all particular religions would be considered symbolic expressions. However, it would be a mistake to regard al-Fārābī as a relativist. He tells us in no uncertain terms that not all religions are

equal either as adequate symbols of truth or as the effective harnessing of men's minds and hearts. Indeed, he believed that there are religious symbolisms that are positively harmful and must be discarded. He did affirm, however, that there are religions which are equivalent in their religious value; and any one of these symbolic systems may be applied in a given milieu, depending upon circumstances. Although al-Fārābī gave no concrete examples of religions or names of prophets, there is little doubt that the prophet Muḥammad was fixed in his mind as a paradigm par excellence of a prophet and a lawgiver. This becomes clear in his insistence that the teachings of a prophet should not only be universal but should also be successful in history.

Al-Fārābī's writings give us a full-scale picture of the basic world view of Muslim philosophy. At the apex of his scheme of reality stands God, who is both the One of Plotinus and the First Cause of Aristotle. From him proceeds the first intelligence, which is also the archangel. The first intelligence has a dual nature and gives rise to two further beings: the highest sphere on the physical side and the second intelligence on the spiritual side. This process of emanation continues until we reach the tenth sphere and the last intelligence, identified as the angel of revelation, Gabriel, on the one hand, and as the sphere of the moon on the other. The entire process of the world below the moon is an interaction between the materials emanating from the sphere of the moon and the spiritual influence generated by the tenth intelligence, called the Active Intellect. This interaction generates the world process, and its culminating product is man, with his fully organized body and rational soul.

The goal of man, wherein lies his ultimate bliss, is to develop his rational faculty by his will. The rational faculty is developed by the action of the active intelligence upon it, through which actual thought arises. The end of man, therefore, is to reach philosophic contemplation, and al-Fārābī categorically states that men whose rational faculty remains undeveloped cannot attain immortality but perish with their physical death. The actual activation of man's rational power, however, demands certain practical virtues as well, and this makes it necessary for man to live in organized societies rather than in isolation. People who are ultimately responsible for organizing and directing human societies are those possessed of philosophical wisdom, for it is not possible to enunciate practical laws for humankind without having theoretical wisdom. Therefore, for al-Fārābī the philosopher and the prophet are identical. It is the philosopher-prophet who can formulate the practical principles and laws that will lead men to their final goal of philosophic bliss. Societies governed by such laws are "good societies"; others are "ignorant societies," "misguided societies," or "retarded societies."

At the final stage of the intellective development, the philosophical mind becomes like matter to the Active Intellect, which becomes its form. This is the absolute apogee of human bliss. The prophet is a person who, having attained this philosophical illumination, transforms the philosophic truth into an imaginative myth that moves people to action and can influence societies toward greater morality. It is because of his imaginative power, the power to represent the intellectual truth in the form of a figure or a symbol, that the prophet is able to make laws and to bring revelation. Revelation, therefore, is not philosophic truth but imaginative truth. Only a few gifted philosophical spirits can pierce the imaginative shell and reach the philosophic truth. In al-Fārābī 's theory of prophethood, there seems to be no place for miracles; the accommodation of miracles on a philosophical basis was the work of Avicenna.

Al-Fārābī likened the ruler to the head in the human organism and, like Plato, developed the idea of a hierarchy in which each stratum receives orders from above and issues commands to those below. Just as at the top there is a ruler who is not ruled, so at the bottom there are those who are ruled but do not rule. It is a fully authoritarian view of government, and some scholars have suggested that al-Fārābī was influenced by Shiʿite doctrine. The fact that al-Fārābī was at the court of the Shiʿite ruler is supposed to lend some support to this view. We do not have sufficient historical evidence for such a judgment, but it should be noted that the ultimate ruler of the Farabian state does resemble the Shiʿite Imam, the repository of divine wisdom.

BRETHREN OF PURITY

During the tenth century, a secret coterie of popular philosophers known as the Brethren of Purity (*Ikhwan al-Safa*) was formed, and they wrote a series of "epistles," or treatises, titled Rasāʾil Ikhwān as Safāʾ, to propagate their views. The epistles exhibit a thoroughly Neoplatonic character. They seek to formulate a worldview culminating in a universalistic religion transcending all organized religions, which, at best, serve as so many different ladders to the ultimate truth. The philosophy preached by the Brethren of Purity is also esoteric, and there are strong reasons to believe that this group was either formed by members of or was connected with the Ismāʿīli movement, a religious sect; it is very likely that it was

through such channels that Ismāʿīlism absorbed those Greek philosophic elements which were rejected by the Muslim orthodoxy but were akin to certain patent Oriental theories and to attitudes about religion and the nature of the ultimate truth. The view of the Brethren of Purity does not constitute philosophy in the strict sense but is a kind of vague and romantic idealism; nevertheless, it is important to note it because its ideas have also influenced the development of another powerful spiritual movement in Islam, Sufism.

AVICENNA

The most important and original of Muslim philosophers was Abū ʿAlī ibn Sīnā, known to the West as Avicenna (980–1037). The philosophic movement in eastern Islam comes to its fullest fruition in the thought of Avicenna, who elaborated one of the most cohesive, subtle, and all-embracing systems of medieval history. In the West his ideas had a profound influence on medieval scholastic philosophy, and in the Muslim world his system is still taught in the traditional centers of Islamic learning. The central thesis of Avicenna's metaphysics is the division of reality into contingent being and Necessary Being. In order to formulate this doctrine, whose influence has been so palpable and enduring in both Eastern and Western thought, Avicenna devised his theory of the distinction between essence and existence. In this theory, he refined the implications of the Islamic doctrine of creation, which al-Kindī had crudely asserted, into an integrated philosophic system.

The bases of this theory of essence and existence are set in Aristotle's doctrine of movement and in the Neoplatonic doctrine of emanation, but in order to achieve the desired results, Avicenna had to effect basic changes both in the doctrine of emanation and in the Aristotelian doctrine of matter and form. Briefly, Aristotle had taught that matter is the principle of potentiality and form the principle of actuality, and that through the interaction of the two the actual movement of the universe takes place, in which potentialities are progressively actualized. Thus, the analysis of any given thing—with the exception of God and prime matter—falls into matter and form. There are, however, grave objections to this view. How can an actual thing come into existence through the interaction of a matter that, according to Aristotle, does not exist and a form that also does not exist? Why should things not remain unactualized in their potentialities, and where is the necessity of movement? Emanation seems to simplify this problem by asserting a single, universal process of outward movement, but it gives no rationale of this movement.

Closer examination led Avicenna to posit three factors—matter, form, and existence—and to postulate a Necessary Being as the basis for the world process. There is little doubt, however, that it was not merely these philosophic reasons that led him to formulate this doctrine but also the fact that Islam demanded a fundamental distinction between God and the world. Since Avicenna could not accept the creationism of the Muslim theologians because it implied temporal priority of God over the world, he affirmed that God is distinguished from the world by the fact that his being is necessary and simple; God cannot be composed of matter and form but must be pure existence. From God emanate the intelligences, which, although they have no matter, are nevertheless composites of essence and existence; the material beings are composed of matter and form, which constitute their essence, and the fact of their existence—all existence flowing from God.

Avicenna was thus able to solve, to his own satisfaction, the contradiction that seemed to exist between the Greek philosophic world view and the Islamic doctrine of creationism: in accord with the philosophers he affirmed the eternity of the world and rejected temporal creation, but with the Islamists he made the world entirely and eternally dependent upon God. This solution led him to establish the relationship between religion and philosophy. Since the findings of religion and of philosophy do not contradict one another on this crucial point but are not identical either, they run parallel to one another. From this, Avicenna expounded his further view that religion is a kind of philosophy for the masses: It does not tell the naked philosophical truth but is an endeavor to make the masses come as near to the philosophical truth as possible. The prophets are, then, mass psychologists who launch religious movements as pragmatic endeavors to make people virtuous. Thus, Avicenna reaffirms al-Farabi's position that revelation is not philosophic truth but symbolic truth.

The possibility of prophethood in Avicenna's system is intimately connected with his theory of knowledge, particularly with his theory of the creative knowledge and of the "internal sense," which appears to be his own contribution to the history of thought. According to Avicenna, all genuine intellectual discovery implies an intuitive act of knowledge, and our ratiocination merely prepares for us this intuitive act. However, there can be—and there are—people who possess a tremendous native intuitive power even without any ratiocination and

process of learning. The ultimate limit of such a gifted mind is the prophetic mind, which does not receive knowledge through learning but creates knowledge. This constitutes the prophetic revelation at the intellectual level. But this intellectual power, in a genuine prophet, flows into the imagination or the "internal sense" as well, thus enabling the imaginative faculty to transform the intellectual truth into images and symbols capable of moving people's minds and bodies. It was on the basis of this power of imagination and suggestion that Avicenna explained the possibility of miracles attributed to prophets. He was thus able to accept even the miracle doctrine of the orthodoxy, although he rejected certain miracles as being "impossible."

AL-GHAZĀLĪ

Avicenna's system went furthest in integrating the traditional demands of the orthodox religion with the purely Greek rationalism, which explains why his works continue to be studied in the traditional Islamic schools even today. However, his system was made the object of denunciatory criticism by the orthodoxy on certain points: the eternity of the world, the inferior status of the *sharī‘a* (religious law) as a mere symbol of the higher truth, and the rejection of the resurrection of the body. The classical criticism was carried out by al-Ghazālī (1058–1111) in his famous work *Tahāfut al-Falāsifa* (Incoherence of the philosophers), which was also rendered into Latin in the thirteenth century under the title *Destructio Philosophorum.*

AVERROES

The unrelenting criticism of philosophy as it appeared in Avicenna's system by al-Ghazālī and others led Ibn Rushd, known in the West as Averroes (c. 1126–c. 1198), to defend the claims of philosophy. In the process of doing this, Averroes sought to resurrect the original Aristotelian doctrines from the later Neoplatonic and Muslim accretion as much as possible. He wrote many commentaries on the works of Aristotle, whom he believed to be the philosopher par excellence. He accused both Avicenna and al-Ghazālī of having mutilated philosophical theses and of having confused them with religious doctrines. Averroes, however, did not advocate a theory of two truths, although this may be a logical conclusion of what he said in his work titled *Faṣl al-Maqāl* (The decisive statement) on the relationship between philosophy and religion.

Averroes rejected Avicenna's distinction between essence and existence. He insisted that existence is, in a way, part of the essence of a thing. The one conspicuous doctrine on which Averroes does not appear to be a faithful follower of Aristotle is that concerning intellect. He declared the passive human intellect also to be eternal and incorruptible and, indeed, to be universal to all humankind, like the Active Intellect. This doctrine of the unity of intellect, besides being apparently unfaithful to Aristotle, was also unacceptable to the followers of the revealed religions. He was thus attacked both by Muslims and, in the West, by Thomas Aquinas, who wrote a special treatise, titled *De Unitate Intellectus,* against the Averroistic doctrine. It must, however, be pointed out that the common objection raised against Averroes' doctrine of the universality of the intellect ever since Thomas's classic formulation of it as *ego intellego* is very superficial. Averroes not only never held that the act of cognition is universal but was, in fact, at pains to prove its individual character. What he seems to be concerned to show is that all thinking, although it occurs individually, becomes in a real sense universal, and that this universal aspect is more intrinsic to human cognition than is the fact that it is the product of such-and-such an individual or individuals. In any case, it is certain that Averroes never denied the individuality of the act of cognition.

Although Averroes believed that religion and philosophy are in two different orbits, he nevertheless felt the necessity of reconciling the two and of so stating the philosophic doctrines as not to offend religion and of so conceiving the religious dogmas that they would not conflict with philosophy. We are, therefore, back at the position of Avicenna. On the question of the eternity of the world, Averroes taught the doctrine of eternal creation. Although he did not reject the religious dogmas of the resurrection of the body, as Avicenna had done, he taught that the numerically same body cannot be resurrected. There was, however, bitter opposition to the doctrines of Averroes, who was also the *qadī* (judge) of Seville, and today very few of his works survive in the original Arabic; they are to be found mostly in Hebrew and Latin translations.

ABU'L-BARAKĀT IBN MALKĀ

In the East we find another important attempt at the *rapprochement* of the content of religion and philosophy in the works of Abu'l-Barakāt ibn Malkā (also known as Abu'l-Barakāt al-Baghdādī, d. c. 1174/1175). A Jew converted to Islam, Abu'l-Barakāt's doctrines show a decisive trend toward Islamic orthodox beliefs. Thus, on the question of the attributes of God, he affirmed all the attributes of the Deity in the positive sense and not as pure nega-

tions, as his predecessors had done. His doctrine that the eternal essence of God can be the subject of changing accidents is palpable proof of his conscious orthodoxy. The doctrine is so obviously removed from the teaching of the early great Muslim philosophers and of Aristotle himself that, while it did not seem to have much appeal for the philosophic tradition in Islam, it evoked enthusiastic approval from such orthodox ʿUlamā' (the "learned") as Ibn Taymiya (thirteenth and fourteenth centuries). Similarly, Abu'l-Barakāt taught that the intellectual and the perceptual faculties are not different but are one and the same. He rejected the teachings of the Aristotelians that God does not know the particulars but only the universals, and he obviously did not accept Avicenna's formulation of the doctrine that God knows every particular but "in a universal way" rather than through perception. According to Abu'l-Barakāt, both sense perception and intellective perception belong to the soul and do not intrinsically involve the body. Then he concludes that God knows the particulars just as he knows the universals.

Although further progress of philosophy was cut off by the blows of the orthodoxy, philosophical developments, especially the system of Avicenna, had exerted a rejuvenating influence on orthodox theology (*kalâm*). After al-Ghazālī's refutation of philosophy, the scope of theology was expanded to include all the epistemological and metaphysical questions the philosophers had dealt with but to which theological answers were now provided. The first person to attempt this and who is, in fact, the forerunner of all Islamic theologians is Fakhr ad-Dīn ar-Rāzī (1149–1209). Logic was simply taken over by *kalam* as a necessary instrumental science. Thus, the official theology set itself up as "the crown of the religious sciences" and began to function as a sufficient substitute for philosophic thought. Rational thought was thus banished from the schools as being redundant; only Avicenna's works (and commentaries and compendia based upon them) were taught, but more in order to be refuted than to instigate independent thought.

Under the attacks of orthodoxy, philosophy went underground, as it were, and lived on in the form of now one theosophy, now another. Instead of continuing as a purely rational expression of the human mind, it emptied its contents into intellectual Sufism. Henceforth, we do not get pure philosophy in Islam but a mystical philosophy. After the activity of the pantheist Sufi theosoph Ibn al-Arabī (1165–1240), the new philosophic mysticism developed into a closely argued and elaborate system in the works of Ṣadr al-Dīn al Shīrazī, commonly known as Mullā Ṣadrā (1571/1572–1640). Mullā Ṣadrā represents a

conjunction of the Shiʿite doctrine, the philosophic tradition of Avicenna, the mystical intellectualism of Shihāb al-Dīn Yaḥyā Suhrawardī (executed at Aleppo in 1192), and of Ibn al-Arabī. He is a typical representative of the intellectual-spiritual tradition of late medieval Islam. A monist, Mullā Ṣadrā believed in a doctrine of mystic "return" to the First Principle of being. The reality as given is constituted by three levels of "worlds"—the spiritual, the imaginative, and the physical. The "imaginative" world (ʿālam al-mithāl) is the world of symbols or images that relates the spiritual and the physical realms to one another, and it is the realm essentially relevant to the genesis and interpretation of symbols given in religious experience. This doctrine exercised a very considerable influence on subsequent developments in Islamic thought until the dawn of modern times. The centrality of "the world of symbols," with its religious implications and with its escapism from the external world, is symptomatic of the refined spiritual and intellectual culture of Islam in the later Middle Ages until the impact of Western influence upon it.

The story of philosophic thought in Islam after Averroes still remains to be written. Modern Western students of Islamic philosophy generally stop short at Averroes because the Muslim philosophic movement exerted an influence on medieval Western philosophy until his time. It is a pity that Muslim philosophy has been studied not as an internal whole but essentially from the point of view of its impact upon and relationship to Western philosophy. However, even a thorough account of the influence of Islamic ideas on Western thought is still lacking.

ISLAMIC PHILOSOPHY [ADDENDUM]

MYSTICISM (SUFISM)

Mysticism is of enormous significance in Islamic philosophy. Few Islamic philosophers were not committed to some form or another of mysticism. Ibn Sabʿīn (1217–1270) led an important school of thought that argued that Aristotelian philosophy and logic were of no use in understanding the way things really are. Logical thought is analytical, a process of dividing a concept into its parts. This method fails to represent the basic unity and wholeness that exists in reality, a unity that reflects the unity of God and everything as part of God, and any system of thought that is accurate is one that is based on unity, not division. The most influential mystical thinker Ibn al-ʿArabī (1165–1240) established this line of thought and represented himself as burying the old Peripatetic form of thought when he transported the bones of Ibn Rushd (Averroes) back to al-Andalus from North Africa.

This antagonism to analytical philosophy is certainly not the only position adopted by those committed to mysticism, though. Many philosophers managed to combine mysticism with peripatetic philosophy, arguing that they were just alternative philosophical methodologies, with different objects of thought. Peripatetic thought deals with the natural world and science, while mysticism goes deeper, and investigates the inner and the secret. The philosophers talked about a science of mysticism, and adopted a systematic attitude to this approach to understanding the nature of reality so that it is seen to represent something different from the exercise of subjective feelings. Sufism takes the searcher after knowledge further, it allows the individual to develop and understand significant experiences as well as valid concepts.

ILLUMINATIONIST (ISHRĀQĪ) PHILOSOPHY

Illuminationist (ishrāqīi) thought comes from the term *ishrāq*, a term linked with the idea of the east, and like Sufism was often adopted by thinkers who combined it with peripatetic thought. There is a more extreme form of illuminationist thought, though, that opposes peripatetic thought by attacking the crucial notion of definition, and using in its place immediate or intuitive knowledge. The peripatetic approach to reasoning has at its core the idea of definition in terms of genus and differentia, a process of explaining something by breaking it down into its smaller parts. Illuminationist thinkers such as al-Suhrawardī (1154–1191) criticize this approach as an attempt at explaining the unknown in terms of something even less known than itself, because the parts of the definition themselves will require definition, and so on ad infinitum. These criticisms also apply to deductive knowledge itself because this sort of knowledge is based on analysis and definition, and so operates on principles that are not philosophically respectable. Aristotelian demonstration is supposed to be the gold standard of argument and proof, and thus attacking it is an effective

way of suggesting that an alternative approach is necessary. The ishrāqī thinkers replace demonstration with knowledge by presence, knowledge that is so immediate that it cannot be doubted. If this knowledge is completely trustworthy, then it is highly appropriate as the starting point of one's reasoning process.

According to many ishrāqī thinkers, there is a type of knowledge that is so self-evident that it cannot be doubted. What counts as self-evident knowledge for the ishrāqī thinkers is that level of knowledge that is so intimately tied in with peoples' perception of themselves that in doubting it they would doubt themselves, and that implies doubting what makes the doubting possible in the first place. The conclusion is taken to be that such doubt is impossible. The truth that is presupposed by any perception is that the subject of perception exists. It is perhaps Suhrawardi who explores this notion of immediate knowledge, *ʿilm al-ḥuḍūrī*, most precisely; he argues that immediate knowledge is so immediate and incontrovertible that it is known in far more than an intellectual sense. That is, there are propositions that are known through reason and that are known perfectly, in the sense that humans grasp all aspects of them and can hold them in their minds all at once perfectly. The sorts of knowledge that are called *ʿilm al-ḥuḍūrī* are not only indubitable, but people experience their indubitability. The light of knowledge that shines on them makes the truth they possess evident to people in more than merely an intellectual sense. Of course, another advantage that perception of the self has over discursive knowledge is that the assumption is made that the self is basically a simple thing, so the use of human intelligence implies the activity of a simple self, a self that is pure agency.

The key term in illuminationist thought, as its name suggests, is light, and the idea is that immediate knowledge is lit up or illuminated in such a way to make it impossible to doubt. Light is commonly experienced as pervasive throughout the universe, and because people notice things clearly if they are brightly illuminated, this concept has familiarity as its basis. Yet people also tend to think that the things that are illuminated already exist before the light strikes them. For most of the ishrāqīs, what things are depends on degrees of their luminosity or light, not on their essences. God is often identified with the Light of Lights, the light that is the source of all other light and that does not itself receive light.

Illuminationism is often combined with both Sufism and Peripateticism, although more often with the former than with the latter. Although it sounds like a mystical approach, it is actually often carried out with analytical

exactitude, and there is a good deal of controversy in the literature as to whether ishrāqī thought represents a long-standing esoteric tradition in philosophy, or whether it is basically logical in the widest sense of that term. Ishrāqī thought is largely limited to the Persian cultural world, and so there is a temptation to see in it something linked with early Iranian ideas such as Zoroastrianism because light was also important there. However, the argument for such influence is difficult to make plausible.

It is difficult to overemphasize the significance of Persians in Islamic philosophy, although they generally wrote in Arabic. Most Islamic philosophers were Persians—albeit often living in other parts of the Islamic world—and Persia has a long history of absorbing philosophical ideas from a wide variety of sources. Mullā Ṣadrā is with little doubt the most outstanding thinker to have emerged from Persia, and his thought has defined the Persian philosophical curriculum since his day. Unlike some ishrāqī thinkers, such as al-Suhrawardī, Mullā Ṣadrā suggested that existence precedes essence, and so the first question in ontology deals with the characteristics of what exists, not with what they would need to be like to exist. He argued that existence is equivalent to God and so when people talk of ordinary things existing, they are really describing a relationship that they have with God. This is always going to be difficult to describe because ordinary language is based on a form of existence that it itself cannot explain. What is required for people to understand existence is first of all to comprehend all the different ways in which things exist, how those different forms of existence are linked, and the nature of the intermediaries between the different levels of existence. This concern for grasping the unity of being links Mullā Ṣadrā with the mysticism of Ibn al-ʿArabī, while the desire to understand the nature of the different levels of existence involves the sort of analysis found in the illuminationist tradition.

CONTEMPORARY ISLAMIC PHILOSOPHY

There are a variety of different approaches to philosophy in the contemporary Islamic world—as is hardly surprising—but some themes do recur. One of these themes comes from the notion of Islamic philosophy and deals with how Islamic it should be and what links it has to have with Islam itself, if any. How does Islamic philosophy's taking place within a particular cultural context shape it? How far should it continue to shape it? Although many Islamic philosophers continue to use techniques and ideas from outside of the region, the links that should

be established between Islam and the rest of the world is frequently a contentious issue. It is worth adding that the Islamic world can no longer, if it ever could, be identified with a specific geographical area because Islamic thinkers are today to be found virtually everywhere in the world.

The issue of the links between Islam and the rest of the world has persisted for some time and was highlighted in the nineteenth century as a result of orientalism and colonialism. In the subsequent centuries this has become an even hotter topic, because globalization and Zionism have been seen as yet another assault on the Islamic world and its distinct ethos. In the past the Islamic world was far in advance of the rest of the world, and yet for many centuries this has been entirely reversed and has led to many debates about the sources and significance of this apparent relative decline. It has been taken to be more than just a social or economic issue; it is a cultural one also, and clearly philosophy is then relevant in trying to resolve it.

THE RENAISSANCE IN ISLAMIC PHILOSOPHY. The *Nahḍa* or Islamic renaissance that started in the nineteenth century and became significant in Egypt in particular played a large role in shaping the modern debate in the Arab world. The *Nahḍa* involved a strategy of maintaining a distinctive Islamic identity while also incorporating within Islamic society those aspects of modernity that are not incompatible with religion. The idea was to combine the traditions of Islam with what was desirable from the rest of the world, in particular science but also aspects of culture such as philosophy.

It is often said that Islam never went through an enlightenment, yet the *Nahḍa* movement was clearly a sort of Enlightenment, albeit one that unlike some advocates of the European Enlightenment did not involve hostility to traditional religion. Jamāl al-Dīn al-Afghānī (1838/9–1897) and Muḥammad ʿAbduh both argued that Islam is perfectly rational and in no way opposed by European and North American scientific and cultural ideas, so there is no problem in not using those ideas. The Egyptian philosopher Muṣṭafā ʿAbd al-Rāziq went so far as to argue that all the main Islamic schools of thought are inherently rational and in no way inimical to European and North American science and rationality. By contrast, Muḥammad ʿAbd al-Jābrī is critical of much traditional Islamic thought, arguing that the reasons for the decline of the Arab world need to be analyzed clearly. He calls for a reexamination of the argument between those who emphasize the glory of the Islamic past and those who praise European and North American moder-

nity. What is required is a liberation of the Arab consciousness from its traditional ties to its Islamic past, and yet also a cautious attitude to the ideas that have come from Europe and North America and are aspects of foreign domination.

Fuʾād Zakariyya agrees that Arab failure is linked with the failure to criticize tradition, while Fazlur Rahman outlines the links between Islam and social progress. He argues that Islamic traditionalism is opposed to Islam itself because the religion is in favor of economic and social development and change. The attempt to fix a rigid and stultified version of Islam as the ideal is to fail to understand how science and technology can improve the lifestyle and moral welfare of the community. Hasan Hanafi uses the methodology of phenomenology to describe the concept of *tawḥīd* or unity. He suggests that Islam is dynamic enough to extend this notion so that it may provide a generally acceptable principle of unity and equality for everyone, something we can observe by examining how unity is actually used within contemporary and prior Islamic culture. He is also critical of blind faith in European and North American progress, suggesting that Europe and North America are now entering into a period of decadence that will require an infusion of ideas from elsewhere and in particular the Middle East. The idea that Islam is based on fixed rules he finds unrealistic, it is based on a revelation appropriate at its own time and place, but now other interpretations of the message should be adopted to match present conditions and represent more accurately the dynamism of Islam.

PHILOSOPHY'S PRESENCE IN THE ISLAMIC WORLD. It is often said that philosophy declined in the Islamic world after the death of Ibn Rushd in the twelfth century, but this is far from the truth. Today there is a lively philosophical presence in most of the Islamic world, often with the infusion into Islamic philosophy of ideas such as logical positivism, hermeneutics, pragmatism, Hegelianism, deconstructionism, and so on. Philosophy continued vigorously in the Persian cultural world, especially the philosophy of Ibn Sīnā and the ishrāqī (illuminationist) thinkers developing and commenting on al-Suhrawardī and Mullā Ṣadrā. In Iran philosophy has now moved away from the theological school, the *madrasa*, into the university. A good example of this is represented by the thought of Mehdi Haʾiri Yazdi. He develops a complex theory of knowledge that is based on knowledge by presence, a form of knowledge that is immediate and incorrigible and that serves as the foundation of other knowledge claims. He uses ideas from both ishrāqī thinkers like al-Suhrawardī, and the modern philosopher Wittgenstein.

Rather similar to Hanafi's phenomenology, ʿAlī Shariati uses the ishrāqī school's intermediary position between mysticism and Peripateticism to develop a view of humanity having God at its essence while maintaining the scope to determine its own form of existence. The notion of unity (*tawḥīd*) is seen as therapeutic—it links both personal and political justice and harmony. He interprets the main figures of Shiʿite Islam as models for people not only in a personal sense but also to bring about more progressive social ideals, and he sees them as representing archetypes that have always been regarded as desirable. Over time these archetypes themselves have not changed in essence, but they have changed in appearance to make them more appropriate to the particular audiences for whom they are designed.

This kind of link of the personal and the political is significant in modern Persian thought. An excellent example is Ayatollah Khomeini (Khumaynī), who led the Islamic revolution in Iran and combined the roles of spiritual and temporal ruler of the Islamic Republic of Iran. He wrote about and practiced a political philosophy that has become much discussed today in the Islamic world and beyond. The arguments for theocracy have become familiar again in political philosophy as a result of the Islamic revolution and its theoretical context.

CONTEXT FOR THE ISLAMIC REVOLUTION. What is the Islamic revolution's theoretical context? In his account of the Islamic state, Khomeini follows the familiar strategy of reflecting on the past and what took place then. He points out that the Prophet instituted a practical way of life as well as transmitting God's message, and also made provision for his successors. (It is on this issue of successors that the big divide in Islam between the Sunni and the Shiʿa occurred, the latter believing that the Prophet's son-in-law ʿAlī was his legitimate successor as head of the polity.) Islam is not only a religion in the sense of a system of belief about spiritual issues, but it also includes specific rules about how people ought to live, and if they can live in those ways then the legal and material provisions of the state must support that form of life.

There are three strong arguments for the continuing relevance of Islamic government. As Khomeini points out, the claim that Islamic government was only appropriate in earlier times might be taken as equivalent to the thesis that Islam itself is only valid at earlier times. Also, if Islam were not supposed to be a comprehensive and constant legislative system, why would it in fact consist of such detailed prescriptions? Finally, had there existed a unified Islamic polity, the constant humiliations of the Islamic world at the hands of its enemies would not have taken place. This is a reference not only to the creation of the State of Israel and its continuing dominance in the Middle East, but also to the repugnant actions of groups such as the Jews, according to Khomeini.

From an Islamic perspective, the state is not neutral. States are either Islamic or founded on unbelief and corruption. The Muslim cannot live in the latter kind of state without being irretrievably affected by it, unless he actively opposes it. It is the duty of all Muslims to struggle against the state unless the state is Islamic. Khomeini denounces the division of the international Islamic community into individual states, one of the effects of imperialism to weaken and divide Islam, in his view. Everything in Islam, he argues, is opposed to injustice, and yet, he argues, we see injustice in what is called the Islamic world. What is needed is the overturning of the corrupt regimes and their replacement by real Islamic governments.

A theme of Khomeini's thought is that religion does not just apply to private morality but must also be applied to the state as a whole, and the religious authorities should be in charge of the state because only then will the community be rightly guided. The school of Qom, of which he was a member, contained also Muhammad Hossein Tabataba'i, Murtaza Mutahheri, and Muhammad Taqi Misbah Yazdi, all important religious Shiʿite thinkers who nonetheless did not reject ideas just because they came from Europe. They argued that traditional Islamic philosophy could only gain by opening itself to some of the important philosophical achievements created outside of the Islamic world. All of the main religious thinkers in Iran disapproved of the work of Abdul Soroush, who took a rather distanced view of religion when he applied what he took to be the arguments of Popper, Moore and Wittgenstein to them. Soroush was opposed by Sadiq Larijani, the chief representative of the School of Qom, who suggested that Soroush had misapplied the theories of Popper, Stalnaker, Watkins, and Hempel. It is interesting that the debate took the form not of the clash between religion and reason, but rather of the correct understanding of philosophical theories, although it is fairly clear that there are serious issues of the role of religion in philosophy implicitly in the debate. Soroush managed to infuriate both the school of Qom and also the supporters of Heidegger, and that left him thoroughly isolated intellectually in Iran.

THE FUTURE OF ISLAMIC PHILOSOPHY Perhaps the best-known Iranian thinker outside the country in the early twenty-first century is Seyyed Hossein Nasr. He enters the debate on modernity by being critical of European and North American science—he praises some of its material achievements but points to the ecological consequences of a worldview that does not base itself on the presence of God. Science without spirituality is blind to moral issues, Nasr believes, because there is nothing that it holds sacred; it bases itself entirely on measurements of quantities, not on the quality of existence. More spiritual philosophies such as those based on Islam are holistic and integrative; they embed spiritual values in the technological agenda and so make ecological disasters less likely. For Nasr, the main question is not what the Middle East should take from Europe and North America, but vice versa.

Along with this view, Nasr has established in some detail the theoretical presuppositions of Sufism, the school of mysticism in Islamic thought. His historical accounts of this doctrine have played a large role in its increasing domestication outside of the traditional Islamic world. Indeed, as the Islamic world spreads out ever more widely, it is likely to involve itself much more in the ideas that it finds in an originally non-Islamic source. In this way Islamic philosophy is returning to its roots, in a sense, because it was the meeting of Islam with Greek philosophy in the early years of Islam that led to the subject coming into existence in the first place.

ISRAELI, ISAAC BEN SOLOMON
(c. 855–955)

Isaac ben Solomon Israeli, the first Jewish Neoplatonist, was one of the most distinguished Jewish physicians of the Middle Ages. He was so renowned for his medical competence, both in theory and in practice, that his works were widely circulated in manuscript, translated into Latin, and printed in the early years of the sixteenth century, as *Omnia Opera Ysaac* (Lyons, 1515). This printed edition and the manuscripts on which it was based contained some of Israeli's philosophic writings as well as his scientific treatises. As a result, his name became well-known, beyond his philosophic deserts; indeed, his fame among Christian scholars was second only to that of Moses Maimonides. Yet Maimonides held Israeli's philosophy in no great esteem, referring to him as "merely a physician."

Isaac Israeli was a native of Egypt. He left his native land to study medicine in the intellectual center of Kairouan, in north Africa, under the tutelage of Ishaq ibn Imram, a Muslim. Later Israeli served as court physician to Ubaydullah al-Mahdi, founder of the Fatimid dynasty in north Africa.

In addition to the philosophic materials in his "Book of Elements" (a medical work), Israeli has long been known as the writer of a "Book of Definitions." Recent studies have added also a "Book of Substances," a "Book on Spirit and Soul," and, probably, a short "Chapter on the Elements," found in a unique manuscript in the Bibliotheca Communale of Mantua and ascribed to Isaac Israeli by A. Altmann. On the basis of these works, Israeli

can be confidently classified as a Neoplatonist whose work is akin to that of other Neoplatonists among the Muslim philosophers of his age.

His surviving works do not include any significant discussion of the existence and nature of God but they do describe God as a perpetually active Creator. God's original creative act is a creation out of nothing; later acts of creativity in nature are not of the same order but are "the passing of corporeal substances from privation to existence" in accordance with God's will. Along with this account, however, Israeli also maintained a doctrine of emanation. Thus, on the one hand God creates because of his goodness, while on the other his creativity is a perpetual overflowing. These two accounts of creation are never reconciled in Israeli's thought.

The process of emanation terminates with the emergence of the visible sphere. From this point, Israeli's explanation of the universe is physical and more closely akin to the views of Aristotle. Retaining the classical Greek theory of the four elements, he accounted for everything in the world of our experience by the combination of the elements earth, air, fire, and water. Once again, however, we are confronted with an uncertainty. In the "Book of Definitions," Israeli asserted that the four elements came into being through the movement of the sphere of heaven, but in the "Book of Elements" they are attributed to the power of God. Except by straining the language, these two views cannot be reconciled.

A similar double view emerges in Israeli's doctrine of the soul. Here he spoke of a cosmic soul, which exists independently of body, appearing in three successive stages of emanation—rational, animal, and vegetable—and also of a divine spark within the individual, striving ever upward toward the cosmic soul. Perhaps in this double account of soul we have a reflection of the Neoplatonic doctrine of man as the microcosm. If so, we can understand the emphasis Israeli put on self-knowledge, the road to the knowledge of the universe. Self-knowledge is knowledge of both body and soul; one who knows himself in both soul and body knows everything, and he alone is worthy of the name of philosopher.

ITŌ JINSAI
(1627–1705)

Itō Jinsai, a Japanese Confucianist of the *kogakuha* ("school of ancient learning"), was born in Kyoto, the son of a poor merchant, and spent his life there as an educator. After studying the official Zhu Xi Confucianist doctrine, he rediscovered ancient Confucianism and became its systematizer and, through the Kogidō, a school he founded in 1680, its propagator. The novelty of his teaching aroused the suspicion of the central government in Edo (Tokyo). However, it was not suppressed although his *kogigaku,* or "learning-of-the-ancient-meaning," was gaining a large following. Through the able guidance of his scholarly son, Tōgai, and of his grandson the school was operated until 1871, when all Confucianist schools were abolished in favor of the new Western system.

Itō's philosophy, stemming from a great admiration for Confucius and Mencius, is quite contrary to the Neo-Confucianism of Zhu Xi. Itō is clearly a monist in the sense that he does not admit any priority of *ri,* the principle (reason), over *ki,* the material force, which for him is material energy. A primordial material energy (*ichi genki*), having neither beginning nor end, is the root of everything. *Ri* is but a pattern of *ki; ki,* through the motion of the yin-yang, or passive-active, elements, forms the great living organism (*dai-katsubutsu*), the universe itself.

Itō holds with Mencius that human nature is originally good, and he does not make the usual Zhu Xi distinction between physical and original nature, which he treats as a spurious Daoist influence. Evil in physical nature need not be explained as if it arose from lack of cultivation of the potentialities of human nature. The four sources of virtue (in Chinese, *ssu tuan*; in Japanese, *shitan*) according to Itō are righteousness, humaneness, ritual or propriety, and wisdom. Righteousness is the pivotal virtue of Itō's ethics. Humaneness is benevolent love, or condescension from the superior to the inferior, for in Confucianism universal equalitarian love is practically nonexistent. Morality, the natural Way of things, has a cosmological meaning in addition to the ethical one. The material energy of the universe is manifested in humankind through humaneness or love. Itō's principles of education centered on forming moral character rather than on imparting knowledge; will is above the intellect.

Itō did not make much of astronomy and mathematics, but he was very fond of history. However, unlike most other Confucianists of the "ancient learning" school, he did not become a nationalist through the study of history. For him China remained the fountainhead of culture. Itō's outstanding merits as a Sinologist were the result of painstaking research in ancient texts, yet he patiently bore the faultfinding of his gifted son and the criticisms of his best pupil, Namikawa Temmin (1679–1718).

See also Chinese Philosophy; Confucius; Human Nature; Mencius; Wisdom; Zhu Xi (Chu Hsi).

IVANOV, VIACHESLAV IVANOVICH
(1866–1949)

A major poet and theorist of the symbolist literary movement in Russia, Viacheslav Ivanov left an elaborate and influential body of work on art, culture, and religion. To the chagrin of his contemporaries, he never formalized his protean and wide-ranging ideas as a philosophical system. However, Ivanov's writings can be divided into several core areas, which succeeded each other at the center of his attention: the ritual roots of tragedy; the artwork as symbol of the transcendent; the role of art in creating historical myth; and the prospects for a religious revival in modernity. Despite his protean views, Ivanov can be seen as a philosopher in the hermeneutic tradition for whom the world reveals itself as an historical continuum of discrete acts of expression and understanding.

BIOGRAPHY

Born in Moscow, Ivanov was educated as a classical historian and philologist at the universities of Moscow (1884–1886) and Berlin (1886–1891). In 1895 he abandoned his academic career and devoted himself to poetry. This awakening was instigated by his move to Italy, his adulterous affair with Lidiia Zinov'eva-Annibal (who became his second wife in 1899), and his discovery of Friedrich Nietzsche. Ivanov entered into contact with the philosopher Vladimir Solov'ëv, who approved some of Ivanov's poems and the title of his first book of poetry *Kormchie zvezdy* (Pilot Stars, 1902). Ivanov followed up on his poetic debut with a series of lectures for Russians in Paris called *Ellinskaia religiia stradaiushchego boga* (The Hellenic Religion of the Suffering God, published 1904; continued in 1905 as *Religiia Dionisa* [The Religion of Dionysus]).

After completing another book of poetry, *Prozrachnost'* (Transparency, 1904), Ivanov moved to St. Petersburg in the revolutionary year 1905. Between 1905 and 1912, Ivanov hosted weekly symposia at his "Tower" apartment which attracted many major writers, artists, and thinkers. The first session, for example, was devoted to the question of "Eros" and chaired by philosopher Nikolai Berdyaev. Ivanov was also active at the St Petersburg Religious-Philosophical Society. His essays from 1904 to 1909 were gathered into the volume *Po zvezdam* (By the Stars, 1909). After his wife's sudden death in October 1907, Ivanov commemorated her in an elaborate poetic cult, the highpoint of which is marked by the two-volume book of poetry *Cor Ardens* (1911–1912).

In 1912 Ivanov married Lidiia's daughter from a previous marriage Vera Shvarsalon, who gave birth to a son Dmitrii; these events inspired Ivanov's 1912 collection *Nezhnaia taina* (The Tender Mystery). Moving to Moscow in 1913, Ivanov became active in the Moscow Religious-Philosophical Society and became close to such "neo-Slavophile" philosophers as Pavel Florenskii, Sergei Bulgakov, and Vladimir Ern. Ivanov identified himself closely with the memory of Fëdor Dostoevsky, on whom he wrote extensively. He also became a friend of the mystical composer Aleksandr Scriabin, on whom Ivanov wrote a series of poems and essays.

During World War I Ivanov published two books of essays: *Borozdy i mezhi* (Furrows and Boundaries, 1916) and *Rodnoe i vselenskoe* (Matters Native and Universal, 1917). In the latter Ivanov's strident political tone reflects his enthusiastic embrace of the February 1917 revolution and his initial opposition to the Bolshevik revolution in October 1917. However by late 1918 Ivanov had assumed an important position in the cultural organs of the fledgling Soviet state and published two earlier works: the autobiographical narrative poem *Mladenchestvo* (Infancy, 1918) and the drama *Prometei* (Prometheus, 1919).

After Vera's death in August 1920 Ivanov moved to Baku, where he taught at the new Azerbaijan State University for four years. In 1921 Ivanov defended his doctoral dissertation, *Dionis i pradionisiistvo* (Dionysus and Pre-Dionysianism, 1923), a more rigorous elaboration of his earlier ideas about Greek religion and tragedy. The Baku period was comparatively barren of original work, especially poetry; Ivanov wrote only a satirical drama *Liubov'—mirazh?* (Is Love a Mirage?, 1924). In 1924 he emigrated to Italy, where in 1926 he became a Roman Catholic. From 1926 to 1935 Ivanov taught at Collegio Borromeo in Pavia.

Ivanov achieved some renown in European intellectual circles between the wars. Most notably, *Perepiska iz dvukh uglov* (The Correspondence from two corners), which Ivanov coauthored in 1920 with cultural historian Mikhail Gershenzon, was translated into numerous languages beginning in 1926. In 1932 he reworked and translated his essays on Fë Dostoevsky as *Dostojewskskij: Tragödie—Myth—Mystik* (Dostoevsky: tragedy, myth, mysticism; translated as *Freedom and the Tragic Life* [1952]), the single best introduction to Ivanov's thought. In 1939 he published *Chelovek* (Man), a philosophical poem written mainly between 1915 and 1919. In 1944 he kept a lyric diary which was included in his posthumous book of poetry *Svet vechernii* (The fading light, 1962).

IVANOV'S THOUGHT

Influenced by Arthur Schopenhauer and by Nietzsche, in his early metaphysics Ivanov viewed the physical world as a veil of *Maya* or nonbeing, which can be overcome only in cathartic ritual or ritual-like tragedy. In Ivanov's initial aesthetic statements, the ineffable transcendent event resisted concrete expression, and so the emphasis fell squarely on the psychological transformation of artist and beholder in mimetic performance. Following Richard Wagner, Ivanov projected the renewal of tragedy as a synthesis of the existing arts that would lead to a religious revival. In particular Ivanov equated the rebirth of the tragic chorus in art to the achievement of *sobornost'*, the spiritual unity of the believing community or nation. Ivanov christianized Nietzsche, identifying the suffering god Dionysus with Christ and ancient tragedy with the Christian liturgy.

In politics Ivanov elaborated a theory of mystical anarchism, predicated on the expectation that the community would be unified inwardly by common ritual practice in symphonic unanimity, or *sobornost'*, instead of by formal legal and political structures. He constructed a cyclical theory of cultural history in which periods of critical or classical culture alternate with organic periods of barbarian (i.e., Scythian, Anglo-Saxon, and Slavic) energy. Ivanov counted the impending rebirth of tragedy, the synthesis of the arts, and the revolutionary tumult of 1905 among the symptoms of a new organic era of mystical activity that would lead to a just society and a reinvigorated church.

By 1908 Ivanov had shifted his attention from tragic and ritual performance to its concretization in aesthetic symbols and religious dogma. His aesthetics became increasingly metaphysical, drawing especially on Plato and Vladimir Solov'ëv, from whom he took the term *theurgy* to denote the artist's transfiguration of phenomena into an ontologically higher reality (the symbol) that approximates the divine prototype. Ivanov described artistic creation and reception as an ascent *a realibus ad realiora* (from the real to the more real). Adopting linguistic terminology, and referring to neo-Kantian philosopher Heinrich Rickert, Ivanov claimed that any proposition is based on the verb "to be" and is a normative projection of being as value. In religious terms, any proposition imbues reality with an assertion of divine being. Therefore Ivanov posited that the statement "Thou art" actually elevates the being of both speaker and addressee through the energies of God contained in language itself.

Ivanov's concepts of catharsis and the linguistic symbol led to a communicative philosophy that took its final shape around the time of his move to Moscow in 1913. In

"On the Limits of Art" (1914), a major restatement of his aesthetics, Ivanov described the aesthetic process as a continuum of expressive and receptive acts, in which art stimulates individuals to further creativity, leading to the gradual transfiguration of reality through human agency (instead of through semimagical theurgy). Ivanov still attributed a central role to the artist in guiding the individual's transformation; however, he was now eager to describe how the transcendent revelation of the art work is transcribed into a narrative myth that communicates memory and projects future human action.

At this time Ivanov also integrated his aesthetics with an account of history. In a series of articles on the history of literature, Ivanov described how Byron's texts contributed to the development of individual consciousness in Russia, which in turn allowed Pushkin and then Dostoevsky to re-appropriate Russian history and spirituality from within modernity. Defining Dostoevsky's major works as "novel-tragedies" allowed Ivanov to explain both their cathartic grip on readers and their ideological influence. In his philosophical and artistic prose, Ivanov elaborated a new myth of Russian history, which he hoped would result in the country's transformation into a truly Christian empire.

In a 1909 essay "On the Russian Idea" Ivanov described the complex interaction of understanding and action in terms of an Aristotelian triad: catharsis (cleansing), mathesis (learning), and praxis (action). This hermeneutic standpoint received its most accomplished expression in *The Correspondence from Two Corners* (1920), an epistolary exchange between Ivanov and Mikhail Gershenzon. Surrounded by the ruins of their former world, both authors grappled with their own lives by inscribing their projected identities into a text, which is immediately read and answered by the other.

In his Italian exile Ivanov adjusted earlier ideas and constructs in the light of his Roman Catholicism. Like Solov'ëv, Ivanov explained his conversion to Catholicism as an affirmation of the Roman Catholic Church as a historical symbol of divine unity. He adopted some of Jacques Maritain's neo-Thomist vocabulary, for example defining art as *transparentia formae*.

In his heyday, Ivanov's intellectual constructs enjoyed broad renown and were key influences on such thinkers as Nikolai Berdyaev, Pavel Florenskii, Sergei Bulgakov, Aleksei Losev, and Mikhail Bakhtin. His views on tragic performance as a social panacea influenced the public celebrations in the early Soviet Union. His impact has also been felt in Orthodox theology, which has sometimes adopted his formulations of the symbol, the idea of

aesthetic ascent and descent, and the primacy of ritual experience in generating *sobornost'*. His conception of culture as a historical continuum of creative acts remains an underappreciated aspect of his work.

JACOBI, FRIEDRICH HEINRICH
(1743–1819)

Friedrich Heinrich Jacobi was a leading representative, with Johann Georg Hamann, of the philosophy of feeling and a major critic of Immanuel Kant. He was born in Düsseldorf on the Rhine. Jacobi received an education preparing him for a business career, but an inner urge drove him to the pursuit of philosophical studies. He studied the works of Claude-Adrien Helvétius, Jean-Jacques Rousseau, Ferguson, and Benedict de Spinoza, the last of which had a negative influence on him, provoking opposition and criticism; he was also influenced by the English philosophers of feeling—the earl of Shaftesbury and others. His friend Hamann, a kindred spirit, lived in his home for a long period, and his influence on Jacobi cannot be overestimated. In 1804, Jacobi was appointed president of the Academy of Sciences in Munich. He was in literary contact with the prominent thinkers of his time—Moses Mendelssohn, Karl Leonhard Reinhold, Jakob Friedrich Fries, and Johann Wolfgang von Goethe. His discussions with his contemporaries are as important for the understanding of his philosophy as are his original works.

Jacobi developed a philosophy of feeling and faith. He was critical of speculations leading to the concept of the prevalence of necessary laws above freedom, hence Jacobi's rejection of Spinoza's pantheism and of the philosophy of Johann Gottlieb Fichte, Friedrich von Schelling, and G. W. F. Hegel, in which there are manifest pantheistic tendencies. Because of Jacobi's concept of the primacy of freedom, he found that the actions of man are not to be deduced from his thinking, for thinking is not the primary force in man. The history of man is not the result of his mode of thought; rather, the former determines the latter. Herein is anticipated the method of the historical school of law as it was later developed by Friedrich Karl von Savigny. For Jacobi the immediately given is the determining factor in our cognition of cultural phenomena. Objects have to be given to us through immediate feeling or faith before thought comes into play. The task of discursive thinking is to observe, analyze, compare, and order perceptions by reducing them to their fundamental principles. But unless something real is previously given through feeling, discursive thinking cannot take place.

Jacobi was a master of criticism. His strength lay in grasping a system of thought as a whole and detecting those elements in it that are incompatible. This capacity

of critical analysis is manifest in his appraisal of dogmatic rationalism and the critical philosophy. Jacobi subjected both Spinoza and Kant to severe criticism. He pointed to hidden contradictions and inconsistencies in both their systems. The dogmatic rationalism of Spinoza employs the mathematical method in the realm of metaphysics; it accepts as real only what can be proven and deduced mathematically. By this method, however, neither God nor freedom can be maintained. These ideas cannot be deduced by an absolute system of causality, which is the essence of Spinozism. Absolute necessity leads to atheism, and the denial of freedom leads to fatalism. To Jacobi, Spinozism and pantheism were synonymous terms, and pantheism was identical with dogmatic rational atheism. (He ignored the possibility of interpreting Spinoza's system as acosmism instead of as atheism—an interpretation that was first suggested by Salomon Maimon and then by Hegel.)

Jacobi's ethicoreligious worldview is the background of this criticism of Spinoza. While recognizing the dangers implied in Spinozism, Jacobi and Gotthold Ephraim Lessing were the first to acknowledge the philosophical genius of Spinoza. Through Jacobi's discussions with Mendelssohn about Spinozism and Lessing's relation to it, in the course of which the arguments for and against Spinoza were brought forth, Spinoza's philosophy became a force in the intellectual life of the time; it acquired a universal significance. Spinoza and Kant were two opposing poles of thought for Jacobi. For the former all being, including man, is determined by necessary laws; for the latter freedom and creativity are the essence of man. The whole period of the development of post-Kantian speculative idealism was determined by the two intellectual forces: the dogmatic rationalism of Spinoza and the critical philosophy of Kant. Jacobi was critical of the philosophy of speculative idealism (Fichte, Schelling, and Hegel) for its manifestation of Spinozistic tendencies.

JACOBI ON KANT

Jacobi's enthusiasm for Kant's precritical essay *Der einzig mögliche Beweisgrund zu einer Demonstration des Daseins Gottes* (The only possible ground for a demonstration of God's existence) is indicative of his conception of the method by which we can attain knowledge of reality. Kant had shown in this work that the absolute and unconditioned being must be grasped as existing in and through itself, not as a predicate or as a consequence of something else. The attainment of some reality that is simple, insoluble, and immediately given is the ultimate aim in our striving for certainty. Cognition by way of dis-

cursive thought cannot attain certainty. A method of deduction of consequences from premises is an endless process that can never attain the original unconditional and primary being. Certainty is acquired only in an immediate perception of a reality not requiring any deduction.

Jacobi admired Spinoza because he had reversed the whole process of philosophizing as it was known since Aristotle. Instead of proceeding from the phenomena of experience, leading gradually to being as such, Spinoza started with a definition of substance as something that is conceived in itself and through itself—that is, a simple and immediately given reality. This simple and indissoluble datum is, however, according to Jacobi, not free from contradiction. Spinoza's substance is not a free, independent, self-sufficient being, but a necessary and causally bound being. The God of Spinoza is nothing else but a manifestation of the logical-mathematical determination of being.

The critical philosophy can be maintained only if it consistently removes all traces of a dogmatic, realistic nature. The concept of a thing-in-itself has to be completely eliminated because it is incompatible with the system as a whole. The Kantian position is, according to Jacobi, pure idealism. As such it cannot retain the concept of things in themselves. The *Critique of Pure Reason* deduces the objects from the constitution of our cognitive capacity. It has therefore to deny objective reality existing independently of and beyond the conditions of cognition. The object has to be completely resolved in subjective presentations of our mind. Kantian philosophy is thus interpreted by Jacobi as pure subjective idealism. Since we perceive the objects through forms of sensibility (space and time) and concepts of understanding, constituting the human capacity of cognition, the "external" objects cannot be beyond us. According to Jacobi, René Descartes intended by the principle *cogito ergo sum* to deduce the totality of the inner subjective world from the consciousness of the self as a thinking subject. Self-consciousness of oneself as a thinking being is the primary condition of man's knowledge of the inner world. In a similar manner Kant tried to prove that external objects are likewise conditioned by and dependent on the subject with its forms of sensibility and understanding. Hence, the subjective idealism of Descartes was extended by Kant to encompass the world of objects, too. The Kantian position is thus, according to Jacobi, universal idealism, but since he took Kant to mean that the cognition of things is determined by the individual ego and not by the objective mind as it is presented in scientific thought, universal ide-

alism, according to Jacobi, is a system of absolute subjectivity, which implies a "nihilism" with reference to the objects. This system recognizes only the ego as real; it is thus speculative egoism. Jacobi found this position self-contradictory. Sensibility is a receptive function, according to Kant. But a consistent idealism excludes a receptive capacity in the process of cognition. It is incongruous with idealism to assume the reality of things-in-themselves existing independently of our mind, yet these things are supposed by Kant to supply the material of experience that affects our senses. The first part of the Kantian *Critique* deals with the forms of sensibility as a receptive capacity. Thus, things-in-themselves are assumed, by which our sensibility is affected. "Hence we cannot enter into the *Critique* without assuming things-in-themselves, but we cannot retain this assumption upon leaving the *Critique*."

Since Jacobi understood the Kantian position as subjective idealism, he did not consider the second edition of the *Critique of Pure Reason* an improvement on the first. The Kantian philosophy that Jacobi took to be a form of pure subjective idealism is presented in the first edition of the *Critique*, and this he took to be its genuine and adequate presentation. To Jacobi belongs the priority of recognizing the difference between the two editions, but he was wrong in its evaluation. He failed to grasp the essential characteristic of critical idealism, which is grounded in analysis of objective scientific cognition and not in analysis of the process of cognition of the individual subject. The problem posed by Kant was How are synthetic propositions a priori in mathematics and natural science possible?, not How is cognition of the individual subject as a psychological phenomenon possible? Whereas the Kantian inquiry constitutes the essence of the transcendental method, leading to objective idealism, the investigation of the individual process of cognition appertains to the psychological method, resulting in subjective idealism. The second edition of the *Critique*, which tries to eliminate the psychological sections of the first edition, is the preeminent presentation of the transcendental method.

FAITH—THE SENSE OF REALITY

In opposition to the critical philosophy, which is, according to Jacobi, absolute subjectivity, he proposed a thesis of absolute objectivity. The objective reality of things-in-themselves existing beyond man and independently of the human cognition is based for Jacobi on an original, immediate certainty that does not require any proof or demonstration. The certainty of the existence of things in themselves is based on faith.

Our consciousness presupposes the reality of things as a necessary correlate of cognition. The idealistic position contradicts an assumption that is inherent in every act of cognition of an object of experience. To be sure, the reality of the things cognized cannot be conclusively derived from the process of cognition as such, which is a subjective phenomenon, but only from the immediate sense of reality accompanying every act of cognition of an object. This sense of reality, which cannot be accounted for logically but is nonetheless present in our mind, is designated by Jacobi by such terms as *faith, feeling*, and, later, *revelation*.

With Kant Jacobi recognized that analysis of cognition cannot lead to things-in-themselves, since the validity of the categories is confined to the realm of experience and does not extend beyond it. But the Kantian *Critique* had also shown that reason leads to a realm of faith in addition to mere cognition. Hence, an object that cannot be proven as real on the basis of cognition may still be real on the basis of faith. Kant employed the concept of faith only with reference to the moral and religious realm, but Jacobi extended the scope of faith to include the knowledge of things-in-themselves. In recognizing the validity of faith for the theoretical realm, Jacobi followed David Hume, who designated the feeling of reality of the natural human consciousness as faith. The skepticism of Hume showed that the reality of things cannot be derived from sense perception. Analysis of perception cannot lead to cognition of substance and causality; only through faith can we know the reality of things. Hume thus ascribed to faith a positive theoretical function inasmuch as it is a source of knowledge of the reality of the things of experience. The belief in the reality of things, which accompanies our sensuous experience throughout our lives, is incomprehensible, but, according to Jacobi, it commands certainty just as if it were an act of revelation. He understood by revelation a certainty that we are aware of but which we cannot explain rationally. This conception of the belief in the reality of things is radically different from naive realism and commonsense philosophy. The latter does not realize the extraordinary nature and the problematic character of the concept of reality, of things-in-themselves. Naive realism takes for granted that we perceive things as they are. Jacobi, however, realized the miraculous nature of such a belief. The possibility of transition from consciousness to things, from the subject to objects, cannot be comprehended by our understanding. Jacobi was right to affirm the position of critical ide-

alism that we can know of things only what we ourselves put into them. While we cannot cognize things-in-themselves, our belief in their reality can be accounted for as something irrational that is an indispensable ingredient of human consciousness. Our rational thinking cannot lead us to cognition of reality of things-in-themselves. However, the necessary condition of the existence of man as a conscious being is grounded in an incomprehensible and irrational act of faith commanding certainty that is not subject to any doubt. In face of this belief as a necessary condition of human consciousness, the arguments of rationalism, of critical philosophy, and of skepticism are powerless.

RELIGION

Jacobi's philosophy of religion is grounded in the same principle on which his theory of cognition of reality is founded. The concept of faith as having a theoretical function is the ground of the certainty of real objects beyond us and of a supersensuous reality. This immediate certainty of reality is present in our consciousness of God as it is present in our perception of objects. Through belief man has the capacity of intuiting God. Dogmatic religionists maintain that through an act of faith God reveals himself to man by grace. For Jacobi faith is a mode of cognition or a form of intellectual intuition. And this is not an exclusively religious phenomenon, for through belief man likewise perceives the reality of things of experience. The distinction between the reality of the things and the transcendent, supersensuous reality is that the former reveals itself through an external perception, whereas the latter is intuited through an internal revelation. Both forms of revelation constitute the very essence of human existence as a conscious being.

For Kant, it is impossible through faith to transcend the sphere of the subject, but for Jacobi we are aware through faith of a reality that is not subjective, since in the act of faith the nature of the real thing reveals itself to us. Faith thus commands not only ethical certainty, as Kant held, but also theoretical certainty. To be sure, the transcendent reality cannot be known by the forms of understanding that are confined to the realm of experience. But faith as a function of reason (*Vernunft*) is capable of transcending experience and thus can perceive the supersensuous by an act of intellectual intuition.

Intellectual intuition, which is attained through faith, overcomes the Kantian dualism of sensibility and understanding, which is a necessary condition of cognition of objects of experience. Kant considered intellectual intuition an idea of knowledge of the infinite mind (*intel-*

lectus archetypus), which is not attainable by the finite, human mind. But for Jacobi intellectual intuition is attained through faith, or immediate feeling. Jacobi thus prepared the way for the post-Kantian speculative metaphysicians to consider intellectual intuition a capacity of human reason.

CRITICISM

By ascribing to belief the function of knowledge of things-in-themselves and of the existence of God and of freedom, Jacobi disregarded the essential difference between the theoretical and the ethical realms. Kant's concept of faith is a new principle of validity but not a mode of knowledge. In the *Critique of Practical Reason* Kant discovered an "unconditioned" in opposition to the conditioned reality of experience. God and freedom as ideas of practical reason are not metaphysical things but principles of ethical conduct. It is the unconditioned of freedom and the "ought to be," not the existence of transcendent reality, that is discovered through faith.

Jacobi is rightly critical of the dogmatic rationalism of the Enlightenment; he realized the limitations of rational thought in face of the endlessness of that which is problematic. But he was wrong in subordinating the realm of science, which is grounded in discursive thinking, to that of feeling and faith. He did not realize the problem involved in his concept of belief and immediate feeling as the highest means of attaining knowledge of reality. The appeal to feeling, belief, and immediate evidence opens up possibilities for abuse and willful arbitrariness. Feeling and immediate sense of reality are subjective, and whenever a capacity of the subject is elevated to a principle of knowledge, objective truth is in jeopardy. The rightful place of faith is therefore the ethical and the religious realm, which is concerned with the "ought," not with being as it is. Theoretical knowledge of reality can be attained only by discursive thinking, which is the scientific method.

Jacobi said of himself that he was a pagan in his mind but a Christian in his heart. He thus recognized the conflict between reason and faith that he caused by the extended role he ascribed to faith. His belief in the reality of things-in-themselves, of a supersensuous being, and of freedom not only claims ethical and religious validity but also pretends to possess the rank of theoretical knowledge; it is therefore in conscious disagreement with reason. The price we pay for extending the scope of faith is its clash with reason.

JAMES, HENRY
(1811–1882)

Henry James, an American philosophical theologian in the Swedenborgian tradition, is perhaps best known as the father of the novelist Henry James and the philosopher-psychologist William James. Although the elder James was physically handicapped from his early teens, an inheritance from his father, a dominant figure in upper New York State real estate provided him with a lifelong income. Henry James graduated from Union College in 1830 and studied for the Presbyterian ministry at Princeton Theological Seminary from 1835 to 1837. Dissatisfied with the ritual formality and absence of spirituality in what he called "professional religion," he left the seminary and traveled to England, where he came under the influence of the idiosyncratic theology of Robert Sandeman, author of *Letters on Theron and Aspasio,* which James edited for American publication in 1838. Soon afterward, through J. J. Garth Wilkinson, James discovered Emanuel Swedenborg. During the remainder of his life, he developed his own insights in the language of, and within the broad framework of, Swedenborgian ideas.

Central to James's view was the belief that selfhood (Swedenborg's *proprium*) is the sin of sins. Since the movement of creation is a move away from God, it is during this phase that selfhood flourishes. Religion and morality form, as it were, a reflecting surface from which the individual is "bounced back" toward God, thus initiating the movement of redemption, in which selfhood is replaced by "sociality" as a dominant motivation. Thus, as one of James's titles indicates, society is the redeemed form of man. Selfhood is destructive of the Divine intention with regard to created nature, whereas sociality is reconstructive. The ideal of redemptive society that James envisioned was largely derived from the social theories of

Charles Fourier and emphasized social solidarity and democracy.

Because of this double allegiance to Swedenborg and Fourier (an allegiance James shared with many of his contemporaries, including Parke Godwin, Horace Greeley, and Albert Brisbane), James was able to assert that the highest points of European life were reached in Protestantism and constitutional liberty, and that both of these had been raised to still higher levels in America. Beneath the sometimes crude externals of American democracy, he saw "the soul of fellowship that animates and redeems it." Thus, he conceived of democracy as the herald of moral perfection and the means of "preparing the way for the reign of infinite Love." In this way James linked his theology of redemptive society to American democratic practice and to its ideal theory.

See also Democracy; Fourier, François Marie Charles; James, William; Liberty; Swedenborg, Emanuel.

JAMES, WILLIAM
(1842–1910)

William James, the American philosopher and psychologist, was born in New York City to Mary Robertson Walsh James and Henry James Sr., the eccentric Swedenborgian theologian. James's paternal grandfather and namesake was an Irishman of Calvinist persuasion who immigrated to the United States in 1798 and became very rich through felicitous investment in the Erie Canal. James had three brothers and a sister; one of them, the novelist Henry James, achieved equal fame.

James's early environment was propitious; his father's enthusiastic and unconventional scholarship, his personal and unorthodox religion, his literary association with men like Oliver Wendell Holmes Sr. and Ralph Waldo Emerson all stimulated free intellectual growth. Even more important was the rather extraordinary respect that the elder James lavished upon the youthful spontaneities of his children; each, he thought, must go his own way and become that most valuable of creatures, himself. There was no straitlaced dogmatism in the James household, and William James was free to accept or reject the ideas of his father and his father's friends. The thought and sympathies of these transcendentalists and romantic humanitarians of the New England tradition never seemed to James the ultimate answers to his own philosophical and personal problems, but they dealt with genuine issues that he did not evade in his later work.

James's primary education took place at his father's table; its main constituents were the spirited discourse that the family held on every topic and the example of the parents, loving and unworldly. Formal education took place irregularly in various private establishments. From 1855 to 1860 James (often in the company of his younger brother Henry) attended schools in England, France, Switzerland, and Germany. There, as his father said, he and his brother were able "to absorb French and German and get a better sensuous education than they are likely to get here" (Ralph Barton Perry, *The Thought and Character of William James,* p. 59). During this European sojourn James's interest was divided between natural science and art, especially painting.

In spite of his continuing enthusiasm and talent for scientific inquiry, James's interest in painting became so strong by 1860 that he resolved to spend a trial period learning to paint. The elder James was not anxious for his son to become a painter, thereby prematurely cutting himself off from the rest of life's possibilities; any definite vocation, according to the father, was sadly "narrowing"

(ibid., p. 171). It was nevertheless arranged that James should begin study with William M. Hunt in Newport. This experiment convinced James that he lacked the ability to be anything more than a mediocre artist, than which there was, he thought, nothing worse. The lesson at Newport permanently discouraged James's pursuit of an artistic vocation, but throughout his scientific and philosophical career he retained the artist's eye, his predilection for concrete sensuous detail, and his concern for style.

In 1861, James entered the Lawrence Scientific School, Harvard, studying first in the chemistry department under Charles W. Eliot, later in the department of comparative anatomy and physiology under Jeffries Wyman and Louis Agassiz. From Wyman he learned the importance of evolution; from Agassiz, an appreciation of "the world's concrete fulness" (William James, *Memories and Studies,* p. 14) and of acquaintance with empirical facts as against abstraction. In 1864, James transferred to the medical school, though without the intention of ever practicing medicine. His medical studies, although fruitful, were attenuated and sporadic.

While at medical school James joined Agassiz as an assistant on the Thayer expedition to Brazil during 1865/1866. In Brazil he contracted smallpox and suffered from sensitivity of the eyes. This was the first serious manifestation of that constitutional failure which was to recur throughout James's life, imposing upon it a pattern of interrupted work and of periodic flights to Europe which were always, at least in part, searches for health.

In 1867 ill health and the desire to study experimental physiology led James to Europe, to Germany in particular. While little formal study of physiology proved to be possible, James read widely and thoughtfully. His first professional literary effort, a revision of Herman Grimm's *Unüberwindliche Mächte,* published in the *Nation* (Vol. 5, 1867), dates from this period.

James returned to Cambridge in November 1868 and received his medical degree in June 1869. After a period of illness and retirement, he began teaching anatomy and physiology at Harvard in 1873, psychology in 1875, and philosophy in 1879. This order is very nearly accidental and gives no adequate indication of James's development. Philosophy was an early interest which grew with his scientific studies; for James the more narrowly scientific questions could never be separated, even theoretically, from the more general questions which philosophy considers.

It was indeed a specifically philosophical concern which precipitated James's profound emotional crisis of 1870. He had been suffering from a sense of moral impotence that only a philosophical justification of the belief in the freedom of the will could cure. In the *Essais de critique générale* of Charles Renouvier, James found the basis of the justification he sought. And throughout his life the problem of maintaining free will and the moral attitude in the face of either religious monism or scientific determinism, as well as the problem of legitimating belief despite various intellectual skepticisms, continued to engage James's attention and to influence his mature philosophy. That philosophy, growing out of personal need and agitation, has a strong eschatological flavor. It cannot, however, be reduced either to a scheme of personal salvation or to an apology for some special way of life. James offered a philosophical, not an emotional, defense of free will, moralism, and belief. These topics became important test cases for a general metaphysics that James sought to elaborate not for its own sake but to satisfy interests which were distinctly rational and theoretical.

Having settled into the career of philosopher and teacher, if one may speak of James's settling into anything, he maintained close but not constant association with Harvard until his final resignation in 1907. He married Alice Howe Gibbens in 1878; the marriage seems to have increased his sense of purpose and coincided with a noticeable improvement in James's health. Thenceforth, he led an intensely active life, teaching at Harvard, lecturing widely, and publishing a series of books which became undeniable classics of American philosophy. Three series of James's lectures deserve special mention. He gave the Gifford Lectures at Edinburgh in 1901/1902, published as *The Varieties of Religious Experience* (1902); lectures on pragmatism at the Lowell Institute and Columbia in 1906 and 1907, published as *Pragmatism* (1907); and the Hibbert Lectures at Oxford in 1908/1909, published as *A Pluralistic Universe* (1909).

CHARACTER OF JAMES'S PHILOSOPHY

This brief biography gives no indication of that range and richness of James's experience which so struck those who knew him and which entered into everything he wrote. James was a highly social man whose friends formed an intellectual community of great distinction. Chauncey Wright, C. S. Peirce, Shadworth Hodgson, Charles Renouvier, Josiah Royce, George Santayana, John Dewey, Henri Bergson, and F. H. Bradley were a few of those whom James knew as friends and fellow laborers.

From all of these men and others James drew philosophical nourishment, and the very number of sources and influences renders the search for antecedents otiose. James was essentially an original thinker, and he borrowed only what fitted his own design. This must be maintained in spite of James's habitual humility and his characteristic generosity of acknowledgment.

James impressed his friends with his vitality and strength of character, with his open-mindedness and sympathy. His spirit and attitude were admired even by those whose philosophical conclusions differed radically from his own. Santayana, for example, in his witty and condescending memoir *Character and Opinion in the United States* is forced to praise James, at least as an enthusiastic and explosive force. Because James wrote as he talked, much of his vividness and personal style is retained in his works. The majority of James's books are simply transcriptions of lectures; they have all the virtues and vices of spoken discourse, and the circumstances of their presentation must help to determine the kind of analysis to which they can be fruitfully subjected.

James addressed himself to the people, not especially to other philosophers, and he listened to the people to find out what life meant to them. He respected not so much their common sense as their common feelings and hopes and would not allow his philosophy to dismiss cavalierly that which figured largely in the experiences of men. The people listened to James, and his books sold well. By the end of his life he was nearly a legendary figure, and he was generally regarded as the chief representative of American philosophy. Nevertheless, professional philosophers, when they have discussed James at all, have tended to concentrate on those of his ideas that, separated from the body of his work and often distorted, have achieved currency. To this general picture there are important exceptions, such as Ralph Barton Perry, who has done more for James scholarship than anyone else.

To provide a proper perspective for the study of James, three corrective measures must be taken. First, attention must be diverted from his life, however interesting, to his published philosophy. For all its validity the biographical motive can be, and has been, pressed to the point where it precludes philosophical clarity. Second, James must be seen within the general philosophical tradition, in relation to the fundamental philosophical problems that he attempted to solve and not in relation to his position as a distinctly American thinker. To attempt to evaluate James's philosophy in terms of his American background is neither more nor less rewarding than to attempt to evaluate Immanuel Kant, say, in terms of his

German background. Third, the objective aspect of James's philosophy must be stressed. James himself thought that philosophy involved the subjective factors of temperament and personal vision. In the first chapter of *Pragmatism,* he drew a very plausible correlation between tough-minded and tender-minded temperaments and empirical and rationalist philosophical positions. Again, in the essay "The Sentiment of Rationality" James argued that there can be no adequate definition of reason which ignores the feeling of rationality, the ultimate sense of logical fit. James believed that the subjective (or what might better be called the aesthetic) dimension was a feature of philosophy as such. James's philosophy is subjective, therefore, because it is philosophy, not because it is James's philosophy. Objectivity, like truth and reality, was redefined, not abandoned, by James.

The remainder of this entry is divided into sections on James's psychology, philosophy of religion, pragmatism, and metaphysics. This arrangement is simply an expository device. If pragmatism is a theory of all belief, then religious philosophy is a subdivision of pragmatism. If pragmatism is a description of what actually happens when men seek truth, then it is part of psychology. If the dualism between human and natural processes is finally inadmissible, then psychology is a chapter of general metaphysics. The interdependence of the various parts of James's philosophy, suggested here, will be exhibited below.

PSYCHOLOGY

The *Principles of Psychology* (1890) is, according to James himself, "mainly a mass of descriptive details"; certainly, this work more than any other justifies Alfred North Whitehead's remark that James's primary task was philosophical assemblage. The *Principles* "assembles" in two senses. First, there is a brilliant gathering, through extensive quotation and reference as well as careful documentation, of relevant material from the Scottish, English, French, and German schools. Second, there is the exhibition of facts which may never have appeared prominently in any system, either of psychology or of philosophy.

It has become customary, and it is certainly legitimate, to praise the *Principles* for its sensitive evocation of the evanescent inner life. It is indeed a kind of generalized psychic autobiography by a master of introspection, but it is much more than a document of literary psychology. The concrete rendering of experience is an essential element in the development of James's mature philosophy, for when he spoke of the world as "a world of pure experience," he referred to experience as it is described in the

Principles. If experience had not the ramifications and possibilities so lovingly and exuberantly detailed by James in his "psychological" writings, it could never have become, as it did for James, the central image of complete reality. Moreover, James was not in his early days merely "collecting" facts whose subsequent careers happened to include the incident of being generalized into a total world view. James, as he said himself, "hated collecting" (Perry, op. cit., p. 225). The material of the *Principles* is already thrown into philosophical form, is already illuminated or stained (however one decides the matter) by the foundational metaphysical categories that recur, with greater generality, in the later works.

DESCRIPTION. If the *Principles* is to be regarded as primarily a descriptive work, one must be clear about what is involved in description as James understood it. He was convinced that pure description in the manner of phenomenology is impossible. Description cannot be other than conceptual; concepts, in turn, are tools of classification that have inexpugnable conventional and theoretical elements. Concepts do not passively mirror; they select according to human interests and purposes. Assumptions, James maintained, have a way of establishing themselves "in our very descriptions of the phenomenal facts" (*Principles,* Vol. I, p. 145). Naive phenomenology attempts to eliminate assumptions from descriptive statements. This is an impossible task if for no other reason than that every allegedly assumption-free phenomenology must itself make doubtful assumptions, including the assumption that there can be description without classification. James's own approach was to examine the assumptions involved in all descriptions, making those assumptions "give an articulate account of themselves before letting them pass" (loc. cit.). Pragmatism as it appears in the *Principles* consists simply in spelling out what claims our theories and assumptions make for us and in eliminating elements which are superfluous, elements, that is, which can be eliminated without changing the tenor of what we really want to say. Pragmatism here can be fruitfully regarded as a general theory of theory criticism, as an attempt to make clear what we are actually committed to by the theories we entertain. The chapters that criticize the conscious automaton theory (Vol. I, Ch. 5) and the mind-stuff theory (ibid., Ch. 6), respectively, are indeed the first extended exercises in pragmatic criticism.

SCIENCE AND METAPHYSICS. Purely phenomenological description being considered impossible by James, the question arises as to what is scientific about the *Principles.*

The standard interpretation—the interpretation upon which the judgment of its great historical importance is based—finds the work very nearly the first attempt to treat psychology from the standpoint of a natural science—that is, descriptively and apart from metaphysical theories. The sharp distinction which we are likely to draw between scientific theories and metaphysical theories is difficult to sustain from James's own point of view and therefore cannot be used to differentiate the *Principles* from metaphysical treatments of the same subject matter.

A much more pregnant distinction is that between a priori and a posteriori metaphysics. A priori metaphysics was, for James, a totally illegitimate enterprise consisting of vacuous abstractions excogitated apart from any experience of the world. Throughout his work James often referred to a priori metaphysics simply as "metaphysics," and his frequent criticisms of metaphysics must therefore be carefully interpreted in their contexts. The *Principles* is antimetaphysical where metaphysics means "scholastic rational psychology" or "philosophical pyschology."

The more interesting problem is defining the relation between the *Principles* and the kind of metaphysics of which James did approve, a posteriori metaphysics, which is continuous with science and, like science, is both descriptive and theoretical. Here the differentiation must be emphatic rather than absolute. The *Principles* may be regarded as a deliberate (and artificial) restriction of general metaphysical scope. Science, as James saw it, must grow into metaphysics. Explanation must become more complete and more comprehensive even if, as James certainly believed, it cannot become total and absolute. But science must *be* science before it can become metaphysics. In the *Principles* metaphysics is, necessarily, postponed; its positivism is provisional rather than dogmatic and final.

The relative autonomy that science is given in the *Principles* is "for the sake of practical effectiveness exclusively," as James said in his essay "A Plea for Psychology as a 'Natural Science'" (*Collected Essays and Reviews,* p. 317). Science left to itself, with its "convenient assumptions" unquestioned, is best able to accumulate a mass of factual details which lead to the subsequent enrichment and "thickening" of the content of metaphysics. The danger of premature metaphysical reconstruction is thinness, impoverishment of content, and abstraction.

MENTAL STATES. The basic assumption of the *Principles* and its "convenient" point of departure is the existence of mental states. The first task of psychology is to describe

the conditions of these mental states with as much detail and completeness as possible. Chapter 2 of the *Principles* is an extended examination of the ways in which various brain states condition various mental states. The search for conditions among bodily experiences generally and brain experiences particularly is the only alternative to treating mental states as frankly miraculous. James, the evolutionary naturalist, had to maintain that mental states grow out of physical states, in spite of whatever difficulties this view entails. Since mental states, in addition to arising from physical antecedents, themselves give rise in all cases to changes in the physical world, it seems utterly impossible to create any kind of dualistic ontological chasm between the two types of process, mental and physical. There is indeed a discriminable subject matter of psychology, which James referred to both as "mental states" and as "mental life." This subject matter must be treated autonomously, which means, in practice, guarding against the reduction of mental phenomena to nothing but physical phenomena in the interest of some schematic monism. In this context James at times spoke of "irreducible dualisms," but what he meant to emphasize might perhaps better be called "irreducible dualities," discriminations that remain what they are no matter what supervenient integrations may also be pointed out.

The whole question of the dualism between the physical and the mental is complicated by the fact that James was, even in the *Principles,* developing a view of physical nature at large which departed radically from the familiar deterministic, mechanical model. It is often maintained, for example, that James's treatment of the will as irreducible to antecedent mechanical factors creates a dualistic chasm between natural processes and characteristically human processes. This would be true only if James had retained the customary deterministic model of nature. James, however, did not retain this model; he would sooner have conceived of all nature as willful than of man's will as an exception to nature.

James believed that the borderline of the mental is vague. Mentality, as James defined it, exists wherever we find the choice of means for the attainment of future ends. Mental life is purposive in a way that involves the overcoming, through suitable invention and appropriation, of any obstacles lying in the way of its purpose. The mind is a tactical power that reveals itself in the struggle with its environment. The only kind of world in which minds can conceivably develop and be found is one in which success is neither automatic nor impossible. An interesting consequence of James's view is that an omnipotent God could not have a mind; neither could a

purely contemplative deity. The notion of mind as an instrument within the general economy of purpose and resistance to purpose, a notion which has justly been called "biological" and "Darwinian," is simply an ungeneralized expression of pragmatism.

Although it is necessary to consider mental states as "temporal events arising in the ordinary course of nature" (ibid., p. 319), with emphasis on their natural antecedents and results, it is also necessary to consider mental states in themselves as realities to be described as they are found with their generic particularity and variety intact. Here again, it must be emphasized that James was not attempting a phenomenology of mental life or consciousness. What he was attempting was the provision of adequate description that would not be guilty of gross oversimplification or distortion.

INTROSPECTION. Adequate description must, of course, be based somehow upon observation, and, James maintained, the principal method of psychology is introspective observation. Introspection, as an observational process, is similar to other kinds of observation. James could find in introspection no peculiar epistemological characteristic; it is neither more nor less fallible than other kinds of observation. Its frequently alleged infallibility, based on some notion of the immediate relation obtaining between a mind and its contents, is simply contradicted by experience. Even if feeling is unmistakably what it is, our "naming, classing, and knowing" (*Principles,* pp. 189–190) of every feeling share in the notorious general human fallibility. The truth of any observation, introspective or otherwise, is not to be found in the character of the source of observation but in the consequent service, especially theoretical service, which the observation and its correlative preservation in description can be made to render. There is therefore no simple and immediate verification of observations, no once and for all validation of descriptions. For James "the only safeguard [of truth] is the final *consensus* of our further knowledge about the thing in question, later views correcting earlier ones until at last the harmony of a consistent system is reached" (ibid., p. 192). James's own descriptions in the *Principles* must lend themselves to this kind of pragmatic corroboration.

THOUGHT. The famous "descriptive" chapter, "The Stream of Thought" (perhaps the heart of the *Principles*), cannot be evaluated from a simply empirical point of view. What is described and how it is described are determined by markedly theoretical affinities and avoidances. James singled out five traits of thought in that chapter: (1) Thought tends to be part of personal consciousness—

that is, thought is not experienced as simply *a* thought but as *my* thought; (2) thought is always changing; (3) within each personal consciousness thought is sensibly continuous; (4) thought deals with objects independent of itself; and (5) thought is selective and has interests. The metaphysical model that James had in mind here is of a process that is partially determined and partially self-determining—that is, centered or focused and essentially temporal. Although the analysis in the *Principles* is limited to one kind of process, consciousness, the structure of the analysis is similar to that Whitehead offers of all actual occasions. James himself came to believe that all of reality must be describable in terms like those used for human experience. This belief is elaborated in *Essays in Radical Empiricism* as the notion of a world of "pure experience."

Each of the five traits of thought which James distinguishes repudiates some important philosophical position. One dimension of James's work clearly apparent in the *Principles* is a sustained criticism of the "classic-academic" version of mind. No easy summary of what this meant to James is available, but its main features would seem to be the marshaling of instances of mental phenomena according to a priori canons of clarity and rationality, the overwhelming influence of the assertive paradigm (as opposed to the judgments implicit in making and doing) in construing the problems of belief and judgment, and allegiance to the spectator theory of knowledge with whatever passivity is therein involved. These attitudes James attacked in the name of a richer experience, encompassing all the concrete information we possess about the functions of mind. This is the information, so carefully assembled and considered in the *Principles,* which James urged the epistemologist to work into his official model and the philosopher generally to consider in making his pronouncements.

EXPERIENCE. The appeal to experience is not new in philosophy; James was solidly in the venerable tradition of empiricism. But empiricism in its classic British form is essentially an epistemological position that regards experience as an exclusive witness before a cognitive tribunal in which other sources of evidence are ruled out of court as uncertain or unreliable. The genius of James's empiricism lies precisely in ruling nothing out of court. His theory of experience, the object of so much of James's later labor, is perhaps the first such theory which is cosmological, rather than strictly epistemological, in intention and logical form. This shift of the total frame of reference within which experience is considered has, for better or worse, influenced a subsequent movement in philosophy typified by Whitehead and his disciples. It is this influence which points to the main philosophical significance of the *Principles.*

PHILOSOPHY OF RELIGION

Even in the introduction to *The Literary Remains of the Late Henry James* (1885), a relatively early work that might be thought no more than an act of filial devotion, James's own ideas about religion were quite clear. There is, of course, a sympathetic exposition of his father's superpersonal theological monism, for William James could honestly admire his father's "instinct and attitude" even if he could not condone the "cold accounts" and abstract formulations of the elder James's system. It is religious experience, rather than religious doctrine, that matters. Unless it is a part of vital experience, religion becomes "fossil conventionalism." Here James shared his father's attitude; his father wrote so much, according to James, because he was dissatisfied with every verbal encapsulation. Writing was a necessary evil and, like the labor of Sisyphus, self-stultifying.

That James could not accept in any unqualified way the religious vision of his father is evident. The difficulty is simply this: "Any absolute moralism is a pluralism; any absolute religion is a monism" (*The Literary Remains,* p. 118). The recognition of the essential opposition of morality and religion was clearly made by the elder James. The logic of his system required him to reject the finite moral agent with his frantic moral efforts. It is certain that James benefited from his father's insight even though he aligned himself with morality and pluralism. The working attitude of the healthy mind must always be, for James, a moral one which takes seriously the difference between good and evil and which commits itself to struggle for the first and against the second. To adopt the religious attitude is to step out of life's fight and to justify that withdrawal by some belief about the character of the world and either the ineffectiveness or superfluity of action within it. For James the character of the world, the nature of reality, does not justify, as a general attitude, the quietism that religion counsels. On the contrary, the world is the kind of place in which moral endeavor is, as a rule, supremely worthy. James neither denied the satisfaction that religion gives to many nor declared that satisfaction illusory. The very fact of pluralism allowed him to suppose at least some aspect, however fragmentary, of reality that justifies the religious option. Religious belief gives us, in James's famous phrase, a "moral holiday." Like any holiday it may be enjoyed for its own sake; more

important to James, however, holidays indirectly affect the work week.

EVOLUTIONARY THEORY. James was strongly influenced by the Darwinian theory of evolution and was therefore predisposed to find in all feelings, including religious feelings, clues about what the world is like. Feelings that evolved in the world must somehow reflect the world. The most eccentric fancy, for example, tells us that we have the kind of world in which such a fancy is possible.

Evolutionary theory, as James saw it, begins with the presupposition that each part of reality has a function, that each part is in some way or other good for something or other. The strictly useless, according to such a theory, cannot endure, and all flourishing realities command a certain minimal respect. Religious experience is not especially justified by evolution because nothing is *especially* justified. Religion and irreligion, insofar as they both exist, are exactly equal before the evolutionary tribunal. Belief in evolution, at least as James interpreted that belief, makes simple dismissal impossible; even that which is evil cannot be negligible. The questions must be asked of religion as it must be asked of everything. How is it that it came to be what it is? What is it for?

ANTECEDENTS AND VALUE OF RELIGION. In his major work on religion, *The Varieties of Religious Experience,* James attempted to account for the antecedents and value of religion. The question of how it came to be what it is, is a matter of classifying religious feelings and religious propensities with other kinds of human experience which are found to be similar to them. The initial task, therefore, of *The Varieties* is the provision of a "descriptive survey" beginning with as many and as varied examples of typically religious experience as possible. The emphasis, here as elsewhere, is on spontaneous religious emotions rather than theological interpretations or institutional prolongation and regularization.

James was scrupulously careful to explain religious phenomena by ordinary scientific laws and principles, if at all possible. Accordingly, religious visitations of all kinds are classed as sudden influxions from the subject's own subconsciousness. Conversion is seen as the radical rearrangement of psychic energy around some new center of interest. Examples of this kind of felicitous theorizing could be multiplied.

James, however, was equally concerned with promoting the thesis that nothing said about the history or genesis of religious phenomena can shed the slightest light on the spiritual worth and significance of those phenomena. The older dogmatists attempted to justify religion once and for all by pointing to its privileged origin in some kind of revelation; newer dogmatists—the "medical materialists"—attempted to discredit religion once and for all by pointing to its disreputable origin in some curious bodily state. Neither approach is acceptable. Religion must be judged in the same way that everything else is judged, by proving itself useful (in specifiable ways) in some possible future. Religion must "run the gauntlet of confrontation with the total context of experience" (*The Varieties,* p. 426). This context includes the collection of all our established truths as well as all the exigencies of our affective and intellectual natures. Therefore, the defense of religion that can be found in James is not based on appeals to either mere social utility or subjective feeling. The question of the truth of religion arises only when religion makes some concrete, specific prediction about the world's future. Religion having framed its hypotheses, these hypotheses are supported or refuted in terms set out by James's general theory of belief, known as pragmatism.

BELIEF. James's notorious defense of the right to believe in the widely read essay "The Will to Believe" and elsewhere, though generally given a limited religious interpretation, is, in fact, not primarily a defense of religious belief but of moral belief, belief in the efficacy of action, including, as an important instance, the active experimentalism of modern science. The point of James's doctrine is its repudiation of the methodological caution epitomized by the Baconian injunction not to "suffer the understanding to jump and fly from particulars to remote and most general axioms" or by the Cartesian rule "that the understanding should always know before the will makes a decision." James was making a general statement in support of the method of empirical science, with special emphasis upon the initially unwarranted character of every scientific hypothesis. We must at least believe our hypotheses sufficiently to bestir ourselves to test them; without our active interest in and partisanship of belief the enterprise of science would come to a silent, ghostly end. It is the theoretical daring of science that inspired James. His doctrine on the will to believe is no fuzzy ad hoc concession to self-indulgent piety but an integral part of his general theory of belief.

The doctrine of the will to believe, with all its genial encouragement of risking belief, is balanced, in James, by an unremitting fallibilism. Belief, however justified originally, is always conditional. Belief must continue to justify itself; there is no possibility of a definitive, once and for all certification. Both the options of practical life and the

tenets of religion may be justified as peculiar kinds of scientific hypotheses, the first sort peculiar because of their limitation to some particular matter or situation, the second because of their elusive generality. There seems to be no difficulty in interpreting the practical decisions of life, with their inherent predictions about relevant future events, as closely analogous to the predictive, if not to the explanatory, activity of science. Religious belief, on the contrary, may seem intrinsically isolated from the arena of confirmation and disconfirmation and, therefore, alien to the scientific pattern. For James all genuine belief, including religious belief, must address itself to the tribunal of experiment. If all possible procedures of verification are irrelevant to some religious doctrine, then that doctrine cannot rightly be the object of any belief; such a doctrine, having no positive content, would be meaningless.

James did, in fact, think that at least a few religious hypotheses were truly empirical, that they made a difference which somewhere could be noticed. James was careful not to prejudice the case against religion by adopting some single restrictive paradigm of verification. If religious belief makes a difference, it is not altogether surprising that we should have to look for that difference with greater sympathy, imagination, and patience than we are used to exercising in more straightforward cases.

JAMES'S RELIGIOUS BELIEF. James's own religious belief, expressed without dogmatism in the last chapter and the postscript of *The Varieties* and again in the last chapter of *Pragmatism,* consists essentially in the affirmation that the world is richer in realities than conventional science is willing to recognize. Religious experience at least suggests that there is what James called a "higher part of the universe" (ibid., p. 516) which, though beyond the immediate deliverance of the senses, is nevertheless effective in the world in a way that makes a noticeable difference. This assertion that the higher part makes concrete and local differences constitutes James's famous "piecemeal super-naturalism" (ibid., p. 520), really only a name for an enlarged and tolerant naturalism. The higher part is perhaps impossible to define given the present state of our knowledge. Certainly, for James it cannot be the infinite and omnipotent God of traditional theism who guarantees the successful outcome of the universe. The higher part is better conceived as a finite power (or perhaps even a polytheistic medley of powers) that, like men, works toward the good and helps achieve it. This is a theological notion compatible with the significance of moral choice in a way that the conventional notion is not.

The vagueness of much of James's treatment, a vagueness he frequently admitted to, has been amply noted by his critics. What must also be noted, however, is the forceful way in which a fundamental idea of our tradition, the idea of God, has been radically reconstructed by James in a manner that makes the idea more consonant with religious experience and that frees it from the congeries of paradoxes associated with the problems, among others, of free will and of evil.

PRAGMATISM

The chief locus for James's pragmatism is, of course, his immensely popular and influential work *Pragmatism: A New Name for Some Old Ways of Thinking.* The origin of pragmatism, however, as James always acknowledged, is found in C. S. Peirce's essay "How to Make Our Ideas Clear," published in 1878. This essay remained generally unnoticed until James's 1898 lecture on pragmatism, "Philosophical Conceptions and Practical Results," at the University of California (in *Collected Essays and Reviews*). This lecture may be taken as the beginning of pragmatism as an explicit, although never a unified, movement, but the essentials of the doctrine as developed by James are found earlier in the *Principles of Psychology* and even in the introduction to *The Literary Remains of the Late Henry James.* Indeed, James rarely wrote anything, early or late, which did not at least imply pragmatism.

Pragmatism may be approached as a mere method, an eristic device which vouchsafes hints as to either the meaning or truth of propositions or to both together; it may be taken as a theory of meaning or a theory of truth or, once again, as a theory of both meaning and truth. A. O. Lovejoy in "The Thirteen Pragmatisms" insisted upon distinctions such as these and chided James for neglecting them. In fact, though James erred in emphasizing the autonomy of the various aspects of pragmatism, he wished to persuade his readers of the truth of whichever part he was recommending at the moment, and he therefore tended to stress the self-contained plausibility of elements which, if plausible at all, are so only when taken together in the total view.

It is the contention of James's sympathetic commentators that his pragmatism is plausible as nothing less than a theory of reality. It is the descriptive naturalism central to James that saves pragmatism from being merely a convenient device for settling philosophical disputes. The fundamental assumption that generates pragmatism is the assumption that "knowledge," "truth," and "meaning," as well as any other possible object of discourse or any other possible subject matter for philosophical dis-

cussion, must be explicable as a natural process or as a functional medley or competition of natural processes. The world, for James, is a plurality of temporal processes related in so many specifiable and concrete ways that it cannot be accounted for by abstract speculation alone.

James believed that an individual's personal, peculiar vision counts most in philosophy; not surprisingly, it is vision, not method, which is primary in James. Reality dictates the method by which it may be known. The gross encounter with the world is primary in the determination of what character the world will have for us. Theories of knowledge and of method, existing at a high level of abstraction, are second to the ineluctable fact of experience breaking in upon us.

TRUTH AND MEANING. James's pragmatism is an attempt to formulate a metaphysics of truth and of meaning. Logically, such an attempt is exactly on a par with the metaphysical treatment of any discriminable subject matter. By metaphysics James meant the quest for adequate general descriptions either of reality as a whole or of some distinguishable part of it. The descriptions offered by metaphysics are, in principle, continuous with those offered by science, although their range and focus may differ. The distinction between science and metaphysics was not crucial for James; he saw the possibility of unrestricted intercourse and cooperation exactly where later thinkers are likely to see division and competition for cognitive respectability. It is therefore helpful from James's own point of view to regard pragmatism's description of truth in the same light, say, as geology's description of continental drift. Both are characterizations of natural processes, and both attempt to portray what actually happens.

The metaphysical perspective of *Pragmatism* itself (even apart from the context of James's total work) is so unmistakable that the prevailing interpretation of pragmatism as a set of newly devised rules that serve a certain practical purpose seems totally unjustified. If James was right, people have always unwittingly followed the "pragmatic method." A purely theoretical illumination like pragmatism will indeed clarify practice and improve it; for James no process—least of all, a process where human influence intervenes—is so canalized that modifications are utterly beyond hope. Metaphysics must recognize the plasticity of its subject matter as well as the limits of plasticity.

Pragmatism discusses truth without falling into the epistemological frame of mind habitually assumed by professional philosophers. James's description of actual processes rejects the usual question of what we ought to believe. If there is something we "ought" to believe, the authority of the "ought" itself must be explained concretely. There is no authority which is merely formal. Pragmatism therefore becomes the justification of truth's prestige in terms of the world's exigencies.

One factor discernible in the complex process called "believing truly" is the compulsion of fact or the unavoidability of a residual nonplastic pole in determination of what is true. It is here that we find truth's authority and importance.

Truth, for James, is what we must somehow take account of if we are not to perish. Men cannot in the long run believe what is false not because truth extracts from them a categorical imperative in its own behalf but because reality compels men in spite of themselves, and it is from this that the authority of truth is derived. "Agreement with reality" as a criterion of truth cannot be taken to indicate any fixed structural relation (such as the "copying" relation). The truth relation is characterized not by stasis but by the fluid resourcefulness of functional harmony. The character of the harmony itself may be anything that is compatible with survival. Even in the Darwinian world that James pictured, there is more than one way to survive as truth.

Raw compulsion may account for the authority of truth, but truth is hardly a mute registry of bruises received from the world. Indeed, people create truth, and truth is so exclusively the result of human activity that James's own view has been called "humanism." Central to this humanism is the distinction (so often insisted on by James, so often neglected by his critics) between ideas and objects, between what takes account and what is taken account of. The objects constitute what James referred to as the "unhumanized fringe," the yet to be conceptualized. What must be taken account of is presumably just what it is. Truth and falsity, however, apply not to objects but only to our ideas of objects. Our ideas of objects are mutable in the sense that we can modify ideas or replace one idea by another. In such a situation ideas are to be judged better or worse; such judgments fall between the ideal limits of complete good and complete bad. These are the same limits usually called "truth" and "falsity." Truth is viewed by James as one species of the good. The good is itself interpreted as a plurality of "good fors." In this view ideas are instruments for taking account theoretically, practically, aesthetically, and so on, of reality.

The point of James's view of truth, as Bergson suggests in *The Creative Mind* (p. 256), is that truth is to be described as an invention rather than a discovery. Truth,

or propositions which are true, might be compared to cleverly made maps or apt predictions. If they serve us as we expect them to serve us, we have no legitimate complaint. There are, of course, ontological relations between such inventions as maps, predictions, and propositions (as well as inventions such as light bulbs and cotton gins) and what, in summary fashion, is referred to as reality. Inventions are conventional but not arbitrary. They are not arbitrary because they must somehow take account of reality; they are conventional because they embody one way (among alternatives) for that taking account.

The relationship between two processes within experience constitutes truth—(1) the inventive process or activity of proposing, of framing propositions, and (2) the particular chain of natural processes with which the proposition in question is concerned. The emphasis on the truth relation as a relation within experience and totally construable in terms of "positive experienceable operation" (*Meaning of Truth,* p. x) is one instance of James's general metaphysical position that all relations are within experience. Experience, as it were, forms a cohesive, self-explanatory whole; it hangs together, as James liked to say, and needs no transcendental connectives or supports.

Since the truth relation was taken by James's contemporaries as transcending experience, the strategic function of pragmatism is apparent. It is an extension of radical empiricism, an attempt to place the particularly troublesome truth relation within the total perspective of metaphysical naturalism.

James spoke of true ideas as those which "work," which "lead" propitiously, which give various kinds of satisfaction, and which bring about various kinds of success. He also spoke approvingly of the "cash value" of ideas and thought that meaningful ideas are those which make "practical differences." These highly (and obviously) metaphorical expressions have confused many commentators.

There are those who have found James vague. He intended, however, that all these metaphors should be functionally specific and indeterminate only in respect to instances. "Working," "leading," "satisfying," and "succeeding" are generic terms as respectable and as precise as terms such as "copying" and "agreeing." They are, however, functional rather than static. For those who see functions as inherently insubstantial, shadowy, and vague, any functional definition of truth will be unacceptable, but this hardly seems to be an insurmountable objection.

Other commentators have seized upon the prominence of the "practical" in James's account of meaning and truth. Surely, this is a difficult term in James, if for no other reason than that he used it as it is used in ordinary language—that is, variously. His prevailing usage, however, cannot be equated with some narrow notion of commercial efficiency. Pragmatism is not a philosophical vindication of the businessperson's common sense or acumen. It was James, after all, who saw the tendency to worship "the bitch goddess, success," as the principal weakness in the American character. It is especially in our theoretical and moral practice that meaningful ideas, according to James, are to make a difference. Belief divorced from action may well be morally effete, and James set forth this point, though not in its crudely athletic form; his main thesis, however, was that belief divorced from action is *theoretically* inexplicable. James's quest was not for a formula that would rouse his fellows to civic virtue or efficiency of some peculiarly American sort but for criteria which would be descriptively adequate to belief. His philosophical purpose was to find out what it means to believe, what it means to entertain ideas which may be meaningful and true.

METAPHYSICS

Although frequently attempted, it is not possible to isolate a final "metaphysical" period in James. The theory of the various kinds of belief, which formed his philosophy of religion and of pragmatism, has as a conspicuous feature the assumption that anything which can be meaningfully said about belief must take into account the grounding of belief in natural processes, particularly human processes. It is possible to formulate a theory of belief apart from a general metaphysics only by adopting an assumption that James explicitly rejected. This is the epistemological assumption that an existentially neutral *logic* of belief can be constructed. In fact, on this assumption existential reference is regarded as the indication of a certain categorial confusion frequently labeled "psychologism." James insisted, even in his least metaphysical passages, that "knowledge," "belief," "truth," and "meaning" indicate discriminable natural existences in the same way that all terms do, or at least all terms that figure as possible subjects of philosophical discussion. This is simply the corrective application of the basic postulate of metaphysical naturalism to the recalcitrant subject matter of epistemology. James regarded the prominence accorded this subject matter since the time of Kant as a distortion of perspective that his own philosophy was intended to correct.

But for the development of James's metaphysics, the psychology—or the treatment of characteristically human processes—was even more important than the theory of belief. His metaphysics was simply the attempt to apply to all reality categories originally framed for human experience. The radical generalization of the concept of experience, so central in James, is necessitated by two ideas. First, James believed that metaphysical dualism is always unacceptable. Whatever dualities or pluralities are distinguished for certain purposes, ultimately the philosopher cannot operate with irreducible categories. Second, if one categorial set or one metaphysical model must be adopted, James believed that this categorial set or metaphysical model must arise from the consideration of our own experience. It is only of human experience that we have anything like "complete concrete data." Anthropocentrism is therefore thought to be a consequence of any genuine empiricism. For James even panpsychism is at least a possible and interesting empirical hypothesis.

In the seminal essay "Does Consciousness Exist?" (1904), James asks us to assume that there is just one "primal stuff" of which everything in the world is made. This stuff, called "pure experience," is not a single entity, like Thales' water; "pure experience" is a collective name for all sensible natures, for all the "that's" which anywhere appear. The monism implied in this concept of the *one* primal stuff is therefore merely formal. Explanatory monism must be accepted before specific metaphysical descriptions may be attempted. In the same essay James provided a sample of metaphysical description. Consciousness is there described as a certain relation of parts of experience to one another. Consciousness is not an unanalyzable substance but simply the name that is given to a certain discriminable function within experience, the knowing function. All other functions are to be explained in the same way as consciousness. Functional explanations in terms of related strands of experience allow the abrogation of traditional dualisms because the same isolable part of experience may enter into many and various relations. What is subject may also be object; what is object may be subject. The knower may also be the known and vice versa, depending on the "context of associates" within which the part of experience so labeled is considered.

James's frequent use of the expression "part of experience" was not meant to suggest that experience has an atomistic constitution. Indeed, James constantly argued against the "pulverization" of experience in British empiricism. We experience not isolated parts but continuities of indeterminate extension. Parts and the rela-

tions between parts, both directly experienced, form new functional wholes. The use of the word *part* indicates nothing more than the theoretical and practical need for emphatic focus.

James regarded the "concrete" data appealed to by British empiricism as abstract, intellectual products; he accused that empiricism of committing what Whitehead later called "the fallacy of misplaced concreteness." If James's philosophy is to be classified historically as a criticism of British empiricism, it must also be emphasized that it is self-consciously offered as an alternative to the criticism of empiricism by idealists from Kant to Royce.

If the facts pointed to by the usual empiricism are abstract in the sense of being incomplete, inadequate, or partial, it still cannot be said, as it is said by absolute idealism, that there are no facts at all or that there is just one fact, the immovable "block-universe," as James referred to this notion that he always found slightly ridiculous. There are no general grounds, according to James, for the rejection of the obvious particularity and individuality that characterize the plural parts of experience. James certainly held that any allegedly self-sufficient fact may turn out from some point of view or for some purpose, intellectual or practical, to be partial or abstract. But there are many points of view and many purposes with equal titles to rationality. There are therefore many levels of fact, and words such as "part," "whole," "unity," "concrete," "abstract," "particular," and "individual" do not qualify any reality simply or always. These words are definable only within purposive contexts. Absolute idealism, in contrast, sets up a single standard of rationality and develops a characteristic vocabulary which it applies *simpliciter.* This procedure yields a certain clarity and neatness but suffers from "vicious intellectualism" or *"the treating of a name as excluding from the fact named what the name's definition fails positively to include"* (*A Pluralistic Universe,* p. 60).

The notion of self-sufficient centers within experience emphasized by James as particulars or individuals is a generalization of that first trait of the stream of thought referred to in *Principles of Psychology.* Although made familiar by Whitehead, it was James who first used the concept of personal order to replace the traditional concept of some fundamental and thinglike substance.

Other traits of existence that impressed themselves on James are first annunciated in the *Principles* as traits of the stream of thought or of the central human process. So, for example, the doctrine that thought is always changing becomes the doctrine that reality is always changing. Again, human freedom is eventually inter-

preted as a special case of universal indeterminism. My future, though continuous with my past, is not determined by it. Just so the future of the world; although it grows out of the total past, it is not a mere result of that past. If I am creative—that is, if human freedom is effectual—then the world is creative, if for no other reason than that I am part of the world. What is constant in my behavior is the result of habits that never entirely lose their flexibility. In the same way the constancies charted by the laws of science are only more inveterate habits.

Objections can be raised against all these contentions, especially in the enthusiastic, unguarded form in which James made them. They do, however, add up to a serious philosophical position which has, in fact, borne fruit in the subsequent history of philosophy and is worthy of continuing serious study.

Bibliography

WORKS BY JAMES

Only James's chief works are listed here. For a complete list see Perry's bibliography, below. Secondary literature is copious, and only the most important works are listed here. Those who wish to sample the periodical literature are advised to consult the fifty-year (1904–1953) index of the *Journal of Philosophy* (New York, 1962), under the heading "James."

The Literary Remains of the Late Henry James. Edited and with an introduction by William James. Boston: Houghton Mifflin, 1885.

Principles of Psychology, 2 vols. New York: Holt, 1890. Regarded by many as James's major work, it is a prime source not only for his psychology but also for his metaphysics.

The Will to Believe and Other Essays in Popular Philosophy. New York: Longman, 1897. In addition to the title essay, the essay "The Sentiment of Rationality" is, if interpreted in the context of James's total thought, an important source of his basic convictions. The book also contains the famous essay "The Dilemma of Determinism," James's fullest statement of his views on free will.

The Varieties of Religious Experience: A Study in Human Nature. New York: Longman, 1902.

Pragmatism: A New Name for Some Old Ways of Thinking. New York: Longman, 1907.

The Meaning of Truth: A Sequel to "Pragmatism." New York: Longman, 1909. A collection of polemical essays; the preface is especially important, for it answers certain criticisms of pragmatism and states James's conception of the relation between pragmatism and radical empiricism.

A Pluralistic Universe. New York: Longman, 1909. A sustained criticism of absolute idealism and intellectualism; contains chapters on G. W. F. Hegel, Gustav Theodor Fechner, and Bergson.

Some Problems of Philosophy: A Beginning of an Introduction to Philosophy. New York: Longman, 1911. James's last project; it is incomplete. Valuable for its many very clear formulations; three chapters outline his theory of perception.

Essays in Radical Empiricism. New York: Longman, 1912. A related series of essays expounding James's mature philosophy; the essays "Does Consciousness Exist?" and "A World of Pure Experience" are especially important.

Memories and Studies. New York: Longman, 1912. Fifteen popular essays and addresses selected by James's son Henry James; includes commemorative addresses on Agassiz and Emerson, an essay on Spencer, and several essays on psychical research and academic life.

Collected Essays and Reviews. New York: Longman, 1920. Thirty-nine articles, selected by Ralph Barton Perry, extending from 1869 to 1910; many historically important works, including the California lecture "Philosophical Conceptions and Practical Results."

Letters. Edited by Henry James. Boston: Atlantic Monthly Press, 1920. Charming letters, primarily of biographical and historical significance, edited by James's son.

WORKS ON JAMES

Aiken, H. D. "American Pragmatism Reconsidered: William James." *Commentary* (September 1962): 238–266.

Bergson, Henri. "On the Pragmatism of William James: Truth and Reality." In his *The Creative Mind,* translated by Mabelle L. Andison. New York: Philosophical Library, 1946. Brief but provocative development of the thesis that to understand James's pragmatism, we must modify our general conception of reality.

Dewey, John. *Characters and Events,* Vol. I. New York: Holt, 1929. Book I, Ch. 12. "William James" consists of three occasional pieces that together provide an informal but penetrating analysis of James's contribution to and place in American philosophy.

Lovejoy, Arthur O. *The Thirteen Pragmatisms and Other Essays.* Baltimore: Johns Hopkins University Press, 1963. In addition to the very influential title essay, there are eight other essays on James or pragmatism.

Moore, G. E. *Philosophical Studies.* London: Routledge, 1922. "William James' 'Pragmatism'" attempts to refute James from the commonsense point of view.

Perry, Ralph Barton. *Annotated Bibliography of the Writings of William James.* New York: Longmans, Green, 1920. A listing of 312 items from 1867 to 1920, with helpful indications of each item's content and value.

Perry, Ralph Barton. *In the Spirit of William James.* New Haven, CT: Yale University Press, 1938. A solid and sympathetic philosophical interpretation of James. The chapters "An Empirical Theory of Knowledge" (Ch. 2) and "The Metaphysics of Experience" (Ch. 3) are especially noteworthy.

Perry, Ralph Barton. *The Thought and Character of William James.* 2 vols. Boston: Little Brown, 1935. A massive, richly documented study; the single most important work on James.

Royce, Josiah. *William James and Other Essays on the Philosophy of Life.* New York: Macmillan, 1911. An attempt to show James's place in American social history.

Russell, Bertrand. *Philosophical Essays.* New York: Longman, 1910. See "William James' Conception of Truth" and "Pragmatism."

Santayana, George. *Character and Opinion in the United States, with Reminiscences of William James and Josiah Royce and Academic Life in America.* New York: Scribners, 1920. Unsympathetic but extremely interesting in its own right.

William James Earle (1967)

JAMES, WILLIAM [ADDENDUM]

William James is to classical American philosophy as Plato was to Greek and Roman philosophy: an originating and inspirational fountainhead. Thinkers as diverse as C. S. Peirce, Josiah Royce, John Dewey and the late work of A. N. Whitehead took their point of departure from William James, especially his monumental *Principles of Psychology.* Influential philosophers elsewhere were also deeply influenced by James, for instance Henri Bergson, Edmund Husserl, Miguel de Unamuno, and Ludwig Wittgenstein.

With the completed publication of all of James's writings, including his manuscripts and notebooks, the full range and philosophical virtuosity of his work comes into focus. For too long the thought of William James was taken to be novel and intriguing but lacking in technical sophistication. In reading James the first response is one of elation at the apparent simplicity and obvious elegance of the literary style. After several careful and close readings, however, the philosophical depth and complexity emerge. The consequence of these more mature readings of James's thought are now found in many areas of contemporary philosophy—for example, the philosophy of mind, ethics, and the philosophy of religion. More significant still is that James represents a helpful philosophical stance, one that is wary of narrowness and rigid conceptual schematisms and affirms the messages of human experience no matter the source. William James believes that philosophy itself is "the habit of always seeing an alternative" ("Essays in Philosophy," *Works*, 1978, p. 4). He was convinced as well that no matter how recondite the issue in question—for example, the meaning of consciousness or his innovative doctrine of radically empiri-

cal relations—the kernel of the position taken could be articulated in prose accessible to the intelligent reader as well as to the philosopher.

The most salutary result of recent commentaries on the philosophy of William James has been the rescue of two of his most beleaguered positions, that of the pragmatic theory of truth and his doctrine of "The Will to Believe." In both areas James's thought was often subject to mocking dismissal and shallow interpretations. With the completion of James's *Works*, the girth and sophistication of his philosophy is now apparent. Witness, for example, the sterling introductory essays by H. Standish Thayer on James's theory of truth as found in "Pragmatism" (*Works*, 1975) and "The Meaning of Truth" (*Works*, 1975). Similarly, one finds an equivalently clarifying essay by Edward H. Madden in his introductory essay to "The Will to Believe" (*Works*, 1979).

The divide that has existed between mainstream analytic philosophy and pragmatism is no longer purposeful. Transformations of this conflict are now at hand. Hilary Putnam, for decades a major figure in contemporary philosophical thought, writes in his *Pragmatism* (1995):

> I believe that James was a powerful thinker, as powerful as any in the last century, and that his way of philosophizing contains possibilities which have been too long neglected, that it points to ways out of old philosophical "binds" that continue to afflict us. In short, I believe that it is high time we paid attention to Pragmatism, the movement of which James was arguably the greatest exponent.

Although in no way gainsaying the importance of specific philosophical contentions held by James, nonetheless it can be said that the most signal reason for paying serious attention to this work is found in his philosophical attitude, his approach to philosophical inquiry. William James was no stranger to philosophical debate or argument, as one finds in his brilliant and jousting correspondence with F. H. Bradley. Yet James was uneasy about closure, answers, and finality of any kind. In a "Notebook" entry of 1903 James writes of "bad taste," by which he means:

> All neat schematisms with permanent and absolute distinctions, classifications with absolute pretensions, systems with pigeon-holes, etc., have this character. All 'classic,' clean, cut and dried, 'noble,' fixed, 'eternal,' *Weltanschauungen* seem to me to violate the character with which life concretely comes and the expression

which it bears of being, or at least of involving, a muddle and a struggle, with an 'ever not quite' to all our formulas, and novelty and possibility forever leaking in.

For the thought and person of William James, the novel call of experience inevitably trumps categories of explanation. Consequently, possibility rather than solution becomes the philosophical watchword, especially in matters of profound human importance.

Bibliography

Since the original publication of *The Encyclopedia of Philosophy*, virtually all of William James's writings have been published in a critical edition. Under the general editorship of Frederick Burkhardt, see *The Works of William James*, 19 volumes (Cambridge, MA: Harvard University Press, 1975–88). William James is widely admired for his brilliant style of writing, and nowhere is that more apparent than in his letters. To that end, with John J. McDermott as general editor and edited by Ignas Skrupskelis and Elizabeth Berkeley, a critical edition of *The Correspondence of William James* has been published in 12 volumes (Charlottesville, NC: University of Virginia Press, 1992–2004). Of commentaries, the finest and most thorough is that of Gerald Myers, *William James: His Life and Thought* (New Haven, CT: Yale University Press, 1986). Other recent studies of note include: Samuel Henry Levinson, *The Religious Investigations of William James* (Chapel Hill, NC: North Carolina University Press, 1981); George Cotkin, *William James: Public Philosopher* (Baltimore: Johns Hopkins University Press, 1990); Charlene Haddock Seigfried, *William James's Radical Reconstruction of Philosophy* (Albany, NY: State University of New York Press 1990); Ruth Anna Putnam, ed., *The Cambridge Companion to William James* (Cambridge, U.K.: Cambridge University Press, 1997); David C. Lamberth, *William James—The Metaphysics of Experience* (Cambridge, U.K.: Cambridge University Press, 1999); Eugene Fontinell, *Self, God, and Immortality: A Jamesian Investigation* (New York: Fordham University Press, 2000); and Phil Oliver, *William James's Springs of Delight* (Nashville: Vanderbilt University Press, 2001). For an "Annotated Bibliography of the Writings of William James" and complete selections from his major works, see John J. McDermott, ed., *The Writings of William James* (Chicago: University of Chicago Press, 1977). The entire family is chronicled by R. W. B. Lewis in *The Jameses: A Family Narrative* (New York: Farrar, Straus and Giroux, 1991). Biographically, see Linda Simon, *Genuine Reality—A Life of William James* (New York: Harcourt Brace and Co., 1998) and Robert Richardson, *William James* (Boston: Houghton Mifflin, 2006).

John J. McDermott (1996, 2005)

JANKÉLÉVITCH, VLADIMIR
(1903–1985)

Vladimir Jankélévitch, the French moral philosopher, was born in Bourges. He was educated at the Lycée Louis-le-Grand and the École Normale Supérieure. Having become an agrégé in philosophy in 1926, he took his doctorate in 1933. After teaching at the French Institute in Prague and at various *lycées*, he served as lecturer at Toulouse from 1936 to 1937 and at Lille from 1938 to 1939. He was dismissed by the Vichy government in 1940 but returned to academic life in 1945 as professor at Lille, going from there to the University of Paris as professor of morals and moral philosophy.

Jankélévitch's philosophy is highly individual, though it displays a sympathetic understanding of widely divergent philosophical traditions. In content it has affinities with Christian morality and with the philosophy of Søren Kierkegaard. In expression it is idiosyncratic and always lively.

Jankélévitch's first notable work was *Henri Bergson*. On its first appearance, in 1931, it bore a prefatory note by Henri Bergson himself, praising its "intellectual sympathy." Jankélévitch's own philosophy made its first appearance in his main doctoral thesis, on Friedrich von Schelling's later philosophy, and even more clearly in his secondary thesis, on bad conscience (*La mauvaise conscience*). Bad conscience is consciousness directed not unreflectingly forward but regretfully backward toward its own past, which is irremediable because time is irreversible. The problem posed is how to restore the flow of living that tends to be halted by retrospective brooding. How is consciousness freed and time unfrozen? Jankélévitch did not favor the detachment from one's predicament effected by irony, precisely because it intellectualizes and detemporalizes that predicament. Time alone, in its flow, frees us.

In two of his postwar works, *Philosophie première* and *Traité des vertus*, Jankélévitch was perhaps at his best. Just as he rejected intellectual recourse to irony or conceptualization as consolations for the discontent attendant upon self-consciousness, so he showed, in *Philosophie première*, that the concern of metaphysics is not with the world of ideas, eternal truths, or transcendent models, which are ultimately as contingent as the

reality that they rationalize, but with the "entirely other Order" of radical contingency. Here, in effect, Jankélévitch suggested that "sufficient reason" is never really sufficient. The instant always brings novelty over and above the schemata that demonstrate its "necessity."

The real importance of this fact is moral and leads to the treatise on the virtues. In this work virtues are classified according to either their intellectual quality of equity or their "non-natural" quality of goodness, to use the language of G. E. Moore. For Jankélévitch the virtues of consistent conduct—the "virtues of the interval," fidelity and justice—are inferior to the creative "virtues of the instant," courage and charity.

JANSENISM

Jansenism is a polemical term introduced by Jesuit critics to label those sympathetic to the theological views of Cornelius Jansen, the Louvain theologian and later bishop of Ypres. Supporters of Jansen protested that Jansenism is merely a "phantom" of the Jesuits and preferred to be called Augustinians. Jean Orcibal (1953) draws attention to the considerable difficulties in providing a precise definition of the term *jansénisme*. Even so, Jansenism can be understood in contrast to Jesuit theology, and the Jansenist movement did play a particularly significant political role in pre-revolutionary modern France. Moreover, Jansenism is of philosophical interest given its connections, both real and perceived, to Cartesianism.

JANSENIST THEOLOGY

Jansen's main theological work is his *Augustinus*, posthumously published in 1640. He called for a return to the emphasis in Augustine on the importance of the workings of grace in the salvation of the elect. He was explicit in rejecting the view of the Jesuits, defended in the sixteenth century by the Spanish Jesuit Luis de Molina, that though grace is needed for salvation, it is also necessary that the will freely cooperate with the working of grace. For Molina, such freedom requires an "indifference" that makes it possible for the will to reject divine assistance. In

response Jansen insisted that since the grace that heals the will is fully efficacious, it determines the will to meritorious action in a way that excludes indifference.

The Jesuit charge was that the theology of the *Augustinus* gives aid and comfort to a heretical Calvinist view that God determines one's salvation in complete independence of the works of one's free will. Jansen's defenders countered that the standard Molinist line supports the heretical doctrine of Pelagius, which Augustine and the early church had condemned as heretical, that one's salvation is due to one's free actions rather than to the workings of grace.

Pope Urban VIII initially condemned the *Augustinus* in the 1643 bull *In eminenti* on the technical grounds that it violated an earlier decree in Rome prohibiting inflammatory remarks concerning free will and grace. This decree was connected to a bitter dispute at the end of the sixteenth century that pitted Molina and the Jesuits against Domingo Bañez and other members of the Dominican order (of which St. Thomas Aquinas had been a member). To resolve the dispute, Pope Clement VIII established the Congregatio de Auxiliis (Congregation on Grace) in 1597 to determine whether Molina's views were heretical. At certain points there were rumors that the decision was about to go against Molina and the Jesuits. However, the congregation ended in a stalemate, and Pope Paul V closed it in 1607 with a decree forbidding either side of the dispute to charge the other with heresy. He further promised a resolution of the issue at "an opportune time," but the issue remains unresolved to this day.

In the case of Jansenism, however, the church took action. In 1653 Innocent X issued the bull *Cum occasione*, which condemned as heretical or temerarious the following five propositions that anti-Jansenist theologians in the Sorbonne had claimed to find in the *Augustinus*:

(1) Some of God's commandments are impossible for the just despite their desire and their effort [to keep them], given the forces that they have presently and also the lack of the grace that makes them possible.

(2) In the state of fallen nature, no one [can] ever resist interior grace.

(3) For merit or demerit in the state of fallen nature, it is not required that man be free from the necessity of willing and acting; it is sufficient for him to be free from constraint.

(4) The Semi-pelagians admitted the necessity of interior prevenient grace for all good works, even

for the beginning of faith; but they were heretical in claiming that this grace is such that the human will may either resist or obey it.

(5) To say that Jesus Christ died and shed his blood for all men, without a single exception, is to speak as a Semi-pelagian (Denzinger 1963, p. 445f).

In 1656 Alexander VII closed a loophole created by *Cum occasione*, which failed to mention the *Augustinus* explicitly, and issued *Ad sacram*, which claimed that the propositions are to be found in Jansen's text in their condemned sense. Thus did Jansenism become a formally defined heresy within the Catholic Church.

FRENCH JANSENISM

Jansen was a friend of the French religious figure Jean Duvergier de Hauranne, abbé de Saint-Cyran, who served as the spiritual advisor to the reformist convent of Port-Royal des Champs. Though Jansenism began in Louvain, several theologians associated with Saint-Cyran and attached to Port-Royal as solitaires came to be identified as the leaders of the Jansenist faction. These individuals were known for their opposition to a moral laxism that they found in the work of the Jesuits. This aspect of Jansenism is most evident in the *Lettres provincials* (1656–1657) of the Port-Royalist solitaire Blaise Pascal (the brother of Jacqueline Pascal, a member of Port-Royal). Another famous solitaire, the Sorbonne theologian Antoine Arnauld (the brother of Jacqueline-Marie-Angélique Arnauld, the prioress of Port-Royal), wrote a defense of Saint-Cyran's penitential theology in the 1643 *De la fréquente communion*, and later was an active supporter of Jansen and the *Augustinus*.

Saint-Cyran had been an opponent of Cardinal Richelieu, the French first minister, and Cardinal Mazarin, Richelieu's successor, inherited a suspicion of those associated with Port-Royal. As part of a campaign against Port-Royal, Mazarin lobbied for an official condemnation of Jansenism in Rome. The effort resulted in *Cum occasione*, but Arnauld argued that the five propositions have both heretical and nonheretical senses and that the *Augustinus* endorses them only in their nonheretical senses. When Rome answered with the explicit condemnation of Jansen's text in *Ad sacram*, Arnauld then insisted on the distinction between questions of faith (*questions de droit*), on which the pope's word is authoritative, and questions of fact (*questions de fait*), on which the pope has no special authority. He appealed to this distinction in claiming that whereas Catholics must accept the pope's claim that the propositions are heretical, they are entitled to retain a "respectful silence" with respect to

the claim that the propositions are to be found in the *Augustinus*. Arnauld was expelled from the Sorbonne in 1656 for writing in support of the Duc de Liancourt (Roger du Plessis-Liancourt), who was refused absolution due to his failure to affirm the presence of the condemned propositions in the *Augustinus*.

After Mazarin's death in 1661, Louis XIV followed his former first minister's policy of suppressing Jansenism and started to put considerable pressure on the nuns and solitaires at Port-Royal. His attempts during the 1660s to impose an anti-Jansenist formulary both on those associated with Port-Royal and on the clergy brought the French church to the brink of schism. However, with the help of Pope Clement IX, Louis was able to institute a Peace of the Church in 1669 that allowed for the respectful silence that Arnauld had advocated. This brought to an end the predominance of what Louis Cognet (1968) calls "First Jansenism," for which theological issues were most crucial. Cognet contrasts this sort of Jansenism with a "Second Jansenism" that started to emerge after the end of the Peace of the Church in 1679 and that was more concerned with political issues. During the 1680s Jansenists such as Arnauld, then in exile in the Spanish Netherlands, took the side of the pope in political disputes between Paris and Rome. After 1700 Louis attempted to ally himself with anti-Jansenist elements of the Roman curia to bring an end to what he took to be a politically subversive form of Jansenism in the work of Pasquier Quesnel. His efforts led Pope Clement XI to issue the bull *Unigenitus* (1713), which condemned Quesnel's views. The Parlement de Paris initially refused to register the bull due to Gallican concerns that the sanctioning there of unjust excommunication compromised French sovereignty. Though Louis succeeded in having the bull registered and approved through intimidation, there was significant parlementary opposition to *Unigenitus* throughout the eighteenth century. Port-Royal could no longer be a source of support for this opposition, however, since Louis, with the encouragement of his confessor, the Jesuit père de la Chaize (Jean Chastain), disbanded the convent in 1709 and had it destroyed the following year.

During the 1730s Jansenism became associated with the *convulsionnaires*, so called because they experienced uncontrollable convulsions at the grave of François de Paris in the cemetery of Saint-Médard. This group of individuals claimed that the grave was the site of miracles that confirmed divine support for Jansenism. In response the French government closed the cemetery and countered Jansenist political opposition by making *Unigenitus*

a law of state. After the 1650s, however, the Jansenist journal *Nouvelles Ecclésiastiques* played a prominent role in the parlementary campaign against the Jesuits, and this campaign ultimately resulted in the suppression of the Jesuit order in France in 1764 (see Van Kley 1975). Jansenist resistance to the French political establishment also arguably helped to set the stage for the French Revolution at the end of the eighteenth century, though the secularism that dominated the revolution was far removed from the Augustinian spiritualism that pervaded the Jansenist movement.

JANSENISM AND CARTESIANISM

Francisque Bouillier, the nineteenth-century historian of Cartesianism, claims that there is "a natural alliance of the doctrine of Jansenius with that of Descartes." His specific proposal is that this alliance derives from the fact that the Cartesians "make God the unique efficient cause, the only actor who acts in us," whereas the Jansenists "give everything to the grace that operates in us without us" (1868, vol. 1, p. 432f).

The association of Jansenism with Cartesianism goes back to the seventeenth century, as indicated by the remark in the 1690 *Voyage du Monde* of the Jesuit Gabriel Daniel that "there are very few Jansenists who are not Cartesians" (1690, p. 285). This association was due in no small part to the interest in Cartesianism at Port-Royal. Cartesianism infuses *La logique ou l'art de penser* (1662) of Arnauld and Pierre Nicole, a text that reflects the teaching in the *petite écoles* of the convent before their suppression in 1660. Moreover, issues involving Cartesianism were prominent at discussions among Port-Royalist sympathizers held at the hôtel of the Duc de Liancourt from 1669 to 1674.

Even so, it is important to keep in mind that René Descartes himself was never associated with Jansenism during his lifetime, although the *Augustinus* was published a decade before his death. The connection between Jansenism and Cartesianism is a genuinely post-Descartes phenomenon. It is also noteworthy that there was significant opposition to Cartesianism from within Port-Royal, as indicated in the record of the Liancourt discussions. Some of this opposition was due to a fear of the heretical implications of Cartesian natural philosophy, particularly with regard to the theology of the Eucharist. Another source of opposition was the belief, widespread among the Jansenists and arguably present in the *Augustinus* itself, that human reason can accomplish little on its own given the corrupted state of fallen human nature. Even Arnauld, who among the Port-Royalists was

the most supportive of Cartesianism and the use of reason in philosophy, criticized Descartes at one point for offering an account of human freedom in his correspondence that is "full of Pelagianism."

The historical realities are thus more complex than Bouillier's thesis suggests. There is need for caution even with respect to his proposal that the Cartesian claim that God is the only cause is naturally connected to the Jansenist emphasis that grace brings about one's meritorious action. Nicolas Malebranche was most responsible for the perception that Cartesianism leads to the occasionalist conclusion that God alone has causal power. But Malebranche insisted, against the Jansenists, that one has the freedom to reject divine grace. Arnauld in fact found such a view to be Pelagian, and he campaigned to have Malebranche's works placed on the *Index of Forbidden Books* in Rome, which they were in 1690. For his part, Malebranche noted the irony that he was being condemned because "I have refuted the opinions that the Church has condemned in Jansenius" (1958–1984, vol. 19, p. 548).

JAPANESE PHILOSOPHY

The first, and perhaps the most interesting, question regarding Japanese philosophy is whether there is such a thing. Or, to be more precise, whether there was any Japanese philosophy before Nishida Kitarō's 1911 *An Inquiry into the Good* (*Zen no kenkyō*). Some Japanese scholars today, such as Sakamoto Hyakudai, deny that there has ever been any Japanese philosophy. Others, like Nakamura Yōjirō, argue that there was none before Nishida. This is somewhat surprising in that since 1920 much of the same literature originating from China has been called Chinese philosophy by the Chinese, while a little later a Korean version was labeled Korean philosophy by the Koreans.

To understand why the Japanese have not followed suit, we need to examine how the notion of "philosophy," as it is known in the West, first took shape in the Japanese intellectual world during the Meiji period (1868–1911). At that time the Japanese government was encouraging the wholesale importation of Western intellectual culture, including something called "philosophy." To designate this newly introduced Western study, Nishi Amane introduced in 1874 a new word, *tetsugaku* (a shortened form of "*kitetsugaku,*" " *kitetsu*" itself abbreviated from *kikyō tetsuchi*), which he formed using two Chinese characters, or *kanji*, meaning the "science of seeking wisdom." The first philosophy instructors were foreigners, who began to arrive three years later, and it was not until 1893 that they began to be replaced by Western-trained Japanese professors of philosophy. This development fostered the idea that that thing called "philosophy" was a solely Western product standing alongside other Western disciplines such as chemistry, physics, and biology.

Since *tetsugaku* was formed of two Chinese characters, the Chinese themselves adopted the Japanese convention and began toward the end of the nineteenth century to refer to Western philosophy using these same two characters (pronounced in Chinese, zhu-shway, or, in pinyin, zhe xue). As in Japan, most Chinese scholars initially thought that *zhe xue* was one of the Western sciences and was therefore something previously nonexistent in either China or Japan except in very rudimentary form. However, as it gradually became clearer that Western philosophy was *not* a science but a metaphysical and speculative world view based largely on a sense of cultural values (partially through the efforts of John Dewey and Bertrand Russell, who visited China just after the World War), Chinese scholars began to see greater similarities between Western philosophy and ancient Confucianism, Mohism, Daoism, and Legalism.

The final shift in definition was achieved following the great debates on this issue in China during 1922–1923, led by Liang Shuming and Chang Chunmai (Carson Chang). Chinese intellectuals now reached the consensus that much ancient Chinese writing (Confucian, Daoist, and some Buddhist texts) should be considered *zhe xue* and that *zhe xue* must be divided into Western, Indian, and Chinese, each representing different value orientations or *Weltanschauungen* of these different cultures. Since philosophy was now deemed not a science but rather the expression of cultural values, Liang and his group successfully argued that the Chinese should embrace Western science but continue to espouse Chinese philosophy.

Shortly afterward Koreans began referring to their ancient literature derived from Chinese sources as "Korean philosophy," but the Japanese disagreed, refusing to designate Japanese versions of this same Chinese literature as Japanese philosophy. It is true, as Japanese intellectuals such as Nakae Tokusuke (pen name Nakae Chōmin 1901) argued, that anything one might want to designate as Japanese philosophy was borrowed and evolved from Chinese sources. But this is no more true of Japanese borrowing from external sources than of British, German, or French philosophy borrowing from Greek sources. A transplanted tradition often becomes culturally identified with its adopted country if and when it takes deep root and permanently transforms the original product into its own image. And this seems no less true of Japanese versions of Chinese philosophy than it is of Korean renditions of Chinese philosophy or of British transformations of Greek philosophy. The important issue, therefore, is not the origins of Japanese philosophy

but how Japanese philosophers interpreted, criticized, modified, developed, and used imported Chinese philosophical ideas and methods in accordance with Japanese predilections and needs, and how their writings contributed to a continuing, distinctively Japanese tradition of thought. Exactly the same criteria should be used to distinguish twentieth-century Japanese philosophy of a Western or international style from the earlier study of European philosophy in Japanese universities (in the late nineteenth and early twentieth centuries).

DISTINGUISHING JAPANESE FROM CHINESE PHILOSOPHY

One difference between Japanese and Chinese philosophy arises from the fact that Japanese philosophy is highly selective about the much larger range of philosophical schools that arose in China. This is partly due to the historical accident that by the time Chinese philosophy was imported to Japan in the seventh century, many earlier Chinese schools had already become obsolete or absorbed into other philosophical schools.

Part of the selection process, however, reflected Japanese political priorities and cultural preferences. In China philosophy had developed independently of government. In Japan, by contrast, philosophy was admitted by the government for the aid it could provide the government in the service of the state. Hence there never developed until quite late an independent class of literary specialists from which scholars could be selected for government service, as was the case in China with its famous meritocratic examination system. In Japan government positions tended to be hereditary.

For all these reasons Japanese tended to select only those aspects of Chinese philosophy best suited to the perceived needs of Japanese government leaders and advisers. So, for example, Japanese never developed (until the late Tokugawa era—eighteenth and nineteenth centuries) the idea, so prominent in China, of the role of philosophy as a tool for self-cultivation. Also, the Japanese were never very interested (again until late Tokugawa) in China's second most important and popular philosophy, philosophical Daoism (*Dao Jia*), which the Japanese government leaders thought encouraged anarchy, rebellion, and lack of loyalty to the government and devotion to the state.

For similar reasons, the Japanese tended to exclude Kongzi's (Confucius's) and, more so, Mengzi's (Mencius's) theory of the "mandate of heaven," the view that to be successful, governments must be acceptable to a moral order of heaven, without which they could be legitimately

overthrown (not a popular idea among government leaders anywhere). Where Mengzi and the Confucian tradition offered advice to governments on how they ought to rule in order to fulfill their moral obligations to their people and to heaven, this advisory function was largely excluded from Japanese Confucianism, at least until very late in the Tokugawa period. Also, Japanese Confucians emphasized loyalty to the state government over filial piety (family loyalty), whereas for the Chinese it was just the reverse.

Japanese Buddhism, in its early centuries, was similarly politically enmeshed, having been introduced into Japan by government leaders as a way to protect and bring good fortune to the state and not as a popular movement of personal faith among ordinary Japanese people. Whereas Chinese Buddhism spread among all classes of people in all parts of the country, the Japan variant was limited for several centuries to aristocratic families living in the capital. Moreover, whereas Chinese Buddhists tried and largely succeeded in staying out of government service, Japanese Buddhists were from the beginning heavily involved in the affairs of state.

The particular selection of texts the Japanese made from the Chinese and Korean traditions and the interpretations these texts received were also much affected by Japanese cultural predispositions. In the later neo-Confucianism of the Tokugawa period, for example, Japanese philosophers rejected the more abstract, transcendental, and rationalist elements of the philosophy of Zhu Xi (Shushi) in favor of material, phenomenal, sensual, immediate, intuitive principles. Japanese philosophers often explicitly criticized Chinese philosophers for being too intellectual, abstract, logical, and otherworldly.

JAPANESE BUDDHIST PHILOSOPHY

Although Confucianism and Buddhism arrived more or less simultaneously in Japan as part of a "package deal" of Chinese culture, for various reasons Buddhism played by far the greater role before Tokugawa (seventeenth century). One reason for this was the rising power of Buddhism over Confucianism in China at the time of significant contact with Japan. In the Sui dynasty (seventh century) Buddhism was at its peak in China and was strongly supported by the Sui rulers. A more practical reason inhibiting the spread of Confucianism was the enormous difficulty Japanese people had in reading Chinese. Although the characters are the same, the grammar of the two languages is completely different. Not until the Tokugawa period a thousand years later were these problems sorted out, affording Japanese greater access to Chinese sources.

Indeed, for nearly a thousand years Buddhism played much the same educational role in Japan as Confucianism had in China. Throughout most of this long period, the Buddhists ran the schools and educated most of the ruling and military elites. Ironically, it was the Zen Buddhists who introduced neo-Confucianism (Zhu Xi and Wang Yangming) to Japanese in the seventeenth century. Even in the early twenty-first century the most successful and distinctively Japanese philosophy is that of the Kyōto school, which combines Zen Buddhism with the European philosophies of Hegel and Heidegger.

In light of the Japanese traditional preference for the aesthetic surface of the world as it directly appears to us, the Japanese in general rejected any transcendent, otherworldly, metaphysical reality "behind" appearances and embraced instead the "here-now" phenomenal world sanctified and glorified as aesthetic ritual.

The philosophically most sophisticated Buddhism to emerge in China (Tien Tai, Hua Yen, and Chan Na [Japanese, Zen]) endorsed the profound and paradoxical idea that the changing, dependent phenomenal world is simply a false way of seeing the eternal, ultimate reality. This striking theory results from carrying to its logical conclusion the idea that there is nothing in the world but this one Buddha reality. There is therefore no dualism by which we might contrast the Buddha reality with the ordinary space-time physical world. What we experience as ordinary mundane existence is simply the one Buddha reality misunderstood. Because this outlook fit in very well with Japanese predispositions, Japanese Buddhist philosophers (Saichō [767–822], Kōkai [774–835], and Dōgen [1200–1253]) developed this aspect of Buddhism to the fullest.

JAPANESE CONFUCIAN PHILOSOPHY

As previously indicated, Confucianism did not have much immediate impact and was for a time hardly studied in any detail. In this early period, as can be seen in Prince Shōtoku's "Constitution" (604 CE), the main Japanese interest in Confucianism was its support for the ancient Chinese customs that Kongzi defended and systematized and that therefore became attached to his name. Many of these customs were similar to ancient Japanese practices—they were understood, that is, as a justification and theoretical support for hierarchy in society and cohesion within the family and more generally within society. The governing principle in both cultures was loyalty to the superior and loyalty to the group.

Neo-Confucianism was introduced at the beginning of the Tokugawa era through Zen Buddhists in whose monastery schools (Song dynasty [960–1279]) neo-Confucianism was studied as a sideline. What Western scholars call neo-Confucianism Chinese call *Dao Xue Jia*, the School of the Study of Dao. And this name indicates the new metaphysical and spiritual direction of Chinese Buddhism and late Daoism, beginning in the Tang dynasty (618–907) but coming to maturity in the Song dynasty. Although neo-Confucians rejected Buddhism because it was not Chinese either in origin or in tradition, they absorbed into Confucianism many elements of both Buddhism and Daoism. Neo-Confucians also selected those Confucian texts more in line with Song dynasty Buddhist-Daoist spiritualism and then interpreted those texts in the new way. Mencius is selected over Xunzi and interpreted spiritually and idealistically, emphasizing the idea in Mengzi that everything lies within us, that we share the goodness of human nature with heaven, that the direct, spontaneous feeling or intuitive thought is the best insight into reality. The key virtues during this period were not so much the social ones of propriety and benevolence but rather the self-cultivation of an inner quality of Buddhistlike mental tranquility and sincerity.

Cosmologically, the *ba gua*, or trigrams (and the sixty-four hexagrams of paired trigrams), were added to the older Daoist cosmology of *qi* in an effort to explain the evolution of the natural world from a single element into the multifaceted world we are familiar with. The original *qi* ether is said to divide into the *yin* and *yang* ethers (representing the passive and active forces in nature), which in turn evolve into the five elements (*wu xing*: earth, wood, metal, fire, and water), which finally produce the "ten thousand things." Philosophically the most important element added during this period is the notion of *li* in opposition to *qi*. *Qi* is the material stuff of the world, and *li* is the formative principle that shapes it into stable and predictable forms.

This idea probably comes from Buddhist Tien Tai and Hua Yen metaphysics (which may, in turn, have been influenced by Daoism, suggestions of which are found still earlier in the *I Jing*), where the root idea is that the inner nature of everything is the same, namely the Buddha nature. In neo-Confucianism the emphasis is more specific and somewhat more secular, each *kind* of thing being governed by its own principle, or *li*. The *li* of chickens makes their eggs hatch into chicks which then grow into chickens, and so on. But as in *Yogō cōra* Buddhism, an understanding of all the *li* lies innate within each person's mind. By quietly reflecting within our own minds, we can come to realize the inner *li* of all things.

Zhou Tunyi, Shao Yung, and Chang Cai (eleventh century), are all "fathers" of Chinese neo-Confucianism, but the tradition really begins with the Cheng brothers, Cheng Hao and Cheng Yi (eleventh century). Cheng Yi and Zhu Xi (late eleventh century) form the Cheng-Zhu *Li Xue* school (also called the Rationalist school), whereas Cheng Hao, along with Lu Jiuyuan (better known under his literary name Lu Xiangshan [twelfth century]) and Wang Yangming (fifteenth to sixteenth century) form the Lu-Wang *Xin Xue* school (also called the Idealist school).

Li Xue held that *li* exist independently of particular things and also independently of human consciousness (or minds). As Fung Yulan points out, this view is akin to Plato's theory of Forms. Xin Xue held that *li* do not exist independently of human consciousness (or particular things). So, for the Li Xue we discover *li* by examining things in the world, whereas for the Xin Xue we discover *li* by examining our own minds. Also, for the Li Xue human nature is *li*, whereas for the Xin Xue human nature is mind (human consciousness). That is, for Li Xue human consciousness is part of the *qi*, the material stuff, or body, whereas for Xin Xue it is the essential characteristic of human beings.

TOKUGAWA CONFUCIANISM

The first phase of Tokugawa Confucianism in Japan was basically a variation of the neo-Confucianism of Zhu Xi. Zhu Xi is clearly the most important neo-Confucian and the one who had the greatest influence outside of China (he is the central figure in Korean and Vietnamese Confucianism as well). Zhu Xi interprets the Supreme Ultimate (*tai qi*) as a metaprinciple, the superprinciple that governs the other principles just as they govern the formation of individual things. So Zhu Xi argues not only that every distinct kind of thing has its own principle but also that everything in the world has the *same* nature or principle (the *Tai Qi*, or Supreme Ultimate, sometimes referred to as the *Dao*), the superprinciple of principles, which governs other principles as they govern particular things in the world.

Unlike Buddhism, however, this inner nature of everything, according to Zhu Xi, is not Buddhahood but the central Confucian virtue of *ren* or human-heartedness. The difference between human beings and plants, rocks, or other animals, each of which has its own *li*, is that this nature (Supreme Ultimate, *tai qi*) is more clearly displayed, more prominent, and more accessible in human beings. Zhu Xi reasoned that in a profound sense

the Supreme Ultimate meta- *li* of *ren* (human-hearted-ness) was the controlling force of the world. No longer, then, is *ren* merely *one* of the human virtues; it has now become a metaphysical principle governing the entire universe.

Because neo-Confucianism was first presented to the Japanese by Buddhists within the context of Buddhism, the antagonism between Confucianism and Buddhism was not apparent at first, and the two coexisted peacefully for centuries. But the new political regime of Tokugawa shōguns, in their attempt to unite the many feudal principalities of Japan into one nation under the nominal head of the Emperor but controlled by the Shōgun, found the differences between Confucianism and Buddhism politically useful and therefore encouraged the development of a new Confucianism that was not only different from Buddhism but also antagonistic to it. Whereas Buddhism was perceived as otherworldly, spiritual, personal, and metaphysical, Confucianism came to be perceived as being this-worldly, humanistic, rational, and focused on social and political concerns. As a result, Buddhism declined as Confucianism rose, though not to such a great extent as in China. Buddhism was disparaged as superstitious, emotional, and socially useless, whereas Confucianism was praised as humanistic, rationalistic, and pragmatic.

Nonetheless, imported Chinese culture was always adjusted to Japanese sensibilities and needs, and neo-Confucianism was no exception. Almost immediately Japanese intellectuals, including Fujiwara Seika (1561–1617), Hayashi Razan (1583–1657), Gahō Razan (1618–1680), Hōkō Razan (1644–1732), Nakae Tōju (1608–1648), Yamazaki Ansai (1618–1682), Kumazawa (1619–1691), and Itō Jinsai (1627–1705) accepted that part of neo-Confucianism that suited their needs and rejected those parts they considered un-Japanese. Basically, they accepted the humanism and rejected the rationalism. The main criticism of Zhu Xi was his stress on rationality at the expense of emotion.

What is most interesting about Japanese followers of Zhu Xi (Shushi) is their complete rejection of his notion that the ultimate reality of the world is the abstract, immaterial, eternal, and unchanging *li*. Korean Confucians, by contrast, took this Platonic element in Zhu quite seriously, actively debating for centuries whether both *li* and *qi* exist (that is, whether the abstract *li* can exist independently of the material *qi*) and, if so, which of the two is primary.

Some 300 years after Zhu Xi, Wang Yangming (*ō yōmei*) rejected Zhu's "*li xue*" (the philosophy of princi-ple) in favor of " *xin xue*" (the philosophy of mind). And this, too, had its important counterpart in Japan, especially in the work of Oshio Heihachirō (1793–1837). Wang Yangming identified the ultimate nature or essence of things with mind, adopting a position similar to Western idealism; the ultimate reality is mind and ideas entertained by mind. For Wang human nature is mind, not *li*, and the Supreme Ultimate (the overarching *Dao* of everything) is Mind (*xin*), not *li*.

Other differences follow from Zhu's privileging of *li* and Wang's preference for *xin*. Whereas for Zhu we follow the *Da Xue* (the Han dynasty [third century BCE to the third century CE] Confucian classic, *The Great Learning*) in "extending learning by investigating things," Wang contends that, following the other Han dynasty Confucian classic, *Zhong Yong* (*Doctrine of the Mean*), one can best learn the ultimate principles of reality by simply reflecting within oneself. The ultimate *Dao* is Mind, and where better to study Mind than one's own mind? The other major difference between these leading neo-Confucians is that whereas Zhu (somewhat like Aristotle) sees a gap between knowledge and action (that one can know the right thing to do and not do it [Aristotle's "weakness of will"]), Wang argues (somewhat like Socrates and Plato) that if one truly understands what is right, one will do it. Of course, part of the disagreement between Zhu and Wang on this point has to do with different notions they have of knowledge, Zhu stressing something akin to ordinary common sense knowledge, and Wang, something closer to meditative quasi-Buddhist enlightenment. While it seems clear that Zhu Xi borrows from Hua Yen Buddhism the *li-qi* (in Hua Yen *li-ji*) distinction, Wang Yangming's indebtedness to Yogōcōra Buddhism is equally clear.

A major contribution to Chinese Mahōyōna Buddhism was Yogōcōra idealism, which held that everything is the Buddha Mind, that the phenomenal world is a mentally produced illusion. Yogōcōra joins with Nōgōrjuna's *Mōdhyamika,* or "middle way" (which holds that reality is empty, not mental) to form most of the leading schools of Chinese Buddhism, especially, when further combined with Daoism, Chan (Japanese Zen). For that reason Wang is often called a closet Chan Buddhist. Most Japanese Buddhist philosophers rejected Yogōcōra idealism as too remote from common-sense realism and too alien from the peculiarly Japanese celebration of the infinite aesthetic richness of the phenomenal world of everyday sense experience. For this reason most Japanese neo-Confucians rejected Wang's idealism, though many Japanese found great sympathy for the spiritual sincerity

of Wang's emphasis on inner reflection and self-cultivation. Nonetheless, Japanese followers of Wang rejected his main idea, just as followers of Zhu rejected *his* main idea. In both cases Japanese adopted Chinese neo-Confucianism in their own, peculiarly Japanese way.

MODERN NATIONALISTIC PHILOSOPHY

In the Qing dynasty (seventeenth through twentieth centuries), Chinese Confucians rejected all the Daoist and especially Buddhist elements with which Song (Zhu Xi) and Ming (Wang Yangming) dynasty neo-Confucianism had become embedded and urged a return to the original Confucianism of the Han and pre-Han period. In reaction to this Buddhistic (and hence Indian, ergo, non-Chinese) Confucianism, the Qing dynasty Confucians led a movement "back to the original (thoroughly Chinese) Confucianism." And this too was closely followed by Japanese Confucians.

More interesting was the Japanese adaptation of this "back to the (nationalistic) origins" as a "return" to *Japanese*, not Chinese, ancient writing. Of course, there is no Japanese writing of comparable antiquity to that of China, but there were the early "histories," such as the *Kojiki*, commissioned in the seventh and eighth centuries by Japanese rulers. These accounts were mostly collections of mythological prehistories of what later became known as Japanese Shintō. Like its Chinese counterpart, this trend represents the first dawning in Japan of a kind of "intellectual nationalism" that became increasingly important all over the world in the early twentieth century, especially in the period from 1920 to 1940.

Whereas Japanese Confucians rejected Confucian rationalism in favor of humanism, their embrace of Confucian humanism was itself qualified. On the whole, it was rejected politically but accepted morally; that is, Confucian humanism was rejected, at least initially (in the seventeenth century), as part of the political philosophy supporting the new Japanese Shōgunate "*bakufu*" government, whereas it was accepted as the foundation for a more general and widespread moral code throughout the country. In its military guise, Japanese government was less paternalistic and more rigidly duty-bound. Military leaders demanded and expected absolute obedience from their citizens. Here again Chinese thought was used to support, justify, and defend Japanese traditions rather than to modify them. On the other hand, Confucianism was a very important factor in the development of Japan's early modern (seventeenth and eighteenth century)

moral consciousness, especially among the rising middle class of wealthy, educated merchants in the cities.

At first Japanese Confucians sought to find this more humanistic side of Confucianism in the earlier Han and pre-Han Confucianism of the *Analects* and the *Mengzi*. But eventually Japanese Confucians turned away from Chinese sources altogether for this missing ingredient and began to look instead within their own ancient Japanese traditions. This opened the door for the focus on the more religious, nonrational ancient *Japanese* (i.e., Shinto) learning, which rejected both the humanism and the rationalism of neo-Confucianism. Japanese ancient learning portrayed the secular humanism of neo-Confucianism as a weakness, not a strength; it was bad because it ignored the ancient Japanese belief in the *kami*, a mysterious power that cannot be discovered by logical analysis or empirical investigation but only by the authority of ancient texts.

The most important of these "National Learning" philosophers was Motoori Norinaga (1730–1801). For more than thirty years Motoori struggled to have the *Kojiki* made the basis of accepted Shintō scripture. The problem was that the *Kojiki* is mainly a loose collection of ancient myths, legends, and genealogical records of the imperial family. It contains little abstract or profound philosophical thought. Motoori, nonetheless, tried to show that this was a strength and not a weakness. He argued that, like other sacred texts, the religious truths in the *Kojiki* are beyond ordinary sense perception, common sense, or reason. He also interpreted certain elements in the *Kojiki* as a purely Japanese sensibility of spontaneous sentiment privileging the emotional and aesthetic side of human nature over its more rational and moral side as favored by the Chinese.

Not surprisingly, Motoori was severely criticized by the neo-Confucian philosophers of his day for his naive and irrational theories. One objection Motoori tackles head-on is the criticism that instead of appealing to a universal human reason that could be appreciated by all people everywhere, as most philosophers try to do, Motoori *isolates* the Japanese people from everyone else in the world. According to Motoori's explanations, only the Japanese who follow the *Kojiki* know the truth and follow the true Way; only they are the chosen people. But that is just the way it is, Motoori responds. The gods favored Japan and more clearly revealed the Way of the gods to them, and the Japanese people have preserved this ancient, sacred tradition better than other people, who have abandoned what religious understanding they once

had in favor of new, man-made philosophical explanations.

Motoori tends to be theistically fatalistic: everything is decreed by the gods, whether for good or evil. How can we explain the existence of evil? Instead of looking for rational reasons to justify the fact of undeserved evil, Motoori simply says that we know from the *Kojiki* that this is what the gods decided and the way they acted. If you go on to ask *why* the gods did things in this way, you are asking a question that cannot be answered. The Way of the gods is not the Way of man.

Instead of constantly trying to control or restrain our emotions, as the rationalistic philosophers are always telling us to do, Motoori insists on a more frank acknowledgment of the power of emotion in our lives. Sometimes, it is true, emotion leads us into indiscretions which we later regret. But we cannot help ourselves. We should not be so judgmentally harsh on ourselves or on other people, Motoori urges us, but rather sympathetically recognize (with fatalistic resignation) the power of emotion to occasionally lead us astray.

Motoori forms the transition to the late-nineteenth-century Meiji rejection of Chinese in favor of Western learning as the only way to compete with the West and avoid Western domination. The central paradox of this early adjustment to the modern ways of the West is that the Japanese suffered no sense of inferiority in their need to emulate at least some aspects of the West. The general consensus among Japanese intellectuals of this period followed Motoori's conviction that the gods arose in Japan and therefore favored the Japanese people, giving them a natural and undeniable edge over all other peoples. By the early twentieth century, Japan had thoroughly mastered Western science and technology but was torn politically between liberal and more conservative Western thought—specifically between British empirical and neo-Kantian ideas on the one hand and German Hegelian and Heideggerian doctrines on the other. In the end the conservatives won the day.

Perhaps the most important thinker in this regard was Watsuji Tetsurō (1889–1960). His 1935 work *Fōdo* (*Climate and Culture*) replaces Heidegger's emphasis on time (in *Being and Time*) with a focus on space. Like other Japanese philosophers, Watsuji did not accept Heidegger's thought without reserve. Indeed, it was deemed by most Japanese to be too concerned with the individual at the expense of the social. In Watsuji's view, Heidegger's neglect of space precluded a description of human existence concrete enough to allow for a true depiction of history and (to cite Watsuji's chosen focus) of the role of

climate within it. Again, we see the Japanese predilection for the empirical and phenomenal over the abstract and transcendental.

In *Rinrigaku* (*Ethics,* 1937–1949) as in *Fōdo*, Watsuji again taxes Heidegger with having scanted space relative to time and thereby the social relative to the individual. The German philosopher, he complains, "stuck fast to an atomistic individuality"(*Rinrigaku*, 224). This Cartesian, Hobbesian notion of self, Watsuji declares, is artificial and must be replaced with a more communitarian view of authenticity. Watsuji's terminological lynchpin for this idea is *ningen,* the Japanese word for "human being," where *nin* means "person" and *gen* signifies "between or together," thus implying a communal relationship. Inseparable from their cultural and social context, humans are fixed in a tensed, contradictory relationship to society; each person is at once an individual and a member of a social order and never wholly one or the other.

In place of Heidegger's "nothingness," Watsuji substitutes the Buddhist notion of emptiness (*sunyata*), an "authentic" surrender of selfish ego out of which compassion may arise. The problem with this idea, of course, is that his "authentic individual" can easily be submerged in totalitarianism because the community of which he or she is a *selfless* member is, in practical terms, inseparable from the state.

THE TWENTIETH-CENTURY KYŌTO SCHOOL

Using our criteria for what constitutes "Japanese philosophy," the first clearly Japanese philosophy of the post-Meiji period is the 1911 publication of *Zen no kenkyō* (*An Inquiry into the Good*), by Nishida Kitarō (1870–1945). Nishida was the pioneer of the *Kyōto-ha*, the Kyōto School of philosophers, which included other notable thinkers such as Tanabe Hajime and Nishitani Keiji. On the one hand, all the school's major members were condemned in some quarters for having collaborated with, or at least having endorsed, ultranationalist objectives; on the other hand, there has been widespread admiration for the quality of their purely philosophical activity, the best of which has been deemed of worldwide significance.

The originality of *Zen no kenkyō* lay in its author's attempt to express the Zen ideal of "unity of thought" within a densely argued philosophical system applying Western methods and concepts. Like his contemporary readers, Nishida faced the problem of reconciling Japan's traditional values with those implicit in the Western-inspired technological revolution. Nishida saw Zen insight as a possible solution for the crisis facing Japan.

Nishida's solution centered on the Western notion of "pure experience." Western writers had used the term "pure experience" in a way that seemed to him fundamentally flawed. What dissatisfied him in Mach, James, and others was their dualistic analysis of pure experience. Nishida held that any theoretical representation of pure experience inevitably introduces falsification. Sense-datum psychologists and philosophers had tried to describe our experience prior to perceptual syntheses and conceptual classifications but had nonetheless presupposed a subject-object dichotomy in which the perceiver is aware of himself looking at a world beyond himself. What Nishida sought to describe was a still more elementary, "pure" experience prior to any subject-object distinction—the experience of a newborn child.

From the standpoint of Zen Buddhism, in which the self is perceived as an artificial construction that inhibits the Buddha vision and is therefore best "dissolved," such a position does not surprise. But expressed philosophically, it took on the power of subversive dialogue with established Western beliefs. If self precedes experience, universal principles posited on the basis of individual experience are suspect. To avoid solipsism, Western thinkers have traditionally had to make assertions *beyond* experience. "Higher" realms and "hidden" essences have become chimerical foci in the hopeful quest of a human commonality. If, however, pure experience precedes self, then such experience itself can be declared a universal principle. The problem for modern Western philosophy—How do I get my private individual self to a reality beyond, understood in terms of universal principles accessible to everyone?—is not a problem in Nishida's notion of "pure experience," for he presupposes no division between "me" and "reality" nor between me and others.

Nishida's "logic of place (*basho*)" or "logic of nothingness" was quite unlike the "objective" logic of Western rationalism. Just as he had criticized the dualistic opposition in the Western representation of pure experience, so he calls here for a regress from the standpoint of reason (ensconced in the constructed subject) to the very starting point of our awareness, prior to the construction of self with its constructions of categories of determinate being. Only after pure experience has been differentiated into self and world—and after world, in turn, has been classified into categories of conceptual thought—can reason and cognition begin their work. Nishida developed a logic prior to the confrontation of a knower confronting an object.

CONCLUSION

Whether there is a Japanese philosophy or not depends on how one defines the word *philosophy* and how one judges the efforts to indigenize, or nationalize, borrowed, alien philosophical sources. Since the early 1920s there has been a general if not unanimous consensus in the philosophical community that there are three independent (literate) philosophical traditions: Greek, Indian, and Chinese (of which Japanese philosophy is an offshoot). Throughout Japan's 1,300-year history, that nation's philosophers have borrowed freely from outside sources—first from Chinese and later from Western philosophical traditions. But the Japanese have always interpreted and used these foreign sources in their own distinctive way. What is perhaps most peculiar about Japanese philosophy is that whereas nearly every other literate (and nonliterate) non-Western tradition is eager to claim for some of its thought the honorific title of "philosophy," the Japanese have mostly been reluctant to do so—or indeed to identify themselves with other cultures in any way that might appear to detract from their cultural uniqueness.

JASPERS, KARL
(1883–1969)

Karl Jaspers was one of the architects of contemporary existentialism and one of the first philosophers to use the term *existentialist*. He was a prolific writer with a prolix style that is often inelegant, superficial, sentimental, and unclear and that over the years showed itself to be repetitious. Yet careful and extensive reading of his works shows him to be a rigorous and responsible thinker. Appearances notwithstanding, he was perhaps the most systematic of all existentialist philosophers. His philosophy is neither linguistic analysis nor metaphysics. It can be best characterized as a disciplined and organized description of the critical fringes of human existence, such as impenetrable limits, unmitigated freedom, and the experienced indefinite expanse of space, time, and consciousness. Jaspers fulfilled the commonsense image of the philosopher through his vital concern with the contemporary political situation and his trenchant reflections on the threats to man's integrity and fulfillment posed by twentieth-century social, economic, and political institutions. He spoke with authority to the nonphilosophic mind because of his deep and successful roots in medicine and psychology. He was suspicious of contemporary overconfidence in science and, as an antidote, stresses the irrational in man. As Jaspers saw it, philosophy begins where reason has suffered shipwreck. Philosophy is an activity, a becoming, not a state of being or a body of facts. Philosophy is philosophizing. To appreciate philosophic insights we must—as Socrates and Sigmund Freud saw—arrive at them ourselves. We must live philosophy, since we cannot meaningfully paraphrase its conclusions. Genuine philosophy arises directly out of the problems confronting the individual philosopher in his existential, or historical, situation. General problems are mere derivatives. Philosophy need not be metaphysics; it can only illuminate some of the potentialities of an individual existence, an existence that is ineffable, unique, and free.

Jaspers was influenced especially by Immanuel Kant, but also by Søren Kierkegaard and Friedrich Nietzsche, whom he admired because they were prophets who articulated the structure of their existence, because they were not academic philosophers, because their thinking welled up directly from their personal existence, and because they illustrated the axiom that philosophic thinking begins in the attempt to communicate to another the nature of one's *Existenz*. The influence of Edmund Husserl is also apparent, although it is perhaps unconscious, since it is mostly unacknowledged. Jaspers used Husserl's method of descriptive phenomenology and adopted Husserl's concept of intentionality as a central function of the self. Furthermore, Husserl's ideas of the transcendental ego and transcendental consciousness conform to Jaspers's descriptions of the inner self (*Existenz*) and the outermost boundaries of the world (*das Umgreifende*). Jaspers's religious thought, although it ignored Aristotelianism and Scholasticism, was deeply influenced by Plotinus, Giordano Bruno, Benedict de Spinoza, and Friedrich von Schelling and gives a modern phenomenological restatement of many of the classical religious intuitions of humankind.

LIFE AND WORKS

Jaspers was born in 1883 in the East Frisian city of Oldenburg. His father was a banker, constable, and jurist. Jaspers studied law at the universities of Heidelberg and Munich, and medicine at Berlin, Göttingen, and Heidelberg. He received his MD from Heidelberg in 1909, upon

completion of his dissertation on *Heimweh und Verbrechen* (Nostalgia and crime). Immediately upon graduation he became a volunteer assistant in psychiatry at Heidelberg. His first major work, *Allgemeine Psychopathologie* (*General Psychopathology*, 1913), is a book on methodology showing the merits and limits of various psychological procedures and descriptions. In 1916 he became professor of psychology at Heidelberg. Shortly after World War I he published his *Psychologie der Weltanschauungen* (Psychology of world views; 1919), which consists of descriptions of many different attitudes toward life. It is based on Wilhelm Dilthey's *Typologie der Weltanschauungen* and marks Jaspers's transition from psychology to philosophy. He later called it the first genuinely existentialist work. Both of these early works were based on his medical experience.

He received a professorship in philosophy at Heidelberg in 1921, after declining similar offers from the universities of Kiel and Greifswald. In 1932 he published his magnum opus, the three-volume *Philosophie*, which is a detailed development of the notions of transcendence and *Existenz*. In 1937 he was relieved of his duties by the National Socialist regime, but was reinstated in 1945. In 1946 he was named honorary senator of Heidelberg University, and from 1948 on he taught at the University of Basel in Switzerland. In 1958 he was awarded the German Peace Prize at the Frankfurt Book Fair. The first volume of his *Philosophische Logik* appeared in 1947. Throughout his life, Jaspers was greatly concerned with communication. Personal relationships had great philosophic significance to him. In addition to his parents, particularly significant persons in his life were his teacher Max Weber, his friend Ernst Meyer, and Meyer's sister Gertrud, who became Jaspers's wife. Since she was Jewish, Jaspers lived, through her, the agony of the Jewish people during World War II, and this led him to publish in 1946 his reflections on the question of German guilt, *Die Schuldfrage, ein Beitrag zur deutschen Frage.*

Any classification of Jaspers's views into traditional philosophic disciplines is artificial. For purposes of exposition, however, such an expedient is necessary.

EPISTEMOLOGY

Jaspers's method is generally skeptical. It consists of the exploration, description, and analysis of first-person experiences. These form the basic data for philosophical generalizations and are for any person the sole source of his information about reality. Jaspers goes far beyond René Descartes in emphasizing the epistemological primacy of subjectivity: My thinking begins and ends with subjectivity, since awareness, as Kant saw, always consists partially of interpretations. Although the results of these descriptions do not form a universal ontology—they apply, strictly speaking, to my own self exclusively—they are nonetheless verifiable inasmuch as egos may compare experiences. Jaspers follows Kierkegaard in describing immediate experiences (which consist not only of sense data but also of love and anxiety, hope and despair) and examining their ontological import. Since he describes fringe states of consciousness, areas of experience that are difficult, perhaps even impossible, to focus sharply, his language necessarily becomes ambiguous.

There is no certainty either in philosophy or in science. I am forced to depend ultimately on the intuitions and decisions of my own ego. Science is not an ultimate form of knowledge because it excludes the observer, because it is replete with unexamined and often erroneous assumptions, and because one method of inquiry is insufficient for a complete world picture. Although the spirit of scientific inquiry is an antidote to dogma in religion, politics, and philosophy, it gives us only surface knowledge, which is, at best, a workable mythology.

PSYCHOLOGY

The nature of the self is discovered through illumination of existence (*Existenzerhellung*), which discloses the possibilities of man, that is, the possibilities of an entity seeking understanding of self and of being. *Existenzerhellung* yields access to the questioner himself. Ordinary modes of perception and cognition, which imply a subject apprehending an object, always bypass the real self (the *Ursprung*). The real and valuable, that is, the authentic, in man is called *Existenz*. *Existenz*, the genuine self, is nonobjective and unique. It is infinitely open to new possibilities and inaccessible to traditional philosophical investigations. Although *Existenz* is that crucial aspect of human existence that cannot be conceptually delimited, it is nonetheless clearly experienced: It can be lived; it is illuminated through philosophical reflection; it can be communicated. *Existenz* is the experience of the total freedom that defines man; it is the experience of the infinity of possibilities for styles of life; it is, finally, the experience of loneliness that cries in the wilderness. *Existenz* is the eternal in man, while *Dasein* (not to be confused with that which Martin Heidegger designates by the same word) is his temporal dimension. *Dasein* is that aspect of man that has describable characteristics and is accessible to theoretical reflection. To confuse mere *Dasein* with the authentic ground of my being, *Existenz*, is crass materialism and leads to shipwreck, while to

ignore *Dasein* altogether leads to nihilism. A tension (*Spannung*) between the two is the golden mean.

Man is alienated from his world. He comes from a dim past and goes into an indefinite future. Life is a flux in which he seeks anchor. Existence is rich in mysterious paradoxes and antinomies, such as those of freedom coexisting with dependence, communication with solitude, good with evil, truth with falsehood, happiness with grief, life with death, and progress with destruction. Authentic *Existenz* is disclosed through reason (*Vernunft*), while intellect (*Verstand*) concerns itself with the pragmatic management of existence. *Verstand* is satisfied with practical results, while *Vernunft* engages in endless searching. Man is both *Vernunft* and *Existenz*.

Existenz is limited by impenetrable boundaries (*Grenzsituationen*). To experience these and to exist are one and the same, since despair can be, in the last analysis, a cognitive and elevating emotion. A defining characteristic of man is his finitude, which he experiences as the limits to his existence. Jaspers's analysis of these boundary situations is the existential formulation of the problem of evil and has been most influential. Authentic existence will push back these limits as far as possible and then accept and bear them. Death is one of the most dramatic of these barriers. It is the source of anxiety, but it also elevates the spirit because it emphasizes the urgency of living authentically without postponement. Consciousness of the inevitable presence of death gives man courage and integrity: It gives him an authentic perspective on the things that matter most. Guilt is another important boundary situation. Man not only *feels* guilty but, because of his total freedom, is guilty. He always could have chosen otherwise. Ultimate guilt cannot be removed: It must be accepted and can thereby become constructive. Our guilt demonstrates the power that our freedom has over our destiny. The boundary of "situationality" is the fact that we are partially thrust and partially choose ourselves into a particular human condition. We can be inauthentic and inevitably fall into these situations or be authentic and make them happen. Other important boundaries are chance, suffering, and conflict.

Freedom is central to man; it leads to the overriding importance of choice, which becomes the problem of moral responsibility.

ETHICS

For Jaspers, ethics is the exploration of the experience and the potential of free will. Freedom is identified with choice, awareness, and selfhood. To choose means to be free, and man's freedom is his being. I am only to the extent that I choose freely. To be is to be conscious that one is free. I do not choose life's meanings; I do not "define" man, as Jean-Paul Sartre contends, since I am limited by my historicity—my past choices bind me. But within these confines my freedom is total. Freedom is experienced as both spontaneity and action; it is thus more important to act and be an *homme engagé* than to observe and be a theoretician. To know and use my freedom is the raison d'être of *Existenzerhellung*. Whenever I choose, I act, I am conscious of my action, I am aware of the values involved, I take chances (since the consequences of my choice are often uncertain), and I realize that commitment to some values is unavoidable.

The presence of anguish adumbrates the sacred nature of my freedom. Since each choice carries with it the accumulated weight of previous decisions, the first choice overshadows all others. Consequently, guilt is the inevitable concomitant of my freedom. My original choice (*Urentschluss*) bears down on my subsequent existence and assumes the role of original sin. I am accountable for that first choice, so that to be responsible means to have accepted that guilt. In addition, I am ceaselessly confronted with the choice between sacrificing my integrity for the sake of a longer life or surrendering myself to my authentic existential possibilities. The inherent difficulty of these choices leads to further guilt, which I may alleviate by imagining absolute standards and then approximating them. But in my heart I know there are no fixed standards and that absolutism is therefore a rationalization: the boundary of guilt is indeed impenetrable.

Anguish also appears when I realize I may lose the promise of my possibilities. But that same anguish gives me the urgency and courage to choose with my full being to implement the authentic potential of my *Existenz*. I reach this pedagogically expedient brink caused by anguish when 1 recognize the limits of scientific thought or when I am faced with critical decisions. Confronted with the abyss, I may accept a philosophic or religious orientation, I may act as if I did not recognize the existence of the abyss before which I stand, or I may adopt the nihilistic position that judges these problems to be meaningless.

Subjectivity is essentially intersubjective. I am only to the extent that another *Existenz* reflects me. Jaspers describes true communication as the feeling that men have known each other since eternity. My own freedom is in essence the search for the "loving strife" of communication with another *Existenz*. In fact, the search for *Existenz* cannot be accomplished in the abyss of absolute estrangement. Existential philosophy is self-disclosure

through communication, even being itself, although it can be represented only in ciphers as symbols, is made transparent solely through authentic communication (*Existenzursprung*). Existential communication is neither friendship nor psychotherapy; it is not fusion, esteem, or unanimity; it is, strictly speaking, as with *Existenz* itself, ineffable.

But in the end, human existence is a failure. There is no escape from man's limits (the limit of death in particular), yet man is condemned to endless striving. In this dreadful paradox between finite existence and striving for infinity, man finds the ultimate symbol of his salvation, which is transcendence.

METAPHYSICS AND THEOLOGY

Jaspers maintained that just as ethical considerations grow out of philosophical psychology, so religious answers emerge from metaphysical descriptions of being.

He follows Kant in criticizing the usual arguments for the existence of God. He rejects theism, pantheism, revealed religion, and atheism alike. All these are but symbols (ciphers), and we are in danger of taking them literally. Phenomenological descriptions of the fringes of inward and outer experiences give us the only accurate understanding of the intuitions that metaphysics and theology have traditionally attempted to articulate.

When man reflects on his freedom, he experiences it as a gift; he dimly knows that he does not stand alone. That gift, in turn, points vaguely to an ultimate horizon as its source and foundation. Awareness of transcendence also originates in the consciousness of our finitude: Through our boundaries we recognize the infinite possibilities within us. In general, the world itself points to a region beyond. Transcendence is thus experienced as the intimation of a power by virtue of which man himself exists. Confronted with these clues, man is free to pursue or to ignore them.

Jaspers uses the term *encompassing* (*das Umgreifende*) to designate the ultimate and indefinite limits of being as we experience it in all its fullness and richness, limits that surround, envelop, and suffuse all there is. It is the ultimate experienceable horizon. He uses the expression "being-as-such" to mean the encompassing or the totality of being as it is thought, conceived, or conceptualized, while he reserves the term *transcendence* to mean man's personal, devoted, and committed effort to reach the encompassing. In other words, the encompassing manifests itself in at least three modes: the total encompassing of the world, the encompassing that is the

empirical world of ordinary and scientific experience, and the encompassing that is one's own self. Although we are at a loss to describe its essence, we can say of the encompassing that it is. In a sense, I and the world are identical with the encompassing. In it, the severance between subject and object disappears, since both are manifestations of the same encompassing. On similar grounds, the encompassing (and this then applies to Jaspers's reinterpretation of God) can never be viewed as one object among many. It is all of being as well as all the differentiations within being. It is likewise beyond idealism, materialism, positivism, and naturalism, since all metaphysical positions are events within the encompassing but do not in any way delimit it. Therefore, in Jaspers's view, God, the unthinkable (*das Undenkbare*), becomes Rudolf Otto's "wholly other." I cannot grasp conceptually the encompassing that I am; similarly, the world is not exactly an illusion, since it is the only language through which the encompassing can reach me. The ultimate encompassing envelops both the I-pole and the object-pole of experience.

Man can search for transcendence by various means. He can explore the world, as science does. In that way he achieves a worldview. Or he can search for it by examining the relation between himself and the world, as we find it in epistemology, ethics, and psychology. He thereby achieves illumination of *Existenz*. Finally, he can search for God, in which case he deals directly with the problem of penetrating being itself. But he must never succumb to the error of identifying the encompassing with a particular substance or substratum of the world.

The encompassing manifests itself through the "footsteps of God," through analogical predication, through symbols, or, in Jaspers's own words, through ciphers (*Chiffren*), a notion borrowed from Pascal. The encompassing is like the horizon that is the perennial goal of the sailor: It always shows itself and yet is forever inaccessible. The major purpose of metaphysics is the disclosure of the ciphers that manifest encompassing, but in the end, metaphysical elucidation of the ciphers is a highly personal undertaking. Ciphers may appear suddenly and spontaneously in the presence of empirical facts, for example, an overwhelming mountain. They may appear in art forms, in religious myths and dogma, and in theological disputations; they may become manifest in the symbolism of the history of philosophy and its metaphysical systems; and finally, they may appear through reflection on the mystery of being as well as on the death that awaits every man.

Jaspers's religious prescription is called philosophic faith (*philosophische Glaube*). It consists of the convictions that man is open to transcendence and consequently wills infinity; that there is in fact a transcendence to the ordinary world; that personal freedom is to be maintained and respected; that man, as he finds himself, is inadequate; that man can rely on help from transcendence; and that the world is grounded and supported. To reject faith means to hold that the immediate world is all there is, that man's destiny is fully determined, that man is perfectible and alone, and that the world is self-supporting. Although there are significant similarities between Jaspers's philosophical faith and that of traditional Christianity, he rigidly opposed the absolutism of the latter to the openness and toleration of his philosophic faith. The Bible, for example, is a highly suggestive instrument for his philosophic faith, especially through its ciphers of one God and its emphasis on love, on choosing between good and evil, on the eternal in man, on the ordered and yet contingent universe, and on the image of God as the refuge. Nevertheless, transcendence is discovered through doubt, not reassurance: There can be no rational justification for the final leap of faith, even for a philosopher.

JEANS, JAMES HOPWOOD
(1877–1946)

James Hopwood Jeans, an English physicist and astronomer was educated at Merchant Taylor's School and Trinity College, Cambridge, where he received high honors in mathematics in 1898. He taught mathematics at Cambridge as university lecturer from 1904 to 1905, at Princeton as professor of applied mathematics from 1905 to 1909, and again at Cambridge as Stokes lecturer from 1909 to 1912. In 1912 he resigned all regular offices to live on a private income and later also on the sale of several popular books. He was honorary secretary of the Royal Society, president of the British Association for the Advancement of Science, and professor of astronomy at the Royal Institution.

Jeans was a man of undoubted ability and originality and early won a deservedly high reputation, being elected a fellow of the Royal Society at the age of twenty-eight. His main contributions to science were in two fields: the kinetic theory of gases, in particular the equipartition of energy and radiation; and cosmogony, in particular the forms of equilibrium of rotating gravitational masses and the kinetic theories of aggregates of stars. The last constitute perhaps his best and most enduring work.

During the early 1930s Jeans wrote a number of highly successful books popularizing science, and these, together with *Physics and Philosophy* (1942), contain his philosophical writings. His popular expositions of scientific theories are marked by their simplicity of expression and by the striking and illuminating examples and analogies they contain.

Although Jeans contributed nothing substantial to philosophy, his views gained attention because of his eminence in the scientific field and because of their being presented together with expositions of abstruse scientific theories widely agreed to be of philosophical interest. Jeans's writings on philosophy were slight in quantity as well as in quality; even *Physics and Philosophy* contained only about fifty pages of his own views.

His position was never consistently developed and is therefore unclear. Indeed, he seems almost to have felt that it would be against the spirit of philosophy to argue with rigor, clarity, and decent caution. His work is certainly characterized by loose reasoning, and not infrequently by plainly false or confused premises. Broadly, however, his views were that science must connect observables with observables by means of chains of mathematical equations. He held that mathematical formalization is the prime part of physical knowledge and that interpretative models of this formalism are outdated and confusing crutches in coming to know about the world. This was not because Jeans believed that only propositions about observables have a meaning. He was no positivist, despite his claim to be one. On the ground that physical measurement reveals only relations between instruments (including one's eyes and ears) and reality, he believed in a Lockean substratum that is forever hidden from us. He also held that modern science suggests that there is some room for the operation of free will, but it is unclear why he adopted this opinion. His attitude to the common fallacy that the uncertainty relations of quantum physics establish the possibility of free will is quite ambiguous.

The most striking and most widely discussed of Jeans's conclusions is that reality, the Lockean substratum, is mental, not material. This conclusion reaches its most startling form in the final chapter of *The Mysterious Universe*, where Jeans argued that the universe consists of the thoughts of a Pure Mathematician, God.

Jeans asserted—it is hardly an argument—that the universe is shown to be rational by the very fact that a mathematical description of it is possible. He argued that as physics has progressed it has discarded models as an aid to explanation and discovery. Post-Galilean physics discarded the biological model of Aristotle, and modern physics has now discarded mechanical theories and models, being content to present its theories as pieces of mathematical formalism. Jeans put the matter this way: We cannot interpret the multidimensional configuration spaces of quantum physics as material space because material space has but three dimensions. Nor can we interpret the axioms of non-Euclidean geometry, especially the geometry of finite spaces, in terms of the congruences of material rods in material space. (This last claim is simply unwarranted.) Consequently, argued Jeans, the formalism of modern physical theory must be given a pure mathematical interpretation. (However,

there is no sense in which we can speak of a pure mathematical *interpretation,* since "pure" here means "*un*interpreted.") Since the subject of pure mathematics is just thoughts, we may conclude, according to Jeans, that the stuff of the universe is mental. It is thought in the mind of God, the Pure Mathematician.

JEFFERSON, THOMAS
(1743–1826)

"Here was Buried Thomas Jefferson
April 2, 1743 O.S. –July 4, 1826
Author of the Declaration of Independence
And of the Virginia Statue for Religious Freedom
and Father of the University of Virginia."

These are the words that Thomas Jefferson wrote for his epitaph. They indicate what he thought were his life achievements. What is notable here is that he does not mention that he was secretary of state, vice president, and president. These political accomplishments were not at the top of his list.

Jefferson was born in Shadwell, Virginia. His father, Peter Jefferson, was a self-taught surveyor and mapmaker. Thomas was sent to William and Mary College in the colony's capital, Williamsburg. Jefferson took to the law under the tutelage of George Wythe. It should be noted that Thomas Jefferson had wide-ranging intellectual interests (as evidenced by the personal libraries he assembled that included natural philosophy, history, and the fine arts). Jefferson was also a man of action and in 1769 was elected to the House of Burgesses. He became active in politics and published "A Summary View of the Rights of British America." This tract took a Whig-oriented republican view. In 1776 he wrote the Declaration of Independence from a Lockean standpoint. And in 1787 he completed his only full-length book, *Notes on the State of Virginia* (part encyclopedia and reflections on the same). Most of his other writings consist of speeches, legislation, and letters. He was the architect for his famous house, Monticello, and he founded the University of Virginia.

HIS PHILOSOPHY

Most commentators cite the influence of John Locke on Jefferson. Locke's *Second Treatise on Government* depicted the strong individual within a state of nature. This individual possessed natural rights that came into play in establishing the social contract. Government was created by the people and could be dissolved if it did not serve popular purposes. Locke's approach is so greatly in evidence within the Declaration of Independence that Carl Becker has said that "Jefferson copied Locke" (1945, p. 79).

This is probably most true of the Declaration but is less true of Jefferson's other works, which show a broad influence from the liberal Enlightenment. The argument for this can be illustrated by Jefferson's repudiation of the Church of England (which set out a default religious position modified by toleration of other religions—a position accepted by Locke). Jefferson, however, insisted upon the absolute separation of church and state. The result of this is the Virginia Statute for Religious Freedom, which Jefferson wrote.

J. G. A. Pocock (1969) has argued that Jefferson's thought reflects the thinking of nonliberal republican thinkers such as Cicero, Machiavelli, and James Harrington. This argument follows from humankind's nature as political beings and the political heritage from ancient Rome onwards. The argument for this interpretation lies largely in discursive passages of the *Notes* and in his correspondence.

The empiricism of Francis Bacon is also present in Jefferson's work on agriculture. In the end, it seems safe to conclude that though Jefferson was greatly influenced by

John Locke, there are many philosophical lights that guided him. What Jefferson did was to assimilate these various influences and apply them to practical problems that confronted him in his role as a prominent man of action.

A MAN OF CONTRADICTIONS

In the end, any evaluation of Thomas Jefferson must come to terms with his many contradictions. On the one hand, he was an agrarian, individualist, advocate for limited government, and yet on the other hand he served in three national offices (including the presidency) and expanded the country greatly—particularly through the Louisiana Purchase. He also stated in the Declaration that "all men are created equal." Slavery certainly flies in the face of equality. At times in both "The Rights of British America" and in his correspondence, Jefferson calls for various versions of ending slavery. And yet Jefferson continued to own slaves himself. This can probably be explained by the fact that Jefferson did not completely believe that nonwhite individuals were fully human. For example, Jefferson says in the *Notes* (query 14) that "Never yet could I find that a black had uttered a thought above the level of plain narration …" If blacks and Native Americans were not fully human, then they have no place in the new Republic. They must be exiled so that the "pure" fully human European Americans might appropriate the wilderness—viewed as the state of nature. In the Lockean state of nature, if one could work the land and make productive use of it, then it was his. Because the native peoples were not fully human, the fact that they were using the land first would be irrelevant.

However, once we set out the above position, we are again faced with a contradiction. In November 1998 the magazine *Nature* published an article that strongly suggested that Thomas Jefferson was the father of his slave Sally Hemmings's last son, Madison Hemmings (1805–1877). It was also possible that Jefferson and Hemmings had five other children: four daughters and one other son. Though the evidence for this is not conclusive (because the DNA tests could have also been the same if another Jefferson relative were the father), still these results raise questions of the relationship between the races in Colonial times. Why would Thomas Jefferson have children with someone he believed to be subhuman? Two possibilities present themselves: (a) either Jefferson thought that interracial sexuality was merely a way to satisfy desire without thought of outcome; or (b) Jefferson's private actions did not match his public writings. The first alternative makes Jefferson into the sort of animal

brute he publicly eschewed. The second alternative humanizes Jefferson and shows that he might fall in love with and honor a woman of color. Under this second hypothesis, he might personally believe in a realm of equality that he could never publicly express (even though it matched his words in the Declaration of Independence). Racism against native peoples and African slaves was the public dogma. Yet, perhaps he found a human with whom he could share and cherish true human love? The real truth may be a combination of (a) and (b). Such tortured reasoning is reminiscent of William Faulkner's *Absalom, Absalom!* The worldviews of the public and private are so riddled with contradictions that they often lead to bizarre and brutal results.

In the context of all these contradictions stands Thomas Jefferson, the third president of the United States—though (in his own mind) most to be honored as the author of the Declaration of Independence, the Virginia Statue for Religious Freedom, and founder of the University of Virginia.

Michael Boylan (2005)

JEVONS, WILLIAM STANLEY
(1835–1882)

The British economist and logician William Stanley Jevons was the son of Thomas Jevons, a Liverpool iron merchant, and Mary Anne Roscoe, a lady of some literary note. After early schooling at Liverpool, he attended University College School and University College, London, where he sat under Augustus De Morgan. In 1854 he left London to take up the post of assayer at the mint in Sydney, Australia, but returned five years later to complete his studies. Soon after, in 1863, he secured a junior teaching position at Owens College, Manchester. By this time he had already published various minor papers on meteorology and economics, a statistical study of commercial fluctuations, and a small work, titled *Pure Logic* (London, 1864, reprinted 1890), reflecting the influence of George Boole. His book on *The Coal Question* (London, 1865) attracted the attention of William Gladstone and was the first to make him known as an economist. In 1866 he was appointed professor of logic and political economy at Manchester, and in the following year married Harriet Taylor, daughter of the proprietor of the *Manchester Guardian.*

Jevons was a conscientious lecturer, but he neither enjoyed nor excelled at the work; and his laborious habits of study led to recurrent breakdowns of health, which had to be repaired by Continental travel, generally to Norway. In spite of this, he wrote prolifically, publishing *The Substitution of Similars* (London, 1869, reprinted 1890); *Elementary Lessons in Logic* (London, 1870), a widely used textbook introductory to J. S. Mill; and *The Principles of Science* (London, 1874; 2nd ed., 1877), his most important contribution to scientific methodology, containing, among much else, an account of his celebrated logical machine. *The Theory of Political Economy* (London, 1871; 2nd ed., 1879) was an equally important landmark in the development of mathematical economics and the theory of utility, followed soon after by a no less influential work of applied analysis and description, *Money and the Mechanism of Exchange* (London, 1875). The once-famous speculations on the relation of sunspot cycles to financial crises, posthumously published in *Investigations in Currency and Finance* (London, 1884), exhibit, more curiously, the range of his interests and the originality of his mind.

Wearying of his duties, Jevons resigned his chair at Manchester in 1876 to take up a similar but more congenial post as professor of political economy at University College, London. This he also resigned, however, in 1880. The main works of this later period were *Studies and Exercises in Deductive Logic* (London, 1880) and *The State in Relation to Labour* (London, 1882). In 1882 he accidentally drowned, probably as the result of a heart attack, while bathing off the coast of Kent. His *Letters and Journal,* edited by his wife (London, 1886), gives an interesting portrait of him. His last work, *The Principles of Economics,* appeared, unfinished, in 1905.

LOGIC

Although marked by no special distinction of style, the writings of Jevons are still worth reading, both for their logical penetration and for their wealth of factual information drawn from many sources of knowledge. His logic owes something to De Morgan and a good deal more to Boole. It represents in the main an attempt to simplify Boole's system by eliminating the more complex and uninterpretable of its mathematical operations and by reducing its procedures of calculation to a mechanical routine. Jevons's own claim to independence in developing his logic as a calculus of qualities, rather than of classes or propositions, is of no great significance; and his method of treating propositions as identities and inferring from them by substitution, though simple enough in

its way, is too lacking in subtlety to have become the "logic of the future" that he once hoped it would be. The most successful of his reforms of the Boolean algebra have been the removal of its inverse operations of subtraction and division and the proposal to read the disjunctive symbol ("either … or") as including the possibility "both"—a practice now universal and resisted at the time only by the conservative John Venn.

Jevons's most interesting adaptation of Boole is to be seen in his method of indirect inference—the principle underlying his "logical piano" and other mechanical aids to calculation—whereby premises are used to eliminate inconsistent combinations of terms from a matrix listing all the possibilities under which a given set of terms and their negatives can be associated. The machine itself, exhibited at the Royal Society in 1870 and described in the *Philosophical Transactions* for the same year, anticipates in its design a number of the features of modern logical computers, while its mode of operation has some fairly obvious affinities with the use of a truth table, though it can hardly be said that Jevons had much grasp of its applications in that respect.

INDUCTION

The logical machine gave its answers only by displaying the combinations compatible with the information fed to it, leaving to the operator the task of finding a compendious formula to express them. The difficulties of this "inverse process" resist mechanical solution and are comparable, in Jevons's view, to those of induction, which he represents accordingly as the inverse operation of deduction—the problem, that is, of deciphering from a given set of phenomena the hidden laws they obey. The treatment of this problem in *The Principles of Science* is in line with the work of William Whewell and De Morgan and in somewhat embittered opposition to the views of Francis Bacon and Mill. Jevons, in short, is an apostle of the hypothetico-deductive method in science, although, unlike Whewell at least, he does not believe it to be a demonstrative procedure or capable of extending knowledge beyond the range of present or past observation. We are necessarily ignorant of the long-term behavior of the universe at large, and when to this ignorance are added the inevitable deficiencies of observation and measurement, it is evident that inductive conclusions can never be more than probable.

PROBABILITY

Jevons was led by the above considerations to give detailed attention to the theories of measurement,

approximation, and error and also to bring the whole conception of inductive inference into closer association with the theory of probabilities than was usual with the writers who preceded him. Probability he holds, with De Morgan, to be essentially subjective, though it is a measure of appropriate, rather than of mere actual, belief. It determines "rational expectation, by measuring the comparative amounts of knowledge and ignorance," as represented by the evidence available. That evidence, as nature presents it in the inductive situation, consists of sets of phenomena in combination. Having previously ascertained them (and presumably selected them, somehow, for relevance), we proceed, by more or less intuitive methods (of which Jevons gives no satisfactory account), to erect a hypothesis to explain them. From this in turn we deduce the direct probability of various sets of possible consequences. We then compare these supposed consequences with the known facts in order to determine the probability of their having occurred under the hypothesis in question. This process being repeated for every conceivable hypothesis, we are thereby in a position to assign a probability to each of them by use of the inversion theorem derived, via De Morgan, from Pierre Simon de Laplace. There is no guarantee that by this method the right answers will be forthcoming; but it justifies the adoption of the most probable hypothesis as a matter of practical policy, and that is the best we can expect.

The mathematical theory of inverse probability is, unfortunately, not equal to the weight that Jevons here put upon it, and his conclusions are accordingly unsound. There is no means of knowing that the a priori probabilities of the rival hypotheses are equal, as the theory requires; and there is still less warrant for its extension, by the "rule of succession," to the prediction of new instances or for the employment, where ignorance is total, of the "principle of indifference" to confer a probability of ½ on a proposition merely because knowledge of its truth or falsity is the same (namely, nil) in either case. The fallacies that Jevons committed under this head have since become notorious; the measurement of ignorance is less simple—and nature less like a ballot box—than he was apt to suppose. Errors of conception apart, however, his general view of scientific method has in recent years met with increasing support and is probably his most enduring legacy to the history of thought.

Bibliography

Jevons had no commentators. For a discussion of his logic, see references in the bibliography to the Logic, History of, entry. There is an early criticism of his theory of induction in Thomas Fowler, *Elements of Inductive Logic,* 3rd ed. (London: Clarendon Press, 1876), and scattered remarks of value occur in such general treatises as J. M. Keynes, *A Treatise of Probability* (London, 1921); William Kneale, *Probability and Induction* (Oxford: Clarendon Press, 1949); and G. H. von Wright, *The Logical Problem of Induction,* 2nd ed. (Oxford, 1949), and *A Treatise on Induction and Probability* (London: Routledge and Paul, 1951). See also the brief sketch in J. A. Passmore, *A Hundred Years of Philosophy* (London: Duckworth, 1957), pp. 132–136.

P. L. Heath (1967)

JEWISH AVERROISM

The thought of Averroes (Ibn Rushd) was popular in Jewish circles in the Middle Ages, as can be seen by the number of translations made into Hebrew. Some of his books survive only in Hebrew. Not all of these readers could be called Averroists, but some certainly did adhere to what they took to be the central ideas of Averroes himself. Jewish Averroism often included some degree of allegiance to Maimonides, who also developed a complex theory of how to link religion and philosophy. The major Averroists were Isaac Albalag, Joseph ibn Caspi, Moshe Narboni, Elijah Delmedigo, and many other more minor figures extending throughout the South of France and Italy.

One of the main features of Jewish Averroism was its way of distinguishing between rational and religious truths. Proving that religion is true by using reason is a mistake because religion and reason involve entirely different forms of argument. The Jewish Averroists nonetheless argued for the rational superiority of Judaism over against Christianity because the former, unlike the latter, does not call for the acceptance of logically self-contradictory beliefs such as those of transubstantiation, the Trinity, and the Virgin Birth.

THE MAJOR JEWISH AVERROISTS

Isaac Albalag came from the Pyrenees region during the second half of the thirteenth century. Albalag, like Averroes, regarded demonstrative argument to be the paradigmatic method of philosophy. Only philosophers can really use this sort of thought, Albalag claimed, and so only philosophers can really be allowed to say that they know what is true. He argues that when the literal sense of a religious text cannot be reconciled with its philosophical sense, both the literal sense and the philosophical understanding have to be accepted, but in different ways. The literal sense is accepted as something that one would understand completely if one were in the same position of the prophets who had originally transmitted the text. This takes him close to the so-called doctrine of double truth often ascribed to the Christian Averroists in their more radical moments.

Joseph ibn Caspi, born in 1279 in Provence, defended the literal sense of many passages in Scripture as accurate accounts of past events. He gives a naturalistic account of miracles and prophecy; the former are ill-understooood natural events, while prophets, according to Ibn Caspi, are people who understand the links between the present and the future.

Moses Narboni was born in Perpignan around 1300 and was critical of Maimonides' use of arguments drawn from Averroes. Narboni recognized that Averroes sought to challenge the Neoplatonic metaphysics of Ibn Sina (Avicenna), which formed an important part of Maimonides's thinking. Narboni also used Averroes's theory of the active intellect to provide an interest account of philosophical psychology. As human thinking becomes gradually perfected it moves from being largely imaginative to becoming more abstract and intellectual, and the material side comes under the control of thought. This is how religion and prophecy work: In themselves they are abstract but come to affect the material by inspiring and moving people to action. The prophets, according to Narboni, are provided for the majority who do not have the ability to use abstract thought because prophecy represents philosophical truths in imaginative language. There is one truth that is expressed in at least two different ways, one intellectually rigorous and the other practical and effective.

JEWISH PHILOSOPHY

The works constituting the Old Testament touch upon various problems that are discussed in philosophical texts, and the literary forms of some of these works, for instance that of the dialogue in the book of Job and that of Ecclesiastes, bear some similarity to those found in certain philosophical writings. However, a conception of philosophy that included biblical wisdom would lose in clarity and definiteness of outline what it would gain in comprehensiveness. Accordingly, there seems to be a certain amount of justification for considering, as is often done, that the history of Jewish philosophy commences in Alexandria around the beginning of the Christian era, when the first noteworthy attempt was made to use Greek philosophical concepts and methods to come to terms with facts that in the philosophical view are most peculiar, namely, Jewish history as interpreted in religious tradition and biblical revelation.

HELLENISTIC PERIOD

PHILO. The attempt to apply Greek philosophical concepts to Jewish doctrines was made by Philo Judaeus (fl. 20 BCE–40 CE), a prominent member of the Jewish community of Alexandria—he was a member of a delegation sent by this community in the year 39/40, when he was in his own view an old man, to the Roman Emperor Caligula to complain of persecution. Philo, a scholar who combined Greek and Jewish learning, was a most elusive thinker. The immense difficulties that beset any inquiry into Philo's basic conception of the world spring from a variety of sources. Some of the difficulties result from our ignorance of the Greek philosophical authors belonging to Philo's time, for we have only secondhand knowledge of them. Also insufficient is our information about post-biblical Jewish beliefs and speculations, which may be supposed to have shaped Philo's outlook—at least in part and perhaps decisively. However, Philo seems to have had some acquaintance with the oral law, which was being evolved in his time, mainly by the Pharisees in Palestine, and which much later was set down in writing in the Mishnah and in other works belonging to the Talmudic literature. He also knew of the Essenes, whom he praised highly. Some of the sect's theological doctrines, its ethical lore, and its pseudepigraphic literature may have been adapted by Philo to his own purposes.

In a sense Philo's main life's work was hermeneutic. On the one hand, he provided Jewish conceptions with the hallmark of intellectual (or cultural) respectability by stating them in Greek philosophical terms; on the other,

he showed that from the point of view of Judaism many Greek notions were unexceptionable—they could be regarded as consonant with Philo's own Jewish doctrine and with the allegorical sense of biblical texts. The homiletic character of most of his writings gave him full scope for his labor of interpretation. He had two schemes of reference—Jewish religious tradition and Greek philosophy—and the fact that he took care to stress the primacy of the former may have been more than mere lip service. In many of Philo's religious speculations the Jewish tradition in the particular form he adopted was not interpreted and explained away—as it was by most of the medieval Aristotelians—as being a mere rehash of philosophical doctrines in a language suited to the limited intellectual capacity of most people. It may be argued with a certain amount of plausibility that in central points of his thought, such as his conception of the Logos, Philo used philosophical notions as trappings for an originally nonphilosophical belief.

A main function of the Logos as conceived by Philo is to serve as an intermediary between the transcendent, unknowable God and the world, a view that probably has a close connection with the view of his Jewish contemporaries concerning the Word (Logos) of God, by means of which he accomplishes his designs. It is significant that the Logos of God is said by Philo to be the place occupied by the world of Ideas: This world is also called by Philo the intelligible world (*kosmos noetos*). The conception of Idea intended here is clearly the Platonic one, conceived of as having been "thought out" by God. The expression used by Philo may indicate that in his time Platonistic philosophers already tended, as the Middle Platonists and the Neoplatonists later did—to place Ideas in the mind of God.

Above philosophical and theological speculations Philo placed mystic ecstasy, of which he may have had a personal experience, "when, … as at noon-tide God shines around the soul, and the light of the mind fills it through and through and the shadows are driven from it by the rays which pour all around it" ("On Abraham," in *Philo,* 10 vols., translated by F. H. Colson and G. H. Whitaker, Cambridge, MA, and London, 1929–1937; Vol. VI, p. 63).

Philo's approach, his method of interpretation, and his way of thinking, as well as some of his conceptions, primarily that of the Logos, exerted a considerable influence on early Christian thought, but not to any comparable extent upon Jewish thought. Later, in the Middle Ages, knowledge of Philo among Jews was either very slight or, in the majority of cases, nonexistent.

TALMUDIC LITERATURE. Most Hellenized Jews were no doubt absorbed into the Christian communities. On the other hand, such historical catastrophes as the destruction of the Temple and the crushing of the various Jewish insurrections by the Romans may have brought about a spiritual withdrawal of the Jews from the circumambient Greco-Roman civilization, a stressing of their separateness. Moreover, as a result of these disasters the spiritual center of Jewry shifted to Iraq, a country that was part of the Persian Empire and less permeated by Greek culture than the regions belonging to the Imperium Romanum.

Some traces of a knowledge of popular, mainly Stoic, philosophy may be found in the Mishnah, a codification of the oral law composed in Palestine in the second century of the Christian era, and in the subsequent Talmudic literature set down in writing in Palestine and Iraq. On the whole, these traces are rather slight. Nevertheless, some scholars believe that the influence of Greek philosophy on Palestinian Jewry was far-reaching, but the case, to say the least, is not proven.

Jewish theological and cosmological speculations occur in the Midrashim, which, under the guise of interpreting biblical verses, propound allegorical interpretations, legends, and myths, and in the *Book of Creation* (*Sefer ha-Yeṣīra*), a work attributed to Abraham, which is a combination of a cosmogony and a grammar. There is no clear evidence of the period in which it was written; both the third century and the sixth or seventh century have been suggested.

MIDDLE AGES

MEDIEVAL LITERATURE. Hayuye (usually called Hivi) al-Balkhī, who appears to have lived in the ninth century in Muslim central Asia, seems to have been a Jewish representative of a brand of free thought also known in Islam, one that under dualistic influence criticized the God of the Bible, who, in view of the prevalence of evil and the fact of his omnipotence, cannot be just. Al-Balkhī seems to have favored Manichaeism—which at that time had a number of adepts—or at least to have been suspected of this heresy; this inference can be made from a preserved fragment of a polemical work directed against him by Saadya in the tenth century. According to Saadya, "the Lord" of al-Balkhī is being eaten, drunk, burnt, and commingled (v. 54 of *Sa'adia Refutatum*), a description that fits the primeval man of Manichaean mythology and the elements belonging to him.

In the ninth and tenth centuries, after a very long hiatus, systematic philosophy and ideology reappeared among Jews, a phenomenon indicative of their accession to Islamic civilization. There is undoubtedly a correlation between this rebirth of philosophy and theology and the social trends of that period, which produced Jewish financiers—some of whom were patrons of learning and who in fact, although perhaps not in theory, were members of the ruling class of the Islamic state—and Jewish physicians who associated on equal terms with Muslim and Christian intellectuals. The evolution of Islam in the ninth and tenth centuries showed that Greek scientific and philosophic lore could be separated at least to some extent from its pagan associations, could be transposed into another language and another culture; it also tended to show—and many Jewish thinkers learned the lesson—that a culture of which the sciences and philosophy and/or theology were an indispensable part could be based upon a monotheistic, prophetic religion that in all relevant essentials was closely akin to Judaism. The question whether philosophy is compatible with religious law (the answer being sometimes negative) constituted the main theme of the foremost medieval Jewish thinkers.

Approximately from the ninth to the thirteenth centuries, Jewish philosophical and theological thought participated in the evolution of Islamic philosophy and theology and manifested only in a limited sense a continuity of its own. Jewish philosophers showed no particular preference for philosophic texts written by Jewish authors over those composed by Muslims, and in many cases the significant works of Jewish thinkers constitute a reply or a reaction to the ideas of non-Jewish predecessors. Arabic was the main language of Jewish philosophic and scientific writings.

There was little regular teaching of philosophy in the religious universities of Islam (though some taught a brand of Kalām approved by the government) and none in the Jewish schools. Many Jewish philosophers seem to have earned their living or a part of it by practicing medicine, a fact that sometimes influenced their thought. A certain number (among them some physicians) were teachers of and authorities in religious law and active in community matters.

Iraq, a very important center of Jewish thought in the ninth and tenth centuries, counted several Jews among its intellectuals steeped in Greek philosophy. However, by far the most productive and influential Jewish thinkers of this period represented a very different tendency, that of the Muʿtazilite Kalām. Kalām (literally, "speech") is an Arabic term used both in Islamic and in Jewish vocabulary to designate several theological schools that were ostensibly opposed to Greek, particularly to

Aristotelian, philosophy; the Aristotelians, both Islamic and Jewish, regarded Kalām theologians (called the Mutukallimūn) with a certain contempt, holding them to be mere apologists, watchdogs of religion, and indifferent to truth. Herein they did not do justice to their adversaries.

SAADYA. The Muʿtazilite school formed in the eighth century appears to have had, at certain periods, representatives actuated by a genuine theoretical impulse. Its theology, forged in disputes with the Zoroastrians, the Manichaeans, and the Christians, claimed to be based on reason. This belief in reason, as well as most of the tenets of Muʿtazilite theology, were taken over by Saadya ben Joseph (882–942). He prepared an Arabic translation of the books of the Bible provided with commentaries and composed a number of legal and polemical treatises.

Saadya's main theological work, whose Arabic title, *Kitāb al-Amānāt waʿl'i tiqādāt,* may be translated "The Book of Beliefs and Creeds," is modeled to a considerable extent on similar Muʿtazilite treatises and on a Muʿtazilite classification of theological subject matter known as the "Five Principles." Like many Muʿtazilite authors, Saadya starts out by setting forth in his introduction a list and theory of the various sources of knowledge. It may be noted that in beginning systematic theological treatises in this way the Jewish and Islamic adherents of Kalām approximated not Greek philosophical practice but the custom of Indian philosophical writings, which also normally begin by propounding a doctrine of the sources of knowledge (*pramānāh*). The Organon and the expositions of logical disciplines stemming from it that in the Corpus Aristotelicum and in the treatises of the medieval Aristotelians precede the disquisitions on the natural sciences and metaphysics are very different from these analyses of the sources of knowledge.

Knowledge. Saadya distinguished four sources of knowledge: (1) The five senses, (2) the intellect, or reason, (3) necessary inferences, and (4) reliable information given by trustworthy persons. Concerning the first source, he was aware of the doubts expressed by skeptics about the truth of the sense data but rejected these doubts. He held that as a rule a healthy man, one without disabilities, may trust his senses. Exceptional cases do not carry the weight attributed to them by the Skeptics. In Saadya's sense of the word, intellect or reason (*al-ʿaql*) means first and foremost an immediate a priori cognition. In "The Book of Beliefs and Creeds" the intellect is characterized as having immediate ethical cognitions, that is, as discerning what is good and what is evil. How-

ever, in his commentary on the book of Proverbs, Saadya also attributes to it the cognition of simple mathematical truths. The third source of knowledge concerns inferences that, if we may judge by the examples given by Saadya, are of the type "if there is smoke, there is fire." These inferences are based on data furnished by the first two sources of knowledge. The fourth source of knowledge is meant to validate the teachings of Scripture and of the religious tradition. Teachings of Scripture must be held to be true because of the trustworthiness of the men who propounded them. One of the main purposes of the work is to show that the knowledge deriving from the fourth source concords with that discovered by means of the other three, or, in other words, that religion and human reason agree.

Saadya's "intellect," postulated as the second source of knowledge, has a function quite different from that of the intellect of the medieval Aristotelians, who did not regard even the most general ethical rules as being a priori cognitions. According to them these rules are accepted as true in virtue of a universal consensus; because of this, validity, unlike that of a priori intellectual truths, can be questioned.

In discussing the third source of knowledge, Saadya does not refer to the Aristotelian theory of the syllogism, but this may be because of ignorance; such knowledge of Greek thought as he possessed was derived mainly from compendiums of doxographers translated into Arabic or adapted by Arabic authors. However, unlike the Muʿtazilites and the Karaites, who were atomists, Saadya adopted a number of doctrines resembling Aristotle's physical views. Nevertheless, he had no use for the conception of an eternal order of nature. This position does not necessarily deny all validity to the theory of genera and species, which is a main concern of the Aristotelian syllogistic, but it certainly tends to limit, or in some cases to negate, the relevance of this theory to the actually existing world.

Theology. Saadya did not merely deny the eternity of the world but held, in common with other, less eclectic partisans of the Muʿtazilite Kalām that the demonstration of the temporal creation of the world must precede and pave the way for the proof of the existence of God the Creator. Of the four arguments which he brought forward in favor of temporal creation, the last is the most noteworthy: Creation in time is an inference from the impossibility of supposing that the past (the whole of time which has elapsed up to the present moment) is of infinite duration—for its infinitude would preclude its coming to an end; the present would never arrive.

Given the demonstrated truth that the world has a beginning in time, it can be proved that it could have been produced only through the action of a Creator. It can further be proved that there can have been only one Creator. God's unity means that he is not a body. It also means, according to a conception taken over from the Muʿtazilites, that he has no attributes superadded to his essence. This applies also to the three attributes that Saadya singled out, perhaps rather inconsistently, as belonging to the Creator: He must be held to be living, possessed of power, and possessed of knowledge.

Justice and free will. The theology of Saadya, like that of the Muʿtazilites, hinges on two principles, of which the unity of God is one; the other is the principle of justice, whose formulation in Islam may have been influenced by attacks of dualists similar to those of Hayuye al-Balkhī (see above), who contended that in view of the existence of evil, an omnipotent God cannot be regarded as just.

This principle takes issue with the view (widespread in Islam and present also in Judaism) that the definition of what is just and what is good depends solely on God's will, to which none of the moral criteria found among men is applicable; according to this view a revelation from God can convert an action now generally recognized as evil into a good action. Against this way of thinking, Saadya and the Muʿtazilites believed that being good and just or evil and unjust are intrinsic characteristics of human actions and cannot be changed by divine decree. The notions of justice and of the good as conceived by man are binding on God himself. In the words of a later thinker, Gottfried Wilhelm Leibniz, he can act only *sub specie boni.* Since, according to Saadya, man has a priori knowledge of good and evil, just and unjust, the fact that human ethical judgments are valid for God means that man's ethical cognitions are also those of the Deity.

This point of view cannot be accorded with strict determinism if one believes, as Saadya professed to do, that men are rewarded for good and punished for evil deeds. It would be contrary to divine justice to condemn or to recompense them for something they cannot help doing; hence, man must be a free agent. For sharing this doctrine with Saadya, the Muʿtazilites were accused of being the dualists of Islam; because of it, they could not regard God as the sole Doer. In Judaism the doctrine of man's free will and free action had very respectable antecedents, and Saadya's position on this point does not seem to have aroused antagonism.

Saadya's simple solution to the problem of reconciling free will with divine prescience seems to be in accord with traditional religious formulas. God has foreknowl-edge of all the actions that men will perform in the future, but this knowledge does not interfere with human freedom, which enables men to do whatever they wish, both good and evil.

Religious law. The function of religious law is to impose on man the accomplishment of good actions and to prohibit bad ones. Because Saadya believed that man has a priori knowledge of good and evil and that this knowledge coincides with the principles underlying the most important portions of the revealed law, he was forced to ask the question whether this law is not supererogatory. He could, however, point out that whereas the human intellect recognizes that certain actions—for instance, murder or theft—are evil, it cannot by itself discover the best possible definition of what constitutes a particular transgression; nor can it, if it has no other guidance than its own reflections, determine the punishment appropriate for a transgression. On both points the commandments of religious law give the best possible answers.

The commandments of religious law that accord with the behests of the human intellect were designated by Saadya as the "intellectual," or "rational," commandments, According to him they include the duty of manifesting gratitude to the Creator for the benefits he has bestowed upon man. Saadya recognized that a considerable number of commandments, for instance those dealing with the prohibition of work on the Sabbath, do not belong to this category. He held, however, that the obligation to obey them may be derived from the "rational" commandment that makes it incumbent upon man to be grateful to God, for such gratitude entails obedience to his orders.

THE KARAITES. Saadya's adoption of the "rational" Muʿtazilite theology was a part of his overall activity, directed toward the consolidation of rabbinical Judaism, which was being attacked by the Karaites. This Jewish sect, which was founded by Anan ben David in the eighth century and which seems to have had some connection or some affinity with earlier Jewish sects of the period of the Second Temple, rejected the authority of the oral Law, that is, of the Mishnah and the Talmud. In the tenth century and after, the Karaites accepted as their guides the Bible and human reason in the Muʿtazilite sense of the word. Their professed freedom from any involvement with postbiblical Jewish religious tradition obviously facilitated a "rational" approach to theological doctrine. This approach led the Karaite authors to criticize their opponents, the rabbinical Jews, for holding anthropo-

morphic beliefs based, in part at least, on texts of the Talmudic period. In formulating his theology Saadya had in mind the need to disprove this enlightened criticism.

The Karaites themselves adopted wholesale Muʿtazilite Kalām, including its atomism. The atomism of the Karaite theologians has only a very slight similarity to what is known of the theories of Democritus and Epicurus, although Epicurus's hypothesis concerning *minima,* about which we are ill informed, does bear some resemblance to an important point in Islamic and Jewish doctrines. These doctrines appear to have a certain similarity to a Greek mathematical atomism, about which we possess very scanty information. It may derive from the theories of the Pythagoreans and of Xenocrates. Furthermore—and it is a significant point—Muʿtazilite and Karaite atomism in important points are reminiscent of Indian atomistic theories, those of Buddhism and that of the Nyāya-Vaiśeṣika; a historical connection is not wholly impossible.

The Muʿtazilite atomists, followed by the Karaites, held that everything that exists consists of discrete parts. This applies not only to bodies but also to space, to time, to motion, and to the "accidents"—that is, qualities—which the Islamic and Jewish atomists regarded as being joined to the corporeal atoms (but not determined by them, as had been believed by the Greek atomists). An instant of time or a unit of motion does not continue the preceding instant or unit. All apparent processes are discontinuous, and there is no causal connection between their successive units of change. The fact that cotton put into fire generally burns does not mean that fire is a cause of burning; rather, it may be explained as a "habit," signifying that this sequence of what is often wrongly held to be cause and effect has no character of necessity. God's free will, which is not bound by the nonexistent laws of nature, is the only agent of everything that occurs, with the exception of one category. Man's actions are causes that produce effects—for instance, a man who throws a stone at another man, who is then killed, directly brings about the latter's death. This inconsistency on the part of the theologians was necessitated by the principle of justice, for it would be unjust to punish a man for a murder that was a result not of his action but of God's. This grudging admission that causality exists in certain strictly defined and circumscribed cases was occasioned by moral, not physical, considerations. It may be added that because of the opposition it aroused, the Kalām's denial of the existence of a necessary succession of events seems to have strengthened the conviction of the Muslim and Jewish Aristotelians that such order exists and that it is immutable.

ISRAELI. Outside Iraq, philosophical studies were pursued by Jews in the ninth and tenth centuries in Egypt and in the Maghreb. Here the outstanding figure is Isaac ben Solomon Israeli, who died in the beginning of the second half of the tenth century—when he was over a hundred years old, if we are to believe his biographers.

Israeli, a famed physician, was the propagator of a type of philosophy that did not satisfy the exigencies of the strict Aristotelians of a later period; Maimonides denied his being a philosopher, saying that "he was only a physician."

In his philosophical works, such as the "Book of Elements" and the "Book of Five Substances," he drew largely upon the Muslim popularizer of Greek philosophy Abū-Yūsuf Yaʿqūb ibn al-Kindī and also in all probability upon a lost pseudo-Aristotelian text. The peculiar form of Neoplatonic doctrine that seems to have been set forth in this text had, directly and indirectly, a considerable influence on medieval Jewish philosophy.

According to Israeli, God creates through his will and power. This reference to two aspects of the Deity has been compared to certain passages in Plotinus and in Arabic texts that in a considerable measure derive from Plotinus. It may be noted in addition that power and will are singled out for mention as attributes of God in some Christian texts (see, for instance, Ignatius's *Epistle to the Smyrnaeans,* in *The Apostolic Fathers,* edited by Kirsopp Lake, Vol. I, London, 1959, p. 253, and "Isaac ex Judaeo, *Liber Fidei,* in *Patrologia Graeca,* edited by J. P. Migne, Paris, 1857–1866, Vol. XXXIII, Col. 1543). The two things that were created first are form, identified with wisdom, and matter, which is designated as the genus of genera and which is the substratum of everything, not only of bodies, as was the opinion of the Aristotelians, but also of incorporeal substances. This conception of matter seems to derive from the Greek Neoplatonists Plotinus and Proclus, particularly from the latter. In Proclus's opinion, generality was one of the main criteria for determining the ontological priority of an entity. Matter, because of its indeterminacy, obviously has a high degree of generality; consequently, it figures among the entities having ontological priority. According to the Neoplatonic view, which Israeli seems to have adopted, the conjunction of matter and form gives rise to the intellect. A light sent forth from the intellect produces the rational soul. The animal soul is an emanation of the rational soul, and in its turn it gives rise to the vegetative soul.

As far as Jewish philosophy is concerned, Israeli's doctrine of prophecy seems to be the earliest theory attributing prophecy to the influence of the intellect on the imaginative faculty. According to Israeli this faculty receives from the intellect spiritual forms that are intermediate between corporeality and spirituality. This explanation implies that these forms "with which the prophets armed themselves" are inferior to purely intellectual cognitions.

IBN GABIROL. In essentials the schema of creation and emanation propounded by Isaac Israeli and his Neoplatonic source or sources was taken over by Solomon Ben Judah ibn Gabirol, a celebrated Hebrew poet of the eleventh century, who seems to have been the earliest Jewish philosopher of Spain.

Ibn Gabirol's chief philosophical work, "The Source of Life" (or *The Fountain of Life*), written in Arabic, has been preserved in full only in a twelfth-century Latin translation titled *Fons Vitae*.

Fons Vitae makes no reference to Judaism or to specifically Jewish doctrines; it is a nonironical dialogue between a disciple and the master who teaches him true philosophical knowledge. In the Middle Ages it was criticized with some reason for its prolixity; it is also full of contradictions. Nevertheless, it is a strangely impressive work. Few medieval texts so effectively communicate the Neoplatonic conception of the existence of a number of planes of being that differ according to their ontological priority, the derivative and inferior ones constituting a reflection in a grosser mode of existence of those which are prior and superior.

A central conception in Ibn Gabirol's philosophy is concerned with the divine will, which appears to be both part of and separate from the divine essence. Infinite according to its essence, the will is finite in its action. It is described as pervading everything that exists and as being the intermediary between the divine essence and matter and form. Will was one of a number of traditional appellations applied in various, mainly negative, theologies to the entity intermediate between the transcendent Deity and the world or, according to another, not necessarily incompatible interpretation, to the aspect of the Deity involved in creation. According to a statement in *Fons Vitae,* matter derives from the divine essence, whereas form derives from the divine will. This suggests that the difference between matter and form has some counterpart in the godhead and also that universal matter is superior to universal form. Some of Ibn Gabirol's statements seem to bear out the latter impression; other pas-

sages, however, appear to imply a superiority of universal form. The apparent contradiction seems to result from two conflicting approaches: the Aristotelian, which assumes that form (which is held to be *in actu*) is superior to matter (which per se exists only potentially), and the Neoplatonic, which in at least one of its manifestations consistently professed the superiority of matter, which, being indeterminate, could be held to be of a more universal, all-encompassing nature than form.

Form and matter, whether they be universal or particular, exist only in conjunction. All things, with the sole exception of God, are constituted through the union of the two; the intellect no less than the corporeal substance. In fact, the intellect is the first being in which universal matter and form are conjoined. In other words, Ibn Gabirol considered—in accord with Israeli—that the intellect is not one simple substance, as was thought by the faithful disciples of Aristotle; in his view its unity proceeds from a duality. The intellect contains and encompasses all things. It is through the grasp of the various planes of being, through ascending in knowledge to the world of the intellect and cognizing what is above it—the divine will and the world of the Deity—that man may "escape death" and reach "the source of life."

In the twelfth century Ibn Gabirol's system seems to have enjoyed a certain vogue among Jewish intellectuals living in Spain. Thus, Joseph Ben Jacob ibn Zaddik (d. 1149) and Abraham ibn Ezra (c. 1092–1167) were at least to some extent disciples of his. Ibn Zaddik was the author of the *Microcosm,* a work written in Arabic but extant only in a Hebrew translation, which draws a parallel between man and the microcosm. However, Abraham ibn Da'ud (see below) criticized Ibn Gabirol at length, denouncing the feebleness of his argumentation and the incorrect (that is, non-Aristotelian) conception of matter.

HALEVI. Yehuda Halevi (c. 1075–1141), also of Spain, who, like Ibn Gabirol, was a Hebrew poet, has the distinction of being the earliest and the most outstanding medieval Jewish thinker whose theology or philosophy (he would have repudiated the latter term) does not merely take Judaism in its stride, as was largely true of Saadya and the Karaites, to mention only two, but is consciously and consistently based upon arguments drawn from Jewish history.

His views are set forth in an Arabic dialogue whose full title is translated as "The Book of Proof and Demonstration in Aid of the Despised Religion." According to a custom that finds some justification in one of Halevi's letters, this work is usually referred to as the "Kuzari," the

Hebrew name of the king of the Khazars who is one of the two protagonists of the dialogue.

Basing his narrative on the historical fact that the Khazars were converted to Judaism, Halevi relates that their king, a pious man who did not belong to any of the great monotheistic religions, dreamed of an angel who said to him, "Your intentions are pleasing to the Creator, but your works are not." To find the correct way of pleasing God, the king seeks the guidance of a philosopher, of a Christian, of a Muslim, and, finally, after hesitating to have recourse to a representative of a people degraded by its historical misfortune, of a Jewish scholar, who converts him to Judaism.

The words of the angel heard in a dream may, in accordance with both religious and philosophical doctrine, be regarded as an (inferior) species of revelation. The use of this element of the story enabled Halevi to suggest that it is not the spontaneous activity of human reason that impels man to undertake the quest for the true religion; for this one needs the gift of prophecy, or at least a touch of the prophetic faculty (or a knowledge of the revelations of the past).

The argument of the philosopher whose advice is sought by the king brings this point home. This disquisition is a brilliant piece of writing, for it lays bare the essential differences—which the medieval philosophers often endeavored to dissimulate by means of circumlocution and double talk—between the Aristotelian God, who is totally ignorant of and consequently wholly indifferent to human individuals, and the God of religion.

Within the framework of philosophical doctrine, the angel's words are quite meaningless. Not only is the God of the philosophers, who is a pure intellect, not concerned with man's works, but the (cultural) activities, involving both mind and body, to which the angel clearly referred, cannot from the philosophical point of view either help or hinder man in the pursuance of the philosophers' supreme goal, the attainment of union with the Active Intellect. This union was supposed to confer knowledge of all the intelligibles. Thus, man's supreme goal was supposed to be of a purely intellectual nature.

In opposition to the philosopher's faith, the religion of Halevi's Jewish scholar is based upon the fact that God may have a close, direct relationship with man, who is not conceived primarily as a being endowed with intellect. The postulate that God can have intercourse with a creature made of the disgusting materials that go into the composition of the human body is scandalous to the king and prevents his acceptance of the doctrine concerning

prophecy expounded by the Muslim sage (just as the extraordinary nature of the Christological dogmas deters him from adopting Christianity). It may be noted that the opposition on this point between the king and the philosopher on the one hand and the Jew and the Muslim on the other reflects one of the main points of controversy between pagan authors and the Church Fathers (and some Gnostics in the first centuries of the Christian era). The moot point is whether a superior kind of man or, as many pagans believed, the souls or spirits ruling the heavenly bodies are the proper intermediaries between God, humankind, and the teachers of the arts and sciences. An echo of this controversy is found in Arabic literature, and Halevi, in developing his point of view, had probably adapted to some extent an older, non-Jewish source, at the same time making extensive use of Jewish religious tradition.

His position is that it is contemplation not of the cosmos but of Jewish history that procures knowledge of God. Halevi was aware of the odium attaching to the doctrine of the superiority of one particular nation; he held, however, that only this doctrine explains God's dealing with humankind, which like many other things, reason is unable to grasp. The controversies of the philosophers serve as proof of the failure of human intelligence to find valid solutions to the most important problems. Halevi's description of the specific Jewish position has also exercised a certain fascination upon several modern Jewish philosophers, such as Franz Rosenzweig.

HALEVI'S CONTEMPORARIES. As a speculative author Halevi was by no means an isolated phenomenon. During the period comprising the second half of the eleventh century and the first half of the twelfth century a number of Jewish thinkers appeared in Spain.

Bahya. In this period Bahya ben Joseph ibn Paquda (second half of the eleventh century) wrote one of the most popular books of Jewish "spiritual" literature, the "Commandments of the Heart," which combines a theology influenced by although not identical with that of Saadya with a moderate mysticism inspired by the teachings of the Muslim Sufis. The commandments of the heart—that is, those relating to men's thoughts and sentiments—are contrasted with the commandments of the limbs—that is, the Mosaic commandments enjoining or prohibiting certain actions. Bahya maintained that both sets of commandments should be observed, thus rejecting the antinomistic position. However, he made clear that first and foremost he was interested in the commandments of the heart.

Bar Hiyya. Abraham bar Hiyya (first half of the twelfth century), an outstanding mathematician, an astrologer, and a philosopher, outlined in *Megillat ha-Megalleh* a view of Jewish history which in some particulars is rather reminiscent of that of Yehuda Halevi but which does not emphasize to the same degree the uniqueness of that history and is set forth in much less impressive fashion. Living in Barcelona under Christian rule, bar Hiyya wrote his scientific and philosophical treatises not in Arabic but in Hebrew.

Ibn Ezra. Hebrew was also used by Abraham ibn Ezra, a native of Spain, who traveled extensively in Christian Europe. His commentaries on the Bible contributed to the diffusion among the Jews of Greek philosophical thought, to which Ibn Ezra made many, although as a rule disjointed, references.

Abu'l-Barakāt al-Baghdādī. The last outstanding Jewish philosopher of the Islamic East, Abu'l-Barakāt al-Baghdādī (died as a very old man after 1164), sometimes called Abu'l-Barakāt ibn Malkā, also belongs to this period. Being a borderline case he illustrates a certain indeterminacy in the definition of a Jewish thinker.

Abu'l-Barakāt al-Baghdādī, an inhabitant of Iraq, was converted to Islam in his old age (for reasons of expediency, according to his biographers). His philosophy appears to have had a very strong impact on Islamic thought, whereas its influence upon Jewish philosophy and theology is very hard to pin down and may be practically nonexistent. His chief philosophical work, *Kitāb al-Muʿtabar,* a title that according to Abu'l-Barakāt's own interpretation means "The Book of That Which Has Been Established by Personal Reflection," has very few references to Jewish texts or topics. His theory appears mainly to represent a kind of dialectic development of Avicenna's doctrine concerning the existence of the soul; it is a radicalization that plays havoc with the greater part of Avicenna's psychology and theology. On the other hand, another important work of his, a philosophical commentary on Ecclesiastes, attests his knowledge of and interest in Jewish tradition.

Ibn Kammūna. Ibn Kammūna, who lived in the second half of the thirteenth century, may be regarded as the last Jewish philosopher of the Islamic East. There is a possibility that he too was converted to Islam. He wrote a curious treatise, *Tanqīh al-abhāth bi'l-mabhath ʿan al-milal al-thalāth,* dealing, ostensibly impartially, with the three monotheistic religions—Judaism, Islam, and Christianity. His philosophical doctrine seems to derive from Avicenna and his thirteenth-century disciple Naṣīr al-Dīn al-Ṭūsī.

IBN DAʾUD. With regard to the adoption of Aristotelianism (including such systems as that of Avicenna, which in many essentials stems from, but profoundly modifies, the pure Peripatetic doctrine) there is a considerable time lag between the Islamic East in the one hand and Muslim Spain and the Maghreb on the other.

Abraham ibn Daʾud (died in the second half of the twelfth century), who is regarded as the first Jewish Aristotelian of Spain, was primarily a disciple of Avicenna. According to a not unlikely hypothesis, he may have translated or helped to translate some of Avicenna's works into Latin, for Ibn Daʾud lived under Christian rule in Toledo, a town that in the twelfth century was a center for translators. His historical treatises, written in Hebrew, manifest his desire to familiarize his coreligionists with the historical tradition of the Latin world, which at that time was alien to most of them. But his philosophical work, *Sefer ha-Emunah ha-Ramah* (The book of sublime religion), written in 1161 in Arabic, shows few, if any, signs of Christian influence.

The doctrine of emanation set forth in *Sefer ha-Emunah ha-Ramah* describes in the manner of Avicenna the procession of the ten incorporeal intellects, the first of which derives from God. This intellect produces the second intellect, and so on. Ibn Daʾud questioned in a fairly explicit manner Avicenna's views on the way the second intellect is produced; his discipleship did not by any means spell total adherence.

Ibn Daʾud's psychology was also, and more distinctively, derived from Avicenna. The argumentation leading to a proof that the rational faculty is not corporeal attempts to derive the nature of the soul from the fact of immediate self-awareness. Like Avicenna, Ibn Daʾud tended to found psychology on a theory of consciousness.

Concerning "practical" philosophy, that is, ethics and political theory, Ibn Daʾud was of the opinion that all that Aristotle discovered in this field of inquiry can be found in the Torah in a more perfect manner.

Sefer ha-Emunah ha-Ramah was said by its author to have been written in response to a question concerning free will and determinism. Obviously, this problem is closely bound up with the problem of God's knowledge. According to Ibn Daʾud events in this world are in part predetermined by necessity and in part contingent. Insofar as they are contingent, their occurrence or failure to occur may depend on man's actions. The necessary events are known by God as necessary, and the contingent as contingent. With regard to contingent events, he has no

certain knowledge of whether they will come about in the future.

Ibn Da'ud often referred to the accord that, in his view, existed between philosophy and religious tradition. As he remarked, *Sefer ha-Emunah ha-Ramah* was not meant to be read either by readers who, in their simplicity, are satisfied with what they know of religious tradition or by those who have a thorough knowledge of philosophy. It was intended for readers of one type only, those who, being on the one hand acquainted with the religious tradition and having on the other some rudiments of philosophy, are "perplexed." It was for the same kind of people that Maimonides wrote his *Guide of the Perplexed.*

MAIMONIDES. Maimonides (Moses ben Maimon, 1135–1204), a native of Spain, is incontestably the greatest name in Jewish medieval philosophy, but it is not because of outstanding originality in philosophical thought, in the proper sense of the term, that his reputation is deserved. Rather, the distinction of Maimonides, who is also the most eminent codifier of Jewish religious law, is to be found in the vast scope of his attempt in the *Guide of the Perplexed* to safeguard both the religious law and philosophy (whose divulgation is, as he was aware, destructive of the law), without suppressing the issues and without trying to impose, on the theoretical plane, a final, universally binding solution of the conflict.

As Maimonides made clear in his introduction to the *Guide,* he regarded his self-imposed task as perilous, and he therefore had recourse to a whole system of precautions destined to conceal his true meaning from the people who, lacking the necessary qualifications, were liable to misread the book and abandon observance of the law. According to Maimonides' explicit statement, these precautions include deliberately contradictory statements meant to mislead the undiscerning reader. It clearly follows that there is no possibility of propounding an interpretation of Maimonides' doctrine which would not be disproved or seem to be disproved by some passage or other of the *Guide.* Nevertheless, a consideration of the system as a coherent whole and of certain indications found in this work appears to suggest that Maimonides' true opinions on certain capital points are not beyond conjecture.

Conception of God. The apparent or real contradictions that may be encountered in the *Guide* are perhaps most flagrant in Maimonides' doctrine concerning God. There seems to be no plausible hypothesis capable of explaining away the differences between the following three views:

(1) God has an eternal will that is not bound by natural laws. Through an act of his will he created the world in time and imposed on it the order of nature. This creation is the greatest of miracles; if and only if it is admitted can other miracles, such as God's interventions, which interfere with the causally determined concatenation of events, be regarded as possible. The philosophers' God who is not free to cut the wings of a fly is to be rejected. This conception is in keeping with the traditional religious view of God and is adopted by Maimonides, if a statement of his is to be taken at its face value, because failure to do so would undermine religion.

(2) Man is incapable of having any positive knowledge concerning God. The ascription to God of the so-called divine attributes—wisdom or life, for instance—should not be regarded as an assertion that God is endowed with a positive quality designated as wisdom or life because it is similar to the corresponding quality found in created beings, for the fact is that their being homonyms is the only resemblance between human and divine wisdom or, for that matter, between man's and God's existence. Contrary to the attributes predicated of created beings, the divine attributes are strictly negative; they state what God is *not*; for instance, he is not *not-wise,* which, as Maimonides believed, is not a positive assertion.

Negative theology of a similar kind may be found in the writings of Islamic philosophers, such as Avicenna, who are known to have had some influence on Maimonides, but they put much less emphasis on this aspect of their doctrine concerning God. Maimonides used it, inter alia, to justify the statement that the only positive knowledge of God possible is that which is known through his acts, identified in the *Guide* as the sometimes beneficent and sometimes destructive operations of the natural order. In other words, human knowledge of God is assimilated into the knowledge of the two sciences that treat of this order, physics and metaphysics.

(3) In accordance with the doctrine of Aristotle, God is an intellect. The formula current among medieval philosophers which maintains that in him the cognizing subject, the cognized object, and the act of intellectual cognition are identical derives from Aristotle's thesis that God cognizes only himself. Maimonides, however, in adopting the formula interpreted it in the light of human psychology and epistemology, pointing out that according to a theory of Aristotle the act of human (not only of divine) cognition brings about an identity of the cogniz-

ing subject and cognized object. The parallel drawn by Maimonides between the human and the divine intellect quite evidently implies a certain similarity between the two; in other words, it is incompatible with the negative theology of other passages of the *Guide.* Maimonides' interpretation also implies that God knows not only himself (if the reflexive pronoun is taken to refer to his transcendent essence only) but also objects of cognition, that is, intelligibles held to be outside himself; however, in virtue of the eternal act of cognition, the objects of cognition—which should perhaps be assimilated into the intelligible structure of the world—are identical with God himself.

In view of the relation that it implies between God and the world, the conception of God as an intellect can scarcely be reconciled with Maimonides' negative theology; nor can it be reconciled with his theological doctrine, which is centered on God's will and which asserts that the structure of the world (created in time) came into being through the action of his will.

Prophecy. The enigma of the *Guide* would be nonexistent if Maimonides could be held to have believed that truth can be discovered in a suprarational way, through revelations vouchsafed to the prophets. This, however, is not the case. Maimonides held that the prophets (with the exception of Moses) combine great intellectual abilities, which qualify them to be philosophers, with a powerful imagination. As he put it, the intellectual faculty of the philosophers and the prophets receives an "overflow" from the Active Intellect. In the case of the prophets this "overflow" not only brings about intellectual activity but also passes over into the imaginative faculty, giving rise to visions and dreams. The fact that prophets have a strong imagination gives them no superiority in knowledge over philosophers, who do not have it. Moses, who belonged to a higher category than the other prophets, did not have recourse to imagination. According to another text of Maimonides, his commentary on the Mishnah, the prophets achieve union with the Active Intellect; hence, they are the supreme philosophers.

The laws and religion as instituted by Moses are intended not only to ensure the bodily welfare and safety of the members of the community but also to facilitate the attainment of intellectual truths by individuals gifted enough to uncover the various hints embodied in religious laws and practices. This does not mean that all the beliefs inculcated by Judaism are true. Some indeed express philosophical truths, although in an inaccurate way, in a language suited to the intellectual capacity of the common people, who in general cannot grasp the import

of the dogmas they are required to profess. Other beliefs, however, are false, but "necessary" for the preservation of a public order upholding justice. Such is the belief that God is angry with wrongdoers.

Religious law. As far as the law—that is, the religious commandments—is concerned, two aspects of Maimonides' position may be distinguished. On the one hand, he had to maintain that it is unique in its excellence; there is no basis of comparison between Moses, who promulgated this law, and any other prophet (or any other man) who existed in the past or who may appear in the future and, consequently, the law is valid for all time. This profession of faith, at least with regard to its assumptions about the future, lacked philosophical justification; however, in view of the Muslim polemics and perhaps also in view of incipient tendencies among the "perplexed" to neglect the observance of the commandments, it could be regarded as necessary for the survival of Judaism.

In its second aspect Maimonides' position is characterized by his awareness of the role of historical contingencies in the institution of the commandments. He insisted time and again that Moses had to fulfill two requirements: His law had to be different, but it could not be too different from the customs and ordinances of the pagans among whom the children of Israel lived. The people could not have borne too sharp a break with the way of life to which they were accustomed. For instance, the commandments concerning sacrifice arise from this awareness of the necessities of a specific historic situation. Like nature, which uses many complicated devices in forming a viable organism, the political leader, who must fashion his community, is sometimes compelled to have recourse to a "ruse" or a roundabout method.

Like Aristotle, Maimonides held that the "theoretical life" constitutes the highest perfection possible to man. But he believed (partly under the influence of the Platonic political doctrine adopted by al-Farabi and others) that certain individuals, for example, the Patriarchs and Moses, are capable of combining contemplation with a life of action. In its supreme manifestation the activity of the prophet-lawgiver imitates that of God or nature.

THE THIRTEENTH CENTURY. For four or five centuries (and in certain regions for an even longer time), the *Guide of the Perplexed* exercised a very strong influence in the European centers of Jewish thought; in the thirteenth century, when the *Guide* was twice translated into Hebrew, these centers were Spain, the south of France, and Italy. Rather paradoxically, in view of the unsystem-

atic character of Maimonides' exposition, it was used as a standard textbook of philosophy—and condemned as such when the teaching of philosophy came under attack. The performance of this function by the *Guide* was rendered possible or at least facilitated by the fact that from the thirteenth century onward the history of Jewish philosophy in European countries acquired a continuity it had never had before. First and foremost, this development seems to have resulted from a linguistic factor: In Spain, where the Christian reconquest was destroying piecemeal the power of Islam, Jewish philosophers abandoned the use of Arabic as the language of philosophical exposition. The Jews did not, however, switch to Latin, the language of Christian philosophy. They and their coreligionists in other European countries wrote in Hebrew, and they read original and translated texts extant in Hebrew, which were much less numerous and less diverse than those found in Arabic philosophical literature. Owing to the existence of a common and relatively homogeneous philosophical background and to the fact that Jewish philosophers reading and writing in Hebrew naturally read the works of their contemporaries and immediate predecessors, something like a dialogue can be discerned. In striking contrast to the immediately preceding period, European Jewish philosophers in the thirteenth century and after frequently devoted a very considerable part of their treatises to discussions of the opinions of other Jewish philosophers. That many of the Jewish philosophers in question wrote commentaries on the *Guide* undoubtedly furthered this tendency.

The influence of Maimonides' contemporary Averroes, many of whose commentaries and treatises were translated into Hebrew, was second only to that of Maimonides. Indeed, it may be argued that for philosophers, as distinct from the general reading public, it often came first. In certain cases, commentators on the *Guide* tend, in spite of the frequent divergences between the two philosophers, to quote Averroes's opinions in order to clarify those of Maimonides.

The influence of Christian scholastic thought on Jewish philosophy was in very many cases not openly acknowledged in the period beginning with the thirteenth century, but it seems to have been of great significance. Samuel ibn Tibbon, one of the translators of the *Guide* into Hebrew and a philosopher in his own right, remarked on the fact that the philosophical sciences were more widely known among Christians than among Muslims. Somewhat later, at the end of the thirteenth century and after, Jewish scholars in Italy (Hillel of Verona and others) translated into Hebrew texts of Thomas Aquinas

and other Scholastics; not infrequently, although by no means always, some of them acknowledged the debt they owed their Christian masters.

In Spain and in the south of France a different convention seems to have prevailed up to the second half of the fifteenth century. Whereas Jewish philosophers of these countries felt no reluctance about referring by name to Greek, Arabic, and of course other Jewish philosophers, as a rule they refrained from citing Christian thinkers whose views had, in all probability, influenced them. In the case of certain Jewish thinkers this absence of reference to the Christian Scholastics served to disguise the fact that in many essentials they were representative of the philosophical trends, such as Latin Averroism, that were current among the Christian Scholastics of their time.

Albalag. Quite evident is the resemblance between certain views professed by the Latin Averroists and the parallel opinions of Isaac Albalag, a Jewish philosopher who lived in the second half of the thirteenth century, probably in Catalonia, Spain, and who wrote a commentary in Hebrew on the "Intentions of the Philosophers," an exposition of Avicenna's doctrine written by the Muslim philosopher Mohammad al-Ghazali. No serious attempt at interpreting Albalag's assertion that both the teachings of the Bible and the truths demonstrated by reason must be believed even if they are contradictory can fail to pose the question whether some historical connections exists between this view and the Latin Averroist doctrine that there are two sets of truths, the religious and the philosophical, and that these are not necessarily in accord.

In most other points Albalag was a consistent follower of the system of Averroes himself (although a few of Albalag's doctrines appear to be in closer accord with Ibn Sīnā). This philosophical position may be exemplified by his rejection of the view that the world was created in time. He professed, it is true, to believe in what he called "absolute creation in time." However, this expression merely signifies that at any given moment the continued existence of the world depends on God's existence, an opinion which is essentially in harmony with Averroes.

Bedersi. Yeda'ya Hapnini Bedersi, of Béziers in the south of France, who lived from the end of the thirteenth century to the beginning of the fourteenth century, appears to have been influenced by the teaching of John Duns Scotus, for he believed in the existence of what he called individual forms, which seem by and large to correspond to the *haecceitas* of the Scotists.

Kaspi. One of Bedersi's contemporaries, Joseph Kaspi, a prolific philosopher and exegetical commentator, maintained a somewhat unsystematic philosophical position that seems to have been influenced by Averroes. He expressed the opinion that knowledge of the future, with that of God himself, is like that possessed by experienced people concerning the way in which business transactions or marriages may be expected to turn out—that is, such knowledge is of a probabilistic nature. The prescience of the prophets is of the same nature. It is more than likely that Kaspi's interest in this problem had some connection with the debate about future contingents in which Christian Scholastics were engaged at that time.

Kaspi also held that in view of the vicissitudes of history the return of the Jews to Palestine may on probabilistic grounds be considered likely. As a result he rejected the distinction—which for Yehuda Halevi, for instance, had been a basic one—between sacred and profane history, the first being the history of the people of Israel and the second that of other nations.

LATE MEDIEVAL PERIOD

KABBALAH. One of the most urgent problems with which Jewish philosophers were faced in the fourteenth and fifteenth centuries was that of the attitude to be adopted toward the Kabbalah (literally, "tradition"), a body of mystic and Gnostic doctrines, part of which was being elaborated in that period in the countries in which the philosophers lived.

Many of the Kabbalists incorporated philosophical doctrines in their writings and claimed Maimonides as a Kabbalist but at the same time regarded philosophy as such as an inferior kind of science. This disdainful attitude was reciprocated by some philosophers. Nonetheless, attempts were made to effect a reconciliation between philosophy and Kabbalah. Such an attempt was made by Joseph ibn Wāqār, a fourteenth-century philosopher of Toledo, who wrote "The Treatise Which Reconciles Philosophy and Religious Law" in Arabic (which in that period and country was atypical for a Jewish philosopher). According to Ibn Wāqār, the opinions of the philosophers are founded on reason, whereas those of the Kabbalists owe their validity solely to their having been transmitted by a tradition whose authority guarantees their truth. Although recognizing in theory the superiority of the Kabbalistic doctrine to the teachings of philosophy, Ibn Wāqār endeavored to show the basic similarity, masked by a difference of terminology, of the two systems of thought. He also affirmed that knowledge of philosophy increases the aptitude to apprehend the mystic doctrine of the Kabbalah.

NARBONI. Moses of Narbonne, or Moses Narboni, who lived in the south of France in the fourteenth century, was, like many other Jewish writers of this period, mainly a writer of commentaries. He wrote commentaries on biblical books, on treatises of Averroes, apocryphal treatises, and on Maimonides' *Guide.* In his commentary on the *Guide,* Narboni often interprets the earlier Jewish philosopher's opinions by recourse to Averroes's views. Narboni also expounded and gave radical interpretations to certain conceptions that he understood as implied in the *Guide.*

According to Narboni, God participates in all things because he is the measure of all substances. From another point of view all things exist in God, "the Agent being the essence of the patient." God is the form of the world. In Narboni's interpretation (which, not quite correctly, he opposed to that of Maimonides) this formula means that God is a form which, although it is not in a body, is "with a body": God's existence appears to be bound up with that of the world, to which he has a relation analogous to that existing between a soul and its body (a comparison already made in the *Guide*). As the form of the world, God also determines the fact that the extension of the world is limited. It may be added that, according to a conception of Narboni that runs counter to the views of many Aristotelian philosophers, prime matter has its place in the thought of God. Narboni seems to have been a consistent (and on the whole unusually outspoken) adherent of the Aristotelian tradition that crystallized in the Arabic period of Jewish philosophy.

GERSONIDES. Gersonides (Levi ben Gerson, 1288–1344), another fourteenth-century Jewish philosopher born in the south of France, wrote the systematic philosophical work *Milhamot Adonai* (The wars of the Lord) as well as many philosophical commentaries. As an astronomer he enjoyed a certain fame among Christian scholars. Gersonides apparently never explicitly mentioned Christian scholastic philosophers; he cited Greek, Arabic, and Jewish thinkers only, and in many ways his system appears to have stemmed from the doctrines of Maimonides or Averroes, regardless of whether he agreed with them. For example, he explicitly rejected Maimonides' doctrine of negative theology. However, a comparison of his opinions and of the particular problems that engaged his attention with the views and debates found in scholastic writings of his period suggest that he was also influenced by the Latins on certain points.

Creation. Gersonides disagreed both with the Aristotelian philosophers who maintained the eternity of the world and with the partisans of the religious who believed in the creation of the world in time out of nothing. He maintained that God created the world in time out of a preexistent body lacking all form. As conceived by Gersonides this body seems to be similar to primal matter. According to the Aristotelian conception, the "now" separates the past from the future; because of this function its existence at any moment of time entails the existence of a past. Hence, an absolute beginning is impossible, which means that the world is eternal. Gersonides rejected this argument because he believed that it is possible for a "now" to be restricted to the function of beginning or terminating an interval of time. Hence, there is no difficulty in supposing that the existence of a "now" at the instant of the creation of the world in time did not entail the existence of a past. This argument was discussed prior to Gersonides in a Latin Averroistic treatise whose author is unknown, and Gersonides may have been influenced by Latin Scholasticism on this point.

Free will and divine omniscience. The problem of human freedom of action and a particular version of the problem of God's knowledge of future contingents form an important part of Gersonides' doctrine. Gersonides—who, unlike the great Jewish and Muslim Aristotelians, believed in astrology—held that all happenings in the world except human actions are governed by a strict determinism. God's knowledge does not, however, extend to the individual human acts that actually occur. It embraces the general order of things that exist; it grasps the laws of the universal determinism but is incapable of apprehending events resulting from man's freedom. Thus, the object of God's knowledge is an ideal world order, which differs from the "real" world insofar as the latter is in some measure formed according to man's free will.

Political philosophy. In political and social doctrine there is a fundamental difference between Maimonides and Gersonides. Gersonides does not appear to have assigned to the prophets any political function; according to him their role consists in the prediction of future events. The providence exercised by the heavenly bodies ensures the existence in a given political society of men having an aptitude for and exercising the handicrafts and professions necessary for the survival of the community. He remarked that in this way the various human activities are distributed in a manner superior to that outlined in Plato's *Republic.* Thus, he rejected explicitly Plato's political philosophy, which, having been adapted to a society ruled through the laws promulgated by a prophet, had been an important element of Jewish philosophy in the Arabic period.

Gersonides' deviations from this philosophical tradition may have involved various factors, such as the influence of Thomas Aquinas (whose conception of human freedom, to mention but this example, resembles that of Gersonides) or Gersonides' belief in astrology or his pronounced predilection for personal speculation. These deviations did not, however, affect his fundamental allegiance to medieval Aristotelianism.

CRESCAS. Both Hasdai Crescas (1340–1410), a Spanish Jewish thinker, and Gersonides had thorough knowledge of Jewish philosophy and partial knowledge of Islamic philosophy, and both seem to have been influenced by scholastic thought; moreover, in certain important respects Crescas was influenced by Gersonides himself. However, in Crescas's main work, *Or Adonai* (The light of the Lord), one of his objectives, quite contrary to Gersonides, was to expose the weakness and insufficiency of Aristotelian philosophy. This attitude may be placed in the wider context of the return to religion itself as opposed to the Aristotelian rationalization of religion and the vogue of Kabbalah, characteristic features of Spanish Jewry in Crescas's time. This change in attitude has been regarded as a reaction to the increasing precariousness of the position of the Jewish community in Spain.

The low estimation of the certainties and the rationalistic arrogance of the medieval Aristotelians coincided chronologically with a certain disintegration of and disaffection toward what may be called the classical Aristotelian Scholasticism. Relevant to this decline were the so-called voluntarism of Duns Scotus, the nominalism of William of Ockham and other Scholastics, and the development, in the fourteenth century and after, of the anti-Aristotelian terminist physics at the University of Paris and elsewhere. It is significant that there is a pronounced resemblance between Crescas's views and two of these trends, Scotism and the "new" physics.

Divine attributes. Crescas accepted Gersonides' view that divine attributes cannot be negative, but unlike his predecessor he centered his explanation of the difference between the attributes of God and those of created existents on the antithesis between an infinite being and finite beings. It is through infinitude that God's essential attributes—wisdom, for instance—differ from the corresponding and otherwise similar attributes found in created beings. In Crescas's as in Benedict Spinoza's

doctrine, God's attributes are also infinite in number. The central place assigned to the thesis of God's infinity in Crescas's system suggests the influence of Duns Scotus's theology, which is similarly founded upon the concept of divine infinity.

Physics. The problem of the infinite approached from an altogether different angle was one of the main themes of Crescas's critique of Maimonides' twenty-five propositions; these propositions, concerned mainly with Aristotelian physical doctrines, had been set forth in the *Guide* as the basis of Maimonides' proofs for the existence of God. Crescas's declared purpose in criticizing and rejecting several of these propositions was to show that the traditional Aristotelian proofs (founded in the first place on physical doctrines) were not valid.

In the course of his critique Crescas attempted to disprove the Aristotelian thesis that the existence of an actual infinite is impossible. He held that space is not a limit but a tridimensional extension, that it is infinite, and that, contrary to Aristotle, the existence of a vacuum and of more worlds than one is possible. He also criticized as being impossible the thesis of the Aristotelian philosophers that there exists an infinite number of causes and effects, which have order and gradation. This thesis refers not to a temporal succession of causes and effects which have a similar ontological status but to a vertical series, descending from God to the lowest rung in creation. His attacks were likewise directed against the Aristotelians' conception of time and of matter.

The physical doctrines that emerged in Crescas's critique resemble the "new," mainly "terminist" physics, which was being worked out in the fourteenth century at the University of Paris and other Christian seats of learning and which had a considerable influence on the classical physical theories of Galileo Galilei and others. There is no difficulty in supposing that Crescas was acquainted with some of the terminist theses. Crescas may on the whole be regarded as an outstanding representative of the medieval "new physics."

Ascendancy of soul over intellect. Crescas's fundamental opposition to Aristotelianism is perhaps most evident in his rejection of the conception of intellectual activity as the supreme state of being for man and for God. Crescas's God is not first and foremost an intellect, and the supreme goal to which man can aspire is to love God with a love corresponding as far as possible to the infinite greatness of its object and to rejoice in the observance of his commandments. God too loves man, and his love, in spite of the lowliness of its object, is proportionate to his infinity.

Crescas attacked the separation of the intellect from the soul as conceived by the Aristotelians and attempted, perhaps under the influence of Yehuda Halevi, to refute the Peripatetic doctrine that the actualized intellect, in contradistinction to the soul, survives the death of the body. According to Crescas the soul is a substance in its own right and can be separated from the body; it continues to subsist after the body's death.

Crescas's depreciation of the intellect did not lead to an emphasis on man's freedom of action. Crescas's view concords with that of Avicenna: There is no such freedom; everything in the world is subject to a strict determinism. Man's actions are as predetermined as all other happenings; they depend on his makeup and conditioning and on his reactions to stimuli from the external world. Crescas did not deny man's freedom only with regard to the domain of external action, for he pointed out that a man's beliefs and knowledge are not within his power.

ALBO. Whereas Crescas unmistakably regarded the Aristotelian philosophers as adversaries to be criticized or combated, the attitude of Joseph Albo (c. 1380–1444), who regarded Crescas as his teacher, is much less clearly defined. Albo did not eschew self-contradiction, apparently considering it a legitimate precaution on the part of a philosophical or theological author; indeed, he indulged in it in a much more obvious way than did Maimonides. But whereas the latter's fundamental philosophical position is fairly clear, the problem being how far he was prepared to deviate from Aristotelian doctrine in the interests of religion, there may be valid doubt whether Crescas and the Jewish religious tradition or Maimonides and Averroes were Albo's true masters. Mainly because of this perhaps deliberate failure to explain to the reader where he really stood, Albo has often been dismissed as an eclectic. He was strongly influenced not only by the authors just mentioned but also by Saadya. He seems to have had a considerable knowledge of Christian theology, even adopting for his own purposes certain scholastic doctrines. He differs from Crescas and to some extent resembles Maimonides in having had a marked interest in political theory.

The proclaimed theme of Albo's magnum opus, *Sefer ha-Ikkarim* (*The Book of Principles*), is the investigation of the theory of Jewish religious dogmas, whose number Maimonides, in a nonphilosophical work, had set at thirteen, whereas Albo, following a doctrine that in the last analysis seems to go back to Averroes, would limit them to three: existence of God, providence in reward and pun-

ishment, and the Torah as a divine revelation. One section, usually including the philosophical and the traditional religious interpretations side by side, is devoted to each of these dogmas. However, as far as Jewish philosophy is concerned, Albo's principal relatively novel (although in view of the likelihood of a Christian influence, probably not original) contribution to doctrinal evolution is the classification, in his introduction, of natural, conventional, and divine law. Natural law is necessary because man, being political by nature, must belong to a community, which may be restricted in size to one town or may extend over the whole earth. Natural law preserves society by promoting right and repressing injustice; thus, it restrains men from stealing, robbing, and murdering. The concept of "natural law" may have been taken over by Albo from the Christian Scholastics; the term is rarely used in philosophical works written in Arabic, and when it occurs it has an altogether different meaning. Albo did not mention whether natural law accords with human nature; he accounted for the need for and acceptance of natural law on purely utilitarian grounds. He did, however, believe that natural law is the same among all people, at all times, and in all places.

The positive laws instituted by wise men take into account the particular nature of the people for whose benefit they are instituted, as well as other circumstances. This means that they differ from the natural law in not being universally applicable. However, neither natural law nor the more elaborate conventional laws lead men toward true spiritual happiness; this is the function of divine laws instituted by a prophet, which teach men true theoretical opinions.

Contrary to Maimonides, but in agreement with the Scholastics and to some extent with Saadya, Albo believed that men are capable of establishing an orderly society by their own efforts, without the help of prophets.

Whereas Maimonides maintained that Judaism was the only divine law promulgated by a true prophet, Albo considered that the commandments given to Noah also constitute divine law, which ensures, although to a lesser degree than does Judaism, the happiness of its adherents. This position justifies a certain universalism; in accordance with a Talmudic saying, Albo believed that the pious among the non-Jews—that is, those who observe Noah's laws—have a share in the world to come. But he rejected the pretensions of Christianity and Islam to be divine laws.

RENAISSANCE. In the last few decades before their expulsion (1492), the Spanish Jews seem to have freely acknowledged the influence of the Christian Scholastics. A tribute to Christian thought was made not only by Habilla, a translator of several scholastic texts into Hebrew, but also by Isaac Arama and Isaac Abravanel, both of whom immigrated to Italy after the expulsion. Both are critical in various degrees of Aristotelians. Some of the views of Arama (who seems to have influenced Abravanel) mark a return to Yehuda Halevi. Abravanel's political doctrine is of some interest because it refers to and bestows praise on the regimes of the Italian republics of the period.

The son of Isaac Abravanel, Judah Abravanel, better known as Leone Ebreo (1460–c. 1521), was the author of *Dialoghi d'amore* and as such is one of the outstanding representatives of Platonism in Italy. He is perhaps the first example in postmedieval times of an important Jewish thinker who does not belong primarily to the history of Jewish philosophy (for the conception of Jewish philosophy presupposed in this assertion, see below).

Elijah del Medigo (c. 1460–1493), who was born in Crete, was a Jewish Averroist and a companion of Giovanni Pico della Mirandola. In his Hebrew treatise *Beḥinat Hadat* (The testing of religion) he opposed the trend among Jewish philosophers to read philosophical meanings into biblical texts by means of allegorical interpretations. Del Medigo, like Averroes, did not countenance any attempt to amalgamate religious law and philosophy. The Jewish philosophers who had such an amalgam in mind—it is pretty clear that Maimonides is the foremost object of these strictures—are neither (true) philosophers nor (true) professors of religious law.

MODERN AND CONTEMPORARY PERIODS

The expulsion of the Jews from Spain and Portugal produced a new center of Jewish thought, Holland, where many of the exiled Jews found a new and safer domicile; the tolerance of the regime seemed to provide guarantees against external persecution. This did not prevent, and indeed may have furthered, the establishment of an oppressive orthodoxy that was prepared to chastise rebellious members of its community.

DA COSTA. Both Uriel da Costa, or Acosta (1585–1640), and Spinoza (1632–1677) rebelled against Jewish orthodoxy. Uriel da Costa came to Amsterdam from Portugal, where, belonging to a family of Marranos (Jews who had converted to escape the Spanish Inquisition), he had been brought up in the Catholic faith; his philosophical position was to a great extent determined by his antagonism

to the orthodox Judaism (the Judaism of "the Pharisees," to use his term) that he encountered in Amsterdam. He was struck by the fact that the commandments as interpreted by his contemporaries did not conform to the text of the Torah, and he formulated a number of theses to prove his point. His growing estrangement from generally accepted Jewish doctrine is attested by his Portuguese treatise *Sobre a Mortalidade da Alma* (On the mortality of the soul). Apparently under the influence of Michael Servetus, he came to the conclusion that the soul is the vital spirit located in the blood and that it dies with the death of the body, there being no difference in this respect between the human and the animal soul. He considered that the belief in the immortality of the soul has had many evil effects, for it impels men to choose an ascetic way of life and even to seek death. According to him nothing has tormented men more than the belief in an eternal good and evil. God tolerates this opinion merely to torture the conscience of those who have abandoned his truth. At this stage da Costa affirmed the authority of the Bible from which, according to him, the mortality of the soul can be proved.

In his autobiography, written in Latin and titled *Exemplar Humanae Vitae* (An example of human life), he takes a more radical position. He proclaims the supreme excellency of the natural moral law (which, when arguing before the Jews, he seems to identify with the divine commandments to Noah—a comparison may be made with the view of Albo). Accordingly, he denies the validity of the argument that natural law is inferior to Judaism and Christianity, because he believes that both these religions teach the love of one's enemies, a precept which is not a part of natural law. According to da Costa, no good can come of demanding a manifest impossibility.

SPINOZA. Although medieval philosophers of Jewish origin for whom Judaism does not constitute a primary philosophical theme are thought of as belonging to the history of Jewish philosophy, a classification of this kind applied to such modern philosophers of Jewish origin as Salomon Maimon, Henri Bergson, Edmund Husserl, and L. I. Shestov might lead to some significant conclusions but would nevertheless seem inappropriate. It would certainly not be in keeping with the intentions of the philosophers themselves, and their views would be taken out of their natural contexts.

These considerations, however, may not, for the following reasons, be quite so valid with respect to Spinoza: (1) It was through the study of Jewish philosophical texts that Spinoza was first initiated into philosophy. (2) It may

be argued with some reason that at least in part (if one abstracts the influence of René Descartes and of seventeenth-century physics and certain other constitutive elements), Spinoza's system is a radicalization or perhaps a logical corollary to medieval doctrines; although its importance may be contested, the impact of Maimonides and of Crescas is evident. (3) A considerable portion of Spinoza's *Tractatus Theologico-politicus* deals with problems related to Judaism. Reference to some of the views set forth in the *Tractatus* and to their connection with medieval Jewish doctrines may not be out of place here.

Prophecy. As the first chapters of the *Tractatus* show, the doctrine of prophecy is of central importance to Spinoza's explanation of Judaism. These chapters can also provide proof that, as far as this subject is concerned, Spinoza to a large extent used Maimonides' categories, although he applied them to different people or groups of people. In fact, the relationship of Spinoza to Maimonides—although antagonistic—is much closer than that of most of the fifteenth-century Jewish philosophers who did not break with Judaism.

Maimonides held that the prophets combined intellectual perfection, which made them philosophers, with perfection of the imaginative faculty. He also referred to a category of people endowed with a strong imagination but possessing no extraordinary intellectual gifts; this category includes, for example, lawgivers and statesmen. Spinoza took over this last category but applied it to the prophets, whom he described as possessing vivid imaginations but as not necessarily having outstanding intellectual capacities. He denied that the biblical prophets were philosophers and used a philosophical and historical approach to the Scriptures to show that the contrary assertion is not borne out by the texts.

Spinoza also denied Maimonides' assertion that the prophecy of Moses was essentially different from that of the other prophets and that this was largely because Moses, in prophesying, had no recourse to the imaginative faculty. According to Spinoza the distinctive fact about Moses' prophecy was that he heard the voice of God in a prophetic vision—that is, in a state in which his imagination was active. In this assertion Spinoza employed one of Maimonides' categories of prophecy, differentiated in the *Guide* according to certain characteristics of prophetic dreams and visions. However, Maimonides thought it improbable that the voice of God was ever heard in prophetic vision; he held that this category is purely hypothetical. It seems evident that in his classification of Moses, Spinoza was concerned not with what

really happened in history but with pigeonholing the evidence culled from the Bible into Maimonides' theoretical framework in such a way that it fit in with his theologicopolitical purpose.

This purpose made it imperative to propound in the *Tractatus* a theory concerning Jesus, whom Spinoza designates as Christus. The category and the status assigned to Jesus are by and large similar to those that Maimonides attributed to Moses. Thus, Jesus is referred to in the *Tractatus* as a religious teacher who makes recourse not to the imaginative faculty but solely to the intellect. However, in following up this hypothesis Spinoza was guilty of an inconsistency. Whereas in the case of the Old Testament prophets he rejected allegorical interpretations predicated on the supposition that the prophets adapted their discourses to the understanding of the general public, in the case of Jesus he adopted this interpretation because he wished to explain away those of Jesus' sayings that he regarded as incompatible with true philosophical doctrine. Both Maimonides' Moses and Spinoza's Jesus are absolutely unique personalities; there is, however, an important difference between them. In the opinion both of Maimonides and of Spinoza, Moses' legislation created the Jewish community and state, whereas Jesus as conceived by Spinoza was not a lawgiver and, as far as his direct activity was concerned, not a statesman, though within Spinoza's blueprint for an ideal State, he is assigned a political function: His authority may be used to institute and strengthen the religion Spinoza called *religio catholica,* which has little or nothing in common with any of the major manifestations of historic Christianity.

Critique of Judaism. The difference between Judaism and Spinoza's *religio catholica* corresponds to the difference between Moses and Jesus. After leaving Egypt the Jews found themselves, in Spinoza's view, in the position of people who had no allegiance to any positive law; they had, as it were, reverted to a state of nature and were faced with the need to enter into a social pact. They were also an ignorant people and very prone to superstition. Moses, a man of outstanding ability, made use of the situation and characteristics of the people in order to make them accept a social pact and a state founded upon it, which, contrary to Spinoza's schema for his ideal communities, were not based first and foremost upon utilitarian—that is, reasonable—consideration of the advantages of life in society over the state of nature.

The social pact concluded by the children of Israel in the desert was based upon a superstitious view of God as "King" and "Judge," to whom the children of Israel owed whatever political and military successes they obtained. It was to God rather than to the representatives of the popular will that the children of Israel transferred political sovereignty. In due course political sovereignty was vested in Moses, God's representative, and in his successors. It should be added that in spite of Spinoza's insistence on the superstitious foundations of the state of the children of Israel in ancient times, his account of its regime was not wholly unsympathetic. He did, however, believe that it contained the seeds of its own destruction and that with the extinction of this state the social pact devised by Moses had lapsed and all the political and religious obligations incumbent upon the Jews become null and void.

"Religio catholica." It could be argued that because the state conceived by Spinoza is based not on superstitious faith but on a social contract originating in rational, utilitarian considerations it does not necessarily need to have its authority safeguarded and stabilized by means of religion. However, Spinoza appears to have held the view—perhaps derived from a purely empirical knowledge of the behavior of the common run of men—that there is a need for religion. In order to fulfill the need for some religion and to obviate the danger of harmful religions, he devised his *religio catholica,* the universal religion, which has the following distinctive traits: (1) Its main purpose, a practical one (which is furthered by recourse to the authority of Jesus), is to impel men to act in accordance with justice and charity. Such conduct is tantamount to obedience to the laws of the state and to the orders of the magistrates, in whom sovereignty is vested. For disobedience—even if it springs from compassionate motives—weakens the social pact, which safeguards the welfare of all the members of the community; in consequence, its evil effects outweigh whatever good it may produce. (2) Although religion, according to Spinoza, is not concerned with theoretical truth, in order to be effective the *religio catholica* requires dogmas, which he set forth in the *Tractatus.* These dogmas are formulated there in terms that can be interpreted in accordance both with the philosophical conception of God that Spinoza regarded as true and with the superstitious ideas of ordinary people. It follows that if they are accepted as constituting by themselves the only creed that everybody is obliged to profess, people cannot be persecuted on account of their beliefs; Spinoza held that such a persecution is liable to lead to civil war and may thus destroy the state. Philosophers are free to engage in the pursuit of truth and to attain, if they can, the supreme goal of man, freedom grounded in knowledge. There can be little doubt that the furtherance of the cause of tolerance for

philosophical opinions was one of Spinoza's main objects in writing the *Tractatus.*

MENDELSSOHN. Moses Mendelssohn (1729–1786) opens what may be called the German period of Jewish philosophy. This period, in which a considerable number of works on Jewish philosophy were written in German and often under the influence of German philosophy, is also marked by the emancipation of the Jews (that is, by the abrogation of discriminatory laws directed against them) and by their partial or complete assimilation. In this period in particular, it appears indicated to apply the term "Jewish philosophy" first and foremost to works whose main purpose or one of whose main purposes consists in proposing a definition of Judaism and a justification of its existence. The second task is often conceived as necessitating a confrontation of Judaism with Christianity rather than with philosophy, which served as a point of comparison for many medieval philosophers. This change seems to have been a result of the demarcation of the sphere of religion in such a way that, at least in the opinion of the philosophers, possible points of collision no longer existed between it and philosophy.

This demarcation was largely furthered by the doctrine of Spinoza—from whom Mendelssohn and others took over and adopted for their own purposes certain fundamental ideas concerning Judaism. Like Spinoza, Mendelssohn held (according to his treatise *Jerusalem* and other writings) that it is not the task of Judaism to teach rational truths, although they may be referred to in the Bible. Contrary to what he called Athanasian Christianity (that is, the doctrine set forth in the Athanasian creed), Judaism has no binding dogmas; it is centered on inculcating belief in certain historical events and on action—that is, observance of religious law (including the ceremonial commandments). Such observance is supposed to lead to happiness in this world and in the afterlife. Mendelssohn did not reject this view offhand, as Spinoza would have done; indeed, he seems to have been prepared to accept it—God's mysteries being inscrutable, and the radicalism and what may be called the consistency of Spinoza being the complete antithesis of Mendelssohn's apologetics. Non-Jews were supposed by Mendelssohn to owe allegiance to the law of nature. He did not affirm the superiority of Judaism over this law and was prepared to regard Jesus as a great prophet. He declared his belief that the differences between the various religions are not eternal and that when the whole earth is united in the knowledge of God, the Jews will be permitted to abandon their peculiar rites and ceremonies. But that time has not yet arrived.

Mendelssohn was well grounded in medieval Jewish philosophy and referred quite frequently to the writings of Maimonides and of other Jewish thinkers of the Middle Ages. The three principles on which he held Judaism to be based call to mind those propounded by Albo. They are God, providence, and the divine law.

FORMSTECHER. Whereas Mendelssohn continued the medieval tradition, at least to some extent, or adopted Spinoza's doctrine for his purposes, the Jewish philosophers of the first half of the nineteenth century (except, at least in a certain measure, Solomon Steinheim) may be regarded as disciples of the philosophers of their own time. In *Die Religion des Geistes* (The religion of the spirit), Solomon Formstecher (1808–1889) was greatly influenced by Friedrich Schelling in his conception of nature and spirit as manifestations of the divine. There are types of religions that correspond to these manifestations: (1) the religion of nature in which God is conceived as the principle of nature or as the world soul, and (2) the religion of the Spirit which conceives of God as an ethical being. According to the religion of the Spirit, God has produced the world as his manifestation in full freedom and not, as the religion of nature tends to profess, because the world was necessary for his own existence.

The religion of the Spirit, which corresponds to absolute religious truth, was first manifested in the Jewish people. The religious history of the world may be understood as a process of universalization of the Jewish religion. Thus, Christianity propagated Jewish conceptions among the nations; however, it combined them with pagan ideas. The pagan element is gradually being eliminated—Protestantism, for instance, in this respect marks considerable progress. When at long last the Jewish element in Christianity is victorious, the Jews will be right to give up their isolation. The process that will bring about this final religious union is already under way.

HIRSCH. The main philosophical work of Samuel Hirsch (1815–1889), titled *Die Religionsphilosophie der Juden* (The philosophy of religion of the Jews) was decisively influenced by G. W. F. Hegel. This influence is most evident in Hirsch's method and in the task that he assigned to the philosophy of religion—the transformation of religious consciousness into conceptual truth. However, contrary to Hegel, he did not consider religious truth to be inadequate as compared to philosophical truth.

Hirsch believed that man's awareness of himself as an ego is identical with his awareness of his freedom. This freedom is, however, abstract; it became concrete in the

various historical religions. Man may renounce this freedom and believe that he is dominated by his senses. This means recognizing the absolute sovereignty of nature regarded as a divine principle, which is the point of departure of the pagan passive religions. If, however, he subordinates his nature to his freedom, his freedom becomes concrete. God is conceived not only as the giver of abstract freedom but as willing man's concrete freedom. This is the principle of Judaism. Christianity, was conceived by Hirsch as it was by Formstecher, as being intermediate between Judaism and paganism.

God revealed himself in the first stages of Jewish history by means of miracles and of prophecy. At present he manifests himself in the miracle that is constituted by the existence of the Jewish people. At its beginning in the time of Jesus, Christianity was identical with Judaism. The decisive break between the two religions was caused by Paul. According to Hirsch, when the Pauline elements are eliminated from Christianity, it will be in all essentials in agreement with Judaism, which, however, will preserve its separate existence.

KROCHMAL. Nachman Krochmal (1785–1840), a native of Galicia (at that time part of Austria), was the author of *Moreh Nebukhei ha-Zman* (Guide of the perplexed for our time), a treatise in Hebrew on philosophy of history and on Jewish history, which had a considerable influence.

Krochmal, like Hirsch, was influenced by Hegel and perhaps also by other German philosophers approximately of Hegel's period, such as Johann Gottlieb Fichte. Krochmal's philosophical thought was centered on the notion of "spirit," Krochmal being mainly concerned with the "national spirit," the particular "spirit" that is proper to each people and that accounts for the peculiar characteristics differentiating one people from another in every domain of human activity.

The national "spirits" of all peoples except the Jewish are, according to Krochmal, essentially particular. Hence, the national spirit either becomes extinct with the extinction of the nation or, if it is a powerful spirit, is assimilated by some other nation. The Jewish people has a special relation to the Universal Spirit, who is the God of Israel. This relation accounts for the perpetuity of the Jewish people.

STEINHEIM. Solomon Ludwig Steinheim (1789–1866), the author of *Die Offenbarung nach dem Lehrbegriff der Synagoge,* (Revelation according to the doctrine of the synagogue), was apparently influenced by the antirationalism of Friedrich Jacobi.

His criticism of science is based on Jacobi's criticism, but he did not agree with Jacobi in opposing discursive reason to our intuitive knowledge of God—Steinheim contrasted human reason to divine revelation. The main point on which the revelation vouchsafed to the prophets of Israel is opposed to reason is to be found in the fact that the God posited by reason is subject to necessity, that he can act only in accordance with laws. Moreover, reason affirms that nothing can come from nothing. Accordingly, God is free to create not a good world but only the best possible world. Revealed religion, on the other hand, affirms the freedom of God and the creation of the world out of nothing.

COHEN. There seems to be little connection between the Jewish philosophers of the first half or two-thirds of the nineteenth century and Hermann Cohen (1842–1918), the head of the Marburg Neo-Kantian school. In a certain sense Cohen may be regarded as a rather unusual case among the philosophers of Judaism of his and the preceding generations, because of the two aspects of his philosophical thought—the general and the Jewish—and the uneasy equilibrium between them. Judaism was by no means the only important theme of his philosophical system; it was one of several and not even his point of departure. There is no doubt that for most of his life Cohen was wholly committed to his brand of Kantianism, in the elaboration of which he displayed considerable originality—it has been maintained with some justification that his doctrine manifests a certain (unintentional) kinship with Hegel's. However, Cohen's idea of God derives from an analysis and a development of certain conceptions of Immanuel Kant.

In Cohen's view, reason requires that nature be conceived of as conforming to *one* rational plan and that harmony exist between the domains of natural and of moral teleology. These two requirements in turn necessitate the adoption of the idea of God—the word *idea* being used in the Kantian sense, which means that no assertion is made about the metaphysical reality of God. Cohen's theory of ethics stemmed to a considerable extent from Kant's, but he held that the most important ethical principles were discovered by the prophets of Israel, who freed religion from its entanglement with mythology. A harmony also exists between the Messianic notion of the Jewish prophets and the exigency of ethics that the task of coming ever closer to moral perfection be pursued unceas-

ingly. This goal will never be wholly attained. Messianism, too, is an idea in the Kantian sense of the word.

Cohen seems to have changed his attitude in the last years of his life; at least, although he did not explicitly renounce his previous positions, a considerable shift of emphasis can be discerned in his doctrines. The notion of the human individual—an individual who is weak and full of sin—comes to the fore, as well as the conception of a *correlation,* a relationship between God and the individual. This relationship is one of love, the love of God for man and the love of man for God. It is difficult to reconcile the conception of God expounded in Cohen's works of his last period with his Kantian or Neo-Kantian attitude toward metaphysics.

The conceptions of God and the individual and cognate conceptions are set forth in Cohen's posthumously published book *Die Religion der Vernunft aus den Quellen des Judentums* (Religion of reason from the sources of Judaism) and in a series of articles reprinted in his *Jüdische Schriften.*

ROSENZWEIG. Franz Rosenzweig (1886–1929) published his main philosophical work, *Der Stern der Erlösung* (The star of redemption), in 1921. This work begins with a rejection of the traditional philosophical attitude that denies the fear of death, maintaining, instead, that this fear is the beginning of the cognition of the All. Man should continue to fear death, despite the indifference of philosophy and its predilection for accepting death. Traditional philosophy is interested exclusively in the universal, and it is monistic—its aim is to discover one principle from which everything can be derived. However, this tendency of philosophy denatures human experience, which knows not one but three separate domains (which Kant had referred to in a different context), namely, God, the world, and man.

According to Rosenzweig, God (like the world and like man) is known through experience (the experience of revelation). In Greek paganism, the most perfect manifestation of paganism in general, every one of these domains subsists by itself: the gods, the cosmos, and man as the tragic, solitary, silent hero. The biblical religion is concerned with the relation between the three: the relation between God and the world, which is creation; the relation between God and man, which is revelation; and the relation between man and the world, which leads to salvation. The philosophy that renounces the ambition to find one principle for everything that exists and that follows biblical religion in centering on the connections between the three domains and between the words and

acts that bring about and develop these connections Rosenzweig termed the "narrative" philosophy; the term and the concept were taken over from Schelling, whose influence Rosenzweig repeatedly emphasized.

The biblical faith brought forth two valid religions, Christianity and Judaism. The first is described by Rosenzweig as the eternal way: The Christian peoples seek in the vicissitudes of time and history the way to salvation. In contradistinction to them the existence of the stateless Jewish people is not concerned with time and history; it is—notwithstanding the hope for final salvation—*already* an eternal life, renewed again and again according to the rhythm of the liturgical Jewish year. Thus, Rosenzweig did not, like Yehuda Halevi (many of whose poems he had translated and who was very much in his thoughts) oppose the sacred history of the Jewish people to the profane history of the rest of the world but rather to what he considered as the historical existence of the Jews, their involvement in the history of the other nations.

BUBER. Since the early years of the twentieth century, Martin Buber (1878–1965) has exercised a powerful influence on both Jews and non-Jews. His theology, centered on the I and Thou relationship, on the conception of a dialogical life, and on the primal importance of the category of "encounter" are discussed in the entry on Buber.

In recent years new works dealing with the history of Jewish thought in one of its aspects or in one of its periods appear on the whole to have been more significant than purely philosophical or purely theological Jewish works; in certain cases scholarly works give expression to a personal attitude toward Judaism or toward religion in general. These remarks apply to the two main centers of Jewish philosophical, theological, and scholarly activities, the United States and Israel, as well as to such other countries as France and England. However, it may be too early to attempt to give a definitive summing-up of the tendencies and achievements of a period that verges upon the present.

JEWISH PHILOSOPHY [ADDENDUM]

Levinas's earlier work seemed to have nothing to do with religion, whereas after the Holocaust his writings often touched on religious and specifically Jewish themes. These latter works are often described as his translations of Judaism into Greek, his explanations of the universal significance of the Torah and all that goes with it in the living experience of the Jewish people. The central problem here is that philosophy is a universal and theoretical enterprise, whereas religion is often practical and its obligations are limited to a particular group of people.

It might be thought even harder to identify Judaism with philosophy because most Jews are Jews because of birth, not through a choice to accept particular doctrines or practices. As human beings we all share certain characteristics, and as members of smaller and more limited groups we share features with others in the same group that we do not share with everyone else. The universal role of philosophy is stressed throughout Levinas's thought. He starts by replacing the usual starting point in metaphysics of ontology with ethics. The obvious place to start philosophically is to ask the question: What is a human being? Once we know the answer to that question, which includes other questions such as what can we know, we can then start to work out our duties and responsibilities for others.

Yet Levinas turns this starting point entirely the other way around. The first question we need to ask is not who we are, but what our responsibilities to others are. Only once we can answer the question who is the other are we in a position to know who we are. Again, the normal way to start constructing a metaphysics is to build up

a model from the self to the other, and then suggest that I have certain responsibilities for others, as they have for me. But these responsibilities for others are limited, because it is unreasonable for them to be otherwise. Levinas transforms this to argue that our responsibilities for others are not limited, but are infinite. The idea is that if one starts with the self and then moves to the concept of the other one is always in the position of trying to demarcate between the roles of different selves in ways that limit, perhaps too severely, the links between these selves. In saying that we have infinite responsibility for the other, Levinas means that we must always be able to respond to the other, because unless we do, we lose our identity as a subject. As he says: "The word *I* means *here I am*, having to answer for everything and everyone" (1981 [1974], p. 145).

This radical turn in philosophy has interesting implications for all the familiar philosophical problems, but one implication that one might assume it would have is to direct attention away from the individual and toward groups of individuals, or indeed the whole of humanity, because it is to the whole of humanity for which the self is answerable. This implication is certainly there, and Levinas seems to have a horror of the solitary life, in marked contrast to his mentor Heidegger who appears to value above all retreating from the world into oneself and being alone with nature. For Levinas the more one tries to retreat into oneself, the less self there is to retreat to. Yet there is a problem in accounting for the treatment of groups larger than the individual self and less than the whole of humanity. If one gives one's attention primarily to a limited group, is this not to take it away from the whole of humanity, and thus deny one's full selfhood? Hence on the one hand Levinas's criticisms of love between people, which he sometimes sees as limiting the links of responsibility that we establish between each other. On the other hand, the way in which love can be embodied in an institution that gives rise both to the possibility of new life and also to new structured links between individuals is positive in the sense that it cements and furthers the ethical links between people. We need to point out here an important feature of such links, because for Levinas they are not reciprocal. We have responsibilities for the other, but they have none for us. The idea is that our responsibility is not based on their appropriate behavior or response; rather, we are responsible, and never stop being responsible however much others ignore, deny, or are unworthy of our concern. Our responsibility even extends further than our lives, into the infinite.

Here we have a system of philosophy that came to be greatly elaborated, and that appears to apply to every human being, if it applies to anyone. What is Jewish about it? Here we get into difficult territory. Judaism is profoundly ethical; it emphasizes the practical as against the theoretical, the group as compared to the individual; it compares speech with prophecy, has a messianic future in prospect for humanity, and is generally suspicious of the capacity of the state to embody ethical life appropriately. In his Jewish writings Levinas examines a wide variety of biblical and other literature that he interprets as bringing out some of the key aspects of his philosophy. What Levinas is doing in these works is using his philosophy to bring out what he thinks are the meanings of Jewish texts, and in this he is following in a long and distinguished tradition in Jewish philosophy.

Levinas is interested in those parts of the Bible that refer to the individual as responsible for others. When God asks Cain "Where is Abel your brother?" (Gen. 4:8) the response that Cain is not his brother's keeper is entirely inappropriate. Nor is the question only directed at Cain, but at everyone. Everyone is responsible for those who are murdered even if they are not directly involved in the crime. Levinas picks out those parts of the Torah in which individuals respond to God by saying "*hineni*" or "I am here." What is meant by that is that the individual recognizes the claim of God to be heard, he accepts that he is the person to whom the divine question is to be put and acknowledges responsibility for the task that God may have in mind. But is this not just the individual responding to God? What is specifically ethical about it? For Levinas references to God are not references only to a being. The point of religion is to bring out to the individual the significance of her links with others, so that when she is involved with others God is available to her, but when she is thinking only of how to come close to God, he is distant. There are plenty of passages in the Torah and other Jewish writings that emphasize the presence of God as contingent on a certain way of human acting. Buber, for example, was impressed with Hasidic stories of ordinary actions being imbued with spirituality when those actions were carried out for the sake of others.

Is Judaism then specifically directed toward practice, toward the ethical? It certainly looks like it, and its legal structure, the integration of the life of the Jew within a ritualistic system, is evidence of the significance of behavior, in particular behavior that is linked with the behavior of others. Levinas describes the move from the particularity of Judaism to the universalism of philosophy as part of a process of liberation that needs to be continued.

This means that we have not yet finished translating the Bible, in the sense that we have only just started bringing out its universalist message. We tend to get it the wrong way around, he suggests, in that we often try to invest a biblical idea with a universalist notion already specified in European or Greek thought, whereas what we should do is bring out the universalist idea that is already there in the Hebrew, and explain it in Greek. So the apparent clash between Athens and Jerusalem, between reason and revelation, comes out as a pseudo-conflict after all, because revelation contains everything that reason does, albeit in a different form.

This is also a familiar solution to the apparent conflict between the Torah and philosophical thought within the tradition of Jewish philosophy. Levinas is thus moving through familiar territory here, although the ways in which he characterizes his theoretical environment differs from his predecessors. One difference lies in the sort of philosophy that Levinas argues runs through the Bible and Talmud, and that is of course his philosophy in a much wider sense than one would expect given the above definition.

When we examine the detailed defense of *halakhah* (Jewish law) that Levinas produces, a number of questions arise. He tends not to defend the practices of halakhah as a whole, but the principle of there being a halakhah. We are supposed to accept that once the principle of there being a halakhah is understood, the details of what to do will be in accordance with the legal texts. Perhaps it does not matter so much exactly which understanding of the precise nature of the law one follows, so long as one adheres to an appropriate legal rule that determines the nature of the law. The general point that Levinas makes is certainly appropriate, that Jews seeking to find a way of embodying their ethical behavior in a practice need look no further than halakhah, which is a form of practice specifically designed to replicate the truths of faith. Yet because Levinas often says that when he talks about Jews he means humanity at large, we are still left not knowing how most people ought to behave. He relishes the prospect of Jews being obliged to follow 613 commandments, whereas the rest of humanity only needs follow the seven Noahide laws (the basic laws of humanity by tradition given by God to Noah), because this exemplifies the idea of owing more to the other than one asks in return. But is the only route to such an ethical life for the Jew the halakhic route? It is one thing to defend the acceptability of such a route, but another to demonstrate its inevitability. Because Levinas is firmly part of the demythological tendency in modern theology,

he cannot argue that one should follow halakhah because God had commanded us to act thus in the Torah. Such appeals to what Levinas rather scathingly calls the numinous are ruled out from the start.

Then we have the problem of knowing how gentiles are to live. Are they to follow the laws of their faith? Are they to consider conversion to Judaism? Are they limited to the seven Noahide laws? They too may wish to be in a position to say *me voici* even if they cannot say *hineni*. Their route to reaching that position is presumably through Greek, because they cannot go through Hebrew, but if they can attain their end along the Greek route, there seems no reason to deny such a route to assimilated Jews. It would be invidious to suggest that a particular ethnic group is especially advantaged in knowing how to live as compared with others, unless one can appeal to some supernatural rationale, which Levinas rejects. Even if my ancestors opened themselves to God in a way different from other ethnic groups, it is difficult to see how that elevates my consciousness above those of members of other ethnic groups.

In a celebrated discussion Levinas argues that what made the Jews unique was that they undertook to obey God's law even before they heard what that law was, and in this way acknowledged the priority of the ethical over the ontological. That is, they accepted that the first question to be answered is where our responsibilities lie, and the second question follows from that, and concerns who we are. But what is the link between that event and the nature of halakhah as it has come down to us today? There is obviously some sort of link in terms of tradition, yet it is the case that for many Jews the ties of tradition no longer have any emotional resonance. The only way for them to find that resonance again is through the Greek, and that is why Levinas seeks to reinvigorate tradition by exploring its universal values in language that is accessible to those who have lost the ability to understand the Hebrew. When he talks of them no longer understanding Hebrew he does not refer to technical mastery of the language, but the ability to link the Hebrew to present-day ethical and political issues. What needs to be brought out is the universalist message of the Hebrew, so that it is not seen as the repository of a small and remote community, but as implicit within the rules of behavior everywhere and at all times.

JINUL
(1158–1210)

Jinul (whose name is spelled Chinul under the McCune Reischauer Romanization system), a Korean Buddhist monk of the Goryeo period, is considered by many scholars to be the most influential figure in the formation of Korean Seon Buddhism. Deeply disturbed at the degree of corruption that had crept into the Buddhist monastic system, he sought to establish a new movement that he called the *samādhi* and *prajñā* society. The goal of this organization was the establishment of a new community of disciplined, pure-minded practitioners deep in the mountains. Jinul eventually brought this mission to fruition with the founding of the Seonggwangsa monastery at Mount Jogye, which still serves as an center for Korean Seon practice.

A major issue that received special attention from Jinul was the relationship between so-called gradual and sudden approaches to Buddhist practice and enlightenment. Drawing on various Chinese treatments of this topic, most importantly those established by Zongmi (780–841) and Dahui (1089–1163), Jinul came up with his "sudden enlightenment followed by gradual practice" approach. Jinul believed that for religious practice—especially meditative practice—to have efficacy, the practitioner must first have a deep and transformative experience of insight into the emptiness of things, to see their nature of innate enlightenment. He believed that if one tries to practice without such an experience, all of one's practice will be based on the dualistic thinking habits that are the causes of delusion, and thus, no matter how hard one might try, progress cannot be made. One metaphor that Jinul used to express this idea was that of the morning dew and the sunshine. Before the sun rises, the cool morning grass is wet with dew. Try as one may to wipe away the dew, it will continue to reappear. Once the sun rises, however, the dew can be wiped away and will be less apt to return. In the same way, once one has had an awakening experience, efforts toward the eradication of bad cognitive and emotive habits will have enhanced efficacy.

Jinul's approach to Buddhist practice ended up becoming an interesting blend of *gongan* (in Japanese *kōan*) meditation, coupled with scriptural study, incorporating a Hwaeom (in Chinese *Huayan*) approach that tended to see the mutual containment of ostensive opposites. While incorporating the *gongan* method into his system of practice, Jinul also believed that scriptural study was a vitally important component of Buddhist cultivation. This approach is enunciated in the oft-repeated story that Jinul did not undergo his enlightenment experiences as the result of the classical so-called personal mind-to-mind transmission between teacher and student as characterized in the Seon school. Rather, each of his three enlightenment experiences came in connection with the contemplation of a passage in a Buddhist text.

Jinul's philosophical resolution of this issue brought a deep and lasting impact on Korean Buddhism and can be seen as a repeated theme in the works of many subsequent Seon masters, including such famous figures as Gihwa (1376–1433) and Hyujeong (1520–1604), who followed Jinul's way of thinking in addressing the issue of practice and study in their own writings. Jinul produced a number of important disciples who passed on his teaching and continued to work within his discourse.

JOACHIM OF FIORE
(c. 1135–1202)

Joachim of Fiore, the Christian mystical philosopher of history, lived in Calabria, Italy, a region characterized by the remote hermit life, yet close to Sicily, the hub of the Mediterranean. This combination of withdrawal from and encounter with the world also characterized Joachim's life. Becoming a Cistercian, by 1177 he was abbot of Curazzo, but he obtained papal permission to retire from monastic administration to a more remote mountainous region, where he founded the order of San Giovanni in Fiore about 1192. Yet he descended to dramatic encounters—in which he prophesied on contemporary events and the advent of Antichrist—with Pope Lucius III (1184), King Richard I of England (1190–1191), and the Holy Roman Emperor Henry VI (1191), and he meditated deeply on contemporary history, especially the two great menaces to Christianity: the infidel and the heretic.

Joachim recorded two mystical experiences: one at Easter, when he was given understanding of the inner concords between the two testaments, and one at Whitsuntide, when he received illumination on the doctrine of the Trinity. Disclaiming the title of prophet, he believed that through the gift of spiritual intelligence he understood the inner spiritual meaning of history.

With papal encouragement, Joachim set out to expound this belief in his three main works, the *Liber Concordiae*, the *Expositio in Apocalypsim*, and the *Psalterium Decem Chordarum*. His exposition turns chiefly on an interwoven double pattern of twos and threes. The two testaments represent history in two eras, culminating, respectively, in the First and Second Advents and marked continually by concords—for example, twelve Tribes and twelve Churches, seven Seals and seven Openings. History is also trinitarian, growing treelike from the Age (*status*) of the Father (Law) to that of the Son (Grace) to that of the Spirit (Spiritual Understanding), yet in a double "procession" of the third *status* from both the first and the second. This third *status* represents an apotheosis of history, which Joachim equated with the Seventh, Sabbath Age of the traditional Seven Ages, placing it between the worst Antichrist and the end of history. He saw himself on the threshold of the last two generations of the Sixth Age, into which will be crowded the greatest tribulations before the church "crosses Jordan" into the Sabbath of the third *status*.

His strong visual imagination led him to embody this philosophy of history in the remarkable *Liber Figurarum*, through which it was widely disseminated. This doctrine contained revolutionary seeds. Joachim avoided dangerous implications by using his pattern of twos to proclaim that the authority of the Scriptures and church would endure until history ended. His pattern of threes culminated in a spiritual state rather than a historic era. Nonetheless, he almost gave it a starting date—1260—and expected its *Ecclesia Spiritualis*, symbolized in John, to "outlast" the church designated in Peter. This inspired fanatical groups to proclaim the Third Age, the overthrow of existing ecclesiastical institutions, and the transfer of authority to the Eternal Evangel. Joachim's prophecies of two new spiritual orders to lead the church into the Third Age were claimed first by Franciscans and then by Dominicans, Augustinian friars, and even Jesuits.

Condemned as a heretic, revered as a saint, Joachim seldom met with indifference to his views. From the thirteenth to the sixteenth century, when an optimistic expectation of history was proclaimed, it usually drew inspiration from Joachimism.

JODL, FRIEDRICH

(1849–1914)

Friedrich Jodl ranks as one of the most significant representatives of German positivism, although this designation by no means adequately characterizes the full scope of his ideas. Jodl was born in Munich, where in 1880 he qualified as a *Privatdozent* in philosophy. Five years later he was named professor of philosophy at the German University in Prague. In 1896 he accepted a call to the University of Vienna. His many publications ranged over the fields of philosophy and the history of philosophy and ethics, as well as psychology and aesthetics.

Jodl categorically rejected metaphysical speculation. For him, the boundaries of experience were at the same time the boundaries of knowledge; hence, there could be no a priori knowledge, nor any metaphysical cognition of the transcendental. The task of philosophy, he maintained, is to order scientific knowledge systematically and to comprehend it in a unified view of the world. The basis of philosophy, like that of science, can only be experience.

As a consistent empiricist, Jodl criticized phenomenalism, preferring critical realism. The factual existence of a transsubjective reality is guaranteed by the thou-experience, by the existence of one's fellow men. Moreover, without the assumption of an objective external world and without the assurance that we know it as such, natural science would be impossible. Hence, the forms of our intuition and of our thought are not subjective in the sense meant by extreme epistemological idealism; rather, they are also conditioned by the relationships of things. Our knowledge of the world is not subject to a theoretical limit beyond which our consciousness is unable to grasp reality; there is only a frontier that can always be pushed further back, with the result that the world in its totality constitutes an endless problem, a task for knowledge that can never be definitively solved.

Jodl sought a naturalistic conception of the world, free of religion and metaphysics, such as that of the monistic movement, which he energetically promoted. "We need no other mediator between us and nature except our understanding and a courageous will, nor any mystery behind nature to console us for her; we are alone with nature, and we feel secure because we possess intellect and she behaves according to laws" (*Vom wahren und vom falschen Idealismus,* p. 40).

Jodl treated the problem of God on the basis of this naturalistic monism. Somewhat like John Dewey after him, Jodl, while denying the existence of God in any traditional sense, retained the term *God* as a designation for the highest ideals to which human beings aspire.

In his psychology too Jodl confined himself to the clearest possible presentation of the empirically given facts of mental life, renouncing all metaphysical assumptions. His psychological investigations are unusually rich in acute analyses and genetic explanations. Consciousness is not a substance but an act; it is the inwardness of a living creature. The bearer of consciousness is not an immaterial soul but the living organism; the soul is nothing other than the unified coherence of experience. "Mental" and "physical" are simply two expressions in different languages for one and the same occurrence. Body and consciousness are one; the psychical is the internal, subjective experiencing of neurological processes. An individual experiences as subject the whole complex of his brain processes in internal perception.

In ethics, Jodl was a convinced evolutionist. Ethical values have been subject to continuous transformation; morality is an evolutionary product of the interaction between the individual and society. Jodl made a sharp distinction between the subjective, psychological basis of morality and the objective, axiological criterion for it, although the two, in his view, were most intimately connected. The basis of morality is the will, which rests on

social instincts, is influenced by reason, and is aimed at the welfare of the whole. A different question is the establishment of moral norms by which to measure the worth of human attributes and deeds. This requires that one take into account both the motivation and the utilitarian value of an action. In his penetrating studies in the history of ethics, Jodl showed that this discipline has, in the course of its development, increasingly freed itself from metaphysics and has replaced the theocentric foundation with an anthropocentric one.

Jodl, characteristically, was not content with theoretical (historical and systematic) studies in ethics, but sought beyond that to carry out in life a practical, ethical idealism. Imbued with a faith in the value of life and a vigorous optimism in regard to culture and progress, he was an "enlightener" advocating the humanization of culture; an ethically based social life in the spirit of a purely secular, humane morality and freedom of thought. He strongly supported and promoted the system of free popular education and the Ethical Culture movement.

JOHN DUNS SCOTUS

See *Duns Scotus, John*

JOHN OF DAMASCUS
(c. 675–c. 750)

John, whose secular name was Mansur, was born in Damascus probably in the third quarter of the seventh century. His father and grandfather had been prominent in the fiscal administration of Syria, and it is believed that his father was in charge of the fiscal administration of the Umayyad Empire, with its capital in Damascus, in the latter decades of the seventh century. John received a good Hellenistic education and probably entered the service of the Caliph at Damascus in his father's footsteps. At some point—probably at the beginning of the eighth century, when the administration of the Umayyad Empire was put in the hands of Muslim officials—John resigned his post and became a monk in the Holy Land, according to a late tradition at the monastery of Mar Saba in the Judaean Desert (though it is more likely that he was associated with the church of the Anastasis in Jerusalem itself). In any event, he was close to John V, patriarch of Jerusalem from 706 to 735, who ordained John of Damascus to the priesthood. It is believed that he died around 750, because at the Iconoclast Synod of Hiereia (754) he was anathematized under his name Mansur as if he was already dead.

John possessed genuine literary gifts, knowledge both theological and philosophical, and considerable intellectual acumen. In his lifetime he achieved fame as a preacher (evident from the references to him in the *Chronicle* of Theophanes); his liturgical poetry still forms the core of the Byzantine liturgical office; through his works of theology he came to exercise an unparalleled influence, not only throughout the Byzantine world, but on theology in the West from the period of Scholasticism (for which he provided the principal access to the developed theology of the Byzantine East) up to at least the time of Friedrich Daniel Ernst Schleiermacher. Many of his theological works are polemical; he wrote a treatise against Manichaeism, as well as treatises against the

Christological heresies of monophysitism, monothelitism, and Nestorianism and is the first Christian theologian explicitly to attack the new religion of Islam, on which he was impressively informed.

John was the most notable defender of icons against the iconoclasm of the Emperor Leo III. His best-known work is a three-part treatise known as *The Fountain Head of Knowledge* (in Greek: *Pēgē gnōseōs*), consisting of an introduction to logic (*Dialectica*), a summary account of heresies (*De haeresibus*) and an epitome of the principal themes of the Christian faith (*Expositio fidei*, or *De orthodoxa fide*). The critical edition published by the Benedictine Dom Boniface Kotter in the last decades of the twentieth century reveals that each of these sections was intended to be a century (or half-century)—that is, a collection of one hundred chapters or paragraphs. The century was a genre of monastic literature, popular in Byzantine circles, and John's choice of this genre makes clear that his purpose in this work was essentially monastic: the intellectual training and learning it provides was ultimately to help monks in their life of prayer. His principal purpose was not to provide a systematic theology, as was suggested by the division of the *Expositio fidei* into four books, corresponding to the four books of Peter Lombard's *Sentences*, a division introduced into the Latin translations in the thirteenth century (and thence into the older editions and translations), but unknown in the Greek manuscript tradition. In fact, although John intended a final version of the work in three parts as indicated above, the most popular form in the Byzantine world was a combination of the *Dialectica* and the *Expositio*, usually known as *Philosophical and Theological Chapters*, usually consisting of 150 chapters.

The *Dialectica* is a compilation—belonging to a tradition of Christian introductions to logic, popular in the seventh and eighth centuries—that provided an introduction to basic philosophical terminology as an aid to understanding the issues raised by Christological controversy in the East, which had raged since the fifth century, and concerned concepts such as being, nature, person, and latterly activity and will. The *Dialectica* in the earlier form (the only one that survives complete; John probably died while revising it) seems to lead up to the notion of *hypostasis* or person, and "hypostatic union," key terms in the Christological orthodoxy to which John belonged. Those who contributed to this tradition of Christian introductions to logic drew their material from the sixth-century Alexandrian commentaries on Aristotle and Porphyry; unlike the sixth-century commentators, however, the compilers of these textbooks (including John himself) were not concerned to advance an understanding of logic, but simply to provide the basic tools for engaging in the theological arguments of the day.

The *Expositio Fidei* is also a work of compilation, drawing, often word for word, on earlier theologians in its presentation of the fundamental concepts of the Christian faith. It concerns the doctrine of God and the Trinity; creation and the nature of the created order, especially human nature; the doctrine of Christ (to which most space is devoted); and various questions of religious practice, especially those that marked off Christians from Jews and Muslims (though there is no explicit reference to the latter). John expressly sets aside any claim to originality; even the selection of authorities is probably not original to John, but represents an established tradition, much influenced by Maximos the Confessor (580–662). The only doctrines where some originality could be claimed for John are the doctrines of the will and its freedom, which had become central to the controversy over the heresy that Christ had only one will (monothelitism), and possibly his treatment of the infinity of God. In both cases, however, John's contribution is not much more than a refinement of the tradition that had reached him. Some aspects of the tradition he had received are ignored, possibly felt to be too daring: for example, his dependence on Maximos (and through him on the fourth-century Nemesios of Emesa) for his understanding of creation and human nature is particularly marked, but he ignores completely Maximos's developed doctrine of the principles (or *logoi*) of creation. It is doubtless the clarity of John's exposition that is the reason for his immense influence.

JOHN OF JANDUN

(c. 1286–c. 1328)

John of Jandun, also known as Jean de Jandun and Johannes de Janduno, was foremost among the Averroists at Paris in the fourteenth century. He was born in the village of Jandun in the French province of Champagne. The estimate of his date of birth is based on the year 1310, the earliest date found on any writing definitely attributable to him; at the time of this first or very early publication, John would have been a recent master of arts, and reckoning by the age and curricular requirements in effect at the University of Paris in the early fourteenth century, he could not have been much more than twenty-four years of age. John was active throughout the next decade and a half as master of arts at the Collège de Navarre, in Paris, although he was nominally canon at Senlis—the kind of preferment awarded a practicing teacher and scholar during the Middle Ages. At Paris he lectured on the standard curriculum of the Faculty of Arts: Aristotle's *Physics, De Coelo et Mundo, De Anima, Metaphysics, Parva Naturalia,* and *Rhetoric* and Averroes's *De Substantia Orbis.* John's commentaries on these works date from 1310 to 1323. Additional writings from this period attest to his interest in particular problems arising in his lectures and commentaries; there still survive many independent *quaestiones* and *disputationes,* which, in the medieval tradition, supplemented the normal course of studies with special studies and advanced seminars.

By 1324 he was closely associated with Marsilius of Padua, also a master of arts at Paris, in connection with Marsilius's famous and controversial *Defensor Pacis,* published that year. Although John does not seem to have shared in the actual composition of the work, he was apparently an intellectual intimate of Marsilius. The *Defensor Pacis,* a powerful affirmation of the temporal and civil authority over the spiritual and papal, occasioned enough ecclesiastical outrage for John and Marsilius to deem it prudent to leave Paris and seek the protection of Louis IV of Bavaria. Louis was himself embroiled with Pope John XXII on matters of political and spiritual authority and was soon to harbor another intellectual fugitive from Paris, William of Ockham. In 1326 and 1327 a series of papal bulls appeared specifically attacking John and Marsilius, and the final one, dated October 23, 1327, excommunicated them as "heretics and heresiarchs."

The remainder of John's life was brief. He followed Louis in the invasion of Italy and was rewarded with the episcopate of Ferrara. Probably en route to assume his new duties, he died at Todi, not later than August 31, 1328.

THOUGHT

To treat John of Jandun's philosophy, as many historians have done, as a blind recapitulation of the Commentator (the title by which Averroes was referred to throughout the Middle Ages and the Renaissance) and his special views on Aristotle would be an oversimplification. It is true that John did, at one point in his commentaries, call himself the "ape of Averroes," but this was in the context of a particular passage of Aristotle's *Metaphysics,* where John considered Averroes's remarks perfectly adequate. It is also true that John preferred, generally, Averroes's rendering of Aristotle, but it is not illuminating to call him "Averroist" without severe qualifications. Other medieval philosophers (for example, Siger of Brabant) can be termed Averroist, but their speculative positions were sometimes methodologically quite distinct from those of John. It is probably most accurate to place him in the philosophical tradition and method sometimes exemplified in Christian Augustinianism, always recognizing, however, that he was oriented intellectually within the traditions of the Faculty of Arts rather than those of the Faculty of Theology.

John's espousal of a *sensus agens* (active principle in the process of sensation), of a plurality of substantial forms in the individual (one for each of the three functions of living: vegetating, sensing, and thinking), of the soul's ability to grasp separate substances (that is, forms) directly, of form as the immanent and essential cause of natural activity, and of other kindred doctrines can be found in the thinking of many Augustinian theologians close to his time, such as Bonaventure, Peter John Olivi,

Roger Marston, John Duns Scotus, and Peter Aureol. John's own advocacy of these views arose, however, out of the use of Averroes in the analysis of Aristotle for the Faculty of Arts curriculum. Although John's version of Averroism and the tradition called Christian Augustinianism had much in common methodologically, they sprang from different institutional contexts.

John's interpretations of Averroes's commentaries on Aristotle were both acute and influential (as late as the seventeenth century his writings were still used alongside those of Averroes by the Paduan pedagogue Cesare Cremonini), but his place in intellectual history is due less to the conspicuous originality of his thought than to his unusually explicit delineation of the respective domains of faith and reason. Whenever confronted, in his analysis of Aristotle, with a conclusion severely at variance with some doctrine of Christian faith, John appended an apologia of the following kind: "It must be noted that, although the *dicta* are … according to the principles of Aristotle and the Commentator, it must be replied firmly according to faith and truth that the world is not eternal." Similar passages abound in John's commentaries; whenever conclusions of reason arrived at in the logic of Aristotle and Averroes differed from the dictates of Christian dogma, John introduced statements proclaiming the consistency of the reasoning but immediately ceding truth itself to the preeminent demands of faith.

Such remarks have had two interpretations. First, John has been indicted, with other so-called Averroists; as holding a theory of "double truth"—that is, that statements of faith, on the one hand, and conclusions of reason, on the other, can be simultaneously true, yet contradictory. This charge has been discounted effectively by Étienne Gilson; no medieval writings maintaining such a self-inconsistent view have yet been found. Medieval thinkers never stated more than the position that although reason can systematically reach certain conclusions, Christian faith is nevertheless the final arbiter of truth when such conclusions conflict with matters of doctrine.

Second, certain of John's disclamatory passages have been interpreted as actually revealing a fundamental religious insincerity. For example, he said:

> This is not known *per se,* nor is it demonstrable by any human proof, but we believe this to be so solely by divine authority and by the Sacred Scriptures. And to the credulity toward things of this kind and similar things, the habit of listening to this sort of thing from childhood adds a good deal.

Or again:

> If anyone knows how to prove this and to make it accord with the principles of philosophy, let him rejoice in this possession, and I will not grudge him, but declare that he surpasses my ability.

And finally:

> although every form inherent in matter is corruptible I say, however, that God can perpetuate it and preserve it eternally from corruption. I do not know the manner of this; God knows it.

Such statements have been interpreted as indicating a radical insincerity in John's thinking, a covert mocking of Christian faith. Thus, some historians have suggested that John was not merely maintaining a "double truth" but actually affirming the superior reliability of the conclusions of unaided reasoning in the mode of Aristotle and could therefore stand as an early precursor of seventeenth-century rationalism and libertarianism.

On close examination, however, John's position on the relation between the claims of faith and claims of reason does not seem to have been distinctively more radical than the thinking of many other medievals. (Similar disclaimers of reason in favor of faith can be found in many commentaries on Aristotle, including those of Thomas Aquinas.) Such discrepancies and apparent conflicts reflect, in small part, a strong institutional rivalry between the faculties of arts and theology and, in large part, a fundamental intellectual crisis occasioned by the confrontation between Greek rationalism and Christian dogma.

JOHN OF LA ROCHELLE
(c. 1190–1245)

John of La Rochelle, or de Rupella, was a Franciscan philosopher, theologian, and preacher at the University of Paris. The first clear reference to him (in Thomas of Cantimpré) indicates that in 1238 he was already a friar and a master in theology. From John's own writings, as well as from his knowledge of and interest in philosophy, we may deduce that he had studied and perhaps taught in the faculty of arts before becoming a theologian. His *Summa de Vitiis* (Summa on vices and sins), which manifests his penchant for ethical questions, is directly dependent on William of Auxerre, Prevostinus, and Stephen Langton, who apparently were John's teachers in the faculty of theology. It seems that only after Alexander of Hales entered the order, in 1236, did John become acquainted with that famous theologian; thereafter John was Alexander's faithful companion and collaborator. Both seem to have taught at Paris until their deaths in 1245.

Though a famous preacher and biblical commentator, John is known primarily as a "summist" interested in questions of psychology and morals. Both topics are combined in his early *Tractatus de Anima et de Virtutibus* (Tract on the soul and the virtues), a kind of rambling compilation of definitions of the soul, the divisions of the soul's powers according to the philosophers, and the division of the virtues according to Plotinus, Cicero, Aristotle, and Augustine. Ethical questions predominate in John's proposed *Summa Theologicae Disciplinae* (Summa of theological learning). As set forth in the prologue to the *Summa De Articulis Fidei* (Summa on the articles of faith), the larger summa of theology was to include both doctrines and morals. "Morals is divided into two parts: on sins and the remedies of sins. These remedies are four in number: commandments, virtues, the gifts of the Holy Spirit, and the sacraments" (ms. Milan, *Brera A.D. IX. 7,* fol. 75a). Only parts of such a summa seem to have been completed: the "Summa on Vices and Sins," *De Praeceptis et Consiliis* (On precepts and counsels; a tract), *De Virtutibus* (On virtues), and the *Summa de Donis* (On the gifts of the holy spirit). The same interest is reflected in the lengthy and influential tract *De Legibus et Praeceptis* (On laws and precepts), which is probably John's work, and in such Disputed Questions as "The Fall of Human Nature," "On Negligence, Hypocrisy, the Seven Capital Sins," "On Usury," and "On the Just War," all as yet unpublished.

His early "Tract on the Soul" was developed into the more mature *Summa de Anima* (Summa on the soul), which is rightly regarded as the first scholastic textbook of psychology. Beginning with proofs (from Avicenna and Augustine) for the existence of the soul, the first part examines the essence, causes, and properties of the soul and its union with the body (giving a none too clear, yet basically Aristotelian, solution of this latter problem), with a final section on immortality and the status of the soul after death. In the second half John considered at length the problem of the powers of the soul: their relation to the essence and their division according to Pseudo-Augustine (*De Spiritu et Anima*), John of Damascus, and Avicenna. The classification of the external and internal senses, the cognitive and motive powers, follows closely the *De Anima* of Avicenna, with some slight additional material. A comparison with the earlier "Tract" leads us to conclude that the *Summa de Anima* is incomplete. It ends abruptly in the midst of a discussion on the will. The large number of extant manuscripts attests to its popularity in the Middle Ages. If not strikingly original, the summa is of interest also for its use of the philosophers at a time when theologians were inclined to reject their help. John pointedly rejected such an attitude in a university sermon:

> If philosophy is neglected, one may fear lest "there be found no smiths in Israel" (I Samuel 13:19), that is, philosophers who will sharpen our wits like "swords" and with shining "lances" attack the enemy at a distance. The devil himself seeks to stamp out the study of philosophy because he does not want Christians to have sharp minds. (*Collectanea Franciscana,* Vol. 28 [1958], 50)

Last, John is to be considered the primary author or compiler of the first and third books of the so-called "Summa of Alexander of Hales."

JOHN OF MIRECOURT
(fourteenth century)

John of Mirecourt belongs to a generation of philosopher-theologians discussing the nature of knowledge and especially the varieties of evidence for human knowledge. Biographical information on him is scarce, but he lectured on the *Sentences* of Peter Lombard (c. 1095–1160) at the University of Paris in 1344–1345. Propositions taken from his work were condemned by the chancellor in 1347. His two apologies are the best-known writings by him, although his commentary on Lombard's *Sentences* has also survived. Traditionally, Mirecourt has been described as a skeptic associated with Nicholas of Autrecourt (c. 1300–after 1350). Research in the last decades of the twentieth century gave a somewhat more accurate picture of his epistemology, but other areas of his philosophy, like his theory of ethics and the will, have not been examined.

In his epistemology Mirecourt distinguishes between abstractive and intuitive cognition, following William of Ockham (c. 1285–?1349), John Duns Scotus (1266?–1308), and some earlier scholars. *Abstractive cognition* can be defined as a cognition that can be had without its object being present, while *intuitive cognition* is dependent of the presence of its object and allows (or even produces) evident knowledge that the object exists. For example, when one sees Peter, one gains an intuitive cognition with Peter as the object of the cognition and is able to give evident assent to the proposition "Peter exists." In abstractive cognition the object need not be present, and thus the examples are often of a conceptual or mathematical nature.

According to Mirecourt's classification, suspicion, opinion, and conjecture constitute *inevident assent*. In contrast, *evident assent* is firm belief, which, as he sees it, can be either supranatural or grounded in natural causes. Mirecourt concentrates more on the latter. There are cases where it is impossible that evident assent is wrong, and Mirecourt talks in this context of *special evidence*. Evidence reducible to the certainty of first principles is like this. Mirecourt's examples include: "If it is a man, it is an animal" and "God is God." The latter is a logical truth, but the former shows that he has in mind also conceptual necessities. Surpassing the border of what may be called analytic truth, there is also special evidence that something exists. Mirecourt proves this by saying, "If one doubts whether something exists or whether one exists, one has to concede that it follows evidently: One doubts whether something exists, therefore one exists, since if one did not exist, one would not doubt. So it follows: one exists, therefore something exists" (*In I librum Sententiarum*, q. 6). Here, knowledge of one's own existence is shown to have special evidence. Mirecourt continues by pointing out that nothing else is known to exist with infallible evidence.

Not all natural evidence is special. Mirecourt faces the skeptical challenge that any belief without special evidence could be false by God's absolute power. Our ordinary experiences could thus be like dreams or hallucinations. Just like René Descartes (1596–1649) some centuries later, Mirecourt accepts that this is in some sense possible. Nevertheless, Mirecourt thinks that ordinary experiences can constitute genuine knowledge and thus he is not really a skeptic in the classical sense.

JOHN OF PARIS
(c. 1255–1306)

John of Paris, or John Quidort, also known as Surdus or Monoculus, was a Dominican scholastic philosopher and theologian, priest, and author. A native of Paris, John studied and taught philosophy at the University of Paris before entering the Dominican order at St. Jacques prior to 1279. As bachelor in theology he lectured on the *Sentences* of Peter Lombard (1284–1286) and energetically defended the then suspect doctrines of Thomas Aquinas in a famous refutation, *Correctorium "Circa,"* of the *Correctorium* of William de la Mare, which had been officially adopted by the Franciscans. Certain unknown adversaries managed to twist or misinterpret sixteen statements delivered in class, and in 1286 they had John denounced to the authorities. Although he ably explained the true meaning of his innocent statements, his academic career was temporarily suspended. In his defense of Thomas, John showed a clear understanding of the Thomistic distinction between essence and existence in creatures, the unicity of substantial form in material substance, the individuation of material substances by matter alone, and the pure potentiality of first matter.

From 1300 on John was again active in Paris, teaching, preaching, and writing. His sermons and treatises testify to the political and social unrest of the times. During the struggle between Pope Boniface VIII and Philip the Fair, John wrote the important treatise *De Potestate Regia et Papali* (On royal and papal power; 1302), in which, following Thomas Aquinas, he defended a middle position between the papalist and imperialist extremes. He clearly distinguished between two autonomous societies in Christendom—church and state—each of which has its independent, legitimate source of authority and its rightful area of concern. For him the source of royal power was not delegation from the pope but the nature of humankind acting reasonably and freely for the common good of society.

In 1304, John was given license to incept in theology, succeeding Raymond Romani as master. In 1305, John presided over a solemn disputation before the bishop of Paris and the faculty of theology, in which he maintained that since the church had not yet defined the doctrine of transsubstantiation, one could hold as equally probable the doctrine that later became known as "impanation"—that is, the continued existence of bread after consecration, now assumed in Christ. This novel view was examined by a number of bishops and theologians, who considered it heretical. John was suspended from all teaching and preaching, perpetual silence being imposed upon him under pain of excommunication. John appealed his case to the papal *curia* at Bordeaux, where he died on September 22, 1306, while awaiting a decision. At the very beginning of the Eucharistic controversy he had publicly expressed his willingness to retract his view should it prove contrary to the teaching of the church.

John was a gifted speculative thinker who, while accepting the basic principles of Thomas Aquinas, was eager to deal with new problems in philosophy and theology.

JOHN OF ST. THOMAS
(1589–1644)

John of St. Thomas, the Spanish theologian and philosopher, was born John Poinsot, the son of an Austrian, at Lisbon, Portugal, and died at Fraga, Spain. When he entered the Dominican order he took his name from St. Thomas Aquinas. John studied philosophy at Coimbra, Portugal, and theology at Louvain, taught philosophy and theology in Dominican houses of study, at Alcalá de Henares (1613–1630), and from 1630 to 1643 was a professor at the University of Alcalá. Apart from certain Latin and vernacular works of devotion, his writings consist of two series of textbooks, one in philosophy, the *Cursus Philosophicus* (which comprises "Ars Logica," covering logic, and "Philosophia Naturalis," on natural philosophy), the other in theology, the *Cursus Theologicus* (a systematic commentary on Thomas's *Summa of Theology*).

The "Ars Logica" is fundamentally Aristotelian logic, but John developed the content of the course in two directions: toward a formal theory of correct reasoning and toward a material logic that attends to the meaning of the actual terms of a proposition and thus anticipates some of the problems of epistemology and semantics. John's terminology differs from that of modern logic (*propositio copulativa* is the modern conjunctive proposition; *propositio disiunctiva* the alternative proposition; *bona consequentia* means *implication*). However, it has been claimed, by J. J. Doyle, that the "Ars Logica" and Alfred North Whitehead and Bertrand Russell's *Principia Mathematica* are fundamentally similar as formal systems. Concerning material implication, John taught that one may infer from the particular proposition ("Some man is rational") to the universal proposition ("Every man is rational") in cases where the matter is necessary. To some extent he anticipated problems in the philosophy of science and the metasciences and also the theory of induction.

His philosophy of nature is a systematic exposition of a type of Thomism much influenced by the commentaries of Cajetan. Nature is the world of bodies, of being that is subject to change (*ens mobile*), explained in terms of the four Aristotelian causes, substance and accidents, act and potency, matter and form.

John treated certain questions in a novel way—for example, immanent action, the sort of activity that begins and ends within one agent and is typical of psychic functions (see *Cursus Philosophicus*, "Philosophia Naturalis," I, q. 14, a. 3). John had no separate treatise on metaphysics, but his views on the ultimate character of reality were fre-quently presented in his explanation of parallel problems (substance, causality, potency) in the "Philosophia Naturalis." The "Theological Course" also contains explanations of problems in speculative philosophy. Cognition, on the sensory and intellectual levels, is explained in terms of a metaphysics of causality (I, q. 1, disp. II, a. 12, n. 4). John was one source of the theory of the distinction between three degrees of knowledge—physical, mathematical, and metaphysical—popularized in the twentieth century by Jacques Maritain.

In his discussion of the gifts of the Holy Ghost (*Cursus Theologicus*, IV, disp. XVII), John had much to say on the relation of knowledge to wisdom. He viewed ethics and political philosophy as speculative sciences and did not write much on practical philosophy. On moral questions he adopted the position called "probabilism"; that is, in moral situations where a person is really in doubt about what he should do, he may solve his doubt by adopting any judgment that has been made by a prudent moralist concerning the proposed action (*Cursus Theologicus*, IV, disp. XII, a. 3, n. 4).

John's writings are useful for their historical information on later scholasticism. He influenced many recent Thomists, notably Maritain, J. M. Ramírez, Joseph Gredt, and Yves Simon.

JOHN OF SALISBURY
(c. 1115–1180)

John of Salisbury, the scholar, humanist, and bishop, was born at Old Sarum (Wiltshire), England. After primary instruction from a rural priest he went to France to study in 1136. He read dialectic first under Peter Abelard, during the latter's last period at Paris, then under Alberic and Robert of Melun. In 1138 he began the study of grammar under Richard of Arranches, probably at Chartres, where he also studied under William of Conches; at Chartres too he studied rhetoric and part of the quadrivium. In 1141 he took up theology at Paris under Gilbert of Poitiers and Robert Pullen and made the acquaintance of other masters. He was then probably secretary for a short time to Abbot Peter of Celle (1147–1148). He was a member of the Roman Curia, and in 1148 attended the Council of Rheims, where he knew well both Bernard of Clairvaux and Gilbert of Poitiers. That year he was introduced by St. Bernard to Theobald, archbishop of Canterbury, with whom he spent a short time. Between 1149 and 1153 John was a member of the Roman Curia in Apulia and elsewhere and was on terms of intimacy with Pope Adrian IV (Nicholas Breakspear). From 1153/1154 to 1161 he was the trusted secretary of Archbishop Theobald and was one of a distinguished household that included Thomas Becket, Roger of Pont l'Évêque, later archbishop of York, and the Italian lawyer Vacarius. He advised and represented the archbishop and wrote his letters, many of which dealt with business of the Curia.

After Theobald's death, John entered the service of Thomas Becket, to whom he remained a loyal, although not blind, supporter during Thomas's later controversy with King Henry. Accused by King Henry II of encouraging appeals to Rome, John preceded his patron into exile in 1163 and spent some years in Rheims living with Peter of Celle, then abbot of St. Rémy, and working in Thomas's interest with King Louis VII of France. He rejoined Thomas shortly before the latter's return to England in December 1170 and preceded him to Canterbury.

John was at dinner with the archbishop when the knights arrived and was present, although perhaps in concealment, at Thomas's murder in the cathedral. He subsequently worked for Thomas's canonization and, in return, was invited by King Louis in July 1176 to become bishop of Chartres. He attended the third Lateran Council in 1179 and died the following year at Chartres, where he was buried.

John was author of a multitude of letters as well as short lives of Anselm and Thomas Becket, the latter a jejune work that is doubly disappointing in view of the writer's literary skill and intimate knowledge of his subject. His *Historia Pontificalis* is a continuation of the *Chronicle* of Sigebert of Gembloux and covers the years 1148–1152. As a scholar he composed the versified *Entheticus de Dog-mate Philosophorum* (1155), a rehearsal of his knowledge of ancient philosophy, as well as the two works on which his medieval reputation rested: the *Policraticus* (The statesman) and *Metalogicon.*

The *Policraticus,* subtitled *De Nugis Curialium et Vestigiis Philosophorum* (Concerning the vain purposes of courtiers and the traditions of philosophers), is a disorderly, rambling work without detailed plan. Dealing in part with such faults and follies of the great as hunting, gaming, dreams, and astrology and with witchcraft, it contains a variety of anecdotes and personal experiences. Books 6–10 deal with the character and duties of a prince, and the work has consequently been called—somewhat misleadingly—the first medieval treatise on political thought. It is, in fact, a sociological study, but it contains a well-known passage on the ministerial function of the prince, who holds the sword in order to perform duties beneath the dignity of the priesthood, which John always considers the superior power, even when emphasizing the virtue of patriotism. The passage shows no clear indication of acquaintance with the almost contemporary teaching of St. Bernard on the possession of two swords by the papacy. In the last book John proclaims the right and duty of citizens to kill a tyrant. The passage has often been quoted in later centuries as authoritative, but it is probably merely an echo of Roman republican rhetoric without any practical application to the world of the twelfth century.

The *Metalogicon* (1159–1160) was written at almost the same time as the *Policraticus.* It is an apologia for true logic, or rather for philosophical training as an introduction to a civilized way of life, contrasted with the technical logic of the schools, which was fit only for sciolists or such careerists as Cornificius, whose name recurs as an unidentified opponent of humane learning. John

recounts his own educational experiences (*Metalogicon* II, 10), with a tribute to Bernard of Chartres and a sketch of his methods, and sets out several current opinions on the nature of universals (ibid., II, 17–20). There are the pure nominalists, such as Roscelin, who held universals to be mere words (*voces*), and Abelard (as John understood—or misunderstood—him), who substituted the term *sermones.* There are those who, like Bernard of Chartres, regarded universals as the Ideas of Plato, and with these may be reckoned Gilbert of Poitiers with his "original forms" (*nativae formae*), while others regarded them merely as a group (*collectio*). John himself adopts an Aristotelian position: Universals are not independent realities, but mental images (*figmenta rationis*) of real kinds (*genera, species*) into which things can be grouped and from which the intellect can abstract those qualities that resemble those of other members of the group. John wrote no systematic philosophical work and declared himself a tolerant skeptic of the Academy, or of what is now known as Late Platonism. Nevertheless, he had great admiration for Aristotle, whom he called "the Philosopher" par excellence; without his New Logic, John maintained, and especially without the *Topics,* dialectic is doomed to be a hit-or-miss affair (*sine eo non disputatur arte sed casu*). Both these considerable works, the *Policraticus* and the *Metalogicon,* and probably also the *Entheticus,* were dedicated to Thomas Becket.

The *Historia Pontificalis,* written over a period of years and finally revised in 1164, is not professedly concerned with thought, although the controversy between St. Bernard and Gilbert of Poitiers is the most important episode contained in it. John gives the theological position of the bishop of Poitiers at considerable length, although he does not clarify the real point at issue.

John was neither a theologian nor an original thinker. He was rather, in the words of Bishop William Stubbs, "the central figure of English learning," or, perhaps more accurately, the writer of the twelfth century who came nearest to the modern critical attitude toward men and their ideas. His celebrated comparison of St. Bernard and Gilbert is the keenest analysis of character and style to appear between the days of Augustine and those of Petrarch, and this is not the only section of his writing that attains such a high level. Moreover, he is the only writer of the twelfth century to pass in review the schools of the day. He read widely, and his style was perhaps the most classical and idiomatic of all medieval attempts to write in imitation of classical models. He lacks the virtuosity and the emotional appeal of Bernard, and his vocabulary and constructions are at times diffi-

cult. He is unable to plan or to discard. But his cool judgment and unemphatic language always satisfy the reader. Similarly, his letters, especially those written during the denouement of the Becket affair, display a caustic wit that does not appear in his longer works. He knew on terms of equality almost all the distinguished men of his day. This width of acquaintance he shared with St. Bernard, but whereas the abbot of Clairvaux saw them as figures in black and white, the objects of his emotion and rhetoric, John saw them with a detached, slightly cynical eye that could observe their foibles as well as their gifts. He has won his reward: We speak of his age and society as the age of John of Salisbury.

Bibliography

The collected works of John of Salisbury were published in Latin as *Joannis Saresberiensis Opera Omnia,* 5 vols., edited by J. A. Giles (Oxford, 1848). A reprint, edited by J. P. Migne, appears in *Patrologia Latina,* Vol. CXCIX. Individual works include the *Entheticus de Dogmate Philosophorum,* edited by C. Petersen (Hamburg, 1843); *Policraticus sive de Nugis Curialium,* 2 vols., edited by C. C. J. Webb (Oxford: Clarendon Press, 1909); *Metalogicon,* edited by C. C. J. Webb (Oxford, 1929); and *Historia Pontificalis,* edited by R. L. Poole (Oxford, 1927).

An English translation of Books 1–4 and parts of Books 7 and 8 of the *Policraticus* may be found in J. B. Pike, *Frivolities of Courtiers and Footprints of Philosophers* (Minneapolis: University of Minnesota Press, 1938); a translation of Books 4–6 and parts of Books 7 and 8 appears in J. Dickinson, *The Statesman's Book* (New York: Knopf, 1927). Other translations are the *Metalogicon,* translated by D. D. McGarry (Berkeley: University of California Press, 1955); and the *Historia Pontificalis,* excellently translated and annotated by M. Chibnall from the Poole edition (Edinburgh and London: T. Nelson, 1956).

Carlyle, *A History of Medieval Humanism in the Life and Writings of John of Salisbury* (London, 1950). A valuable introduction appears in W. J. Miller, H. E. Butler, and C. N. L. Brooke, *The Letters of John of Salisbury,* Vol. I (1153–1161) (Edinburgh and London: T. Nelson, 1955).

David Knowles (1967)

JOHN OF THE CROSS, ST.
(1542–1591)

St. John of the Cross, or Juan de la Cruz, the Spanish mystic and poet, was born at Fontiveros, near Ávila. His family was poor, and as a child he worked in a hospital at Medina del Campo in return for training at the Jesuit school. In 1563 he entered the Carmelite order in Medina, and in the following years he studied at the University of Salamanca. In 1567, the year he was ordained priest, he met St. Teresa of Ávila and planned to start a monastic community in line with the kind of reform she had effected among nuns. Such a community was started in 1568, under the original Carmelite rule and in conditions of great poverty and austerity. This was a prelude to energetic reforming work by St. John and growing opposition on the part of his superiors. In 1577 he was imprisoned at Toledo for eight months and was maltreated. In 1591 he was banished to a lonely monastic house at Úbeda, where he died near the end of that year. His chief prose writings were *The Ascent of Mount Carmel, The Dark Night of the Soul, The Spiritual Canticle*, and *The Living Flame of Love*. His poems have given him a secure place in the history of Spanish literature.

The best-known feature of St. John's mystical writings is his description of the dark night of the soul (or spirit—*noche oscura del espíritu*). The imagery of night is indeed very prominent in his works and was used by him in a variety of senses. By "the dark night" he principally meant the extreme sense of desolation and despair that overcomes the soul after its first illumination by God. This illumination is not the highest state, for eventually the soul will achieve a perfect, lasting union with God—the Spiritual Marriage. The earlier illumination, which St. John called the Spiritual Betrothal, is a "high state of union and love." It thus appears that the dark night is brought on by the deprivation felt when the mystical state of illumination ceases.

St. John saw this dark night in relation to what he called the dark night of sense. This is the purgation of the body and of sense experience, in which the contemplative turns inward from the world. This self-discipline, which involves great asceticism and which constitutes the preliminary training needed for contemplation, culminates in the emptying of the mind of discursive thought and mental images. It is in this state that the Spiritual Betrothal can take place. The dark night of the soul that follows this was explained by St. John as follows.

The soul, despite the Betrothal, still has to endure further purgation, which is psychologically rather than physically painful. This is not due to a change of attitude on the part of God but results from the continued impurity of the soul, which is not able to withstand the glory of the divine illumination. In this situation the theological virtues of faith, hope, and love are essential. Faith enables the contemplative to continue undismayed through the "night"; hope turns the soul toward the future rather than to the memory of deprivation; love turns the soul toward God and men. Ultimately, then, the soul will gain the full union of the Spiritual Marriage. This is described as a complete transformation of the soul in God; and St. John tended to use language identifying the soul with God at this stage, which is contrary to theistic orthodoxy. It is interesting that in his commentary on the poem *The Living Flame of Love* he expressed great unwillingness to write about this, the loftiest state he had experienced. He also said, like other mystics, that the communication of God to the soul is ineffable. However, his use of the imagery of marriage and love indicated that he affirmed the essential distinction between the soul and its Lover.

The attainment of the highest state, according to St. John, is limited to very few persons. Such mystics long for death, after which they may enjoy the Beatific Vision in perpetuity in the next life.

St. John of the Cross and St. Teresa influenced each other, and they are the two most important figures in the history of Christian mysticism in Spain.

JOHNSON, ALEXANDER BRYAN
(1786–1867)

Alexander Bryan Johnson, an American philosopher and semanticist, was born in Gosport, England, of Dutch-Jewish ancestry. He immigrated to the United States in 1801 and settled in Utica, New York, where he achieved wealth and prominence as a banker. His main interests were intellectual, primarily in theory of knowledge and the problem of linguistic meaning. He published works on the politics of his day, on economics and banking, and moralistic tales for the young, as well as a series of philosophical works.

LANGUAGE AND NATURE

Johnson's preoccupation with language derived from his view that "our misapprehension of the nature of language has occasioned a greater waste of time, effort, and genius than all the other mistakes and delusions with which humanity has been afflicted" (*A Treatise on Language,* p. 300; except where otherwise noted, page references are to the 1959 edition of this work). He found its source in our tendency to interpret nature by language. "My lectures," he wrote, "will endeavor to subordinate language to nature—to make nature the expositor of words, instead of making words the expositor of nature. If I succeed, the success will ultimately accomplish a great revolution in every branch of learning" (p. 40). A rich harvest of philosophically important insights arose from the detailed application of this principle to a wide variety of topics.

Nature, or reality as it appears to us in objects apprehended, is divisible, according to Johnson, into three irreducible classes—the physical (that is, the sensible), the emotional, and the intellectual (thoughts and concepts, which Johnson called "intellections"). Each class includes several subclasses. Sights, sounds, tastes, (tactile) feels, and smells constitute the physical class; the emotions of joy, pain, fear, awe fall into the second class; and concepts (intellections) such as cause, identity, and infinity fall into the third. Words occurring in discourse constitute a subclass of the physical; insofar as they occur in thinking, they are intellectual in nature. The inevitable discrepancy between the practical infinity of natural existences and the necessarily limited number of words of a language results in a one-many relation between words and things (objects of reference). This ambiguity, along with carelessness and ignorance, accounts for the intellectual confusions whose elimination, or at least marking, was the aim of Johnson's lessons on the nature of language.

The terms *physical, emotional,* and *intellectual* throw no light on the nature of the realities they name, but simply refer to them. Only sensing, feeling, and conceiving can inform us what is so referred to. And as the objects, even within each category, are themselves different, acquaintance with some objects of a given kind will not give knowledge of others not confronted. This is not to deny that distinct elements within a given domain resemble one another sufficiently to justify referring to them by a common term. But we err if we suppose that the word *resembles* refers unambiguously to a unique relation. To know that *A* resembles *B* is not to know how it resembles *B*; this can be learned only by specific experience. The elements—the sights, emotions, intellections—that constitute the ultimate referents of significant words are not thought of as mental in the sense of, say, René Descartes or George Berkeley. They are precisely what we find when we confront them, and no words or theories can enlighten us as to their natures. Ultimate meanings can only be *shown* or *had,* never *said.* To understand language we must pass beyond it to the world. Language does not explain the world; the world explains language.

WORDS AND THE MULTIPLICITY OF NATURE

Johnson used his theory to throw light on practically the whole body of traditional philosophical puzzles, most of which are the result of projecting upon nature our misunderstandings of our language about it. For example, we impute to nature a oneness corresponding to the unitary words used to refer to it. Finding nature not always in

agreement with our verbal predications or imputations, we deem this to be ground for impugning our knowledge of its character. The term *gravity* is a verbal unit, but its referents constitute a multiplicity of diverse phenomena. The discrepancy between verbal unity and phenomenal multiplicity leads us to distinguish between gravity and its appearances or manifestations and finally to the view that what gravity is in itself is a mystery, or unknowable. Similar considerations apply to truth, magnetism, cholera, death, the self, and other concepts. "The word gravity names many interesting and important phenomena; but if, in addition to these, we look for gravity itself, we act as ignorantly as the child at the opera, who, after listening with impatience to the musick, singing, and dancing, said, 'I am tired of these; I want the opera'" (p. 77).

In the same vein Johnson criticized Berkeley's view that distance is invisible, by pointing out the obvious fact that "distance" names feels as well as sights. The theory that we cannot see distance derives from our often unconscious restriction of the term to the feel.

Similarly, the question "whether seeing can or not inform us of an external universe, depends on the meaning which we attach to the word external. The question relates to language, not to nature" (p. 63). If *external* is used to refer to what can be tactually felt only, then seeing cannot inform us of an external universe. A sight is not a feel. If we use *external* as referring to a sight, as we frequently and properly do, then seeing can inform us of such a universe.

The origin of theories, according to Johnson, is frequently simply our desire to reconcile these incongruities between what we suppose our language implies and what in fact nature discloses. We invent theories to reconcile the multiplicity of nature to the oneness of language, to supply the unit we suppose must exist but which we fail to find in nature.

KINDS OF MEANING

In his early writings Johnson assumed that if a word had no sensible meaning (referent) it must refer to some inner feeling, or to some other word; otherwise it would be void of meaning, "an empty salvo." Such words as *love* and *hope,* insofar as they do not refer to anything accessible to our senses, would mean other words, their synonyms or definitions, except insofar as they referred to inner feelings. For a person lacking these feelings the word *love* would have only verbal meaning. However, such a person could engage in meaningful discourse involving the word *love* by virtue of being able to explain it by means of other words. He could even have verbal knowledge about love, in the sense that he could make correct verbal deductions from statements containing the term to others entailed by them. In this sense a blind man might have much knowledge of optics, making correct deductions from given premises, even though the sensible meanings, if any, would be beyond his comprehension.

SENSIBLE AND VERBAL SPACE

The distinction between sensible and verbal meaning led Johnson to the difference between physical (sensible) and mathematical (verbal) space, and to the distinction between pure and applied mathematics. The infinite divisibility of space (or matter), not being ascertainable by any of our senses that are cognizant of sensible space, must therefore, he argued, be verbal in nature, since the theory obviously does not refer to any of our inner feelings. Verbal or mathematical space *is* infinitely divisible, our common notion of space entailing such divisibility. The paradox of Achilles and the tortoise is to be explained in terms of this distinction between sensible and mathematical space. In the visual space in which the race is run, Achilles overtakes the tortoise at precisely the moment no light is visible between the two by an observer standing on a line at right angles to the just-touching racers. In mathematical space the process of increasing the denominator of the fraction expressing the "distance" separating them can go on forever. The puzzle is due to our failure to understand that the one-to-one correspondence between the sensible distance and the mathematical distance separating Achilles and the tortoise during the early moments of the race no longer exists at the later stages. When calculation shows that Achilles is one yard behind the tortoise there exists a sensible gap separating them, but when calculation tells us that Achilles is behind the tortoise a distance of one-billionth of an inch nothing in visible space corresponds to this quantity. Hence while still separated in mathematical space they are no longer so in sensible space. The calculations are not faulty. We err in supposing that there must always be a correspondence between the calculated and the observed distance separating them simply because there once was. What is true of mathematical space need not be true of sensible space.

SENSIBLE SPACES

Johnson was aware that there are many different sensible spaces having different properties. Visual space is not identical with tactile space. This fact is important in dealing with certain epistemological puzzles, such as the dis-

crepancy between seen distance and felt distance, seen and felt size or shape, seen location and felt location. The well-known skeptical conclusions derive largely if not entirely from a failure to realize or draw the correct conclusions from the fact that what kind of correlations are found to hold between the diverse referents of such ambiguous terms as *size, shape,* and *location* is a matter purely of experiences—experiences a sensible man will adjust his theories to, but which do not require that he invoke the two-world theory of appearance and reality.

QUALITIES

The question whether secondary qualities are located in things in the external, or physical, world or are subjective representations of objective primary qualities is, according to Johnson, the unhappy result of our failure to realize the ambiguity of spatial prepositions. When we ask for the location of something—whether, for example, the green we see is in the leaf, in our minds, or in the brain—we fail to appreciate that there are several different sensible spaces and that visual, tactile, and olfactory space have each their peculiar properties. In the sense appropriate to visual space the term *in* is correctly used when we say that the (seen) color is in the visual leaf. If we speak of the tangible leaf, the color is neither in the leaf nor not in it. All that can sensibly be said to be in it or not in it is a feel. Colors not being feels, there is no sense to the question if it is based on the presupposition that a sight is a feel or can be felt.

MEANING

Johnson thus understood that in some cases it makes no sense either to assert or deny that a certain object has a certain property, and hence that the law of excluded middle breaks down in certain ways. He made this insight the key to his treatment of many philosophical puzzles.

Since our questions and answers involve sentences, not isolated words or phrases, the meaning of such expressions is of fundamental importance. Declarative sentences, possibly expressing theories, such as "Air has weight," invoked to explain the phenomenon of water rising in a vacuum, gain their referential meaning from the facts, if any, to which they refer. To determine which facts these are, we must ascertain to what phenomena the sentences are attached by a given speaker.

> Pressure, like every other word, possesses no invariable signification, nor any inherent signification. Its signification is governed by the existence to which we attach it. When it refers to the effort of my hand against this table, it names a

feel; and when applied to the ascent of water in a vacuum, it names the ascent. If we suppose it names also some insensible operation of the air on the water, this is merely our theory, which signifies nothing; or rather it signifies all to which we refer in proof of the pressure. (p. 227)

The last clause expresses Johnson's view of statement or propositional meaning. A statement means, for a speaker, whatever evidence he adduces or can adduce in support of it. Speaking of Earth's sphericity, Johnson advises us to pay attention to the evidence given in support of it by an astronomer, such as Earth's shadow in an eclipse of the moon or various calculations, and concludes: "After hearing all that he can adduce in proof of the earth's sphericity, consider the proposition significant of these proofs. If you deem it significant beyond them, you are deceived by the forms of language" (p. 129).

This principle of the meaning of propositions is of the type now called the "operational" theory of meaning. Johnson's version, by virtue of his concentration on the referential function of language, implies that propositions change their meaning with every accretion of evidence in support of them. Propositions purportedly about the future must in fact refer to what has already occurred, since one cannot refer to what is not, nor can a speaker refer to what he has not experienced. False propositions must be devoid of (sensible) meaning, since they are false precisely because what they purport to refer to does not exist. Since, however, one is rarely—if ever—unable to adduce some kind of evidence in support of one's assertions, genuinely meaningless or false propositions are extremely rare. In fact, Johnson held that "nearly every proposition is true when interpreted as the speaker interprets it" (p. 133).

Despite the obvious difficulties of this conception of propositional meaning, which needs emendation to allow for what is called "sense" as well as "reference," Johnson was able to suggest some very interesting interpretations of statements that anticipate views now in the center of philosophical controversy.

He held that a theory is a tool whose value is determined by its utility in correlating phenomena already known and enabling us to make true predictions.

He claimed that psychological statements, especially those about other minds, feelings, and thoughts, exhibit duality of meaning. They refer in one interpretation to expressive, that is, external, manifestations; in another to what is supposedly expressed or manifested. This, he

held, explains the dispute concerning the possibility of knowing other minds.

He said that true unrestricted universal propositions are such not because they hold in an infinite number of cases, but because the evidence offered in their support is our failure to find an exception. The statement asserting an exception refers to nothing and lacks sensible meaning—hence the unrestricted scope of the universal.

Typical religious or theological propositions have meaning by virtue of their reference to sacred texts or to inner feelings. It is sensibly, but not verbally, meaningless to assert that the universe either had or did not have a creator.

In his later writings Johnson allowed conceptual as well as verbal meaning to propositions. He came to believe that there are certain "predestinate ideas," concepts or intellections, that express man's intellectual nature. For example, in certain senses of the term, causal connections cannot be sensed, but all men nevertheless think causally. Men likewise impute personal identity to themselves and others, although what is sensibly or emotionally given does not exhibit the implied unity or connection. The verbal meaning that remains when sensible and emotional meanings are eliminated seemed no longer adequate in such cases, and he invoked intellectual meanings, which however are not objective or external; the intellectual words standing in relation to their referents, according to Johnson, as imprecations do to the feelings that give rise to them: "as therefore, the internal organic feeling which prompts an imprecation is the unverbal meaning of the imprecation; so the organism of the intellect that conceives any given words is the unverbal meaning of the verbal conception" (*The Meaning of Words,* p. 202). He thus treated them as expressing certain tendencies of our intellectual nature, though using the language of referential meaning.

THE MEANING OF QUESTIONS

Johnson's anticipation of a form of the operational theory of propositional meaning was accompanied by a detailed discussion of the topic of the meaning of questions. Like Ludwig Wittgenstein he arrived at the view that "the riddle does not exist," that there are no unanswerable questions. Corresponding to the verbal meanings of statements are the verbal questions to which the statements are answers. In every interrogation we must make clear the nature of the answer desired, whether verbal, emotional, sensible, or intellectual. For example, the question, "What is life?" may be answered by a definition

or a theory, by an inner experience, or by indicating certain forms of overt observable behavior.

NECESSARY TRUTHS

Concerning necessary, analytical, logical truths, Johnson held to a twofold doctrine. These truths express verbal necessities based on meanings assigned to their constituent words, but these definitions or verbal necessities are themselves based on physical, nonverbal necessities.

> Why cannot the same spot be, at the same time, both white and black? Because the word white implies that the spot is not black. But how came white by this implication? Was it arbitrarily imposed by the framers of language? No. The incompatibility of the two colours is a result of experience. If I assert that the same spot cannot be both white and hard, the proposition will be untrue. Why? Because my senses can discover such a coincidence. No other reason exists. (*A Treatise on Language,* p. 195)

The same reasoning applies to the axioms of geometry. For instance, the transitivity of the relations of equality is ultimately based not on verbal but on physical facts. Nothing will explain why two sticks equal in length to a third are necessarily equal in length to each other except what one finds when one tries to construct two sticks equal in length to a third but not to each other.

APHORISMS

Johnson's works are studded with striking and revealing aphorisms:

> The heathen make graven images—we make verbal ones; and the heathen worship not more ardently the work of their hands, than we the work of our pens. (*A Treatise on Language,* p. 205)

> Though we deem any mental phenomenon inexplicable unless we can show it to be analogous to physical operations, we deem the operations of Deity well explained when we can show them to be analogous to mental operations. (p. 263)

> We employ words as though they possess, like specie, an intrinsick and natural value; rather than as though they possess, like banknotes, a merely conventional, artificial, and representative value; … We must convert our words into the natural realities which the words represent, if

we would understand accurately their value. (p. 174)

We can no more exemplify with words that there is a limit to their applicability, than a painter can demonstrate with colours, that there are phenomena that colours cannot delineate. (p. 246)

WORKS ON JOHNSON

Johnson's views were ignored in his lifetime and were lost sight of for nearly a century. Despite the recent publication of some of his writings, he remains almost completely neglected. For biographical and bibliographical information and evaluations see the introduction and the critical essay in D. Rynin's 1947 edition of *A Treatise on Language* and M. M. Bagg's *The Pioneers of Utica* (Utica, NY: Curtiss and Childs, 1877). The *Dictionary of American Biography* contains a brief entry on Johnson. For an account of Johnson as an economist see Joseph Dorfman's *The Economic Mind in American Civilization* (New York: Viking, 1946).

David Rynin (1967)

JOHNSON, SAMUEL
(1696–1772)

Samuel Johnson, the American philosopher, was born in Guilford, Connecticut. He studied and taught at the college at New Haven, later called Yale. One of the first colonials to read Francis Bacon, John Locke, and Isaac Newton, he introduced their thought into the college program. In 1722, having abandoned the Calvinism in which he had been raised, he went to England to receive orders in the Anglican Church. On George Berkeley's arrival in Rhode Island in 1729, Johnson paid him several visits, corresponded with him, and became one of his disciples. At the invitation of Benjamin Franklin, Johnson collaborated in the founding of the University of Pennsylvania. In 1754 he helped found King's College, later called Columbia University; he was its first president (until 1763).

Johnson wrote an autobiography and numerous letters, including correspondence with Cadwallader Colden as well as with Berkeley. His philosophical works include *Synopsis Philosophiae Naturalis*, written about 1714; *Logic*, written in 1714; *Encyclopedia of Philosophy*, written in 1714 and revised in 1716; and *Elementa Philosophica*, published by Benjamin Franklin. The *Elementa* was the first textbook in philosophy published in America. It has two parts, "Noetica" and "Ethica"; the "Ethica" had been published alone under the title *A New System of Morality* (Philadelphia, 1746).

Johnson's early works reflect the scholastic Platonism and Calvinistic theology in vogue in the New England colonies during the seventeenth century. The *Encyclopedia*, also called *Technologia sive Technometria*, was a product of his school days and shows the influence of the method and ideas of Peter Ramus. While using Aristotle's physics, it criticizes his metaphysics and ethics as secular and irreligious. Johnson held that there should be no secular science but that all learning should enter into religion and foster it.

Johnson's reading of Bacon, Locke, and Newton broadened and liberalized his thinking. He became an enthusiastic follower of Berkeley's immaterialism, blending with it elements of Puritan Platonism. The English divines, especially Samuel Clarke, influenced him to give up Calvinism and to join the Church of England.

His mature philosophy is contained in his *Elementa Philosophica*. The first part, "Noetica," contains his views on reality and mind; the second, "Ethica," concerns moral behavior. Mind or spirit is defined as intelligent, active being. The objects of mind are ideas or notions. There are no material substances corresponding to our ideas; sensible reality is a system of ideas communicated to us by God as copies of the archetypal ideas in the divine mind.

Arguing against Cadwallader Colden, Johnson maintained that minds are the only agents or active causes; matter is purely passive. Bodies, which are a set of ideas impressed on our minds by God, are entirely inactive and powerless. In Johnson's view, the *vis inertiae*, which Newton attributed to matter, is not a power at all; it is simply

resistance, and resistance is the direct action of God on the human mind.

The existence of God is proved by the presence of eternal truths in our minds. Since these truths do not depend on our minds or on the actual existence of things, they must be communications of an eternally existing and necessary mind or God. We know these truths when our minds are illuminated by the divine mind. God is the fullness of being, and consequently he has the positive perfection of infinity.

Johnson defended the freedom of the will on moral grounds. If human actions are not free, then moral laws, rewards, and punishments are meaningless. God is not the only active cause; human minds are also genuine agents, endowed with freedom to choose or to reject, to act or not to act. Johnson accepted Newton's laws as regulating the movement of inanimate nature, but he insisted that the human spirit is not bound by necessary laws. In opposition to his former pupil Jonathan Edwards, he upheld the freedom of the human will and rejected the Calvinist doctrine of predestination as incompatible with genuine human freedom and as destructive of morality.

Johnson's writings are an important source for the condition of philosophy in pre-Revolution America and for the changes it underwent owing to the impact of eighteenth-century English thought.

JOHNSON, SAMUEL
(1709–1784)

Samuel Johnson, the English man of letters, poet, lexicographer, moralist, and humanist, was born in Lichfield, the son of an indigent bookseller. After his early education at Lichfield Grammar School, he tried schoolmastering for a brief period. In 1728 he entered Pembroke College, Oxford, but was compelled to leave the following year because of lack of funds. As a child he had suffered from scrofula and later from melancholia, a mental illness that plagued him throughout life, at times pushing him to the brink of insanity. In 1735 he married Mrs. Henry Porter, a widow who was twenty years his senior. After more futile attempts at schoolmastering, Johnson set out for London on horseback in 1737, taking with him one of his pupils, David Garrick. A journalist and hack writer par excellence, Johnson wrote for the *Gentleman's Magazine* and in addition produced poetry, essays, biographies, translations, a play, a proposal for a new edition of William Shakespeare, and a proposal for a new dictionary. As a "harmless drudge" he labored from 1746 to 1755 on the *Dictionary of the English Language,* a work that established the practice of elucidating definition of words by quotations from leading authors. Its appearance brought him fame and belated honorary doctorates from Dublin (1765) and Oxford (1775), but little money. Johnson's famous letter of 1755 to Lord Chesterfield repudiated the system of personal patronage. In 1762, however, despite the fact that he had defined "pension" as "pay given to a state hireling for treason to his country," he set aside his scruples to accept a pension from George III.

The Rambler (1750–1752) and *The Idler* (1758–1760) essays, although acclaimed as literature and as statements on morality, were hardly successful financially. The novel *Rasselas* (1759) was well received, as were the edition of Shakespeare (1765), *A Journey to the Western Islands of Scotland* (1775), and finally, *The Lives of the English Poets* (1779–1781). Johnson's political publications, *The False Alarm* (1770), *Thoughts on The Late Transactions Respecting The Falkland Islands* (1771), and *Taxation No Tyranny* (1775), were, on the contrary, mere diatribes and did him no credit. Yet the charge that they were written as repayment for his pension has no foundation in fact. His general theory of politics was close to that of Edmund Burke: conservative, traditional, and distrustful of all popular upheavals.

With a royal pension of £300 a year, poverty and Grubstreeting were over, and Johnson was able to indulge more freely his social proclivities and his desire to travel. The meetings with James Boswell in 1763, and with the wealthy Mr. and Mrs. Henry Thrale in 1764, and the founding of "The Club" in the same year, were happy omens of the new life. Charter members of "The Club" included Joshua Reynolds (who originated the idea), Edmund Burke, and Oliver Goldsmith. Later members of note included Boswell, Garrick, Thomas Warton, Bishop Percy, Sheridan, Fox, Edward Gibbon, and Adam Smith.

Johnson has been immortalized by his great biographer Boswell in *The Journal of a Tour to the Hebrides with Samuel Johnson* (1791), *The Life of Samuel Johnson* (1785), and in present times in the ever increasing number of volumes based upon Boswell's private journals and papers now in the archives of Yale University. Boswell's ability to draw Johnson out in conversation has presented posterity with a wide panorama of the latter's opinions and beliefs. Indeed, it is no exaggeration to say that more intimate details are known about both Johnson and Boswell than about any other persons of that or any previous age. As he grew older Johnson mellowed considerably; he was no longer the irascible, bitter, and not infrequently rude man of earlier years. Although he loved life, he feared death—despite (or perhaps because of) a deep religious faith. As he once put it, life is everywhere "supported with impatience and quitted with reluctance." He died in 1784 after a prolonged and painful siege of the dropsy. His last words are said to have been, *Iam moriturus*, "I who am about to die." He was buried in Westminster Abbey.

RELIGION AND MORALITY

Johnson acknowledged an early predilection for becoming a metaphysician, but instead he became a philosopher, in the wider sense of a thinking man struggling with the problems of life, death, and immortality. A notable excursion into the realm of metaphysics, however, is his 10,000-word critical review of Soame Jenyns's *Free Inquiry into the Nature and Origin of Evil* (1757). The rationalistic optimism inherent in the Great Chain of Being—an optimism wherein whatever is conceivable must exist (a concept justifying the necessity of evil)—was to Johnson morally monstrous as well as metaphysically illogical. It is illogical because however many links there may be in the Chain, from the Godhead at the one extreme to the lowliest atom at the other, it is always possible to conceive of gaps between the links ad infinitum. The morality of justifying poverty and pain as cosmologically necessary was monstrous to a humanist who had personally suffered both poverty and pain. Although God may move in a mysterious way his wonders to perform, it is idle to be told by a metaphysician that in some mysterious way evil in reality is good. It is small comfort to be complacently informed that poverty is merely the want of riches, and that, just as man has animals for food and diversion, so beings superior to man may be privileged to deceive, torment, or destroy man simply for the sake of utility or pleasure. In short, it was Johnson's belief that "life must be seen, before it can be known." His philosophical novel *Rasselas*, a fictional assault on metaphysical optimism, again exemplifies Johnson's favorite admonition, "Clear your mind of cant."

Johnson never systematized his thinking on morality and religion and consequently exhibits many inconsistencies. An ardent Christian and Anglican high-churchman, although not a regular churchgoer, he was forever seeking further evidence and reasons that would bolster his will to believe. He held that every man is entitled to liberty of conscience, but not necessarily the liberty of talking, preaching, or publishing. It is the prerogative of the magistrate to prohibit what he deems politically injurious to the society over which he presides. If the magistrate is morally or theologically wrong in his prohibitions, then truth may suffer. Consequently, the only way in which religious truth can be established is by martyrdom. In the persecution of a martyr, the magistrate is right politically and the martyr is right morally and religiously.

Johnson was afraid of death not only because he was fond of life (even though he held a tragic sense of life), but also because he was acutely aware of the wages of sin. The occasional sermons that Johnson composed for cler-

ical friends and acquaintances (frequently for a fee) are revealing as expressions of his views on specific theological issues. On a deeply intimate level, the "Prayers and Meditations" (begun in 1729 while he was still at Oxford and continued until a few days before his death) provide poignant evidence of repeated resolutions to reform his mode of living (that is, his habitual indolence), to steel himself against religious doubts, scruples, and fear of damnation, and to purge his mind of morbidity and the dread of recurring insanity.

Johnson claimed that we know the distinction between right and wrong by reason; from experience he also knew the difficulties that man encounters in trying to live the life of virtue. Accordingly, he felt the necessity of a mandate from Christian revelation—but never, to be sure, in the sense of the personal "enthusiasm" of seventeenth-century Puritans or eighteenth-century evangelists. He was thus both a rationalist and fideist, but the former tempered by a healthy empiricism and the latter by the requirement of "works." On the one hand, he had unbounded admiration for the Anglican rationalist theologian, Samuel Clarke (1675–1729), and on the other, for the nonjuring pietist and mystic, William Law (1686–1761), neither of whom qualify as orthodox. The sermons of Clarke provided Johnson with rational treatment of thorny theological problems; for example, Law's *Serious Call to a Devout and Holy Life* (1728) augmented faith through a reason that provides spiritual light. Johnson was sufficiently the ethical rationalist (with the qualifications mentioned above) to oppose the nonrational moralists of sentiment or moral sense, such as the earl of Shaftesbury, Francis Hutcheson, Joseph Butler, David Hume, and Adam Smith. Johnson, like Thomas Hobbes, did not consider benevolence or the will to do good to others a natural instinct. Charity, however, as a requisite Christian virtue, Johnson practiced religiously throughout his life. The desire for fame, he maintained in a *Rambler* essay, is basically the desire of "filling" the minds of others. Johnson achieved fame as a didactic writer and moralist who regarded the end and the rites of religion as divinely instituted for "the perpetual renovation of the motives to virtue." This concept of religious need and Christian stoicism received its most memorable poetical statement in one of Johnson's earliest works, *The Vanity of Human Wishes* (1749); it was a statement that was to be reaffirmed countless times throughout his life.

JOUFFROY, THÉODORE SIMON
(1796–1842)

Théodore Simon Jouffroy, a French commonsense and spiritualist philosopher, was born at Pontets, near Pontarlier, in the department of Doubs. After his preliminary schooling he entered the École Normale in Paris in 1814 and began teaching there three years later. He was attracted to the study of philosophy by Pierre Paul Royer-Collard and Victor Cousin, who were lecturing on the Scottish school. In 1826, Jouffroy published a translation of Dugald Stewart's *Outlines of Moral Philosophy,* and in 1828 he prepared a six-volume translation of the works of Thomas Reid. Jouffroy's rise in the academic hierarchy was rapid; by 1828 he was lecturing at both the École Normale and the Collège de France, where he was appointed professor of Greek and Roman philosophy in 1833. In the same year he was made a member of the Academy of Science.

Jouffroy's interests were varied, covering psychology, aesthetics, legal philosophy, and epistemology, yet he published very little. He is best known for two volumes of miscellaneous essays, *Mélanges philosophiques,* published in 1833, and *Nouveaux Mélanges philosophiques,* which appeared the year of his death.

Jouffroy's ambition was to found a science of psychology based on Scottish philosophy. A survey of the soul's activity revealed to him six different faculties; basic to each of these is a fusion of love of power, curiosity, and sympathy. Upon this foundation rest sensitivity to pleasure and pain, intelligence, "expression," movement, and volition. The soul is thus a community of faculties, all of which must cooperate if the truth is ever to be discovered. It reproduces in the individual that fusion of human souls which is known in the Scottish philosophy as common sense.

It is common sense that alone possesses absolute truth, access to which is denied individuals. Each of us, Jouffroy believed, should attempt to reach the truth by the use of reasoning, but we must accept its conclusions by "a blind act of faith." For none of our faculties is capable of acting in the name of the collective wisdom of the race. Jouffroy held so strongly to this idea that he regarded individual philosophers as mere mouthpieces for the societies and cultures in which they live. As early as 1827 he showed an interest in society as a being having its peculiar influence on the individuals who compose it, but he was never clear about the nature of this being. Jouffroy maintained that if people understood their

dependence on the totality of individuals, they would cease to fight with one another and would form a unified fraternal community. This community would be the explicit embodiment of common sense, which already exists implicitly in all human beings.

Common sense expresses itself in self-evident principles that appear in logic and in the dictates of the moral conscience. They are the source of an all-inclusive philosophy illustrated in natural law, which is that system of moral and political principles that underlies the statutes of all nations. Since this system is always consistent, it can act as a test for all truths. What William James, in his *Varieties of Religious Experience,* called Jouffroy's conversion to skepticism stemmed from this idea. For what man other than a mystic could transcend the limits of his individuality to grasp ideas that were overindividual?

In spite of this, Jouffroy maintained that intelligence can apprehend these self-evident principles, just as conscience can apprehend the difference between right and wrong. Here he departed from his theory that men express the ideas of periods and societies and insisted instead that each man's conscience is his sole guide to the good. For the good turns out to be the accomplishment of a man's destiny and evil the failure to accomplish it. A man's destiny is incorporated in his individuality, no two men having precisely the same goals. In general, however, pleasure and pain indicate to a man whether he is fulfilling his destiny, which is apparently the reason men are pleased by different experiences. Unfortunately, Jouffroy's conclusions on this point are lost. And, indeed, he may not have drawn any conclusions, for he was more given to preparatory analyses than to inferences.

Aesthetics, according to Jouffroy, deals exclusively with the nature of beauty. Just as truth is not the possession of any individual, neither is beauty. Beauty does not reflect the character of our life; it is the sublime that takes beauty's place in experience. "The ideas of our present life," Jouffroy said in his *Cours d'esthétique,* "are more familiar to us than the ideas of a more perfect life, and we are consequently less sensitive to beauty than to the sublime." Though the *Cours d'esthétique* consists of notes taken by his pupils and hence cannot be regarded as wholly his, it is clear that the metaphor of the whole of which we know but limited parts dominated Jouffroy's thought. Whether the problem was that of truth, goodness, or beauty, he believed it is the nature of the whole that contains the answer and men are condemned never to possess the answer.

JOURNALS, PHILOSOPHICAL

JUNG, CARL GUSTAV
(1875–1961)

Carl Gustav Jung, the originator of analytical psychology, was born in Kesswil, Switzerland, studied medicine in Basel, and then became an assistant in psychiatry at Zürich, interrupting his stay there to visit and study under Pierre Janet in Paris. He was a pupil of Eugen Bleuler, and he became Sigmund Freud's friend and collaborator for a few years, after having been influenced by his writings. He became the first president of the International Psychoanalytic Society in 1911. In 1914 he broke with Freud, founding his own school of analytical psychology. His earlier studies of association tests and of dementia praecox were followed by an attempt to classify types of personality and by the gradual development not only of a theory of the collective unconscious but also of the implications of that theory for the study of culture and especially for the study of mythology and religion.

Jung traveled widely in Africa, America, and India and collaborated with Richard Wilhelm in Chinese stud-ies and with Kárly Kerényi in the study of mythology. In June 1933 the German Society for Psychotherapy came under Nazi control. Ernst Kretschmer at once resigned from the office of president, and it is regrettable and noteworthy that Jung took his place. Among many other distinctions, he received honorary degrees from Harvard (1936), Oxford (1938), and Geneva (1945).

THEORY OF PSYCHOLOGICAL TYPES

Jung, like Kretschmer, distinguished initially between the extraverted type of personality—sociable, outgoing, and optimistic—and the introverted type—more apt to withdraw from external reality, less sociable, more absorbed in his own inner life. This initial distinction was accompanied by a distinction between four functions of personality—sensation, thinking, feeling, and intuition. By "sensation" Jung meant all that we acquire through sense perception. "Thinking" was used in its familiar meanings. "Feeling" was the capacity for making evaluations of oneself and of others. "Intuition" was the perception of realities that are not consciously perceived; it worked spontaneously for the solution of problems that cannot be grasped rationally.

Types of personality were discriminated in terms of which function is dominant and whether the person is extraverted or introverted. For example, the extravert in whom thinking is dominant will be fascinated by facts and concerned to order them rationally, will tend to underrate the emotions and thus be subject from time to time to uncontrolled and perhaps unrecognized bursts of emotion. The introverted thinking type is one in which facts are never of value for their own sake but only in relation to the creative inner theorizing of the thinker. Both types of thinking are accompanied by an undeveloped feeling function, for thinking and feeling are essentially opposite and even inimical. Sensation and intuition are paired in the same way.

On Jung's view one very rarely finds a person who is a pure example of one of these categories. Most often one function is dominant, although modified by the presence of one of the others. In more complex personalities two functions may coexist in dominance, and very occasionally three, but there will always be at least one function neglected and unacknowledged. Jung's classification into types is, of course, a classification in terms of types of conscious response to the world; however, the notion of parts of the self that are unacknowledged requires some reference to the unconscious.

PERSONAL AND COLLECTIVE UNCONSCIOUS

The personal unconscious consists of those associated webs of ideas and emotions that Jung named complexes, which have been repressed from consciousness because it found them too painful to acknowledge, and also of those perceptions of reality that have never forced their way into consciousness. Each individual's personal unconscious is thus to some extent explicable in terms of his own life history. Even the personal unconscious, however, has features that are common to every individual and do not derive from his personal history.

Consider the contrast between what Jung termed the "persona" and the "shadow." The persona is the socially accepted and socially imposed mask behind which dwells the true ego. The existence of such a mask is an unavoidable necessity, but the ego can fail to achieve self-realization either by identifying itself too strongly with its persona or by not developing an adequate persona at all. The counterpoint to this accepted and exposed part of the personality is the shadow, the rejected and usually imprisoned set of desires, emotions, and attitudes that we personify in dreams as an unpleasant or hostile figure. The shadow is essentially infantile, for it is untouched by the process of maturation or education. The inability to acknowledge one's shadow is always a potential danger to the personality, for the shadow unacknowledged and unrecognized is stronger and more wayward than the shadow recognized and accepted.

Although every individual has a shadow, since the shadow is the product of what his particular consciousness has repressed, it belongs to the personal unconscious. However, beside it in the personal unconscious is found another major force, the image, the image that constitutes the feminine in a man or the masculine in a woman, termed by Jung "anima" and "animus," respectively. The character of the anima is not determined by a man's private history in the way the character of the shadow is; rather, the anima determines how the opposite sex is perceived or misperceived. The anima is an inherited collective image of woman as such. Thus, what matters to the child is not merely how his mother treats him; his experience of the mother is produced both by the mother's actual behavior and by the way his anima determines his view of and feelings about her. Jung connected the anima especially with the function of feeling, the animus with that of thinking, supposing that thinking is more likely to be dominant in the man, feeling in the woman.

The animus and anima belong to the collective unconscious of humankind, along with persona and shadow. They are among the "archetypes," inherited tendencies of psychic functioning contained in the collective unconscious. Other key archetypes are those of the old wise man, the earth mother, and the self. An archetype plays a variety of roles: Not only does it condition the ways in which our conscious experience is formed but also it can appear directly in a number of guises in dreams and fantasies, and the individual may even unconsciously come to be so dominated by one of these images that he might be said to be possessed by it or to identify himself with it. When this happens the personality is itself in danger; it has been taken over and magnified into something that expresses not the individual person but the collective image. This Jung called inflation.

Jung contrasted the self with the ego. The ego is the actual center of consciousness; the self is spoken of by Jung as the center of the unconscious, but clearly it is potentially rather than actually so. Religious visions, dreams, and the magic diagram that Buddhists call the mandala are all images of a possible unity in which the self is at the center. The achievement of this unity by any given individual is a task that belongs especially to the second half of life. In the first half of life the individual is necessarily largely preoccupied with work, marriage, and the bringing up of children; it is when these tasks are mostly accomplished that the individual has to come to terms with himself. Hence the psychological crisis period that occurs in the late forties. At this point the nature of Jungian psychotherapy becomes important.

PSYCHOTHERAPY

According to Jung a neurotic symptom is never to be explained solely in terms of the patient's past. It always represents something positive in the present, an attempt to solve the problems that confront the patient. Jung was prepared to accept that Freud was correct in ascribing many neuroses to the problems arising out of repressed sexuality and that Alfred Adler was correct in ascribing many others to an unrecognized will to power. However, he felt that behind sexuality and the will to power lie other more fundamental causes. Sexuality, for example, is important because it represents the chthonic element in man, an element represented in pre-Olympian Greek religion and in other mythologies. Moreover, the type of neurosis that can be understood correctly, within limits, in Freudian or Adlerian terms belongs characteristically

to the earlier part of life. It arises from the inability to carry through the practical tasks of life.

In psychotherapy the patient comes to acknowledge hitherto unrecognized parts of his personality. Jung believed that free association, as practiced by Freudian analysts, leads not toward but away from the complexes of which we need to become aware. However, more is involved in the therapeutic process that ridding oneself of symptoms, as the patient discovers when he brings what was repressed into view, for example through a new awareness of the significance of his dreams, which function, according to Jung, as compensations for deficiencies in the dreamer's waking life. To rid oneself of symptoms, one has to become aware of the process of individuation, of the need for the creation of a harmonious synthesis of the functions in which the nature of the shadow and the power of the archetypes of the collective unconscious have been reconciled with the demands of the conscious personality.

MYTHOLOGY AND RELIGION

Jung used his central theoretical concept, that of the collective unconscious, to explain not only the occurrence in dreams and the awareness in analysis of contents of the unconscious that could not have been repressed into it by the individual psyche but also the widespread recurrence of the same symbols and themes in widely different times and places in mythologies and religions. Thus, Jung found in the dreams and paintings of patients material that closely resembles that in Eastern religious writings, and in literature and art the archetypal images continually recur. Modern man stands, however, in a peculiar relationship to the contents of the collective unconscious.

Jung held that the increase in scientific understanding has led to a dehumanization of the natural and social worlds. A former unconscious acceptance of natural phenomena, which involved endowing them with symbolic power, has disappeared. To treat thunder, for example, not as the voice of a god but as an explicable phenomenon is to have become alienated from external nature. A loss of belief in gods and demons has produced a lack of awareness of the powers within human nature. Modern man is thus specially a prey to psychological disorders.

It follows that men have a strong need for religious beliefs and experiences, since in religious form they are able to encounter and accept the contents of the collective unconscious. Religious beliefs, Jung conceded, cannot be shown to be true; but he held that they cannot be shown to be false, either. Whether to believe or not is thus a matter of choice, on purely pragmatic grounds. Jung regarded

with deep suspicion, as essentially one-sided and distorting, the rationalist traditions of scientific thought. Indeed, he dated the disorientation of modern man partly from the original Christian break with paganism, but more importantly from the Enlightenment.

CRITICISM

Of all Jung's work his classification of types of personality as extravert or introvert has won the widest acceptance. H. J. Eysenck has developed this distinction for use in experimental psychology, and it may well be that other Jungian concepts and theories can also be tested experimentally. However, the linchpin of Jung's theorizing, the concept of the collective unconscious, is so formed that it appears that whereas the existence of the collective unconscious was advanced as an explanatory hypothesis, the question of whether the collective unconscious exists cannot be answered by any possible observation or experiment. That the existence of the collective unconscious is intended as a hypothesis seems clear from the fact that it is avowedly introduced to explain why the same symbols keep recurring in dreams, mythologies, and works of art. However, there are no predictions that we can deduce from this hypothesis other than the vague generalization that such symbols do and will recur—and this, after all, is what the hypothesis was originally intended to explain. Moreover, Jung is open to criticism for treating the collective unconscious not as a theoretical entity to which reference is made in an as yet untested hypothesis but as something whose existence is an established fact. Jung actually asserted that although the facts about personality and the unconscious are undeniable, they cannot, by their very nature, be formulated in such a way as to satisfy the demands of either science or logic.

At the root of the problem lies an ambiguous set of ontological claims. Jung insisted that the contents of the psyche are as real as what exists in the external world. He clearly meant by this more than the obvious, which nobody would be disposed to deny, for example, that there are recurrent patterns of symbolism. But what he meant beyond this remains unclear. Sometimes he seems to have treated the archetypal images as autonomous agents and the collective unconscious as a realm where they dwell. However, his insistence on the inapplicability of the ordinary canons of logic in these matters makes it difficult to press the questions that this seems to raise.

Finally, it is worth noting that we possess no statistical evidence of a worthwhile kind about the efficacy of Jungian psychotherapy. Lacking this evidence, we are forced to conclude that although Jung established a psy-

chological system of some complexity, there are as yet no grounds for believing any of its propositions that go beyond recording empirical data, either as to the nature of personality or as to the process of cure.

JÜNGER, ERNST
(1895–1998)

Ernst Jünger was a German novelist and cultural critic who, by embracing total war as an exemplary pattern of life, helped to prepare the ideology of the National Socialist revolution of 1933. He was born in Heidelberg and educated in Hanover. In 1913 he joined the French Foreign Legion in north Africa in search of "the extraordinary beyond the social and moral sphere … a zone in which the war of the forces of nature found its pure and aimless expression." This quest for an exotic life in artificially heightened experience revealed Jünger's metaphysical attitudes and anticipated his later pattern of life. Jünger joined the German army at the outbreak of World War I. He fought on the western front and was commissioned, repeatedly wounded, and highly decorated. To him the war appeared "a means for self-realization, a wild upsurge of life … a splendid bloody play which makes the gods rejoice" that offered the key to all essential experience: "ecstasy, sleep and death." After the war Jünger developed his views in a series of brilliant war descriptions: *In Stahlgewittern* (1920); *Der Kampf als inneres Erlebnis* (1922); *Das Wäldchen 125* (1925); *Feuer und Blut* (1925; Adolf Hitler annotated his gift copy); culminating in *Totale Mobilmachung* (1930) and *Der Arbeiter* (1932).

Jünger was also fascinated by modern technology, which had transformed the character of warfare and was creating a new form of industrial society. He envisioned the emergence of a new type of technical elite: the worker-soldier in the nationalized, socialist, militarist-imperialist, and dictatorial state of the future. He also discerned a "new consciousness of reality," nihilist in its relations to traditional values. But although he welcomed the rise of technology as a triumph of man, Jünger deplored its mechanization and dehumanization of life. In the Marxian solution of this problem, the common existential experience of the proletariat leads to class solidarity; its mastery of the tools of production leads to the liberation and human autonomy of the proletariat, which represents humankind. Similarly, Jünger's worker-soldier, simultaneously savior and saved, was to achieve the collective salvation of the rotting democratic-humanist society.

Technology, however, was inseparably bound up with war, "a fiery marriage between the spirit of chivalry and the severe coldness of our forms of work." The world of factories and calculated organization, of production, and of transport finds its true measure in battle. "The battle is a tremendous touchstone of industry, and victory marks the success of a competitive effort which knows how to work more quickly and ruthlessly." The individual worker-soldier finds his liberty in accepting the necessity to be part of "the greater force. Here one can only drift and be formed under the grip of the *Weltgeist.*" The worker-soldier type thus replaced the individualist personality of the nineteenth century. Technology became both the means and the end of human endeavor—the means because it procured mastery over others, the end because the old values were dead, and collective power, the product of technology, was equated with value: "Technology and ethos have become synonymous."

Jünger's "national-Bolshevist" conception of technology provided a scintillating and heady approach to totalitarianism, an approach based also on his belief in inexorable historical trends and his romantic conviction that the individual finds fulfillment only by sacrificial immersion of himself in the whole. Jünger promised redemption for the sacrifice of the obedient soldier but showed scant sympathy for that of the Socratic nonconformist. His *Der Arbeiter* is thus less a sociological interpretation of his times than the revelation of a political myth, a clarion call that exerted a wide influence in Germany among the bewildered generation of the 1920s.

Jünger's misinterpretation and rejection of liberalism prevented his playing a constructive part as a citizen and caused him to be a destructive intellectual force. An anarchic pride in his own independence, however, saved him from effective collaboration with National Socialism. Jünger first parted ways with the Nazi Party in 1929, when he backed a terrorist peasant movement opposed by Hitler. Between the lines of his novel *Auf den Marmorklippen* (1939) he criticized the prevailing tyranny, but he took no part in active resistance to the regime. He again fought in the German army in 1940, although he suffered misgivings as a member of the army of occupation in France and Russia. These feelings found expression in *Strahlungen* (1949), Jünger's journals from 1939 to 1949, in which he corrected certain of his former tenets and, in a fashion, held out a hand to Western values and to the Christian religion. In his novel *Heliopolis* (1949) he took up once more the problems raised in *Auf den Marmorklippen. Heliopolis* contained an indictment of a closely knit totalitarian order but, at the same time, preserved Jünger's distance from Western rationalism and liberalism. The same theme recurred in *Der Waldgang* (1951); *Gläserne Bienen* (1957), which again expressed Jünger's fascination with technology; and *Der Weltstaat* (1960), which called for international political unity as a historically determined necessity.

Jünger conceived of the writer as a seer and pathfinder. His diagnosis of his times was, however, based on an untrained and intuitive sociological and economic knowledge, poetical and pretentious rather than scholarly. His widely acclaimed concept of the Gestalt, or Typus, of the worker offered no methodological advance and in substance was merely ideological. Jünger's significance was as a spokesman of the powerful romantic strand in the German intellectual tradition that unites elements of *Naturphilosophie,* Neoplatonic mysticism, and a Protagorean theory of knowledge with the negative aspects of Jean-Jacques Rousseau's and Edmund Burke's critiques of society and the Enlightenment. In its modern representatives, such as Jünger and Oswald Spengler, such thinking leads to a rejection of the rational, abstract, and mechanical achievements of civilization, the "high-treason of the intellect against life," and to the extolling of the instinctive, oceanic "night side" of life. Although not original, Jünger's philosophy was presented in a highly personal manner and in an evocative style, drawn from military language and a minute observation of nature. As a novelist, however, he did not succeed in creating concrete character.

JUNGIUS, JOACHIM

(1587–1656)

Joachim Jungius, of Lübeck, represents the German counterpart to Galileo Galilei in Italy, René Descartes in France, and Francis Bacon in England as an innovator in science and philosophy. Unlike these men, Jungius did not achieve an international reputation; even among scholars, interest in him has been largely confined to Germans, whose curiosity has been whetted by Gottfried Wilhelm Leibniz's enthusiastic praise of his merits as a philosopher. But Jungius exercised a wide personal influence in Germany as an active teacher. Furthermore, like Bacon, he envisaged a scientific society that would promote the welfare of humankind: Jungius actually organized a group called the Societas Ereunetica, whose stated objective was to promote sound science and combat false opinions. This group, with its stress on mathematics and logic as an antidote to metaphysical and mystical speculation, invites comparison with the Vienna circle of the twentieth century as well as with the Royal Society. Although Jungius has been linked by legend with the Rosicrucians, there is no evidence whatsoever to support this conjecture, according to G. C. Guhrauer.

Jungius studied at Rostock and Giessen before traveling to Italy to take a medical degree from Padua in 1618. During the early seventeenth century, philosophy in the German schools relied to a large extent on Aristotelian compendia drawn up by Philipp Melanchthon or by Peter Ramus, supplemented by metaphysics of the Suarezian type. Both traditions were diligently studied by Jungius before he rejected them. Jungius had taught mathematics at Rostock; hence, he must have found the atmosphere of Padua congenial, because of the school's emphasis on a research-oriented natural philosophy, medical training, and mathematics.

On his return to Germany, Jungius resumed his teaching duties, presiding over disputations in which Aristotelian views in physics were mercilessly criticized. He was dissatisfied with the doctrine of the four elements and wished to substitute for it an atomism that, he believed, would be confirmed by future research but which, in any event, offered a more promising hypothesis. Jungius considered atomism more sound from the methodological point of view since it did not require the postulating of entities ("forms") to explain the rise of all sorts of new qualities in things. "Democritus was an Ockhamist," he remarked.

In 1625 Jungius began teaching medicine at Helmstedt, stressing the value of Galen, whose logical empiricism he found congenial. In 1628 Jungius took an unusual step—he left university teaching to assume charge of a secondary school in Hamburg. Jungius rescued the school from the decline into which it had fallen, sending out from it students trained to a high level of critical analysis. For them Jungius composed the famous "Hamburg Logic" (1638), called by Heinrich Scholz "the most significant logic of the seventeenth century," eclipsing the better-known Port-Royal logic. Jungius's critical presentation of traditional logic shows what the more sophisticated neo-Aristotelian contemporaries of Descartes were thinking about causation, induction, and the nature of scientific demonstration. Jungius was also interested in natural history; he and his students collected plants, minerals, and fossils. His botanical views attracted the attention of Johann Wolfgang von Goethe, who planned a monograph about him.

Most of Jungius's writings in manuscript were destroyed by fire in 1691. The works posthumously published under his name, such as the *Doxoscopiae Physicae Minores* (Hamburg, 1662), were compilations made by students. Such writings as we do have bear the stamp of an active and critical mind, free from any mystical leanings and directed toward a scientific reconstruction of philosophy.

JURISPRUDENCE

See *Analytical Jurisprudence*; *Historical School of Jurisprudence*; *Legal Positivism*; *Philosophy of Law, History of*; *Philosophy of Law, Problems of*

JUSTICE

Justice names not a thing, but a property of things. It makes sense therefore to focus the explication on the adjective "just"—or, better still, "unjust." Doing so facilitates clarification of how justice judgments are distinctive within the larger realm of moral judgments, and the even larger universe of evaluative judgments.

The application of ordinary empirical predicates, such as "tree" or "hard," is two-tiered: based on a definition and empirical facts. Any dispute about whether such a predicate applies thus reduces to linguistic and empirical differences. Such a dispute can be resolved by agreeing on a definition and settling the empirical disagreement.

Evaluative predicates, by contrast, have this special feature that their application is only conditioned, not determined, by their definition and the empirical facts. Thus, people can disagree about whether a painting is beautiful, even if they use this predicate in exactly the same sense and also agree about all empirical features of the painting. In such cases it may be said that they have different conceptions of beauty.

The same holds for moral predicates. Despite agreement on all relevant empirical facts, people disagree about whether something is praiseworthy or not. Such a disagreement could stem from one party's failure to understand the meaning of the word; but more typically the disputants know what the word means, and their disagreement shows then that the empirical facts and the meaning of the word together do not determine its correct application. Those who judge it praiseworthy to teach children through beatings are morally mistaken; they need not linguistic instruction to improve their understanding of "praiseworthy," but a good discussion about how children should be educated.

A dispute over the application of an evaluative predicate such as "just" may thus be due to differences of three kinds: *linguistic* differences about its meaning; *theoretical* differences about which substantive conception or criterion of justice should guide its application; and *empirical* differences about the evaluated object.

The boundaries between these three kinds of differences is not sharp and may shift over time, as Wittgenstein memorably describes:

> It might be imagined that some propositions, of the form of empirical propositions, were hardened and functioned as channels for such empirical propositions as were not hardened but fluid; and that this relation altered with time, in that fluid propositions hardened, and hard ones became fluid. The mythology may change back into a state of flux, the riverbed of thoughts may shift. But I distinguish between the movement of the waters on the riverbed and the shift of the bed itself; though there is not a sharp division of the one from the other.… And the bank of that river consists partly of hard rock, subject to no alteration or only to an imperceptible one, partly of sand, which now in one place now in another gets washed away, or deposited. (Wittgenstein 1969, §§ 96, 97, 99)

Not discussed by Wittgenstein, the boundary between linguistic and theoretical differences (in the case of evaluative predicates) is fuzzy and fluid in part because the controversies among competing conceptions reflect back upon the concept. Each conception seeks to introduce a certain order and unity. And sometimes elements of such a conception are widely found to be so convincing that they harden into an element of the concept.

CONDUCT-GUIDING FUNCTION

The predicates "just" and "unjust" have not merely an evaluative but also a normative—hence conduct-guiding—function. Calling a possible action or law unjust is to oppose its implementation. To be sure, people do make justice judgments about the distant past, about hypotheticals and fiction. But even these judgments imply oughts—for example: that the Athenians ought not to have attacked neutral Melos; that it would have been all right for them to attack a Melos allied with Sparta; or that Angelo (in Shakespeare's *Measure for Measure*) ought not to have demanded Isabella's virginity for the life of her brother.

The words "rational" and "irrational" are also conduct-guiding in this sense. Yet there is a difference. Whether an action is rational or irrational depends on the ends of the actor. Whether it is just or unjust is independent of these ends. Insofar as even an agent's ultimate ends can be criticized as irrational (Parfit), this difference becomes less deep. Like morality, rationality can then deliver unconditional judgments: an action is irrational if it was performed in pursuit of an irrational end.

Generally, claims of injustice are meant to evoke emotional rejection: condemnation, outrage, resentment. But this may be part not of the meaning of the word but of the usual pragmatic context of its employment.

JUDICANDA

The meaning of predicates is partly determined by their domain of application. Anyone who understands the meaning of "beautiful" and "just" knows how the domains of these predicates differ—knows, for instance, that a painting can be (un)beautiful but not (un)just whereas a patent regime can be (un)just but not (un)beautiful.

Things to which evaluative predicates are applicable can thus be called judicanda, from the Latin *judicandum*: that which is to be judged. The judicanda of justice may be categorized under four headings:

(a) individual and collective actors; that is, individuals as well as organized and unorganized groups such as a family, firm, state, or mob;

(b) the conduct of such actors, their actions and omissions;

(c) social rules, such as laws, social institutions, and conventions;

(d) states of affairs and events, such as the fact that some are much worse off than others or that some

good persons suffer while some bad ones enjoy good fortune.

Because of the normativity of justice assessments, judicanda of the first two categories have a certain primacy. It is ultimately actors—and their conduct—who bear responsibility for the justice of social rules and, in part through these rules, for the justice of states of affairs. To be sure, sometimes people complain of injustice in states of affairs beyond human control. Such complaints may have a religious context; but they may also, where religion has faded, constitute a purely evaluative (non-normative) use of "unjust."

One may think that this list is underinclusive, that human feelings constitute a fifth judicandum as exemplified by the anger of Achilles and its critique as unjust. But such locutions are better understood as meaning to assess the person and her or his conduct. It is Achilles whose justice is in question—on account of his tendency to get angry allegedly without good reason. Thus, talk of unjust feelings is imprecise, meant to call into question the justice of the person who feels this way.

One may think that the first category reduces to the second in a similar way: that justice assessments of actors really mean to judge these actors' conduct, and that the list is therefore overinclusive. But the nature of such a reduction would be controversial: Do assessments of actors refer to their actual conduct, to their conduct dispositions, to their intentions (toward conduct)? Such controversy shows that the proposed reduction does not hold as a matter of meaning. It can be a substantive element in a conception of justice. But, to state it as such, actors must be shall be a separate category of judicanda.

The same holds for the possible reduction of the third category to the second. One may think, for instance, that social rules are unjust if and only if it would be unjust to (help) impose them. But here, too, there are various other ways of formulating the reduction; and it is a substantive moral question which of these formulations, if any, is correct.

In view of the diversity of judicanda, one may dispair of Plato's grand ambition in the *Republic* and conclude that it is impossible to give a general characterization of the concept—let alone a general conception—of justice that plausibly covers all four categories of judicanda. Such doubt can only be dispelled by setting forth a plausible general structure for the concept (building on the general points already made) and some main hypotheses toward a unified conception of justice. This attempt is made in what follows.

A UNIFIED CONCEPT OF JUSTICE

In contrast to many one-place evaluative predicates (beautiful, good, conscientious, modest), "unjust" has an essential second place. It is indeed often used as a one-place predicate (as in "this man is unjust"). But reference to a second place is always implicit. In this respect, "unjust" is like the predicate "mother." To say that she is a mother is to say that she is the mother of someone. One cannot understand what it is to be a mother without understanding what it is to be the mother of someone. Likewise here: To call a man unjust is to say that he is unjust to others. One cannot understand what it is for a judicandum to be unjust without understanding what it is for it to be unjust to someone. Injustice conceptually requires *recipients*: those who receive unjust treatment from the judicandum.

To be sure, one may call a proposed law unjust even if it fails to pass and thus never treats anyone unjustly, and one may call a woman unjust, even if she treats no one unjustly, on account of her intentions or dispositions. But even in such cases an implicit reference to recipients is essential: one implies that the proposed law, if adopted, would treat some persons unjustly, and that the woman intends, or is disposed, to treat others unjustly.

Recipients need not necessarily be victims. It is possible that the injustice of an action or rule entails that some are treated better than they should be. In such cases, there may be other victims—people who, because of the action or rule in question, are unjustly treated worse than those who were treated too well. But when there are no such victims, can one then still speak of (victimless) injustice? To use an example from Kant's *Metaphysics of Morals* (p. 333): Would it be unjust if a society about to dissolve itself were to set free a convicted murderer from its jail? (Kant suggests that this would be unjust—but not because his execution is owed to the murderer himself, but because it is owed to his victim(s) and to all of humankind.) The concept of justice does not settle this question; different conceptions of justice will answer it differently.

The concept of justice involves an essential third place in that the notion of recipients, of those who receive just or unjust treatment, presupposes benefits and burdens that these recipients either should but do not have or do but should not have. What sorts of benefits and burdens these are, and whether they are understood in absolute terms or relative to what other recipients have, varies with judicandum and context.

Various aspects of justice have traditionally been distinguished. These distinctions can be displayed in three dimensions.

DIMENSION ONE: FIRST-ORDER AND PROCEDURAL (IN)JUSTICE. In a first dimension, one can distinguish assessments of a particular allocation of benefits and burdens (*first-order* justice) from assessments of the way in which such an allocation comes about (*higher-order* or *procedural* justice, sometimes also called *fairness*). Thus a judicial divorce may be unjust on account of the ordered division of marital property, and it may also, and independently, be unjust because avoidably only one of the two parties was allowed to speak. The latter injustice—a violation of the classical precept *audiatur et altera pars*—involves (relative) second-order benefits and burdens: the advantaging of one party and the disadvantaging of the other in the decision-making process. In other cases, violations of procedural justice may involve absolute higher-order benefits or burdens, as when exculpatory or incriminating evidence or witnesses are arbitrarily excluded from a criminal trial.

Procedural justice plays an important role even outside jurisprudence. Rules and decisions about the awarding of honors, contracts, jobs, promotions, and university admissions may violate procedural justice. There are blatant cases, as when a coveted job goes to an insider's spouse without advertisement or search. In other cases it is controversial what the requirements of procedural justice are, exactly. The most important such controversies in recent decades have centered around the question of whether certain selection processes may or should favor people of a particular color, gender, or ethnicity so as to compensate for, or to help overcome, group disadvantages due to past or present discrimination.

In the realm of politics, especially, there may be third-order and fourth-order judgments of justice. This is the case when the rules or the participants for some procedure are selected through a metaprocedure. Thus, the electoral law of a country may be unjust independently of whether this has any effect on the composition of its legislature and, thereby, on its legislative output.

Even in private life one may find violations of procedural justice. It may be unjust if on the basis of a nasty rumor one discriminates against a person, or perhaps even repeats the rumor to third parties, without giving this person an opportunity to respond to the allegation. Insofar as the injustice of such conduct is independent of the truth of the rumor in question, it involves once more a higher-order burden.

DIMENSION TWO: FORMAL AND MATERIAL (IN)JUS-TICE. Perpendicular to this first dimension is the common distinction between formal and material (in)justice. *Formal* justice requires that relevantly similar cases be treated similarly. There is much room for controversy about whether particular cases are relevantly similar and about what is to count as similar treatment. The requirement of formal justice is therefore primarily a demand for justification. The complaint that relevantly similar cases are being treated in a dissimilar way demands a justification, showing that the treatment was not dissimilar or else was appropriately responsive to dissimilarity among cases. This requirement of justification holds across the first dimension: The procedures through which benefits and burdens are allocated to recipients as well as these allocations themselves must satisfy formal justice. It must be justifiable that one accused was acquitted and another convicted (first-order justice), say, and also that one accused but not another was provided an attorney at public expense (procedural justice).

Judicanda can be gravely unjust even when they clearly do treat similar cases alike. Thus, parents who beat all their children without cause violate material justice, as do judicial systems that deny all accused rights to speak, to appeal, and to consult legal counsel.

One might think that justice reduces to material justice: When dissimilar treatment of cases cannot be justified, this merely shows that the treatment of some of these cases is materially unjust, independently of how the others are treated. But this view is surely not implicit in the concept of justice. And it is substantively implausible. In many cases, justice is comparative. To illustrate, there are indefinitely many schedules according to which individuals and businesses might be taxed. While the demands of material justice disqualify a wide range of these options, they do not mandate one uniquely just tax code. Still, it would clearly be unjust to impose diverse materially just tax codes—some more advantageous than others—upon the various households or businesses of a single jurisdiction. Unjust is here the unequal treatment of taxpayers, which is a violation of formal justice.

DIMENSION THREE: VARIOUS DOMAINS OF MATE-RIAL (IN)JUSTICE. *Material* justice imposes various requirements whose content is controversial. This multiplicity can be ordered in a third dimension by distinguishing various domains. Thus *distributive* justice deals with access to scarce resources—from the division of a pie to the structure of an economic order that regulates access to raw materials and the distribution of the jointly created social product. *Commutative* justice governs exchanges, which may be faulted for first-order flaws, as when the items exchanged are not equivalent, or for higher-order (procedural) flaws, such as excessive inequalities in information or bargaining power. *Corrective* or *restitutive* justice is concerned with how to make up for violations of social and moral rules and how to deal with the costs such violations cause. *Retributive* justice, finally, deals with the ascertainment and punishment of such violations.

In each of these four domains there are procedures, which may be formally or materially unjust, as well as particular allocations of benefits and burdens, which also may be formally or materially unjust. The traditional three-dimensional schema, as here reconstructed, thus contains sixteen boxes for sorting particular justice assessments. In the first dimension, the assessment is either first-order or higher-order. In the second dimension, it concerns either formal or material justice. And in the third dimension, it falls into the domain of distributive, commutative, corrective, or retributive justice.

This conceptual structure leaves open the possibility that some of these boxes may contain no substantive constraints. For example, there may be no first-order material demands of commutative justice if any exchange, no matter how lopsided, is morally acceptable so long as it has been performed freely by the exchanging parties without unfair inequalities in bargaining power or information. But this is not a conceptual point, but rather a substantive claim, affirmed by some (especially modern) and denied by other (especially medieval) conceptions of justice.

This complexity can be increased to sixty-four because—perpendicular to the three dimensions in which the character of diverse justice assessments can be differentiated—there is still the distinction between four categories of judicanda (introduced earlier) to which any such justice assessments can be applied: namely, individual and collective actors, their actions and omissions, social rules and institutions, and states of affairs and events.

In some accounts, *international* justice is given as a separate domain that, traditionally, is heavily focused on the use of force and, in particular, on just and unjust causes for going to war (*ius ad bellum*), and on just and unjust ways of fighting a war (*ius in bello*). (In his *Metaphysics of Morals* [pp. 343, 347–349], Kant adds a third theme: the just way of concluding a war so as to lay the foundation for a stable peace [*ius post bellum*]) It seems more appropriate, however, to think of states as one class

of collective actors among others. It may indeed be claimed that states are a special class of actors and that their conduct and relations are subject to distinctive justice requirements. But this is a substantive moral claim that should not be prejudged in the conceptual explication.

A state is understood not merely as a collective actor, but also as a comprehensive system of social rules and institutions enforced in a particular territory. A state can therefore be criticized as unjust not merely on account of its conduct toward or institutional relations with outsiders, but also on account of its internal institutional order—for instance, on account of how it distributes rights and duties, regulates and taxes economic cooperation, and enforces its laws against its members. So understood, states exemplify one kind of institutional scheme among others, whose special status once again should not be prejudged in the conceptual explication.

TOWARD A UNIFIED CONCEPTION OF JUSTICE

The preceding sections were meant to sketch the structure of the contemporary concept of justice and thereby to characterize the linguistic consensus that underlies current debates about questions of justice. Even these general thoughts may not be wholly uncontroversial. But they are much less controversial than the thoughts to follow, which are meant to describe plausible elements of a conception of justice. Should these elements be found convincing, they might gradually become elements of a clearer and more unified concept of justice. But they do not now fully accord with the various understandings of this concept that are dominant in contemporary public and academic discussions.

It is possible to begin once more from the question, briefly raised in (1): What is specific about justice, how justice judgments are distinctive within the larger realm of moral judgments; what is being said with the complaint that some judicandum is unjust, over and above the claim that this judicandum is immoral (morally flawed)? What follows are four hypotheses toward answering this question.

FIRST HYPOTHESIS: INJUSTICE INVOLVES ABUSE OF MORALITY ITSELF.
Morally flawed judicanda are unjust only if they involve an abuse of morality itself—that is, only if they appear with a moral pretension they do not live up to. Unjust is someone who is prepared to violate moral principles she herself likes to appeal to. Unjust is someone who allows his official conduct to be influenced

by bribes even while he pretends to be an impartial judge, umpire, or mediator. Unjust is a beating falsely presented as deserved punishment. And unjust is legislation designed for the benefit of a small minority and yet claimed to impose moral obligations on the oppressed population. In all these cases, the injustice comes about through the false moral claim: Without the pretense of deserved punishment, the beating is wrong but not unjust. Without the claim of moral authority (that compliance is morally required), coercive rules can be wrong, but not unjust.

According to this first hypothesis, then, justice is a part of morality that defends the authority and dignity of morality itself. This would explain the central place justice is thought to occupy within morality. Unjust are only those judicanda that do not merely—openly or covertly—violate morality, but also appear under color of morality.

SECOND HYPOTHESIS: JUSTICE MAY IN PRINCIPLE BE ENFORCED.
A second essential mark of injustice may be that it involves a violation of a right and, more precisely, of a moral right. (Injustice need not violate positive law. To the contrary, because positive law may be unjust or otherwise immoral, conduct it permits or even requires may still be unjust.) Violations of rights are those moral infractions that may in principle be averted through the use or threat of coercive force. The main implication of the second hypothesis therefore is that any injustice may in principle be forcibly averted. Justice may be enforced.

The expression "in principle" flags two qualifications. First, it is not meant that anyone is permitted forcibly to avert any rights violations. In a well-ordered society, for instance, only the police and the courts are permitted to use force in response to rights violations—ordinary citizens may use or threaten force only in urgent emergencies. Second, there is no permission to use force regardless of the morally significant costs of doing so. Defensive force may be grossly disproportionate and therefore impermissible. And efforts forcibly to avert a rights violation may also be impermissible when they carry the risk of triggering much graver violations of the rights of third parties (a point well illustrated in Heinrich von Kleist's story "Michael Kohlhaas"). That any rights violation may in principle be forcibly averted thus means only that those responsible for it and those profiting from it have no moral right against having this violation blocked by force. Here justice contrasts with other moral qualities. No moral rights are violated by judicanda lack-

ing in generosity, civility, charity, humanity, decency, kindness, courtesy, mercy, or beneficence. Enforcing these virtues is wrong in principle and violates moral rights of those against whom they are enforced.

THIRD HYPOTHESIS: INJUSTICE HARMS IN VIOLATION OF NEGATIVE DUTIES. Related to the preceding, another essential mark of injustice may be that it always involves a violation of negative duties on the part of those who are responsible for the moral quality of the judicandum in question. What is at issue here, roughly speaking, is the traditional distinction between moral infractions that harm recipients and those that merely fail to help them. However this distinction may be made precise, the third hypothesis is simply that a claim of injustice always involves a claim of undue harm.

This hypothesis is related to the second hypothesis insofar as the two distinctions may wholly or largely coincide. That they coincide precisely would mean that people in every case have a right not to be harmed but in no case a right to be helped. Therefore, only harmings may be forcibly averted, refusals of help must not be.

It is doubtful that the two distinctions coincide precisely. Many civil-law countries have "Good Samaritan" laws proscribing failure to render assistance. These statutes presuppose, as seems plausible, that there are cases in which morally mandatory assistance may be compelled through threat of criminal sanctions. Conversely, there may also be harmings that are so trivial that in principle they must not be forcibly averted.

Still, the two distinctions largely coincide, and some moral predicates fall entirely on one side or the other. Judicanda lacking in morally required or recommended generosity, civility, charity, humanity, decency, kindness, courtesy, mercy, or beneficence fail to help people without harming them. Such infractions may not be forcibly averted. Any injustice in a judicandum, however, does harm people and thus may in principle be forcibly averted.

The last two hypotheses differ in their informative value for the investigation of justice. The second hypothesis is illuminating: something important is learned about justice, if one finds that in principle every injustice may be forcibly averted. The third hypothesis would be similarly informative if it started out with a clear justice-independent notion of harm. The claim would then be that a judicandum is unjust only if it harms persons (in this independent sense). But the connection postulated by the third hypothesis can also be taken in the opposite way: Any unjust treatment is to count as a harming. So

understood, this claim would be using a harm-independent notion of injustice to illuminate the notion of harm—rather than the other way around. Still, although the latter definitional sequencing seems more adequate, it is moderated by the need to preserve the core meaning of harm. Coming back to Kant's example, failure to give a criminal his deserved punishment cannot plausibly be presented as an instance of harming him. If one wants to call such an act of grace unjust (while maintaining the third hypothesis), then one must identify another harmed party—other criminals arbitrarily excluded from the amnesty, perhaps, or future victims of crimes that would not have occurred but for this failure to punish. Given this constraint imposed by the core meaning of harm, the third hypothesis is not then entirely uninformative.

FOURTH HYPOTHESIS: JUSTICE IS NOT PURELY RECIPIENT-ORIENTED. The last hypothesis is negative in character. It merely rejects a hypothesis that has come to dominate Anglophone academic discussions of justice. The refutation of this approach eliminates only one of many possibilities and may thus seem to make little progress. But because the rejected approach is so elegant and influential, it is interesting nonetheless to explore how it fails.

The approach to be criticized has developed out of utilitarianism, which holds that the moral assessment of actors, conduct, and social rules should be based solely on each such judicandum's relative impact on the world, and on human happiness in particular.

If such a view is accepted, the ordinary distinctions among moral predicates lose much of their significance. Whatever moral predicate may be used to criticize a rule, action, or person—cowardly, unjust, evil, indecent, and so on—the complaint always boils down to the judicandum's failure to be optimally happiness-promoting. Utilitarians have little use for the received panoply of moral predicates because it ultimately does not matter how a suboptimal judicandum is squandering potential human happiness.

Those who reduce the traditional multiplicity of moral defects in this way may simply want to do away with the surplus predicates. Alternatively, they may prefer to redeploy these predicates—using them not (as traditionally) for different defects of the same judicanda, but instead for defects in different kinds of judicanda. In this way, justice has come to name the specific moral virtue of social rules.

In his famous *A Theory of Justice* (1999 [1971]), John Rawls adopts this redeployment. His theory is focused exclusively on social institutions and, even more narrowly, on a society's basic institutional design. And, presenting justice as the first virtue of social institutions, he recognizes no further moral predicates by means of which such institutions might be subjected to potentially competing moral judgments.

Rawls further follows the utilitarians by adopting a broadly consequentialist mode of moral assessment, and one that focuses specifically on the well-being of individuals. Thus he shares with utilitarianism the purely recipient-oriented mode of moral assessment. The unique characteristic of this approach can be expressed as the assumption that the only information needed in the moral assessment of any judicandum is information about its relative impact on persons, that is, information about how persons fare with the judicandum as it is versus how they would fare if the judicandum were different.

Unlike the utilitarians, Rawls employs the purely recipient-oriented approach on two distinct levels and moreover rejects, on both levels, utilitarian conceptions of well-being as happiness or desire fulfillment. Central to his theory is a criterion ("the two principles") of justice that assesses alternative institutional designs on the basis of the distribution of social primary goods each would produce. The just design is the one that would produce the best feasible distribution among citizens of basic rights and liberties, income and wealth, powers and responsibilities of office, and other social bases of self-respect. This proposed criterion of justice is justified, again in a purely recipient-oriented manner, on the ground that its public adoption would lead to a better fulfillment of citizens' three higher-order interests than the public adoption of any alternative criterion of justice. The argument on this second level is presented in terms of a contractualist thought experiment ("original position") in which representatives of citizens, informed only that their clients have the three higher-order interests but given no further specific information about them, come to agree on a particular public criterion of justice.

Rawls's theory, with its particular assessment standards on the two levels, has received much lively critique. Under the *Equality of What?* label, academics debate whether human well-being should be conceived in terms of happiness, welfare, desire fulfillment, Rawlsian social primary goods, Dworkinian resources, or capabilities à la Sen or Nussbaum. And academics also debate how such well-being information about individuals should be aggregated: Should well-being simply be averaged or

should special weight be given to equality, sufficiency, or the worse off? Yet, beneath all this disagreement, the purely recipient-oriented approach is largely taken for granted in the Anglophone countries.

The fourth hypothesis is that any such purely recipient-oriented conceptions of justice are untenable.

DEFENSE OF THE FOURTH HYPOTHESIS. When it comes to actors and their conduct, the fourth hypothesis is—at least outside academic philosophy—hardly controversial. Here any conception of the form "to be just is to promote a good distribution among one's recipients" is bound to be unacceptable because it disregards morally relevant information about how a judicandum has its effects. It is widely taken to make a great moral difference whether some conduct brings about the death of an innocent person or merely fails to prevent such a death. The world at large may be worse, perhaps even less just, if two good persons die prematurely than if a single less deserving person dies in their stead. And yet, it is not morally required, nor even permitted, to save the former by killing the latter.

An analogous point applies to social institutions. This is clearest when one reflects on the criminal law. Here Rawls's first priority rule (*A Theory of Justice* 1999 [1971], p. 266) holds that basic liberties may be restricted whenever such restriction, by making the remaining basic liberties more secure, is a gain on balance for the basic liberties of the representative citizen. This claim fits well with his purely recipient-oriented approach as enshrined in the contractualist thought experiment of the original position. But it is inconsistent with the considered judgments his theory was meant to accommodate and to unify. One of the examples Rawls gives (*A Theory of Justice* 1999 [1971], pp. 212–213) involves a strict-liability criminal statute that permits conviction without a showing of mens rea. Although it violates citizens' basic liberties, this law is nonetheless said to be permissible as "the lesser of two evils" if it is necessary to block even greater dangers to citizens' basic liberties (a danger of civil war, in his example).

Similar arguments could plausibly be made in regard to other aspects of the criminal law. Constraints on searches, seizures, and interrogations should be relaxed if this would entail, through more effective crime fighting, a net gain for citizen's basic liberties. Standards of evidence ("beyond a reasonable doubt") should be lowered, and less than unanimity be required for a jury conviction, if this would, through increased deterrence and through disabling more repeat offenders, produce a net gain for

citizen's basic liberties. And draconian punishments (e.g., execution) should be imposed for high-elasticity crimes (e.g., drunk driving) if citizens' overall risk of a premature violent death can thereby be reduced.

These theory-produced judgments collide with people's intuitive sense of justice, which is responsive not merely to the magnitudes, probabilities, and distribution of morally significant goods and ills, but also to the attitude social rules manifest and to the causal pathways on which they affect their recipients. Even if these recipients themselves have no reason to care whether burdens falling on them (such as hunger or risks of premature death) are imposed by social rules or merely not averted by them, this difference is nonetheless morally significant. The purely recipient-oriented approach cannot then fulfill Rawls's stated ambition of accommodating and unifying his compatriots' considered judgments.

The reason is that judgments of justice take account not only of the passive perspective of recipients, of citizens as governed by social rules, but also of the active perspective of authors, of citizens as co-responsible for these rules. For citizens as recipients, all threats to their basic liberties are indeed on a par—whether they arise from criminal or crime-fighting activities. But for citizens as co-legislators it makes a considerable difference whether people are roughed up by criminals or by police interrogators, are killed prematurely by a drunk driver or through execution for drunk driving. As co-legislators, people take greater moral responsibility for harms they mandate or authorize through their institutional order than for equal harms they could prevent through it. That some institutional arrangements would be better for citizens as recipients is not sufficient to show that they are morally permitted—let alone required. Purely recipient-oriented conceptions of justice are bound to fail because they systematically ignore the active perspective of those who bear responsibility for a particular judicandum.

Plausible justice assessments of social rules must be sensitive to both citizen perspectives. What matters in the moral assessment of social rules is not merely how these rules affect, but how they treat their recipients. The importance of this point extends well beyond the criminal law. A rule under which those suffering from some genetic defect are not entitled to life-saving treatment may be exactly as bad for them as a rule mandating execution for those with certain physical features is for the executed. Though comparable in their relative impact on recipients, these two rules are nonetheless worlds apart in how they treat such recipients.

Once such differences in attitude and causal pathways have been restored their proper moral significance, people may well find that justice is not the only moral virtue of social institutions. If a society's institutional order provides little funding for public health services, more citizens will avoidably die or suffer. And yet, such an order is surely less unjust than one under which equal suffering and deaths are explicitly imposed by the rules, perhaps on members of a certain ethnic or religious minority. In fact, in a poor society with other urgent needs, low funding for public health services may not be unjust at all. And even in an affluent society, such low funding may not be unjust, so long as society helps treat the medical conditions it causes (e.g., through pollution). Still, if the institutional order of an affluent society ignores the plight of citizens with congenital medical conditions, say, it may well be morally flawed in other ways: be ungenerous, mean, or inhumane.

This result supports the fourth hypothesis by showing it to be a step toward a conception of justice that covers all judicanda in a unified way: In regard to actors and their conduct people are already familiar with the possibility of actors being beyond reproach in terms of justice and yet morally flawed in other ways.

JUSTIFICATION OF MORAL PRINCIPLES

See *Moral Principles: Their Justification*

JUST WAR THEORY

In traditional just war theory there are two basic elements: an account of just cause and an account of just means. Just cause is usually specified as follows:

(1) There must be substantial aggression.

(2) Nonbelligerent correctives must be either hopeless or too costly.

(3) Belligerent correctives must be neither hopeless nor too costly.

Needless to say, the notion of substantial aggression is a bit fuzzy, but it is generally understood to be the type of aggression that violates people's most fundamental rights. To suggest some specific examples of what is and is not substantial aggression, usually the taking of

hostages is regarded as substantial aggression while the nationalization of particular firms owned by foreigners is not so regarded. But even when substantial aggression occurs, frequently nonbelligerent correctives are neither hopeless nor too costly. And even when nonbelligerent correctives are either hopeless or too costly, in order for there to be a just cause, belligerent correctives must be neither hopeless nor too costly.

Traditional just war theory assumes, however, that there are just causes and goes on to specify just means as imposing two requirements:

(1) Harm to innocents should not be directly intended as an end or a means.

(2) The harm resulting from the belligerent means should not be disproportionate to the particular defensive objective to be attained.

While the just means conditions apply to each defensive action, the just cause conditions must be met by the conflict as a whole.

It is important to note that these requirements of just cause and just means are not necessarily about war at all. Essentially, they constitute a theory of just defense that can apply to war but can also apply to a wide range of defensive actions short of war.

THE INTENDED/FORESEEN DISTINCTION

Just war theory presupposes that we can, in practice, distinguish between what is foreseen and what is intended, and some have challenged whether this can be done. So first one needs to address this challenge.

The practical test that is frequently appealed to in order to distinguish between foreseen and intended elements of an action is the Counterfactual Test, according to which two questions are relevant:

(1) Would you have performed the action if only the good consequences would have resulted and not the evil consequences?

(2) Would you have performed the action if only the evil consequences resulted and not the good consequences?

If an agent answers "yes" to the first question and "no" to the second, some would conclude that (1) the action is an intended means to the good consequences, (2) the good consequences are an intended end, and (3) the evil consequences are merely foreseen.

But how well does this Counterfactual Test work? Douglas P. Lackey argues that the test gives the wrong result in any case where the "act that produces an evil effect produces a larger good effect" (1987, p. 260). He cites the bombing of Hiroshima, Japan, as an example. That bombing is generally thought to have had two effects: the killing of Japanese civilians and the shortening of World War II. Now suppose we were to asked:

(1) Would Harry S. Truman have dropped the bomb if only the shortening of the war would have resulted but not the killing of the Japanese civilians?

(2) Would Truman have dropped the bomb if only the Japanese civilians would have been killed and the war not shortened?

And suppose that the answer to the first question is that Truman would have dropped the bomb if only the shortening of the war would have resulted but not the killing of Japanese civilians, and that the answer to the second question is that Truman would not have dropped the bomb if only the Japanese civilians would have been killed and the war not shortened. Lackey concludes from this that the killing of civilians at Hiroshima, self-evidently a means for shortening the war, is by the Counterfactual Test classified not as a means but as a mere foreseen consequence. On these grounds Lackey rejects the Counterfactual Test as an effective device for distinguishing between the foreseen and the intended consequences of an action.

Unfortunately, this is to reject the Counterfactual Test only because one expects too much from it. It is to expect the test to determine all the following:

(1) Whether the action is an intended means to the good consequences.

(2) Whether the good consequences are an intended end of the action.

(3) Whether the evil consequences are simply foreseen consequences.

In fact, this test is capable of meeting only the first two of these expectations. And the test clearly succeeds in doing this for Lackey's own example, where the test shows the bombing of Hiroshima to be an intended means to shortening the war, and shortening the war an intended consequence of the action.

To determine whether the evil consequences are simply foreseen, however, an additional test is needed, which can be called the Nonexplanation Test. According to this test the relevant question is: Does the bringing about of

the evil consequences help explain why the agent undertook the action as a means to the good consequences? If the answer is "no," that is, if the bringing about of the evil consequences does not help explain why the agent undertook the action as a means to the good consequences, the evil consequences are merely foreseen. But if the answer is "yes," the evil consequences are an intended means to the good consequences.

Of course, there is no guaranteed procedure for arriving at an answer to the Nonexplanation Test. Nevertheless, when we are in doubt concerning whether the evil consequences of an act are simply foreseen, seeking an answer to the Nonexplanation Test will tend to be the best way of reasonably resolving that doubt. For example, when applied to Lackey's example, the Nonexplanation Test comes up with a "yes," since the evil consequences in this example do help explain why the bombing was undertaken to shorten the war. For, according to the usual account, Truman ordered the bombing to bring about the civilian deaths, which by their impact on Japanese morale were expected to shorten the war. So, by the Nonexplanation Test, the civilian deaths were an intended means to the good consequences of shortening the war.

Just war theory has been challenged in various ways. Three of the most important are a conventionalist challenge to just means, a collectivist challenge to just means, and a feminist objection to just cause and just means.

A CONVENTIONALIST CHALLENGE TO JUST MEANS

The criteria of just means have been incorporated to some degree into the military codes of different nations and adopted as international law. George Mavrodes (1984) contends that the criteria of just means ought to be met simply because they have been incorporated into military codes or adopted as international law. Mavrodes arrives at this conclusion largely because he finds the standard attempts to specify the convention-independent basis for condition (2) of just means to be so totally unsuccessful. All such attempts, Mavrodes claims, are based on an identification of innocents with noncombatants. But by any plausible standard of guilt and innocence with moral content, Mavrodes contends, noncombatants can be guilty and combatants innocent. For example, noncombatants who are doing everything in their power to support an unjust war financially would be morally guilty, and combatants who were forced into military service and intended never to fire their weapons at anyone would be morally innocent. Consequently, the guilt-

innocence distinction will not support the combatant-noncombatant distinction.

Hoping to support the combatant-noncombatant distinction, Mavrodes suggests that the distinction might be grounded on a convention to observe it. This would mean that our moral obligation to abide by condition (2) of just means would be a convention-dependent obligation. Nevertheless, Mavrodes does not deny that we have some convention-independent obligations. Our obligation to refrain from wantonly murdering our neighbors is given as an example of a convention-independent obligation, as is our obligation to reduce the pain and death involved in combat. But to refrain from harming noncombatants when harming them would be the most effective way of pursuing a just cause is not included among our convention-independent obligations.

Still, Mavrodes does not claim that our obligation to refrain from harming noncombatants is purely convention-dependent. He allows that, in circumstances in which the convention of refraining from harming noncombatants does not exist, we might still have an obligation to unilaterally refrain from harming noncombatants, provided that our action will help give rise to a convention prohibiting such harm with its associated good consequences. According to Mavrodes, our primary obligation is to maximize good consequences, and this obligation requires that we refrain from harming noncombatants when that will help bring about a convention prohibiting such harm. By contrast, someone who held that our obligation to refrain from harming noncombatants was purely convention-dependent would never recognize an obligation to unilaterally refrain from harming noncombatants. On a purely convention-dependent account, obligations can only be derived from existing conventions; the expected consequences from establishing a particular convention could never ground a purely convention-dependent obligation. But while Mavrodes does not claim that our obligation to refrain from harming noncombatants is purely convention-dependent, he does claim that this obligation generally arises only when there exists a convention prohibiting such harm. According to Mavrodes, the reason for this is that, generally, only when there exists a convention prohibiting harm to noncombatants will our refraining from harming them, while pursuing a just cause, actually maximize good consequences.

But is there no other way to support our obligation to refrain from harming noncombatants? Mavrodes would deny that there is. Consider, however, Mavrodes's own example of the convention-independent obligation

not to wantonly kill our neighbors. There are at least two ways to understand how this obligation is supported. Some would claim that we ought not to wantonly kill our neighbors because this would not maximize good consequences. This appears to be Mavrodes's view. Others would claim that we ought not to wantonly kill our neighbors, even if doing so would maximize good consequences, simply because it is not reasonable to believe that our neighbors are engaged in an attempt on our lives. Both of these ways of understanding how the obligation is supported account for the convention-independent character of the obligation, but the second approach can also be used to show how our obligation to refrain from harming noncombatants is convention-independent. According to this approach, since it is not reasonable to believe that noncombatants are engaged in an attempt on our lives, we have an obligation to refrain from harming them. So interpreted, our obligation to refrain from harming noncombatants is itself convention-independent, although it will give rise to conventions.

Of course, some may argue that whenever it is not reasonable to believe that persons are engaged in an attempt on our lives, an obligation to refrain from harming such persons will also be supported by the maximization of good consequences. Still, even if this were true, which seems doubtful, all it would show is that there exists a utilitarian or forward-looking justification for a convention-independent obligation to refrain from harming noncombatants; it would not show that such an obligation is a convention-dependent obligation, as Mavrodes claims.

A COLLECTIVIST CHALLENGE TO JUST MEANS

According to a collectivist challenge to just means, more people should be included under the category of combatants than the standard interpretation of just means allows. Just means, as noted earlier, imposes two requirements:

(1) Harm to innocents should not be directly intended as an end or a means.

(2) The harm resulting from the belligerent means should not be disproportionate to the particular defensive objective to be attained.

According to advocates of this challenge to just means, the problem is that the standard interpretation of (1) does not assume that the members of a society are collectively responsible for the actions of their leaders unless they have taken radical steps to oppose or disassociate themselves from those actions, for example, by engaging in civil disobedience or by emigrating. Of course, those who are unable to take such steps, particularly children, would not be responsible in any case; but for the rest, advocates of this collectivist challenge contend that failure to take the necessary radical steps, when one's leaders are acting aggressively, has the consequence that one is no longer entitled to full protection as a noncombatant. Some of those who press this objection against the just means criteria of just war theory, like Gregory Kavka (1985), contend that the members of a society can be directly threatened with nuclear attack to secure deterrence, and so reject noncombatant immunity, but then deny that carrying out such an attack could ever be morally justified. Others, like James W. Child (1986), reject both noncombatant immunity and proportionality by contending that the members of a society who fail to take the necessary radical steps can be both indirectly threatened and indirectly attacked with what would otherwise be a disproportionate attack.

In response to this collectivist challenge the first thing to note is that people are more responsible for disassociating themselves from the unjust acts of their leaders than they are for opposing those same acts. For there is no general obligation to oppose all unjust acts, even all unjust acts of one's leaders, because this would impose an unreasonable demand on individuals, and we are not morally required to be saints. Nevertheless, there is a general obligation to disassociate oneself from unjust acts and to minimize one's contribution to them, because this is not an unreasonable demand to impose on each of us. Of course, how far one is required to disassociate oneself from the unjust acts of one's leaders depends on how much one is contributing to those actions. If one's contribution is insignificant, as presumably a farmer's or a teacher's would be, only a minimal effort to disassociate oneself would be required, unless one's action could somehow be reasonably expected, in cooperation with the actions of others, to put a stop to the unjust actions of one's leaders. However, if one's contribution is significant, as presumably a soldier's or a munitions worker's would be, a maximal effort at disassociating oneself would be required immediately, unless by delaying one could reasonably expect to put a stop to the unjust actions of one's leaders.

In support of this collectivist challenge to just war theory Child (1986) offers the example of a member of a board of directors of a company that is engaging in the immoral and illegal activity of pouring large quantities of arsenic into the public water supply as a matter of ongo-

ing operations. When the policy is before the board, she votes no but does nothing else. Later, when sued in tort (or charged in crime) with these transgressions of duty, she pleads that she voted no. Child argues that mere formal dissent in this case does almost nothing to relieve her liability, legal or moral.

But while one might agree with Child that in this case the member of the board of directors had at least the responsibility to disassociate herself from the actions of the board by resigning, this does not show that farmers and teachers are similarly responsible for disassociating themselves from the unjust action of their leaders either by engaging in civil disobedience or by emigrating. This is because neither their contributions to the unjust actions of their leaders nor the effect of their disassociation on those unjust actions would typically be significant enough to require such a response.

This is not to deny that some other response (e.g., political protest or remunerations at the end of the war) would not be morally required. However, to meet this collectivist challenge, it suffices to show that not just any contribution to the unjust actions of one's leaders renders the contributor subject to attack or threat of attack; one's contribution must be significant enough to morally justify such a response.

A FEMINIST CHALLENGE TO JUST CAUSE AND JUST MEANS

A formidable challenge to both the just cause and just means criteria of just war theory comes from feminism. According to the feminist challenge to just war theory, sexism and militarism are inextricably linked in society. They are linked, according to Betty Reardon (1985), because sexism is essentially a prejudice against all manifestations of the feminine, and militarism is a policy of excessive military preparedness and eagerness to go to war that is rooted in a view of human nature as limited to masculine characteristics. Seen from a militarist perspective, other nations are competitive, aggressive, and averse to cooperation, the same traits that tend to be fostered primarily in men in a sexist society. By contrast, the traits of openness, cooperativeness, and nurturance that promote peaceful solutions to conflicts tend to be fostered primarily in women, who are then effectively excluded from positions of power and decision making in a sexist society. Consequently, if people are to rid society of militarism, Reardon argues, they need to rid society of sexism as well.

But even granting that sexism and militarism are inextricably linked in society in just the way Reardon maintains, how does this effect the validity of just war theory? As just war theory expresses the values of proportionality and respect for the rights of innocents, how can it be linked to militarism and sexism? The answer is that the linkage is practical rather than theoretical. If the leaders in militarist-sexist society have been socialized to be competitive, aggressive, and averse to cooperation, then they will tend to misapply just war theory when making military decisions. This represents an important practical challenge to just war theory. And the only way of meeting this challenge seems to be to rid society of its sexist and militarist attitudes and practices so as to increase the chances that just war theory will be correctly applied in the future.

Of course, still other challenges could be raised to just war theory but, in large measure, just war theory has stood the test of time. Moreover, if the theory can be reconciled with the most morally defensible form of pacifism, such that the only wars and large-scale conflicts that definitely satisfy the requirements of just war theory are the only wars and large-scale conflicts to which antiwar pacifists cannot reasonably object, then it is really hard to see how the theory could be displaced.
