Attachment Theory and Research

Core Concepts, Basic Principles, Conceptual Bridges

PHILLIP R. SHAVER
MARIO MIKULINCER

A person coming to the literature of social psychology from ordinary life, in any society, or from the humanities—an expert on modern fiction, for example—would expect to hear a great deal about life in families, beginning with the total dependency of young children on their adult caregivers; the construction and maintenance across the lifespan of a self or identity in the context of relationships with family members and friends; sexual attraction, sexual behavior, mating, marriage, and parenting; and people's reliance on each other for protection, emotional support, and comfort in the face of life's inevitable disappointments, stresses, illnesses, conflicts, and losses. Although these topics do receive attention in contemporary social-psychological journals and textbooks, until fairly recently they were considered tangential to a field focused on social perception, attitudes, attitude change, and social behavior in task-oriented groups of various kinds.

There are multiple ways one could think about reasons for this intellectual history, but certainly one of them is that modern social psychology came of age during and after World War II, when propaganda and persuasion, group dynamics, and interethnic prejudices and conflicts were all very salient. Moreover, during those years the field was primarily a masculine enterprise, many of whose leaders had served in the armed forces and/or been captivated intellectually and emotionally by its ghastly examples of hatred, prejudice, and human cruelty. Less salient at that time were the many aspects of life that seemed more feminine and, at least to social psychologists, to fall within the disciplinary provinces of developmental, clinical, or personality psychology.

What then was hidden in shadows has steadily moved into the limelight as an increasing number of women have entered the field, family relationships (including abusive ones) and divorce have emerged as societal concerns, health and social contributions to health have become increasingly important, and research methods pioneered in more traditional social-psychological topic areas have proven useful in tackling subject matter that once seemed to defy empirical analysis (e.g., intimacy, trust, love, and grief). Also relevant to this chapter is the fact that social psychology has increasingly taken notice of evolutionary biology (e.g., Simpson & Kenrick, 1997). Earlier in its history (when social relations departments and interdisciplinary programs in social psychology were common), the field seemed more naturally linked with sociology and cultural anthropology, fields in which people's motives and attitudes were viewed as emerging from social and cultural roots without much basis in pan-human biological substrates.

Within the contemporary field of social psychology, attachment theory (Bowlby, 1969/1982) has proven to be a congenial and productive meeting place for researchers interested in close relationships, the development of self and personality in the context of such relationships, and the evolutionary background of core human needs and motives that find expression in relationships. From the beginning, attachment theory was interdisciplinary, crossing boundaries and borrowing concepts from ethology; evolutionary biology; cognitive, developmental, and clinical psychology; and psychoanalysis. The theory's creator, John Bowlby, was a British psychiatrist and psychoanalyst interested in normal and abnormal personality

development and its implications for social problems such as crime and delinquency, in addition to such clinical phenomena as anxiety disorders, disordered grieving following divorce or the death of a loved one, and depression. Bowlby's theory is now one of the leading intellectual frameworks in developmental, personality, and social psychology, partly because of methodological contributions made by Mary Ainsworth. Based on her empirical tests of the theory in observational and laboratory studies of infant–parent relationships, we and other social psychologists have been able to extend the theory to topics of interest to contemporary social psychologists: social schemas, affect regulation, romantic love, marital functioning, and even (going back to our World War II predecessors) group dynamics, prejudice, and intergroup relations.

In this chapter we explain attachment theory in its classic and contemporary forms, placing special emphasis on core concepts, basic principles, and conceptual comparisons and bridges with other theoretical frameworks. Although our primary goal is to explain the theory's core concepts and principles, we of course provide empirical evidence throughout. It is the theory's already proven ability to generate creative and revealing research that makes it worth considering.

CORE CONCEPTS IN ATTACHMENT THEORY AND RESEARCH

In his classic trilogy, *Attachment and Loss*—one of the most cited book series in contemporary psychology—Bowlby (1969/1982, 1973, 1980) asked and answered the following question: Why does "maternal deprivation" (loss of a primary caregiver, such as one's mother, during childhood) have such a potent effect on subsequent personality development (as documented in scores of studies, summarized in Cassidy & Shaver, 1999). By considering a vast array of sources ranging from clinical psychoanalysis to primate ethology and cognitive and cognitive-developmental psychology, Bowlby came to the conclusion that a person's fundamental sense of safety, social acceptance, and well-being rests on the quality of his or her social relationships with "attachment figures." Moreover, when a child has no reliable, trustworthy, secure relationship with one or more such figures, social and affective development is distorted in ways that can eventuate in emotional disorders ranging from anxiety and depression to antisocial personality and other personality disorders. In conceptualizing the importance of attachment relationships to personality development, Bowlby had already moved beyond related but subsequent notions in the literature of social psychology, such as Baumeister and Leary's (1995) claim that human beings have a fundamental "need to belong."

In explaining the motivational bases of personality development, Bowlby (1969/1982) borrowed from ethology the concept of *behavioral system*, a species-universal, biologically evolved neural program that organizes behavior in ways that increase the chances of survival and reproduction despite environmental dangers and demands. Theoretically, the attachment behaviors observed when a person encounters threats and stressors—for example, distress signals, proximity seeking, clinging to a caregiver, and relaxing once proximity and support are provided—are due to a hardwired "attachment behavioral system," just as a caregiver's reactions to a relationship partner's (especially a dependent child's) distress signals and attachment behaviors are due to an innate "caregiving behavioral system." By dividing motivational systems into functional categories such as attachment, caregiving, exploration, affiliation, and sex, Bowlby was able to conceptualize links among, and functional and dysfunctional properties of, these systems in a wide variety of life situations across the lifespan. In the following sections we outline these and other concepts of attachment theory, which have guided research for more than 30 years and contributed to a deep understanding of cognitive, emotional, and self-regulatory processes in close relationships.

The Attachment Behavioral System

According to Bowlby (1969/1982), the *attachment behavioral system* is part of a network of phylogenetically evolved behavioral systems, such as exploration, affiliation, caregiving, and sex, which govern the choice, activation, and termination of behavioral sequences designed to attain particular set goals—states of the person–environment relationship that have adaptive advantages for individual survival and reproduction of genes. These behavioral sequences are "activated" by certain stimuli or kinds of situations that make a particular set goal salient (e.g., loud noises signaling danger, sudden darkness, the presence of a predator) and "deactivated" or "terminated" by other stimuli or situations that signal attainment of the desired goal state.

In Bowlby's (1969/1982) view, behavioral systems also include "ontogenetically learned" components reflecting the particular history of behavioral system activation by a particular person in specific kinds of contexts. Although behavioral systems presumably operate mainly at a subcortical level and in a reflexive, mechanistic manner, their ability to achieve set goals depends on a person's actual transactions with the external world. Therefore, to make goal attainment more likely, behavioral systems include cognitive-behavioral mechanisms, such as monitoring and appraising the effectiveness of behaviors emitted in a particular context, which allow flexible, goal-corrected adjustment of the system's "programming" when necessary to put an individual back on the track of goal attainment. Over time, after operating repeatedly in certain environments, a person's behavioral systems become molded by social encounters, "programming" the neural/behavioral capacities so that they fit with important relationship partners (e.g., parents) and yield effective action in that relational environment. Through this process, a person learns to adjust his or her behavioral systems to fit contextual demands and form reliable expectations about possible access routes and barriers to goal attainment. These expectations, which operate partly at a more conscious and intentional level, become

part of a behavioral system's programming and are sources of both individual differences and within-person continuity in the system's operation.

The presumed biological function of the attachment behavioral system is to protect a person (especially during infancy and early childhood) from danger by assuring that he or she maintains proximity to caring and supportive others (*attachment figures*). In Bowlby's (1969/1982) view, the need to seek out and maintain proximity to attachment figures (what he called "stronger and wiser" caregivers) evolved in relation to the prolonged helplessness and complete dependence of human infants who cannot defend themselves from predators and other dangers. According to Bowlby's evolutionary reasoning, infants who maintained proximity to a supportive caregiver were more likely to survive and eventually to reproduce, causing genes that fostered proximity seeking and other attachment behavior in times of danger to be selected and passed on to subsequent generations. Bowlby (1969/1982, 1988) assumed that although the effects of attachment-system activation are most easily observed during infancy, and the attachment system may operate somewhat differently at different age periods, it continues to function throughout life, as indicated by adults' needs for proximity, support, comfort, and security (Hazan & Zeifman, 1999).

During infancy, primary caregivers (usually one or both parents, but also grandparents, older siblings, daycare workers) are likely to serve attachment functions. Research has shown that, when tired or ill, infants tend to seek proximity to a primary caregiver (e.g., Ainsworth, 1973) and be notably reassured and soothed in that person's presence (e.g., Heinicke & Westheimer, 1966). In adulthood, a wider variety of relationship partners can serve as attachment figures, including familiar coworkers, friends, and romantic partners. They form what Bowlby (1969/1982) called a person's *hierarchy of attachment figures*. There may also be context-specific attachment figures, who are real or potential sources of comfort and support in specific milieus, such as teachers and supervisors in academic settings or therapists in therapeutic settings. Moreover, groups, institutions, and symbolic personages (e.g., God) can become targets of proximity seeking. There is evidence that many young children have imaginary friends (e.g., Gleason, 2002); that some married adults who suffer the death of a spouse continue to experience the spouse's presence and seek his or her assistance and support in times of need (e.g., Klass, Silverman, & Nickman, 1996); and that many adults believe they can and do obtain protection and comfort from gods, angels, and saints (e.g., Fraley & Shaver, 1999; Kirkpatrick, 1999). In addition, there are components of the self that result from internalization of and identification with attachment figures' traits (we call these self-caregiving representations; Mikulincer & Shaver, 2004), and they can serve successfully as symbolic sources of support and comfort.

It is important to understand that the concept of "attachment figure" has a specific meaning in attachment theory. Attachment-related interactions with these people are not viewed as being simply the same as other forms of social interaction. According to attachment theory (e.g., Ainsworth, 1991; Hazan & Shaver, 1994; Hazan & Zeifman, 1994), an attachment figure should accomplish three functions. First, he or she should be a target for proximity seeking. People tend to seek and enjoy proximity to their attachment figures in times of need and to actively resist separation from them. Second, an attachment figure should be, or provide, a *safe haven* in times of need (i.e., reliably provide protection, comfort, support, and relief). Third, an attachment figure should be, or should function as, a *secure base*, allowing a child or adult relationship partner to pursue nonattachment goals in a safe environment. Based on this narrow definition of attachment figures, we view an interaction as attachment relevant when it occurs with a familiar other, or the mental representation of a familiar other, in a stressful context, with the expectation of receiving protection, comfort, or support. This protection and support in the realm of attachment allows a person to function better in nonattachment domains such as exploration, creative thinking, empathic and prosocial behavior toward others, and sexual mating.

In studies of adults, researchers are able to identify a research participant's attachment figures by using a standard measure, the WHOTO questionnaire, developed by Hazan and Zeifman (1994) and Fraley and Davis (1997). The measure asks a respondent to name the particular people on whom he or she relies for various forms of protection, guidance, and support and then to describe the role of each such person in the respondent's life (e.g., mother, father, sibling, romantic partner, and friend). We (Mikulincer, Gillath, & Shaver, 2002) conducted several experiments in which we subliminally primed participants with threat words (e.g., failure and separation) and then determined indirectly (using reaction times in a lexical decision or Stroop task) which names became more available for mental processing when a person felt threatened. It turned out that the names of attachment figures (identified with the WHOTO questionnaire) became more available in response to a threatening word, something that did not happen with the names of other close relationship partners not mentioned in the WHOTO. This and other evidence indicates that attachment figures are not just any relationship partners; rather, they are special individuals to whom a person turns when he or she needs protection and support.

Bowlby (1969/1982) also specified the set goal of the attachment system and described the typical cycle of attachment-system activation and deactivation. The goal of the system is a sense of protection or security (called by Sroufe & Waters, 1977, felt security), which normally terminates the system's activation. This goal is made particularly salient by encounters with actual or symbolic threats and by appraising an attachment figure as not sufficiently near, interested, or responsive. In such cases, the attachment system is activated and the individual is driven to seek and reestablish actual or symbolic proximity to an attachment figure (a process Bowlby called the "primary strategy" of the attachment system). These bids for proximity persist until protection and security are attained. When the set goal of security is attained, the at-

tachment system is deactivated and the individual calmly and coherently returns to nonattachment activities.

In infants, attachment-system activation includes non-verbal expressions of neediness and desire for proximity, such as crying, calling, and pleading, as well as locomotor behaviors aimed at reestablishing and maintaining proximity, such as moving toward the caregiver and clinging (Ainsworth, Blehar, Waters, & Wall, 1978). In adulthood, the primary attachment strategy is not necessarily to engage in actual proximity-seeking behavior. Instead, it may be sufficient to activate soothing, comforting mental representations of relationship partners who regularly provide care and protection or even self-representations associated with these partners (Mikulincer & Shaver, 2004). These cognitive representations can create a sense of safety and security, help a person deal successfully with threats, and allow the person to continue pursuing nonattachment goals without having to interrupt these activities to engage in actual proximity bids.

In support of these ideas, recent studies (Mikulincer, Gillath, et al., 2001; Mikulincer, Gillath, et al., 2003; Mikulincer, Hirschberger, Nachmias, & Gillath, 2001; Mikulincer & Shaver, 2001) show that a variety of experimental techniques designed to activate mental representations of internalized attachment figures (e.g., subliminal presentation of the names of people nominated as attachment figures in the WHOTO; guided imagery concerning the availability of these attachment figures; and visualization of the faces of these figures) improve participants' self-reported mood during an experimental session and unconsciously endow formerly neutral stimuli with positive affect. Specifically, activation of mental representations of attachment figures led to higher liking for unfamiliar Chinese ideographs even under threatening conditions and eliminated the detrimental effects that threats otherwise had on liking. Similar experimental interventions eliminated outgroup negativity, even when participants thought an outgroup member had insulted or challenged their ingroup. Thus, activation of mental representations of security-providing attachment figures seems to have a calming, soothing effect, which reduces threats and has positive effects on assessments of human and inanimate stimuli.

Bowlby (1969/1982), along with Harlow (1959), rejected classical psychoanalytic and Pavlovian behavioral frameworks that portrayed social attachment as a secondary effect of feeding (viewed in terms of drive reduction). In line with "object relations" approaches to psychoanalysis, Bowlby viewed human beings as naturally relationship seeking, naturally oriented to what Harlow called "contact comfort" (in his well-known studies of infant monkeys' attachments to and reliance on real and cloth-surrogate mothers), and as naturally inclined to seek proximity to familiar, comforting figures in times of need. That is, Bowlby viewed proximity–contact and maintenance over time of affectionate, trusting, and supportive interpersonal relationships as innately sought-after goal states and rejection, separation, and the loss of such relationships as aversive antigoal states. Moreover, he viewed successful bids for proximity and the attainment of felt security as necessary for the formation of sat-

isfying interpersonal relationships. Every attachment interaction that alleviates distress and enhances felt security reaffirms the adaptive advantage of closeness and strengthens affectional bonds with a particular relationship partner.

From an emotion-regulation perspective, smooth operation of the attachment system can be viewed as a dynamic, homeostatic process aimed at restoring emotional equanimity. In fact, emotional arousal (e.g., fear, anxiety, and anger) is associated with attachment-system activation; distress alleviation results in attachment-system deactivation; and basic emotions (e.g., love, joy, fear, anger, and sadness) frequently occur during attachment-related interactions. For this reason, the attachment system plays an important role in arousing, regulating, and deescalating emotional states, shaping—over time—a person's affective tone and maintaining emotional equanimity.

Bowlby (1973) and Ainsworth (1991) were especially interested in the reciprocal associations between the attachment system and the exploration and affiliation systems, because they viewed attachment insecurity as a hindrance to the full development of skills associated with the other systems. A child or adult who feels threatened and inadequately protected or supported has a difficult time directing attention and other psychological resources to free play, curious investigation of objects and environments, and the social skills necessary for satisfying affiliative relationships with peers. Considered more generally and extended over a longer period of development, this same interference process is thought to disrupt the normal development of self-efficacy, self-esteem, coping (affect-regulation) skills, and positive, trusting social orientation. Just as being harassed or distracted at school interferes with normal cognitive development, being forced by one's social environment to focus only on threats and insecurity distorts and interferes with social development and results in a person with measurably diminished capacities.

Individual Differences in Attachment-System Functioning

Attachment-Figure Availability, the Sense of Security, and Secondary Strategies

Although nearly all children are born with a normal attachment system, which motivates them to pursue proximity and security in times of need, proximity maintenance and security attainment also depend on the responses of particular relationship partners to one's bids for proximity and safety. According to Bowlby (1973, 1988), the quality of attachment-system functioning depends on the availability of a relationship partner in times of need; the partner's sensitivity and responsiveness to one's bids for closeness, comfort, and support; and the attachment figure's ability and willingness to alleviate distress and provide a secure base from which to activate other behavioral systems. These variations in the nature of the caregiver's, or attachment figure's, responses are thought to be the major sources of individual

differences in attachment-system functioning, because of their impact on operating parameters of the system. (There may also be genetically based temperamental causes of individual differences in infant attachment behavior, but if so they have yet to be convincingly demonstrated empirically; see, for example, O'Connor & Croft, 2001.)

When a relationship partner is available, sensitive, and responsive to an individual's proximity-seeking efforts in times of need, the individual is likely to feel an inner sense of attachment security—a sense that the world is a generally safe place, that attachment figures are helpful when called on, and that it is possible to explore the environment curiously and confidently and to engage rewardingly with other people. This sense is an inner signal that the attachment system is functioning well and that proximity seeking is an effective emotion-regulatory strategy. Moreover, the individual acquires important procedural knowledge about distress management, which becomes organized around a relational script (Waters, Rodrigues, & Ridgeway, 1998). This *secure-base script* includes something like the following if–then propositions: "If I encounter an obstacle and/or become distressed, I can approach a significant other for help; he or she is likely to be available and supportive; I will experience relief and comfort as a result of proximity to this person; I can then return to other activities." This script is a cognitive reflection of the phylogenetically "hardwired" program at the heart of the attachment system; as such, it requires little in the way of changes in the system's operating parameters.

However, when a primary attachment figure proves not to be physically or emotionally available in times of need, not responsive to a person's proximity bids, or poor at alleviating distress or providing a secure base, attachment-system functioning is disrupted and the set goal is not attained. In such cases, the individual does not experience comfort, relief, or felt security. Rather, the distress that initially activated the system is compounded by serious doubts about the feasibility of attaining a sense of security: "Is the world a safe place or not? Can I trust others in times of need? Do I have the resources necessary to manage my own negative emotions?" These worries about self and others, and the resulting sense of vulnerability, can maintain the attachment system in a continually activated state, keep a person's mind preoccupied with threats and the need for protection, and interfere drastically with the functioning of other behavioral systems.

Negative interactions with an inadequately available and responsive attachment figure also signal that the primary attachment strategy is failing to accomplish its set goal. As a result, the operating parameters of the attachment system have to be adjusted and certain *secondary attachment strategies* are likely to be adopted. Attachment theorists (e.g., Cassidy & Kobak, 1988; Main, 1990) have emphasized two such secondary strategies: *hyperactivation* and *deactivation* of the attachment system. Viewed in terms of the famous fight–flight distinction (Cannon, 1939), hyperactivating strategies are "fight" responses to the frustration of attachment needs (Bowlby called it

"protest"). This response comes about in relationships in which the attachment figure is sometimes responsive but only unreliably so, placing the attached person on a partial reinforcement schedule that seems to reward persistence of energetic, strident, noisy proximity-seeking attempts, because they sometimes appear to succeed. In such cases, the individual does not easily give up on proximity seeking and in fact intensifies it to coerce the attachment figure's love and support. The main goal of these strategies is to get an attachment figure, viewed as unreliable or insufficiently available and responsive, to pay attention and provide protection or support. The way to try to attain this goal is to maintain the attachment system in a chronically activated state until an attachment figure is perceived to be adequately available and responsive. This involves exaggerating appraisals of danger and signs of attachment-figure unavailability and intensifying one's demands for attention, affection, and assistance.

Deactivating strategies are a "flight" reaction to an attachment figure's unavailability, which seem to develop in relationships with figures who disapprove of and punish closeness and expressions of need or vulnerability. In such relationships, an individual learns to expect better outcomes if signs of need and vulnerability are hidden or suppressed, proximity-seeking efforts are weakened or blocked, the attachment system is deactivated despite a sense of security not being achieved, and the person attempts to deal with threats and dangers alone (what Bowlby, 1969/1982, called *compulsive self-reliance*.) The primary goal of deactivating strategies is to keep the attachment system turned off or downregulated to avoid frustration and distress caused by attachment-figure unavailability. This deactivation requires denying attachment needs, steering clear of closeness and interdependence in relationships, and distancing oneself from threats that can cause unwanted activation of the attachment system.

Attachment Working Models

According to Bowlby (1969/1982), variations in caregiver responses to an attached individual's bids for proximity and protection not only alter the operation of the attachment system in a particular interaction or short-term series of interactions but also gradually produce more enduring and pervasive changes in attachment-system functioning. According to Bowlby (1973), these long-term effects are explicable in terms of the storage of significant interactions with an attachment figure in an associative memory network. This stored knowledge allows a person to predict future interactions with the relationship partner and adjust proximity-seeking attempts without having to rethink each one. The repeated recording in memory of attachment-related interactions results in increasingly stable mental representations of self, partner, and the relationship. Bowlby called these mental representations *working models* and viewed them as the basis of stable individual differences in attachment-system functioning. The concept is interesting from a social-psychological standpoint, because it is similar to such concepts as "script" and "social schema." As with those

concepts, which originally seemed coolly cognitive because they were inspired by digital computer programs and cybernetic devices, Bowlby viewed them as cognitive-affective structures that include affective memories and contribute importantly to expectations and appraisals that evoke emotion (Shaver, Collins, & Clark, 1996).

Bowlby (1969/1982) thought that interactions with attachment figures were stored in at least two kinds of working models: representations of attachment figures' responses (*working models of others*) and representations of the self's lovability and competence (*working models of self*). Bowlby argued that "if an individual is to draw up a plan to achieve a set-goal not only does he have to have some sort of working model of his environment, but he must have also some working knowledge of his own behavioral skills and potentialities" (p. 112). Thus the attachment system, once it has been used repeatedly in a given relational setting, includes representations of the availability, responsiveness, and sensitivity of a relationship partner as well as representations of the self's own capabilities for mobilizing the partner's support and one's feelings of being loved and valued by the partner. These representations organize a person's memories of attachment interactions and guide future proximity-seeking efforts.

Because working models, at least initially, are based on the internalization of specific interactions with a particular attachment figure, a person can hold multiple working models that differ in the outcome of the interaction (success or failure to attain security) and the strategy used to deal with insecurity in that interaction (hyperactivating, deactivating). Like other mental representations, these working models form excitatory and inhibitory associations with one other (e.g., experiencing or thinking about an episode of security attainment activates memories of congruent episodes of successful proximity maintenance and renders memories of hyperactivation and deactivation less accessible), and these associations favor the formation of more abstract and generalized representations of attachment-system functioning with a specific partner. Thus, models with a specific attachment figure (relationship-specific models) are created, and through excitatory and inhibitory links with models representing interactions with other attachment figures, even more generic working models are formed to summarize different relationships. The end result of this process can be conceptualized as a hierarchical associative memory network that includes episodic memories, relationship-specific models, and generic models of security attainment, hyperactivation, and deactivation. As a result, with respect to a particular relationship and across different relationships, most people can sometimes think about interpersonal interactions in secure terms and at other times think about them in hyperactivating or deactivating terms.

In a recent study, Overall, Fletcher, and Friesen (2003) obtained preliminary evidence concerning the hierarchical nature of the cognitive network of attachment working models. They asked participants to complete attachment measures for three specific relationships within each of three domains—family, friendship, and romantic—and then examined the structural organization of these relationship descriptions. Confirmatory factor analyses revealed that a hierarchical arrangement of specific and global working models best fit the data, indicating that models for specific relationships (e.g., with particular family members) are nested within relationship-domain representations (e.g., family members), which in turn are nested within more global models.

The neural network of attachment-related models has all the usual properties of any cognitive network (e.g., differentiation, integration, and coherence between the various models) (Collins & Read, 1994). In addition, each working model within the network differs in cognitive accessibility (the ease with which it is activated and used to guide the functioning of the attachment system in a given attachment interaction). As with other mental representations, the strength or accessibility of each model is determined by the amount of experience on which it is based, the number of times it has been applied in the past, and the density of its connections with other working models (e.g., Baldwin, 1992; Collins & Read, 1994; Shaver et al., 1996). At a relationship-specific level, the model representing the typical interaction with an attachment figure has the highest accessibility in subsequent interactions with that person. At a generic level, the model that represents interactions with major attachment figures (e.g., parents and romantic partners) typically becomes the most chronically accessible attachment-related representation and has the strongest effect on attachment-system functioning across relationships and over time.

Consolidation of a chronically accessible working model is the most important psychological process accounting for the enduring, long-term effects on personality functioning of attachment interactions during infancy, childhood, and adolescence (Bowlby, 1973; Waters, Merrick, Treboux, Crowell, & Albersheim, 2000). Given a fairly consistent pattern of interactions with primary caregivers during infancy and childhood, the most representative or prototypical working models of these interactions become part of a person's implicit procedural knowledge, tend to operate automatically and unconsciously, and are resistant to change. Thus, what began as representations of specific interactions with a primary caregiver during childhood become core personality characteristics, tend to be applied in new situations and relationships, and shape attachment-system functioning in adulthood.

Although activation of a particular working model depends on the history of attachment interactions, attachment theory also emphasizes the importance of contextual factors that contribute to this activation (e.g., Collins & Read, 1994; Shaver et al., 1996). Recent studies have shown that contextual cues concerning a partner's availability as well as imagined encounters with supportive or nonsupportive others can activate congruent working models, even if they are incongruent with a person's chronically accessible working model (e.g., Mikulincer, Gillath, et al., 2001; Mikulincer & Shaver, 2001). In fact, this chronically accessible model coexists with less typical

working models in the memory network, and these models can be activated by contextual factors in a given situation or social interaction.

An Integrative Model of Attachment-System Functioning in Adulthood

In an attempt to integrate previous control-system representations of the attachment behavioral system (e.g., Bowlby, 1969/1982; Fraley & Shaver, 2000; Shaver & Hazan, 1993) and the immense accumulating empirical evidence on the functioning of this system in adulthood, we (Mikulincer & Shaver, 2003; Shaver & Mikulincer,

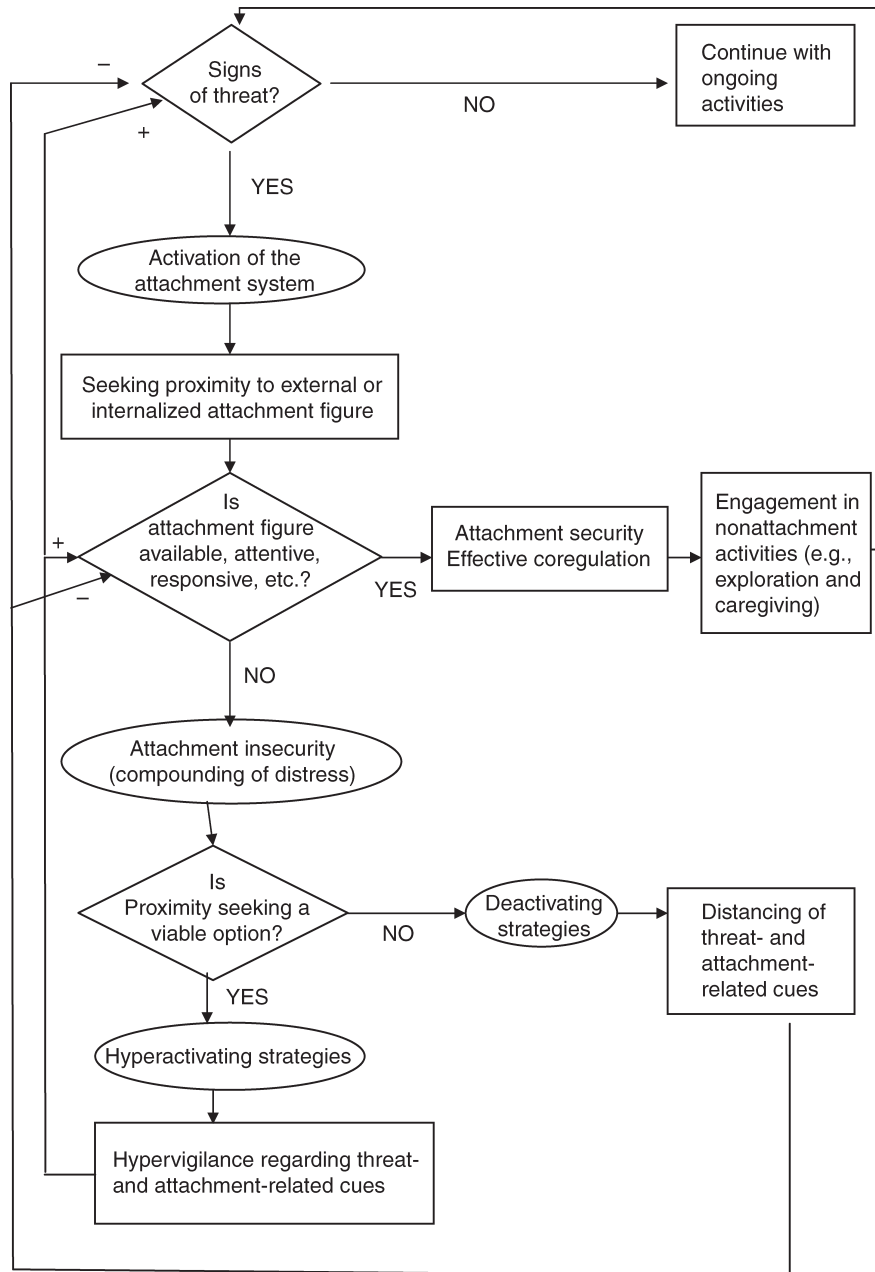
2002) proposed a three-phase model of attachment-system activation and dynamics in adulthood. The model (see Figure 28.1) includes three major components. The first component concerns the monitoring and appraisal of threatening events and is responsible for activation of the attachment system. The second component involves the monitoring and appraisal of the availability and responsiveness of attachment figures and is responsible for variations in the sense of attachment security. According to our model, once the attachment system is activated, an affirmative answer to the question, "Is an attachment figure available and likely to be responsive to my needs?" results in a sense of security, fosters the application of the


FIGURE 28.1. Shaver and Mikulincer's (2002) integrative model of the activation and dynamics of the attachment system in adulthood.

secure base script, and facilitates engagement in nonattachment activities. The third component concerns monitoring and appraisal of the viability of proximity seeking as a means of coping with attachment insecurity and is responsible for variations in the use of hyperactivating or deactivating strategies. Whereas the appraisal of proximity seeking as likely to be successful, assuming sufficient effort is expended, favors the reliance on hyperactivating strategies, appraising proximity seeking as unlikely to alleviate distress and perhaps even likely to exacerbate it favors the adoption of deactivating strategies. The model also includes hypothetical excitatory and inhibitory "neural circuits" (shown as arrows on the lefthand side of the diagram), resulting from the recurrent use of hyperactivating or deactivating strategies, which affect the monitoring of threats and attachment figures' availability.

The model is sensitive to both context and personality. On the one hand, each component of the model can be affected by specific contextual factors (e.g., actual threats and information about attachment-figure availability or proximity-seeking viability), which initiate a bottom-up process in a person's working models, activating congruent attachment representations, and producing immediate changes in attachment-system functioning. On the other hand, each component of the model is affected by chronically accessible working models, which bias the appraisals of threats, attachment-figure availability, and proximity-seeking viability. These biases are part of a top-down process by which the attachment system functions in accordance with a person's chronic attachment working models. Overall, the model acknowledges the importance of both the context in which the attachment system is activated on a particular occasion and person-specific variations resulting from attachment history and chronically accessible working models.

Conceptualization and Measurement of Attachment Style

According to attachment theory (Bowlby, 1988; Fraley & Shaver, 2000; Shaver & Hazan, 1993), a particular history of attachment experiences and the resulting consolidation of chronically accessible working models lead to the formation of relatively stable individual differences in attachment-system functioning. These stable and generalized individual differences can be empirically examined by measuring a construct called *attachment style*—a person's habitual pattern of expectations, needs, emotions, and behavior in interpersonal interactions and close relationships (Hazan & Shaver, 1987). Depending on how it is measured, attachment style characterizes the functioning of a person's attachment system in a particular relationship (relationship-specific style) or across relationships (global attachment style).

The concept of attachment style, although not given that name, was first proposed by Ainsworth (1967) to describe infants' patterns of responses to separations from and reunions with their mother in the laboratory "Strange Situation" assessment procedure. Using this procedure, infants were originally classified into one of three style categories: secure, avoidant, or anxious. Main and Solomon (1990) later added a fourth category, "disorganized/disoriented," characterized by odd, awkward behavior and unusual fluctuations between anxiety and avoidance.

Infants classified as secure seem to hold chronically accessible working models of security attainment, and their pattern of responses to separation and reunion reflects a stable sense of attachment security. Specifically, they react to separation from their mother with overt expressions of distress but then recover quickly and continue to explore the environment with interest. When reunited with mother, they greet her with joy and affection, respond positively to being held, and initiate contact with her (Ainsworth et al., 1978). Avoidant infants seem to hold chronically accessible working models of unsuccessful proximity-seeking attempts organized around attachment-system deactivation. This organization is manifested in their responses to separation and reunion episodes, where they show little distress when separated from mother and avoid her upon reunion (Ainsworth et al., 1978). Anxious infants also seem to hold chronically accessible working models of frustrated proximity-seeking attempts, but these models seem to be organized around attachment-system hyperactivation. This organization is manifested in the expression of protest and distress during separation episodes and conflictual, angry responses toward mother at reunion (Ainsworth et al., 1978).

In the 1980s, researchers from different psychological fields (developmental, clinical, personality, and social) constructed new measures of attachment style in order to extend attachment research into adolescence and adulthood. Based on a developmental and clinical approach, Main and her colleagues (George, Kaplan, & Main, 1985; Main, Kaplan, & Cassidy, 1985; see Hesse, 1999, for a review) devised the Adult Attachment Interview (AAI) to study adolescents and adults' mental representations of attachment to their parents during childhood. In the AAI, interviewees answer open-ended questions about their childhood relationships with parents and are classified into three categories paralleling Ainsworth's infant typology: "secure" (or free and autonomous with respect to attachment), "dismissing" (of attachment), or "preoccupied" (with attachment). Using the AAI coding system (George et al., 1985), a person is classified as secure if he or she describes parents as available and responsive and his or her memories of relationships with parents are presented in a clear, convincing, and coherent manner. Dismissing persons play down the importance of attachment relationships and tend to recall few concrete episodes of emotional interactions with their parents. Preoccupied individuals are entangled in worries and angry feelings about parents, are hypersensitive to attachment experiences, and can easily retrieve negative memories, but they have trouble discussing them coherently without anger or anxiety. Despite the richness of AAI narratives, which are particularly useful in clinical settings, the interview is costly to administer and score, and it deals exclusively with memories of child–parent relationships.

Working from a personality and social psychological perspective and attempting to apply Bowlby's ideas to the study of romantic relationships, Hazan and Shaver (1987) developed a self-report measure of adult attachment style suitable for use in experiments and surveys. In its original form, the measure consisted of three brief descriptions of feelings and behaviors in close relationships that were intended to embody adult romantic analogues of the three infant attachment styles identified by Ainsworth and colleagues (1978). Participants were asked to read the descriptions and then place themselves into one of the three attachment categories according to their predominant feelings and behavior in romantic relationships. The three descriptions were:

- *Secure*: I find it relatively easy to get close to others and am comfortable depending on them and having them depend on me. I don't worry about being abandoned or about someone getting too close to me.
- *Avoidant*: I am somewhat uncomfortable being close to others; I find it difficult to trust them completely, difficult to allow myself to depend on them. I am nervous when anyone gets too close and often, others want me to be more intimate than I feel comfortable being.
- *Anxious*: I find that others are reluctant to get as close as I would like. I often worry that my partner doesn't really love me or won't want to stay with me. I want to get very close to my partner and this sometimes scares people away.

Hazan and Shaver's seminal study was followed by hundreds of others that used the simple forced-choice self-report measure to examine the interpersonal and intrapersonal correlates of adult attachment style (see reviews by Shaver & Hazan, 1993; Shaver & Mikulincer, 2002). Over time, attachment researchers made methodological and conceptual improvements to the original self-report measure. These improvements included the use of Likert scales for rating the extent to which each of the three descriptions captured one's experiences in romantic relationships (e.g., Levy & Davis, 1988); decomposition of the descriptions into separate items that could be included in multi-item scales (e.g., Collins & Read, 1990; Feeney & Noller, 1990; Simpson, 1990); splitting the avoidant category into "dismissing" and "fearful" subtypes, thus moving from a 3- to a 4-category classification scheme (Bartholomew & Horowitz, 1991); and rewording the instructions and items to examine global attachment style in close relationships generally (not only in romantic relationships) and relationship-specific styles (e.g., Baldwin, Keelan, Fehr, Enns, & Koh Rangarajoo, 1996; LaGuardia, Ryan, Couchman, & Deci, 2000; Mikulincer, Florian, & Tolmacz, 1990).

Today, adult attachment researchers in the fields of personality and social psychology (e.g., Brennan, Clark, & Shaver, 1998) largely agree that attachment styles are best conceptualized as regions in a two-dimensional (anxiety-by-avoidance) space, partly because two dimensions are consistently obtained in factor analyses of attachment measures and partly because Fraley and Waller (1998) demonstrated that dimensional representations of attachment style are more accurate than categorical representations. Interestingly, the two-dimensional space is very similar to the one defined by two discriminant functions in Ainsworth and colleagues' (1978) early summary of research on infant–mother attachment (Fig. 10, p. 102).

The first dimension, attachment-related *avoidance*, is concerned with discomfort with closeness and dependence on relationship partners, preference for emotional distance and self-reliance, and the use of deactivating strategies to deal with insecurity and distress. The second dimension, attachment-related *anxiety*, is concerned with a strong desire for closeness and protection, intense worries about partner availability and one's own value to the partner, and the use of hyperactivating strategies for dealing with insecurity and distress. People who score low on both dimensions are said to be secure or to have a secure attachment style. This region of low anxiety and low avoidance is defined by a chronic sense of attachment security, trust in partners and expectations of partner availability and responsiveness, comfort with closeness and interdependence, and coping with threats and stressors in constructive ways. Throughout the remainder of this chapter we refer to people with secure, anxious, or avoidant attachment styles, or people who are relatively secure, anxious, or avoidant. Although our categorical shorthand can misleadingly foster typological thinking, we will always be referring to fuzzy regions in a two-dimensional space in which people are continuously distributed.

The two attachment-style dimensions can be measured with the 36-item Experiences in Close Relationships (ECR) scale (Brennan et al., 1998), which is reliable in both the internal-consistency and test–retest senses and has high construct, predictive, and discriminant validity (Crowell, Fraley, & Shaver, 1999). Eighteen items tap the avoidance dimension (e.g., "I try to avoid getting too close to my partner" and "I prefer not to show a partner how I feel deep down"), and the remaining 18 items tap the anxiety dimension (e.g., "I need a lot of reassurance that I am loved by my partner" and "I resent it when my partner spends time away from me"). The two scales were conceptualized as independent and have been found to be empirically uncorrelated in most studies.

Hundreds of studies using self-report measures of adult attachment style, some based on three categories, some on four categories, and some on two dimensions, have found theoretically coherent attachment-style variations in relationship quality, mental health, social adjustment, ways of coping, emotion regulation, self-esteem, interpersonal behavior, and social cognitions (see Mikulincer & Shaver, 2003; Shaver & Clark, 1994; Shaver & Hazan, 1993, for reviews). Moreover, recent studies have shown that, despite substantial differences in focus (parent–child vs. adult–adult relationships) and method (brief self-reports vs. extensive interview transcripts), self-report measures of adult attachment style are related to AAI coding scales (Bartholomew & Shaver, 1998; Shaver, Belsky, & Brennan, 2000). These findings

imply that scores on the two kinds of measures are related to each other in sensible ways, and that both are reflections of underlying attachment working models and strategies.

BASIC PRINCIPLES OF ATTACHMENT THEORY

In the previous section, we outlined the operating characteristics of the attachment system, explained some of the context-sensitive and partner-specific variations in the system's functioning, and showed how these variations are studied with interview and self-report measures of adult attachment style. We now consider in more detail some of the personal, dyadic, and broader social consequences of variations in attachment-system functioning. Specifically, we focus on three basic issues related to the core principles of attachment theory: (1) the involvement of the attachment system in emotion regulation; (2) the positive implications of attachment-figure availability and the resulting sense of attachment security for social judgments, self-image, personality development, mental health, and relationship quality; and (3) the defensive biasing of cognition, motivation, and behavior by secondary attachment strategies, either deactivating or hyperactivating, and potential emotional and adjustment problems resulting from these biases.

The Emotion-Regulatory Function of Attachment-System Activation: Seeking Proximity and Support

One basic principle of attachment theory is that encounters with threats and dangers automatically activate the attachment system and increase the salience and urgency of the goal of attaining felt security by gaining proximity to and comfort from an attachment figure. This goal can be viewed either in terms of actually attaining safety or security (i.e., being protected and eliminating or reducing environmental threats) or attaining a more desirable emotional state—felt security rather than fear, anxiety, or anger. According to Bowlby (1969/1982), proximity and support seeking are fundamental elements of a person's repertoire of self-regulation skills. Without the relief and reassurance provided by attachment figures, it is difficult for a person, especially a young child, to acquire and develop other potential social and coping capacities.

In our model of attachment-system functioning in adulthood (Mikulincer & Shaver, 2003; Shaver & Mikulincer, 2002), we describe a two-stage process by which the attachment system can perform its regulatory function when a person is threatened or distressed. In the first stage, threat appraisal results in preconscious activation of the attachment system and automatic heightening of the accessibility of security-providing cognitions in a person's associative memory network (e.g., representations of supportive attachment figures; episodic memories of comforting interactions with these figures; self-representations associated with these figures; and

thoughts related to love and support). These preconsciously activated nodes become ready for use in information processing and, based on recent findings from social cognition research (e.g., Wegner & Smart, 1997), affect a person's state of mind and behavioral intentions even before the person experiences any sign of them in his or her stream of consciousness. In the second stage, this preconscious activation can give rise to conscious thoughts about seeking proximity to security-providing figures as well as conscious behavioral intentions and actual proximity- and support-seeking behavior.

In adulthood, as mentioned earlier, preconscious activation of the attachment system does not necessarily lead to actual proximity-seeking behavior, because activation of mental representations of caring and protecting partners can create a sense of safety and security that soothes the person, allowing him or her to continue to deploy attention in desired directions, carry on with chosen activities, and so on. In such cases, the adult attachment system can accomplish its regulatory function intrapsychically without awareness. There are situations, however, such as physical and psychological traumas, illnesses, or losses, in which symbolic proximity to internalized figures is not sufficient to provide adequate comfort and relief, and in such situations attachment-system activation leads to proximity-seeking behavior. There are also periods of development, such as old age, in which people's resources may be taxed to the point where it becomes necessary to seek actual support from others (Shaver & Mikulincer, 2004).

The self-regulatory processes attendant upon attachment-system activation do not depend only on demands imposed by a specific threat encountered; they can also be biased by excitatory and inhibitory processes related to chronic reliance on hyperactivating or deactivating strategies. For example, these chronic secondary strategies can bias subjective appraisal of threats, with hyperactivating strategies leading to exaggerated threat appraisal and deactivating strategies leading to dismissal of threats and suppression of threat-related thoughts. Second, insecure strategies and working models can affect which attachment-related nodes are automatically activated by threat appraisals, increasing the accessibility of negative attachment-related /thoughts (e.g., worries about attachment-figure unavailability and thoughts about separation and rejection). Third, hyperactivating and deactivating strategies can affect actual engagement in proximity and support seeking, with avoidant people preferring self-reliance and perceiving support seeking as a risky or potentially humiliating strategy and anxious people exaggerating overt expressions of helplessness as a means of eliciting others' compassion and care (Shaver & Mikulincer, 2002).

Preconscious Activation

In recent studies, we examined preconscious activation of the attachment system (Mikulincer, Birnbaum, Woddis, & Nachmias, 2000; Mikulincer, Gillath, &

Shaver, 2002) and found that subliminal priming with a threat-related word (e.g., illness, failure, and separation), as compared with a neutral word (e.g., hat), heightened the cognitive accessibility of attachment-related mental representations. This heightened activation was indicated by faster lexical decision times for proximity-related words (e.g., love and closeness) and names of people designated in the WHOTO as security-providing attachment figures (e.g., the name of a parent, spouse, or close friend). Interestingly, these effects were circumscribed to attachment-related representations and were not found for attachment-unrelated words or the names of people, including very familiar ones, other than attachment figures.

We also documented attachment-style variations in preconscious activation of the attachment system. For example, we found that anxious, hyperactivating strategies lead to attachment-system activation even in neutral contexts and color this activation with worries about separation and rejection. Specifically, people who score relatively high on attachment anxiety (measured by the ECR) exhibit heightened accessibility of attachment-related themes and attachment figures' names following subliminal priming with either threatening or nonthreatening words, and they also exhibit heightened access to words associated with separation and rejection. This pattern of attachment-system activation serves the function of hyperactivating strategies, which is to hold threat-related thoughts in working memory, thereby maintaining chronic activation of the system.

Second, avoidant (deactivating) strategies involve suppressing attachment-related worries and inhibiting attachment-system activation during encounters with attachment-related threats. For people who score relatively high on the avoidance scale of the ECR, worries about rejection and separation are relatively inaccessible. However, these worries *do* become accessible to avoidant individuals in response to threat primes when a "cognitive load" is added to a lexical decision task. Social cognition research has demonstrated that the addition of a "cognitive load" results in increased accessibility of to-be-suppressed material (e.g., Wegner, Erber, & Zanakos, 1993). Thus, our results support the theoretical notion that avoidant people actively suppress attachment-related worries and concerns but have trouble continuing to do so when a cognitive load is added. In addition, when we used the word "separation" as a threat prime, avoidant individuals exhibited decreased access to the names of their attachment figures. It thus seems that avoidant people's attachment system is preconsciously inhibited following thoughts of separation, which may have something to do with prior experiences in which expressions of emotion led to attachment figures' threats to leave.

Our studies have also revealed the functional and adaptive nature of attachment-system activation among more securely attached individuals (those with low scores on the attachment avoidance and anxiety dimensions). For them, heightened accessibility of attachment-related representations has occurred only in response to priming with threat words, and the activation is circumscribed to attachment themes with positive affective connotations. That is, secure people's encounters with threats heighten access to positive thoughts about love, support, and comfort, which, in turn, lead to anticipated relief and comfort (Mikulincer & Shaver, 2003).

The functional and adaptive nature of attachment-system activation in secure individuals was also observed in a recent study focusing on the accessibility of what we call security-based self-representations (Mikulincer & Shaver, 2004)—components or subroutines of the self that originate in interactions with supportive attachment figures. Based on social cognition research dealing with the relational basis of self-representations (e.g., Andersen & Chen, 2002; Baldwin, 1992), we argued that securely attached people, through repeated interactions with responsive attachment figures, form two kinds of self-representations: (1) those derived from how a person sees and evaluates him- or herself during interactions with these figures (*self-in-relation-with-a-security-enhancing-attachment-figure*) and (2) those derived from identification with features and traits of these attachment figure (*self-caregiving representations*). In addition, we proposed that secure people, who react to threats with heightened accessibility of representations of security-enhancing attachment figures (Mikulincer, Gillath, & Shaver, 2002), tend to experience a parallel heightened access to security-based self-representations. These self-representations, which have been formed in connection with threats that were alleviated by attachment figures, are mentally associated with attachment-figure representations and the positive feelings that arise from interactions with these figures. As a result, security-based self-representations can be automatically activated in new situations appraised as threatening and have a self-soothing effect.

To test these ideas, we conducted two two-session studies. In the first session of each study, we asked participants to generate traits that described either a security-enhancing attachment figure (study 2) or their self-in-relation-with-this-figure (study 1). In the second session, we exposed participants to either a threatening or a neutral condition, noted the accessibility of various categories of traits within their self-descriptions, and assessed their emotional state. As predicted, securely attached people reacted to the threat condition with heightened accessibility of security-based self-representations. They rated traits that they had previously used to describe a security-enhancing attachment figure or themselves in relation to this figure as more descriptive of their current self in threatening as compared with emotionally neutral conditions. This heightened accessibility of security-based self-representations was not observed among insecurely attached persons. Moreover, security-based self-representations had a soothing effect: The higher the accessibility of these self-representations, the more positive was a participant's emotional state following a threat. Thus, it appears that securely attached individuals can mobilize caring qualities within themselves as well as representations of being loved and valued in times of need that provide real comfort and allow a person to feel unperturbed.

Seeking Proximity and Support

There is extensive evidence, emanating from different theoretical traditions, that encounters with threats activate proximity and support seeking (e.g., Lazarus & Folkman, 1984; Schachter, 1959). For example, a recent series of "terror management" studies (i.e., studies of ways in which people regulate their fear of death) have shown that the threat generated by death awareness leads people to seek proximity as a means of buffering death concerns (see Mikulincer, Florian, & Hirschberger, 2003). These studies also show that proximity seeking can override other defensive maneuvers, such as endorsing one's own cultural beliefs while derogating deviants and outgroup members or engaging in other efforts to bolster one's self-esteem. Interestingly, and surprisingly in terms of terror management theory, people exposed to death reminders are willing to have their cultural worldview challenged or their self-esteem threatened in order to maintain proximity to relationship partners (e.g., Hirschberger, Florian, & Mikulincer, 2003; Wisman & Koole, 2003).

Research has also documented effects of dispositional attachment style on the use of proximity and support seeking as self-regulatory devices. For example, death concerns have been found to heighten proximity seeking mainly among securely but not among insecurely attached people (Mikulincer & Florian, 2000; Taubman Ben-Ari, Findler, & Mikulincer, 2002). These results fit with Fraley and Shaver's (1998) findings about proximity seeking in response to an impending separation from a romantic partner. They unobtrusively coded behaviors of separating couples in an airport and found that higher scores on attachment avoidance were associated with less frequent contact seeking and more frequent avoidance behavior (turning away, looking elsewhere, watching TV) as separation loomed.

In adult attachment research, there is extensive evidence that the sense of attachment security favors the seeking of support from both informal sources, such as parents, friends, and romantic partners, and formal sources, such as physicians, teachers, and counselors (e.g., Larose, Bernier, Soucy, & Duchesne, 1999; Larose, Boivin, & Doyle, 2001). Moreover, many studies have shown that higher levels of attachment insecurity, mainly along the avoidance dimension, are associated with less reliance on support seeking as a way of coping with stressful events (e.g., Alexander, Feeney, Hohaus, & Noller, 2001; Birnbaum, Orr, Mikulincer, & Florian, 1997; Feeney, 1998; Mikulincer & Florian, 1995, 1998; Mikulincer, Florian, & Weller, 1993).

These attachment-style differences have also been noted in observational studies of actual support-seeking behaviors. For example, Simpson, Rholes, and Nelligan (1992) invited heterosexual dating couples to the laboratory, told the woman in each couple that she was about to experience an anxiety-provoking laboratory procedure, and then asked them to wait with their partner for 5 minutes while the experimenter prepared the apparatus. During this "waiting period," participants' behavior was unobtrusively videotaped, and raters later coded the ex-

tent to which each participant sought the partner's support. As expected, higher scores on the avoidance dimension were associated with less support seeking from the partner mainly when women reported relatively high levels of distress (i.e., where pretheoretical intuitions would lead an observer to expect greater support seeking). Avoidant women often attempted to distract themselves by reading magazines instead of asking for support. In a more recent study, Collins and Feeney (2000) asked people to talk with their dating partner about a personal problem. This interaction was videotaped and raters coded the extent to which participants used direct and indirect ways of seeking support (e.g., directly asking for help and conveying a need for help through expressions of distress). Whereas attachment avoidance was associated with less frequent support-seeking behavior, attachment anxiety was associated with indirect methods of seeking support.

Overall, research indicates that threats activate attachment-related representations and heighten the tendency to seek proximity and support, but the studies also reveal attachment-style differences in the use of proximity seeking as a self-regulatory device: Whereas attachment security heightens reliance on proximity seeking, attachment insecurities interfere with fruitful proximity and support seeking. Anxious individuals evince chronic preconscious activation of attachment-related representations, but the associated concomitant preconscious activation of worries about rejection and abandonment seem to disorganize or unbalance the overt expression of support seeking. Avoidant individuals exhibit a dissociated self-regulatory stance: They react to threats with preconscious activation of the attachment system, but this activation does not reach awareness and is not translated into proximity-seeking behavior. This dissociated stance reflects deactivating strategies, which suppress the ever-present need for love and block access to attachment-related representations (Fraley, Davis, & Shaver, 1998).

Secure Attachment as an Inner Resource: The "Broaden and Build" Cycle of Attachment Security

Another principle of attachment theory is that attachment security has positive effects on self-image, coping, adjustment, interpersonal functioning, and personal growth. According to Bowlby (1988), interactions with available and loving attachment figures are natural building blocks of a solid psychological foundation, and the sense of attachment security that results from these interactions makes people more resilient in the face of adversities and hardships. In our model of attachment-system functioning (Mikulincer & Shaver, 2003), repeated episodes of attachment-figure availability create what we, following Fredrickson (2001), call a *broaden-and-build* cycle of attachment security, which provides inner resources for maintaining emotional equanimity in times of stress, fosters formation of satisfying close relationships, broadens one's repertoire of skills and perspectives, and contributes to natural processes of growth and self-actualization. In the fol-

lowing sections we present theoretical ideas and review empirical evidence concerning these salutogenic effects of attachment security.

Self-Representations

One "build" component of the broaden-and-build cycle of attachment security is the formation of authentic, solidly grounded feelings of self-worth, competence, and mastery that allow people to find comfort and reassurance in their own attributes and qualities while confronting threats and stressors. As mentioned earlier, Bowlby (1973) argued that children construct a model of themselves while interacting with attachment figures in times of need. During episodes of attachment-figure availability, children can easily perceive themselves as valuable, lovable, and special, thanks to being valued, loved, and regarded as special by a caring attachment figure. Moreover, they learn to view themselves as active, strong, and competent because they can effectively mobilize a partner's support and restore emotional equanimity. In this way, interactions with available and responsive others and the resulting sense of attachment security become primary sources of feelings of self-worth and mastery and natural building blocks of what Rogers (1961) called the "real self"—positive self-perceptions derived from others' positive regard during the course of a person's development.

Research consistently shows that attachment security is strongly associated with positive self-representations. As compared with anxiously attached persons, secure persons report higher self-esteem (e.g., Bartholomew & Horowitz, 1991; Mickelson, Kessler, & Shaver, 1997), view themselves as more competent and efficacious (e.g., Cooper, Shaver, & Collins, 1998), and possess more optimistic expectations about their ability to cope with stressful events (e.g., Berant, Mikulincer, & Florian, 2001; Cozarelli, Sumer, & Major; 1998). For example, Cozarelli et al. (1998) found that securely attached women undergoing an abortion reported higher levels of self-efficacy for coping with the abortion beforehand and higher self-esteem several months afterward.

Attachment security is also associated with having a coherent, balanced, and well-organized model of self. In a series of four studies, Mikulincer (1995) found that, although participants who endorsed a secure attachment style tended to recall more positive than negative self-relevant traits, they had ready cognitive access to both positive and negative self-attributes in a Stroop task. In addition, they revealed a highly differentiated and integrated self-organization in trait-sorting tasks and had relatively small discrepancies between actual-self representations and self-standards (ideal-self and ought-self representations). That is, attachment security not only encourages positive self-appraisals but also seems to allow people to tolerate weak points of the self and integrate them within a coherent and overall positive self-structure. Hence, securely attached people are able to feel good about themselves and maintain a stable sense of self-esteem even when they become aware of personal faults or imperfections.

Emotion Regulation and Mental Health

Another "build" component of the broaden-and-build cycle of attachment security is a set of constructive ways of coping, by which people can effectively handle problematic situations and manage distress without creating negative side effects. According to attachment theory, interactions with available attachment figures and the resulting sense of attachment security provide actual and symbolic contexts in which to learn constructive coping strategies (Mikulincer & Shaver, 2003). Beyond strengthening a person's confidence in the effectiveness of support seeking, episodes of attachment-figure availability and support facilitate the adoption of other constructive regulatory strategies embodied in the "secure base script" (Waters et al., 1998): acknowledgment and display of distress, positive reappraisal of the distress-eliciting situation, and engagement in instrumental problem solving.

Interactions with emotionally accessible and responsive others provide the context in which a child comes to openly and flexibly organize and express emotions and understand their functional assets (Cassidy, 1994; Mikulincer & Shaver, 2003). During these interactions, expression of negative affect is responded to sensitively by the attachment figure and reliably leads to distress-alleviating interventions by this caring person. The child thus learns that emotional states can be tolerated and transformed, that acknowledgment and display of emotions are functional steps toward restoring emotional equanimity, and that one can feel comfortable exploring, acknowledging, and expressing one's own emotions (Cassidy, 1994).

In adult attachment research, there is extensive evidence that self-reports of attachment security are associated with higher scores on self-report and behavioral measures of emotional expressiveness (e.g., Feeney, 1995, 1999; Searle & Meara, 1999) and self-disclosure (e.g., Bradford, Feeney, & Campbell, 2002; Keelan, Dion, & Dion, 1998; Mikulincer & Nachshon, 1991). For example, Mikulincer and Nachson (1991) content-analyzed participants' face-to-face verbal disclosure of personal information to another person in a laboratory situation and found that secure participants disclosed more intimate and emotion-laden information than did avoidant participants. Moreover, using a biographical memory task in which participants were asked to recall specific, early memories of positive and negative emotions, Mikulincer and Orbach (1995) found that participants who classified themselves as securely attached had ready mental access to painful memories of anger, sadness, and anxiety and were able to reexperience some of the accompanying negative affect. However, they still had better access to positive memories of happiness and did not experience an automatic spread of associations to memories of other negative emotional experiences. This allows secure people to maintain a positive cognitive context and a well-differentiated emotion-memory architecture, which in turn allows them to process negative memories without becoming overwhelmed by negativity, as often happens in the laboratory and real life for anxious individuals.

According to attachment theory (Bowlby, 1988; Mikulincer & Shaver, 2003), interactions with available and supportive attachment figures promote and reaffirm optimistic and hopeful appraisals of person–environment transactions. During positive interactions with good attachment figures, children gradually become convinced that distress is manageable, external obstacles can be overcome, and restoration of emotional equanimity is only a matter of time. As a result, secure people can make self-soothing reappraisals of aversive events that help them resolve distressing episodes with less strain than experienced by less secure people. That is, they can use what Lazarus and Folkman (1984) called "reappraisal strategies" and Rothbaum, Weisz, and Snyder (1982) called "secondary control"—construal of aversive events as controllable, temporary, and context-specific and construal of the self as capable of managing problematic situations (see Ochsner & Gross, 2004, for documented benefits of reappraisal strategies).

The association between self-reports of attachment security and positive, optimistic appraisals of stressful events has been well documented in social psychological studies (e.g., Berant et al., 2001; Birnbaum et al., 1997; Mikulincer & Florian, 1995, 1998). For example, Berant and colleagues (2001) found that securely attached mothers of infants who were diagnosed with congenital heart defects reported more positive appraisals of motherhood-related tasks, both immediately after the diagnosis and 1 year later, than anxious or avoidant mothers. Moreover, self-reports of attachment security were associated with less use of threat/loss frames in thinking about relationships (e.g., Boon & Griffin, 1996) and the appraisal of romantic interactions, daily social interactions, and small-group interactions in more positive terms (e.g., Pietromonaco & Feldman Barrett, 1997; Rom & Mikulincer, 2003; Tidwell, Reis, & Shaver, 1996).

Experiences of attachment-figure availability also offer opportunities to learn that one's own instrumental actions are often able to reduce distress. For example, a child learns that his or her bids for proximity alter a partner's behavior and result in the restoration of emotional equanimity. As a result, security-providing interactions strengthen a person's reliance on active, instrumental approaches to problem solving. This heightened reliance is further facilitated by another core feature of episodes of attachment-figure availability: Experiencing attachment figures as loving and approving allows secure people to revise erroneous beliefs without excessive fear of criticism or rejection, thus facilitating cognitive changes that are often necessary when designing an effective plan for solving a problem. That is, secure people's confidence that support is available in case of confusion, uncertainty, or disorganization allows them to open their cognitive structures to new information and flexibly adjust their plans for dealing realistically with problematic situations.

In support of this view, secure people have been found to rely on problem-focused strategies while coping with stressful events (e.g., Lussier, Sabourin, & Turgeon, 1997; Mikulincer & Florian, 1998) and to deal with interpersonal conflicts by compromising and integrating their own and their partner's positions (e.g., Carnelley,

Pietromonaco, & Jaffe, 1994; Levy & Davis, 1988) as well as openly discussing the problem and resolving the conflict (e.g., Scharfe & Bartholomew, 1995; Simpson, Rholes, & Phillips, 1996). This constructive approach to emotion regulation was illustrated by Mikulincer (1998b), who found that secure participants' recollections of personal experiences of anger were characterized by adaptive problem-solving actions aimed at repairing the relationship with the instigator of anger.

Attachment security promotes what Lazarus (1991) called a "short circuit of threat," sidestepping the interfering and dysfunctional aspects of emotions while retaining their functional, adaptive qualities. Efficient management of distress results in more and longer periods of positive mood, thereby rendering mood disorders, maladjustment, and psychopathology less likely. Indeed, several studies have documented positive associations between secure attachment and measures of well-being (e.g., Berant et al., 2001; Birnbaum et al., 1997) and negative associations between security and symptoms of depression, anxiety, and hostility (e.g., Cooper et al., 1998; Mickelson et al., 1997; Roberts, Gotlib, & Kassel, 1996), and between security and eating disorders, substance abuse, and conduct disorders (Brennan & Shaver, 1995; Cooper et al., 1998; Mickelson et al., 1997). Recent studies indicate that both dispositional measures of attachment security and contextual manipulations of the sense of attachment security are associated with lower levels of posttraumatic symptoms (e.g., intrusion of traumatic thoughts) among people who were exposed to the traumas of war or terrorism (Mikulincer, Shaver, & Horesh, 2006).

Relationship Quality

The "build" components of the broaden-and-build cycle of attachment security are also manifested in interpersonal behaviors and close relationships. Episodes of attachment-figure availability promote and reaffirm positive beliefs about others' sensitivity, responsiveness, and goodwill. The secure child learns that he or she can count on others' good intentions and depend on others as providers of comfort and relief. These experiences ensure a person that proximity maintenance is rewarding and that interdependent relationships are important for regulating emotions and satisfying needs. As a result, secure people find it relatively easy to trust others, experience and express gratitude, and feel affection toward relationship partners; they also find it easier to tolerate and accept ambiguous or even negative partner behaviors. Accordingly, they feel comfortable with intimacy and interdependence, emphasize the benefits of being together, and organize their interactions around the perceived benefits of intimate, mutually supportive relationships. Thus, attachment security enhances the motivation to be involved in stable couple relationships and contributes to the quality of those relationships.

There is now good evidence that secure people maintain more stable romantic relationships and report higher levels of relationship satisfaction and adjustment (see Mikulincer, Florian, Cowan, & Cowan, 2002, for an

extensive review). This pattern has been repeatedly documented in studies of both dating and married couples and cannot be explained by other personality factors, such as the "big five" personality traits or self-esteem (Mikulincer, Florian, et al., 2002). For example, Davila, Karney, and Bradbury (1999) collected data every 6 months for 3 years from newlywed couples and found that changes in husbands' and wives' reports of secure attachment predicted concurrent changes in both partners' reports of marital satisfaction. Studies have also linked attachment security with greater intimacy (e.g., Feeney & Noller, 1990; Hazan & Shaver, 1987) and stronger commitment (e.g., Shaver & Brennan, 1992; Simpson, 1990).

There are many studies examining associations between attachment security and positive perceptions of romantic partners. As compared to insecure individuals, securely attached people have more positive views of their romantic partners (e.g., Collins & Read, 1990; Feeney & Noller, 1991), perceive their partners as more supportive (e.g., Collins & Read, 1990; Ognibene & Collins, 1998), and feel more trusting and affectionate toward their partners (e.g., Collins & Read, 1990; Mikulincer, 1998c; Simpson, 1990). Attachment security is also associated with positive expectations concerning partner behaviors (e.g., Baldwin, Fehr, Keedian, & Seidel, 1993; Baldwin et al., 1996; Mikulincer & Arad, 1999). For example, Baldwin and colleagues (1993) examined the cognitive accessibility of expectations concerning partner's behaviors in a lexical decision task and found that secure people had poorer access to negative partner behaviors (e.g., partner being hurtful) than did anxious and avoidant people. Attachment security is also associated with more positive explanations of a relationship partner's behavior (e.g., Collins, 1996; Mikulincer, 1998b, 1998c). Collins (1996) asked participants to explain hypothetical negative behaviors of a romantic partner and found that more secure individuals were more likely to attribute partner's negative behaviors to unintentional, unstable, and highly specific causes and less likely to provide explanations that had negative implications for relationship stability.

Broadening of Skills and Perspectives

As mentioned earlier, Bowlby (1969/1982) conceptualized a dynamic interplay between the attachment system and other behavioral systems (e.g., exploration, caregiving, affiliation, and sex). We view this dynamic interplay as the basis for the "broaden" aspect of the broaden-and-build cycle of attachment security, which contributes to the expansion of nonattachment skills, the opening of cognitive structures to novel perspectives, and the actualization of a person's natural talents. We endorse and have pursued Bowlby's idea that insecurity interferes with the activation and unfettered operation of other behavioral systems. Only when an attachment figure is available and a sense of attachment security is restored can a temporarily insecure person devote full attention to nonattachment activities. Moreover, being confident that support is available when needed, securely attached people can take necessary risks and accept important challenges in an effort to expand their skills and perspectives and actualize their potentials.

This implies that attachment security should enhance curiosity and encourage relaxed exploration of new, unusual information and phenomena and favor the formation of open and flexible cognitive structures despite the uncertainty and confusion that a broadening of knowledge might entail. Indeed, several studies have shown that attachment security is associated with greater trait curiosity (Mikulincer, 1997), more willingness to explore new environments (Green & Campbell, 2000), stronger endorsement of mastery-approach goals in achievement settings (Elliot & Reis, 2003), heightening of creativity following induction of positive affect (Mikulincer & Sheffi, 2000), greater cognitive openness and tolerance for ambiguity (Mikulincer, 1997), and less dogmatic thinking (Mikulincer, 1997).

Attachment security is also associated with the incorporation of novel and even inconsistent information into existing cognitive structures (e.g., Green-Hennessy & Reis, 1999; Mikulincer, 1997; Mikulincer & Arad, 1999). For example, Mikulincer (1997) assessed the tendency to make judgments on the basis of early information and to ignore later data. He found that securely attached individuals were less likely than anxious or avoidant individuals to rate a target person based on the first information received. Interestingly, Green and Campbell (2000) found that contextual priming of attachment security heightened people's willingness to explore novel stimuli, and Mikulincer and Arad (1999) reported that asking participants to visualize a supportive other increased cognitive openness and led even chronically anxious or avoidant people to revise their beliefs based on new information.

These effects of attachment security on cognitive openness have also been documented in a recent series of studies on attitudes toward outgroup members (Mikulincer & Shaver, 2001). In these studies we showed that the greater a person's chronic sense of attachment security, the weaker his or her hostile responses to a variety of outgroup members. In addition, priming techniques that momentarily heightened the sense of attachment security eliminated hostile responses to outgroup members. That is, the sense of attachment security promotes tolerant and accepting attitudes toward people who do not belong to one's own group.

Theoretically, the "broadening" effect of attachment security should promote optimal functioning of the caregiving system, which should show itself in a person's proneness and willingness to provide support and care to others who are chronically dependent or temporarily in need. In line with this prediction, studies have shown that attachment security is associated with higher scores on self-report scales tapping responsiveness to a relationship partner's needs (e.g., Feeney, 1996; Kunce & Shaver, 1994) and more supportive actual behaviors toward a distressed partner (e.g., Fraley & Shaver, 1998; Simpson et al., 1992). In a recent study, Westmaas and Silver (2001) found that attachment-related avoidance was associated with negative attitudes toward a person who had been diagnosed with cancer, and attachment anxiety was associ-

ated with high levels of distress during an interaction with the ill person. In addition, Mikulincer, Gillath, and colleagues (2001) found that both dispositional and situationally augmented attachment security were associated with heightened empathy and compassion for a suffering individual.

There is also evidence that attachment security promotes prosocial values. Mikulincer, Gillath, and colleagues (2003) reported that chronic and contextually augmented attachment security was associated with stronger endorsement of personal values reflecting concern for other people's welfare. Recently, Gillath and colleagues (2004) found that avoidant attachment was negatively associated with engagement in various altruistic activities such as caring for the elderly and donating blood. Although attachment anxiety was not related to overall involvement in such volunteer activities, it was associated with more self-enhancing or self-soothing motives for volunteering (e.g., to feel better about oneself and to enjoy a sense of belonging). Overall, these studies indicate that attachment security provides a solid foundation for compassion and altruistic caregiving, whereas attachment insecurities interfere with prosocial feelings and behaviors.

The Defensive Nature of Secondary Attachment Strategies

A third principle of attachment theory is that defensive biases associated with secondary (insecure) attachment strategies distort and damage emotion regulation, negatively color mental representations of self and others, and contribute to psychological and social problems. According to attachment theory (Main, 1990; Mikulincer & Shaver, 2003; Shaver & Mikulincer, 2002), secondary attachment strategies (hyperactivation and deactivation) include psychological defenses against the frustration and pain caused by attachment-figure unavailability. Although they are attempts at adaptation carried out under adverse environmental circumstances, they end up being maladaptive when used in later relationship situations where security would be more productive. Each of the secondary strategies is aimed originally at achieving a workable relationship with an inconsistently available or consistently distant or unavailable attachment figure. To sustain these strategies, a person has to build otherwise distorted or constraining working models and affect-regulation mechanisms that are likely to interfere with subsequent development and attempts to create rewarding close relationships. In the following pages, we review theoretical proposals and empirical evidence regarding the various defensive biases imposed by secondary attachment strategies and their potentially pathogenic effects on adjustment and mental health.

Emotion Regulation

Secondary attachment strategies defensively bias emotion regulation and alter, obstruct, or suppress the experience and expression of emotions (Cassidy & Kobak, 1988; Mikulincer & Shaver, 2003). The deactivating strategies used by avoidant individuals are intended to dodge or suppress every emotional state associated with threat-related thoughts (e.g., fear, sadness, and shame), because these thoughts can activate unwanted attachment-related needs, memories, and behaviors. Moreover, avoidant people often view negative emotions and expressions of weakness or vulnerability as incompatible with their desire for and maintenance of self-reliance. This causes them to inhibit natural emotional reactions to relationship threats, such as rejection, separation, and loss; and to try to keep these feelings out of consciousness.

Unlike relatively secure people, those who are avoidant cannot engage readily in optimal problem solving because this often requires opening knowledge structures to new information, admitting frustration and possible defeat, dealing with uncertainty and confusion, and running freely through one's memories without attempting to block attachment-system activation (Mikulincer, 1997). Avoidant people have difficulty reappraising emotion-eliciting events because, during frustrating interactions with unavailable, unresponsive, or disapproving attachment figures, they have been forced to doubt the general goodness of the world and good intentions of other people. They have trouble looking on the bright side of troubling events, transforming threats into challenges, and anticipating other's support if they allow themselves to become demoralized.

Deactivating strategies may also block direct confrontation with undesirable emotional states. Avoidant people often prefer to dissociate their emotions from their thoughts and actions, using what Lazarus and Folkman (1984) called *distancing coping*. This requires suppression of emotion-eliciting thoughts, repression of painful memories, diversion of attention from emotion-related material, and inhibition of verbal and nonverbal expressions of emotion.

Bowlby (1980) characterized avoidant individuals' deactivation of emotions in terms of defensive exclusion and segregated mental systems. Bowlby (1988) suggested that the excluded information is stored in mental representations that are blocked from consciousness, not integrated into the stream of consciousness and the conscious determination of behavior, and inaccessible to new information or constructive reappraisal. Defensive exclusion lowers the accessibility of threat- and attachment-related cognitions and creates difficulties in encoding material that is congruent with them. When encoded, this information tends to be processed in a shallow way, because it has no strong excitatory associations with other accessible cognitions.

Unlike secure and avoidant people, who perceive threat-related emotions as goal-incongruent states that should either be managed effectively or suppressed, anxiously attached people perceive these emotions as congruent with their goal of attachment-system hyperactivation. In the process of emotion regulation, anxious hyperactivating strategies are manifested in effortful attempts to generate and intensify emotional states. These states include every emotion that plays a role in activating the attachment system—threats, dangers, and negative interactions with attachment figures. They also include

emotions that emphasize a person's wounds and incompetence, such as sadness, anxiety, shame, and guilt, because these make it natural to insist on attachment figures' attention and care (Cassidy, 1994).

How do anxious people accomplish their goal of intensifying their emotions? One method is to overemphasize the potentially threatening aspects of even benign events, another is to transform challenges into threats, and another is to ruminate on pessimistic beliefs about one's inability to manage distress (Mikulincer & Florian, 1998). Another method is what Lazarus and Folkman (1984) called *emotion-focused coping*—shifting attention to internal indications of distress, thereby making them seem more urgent and destabilizing. This maneuver includes hypervigilance to the physiological aspects of emotional states, heightened recall of threat-related experiences, rumination on real and potential threats, exacerbation of negative feelings, and exaggerated displays of distress (Shaver & Mikulincer, 2002). Another hyperactivating strategy is to engage in wild, counterphobic behavior that makes danger more real or to adopt ineffective courses of action that are likely to be self-defeating and result in failure. All these strategies create a self-amplifying cycle of distress, which is maintained cognitively by ruminative thoughts and feelings even after a threat objectively ends.

Interestingly, although hyperactivating and deactivating strategies lead to opposite patterns of emotional expression (intensification versus suppression), both result in dysfunctional emotional experiences. Avoidant people lose out on the adaptive aspects of emotional experiences because they have poor access to their emotions; anxious people lose out because their attention is devoted to the threatening and interfering aspects of emotions more than their functional aspects. These tendencies, once the province of psychoanalytical clinicians, have now been extensively documented in empirical studies of attachment style and ways of coping with stressful events (see Fuendeling, 1998; Mikulincer & Florian, 1998; Shaver & Mikulincer, 2002, for reviews). In these studies, higher avoidance scores are associated with higher scores on measures of coping by distancing, and attachment anxiety is associated with higher scores on measures of emotion-focused coping. For example, Mikulincer and Orbach (1995) reported that avoidant attachment was associated with a repressive coping style, Feeney (1995) reported that avoidance was related to behavioral blunting (seeking distractions when dealing with stress), and Mikulincer and Florian (1998) found that people who classified themselves as anxiously attached tended to report more frequent task-related, ruminative worries after failing cognitive tasks than were reported by their secure and avoidant counterparts.

Attachment strategies are also manifested in the ways people cope with attachment-related threats (see Mikulincer & Shaver, 2003; Shaver & Mikulincer, 2002, for reviews). For example, Mayseless, Danieli, and Sharabany (1996) and Scharf (2001) found that whereas anxiously attached people reacted to imagined separations in the projective Separation Anxiety Test with strong emotional responses (distress intensification, self-blame), avoidant people refrained from dealing with the threat of separation. In a related pair of studies, Fraley and Shaver (1997) examined the role of secondary attachment strategies in the suppression of separation-related thoughts. Participants wrote continuously about whatever thoughts and feelings they were experiencing while being asked to suppress thoughts about their romantic partner leaving them for someone else. Attachment anxiety was associated with poorer ability to suppress separation-related thoughts—more frequent thoughts of breakup following the suppression task and higher skin conductance during the task. In contrast, more avoidant individuals were better able than less avoidant individuals not only to stop thinking about separation but also to reduce the intensity of their autonomic responses to these painful thoughts. Fraley, Garner, and Shaver (2000) showed that these avoidant defenses act in a *preemptive* manner by holding attachment-related material out of awareness right from the initial encoding of the information.

In a series of studies examining the experience and management of death anxiety (e.g., Mikulincer & Florian, 2000; Mikulincer et al., 1990), anxious individuals were found to intensify death concerns and keep death-related thoughts active in memory. Specifically, attachment anxiety was associated with heightened fear of death at both conscious and unconscious levels, as well as heightened accessibility of death-related thoughts even when no death reminder was present. In contrast, avoidant individuals tended to suppress death concerns and dissociate their conscious claims from their unconscious (but measurable) anxiety. Although avoidance was related to low levels of self-reported fear of death, it was also related to heightened death anxiety in projective Thematic Apperception Test (TAT) stories.

Avoidant people's dissociative tendencies were also documented by Mikulincer (1998a), who found that avoidant individuals, as compared with secure ones, reacted to anger-eliciting episodes with lower levels of self-reported anger and higher levels of physiological arousal (heart rate). Two other studies examined access to emotions during the AAI, finding that avoidant people expressed fewer negative feelings during the interview but displayed higher levels of physiological arousal (heightened electrodermal activity; Dozier & Kobak, 1992) and a high rate of facial expressions of anger, sadness, and negative surprise (Zimmerman, 1999) while speaking about their relationships with parents.

The biases associated with anxious and avoidant approaches to emotion regulation were also documented in Mikulincer and Orbach's (1995) study of emotional memories. Anxious individuals quickly accessed negative emotional memories and then had difficulty controlling the spread of activation from one negative emotional memory to another (a process associated with being classified as anxious, or preoccupied, in the AAI; Hesse, 1999). These findings fit with the theoretical portrayal of anxious people as having an undifferentiated, chaotic emotional architecture, which makes emergence from negative emotional spirals difficult. In contrast, Mikulincer and Orbach found that avoidant individuals

had poor access to negative emotional memories, and those that were recalled were rather shallow (a pattern also characteristic of dismissingly avoidant individuals in the AAI).

Defensive Distortions of Mental Representations of Self and Others

According to attachment theory, secondary attachment strategies defensively bias insecure persons' working models of self (e.g., Bowlby, 1988; Main, 1990; Mikulincer & Shaver, 2003). Whereas hyperactivating strategies negatively bias anxious people's sense of self-esteem, deactivating strategies favor defensive processes of self-enhancement and self-inflation. On the one hand, the excitatory pathways (in Figure 28.1) running from hyperactivating strategies to the monitoring of threat-related cues causes attention to be directed to self-relevant sources of distress (e.g., thoughts about personal weaknesses), thereby fostering chronic doubts about self-worth. This low self-esteem can be exacerbated by self-defeating self-presentational tendencies, which involve emphasizing helplessness and vulnerability as a way of eliciting other people's compassion and support. On the other hand, the inhibitory circuits associated with deactivating strategies (in Figure 28.1) divert attention from self-relevant sources of distress and therefore inhibit consideration of negative self-aspects and contribute to the maintenance of high self-esteem. This defensive inflation of self-esteem is further reinforced by adopting a self-reliant attitude, which requires exaggeration of strengths and self-worth, and by strategic attempts to convince others that one does not need their support.

In a direct examination of these defensive biases, Mikulincer (1998a) exposed people to various kinds of threatening and neutral situations and assessed self-appraisals following the manipulations. Participants with an avoidant attachment style made more explicit and implicit positive self-appraisals following threatening, as compared with neutral, situations. In contrast, anxiously attached participants reacted to threat with self-devaluation, making more explicit and implicit negative self-appraisals following threatening than neutral conditions. Mikulincer also noted that introducing contextual factors that inhibited defensive tendencies (a "bogus pipeline" device that measures "true feelings about things" or the presence of a friend who knew the participants) inhibited avoidant participants' self-inflation response to threats as well as anxious participants' self-devaluation response. That is, insecure people's self-appraisals seemed truly to be strategic defensive maneuvers aimed at convincing other people of the strength of the avoidant self or the neediness of the anxious self.

Secondary attachment strategies are also likely to bias person perception. In the case of avoidant individuals, who want to maintain distance from others and view themselves as strong and perfect, their deactivating strategies are likely to be directed toward increasing distinctiveness, uniqueness, and devaluation of others. In contrast, in the case of anxiously attached people, who want

to be loved and accepted, their hyperactivating strategies are likely to be directed toward increasing the sense of connectedness and belongingness and creating a false sense of consensus. Indeed, Mikulincer, Orbach, and Iavnieli (1998) found that whereas anxious individuals were more likely than their secure counterparts to perceive others as similar to themselves, and to exhibit a false consensus bias in both trait and opinion descriptions, avoidant individuals were more likely than secure individuals to perceive others as dissimilar to them and to exhibit a false distinctiveness bias. Importantly, Mikulincer and colleagues also found that anxious individuals reacted to threats by generating a self-description that was more similar to their partner's self-description, thereby increasing the justification for solidarity. Avoidant individuals, in contrast, reacted to the same threats by generating self-descriptions that were less similar to their partner's self-description and by forgetting more traits that they and their partner shared.

In a subsequent study, Mikulincer and Horesh (1999) found that avoidant people defensively projected their own unwanted traits onto others, which increased self–other differentiation and, by comparison, enhanced their own sense of self-worth. In contrast, anxiously attached participants projected their own traits onto others, which increased their sense of self–other similarity, compatibility, and closeness. Importantly, these two seemingly different mechanisms resulted in a negative appraisal of others. In the case of avoidant persons, the negative appraisal was derived from the projection onto others of negative self-relevant traits. In the case of anxious individuals, it was derived from a tendency to perceive others the way they perceive themselves—as relatively weak, helpless, unworthy, and unlovable.

Problems in Mental Health and Adjustment

Attachment theorists view secondary attachment strategies as risk factors that reduce resilience in times of stress and contribute to emotional problems and poor adjustment (Bowlby, 1988; Mikulincer & Shaver, 2003). Hyperactivating strategies lead to distress intensification and a chaotic emotional architecture that impairs anxious people's ability to regulate negative emotions. As a result, the anxious person experiences an endless and uncontrollable flow of negative thoughts and emotions, which in turn can lead to cognitive disorganization and, in certain cases, culminate in psychopathology. Although avoidant, deactivating strategies contribute to defensive maintenance of a façade of security and calmness, they block access to emotions and hence can impair a person's ability to confront and cope with life's adversities. This impairment is particularly likely to be manifested during prolonged, highly demanding stressful experiences that require active confrontation of a problem and mobilization of external sources of support. In addition, although deactivating strategies involve suppressing the conscious experience and display of distress, the distress can still be indirectly manifested in somatic symptoms, sleep problems, and other health problems. Moreover, negative attitudes toward close relationships and rela-

tionship partners can channel unresolved distress into feelings of hostility, loneliness, and estrangement from others.

With regard to hyperactivating strategies, a large number of studies have shown that attachment anxiety is inversely associated with well-being and positively associated with global distress, depression, anxiety, eating disorders, substance abuse, conduct disorders, and severe personality disorders (see Lopez & Brennan, 2000; Mikulincer & Florian, 2001; Mikulincer & Shaver, 2003, for extensive reviews). These associations have been found in different age groups, ranging from adolescents to elderly adults, community samples, psychiatric inpatients and outpatients, and individuals experiencing acute stressful events (e.g., abortion) or more chronic stressful conditions (e.g., chronic pain).

For avoidance, the findings are more complex. On the one hand, a host of studies yielded no significant associations between avoidant attachment and self-report measures of well-being and global distress (see Mikulincer & Florian, 2001; Mikulincer & Shaver, 2003, for reviews). On the other hand, several studies indicate that avoidant attachment is associated with particular patterns of emotional and behavioral problems that may result from the underlying action of deactivating strategies. Specifically, significant associations have been found between avoidance and a pattern of depression characterized by perfectionism, self-punishment, and self-criticism (e.g., Zuroff & Fitzpatrick, 1995), heightened reports of somatic complaints (e.g., Mikulincer et al., 1993), a hostile view of other people (e.g., Mikulincer, 1998b), substance abuse and conduct disorders (e.g., Brennan & Shaver, 1995; Cooper et al., 1998; Mickelson et al., 1997), and schizoid and avoidant personality disorders (e.g., Brennan & Shaver, 1998).

In addition, whereas no consistent association has been found in community samples between avoidant attachment and global distress, studies that focus on highly demanding and distressing events reveal that avoidant attachment is related to higher levels of reported distress. For example, Berant and colleagues (2001) assessed mothers' reactions to the birth of an infant with a congenital heart defect and found that avoidance, as assessed at the time of the initial diagnosis of the infant's disorder, was the most potent predictor of maternal distress a year later. Moreover, Mikulincer, Horesh, Eilati, and Kotler (1999) found that avoidance was positively associated with global distress among Israeli Jewish settlers whose lives were in danger because of residing in disputed territory controlled by the Palestinian Authority.

It seems that deactivating strategies may contribute to mental health under fairly normal circumstances characterized by only mild encounters with stressors. Under highly demanding conditions, however, these strategies seem to collapse, and in such cases avoidant individuals may exhibit high levels of distress and emotional problems. This conclusion is supported by two of our recent laboratory studies (Mikulincer, Dolev, & Shaver, 2004), which showed that the addition of a demanding cognitive task, which had previously been shown to interfere with mental suppression (e.g., Wegner et al., 1993), impaired avoidant individuals' ability to block the activation of attachment-related worries. Under low cognitive-load conditions, avoidant individuals were able to suppress thoughts related to the painful breakup of a romantic relationship and did not exhibit activation of negative self-traits after being asked to think about this painful episode. However, when a cognitive load was imposed (a secondary but demanding cognitive task), avoidant individuals exhibited a strong rebound of previously suppressed thoughts about the painful separation and heightened activation of negative self-traits. In other words, under high-load conditions, avoidant participants resembled their anxiously attached counterparts, exhibiting high accessibility of separation-related thoughts and an automatic spread of activation from these attachment-related thoughts to negative self-representations.

Adult attachment studies also provide insights into the psychological mechanisms that may account for the association between insecure attachment patterns and measures of emotional and adjustment problems. For example, Roberts and colleagues (1996) found that negative concepts of the self, others, and the future mediated both cross-sectional and prospective associations between attachment anxiety and depression. In addition, the core procedural components of hyperactivating and deactivating strategies play an important mediating role. Whereas the association between attachment anxiety and negative affectivity is explained by heightened reliance on emotion-focused coping and mental rumination on threat-related thoughts (e.g., Birnbaum et al., 1997; Cozzarelli et al., 1998), the association between avoidance and negative affectivity is mediated by heightened reliance on distancing coping, high levels of emotional control, and reluctance to engage in support seeking (e.g., Birnbaum et al., 1997; Cozzarelli et al., 1998).

BUILDING CONCEPTUAL BRIDGES BETWEEN ATTACHMENT THEORY AND OTHER THEORETICAL FRAMEWORKS

In the remaining sections, we point to similarities and differences between attachment theory and four other broad psychological approaches to understanding the human mind: psychoanalysis; relational interdependence theories; social cognition theories; and humanistic and "positive psychology" perspectives on personal development. In so doing, we hope to deepen the reader's understanding of the implications of attachment theory and build conceptual bridges to other theoretical approaches.

Psychodynamic Foundations of Attachment Theory

The links between attachment theory and psychoanalysis were evident in Bowlby's early writings (e.g., Bowlby, 1956). He was trained as a child psychiatrist and psychoanalyst, and like other psychoanalytic thinkers, he assumed that the explanation of adult behavior lay

somewhere in childhood, especially in early social relationships. Although he was dissatisfied with the conventional psychoanalysis of his time, especially the ideas of Anna Freud and Melanie Klein, he still believed that the quality of a child's emotional ties with mother had tremendous effects on normal and abnormal patterns of personal, interpersonal, and social functioning across the life span. Furthermore, Bowlby constructed attachment theory around themes that defined most of the psychoanalytic theories of his time: satisfaction and frustration of basic inner wishes (for security and protection), inner conflicts associated with barriers to wish fulfillment, psychological defenses aimed at avoidance or suppression of negative emotions associated with inner conflicts, and emotional problems related to the overuse of defenses.

These conceptual commonalities become more evident when analyzing the basic postulates that define contemporary psychodynamic approaches (Westen, 1998). In his impressive review of contemporary psychoanalysis, Westen (1998) asserted that all contemporary psychodynamic theorists agree with five core postulates. First, a large portion of mental life is unconscious. Second, cognitive and affective processes operate in parallel so that people can have conflicting motives, thoughts, and feelings toward the same situation or person, and psychological defenses are often used to deal with these conflicts. Third, childhood experiences play a crucial role in the formation of adult personality. Fourth, mental representations of the self and others are major components of personality; they often explain a person's behavior in interpersonal and social settings, and account for or contribute to psychological disorders. Fifth, healthy personality development is a journey from social dependence to mature autonomy.

Attachment theorists and researchers adhere to all five postulates. According to attachment theory, many components of the attachment behavioral system can operate unconsciously (Mikulincer & Shaver, 2003). As reviewed earlier, recent studies have shown that activation of the attachment system can occur at an unconscious level and can shape a person's processing of information and behavior before he or she reflects on any of it in the stream of consciousness (e.g., Mikulincer, Gillath, & Shaver, 2002). In addition, deactivating strategies seem to operate at an unconscious level. Avoidant people often seem not to be consciously aware of suppressing or denying attachment needs and attachment-related thoughts and memories (Cassidy & Kobak, 1988). Furthermore, according to Bowlby (1988) and some of our own research, these suppressed needs, memories, and thoughts continue to remain active in unconscious, segregated mental systems and at times resurface in experience and action when deactivating strategies prove insufficiently strong given other cognitive or emotional demands on mental resources.

In attachment theory, the concepts of inner conflict and psychological defense are central to the characterization of the goals and operation of secondary attachment strategies. Specifically, these strategies seem to reflect the underlying presence of distress-eliciting, conflicting tendencies toward the self and relationship partners and are organized around specific defensive maneuvers against these attachment-related sources of distress (Mikulincer & Shaver, 2003). Hyperactivating strategies reflect a compromise between conflicting, ambivalent tendencies toward attachment figures—anger and hostility toward unavailable attachment figures together with an intense need for proximity to and love from these frustrating figures (Cassidy & Kobak, 1988). Deactivating strategies are organized around conflicting tendencies at different levels of awareness, with lack of negative emotions and a detached attitude evident at the conscious level while high levels of unresolved attachment-related distress exist at an unconscious level (Shaver & Mikulincer, 2002).

Three additional features of attachment theory fit with the remaining postulates of contemporary psychodynamic theories. According to Bowlby (1973), childhood experiences with primary caregivers have important effects on attachment-system functioning in adulthood, and as stated earlier, mental representations of the self and others (attachment working models) explain how mental residues of these early experiences become building blocks of a person's cognitions and behaviors in adulthood and have a shaping influence on emotion regulation, interpersonal relations, and mental health. Furthermore, in attachment theory, the consolidation of dispositional attachment security, a sign of healthy personality development and functioning, provides a foundation for increased exploration, self-regulation, and a flexible balance between self-reliance and reliance on others, which facilitates a move toward maturity and relative autonomy combined with an ability to rely comfortably on others when necessary (Mikulincer & Shaver, 2004). This developmental progression stands in marked contrast with the overly dependent, infantile position of the anxious person and the rigidly self-reliant attitude of the avoidant person.

This does not mean, however, that attachment theory can be simply equated with psychoanalysis. In fact, attachment theory offers a unique perspective on the developmental trajectory of working models and the role played by contextual factors in shaping cognitions and behaviors in adulthood. While contemporary psychoanalysis still views mental representations of self and others in adulthood as mental residues of childhood experiences, Bowlby (1988) believed that the developmental trajectory of working models is not linear or simple and that these mental representations in adulthood are not exclusively based on early experiences. Rather, they can be updated throughout life and can be affected by a broad array of contextual factors, such as current interactions with a relationship partner, the partner's attachment style and dynamics, and a person's current life situation, which can moderate or even override the effects of mental residues of past experiences. Research supports this complex version of the developmental trajectory of working models, with longitudinal studies showing only a moderate level of stability in attachment orientations

from infancy to adolescence and indicating that life events (e.g., parental death) can substantially alter a person's working models (see Fraley, 2002, for a review and meta-analysis of these studies). In this respect, attachment theory, especially as fleshed out by social psychologists, owes a great deal to other conceptual and methodological paradigms in social psychology.

The changing nature of attachment styles and underlying mental representations and affect-regulation strategies is also evident in our model of attachment-system functioning (Mikulincer & Shaver, 2003), in which bottom-up processes initiated by the presence of contextual cues about attachment-figure availability or proximity-seeking viability can alter the functioning of the system. As discussed earlier, attachment theory and research suggest that a particular individual can possess multiple, even conflicting, working models of self and relationship partners beyond the working models that evolved from childhood experiences with parents, and these different models can be contextually activated in experimental settings and have varying effects on cognitions and behaviors (e.g., Baldwin et al., 1996; Collins & Read, 1994; Shaver et al., 1996). Indeed, recent studies have shown that positive effects of contextual priming of security-enhancing representations are also found even among chronically insecure people (e.g., Mikulincer, Gillath, et al., 2001; Mikulincer & Shaver, 2001). Thus, attachment theory does not assert that a person's current attachment orientation must mirror or match his or her attachment orientations with parents during childhood. Rather, the current orientation is a complex amalgam of historical and contemporary contextual factors, which enable the "reworking" of mental representations of self and attachment figures across the lifespan.

There is more to learn about how these changes occur and what psychological mechanisms are involved. Two recent studies provide initial information about the mechanisms, while highlighting the crucial role played by the subjective appraisal of person–environment transactions (Davila & Cobb, 2004; Simpson, Rholes, Campbell, & Wilson, 2003). Simpson and colleagues (2003) examined changes in attachment orientations during the transition to parenthood and found that prenatal appraisals of support and anger explained the way attachment orientations changed across this transition. Specifically, women who perceived less spousal support and more spousal anger during pregnancy became more anxiously attached across the transition, whereas husbands who perceived themselves as providing more spousal support during pregnancy became less avoidant across the transition to parenthood. Davila and Cobb (2004) conducted an 8-week daily diary study, during which participants reported on daily life events and daily levels of attachment security, and found that negative fluctuations in attachment security were explained by the extent to which people appraised the events as involving interpersonal loss. The findings from these two studies indicate that life events can change attachment orientations if people construe the events as disconfirming their chronically accessible working models.

The Relational Basis of Attachment Theory

The preceding discussion of updating working models highlights the importance of the relational context in which the attachment system is activated. Although attachment-system functioning is a reflection of intrapsychic processes related to a person's wishes, fears, and defenses, it can be expressed in behavior (proximity seeking to a relationship partner) and is sensitive to the relational context in general and to the relationship partner's particular responses (availability, responsiveness) on a specific occasion (Shaver & Hazan, 1993). In fact, attachment-system functioning involves real or imagined interpersonal interactions with actual or internalized attachment figures and can be altered by these figures' responses to one's proximity bids. In this respect, attachment theory has a lot in common with interdependence theories of close relationships (e.g., Thibault & Kelley, 1959; Van Lange, De Cremer, Van Dijk, & Van Vugt, Chapter 23, this volume), which focus on the interpersonal interaction as the unit of analysis and emphasize the powerful influence that one person's responses can exert on a partner's cognitions and behaviors. In attachment theory, this interdependence is evident when the attachment system becomes activated and the responses of an attachment figure can affect the operation of the attachment system.

Attachment theory acknowledges the important effects of the relational context on a person's attachment orientation and on relational cognitions and behaviors in a particular interaction (Shaver & Hazan, 1993). In our model (Mikulincer & Shaver, 2003), the three modules of attachment-system functioning can be affected by a partner's behaviors: The partner can be a source of threat and therefore trigger attachment-system activation (e.g., by threatening abandonment or violence) and can affect the appraisal of attachment-figure availability as well as the viability of proximity seeking as a means of achieving security. Moreover, a person's relational cognitions and behaviors depend not only on the functioning of his or her attachment system but also on the partner's attachment behaviors. Indeed, several studies have shown that both partners' attachment orientations contribute uniquely to the prediction of both partners' relationship satisfaction (e.g., Brennan & Shaver, 1995; Collins & Read, 1990). In addition, other studies, using observational techniques, diary keeping, and narrative accounts, have revealed that a person's attachment anxiety and avoidance have differential effects on relational emotions, cognitions, and behaviors depending on the partner's attachment scores (e.g., Collins & Feeney, 2000; Feeney, 2002; Simpson et al., 1992).

It is important to recall, however, that attachment theory is not exclusively relational. As discussed earlier, the theory includes the important idea that the internalization of interactions with attachment figures can be biased by defensive processes related to secondary attachment strategies (e.g., gaining proximity to an insufficiently available attachment figure by hyperactivating the attachment system or avoiding punishment or perpetual frustration by deactivating the system). Because of such bi-

ases, working models of the self and others do not exclusively reflect the ways the person and the partner actually behave in a given interaction. Rather, they are blended reflections of what actually happens in a social encounter as well as subjective biases resulting from attachment working models and strategies.

These defensive biases can also be noted in the subjective appraisal of a partner's responses to one's proximity bids. Whereas anxious people's hyperactivating strategies slant perception in the direction of noticing or imagining insufficient interest, availability, and responsiveness on the part of a partner, avoidant individuals' deactivating strategies increase the likelihood that genuine and clear-cut signals of attachment-figure availability are missed (Mikulincer & Shaver, 2003). These biases reflect a top-down process by which the most chronically activated working models moderate or override the potential influence of a relationship partner's actions, thereby constraining the nature of the interdependent interaction.

Furthermore, attachment-system activation in adulthood can occur intrapsychically without any overt expression in interpersonal behavior and without demanding the intervention of an actual relationship partner. In such cases, a person can search for comfort and security in his or her own mental representations without seeking proximity to or support from an actual relationship. In our recent analysis of security-based self-representations (Mikulincer & Shaver, 2004), we argued that these mental representations can be applied even in situations that are not explicitly social–relational. We showed empirically that secure people are likely to have internalized both self-soothing processes and some of their attachment figures' personal qualities, which they then use when encountering the frustration of failing repeatedly at a laboratory task, even though dealing with feelings of task failure is not particularly social or relational. This is just one example of ways in which attachment-related experiences may affect a person's cognitions and behaviors outside relational contexts. Another example is the case of the avoidant person, in which the dynamics associated with attachment needs, concerns, worries, and pain tend to occur at an intrapsychic, even unconscious, level without necessarily being expressed in interpersonal behavior.

Attachment theory has both intraindividual and interpersonal aspects; it is a prime example of "person by situation" approaches to human behavior. The person in this case is represented by the "hardwired" programming of the attachment behavioral system, the attachment working models of self and others, the procedural knowledge implicit in attachment strategies, and the associative neural networks connecting these strategies to the appraisal of person–environment transactions. The situation consists of the relationship partner's responses and other relevant contextual cues that can affect appraisal of social transactions and alter the functioning of the attachment system. The complexities in this equation stem from the fact that major parts of the "person" component were originally based on variations in the availability and responsiveness of primary caregivers in threatening situa-

tions, and major parts of the "situation" component are shaped by the person's attachment style, which may affect both the appraisal of the situation and the partner's own expressions of love, intimacy, or care. Dropping either the person or the situation component of the explanatory story results in the transformation of attachment theory into either an interdependence theory or a psychoanalytic theory.

Social Cognition Approaches and Attachment Theory

The role assigned by attachment theorists to working models of self and others in guiding attachment-system functioning is similar to the role played by schemas in the field of social cognition (e.g., Baldwin, 1992; Fiske & Taylor, 1991). Both attachment theory and social-cognitions theories emphasize the extent to which people subjectively construe person–environment transactions, store representations of typical transactions (working models in attachment theory terms; schemas, prototypes, or scripts in social-cognition language), and use these representations for understanding new transactions and organizing future action plans. In both theoretical approaches, these mental representations guide and coordinate emotion regulation, self-image, person perception, and cognitions, goals, feelings, and behavior in interpersonal settings. Furthermore, attachment theory conceptualizes working models in the same way social-cognition theorists conceptualize mental representations: They are stored in an associative memory network, maintain excitatory and inhibitory connections with other representations, and have a particular level of accessibility determined by past experiences and other factors, and this accessibility can be heightened in a given situation by relevant contextual cues (e.g., Baldwin, 1992; Collins & Read, 1994; Shaver et al., 1996).

The commonalities between attachment theory and social-cognition theories become even more evident in the analysis of the topics and methods appearing in recent adult attachment studies. As explained earlier, attachment researchers have invested a great deal of energy in assessing attachment-style variations in cognitive structures that had previously been conceptualized and examined in social-cognition research, such as person perception (e.g., Zhang & Hazan, 2002), the accessibility and organization of self-representations (e.g., Mikulincer, 1995), the accessibility of expectations about others' behavior (e.g., Baldwin et al., 1993), the accessibility of memories of social interactions (e.g., Miller & Noirot, 1999), and the way people interpret relationship partners' behavior (e.g., Collins, 1996). Moreover, adult attachment research tends to rely more and more on techniques and methods borrowed from social-cognition research, such as implicit memory tasks, semantic priming techniques, and measuring reaction times in lexical decision and Stroop color-naming tasks (e.g., Baldwin et al., 1993; Mikulincer, Gillath, et al., 2001; Mikulincer, Gillath, & Shaver, 2002).

Despite these commonalities, however, it would be a mistake to equate attachment working models with the

cognitive structures usually studied in social-cognition re- search. In their thoughtful review of the nature, content, structure, and functions of attachment working models, Shaver and colleagues (1996) enumerated four differ- ences between these constructs: As compared to other mental representations, (1) working models also tend to deal with a person's wishes, fears, conflicts, and psycho- logical defenses, and they can be affected by these psy- chodynamic processes; (2) working models seem to have a larger and more powerful affective component than most social schemas and tend to be shaped more by emotion-regulation processes; (3) working models tend to be construed in more relational terms and to organize representations of the self, others, and social interactions in a highly interdependent fashion; and (4) working mod- els are broader, richer, and more complex structures, and can include tandem or opposite representations of the same person–environment transaction at episodic, semantic, and procedural levels of encoding. Overall, at- tachment working models cannot be equated with most other social cognitions, because they evolve not only from simple memories of actual experiences but from dy- namic processes of goal pursuit, emotion regulation, and psychological defenses involved with wishes for proxim- ity and security and fears of separation and helplessness. As a result, they can distort a person's perceptions of so- cial reality, even though many are based on actual social interactions.

These differences call attention to the dialectical ten- sion between the goal-oriented and emotion-regulation functions that working models accomplish. On the one hand, due to the goal-oriented and goal-corrected nature of the attachment system, working models have to be what Bowlby (1973, p. 235) called "tolerably accurate re- flections" of what actually happened in attachment rela- tionships; otherwise, people would not be able to plan effective goal-oriented behavior and attain important re- lational goals. In this respect, working models resemble other cognitive representations that store factual knowl- edge and semantic and procedural information about re- ality constraints and demands. On the another hand, due to the emotion-regulation function of working models, they sometimes have to distort declarative and proce- dural knowledge in order to manage attachment-related fears, worries, and insecurities and protect a person from the distress and pain of attachment-figure unavailability. This dialectical tension between the goal-oriented and emotion-regulation functions of working models seems to be unique to attachment theory and differentiates it from most theories of social cognition.

Positive Psychology and Attachment Theory

The broaden-and-build cycle of attachment security calls attention to the optimistic, hopeful, constructive, and actualization-oriented tone of attachment theory, which makes it different from most other psychodynamic, rela- tional, and social-cognition theories. As already noted, people who possess a stable sense of attachment security generally feel safe and worthy, hold an optimistic and

hopeful outlook of life, rely on constructive ways of cop- ing and regulating distress, and interact with others in a confident and open manner. Moreover, they can devote mental resources that otherwise would be employed in defensive maneuvers to growth-oriented activities that contribute to the broadening of their perspectives and capacities and the actualization of their natural talents. This health- and growth-oriented theme in attachment theory has much in common with the "humanistic psychology" movement of the 1950s and 1960s (e.g., Maslow, 1968; Rogers, 1961) and today's "positive psy- chology" movement (Aspinwall & Staudinger, 2003; Seligman, 2002). Both movements are attempts to coun- terbalance psychology's traditional focus on con- flicts, fears, egoistic defenses, destructive tendencies, and psychopathology by directing attention to human strengths, potentials, and virtues that contribute to self- actualization and the development of what Rogers (1961) called a *fully functioning person*.

According to attachment theory, the sense of security is a basic human strength (Mikulincer & Shaver, 2005). It facilitates the development of other personality charac- teristics that fall under the rubric of "positive" psycholog- ical traits, such as resilience, optimism, hope, positive affectivity, curiosity and exploration, healthy autonomy, a capacity for love and forgiveness, feelings of intercon- nectedness and belongingness, tolerance, and kindness (see Lopez & Brennan, 2000; Mikulincer & Shaver, 2003, 2005; Shaver & Mikulincer, 2002). Moreover, one can easily recognize major similarities between the way the broaden-and-build cycle of attachment security evolves from repeated episodes of attachment-figure availabil- ity and ideas discussed by humanistic psychologists about the parenting style that facilitates a child's self- actualization. For example, the notion of having an available, caring, and loving attachment figure resonates with Maslow's (1968) concept of B-perception— nonjudgmental, forgiving, loving acceptance of another human being, and with Rogers's (1961) view of optimal parenting in terms of "unconditional positive regard." The common idea that recurs across the various theoreti- cal frameworks is that experiences of being loved, ac- cepted, and supported by others constitute the most im- portant form of personal protection and provide a solid psychological foundation for confronting adversity and maintaining equanimity and effective functioning in times of stress without interrupting natural processes of growth and self-actualization.

Recently, we (Mikulincer & Shaver, 2005) reviewed ex- tensive evidence showing that chronic or contextual acti- vation of the sense of attachment security attenuates the defensive motives that social psychologists tend to view as universal, such as the need for self-enhancement, needs for consensus and uniqueness, intergroup biases, defense of knowledge structures, and defense of cultural worldviews. Adult attachment studies have consistently shown that a sense of attachment security acts as a de- fault inner resource superseding defensive needs and rendering defensive maneuvers less necessary. In fact, as explained earlier, these defensive maneuvers and the re-

sulting biases in the appraisals of self, others, and social reality tend to be more characteristic of insecurely attached people. Mikulincer and Shaver (2005) noted that that these defensive needs and maneuvers seem to indicate that a person has been forced by social experiences to transact with the environment without adequate mental representations of attachment security and has had to struggle for a sense of self-worth, despite experiencing serious doubts about being lovable and possessing good inner qualities.

Despite these commonalities, there is an important difference between attachment theory and humanistic or positive psychology. Whereas the positive, humanistic approaches focus mainly on growth-oriented, promotion-focused aspects of development and personality, attachment theory emphasizes both the prevention and the promotion aspects of the attachment system. This dual focus is well illustrated in the two basic functions of "safe haven" and "secure base" served by available, responsive, caring, and loving attachment figures. These figures need to protect a person from threats and dangers; prevent the experience of negative, painful outcomes; and calm the person's fears and conflicts. At the same time, they need to provide a "secure base" from which the individual can take risks, explore the environment, and engage in promotion-oriented activities. Failure to provide either a "safe haven" or a "secure base" results in attachment-related worries and doubts as well as the development of psychological defenses that sometimes compensate for the lack of a sense of security, but at the cost of cognitive distortion, rigidity, narrowness, alienation, and an increase in interpersonal and intergroup conflict. Unlike positive psychology, attachment theory emphasizes both the "dark" and the "bright" sides of human nature and experience and explains how the attachment system deals with fears, anger, conflicts, and defenses, as well as the equally natural capacities for happiness, love, growth, and self-actualization. We believe that it makes sense to explore positive psychology within a framework that also illuminates negative psychology, because they are two natural sides of the same human coin.

CONCLUSIONS

In this chapter, we have emphasized three fundamental, interrelated principles of attachment theory that are crucial for studying and understanding the social mind. *Principle 1* concerns the adaptive, self-regulatory functions of proximity and support seeking: When a person encounters threats and dangers, whether stemming from environmental demands or internal rumination, the attachment system is activated and urgent goals become salient—to gain proximity to, and protection and comfort from, attachment figures. Beyond childhood, a person is also likely to rely on internal images of being supported by attachment figures and feelings of being comforted and supported. *Principle 2* concerns the temporally extended beneficial effects of interactions with available and responsive relationship partners and the resulting

sense of attachment security. The sense of security (or, in cases in which insufficient support is provided, the corresponding sense of insecurity) affects a person's resilience in the face of adversities and hardships, coping strategies and effectiveness, self-image, personal and social adjustment, behavior in social relationships, and personal growth. Many mental and social processes studied by personality and social psychologists working outside the attachment paradigm are affected and moderated by attachment style. *Principle 3* concerns the predictable defensive biases that arise and become established in the mind when failure of the primary attachment strategy, which is to maintain proximity to a security-providing attachment figure, results in hyperactivation or deactivation of the attachment system. According to attachment theory, these two strategies are attempts at adaptation to an inconsistently available or consistently distant or unavailable attachment figure, but once established as salient coping strategies they distort and interfere with emotion regulation, destructively color mental representations of self and others, and contribute to psychological and social problems. Because of the centrality of these principles to any understanding of the human mind, especially its social or relational aspects, the ideas and findings generated by attachment researchers tie together many of the basic concepts and findings of personality, social, developmental, and clinical psychology—whether "positive" or "negative."

Attachment theory acknowledges and integrates different, even seemingly contradictory views of human nature and maintains dialectical tension between opposites of four kinds: (1) the constraining influence of past experiences versus the forces for change in current experiences; (2) the intrapsychic nature of the attachment system, working models, and attachment strategies versus the relational, interdependent nature of attachment-related feelings, experiences, and behaviors; (3) the goal-oriented, self-regulatory function of the attachment system versus its distress-regulation, self-protective function; and (4) the importance of fears, conflicts, and prevention-focused mechanisms versus the importance of promotion-focused mechanisms and the capacity for growth and self-actualization. Given this complexity, when tied to an impressive array of research techniques and paradigms, including those borrowed from contemporary social-cognition research, attachment theory provides a unique and highly generative framework for conceptualizing and empirically exploring the full range of human constructive as well as destructive potentials. It has a remarkable 30-year record of suggesting creative, probing empirical studies that can be integrated into an expanding yet coherent scientific story. The theory shows every indication of being able to benefit from new methods, such as neuroimaging. Future theorizing and research within the attachment tradition promise to result in a comprehensive understanding of social and emotional processes, their development and incorporation into conscious and unconscious mental structures, and their amenability to education and clinical intervention.

Social Power

SUSAN T. FISKE
JENNIFER BERDAHL

Basic principles of social power all follow from power as control over valued resources. People who have what they want—and what other people want—create social forces. Powerholders can be forces for ill or good, reflecting the tension between unconstrained greed and unconstrained generosity. With the unconstrained freedom to do what they want, people's behavior is tempered by their self-interest, ignorance, and exploitative intent, on the one hand, or by their felt responsibility for the welfare of others, on the other hand. We argue that the person, the position, and the situation combine to predict social power's effects for harmful or beneficial behavior.

DEFINING POWER

To analyze power we must define it, not an easy task. Arguably, the concept of power runs so deep that searching for a simple definition is a mistake (Lukes, 1986; Ng, 1980). Many consider power to be the most basic force behind human behavior (e.g., Cartwright, 1959; Russell, 1938), so no wonder power concerns disciplines spanning the social sciences and humanities (i.e., philosophy, psychology, sociology, economics, history, political science, and anthropology). Indeed, the construct of power is so broad that "some students of the subject think that the whole study of 'power' is a 'bottomless swamp' " (Dahl, 1957, p. 201). Despite this morass, the need to be explicit has led to several definitions,[1] which we can group into three categories: (1) power as influence, (2) power as potential influence, and (3) power as outcome control (see Figure 29.1).

Power as Influence

Definitions of *power as influence* define power by its effect (see right side of Figure 29.1). When one person causes, or influences, another to behave a certain way, the former has power over the latter. For example, Simon (1957) defined "A" as having power over "B" when "A's behavior causes B's behavior" (p. 5). According to Dahl (1957), "A has power over B to the extent that [A] can get B to do something that B would not otherwise do" (p. 202). Russell (1938) claimed that "A has more power than B, if A achieves many intended effects and B only a few" (p. 35). Most of the power literature in fact addresses social influence: Compliance, identification, and internalization were processes defined by French and Raven (1959), as well as by Kelman (1958). The social influence literature focuses on the strategies that change behavior as a result of interpersonal interaction (Chaiken, Wood, & Eagly, 1996; Cialdini & Trost, 1998; Turner, 1995). All these focus on the target's response to influence attempts.

We believe defining power in terms of influence is problematic because it defines power in terms of what it *does*, not what in terms of what it *is*. This is a we-know-it-when-we-see-it way of defining power that requires back-

Outcome Control (source of power)	→	Potential for Influence (capacity for effect)	→	Influence (effect of power)

Thibaut & Kelley (1959, p. 101): "The power of A over B increases with A's ability to affect the quality of outcomes attained by B."

Emerson (1962, p. 32): "The power to control or influence the other resides in control over the things he values."

Kipnis (1976, p. x): "access to resources needed by others."

Dépret & Fiske (1993): "asymmetrical control over another person's outcomes."

Max Weber (1914/1978, p. 152): "the probability that one actor within a social relationship will be in a position to carry out his own will despite resistance."

French & Raven (1959, p. 152): "The strength of power of O/P in some system a is defined as the maximum potential ability of O to influence P in a."

Cartwright (1965, p. 4): "If O has the capability of influencing P, we say that O has power over P."

Russell (1938, p. 35): "A has more power than B, if A achieves many intended effects and B only a few."

Simon (1957, p. 5): "For the assertion, 'A has power over B,' we can substitute the assertion, 'A's behavior causes B's behavior.' "

Dahl (1957, p. 202): "A has power over B to the extent that he can get B to do something that B would not otherwise do."

FIGURE 29.1. Definitions of power placed within a causal continuum from source to effect of power.

ward inference to identify the presence of power by its consequence. This definition does not address what it is about power that might lead to influence in the first place.

Power as Potential Influence

Others have defined *power as potential influence*. For example, Weber (1914/1978) defined power as "the probability that one actor within a social relationship will be in a position to carry out his own will despite resistance" (p. 152). Lewin (1944, 1951/1997) described power as the possibility of inducing forces. In one of the most cited papers on power to date, French and Raven (1959) based their "model of influence" on Lewin's conceptions of psychological force fields (Raven, 1993) and defined power this way: "The *strength of power* of O/P in some system *a* is defined as the maximum potential ability of O to influence P in *a*" (p. 152). Cartwright (1965) echoed with, "If O has the capability of influencing P, we say that O has power over P" (p. 4). According to these definitions, power can exist without *actual* influence.

The definitions themselves do not explain the origins of capacity to influence. Many who define power as potential influence view this capacity as stemming from control over valued resources. Cartwright (1965), for example, argued that influence derives from "the possession, or control, of valued resources" (p. 5). Dahl (1957) defined the base of power as "all the resources—opportunities, acts, objects, etc.—that [A] can exploit in order to affect the behavior of [B]" (p. 203). More recently, Manz and Gioia (1983) defined power as "the ability or potential to influence others" (p. 461) through resource control, and Vescio, Snyder, and Gervais (in press) define it as "the potential to influence others in meaningful ways . . . through the awarding and withholding of resources or through punishment." In short, these approaches all define A as having potential influence over B (i.e., power) *because* A controls resources of value to B.

Power as Outcome Control

Others have dropped influence from the definition of power altogether and have homed in on *power as resource or outcome control* (e.g., Dépret & Fiske, 1993; Emerson, 1962; Keltner, Gruenfeld, & Anderson, 2003; Kipnis, 1976; Thibaut & Kelley, 1959). Early advocates of this approach in social psychology include Thibaut and Kelley (1959), who defined power as the ability to affect another's reward–cost position, and Emerson (1962), who claimed "the power to control or influence the other resides in control over the things he values" (p. 32). More recently, Dépret and Fiske (1993) defined power as *asymmetrical control over another person's outcomes* (see also Fiske, 1993), and Keltner and colleagues (2003) defined it as "an individual's relative capacity to modify others' states by providing or withholding resources or administering punishments" (p. 265). Rather than identifying power by its consequences, these definitions identify it in the structural properties of social relations. This is the approach we adopt. We define power as *relative control over another's valued outcomes*.[2]

We believe influence effects need to be separated from the control of outcomes per se, whether or not the influence attempt is successful or even intended in the first place. People who control others' outcomes have power, like it or not. They may not even intend or want to use their power, though the control of valued outcomes gives them the potential. Making influence part of the definition of power presupposes target volition (Raven, 1993). It conflates a structural feature, the powerholder's control over valued outcomes, with a psychological factor, the target's choice to cooperate with an influence attempt (Dépret & Fiske, 1993; Fiske & Dépret, 1996). In that view, power is ceded by the powerless, which seems ironic. Control over valued outcomes still constitutes power, even if the target chooses to resist. That is, the target may care about the outcomes, even while refusing to enact the powerholder's conditions for obtaining the outcomes desired. *Power over* someone persists, even without the *power to* make the person comply.

**Implications of Defining Power
as Relative Outcome Control**

Defining power as relative control over another's valued outcomes has implications for how power is conceptualized and measured as well as the different types of power possible.

Power Is Relative

As the relative control over another's valued outcomes, power is always socially situated, hence our title, "Social Power." *Relative* means that power is an inherently comparative construct, defined within a particular social relationship. Power is not an "attribute" of an individual but a structural property of a social relation that derives from relative control over outcomes. That is, one cannot say that someone has power without specifying over *whom* (Arendt, 1960; Emerson, 1962; French & Raven, 1959; Wartenberg, 1990). A person can be powerful in one context and powerless in another. Some individuals may be more likely than others to obtain power in social situations when it is up for grabs; some may be used to having power and conditioned to experience and view the world from that perspective. In a given social relationship, however, these people may be interacting with another who is even more likely to obtain power or to experience it in daily life. Therefore, researchers must measure the relative power between individuals in a social situation, particularly their relative control over each other's outcomes, and not treat power as an individual-level construct or characteristic. Later, we distinguish social power from having a dominant personality and related constructs.

Control Varies

The relative *control* a powerholder has over another's outcomes stems from the powerholder's ability to administer or withhold rewards or punishments (Dépret & Fiske, 1993; Emerson, 1962; Keltner et al., 2003; Kipnis, 1976; Thibaut & Kelley, 1959). This control can vary in how formal, stable, and legitimate it is. Formal control is accompanied by an official title or explicit role (e.g., "boss"), whereas informal control is designated through social roles and status (e.g., typically, rich people are dominant, and poor people are subordinate). Control can range from being stable, not easily lost or removed (e.g., a physical advantage) to being unstable, easily usurped (e.g., an elected position). When control is unstable, power differences between two people (or parties) is likely to vary over time and is a state, rather than a trait, of the relationship. Finally, the control over another's valued outcomes may be considered legitimate (e.g., based on merit) or illegitimate (e.g., based on luck). The nature of a powerholder's control over another's outcomes affects the use and consequences of power. For example, power should be greater, and influence more likely, when control is stable and legitimate. A powerholder should be more likely to use "harsh" tactics of influence (Raven,

1992, 1993) when control is formal, stable, and illegitimate but "soft" tactics of influence when it is informal, unstable, and legitimate (Kipnis, 1972).

Outcomes Vary

As the relative control over another's *valued outcomes*, having power depends on the ability to control outcomes that others desire, in other words, outcomes that affect others' well-being. Food, safety, material goods, social acceptance, and the well-being of loved ones are but a few examples. Given the number of valued outcomes that someone else can control, classifying outcomes into a broad framework is useful. Primary categories certainly include physical, economic, and social outcomes.

   Physical outcomes define a person's health and safety, such as food, shelter, physical harm, and physical pleasure. *Economic outcomes* define a person's material well-being. Money and tangible goods are obvious examples, but evaluations, opportunities, and formal positions that determine economic rewards also fit into this category.

   Social outcomes define a person's societal and interpersonal well-being. These outcomes include at the core (1) social belonging (acceptance), arguably essential to people's survival in both ancestral and current times (Fiske, 2004). Belonging is intensely motivating (Baumeister & Leary, 1995), and it has even been defined as the core basis for power (Vescio, et al., in press). Other social outcomes that facilitate belonging all acquire value as means or measures of it. For example, another core outcome, (2) socially shared understanding, provides information about norms, which enable people to belong; providing or withholding normative information can be a source of power. Likewise, providing or withholding (3) a sense of social control is a crucial outcome; a powerholder can be predictable and responsive, encouraging people's own effectiveness, or not. Senses of understanding and control are social cognitive outcomes that powerholders can facilitate or impede. Less cognitive, more social–affective outcomes include facilitating or impeding another's (4) self-enhancement (via support, respect, and affection) and (5) social trust (creating benign, reliable ingroup expectations). These social outcomes—belonging, understanding, controlling, enhancing, and trusting—together constitute strong social incentives held by the powerful.

BASES OF POWER

All three types of outcome—physical, economic, and social—affect the well-being of individuals and are therefore likely to be valued results that, when controlled by someone else, give the controller power over the individual whose outcomes are controlled. In this way, physical, economic, and social outcomes form different bases of power. In the single most influential view of power to date, French and Raven (1959) outlined six different bases of power. Their bases of power resulted from analyzing the kinds of resources a person might use to exer-

cise influence: rewards (e.g., support, benefits, favors), coercion (annoyance, abuse, making trouble), legitimacy (socially accepted obedience, duty to conform, right to order), expertise (reputation for knowledge, intelligence, judgment), reference (ideal, model, aspiration), and information (persuasion, logic). According to our definition of power as outcome control, French and Raven's reward and coercive power *is* power, period. Their other bases of power describe the variety of resources a powerholder can wield to try to influence another, consistent with their definition of power as potential influence. In our view, legitimacy, expertise, reference, and information power are bases of power insofar as they yield reward or coercive power—in other words, control over another's outcomes.

French and Raven's bases of power have provided useful insight into different types of power. Global measures of perceived power relate to these bases of power and more (Nesler, Aguinis, Quigley, Lee, & Tedeschi, 1999). A later revision, the interpersonal power interaction model (IPIM; Raven, 1993, 2001) expanded these bases by subdividing sanctions (into impersonal, e.g., tangible, vs. personal, e.g., approval), legitimacy (into formal position, reciprocity, equity, and responsibility), expertise and reference (both into positive and negative), and information (into direct and indirect, e.g., overheard). This provides a detailed framework of the resources one might leverage to influence others.

The IPIM examines both target and agent. IPIM takes a cost–benefit approach to strategy choice (Koslowsky & Schwarzwald, 2001). Consistent with this approach, it notes that all the original French–Raven bases of power involve volition on the part of the target (Raven, 1993). The target theoretically can decide whether or not to cooperate, depending on the relative costs and benefits. The IPIM adds two new bases of power—force and manipulation—that do not fit their earlier volitional view. Brute force ignores the target's volition, by definition. And manipulation of the target's environment to force or prevent behavior likewise bypasses target volition, unless the target is able to exit the situation, knows it, and chooses to do so. Including target volition in the conception of power is problematic because targets may not have or perceive better alternatives. When a target refuses to go along, theorists have taken it as evidence of reduced power differential, when in fact someone controlling the target's outcomes has power over the target regardless of the target's choice.

Harsh and Soft Power

A series of scales has emerged to measure Raven's expanded list of perceived bases of power. The Interpersonal [Bases of] Power Inventory (IPI; Raven, Schwarzwald, & Koslowsky, 1998) validates 7 factors of the revised 11 bases from the subordinate's perspective. A further factor analysis of these 7 scales demonstrates a two-factor solution, identifying (1) *soft or weak bases*: use of credibility (expert and information power), referent and personal reward power, or legitimate power (de-

pendence) to influence a target through the trust, respect, and liking associated with these bases of power; and (2) *harsh or strong* bases: use of sanctions (impersonal rewards and punishments and personal punishments) and legitimate power (equity, reciprocity, and position) to influence a target with the mostly economic rewards associated with these bases of power (Raven et al., 1998).

Another way to view the distinction between soft and harsh forms of power is that soft power uses social outcomes (e.g., liking and respect) and harsh power uses economic and physical ones to attempt to influence a target. Outcomes vary in how concrete they are, with implications for ease of analysis by both lay and scientific observers. Physical, economic, and social outcomes together array on a continuum from tangible to intangible, or objective to subjective, with physical outcomes on one end (objective/tangible) and social outcomes on the other (subjective/intangible). Power differentials should be more obvious to the degree that they reflect objective, tangible outcomes, but differentials should be less obvious to the degree that they reflect subjective, intangible outcomes. Thus, the use of power is easy to recognize when it entails tangible outcomes (e.g., an economic bribe or a physical threat), and may more likely be considered "harsh," than when it entails intangible outcomes (e.g., liking and respect), more likely considered "soft."

The terms "harsh" and "soft," however, should not be confused with how threatening and effective these different forms of power are. The use of physical power is not necessarily more threatening or effective than the use of economic power and the use of economic power is not necessarily more threatening or effective than the use of social power. What matters is value. The strength (i.e., threat) of power depends on the value of the outcome controlled. Because social belonging is a primary value of critical importance to most people, using this outcome to wield power is likely to be quite threatening and effective, even if the exercise of this power appears "soft" or is difficult to recognize as a coercive tactic.

Raven and colleagues' (1998) "harsh" and "soft" power distinction fits other analyses (Bass, 1981; Elias & Loomis, 2004; Erchul, Raven, & Ray, 2001; Kipnis, 1984; Yukl & Falbe, 1991). Soft, relational power works well. Relational power predicts subordinate job satisfaction and compliance, consistent with the leadership literature (Bass, 1956; Erchul, Raven, & Whichard, 2001; Gerster & Day, 1997; Imai, 1991, 1994; Koslowsky, Schwarzwald, & Ashuri, 2001; Lowe, Kroeck, & Sivasubramaniam, 1996; Mullen, 1991; Raven et al., 1998; Wofford & Liska, 1993). In one setting, reference (relational) power mediated the effects of all other kinds of power on job performance (Rahim, Antonioni, & Psenicka, 2001). Women tend to show relational types of leadership (i.e., transformational and contingent transactional), rather than management by laissez-faire or by exception (Eagly, Johannesen-Schmidt, & van Engen, 2003). The relational style tends to work well for both genders when they use it. Note, however, that the contrast here falls between relational as respect, liking, and task-contingent rewards, on the one hand, and autocratic as sheer legitimacy with sporadic

punishment, on the other hand. Thus the distinctions overlap but are not identical.

In a praiseworthy variety of applied research settings, harsh and soft power demonstrably vary in effectiveness, but the pattern tends to favor soft power: Relating instructor power bases and undergraduate compliance, soft bases of power were especially effective for African American men (Elias & Loomis, 2004). In school consultants, teachers, and psychologists favored soft power (standard forms of information, expert, legitimate, and reference power; Erchul, Raven, & Ray, 2001; Erchul, Raven, & Wilson, 2004). In hypothetical doctor–patient scenarios, soft power again is rated most effective (information, referent, and expert power; Brown & Raven, 1994). Relating faculty power bases and graduate student outcomes, expert power (soft) and reward power (can be either) were especially effective (Aguinis, Nesler, Quigley, Lee, & Tedeschi, 1996). This taxonomy also applies to case studies analyzing historic political encounters (Gold & Raven, 1992; Raven, 1990, 2001) and mechanisms of religious influence (Raven, 1999, 2001). In numerous organizational settings, as just noted, soft power predicts subordinate job satisfaction, and expert power specifically (a component of soft power) seems to influence effectively everywhere.

Some studies do not use French and Raven's taxonomy but still examine influence tactics that could be mapped onto soft and harsh. Managerial preference across cultures (U.S. and Latin American) for conflict resolution tactics rank advising and mediation (soft) first in the United States, Argentina, and Mexico, and autocratic arbitration ("inquisitorial," harsh) second (although those ranks reversed in Dominican Republic); all rejected avoidance/ignoring and mostly rejected providing impetus/incentives; an adversarial/arbitration process was seen neutrally (Cropanzano, Aguinis, Schminke, & Denham, 1999).

Across vignettes varying jobs, roles, and goals, student-rated consensus ranked rationality, ingratiation, assertiveness, and exchange, in that order; note that the first two are softer than the last two (Aguinis, Nesler, Hosoda, & Tedeschi, 1994). Manager role-congruent strategy (direct influence) may also be favored (Aguinis & Adams, 1998); this could be harsh or soft. Note, however, that some studies merely ask people what they prefer, creating issues of demand, self-presentation, and lack of introspective access. Other studies ask about subordinate satisfaction or examine measures of effectiveness, which probably better index the different exercises of power.

One of the founders of work on the social psychology of power, David Kipnis (2001), just before his death, contrasted strong, controlling (harsh) tactics with rational and weak (soft) tactics. His metamorphic theory of power (Kipnis, 1976, 1984) notes that when the powerholder controls someone overtly, both of them attribute the target's actions to force; the powerholder then demeans the subordinate for being weak, and the subordinate resents the powerholder. Also, the desired behavior ceases as soon as surveillance ceases. When powerholders use rational (expert), relational tactics, both parties perceive

choice, each respects the other, the subordinate has self-respect, and the desired behavior is self-sustaining.

POWER AND STATUS

Much informal debate in the field contests whether power and status, often used interchangeably, are in fact distinct constructs. In our view, both are distinct structural positions. Status is a structural position (either formal or informal) involving relative respect and esteem, and it can be a form of power (outcome control). Status relates to power in that it yields control over social outcomes of value to others, namely, liking and respect. That is, people generally want to be liked and respected by those who are relatively high in status. As such, high-status individuals often have social power over others. Although both are structural positions, status and power are distinguishable, because only power necessitates outcome control. One may have high status and low outcome control, as in a lame-duck administrator. Or, one may control resources but have a position that lacks the respect, as in a low-status gatekeeper. Status entails formal position (legitimacy, in French & Raven's terms), but outcome control is separable.

An alternative taxonomy of power (Bass, 1960) provides a different way to think about status by focusing on personal and positional power, at a more abstract level than the French–Raven bases of influence (Yukl & Falbe, 1991). *Positional power* includes legitimacy and sanctions (reward, coercion), whereas *personal power* includes referent (relational) and expert power, which can be independent of one's position in an organization. *Political power* adds coalition building and decision control (Yukl, 1989). Because social status correlates with various kinds of outcome control (economic, social, and physical), observers therefore view it as a form of power.

ANTECEDENTS OF POWER

Demographic Antecedents

Whence comes power? Expectation states theory argues that certain characteristics confer status and afford power (Berger, Cohen, & Zelditch, 1972). For example, when they barely know each other, juries are more likely to pick as foreperson men over women, older people over younger ones, and whites over people of color (e.g., for gender, see Beckham & Aronson, 1978). In effect, certain fixed characteristics are treated as if they are resources, which then contribute to people in fact controlling resources.

Similarly, social role theory (Eagly, 1987) also argues that certain demographic groups are more likely than others to land in certain social roles, leading observers to attribute stereotypic personality characteristics (e.g., leadership qualities) to group members that may result more from their most frequent roles than from the individuals' own dispositions. Thus, women and men disproportionately and respectively inhabit caretaking and

breadwinning roles, so people infer that women are communal nurturers and men are agentic leaders.

The result is that demographic characteristics predict who is seen as powerful. Women are implicitly associated with egalitarian structures and men with hierarchical ones, especially by male perceivers (Schmid Mast, 2004). Hierarchical associates include *rank*, *status*, and *hierarchy*, whereas egalitarian associates include *equality*, *egalitarian*, and *similar*. Note that all terms reflect status (social position) not simply power (resource control). These gendered associations doubtless reflect a mix of expectations and self-selection. That is, women are devalued in traditionally male domains (for a meta-analysis, see Eagly, Makhijani, & Klonsky, 1992). But women are also less motivated to lead in hierarchically organized settings (for a meta-analysis, see Eagly, Karau, Miner, & Johnson, 1994) and use a less autocratic or directive style when they do lead (for a meta-analysis, see Eagly & Johnson, 1990). Consistent with these gender differences in hierarchy, all-male groups are more hierarchical than all-female groups, as indicated by speaking time (Schmid Mast, 2002a), yielding to interruptions (Schmid Mast, 2002b), and patterns of leadership centralization (Berdahl & Anderson, 2005). Also consistent are gender differences in social dominance orientation (SDO); men on average score higher on beliefs that group hierarchies are inevitable and good (Pratto, Stallworth, & Sidanius, 1997) and are less likely to prefer egalitarian norms in their ideal company or team (Berdahl & Anderson, 2005). Hierarchies differentiate on the basis of status, most often yielding power to those at the top.

Traditionally male domains also favor perceived male power. Perceived coercive, expert, and informational power all favor men, as rated by men (Elias, 2004). Men link bodily force to power, whereas women link bodily force to loss of power. Making a fist activates power concepts for both genders, but for men it also activates hope for power and favoring an assertive target, with the opposite results for women (Schubert, 2004). All these patterns correlate with the roles that men and women each disproportionately inhabit, but of course the causality can go from roles to associations, from associations to roles, and from third variables (e.g., testosterone) to both.

Although gender has been most studied, other fixed indicators of status include height (Wilson, 1968) and age (Berger et al., 1972; Mazur, 1985). Physical attractiveness predicts men's actual social status in groups (where status is defined as prominence, respect, and influence; Anderson, John, Keltner, & Kring, 2001). But baby-faced individuals come across as weak (Zebrowitz-McArthur & Montepare, 1989), and large eyes signal low dominance (Keating & Doyle, 2002). Of course, this type of appearance indirectly implicates gender as well, which appears throughout the relationships between status and power.

Personality Antecedents

Just as the Lewinian tradition has equated power with its frequent consequences (social influence), the personality approaches to power equate power with needs for general agency (causing changes in the environment), for personal control, for social dominance, and for social influence. The general need for agency dates back a century. Groos (1901) argued that people feel "joy in being a cause" (p. 385); White (1959) described a fundamental effectance motive that seeks competence; deCharmes (1968) posited the importance of personal causation. A need for mastery (Maslow, 1970; McClelland, 1976) theoretically builds self-esteem. A basic striving for power appears in work by Sullivan (1947) and Adler (1966). Ever since, many psychologists agree that people generally, as social beings, have motives both to predict and to control their outcomes, although people in the West tend to prefer personal control more than people in the East, who tend to prefer harmony and group control (Fiske, 2004; Morling & Fiske, 1999).

Individuals also differ in the extent to which they seek to control their own outcomes and to dominate other people. For example, people vary in need for personal control (Rotter, 1966), (own) mastery orientation (Dweck & Elliott, 1983), and self-efficacy beliefs (Bandura, 1977). And individuals differ in need for power over others (McClelland, 1976; Winter, 1975); high need for power predicts making oneself visible and taking risks to do so (McClelland & Teague, 1975; McClelland & Watson, 1973; Winter, 1973). Leaders high in need for power handle conflict and stress in their groups less well (Fodor, 1984, 1985), share less information and consider fewer ideas (Fodor & Smith, 1982), and produce more negative self-views among their subordinates (Fodor & Riordan, 1995). People high in need for power positively evaluate followers who ingratiate themselves (Fodor & Farrow, 1979). People high on need for dominance also like ingratiators (Gough, 1990; Murray, 1938; Operario & Fiske, 2001; Rotter & Hochreich, 1975), but they do not respect them (Operario & Fiske, 2001).

Similarly, personality matters to preferred influence strategies (Koslowsky & Schwarzwald, 2001). For example, high need for achievement correlates with tight control strategies (Raven, Freeman, & Haley, 1982), and high authoritarianism correlates with coercive and legitimacy-based influence strategies (Adorno, Frenkel-Brunswick, Levinson, & Sanford, 1950; Altemeyer, 1988). An often-forgotten point: High authoritarians also submit to the influence of their own superiors. These results suggest that authoritarians are especially sensitive to power differences and are likely to exaggerate normal reactions to power inequality, such as using more coercive tactics when powerful and more ingratiating ones when powerless. An intriguing connection may link some forms of self-esteem to authoritarianism: Low self-esteem individuals use harsh influence strategies, without regard for the target's feelings (Raven & Kruglanski, 1970). Perhaps they feel threatened or see the world as more dog-eat-dog. People high on power motives (ability, need, and enjoyment of influence; Bennett, 1988) also see others as wielding power (Imai, 1993); from their perspective, power is everywhere, and they have to behave accordingly.

ACTUAL VERSUS PERCEIVED POWER

Power is not a consequence (influence) or an individual attribute (personality), it is outcome control. To be effective, people must know or believe the powerholder controls their outcomes. Actually controlling physical, economic, and social outcomes is power, with the potential and sometimes the consequence to influence, in our perspective. For example, listening to a discussion but withholding decisive information would constitute actual power but not perceived power. Surprisingly little work addresses how people discern who controls or might control outcomes.

Perceived power is partially captured by the IPI (Raven et al., 1998), described earlier, but also by a Perceived Social Power Scale (Imai, 1989), tapping perceptions that another person controls valued outcomes corresponding to five of the French–Raven bases: reward, coercion, expertise, legitimacy, and reference. People tend to try to influence those who control rewards (Imai, 1993). In vignette studies, coercive and reward power each inflate ratings of both referent and legitimate power (Aguinis, Nesler, Quigley, & Tedeschi, 1994). Although rewards matter, legitimate position as a power basis can be central: Being the supervisor, having the right to make requests, creating an obligation to obey (all features of legitimacy) matters most in both American and Israeli (Raven et al., 1998), as well as Japanese, data (Imai, 1989). While the former datasets pertain to supervisors, the latter ranges from parents to friends to supervisors and subordinates, so the importance of legitimacy generalizes.

Perceived status does not just come from actual roles and positions but also from correlated cues. Expectation states theory, described earlier, explains demographic effects on perceived status by nonverbal mediation. People can in fact assess each other's organizational status accurately, based on nonverbal cues in photographs (Schmid Mast & Hall, 2004). Note that this study defines status as we do power: ratings of control or influence and access to restricted resources, so it seems relevant to actual power. Accurate judgments of women's power used downward *head tilt*, whereas accurate judgments of men used more *formal dress* and *forward lean*. Perceivers also used lowered eyebrows and forward lean for women, and age for men, to judge power, but these cues did not increase their actual accuracy. To judge the related personality trait of assertiveness (Schmid Mast, Hall, Murphy, & Colvin, 2003), accurate judgments of women used *stumbling speech* and *erect posture*. Accurate judgments of men also used *erect posture*, as well as *fillers* and *looking while listening*. For accurately judging women, observers specifically had to avoid judgments based on speaking time and looking while speaking; to be accurate for men, they marginally had to avoid pleasant speech style and talking with hands.

In addition to the demographic and physical traits, personal traits such as perceived credibility impact perceived power (Nesler, Aguinis, Quigley, & Tedeschi, 1993). Credibility—defined as objective truthfulness, follow-through, and accuracy—resembled informational and expert bases of influence but may be viewed as a more personal version of perceived power. One could possess information or have a reputation for knowledge (informational or expert bases) without being an honest broker of it (personally credible). Nevertheless, credibility is closely related to the French–Raven control over information as a basis of potential influence (Eyuboglu & Atac, 1991; Pettigrew, 1972; Raven, 1974, 1988; Raven & Kruglanski, 1970; Yukl & Fabe, 1991).

But how are personal characteristics, such as credibility, communicated? Although many general principles of power's nonverbal cues currently elude us, power does influence eye gaze, which also influences perceived power. Gender enters here, again. In actual interaction, visual dominance ratio (gaze while talking vs. listening) links to manipulations of both expert and reward power for both genders (Dovidio, Ellyson, Keating, Heltman, & Brown, 1988). Both genders, when in tasks linked to their own gender (placing them in positions of expert power), show visual dominance, and men show it in mixed-sex dyads on neutral tasks (Dovidio et al., 1988), consistent with expectation states theory. These differences evaporate when both participants receive training on the topic, whether gender related or neutral (Brown, Dovidio, & Ellyson, 1990), again supporting the importance of expertise. Direct manipulations of status per se, as well as personality measures of expressed control, similarly affect visual dominance (Ellyson, Dovidio, Corson, & Vinicur, 1980).

People apparently know all this, because when observing videotaped speakers with varying gaze dominance ratios, attributions of power increased with look–speak and decreased with look–listen rates (Dovidio & Ellyson, 1982). In vignettes describing male dyads, direct eye contact indicated credibility to perceivers (Aguinis, Simonsen, & Pierce, 1998). For a woman interacting with a man, direct eye contact instead increased her perceived coercive power (Aguinis & Henle, 2001).

In the same pair of studies, going beyond gaze, the manipulated descriptions of nervous versus relaxed expressions reliably indicated both females' and males' perceived referent, reward, legitimate, expert, and credibility power, as well as males' coercive power. Other facial expressions have influenced perceived dominance: happy, angry, and surprised faces, but not sad and fearful faces (Montepare & Dobish, 2003), as well as not smiling (Halberstadt & Saitta, 1987; Keating et al., 1981). Expressing anger as opposed to sadness for a transgression can confer status (Tiedens, 2001). Apparently, conveying one's harmlessness or agreeableness can communicate submission. Indeed, subordinate women who prefer that position did smile more (Schmid Mast & Hall, 2004; see also Schmid Mast & Hall, 2003). Thus, gaze and facial expression interact with gender to communicate power.

Posture can also communicate power. We saw earlier that erect posture communicates status (probably power). Postural expansion (limbs spread out from body) also communicates power (Argyle, 1988; Aries, Gold, & Weigel, 1983; Eibl-Eibesfeldt, 1989; Gifford, 1991; Mehrabian, 1972; Spiegel & Machotka, 1997). When people adopt expanded or conversely constricted posture, other people get the message and tend to recipro-

cate the complementary posture (Tiedens & Fragale, 2003). Unlike other kinds of nonverbal communication, where mimicry creates comfort (Chartrand & Bargh, 1999), for dominance and submission, complementary posture instead creates comfort and liking.

Talking time reliably elicits perceived dominance, especially for men (for a meta-analysis, see Schmid Mast, 2002a). People are not necessarily wrong to judge so; people express dominance through speaking time, especially assigned a dominant role. But perceivers apparently exaggerate the relationship.

SOCIAL PSYCHOLOGY OF POWER: AMBIVALENT MOTIVES

Relative control over valued resources—our definition of power—creates for powerholders a tension between independence from others and responsibility for others.[3] On the one hand, powerholders are relatively free to pursue their own goals with little interference. On the other hand, powerholders are in a position to assist others in pursuing their own goals. These two themes, the evil and virtue of power, reflect two overall approaches in the literature, which contrasts the exercise of power for worse or better, for greed or for good. This dual nature of power taps the basic issue of self versus other, individual versus group, which may help explain why power is considered such a fundamental concept to so many social science disciplines.

Power as Independence

Most of the literature on power to date emphasizes the independence that relative control over valued outcomes affords the powerful and the relative dependence that a lack of control means for the less powerful, along with the positive implications of this arrangement for the powerful and the negative implications for the powerless. For example, power's lack of constraint enables rewards and freedom, encouraging positive affect and approach tendencies, and lacking power activates a threat orientation, negative affect, and inhibition (Keltner et al., 2003). Consistent with this perspective, people who are situationally powerful are more likely than those who are not to speak their mind, see others as liking them, and experience more positive relative to negative emotions (Anderson & Berdahl, 2002; Berdahl & Martorana, 2006), and when power is primed in individuals, they are more likely to take action, whether it is pro- or antisocial in nature (Galinsky, Gruenfeld, & Magee, 2003).

People need to feel control, some contingency between how they behave and what happens to them, between what they do and what they get (as noted earlier, Fiske, 2004, reviews the control literature). Because powerholders control valued resources, their own needs for control are met, whereas the relatively powerless are left out of control, uncertain about their fates. The *power-as-control (PAC) model* takes these ideas seriously (Fiske, 1993).

Attention and Accuracy

For the powerless, their dependence means that they must observe the powerful to understand the contingencies for receiving valued outcomes. Manipulating outcome dependency reliably makes the powerless attend to the powerful, especially their unexpected qualities (most informative); the powerless view the powerholders in more individuated and idiosyncratic ways. Beginning with symmetrical outcome dependency (Erber & Fiske, 1984; Neuberg & Fiske, 1987; Ruscher & Fiske, 1990; Ruscher, Fiske, Miki, & van Manen, 1991), people reliably attend to the person who controls their outcomes, especially to the most diagnostic (unexpected) information; they make dispositional attributions and reach impressions idiosyncratic to their own perspective. Subordinates better recall their superiors' nonverbal behavior than vice versa (e.g., Hall, Carter, & Horgan, 2001). They do not necessarily increase accuracy, but they are motivated by a need to feel accurate. The initial work on symmetrical outcome dependency confounded own dependency with responsibility for the other, as when teammates or competitors both depend on and control each other's fates. However, subsequent studies showed the same attentional and accuracy motivation effects for those who are asymmetrically outcome dependent, here defined as powerless (Dépret & Fiske, 1999; Goodwin, Gubin, Fiske, & Yzerbyt, 2000; Stevens & Fiske, 2000).

Motivation to be accurate mediates the effects of outcome dependency on impression formation (Neuberg & Fiske, 1987). Consistent with the idea of accuracy motivation, less powerful negotiators ask more diagnostic questions of their partners, as a result of greater accuracy and impression motivation (De Dreu & Van Kleef, 2004). Although people are motivated to believe they are accurate, of course they may or may not actually be more accurate. Powerful groups indeed can be less accurate (Ebenbach & Keltner, 1998; Keltner & Robinson, 1997), but that need not always be the case. At a minimum, people reliably attend upward more than downward, consistent with the effort to control (or at least predict) their own outcomes, the main mechanism of the PAC model. Powerful people are freed from constraints imposed by external control, so they can operate as they would by default.

Stereotyping and Discrimination

Besides being unconstrained, as predicted by PAC, powerholders may be motivated to neglect or oppress their subordinates in order to maintain the status quo. That is, they may operate not only by default but by design. Powerholders could use negative stereotypes to legitimate their privileged position. Some evidence fits this interpretation. Powerholders use stereotypic categories more than individuating traits (Goodwin et al., 2000), and this stereotypic focus holds especially for negative stereotypes and for illegitimate power positions, consistent with the idea that threatened powerholders use demeaning stereotypes to legitimate their positions (Rodriguez-Bailon, Moya, & Yzerbyt, 2000).

The first experiments to show self-serving effects of power used the minimal group paradigm, in which people are arbitrarily assigned to ingroup and outgroup and then have the opportunity to distribute rewards. When power was explicitly manipulated, powerful group members discriminated against subordinate group members; they felt comfortable and satisfied in doing so (Sachdev & Bourhis, 1985). As power levels increase, evaluations of others become increasingly negative and evaluations of the self become increasingly positive (Georgesen, & Harris, 1998, 2000). When status (prestige, skill) was manipulated orthogonally to outcome control and group size, both power and status predicted discrimination, especially for numerical minorities. High-status minority powerholders discriminated the most, and low-status minority subordinates discriminated the least, even showing outgroup favoritism (Sachdev & Bourhis, 1991). These results fit justifying the status quo hierarchy, especially under threat. That is, both high- and low-status minorities both gave resources to the higher-status groups. The twist here is that even subordinates justify the hierarchy; we return to this point.

Other research implicates the unconstrained use of power as begetting social ills. Sexual harassment constitutes a form of power abuse. Among men with a proclivity to sexually harass (individual differences in likelihood to sexually harass), subliminally priming power caused them to find a female subordinate more attractive (Bargh, Raymond, Pryor, & Strack, 1995). The link between organizational power (i.e., control over economic outcomes) and sexual harassment has long been known. The first and most widely recognized form of sexual harassment—quid pro quo harassment—involves an organizational superior promising or threatening work-related outcomes to a subordinate in exchange for sexual cooperation. In addition to control over economic outcomes, however, sexual harassers can use control over physical and social ones (i.e., their relative physical might and social status) to harass targets. This helps to explain why "contra-power harassment" is possible: Subordinate males sexually harass their female superiors (DeSouza & Fansler, 2003; McKinney, 1992). It also explains why men who are particularly concerned with protecting their status as men are most likely to harass (Maass, Cadinu, Guarnieri, & Grasselli, 2003), and why women (and men) who threaten male supremacy are most likely to be targeted (Berdahl, in press; Dall'Ara & Maass, 2000; Maass et al., 2003).

Regardless of its intent, the behavior of powerholders can have enormous impact on subordinates. In cross-gender interactions, powerful men praise powerless women but withhold resources from them; women treated this way feel angry, and their performance suffers. Male subordinates treated similarly by a powerful man also feel angry, but it apparently motivates them to perform better (Vescio, Gervais, Snyder, & Hoover, 2005). The fit between the stereotypes and the power positions seems to matter. That is, because female stereotypes include weakness, their stereotype fits the subordinate position as well as influence strategies that patronize them as subordinate (Vescio et al.,

2005). Power interacts with gender once again, in this case reinforcing male dominance.

In dyads, regardless of gender, the powerful tend to influence the subordinate, as suggested by the conflation of power and influence in the literature. For example, powerholders are more able to influence subordinates to confirm their expectancies about them because subordinates are motivated to have an agreeable interaction (Copeland, 1994). Arguably, subordinates are motivated to get along, and powerholders are motivated to get to know (Snyder & Kiviniemi, 2001). When getting to know entails a stable impression, such powerholder motivations merely confirm expectations, both perceptually and behaviorally (Snyder & Haugen, 1994, 1995). In close relationships, less powerful partners adjust to more powerful partners, becoming more emotionally similar over time (Anderson, Keltner, & John, 2003). In decision-making contexts, the less powerful tend to go along with the preferences of the more powerful (Agnew, 1999; Anderson & Berdahl, 2002), unless going along violates a strongly-held belief (Berdahl & Martorana, 2006).

System Justification

More generally, societal theories of power particularly emphasize the system-justifying nature of dominant ideology, or the ideology of the powerful group that also may get adopted by the powerless (Bourdieu, 1972/1977; Engels, 1902/1942; Jost & Banaji, 1994; Jost, Burgess, & Mosso, 2001; Marx, 1867/1987). High-status groups can justify the system and maintain their position, whereas low-status groups justify the system only at their own expense. Evidence indicates that they do so. Not surprisingly, low-status groups exhibit ambivalence toward their own group, especially when they are told or they believe status differences are legitimate (Jost & Burgess, 2000). Low-status groups favor high-status groups and attribute intelligence and responsibility to them, and they do this especially when explanations (even meaningless) are provided for the power difference (Haines & Jost, 2000). The most socially disadvantaged groups are most likely to defend and justify the status quo (Jost, Pelham, Sheldon, & Sullivan, 2003). What is more, low-status groups favor high-status groups even on implicit measures (Jost, Pelham, Brett, & Carvallo, 2002).

Clearly, people do systematically defend the societal bases for hierarchy. For example, people overwhelming report that high-status groups are more competent than low-status groups, around the world (Cuddy, Fiske, & Glick, in press; Cuddy, Fiske, Kwan, et al., in press; Fiske, Cuddy, Glick, & Xu, 2002). Stereotypes of poor people as incompetent and not especially nice, perhaps even exploiting the system, occur in over a dozen cultures (Cuddy, Fiske, & Glick, in press), and they predict observers' disgust, passive harm (exclusion), and active harm (attack) (Cuddy, Fiske, Kwan, et al., in press). Although most poor people elicit a mixture of pity and contempt, subtypes of poor people may prompt pity, for example, the poor-but-happy or poor-but-honest subtypes (Kay & Jost, 2003). There are many routes to system justification.

People endorse a variety of legitimating myths, according to social dominance theory (Sidanius & Pratto, 1999). Believing that some groups naturally dominate other groups in a dog-eat-dog world, which is high SDO, predicts favoring high-status groups, regardless of one's own status (Levin, Federico, Sidanius, & Rabinowitz, 2002). Believing that race-based affirmative action, but decidedly not legacy admission, is preferential treatment constitutes another kind of legitimating myth; a cloaked policy, benefiting the already-advantaged, allegedly differs from a publicized policy benefiting the disadvantaged (Chen & Tyler, 2001).

In sum, a variety of findings show that lack of constraints enable powerholders to justify their disproportionate control over outcomes. Power might create status on a societal level, as noted earlier when control over physical outcomes leads to control over economic ones, leading to control over social ones (i.e., social ideology, stereotypes, and status).

Power as Responsibility

Having relative control over others' valued outcomes means that powerholders are more independent of others, but the flip side is that their behavior and choices have a disproportionate impact on others. This introduces a potential tension in the subjective experience of having power: between independence from others and responsibility for others; between using control over outcomes to pursue one's self-interest and using it to help others pursue theirs. Of these two sides of power, the responsibility side has received much less attention in the literature.

If powerholders are unconstrained by dependency on others, that constraint can operate for ill if the default or more explicit motivation harms other people. But, similarly, lack of constraints can operate for the greater good, if the default motivation helps other people. If powerholders can operate however they will, it follows that their behavior will be more variable than that of subordinates, and indeed it is (Guinote, Judd, & Brauer, 2002). This variability may be experienced as arbitrary by subordinates, who need to predict and try to influence those who control their outcomes. Ironically, or perhaps in some cases deliberately, variability serves to focus attention on dominants (a phenomenon noted earlier). A Machiavellian powerholder would behave randomly just to maintain a sense of power and influence. Regardless of intent, the variability of powerholders' behavior doubtless contributes to their being then viewed as unique individuals (Dépret & Fiske, 1999; Fiske & Dépret, 1996).

"Choice" being the operative term for those unconstrained by other people's control over valued resources, what determines when powerholders choose to behave for good or ill? Both personality and situations can move powerholders in specific directions. First, powerholders are freer to express their personalities. Thus, for example, powerholders with a tendency to be communal (oriented to mutual needs) or have interdependent self-construals treat power as an occasion for social responsibility, whereas exchange-oriented powerholders and those with independent self-construals treat it as an occasion for self-interest (Chen, Lee-Chai, & Bargh, 2001; Chen & Welland, 2002). The Misuse of Power (MOP) scale correlates positively (convergently) with SDO, right-wing authoritarianism, a cynical philosophy of human nature, Machiavellianism, likelihood to sexually harass, and attractiveness of sexual aggression (Lee-Chai, Chen, & Chartrand, 2001). The MOP scale predicts a low communal orientation, consistent with the earlier results (Chen et al., 2001), as well as power-abusing responses to hypothetical scenarios.

In the opposite vein, a Helping Power Motivation scale (Frieze & Boneva, 2001) assesses responsible nurturance, in contrast to egoistic dominance associated with traditional measures of power (McClelland, 1976; McClelland & Teague, 1975; McClelland & Watson, 1973; Winter, 1973, 1975). The Helping Power Motivation scale reassuringly predicts wanting a job that helps others. Communal orientations could theoretically combine with unequal power to create paternalistic exploitation in the name of caring (Pratto & Walker, 2001). An example of such caretaking that demeans the other is the benevolent sexism component of Ambivalent Sexism Inventory (Glick & Fiske, 1996, 2001); so-called protection can lead to denying the protected group education, health care, and economic participation (Glick et al., 2000). Thus, a variety of individual differences can prime more pro- or antisocial responses to power.

Similarly, situations that prime interpersonal concerns can orient powerholders toward individuating and caring for their subordinates, whereas priming an organizational (exchange)-related focus orients them more toward self-interest (Overbeck & Park, 2001). Effectively, we need a person × position × situation understanding of power, whereby personality, structural control over resources, and situational cues all conspire to explain the use of power for good or ill.

To illustrate this *person × position × situation* account, consider research on adult–child interactions (e.g., Bugental & Lin, 2001), where the adult is in a position of structural power (older, bigger, more actual resource control) but can experience self as low power (chronically accessible low-perceived-power schema). The third component, the current situation, then has an inordinate effect on the adult's behavior, as if the person were obsessed with control issues. Under circumstances of clear, veridical high control, the low-perceived-power adult exercises assertiveness and engagement. Under veridically low-control circumstances, the low-perceived-power adult responds with excessive submissiveness and disengagement. In ambiguous circumstances, the same adult exhibits variable patterns. This polarized behavior thus leads someone with structural power to behave in highly variable fashion, but not exactly because of freedom and lack of constraint. On the contrary, the changeable, seemingly arbitrary behavior comes from an insecure powerholder. This style might well generalize beyond adult–child settings as a distinct explanation for the variability of some powerholders' behavior.

DIRECTIONS FOR FUTURE RESEARCH

Research on power in social psychology is in the midst of a revival. Not since the postwar era have so many social psychologists turned their attention to this fundamental aspect of individual experience and social dynamics. Current research on power tends to focus on how power affects individual perceptions, emotions, and behaviors, and the research emphasizes power as independence or freedom that yields positive benefits for the powerful and negative repercussions for the powerless. More research needs to study power in context—not as an individual attribute or orientation that exists independent of a social relationship but as a socially relative and situated phenomenon. By studying power in the context of actual interacting social systems, be they dyads, groups, or organizations, research can also shed light on how the effects of power on individual tendencies manifest themselves in the presence of others. We might also learn about how power affects social outcomes, such as the well-being, decisions, and performance of the social systems under study.

Particularly interesting but understudied aspects of power are its effects over time. More longitudinal designs could address questions about how power emerges, is maintained, and gets challenged (e.g., Fiol, O'Connor, & Aguinis, 2001; Martorana, Galinsky, & Rao, 2005), as well as how fleeting or permanent are its effects for individuals and groups.

Finally, more attention should be paid to the double-edged sword of power, or the ambivalent motives presented by the simultaneous experience of greed and guilt that are likely to follow from having relative control over valued outcomes. Western individualistic ideologies—ideologies perpetrated by the powerful and the independent—focus on power as an opportunity to pursue self-interest and downplay the responsibility for others that comes with it. This may help to explain why this perspective has been the emphasis of the literature on power by scholars in North America and Europe. An interesting avenue for future research would be to study just how individuals, and social systems, manage the dual implications of power, and how they come to emphasize power as an opportunity to maximize selfish desires versus how they come to emphasize power as an obligation to help others.

CONCLUSION

Work on power always begins with long definitional discussion, uncharacteristic of most other social psychology. One can only wonder why, but perhaps the ubiquity of power, status, and influence in social life explains the obsession to understand these concepts, as well as the variations on a theme that defines them. Our assessment is that the field knows more now than it did 10 years ago, and certainly more now than before we started studying power phenomena in rigorous scientific fashion. But plenty remains, particularly in simultaneously assessing personality differences, structural effects, and short-term cues, a research strategy that might capture the complex challenge of the phenomenon of social power.

NOTES

1. We limit our discussion to definitions of what has been called social power, or the power one person may have over another, as this is the focus of this chapter. There is also intrapersonal power, or power over oneself, with which we do not concern ourselves here. The term "power" in this chapter is therefore used with "power over" another in mind.
2. If two people have equal control over each other's outcomes, interdependence increases with this control. That is, when two people both have high control over each other's outcomes, interdependence is high; when they have low or no control over each other's outcomes, interdependence is low. The motive for cooperation and the possibility of conflict increases with interdependence, so individuals with high but equal levels of power may witness the highest levels of cooperation or conflict, but individuals with low but equal levels of power may witness little of either.
3. For the powerless, the tension lies between dependence on others and a lack of responsibility for them. System-justifying ideologies flip responsibility around, absolving the powerholder of responsibility and placing responsibility for self (and even others) on the powerless. To be systematic, one would discuss implications for lacking power as well as having it.

GROUP AND CULTURAL SYSTEM

The Social Psychology
of Intergroup Relations

Social Categorization, Ingroup Bias,
and Outgroup Prejudice

MARILYNN B. BREWER

Our understanding of intergroup relations draws on research from all domains of social psychology. Research in this area encompasses intraindividual, interpersonal, and group processes and incorporates theory and data from the study of self and identity, social cognition and attribution and attitudes to competition, aggression, and conflict. An empirical review of this vast literature is beyond the scope of this chapter. Rather than an exhaustive review of empirical findings, my purpose here is to extract some basic principles that have emerged from social psychological research on intergroup relations that illustrate how social psychology can inform both basic research and public policy in this important arena of human behavior. The organization of the chapter begins with an elaboration of three basic principles and concludes with the application of these three principles to reducing prejudice and intergroup conflict.

In brief, I argue that the social psychology of intergroup relations rests on the following fundamental propositions:

1. Group-based attitudes, perceptions, and behavior arise from basic cognitive categorization processes that partition the social world into *ingroups* and *outgroups.*
2. Attachment to and preference for ingroups is the primary driver of intergroup relations. *Ingroup favoritism* gives rise to intergroup discrimination, irrespective of attitudes toward specific outgroups.
3. Attitudes and emotions toward specific outgroups reflect appraisals of the nature of the relationships be-

tween ingroup and outgroup that have implications for the maintenance or enhancement of ingroup resources, values, and well-being. *Outgroup prejudices* both reflect and justify the existing structure of intergroup relations.

In the following pages I summarize the research literature that supports these basic propositions and then show how these principles have been integrated in social psychology's contributions to social programs designed to reduce intergroup prejudice and conflict.

PRINCIPLE 1: SOCIAL CATEGORIZATION

At least since the 1950s (cf. Allport, 1954; Campbell, 1956; Tajfel, 1969), social psychologists have recognized that intergroup prejudice and stereotyping arise in part from normal processes of categorization of the social world. Categorization (1) partitions the multidimensional variability among human beings into discrete subsets, accompanied by (2) accentuation of perceived intracategory similarities and intercategory differences (Doise, Deschamps, & Meyer, 1978; Tajfel, 1969; Tajfel & Wilkes, 1963).

The basic processes of categorization and category accentuation are presumed to be the same whether we are talking about individuals' partitioning of the world of physical objects and events or the social world. Individuals learn to classify objects as functionally interchangeable and develop concepts that distinguish members of

one category from those of another as a fundamental tool for negotiating the physical and social environment. Just as category learning and category representations are functional necessities for dealing with objects and events in the environment generally, discrete social categories serve to simplify, structure, and regulate our understandings of and interactions with other people. By carving variability among individuals into discrete groupings, categorization reduces complexity and leads to enhanced perceived similarity within categories and contrast (differentiation) between categories. Category distinctions influence both perception of and behavior toward category members, individually and collectively.

Social categorization underlies the phenomena of group cognition and social stereotypes. Social categorization also underlies ingroup–outgroup differentiation and associated intergroup processes. Because of this common origin, there has been a tendency in the social psychological literature to conflate studies of stereotyping, prejudice, and ingroup bias—as if *group* cognition and *intergroup* relations were one and the same. By contrast, I think it is important to maintain a distinction between these two consequences of social categorization, as represented in Figure 30.1.

On the one hand, as represented on the left side of Figure 30.1, social categorization gives rise to social stereotypes in the form of category prototypes, perceived trait distributions, and implicit theories about the social meaning of the category. Category stereotypes in turn have both evaluative and behavioral implications. Evaluations of individual category members and the category as a whole are derived from the positivity and negativity of the category stereotype, which may be predominantly positive, predominantly negative, or a mixture of both positive and negative characteristics.

Category stereotypes also regulate behavior toward category members. Stereotype-based discrimination arises when persons are treated differentially as a function of their category membership based on beliefs about the category as a whole. Gender discrimination provides a good illustrative case for the disassociation between stereotype-based discrimination and negative prejudice. Stereotypes about women are predominantly positive in

evaluative connotation, yet women are often disadvantaged in employment selection and promotion because of the implications of those stereotypes for expectations regarding competency and power. An important feature here is that such stereotype-based discrimination can follow from beliefs about *any* social category, *regardless of whether the perceiver is a member of that category or not*. In that sense, stereotyping is the product of "cold cognition," uninfluenced by self-referencing and associated emotional significance.

It is precisely this element of self-referencing or self-involvement that distinguishes stereotyping from prejudice, as represented on the right side of Figure 30.1. Prejudice arises when ingroup–outgroup differentiation is engaged in connection with particular social categorizations. In other words, prejudice involves thinking of social groups or categories in me–not me terms. Category membership alone is not sufficient to engage this differentiation between self and not-self. Even though I recognize that I am a member of the category "women," I can think about women as a social category (with associated stereotypes) without thinking of women as an "ingroup." Ingroup differentiation involves an additional process of *self*-categorization (Turner, Hogg, Oakes, Reicher, & Wetherell, 1987) or social identification whereby my sense of self is extended to the group as a whole. Similarly, I can think about a category (e.g., "librarians") to which I do not belong without invoking "outgroup" feelings. A category becomes an outgroup only when the self is actively disassociated from the group, in a "not-me" sense.

As depicted in Figure 30.1, prejudice arising from ingroup–outgroup differentiation processes can have three different loci. One form is the *ingroup* favoritism that has been the focus of much of the research on intergroup relations conducted within the social identity theory tradition. Here the focus is on differentiation of the ingroup from everyone else (the "us"–"not us"distinction). In this case there may or may not be any explicit outgroup; just the generalized "others" is sufficient. Prejudice and discrimination arise from differential favorability/positivity toward those who share this ingroup identity, but without any corresponding negativity or hostility toward non-ingroup members. Discrimination results from withholding from others favors and benefits that are extended only to the ingroup.

A second form of prejudice—perhaps the most virile form—is focused on the outgroup, without the necessity of any explicit ingroup identification being involved. The important distinction here is between "them" and "me," an explicit dissociation of the self from the target outgroup usually accompanied by negativity and hostility toward that group. In many cases, prejudice against gays or against specific stigmatized groups such as "skinheads" is probably outgroup prejudice of this type. Discrimination that is derived from outgroup prejudice (hate) is actively directed at harming or disadvantaging members of the outgroup, whether or not any personal benefit is gained in the process.

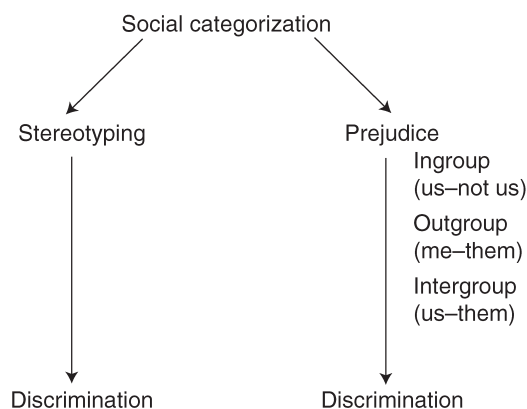
Finally, a third form of prejudice derives from the relationship *between* an ingroup and specific outgroups—the


FIGURE 30.1. Consequences of social categorization.

classic "us"–"them" distinction. This is the type of prejudice that is aroused when intergroup comparison and competition is activated, with the consequence that ingroup benefits come at the expense of the outgroup and vice versa. It is the type of prejudice aroused when the outgroup is perceived as a threat, not only to the self but to the integrity, interests, or identity of the ingroup as a whole. Discrimination derived from this form of prejudice is motivated more by ingroup protection (rather than enhancement) as well as antagonism toward the outgroup.

These forms of ingroup–outgroup prejudice are, of course, not mutually exclusive. All share the characteristic of strong emotional and affective investment ("hot" cognition) associated with self-involvement. Many chronic prejudices (and associated discrimination) probably involve elements of all three types of ingroup–outgroup prejudice. In some cases, however, claims of ingroup preservation and protection may be used to justify what is really outgroup prejudice or hate. White supremists, for instance, frequently claim that their real purpose is enhancing and maintaining the identity and interests of the white race (as opposed to being anti-outgroups). But close scrutiny of their rhetoric and internal communications reveals a heavy dominance of outgroup hate speech relative to ingroup promotion (Von Hippel, Brewer, & Polifroni, 2001).

Separating Intergroup Relations from Group Cognition

My emphasis here on the conceptual and empirical distinction between group cognition as represented by stereotyping, and intergroup processes as represented by ingroup–outgroup prejudice is not meant to imply that the two are unrelated. On the contrary, there is probably a great deal of "leakage" between group cognition and ingroup–outgroup feelings and vice versa. Strong negative stereotypes of a particular social category (to which one does not belong) are very likely to lead to negative affect and prejudice directed against that group. On the other hand, ingroup favoritism and outgroup antagonism can color the evaluation of characteristics associated with that social category. Even positive stereotypical traits can become negatively valued when they are attributed to an outgroup, and ingroup traits can be positively valued even when they are stigmatizing characteristics (Campbell, 1967). Nonetheless, even though there is certainly this type of mutual influence between stereotypes and prejudices, it is important to understand and recognize the difference between discrimination that is based on group cognition and discrimination that is driven by group identification and emotion.

Some compelling evidence for the distinction between stereotype-based processes and ingroup–outgroup processes comes from recent research on implicit cognition. Initial research on behavioral priming (Bargh, Chen, & Burrows, 1996; Dijksterhuis, Bargh, & Miedema, 2000) indicated that priming the label or content of a social category automatically activates stereotype-related concepts, which in turn elicit behavioral responses that are assimilated to the activated concept. This assimilation to the category stereotype occurs even for persons who are not themselves members of the primed category. Thus, young college students who have been primed with terms associated with the elderly have been found to walk more slowly (Bargh et al., 1996), and intelligent college students primed with the category "hooligans" perform more poorly on a subsequent cognitive task than students primed with the category "professor" (Dijksterhuis & van Knippenberg, 1998) Such assimilative behavioral priming is apparently elicited by the mere activation of the mental representation of the social category, independent of its self-relevance.

More recent experiments, however, demonstrate that these priming effects are significantly altered when ingroup–outgroup categorization is made salient prior to the category priming experience. In this case, priming the outgroup category label elicits automatic behavioral *contrast* rather than assimilation (Schubert & Hafner, 2003; Spears, Gordijn, Dijksterhuis, & Stapel, 2004). Apparently, engaging the self-concept and social identities significantly changes responses to the category representation, even at this nonconscious level. Thus, the most current work on group cognition serves to validate historical differences within social psychology between the study of social cognition and the study of prejudice and intergroup relations. Although I agree that we have much to gain from better integration of these two literatures (e.g., Mackie & Smith, 1998) we also have something to lose if we fail to understand the differences as well.

For purposes of this chapter, I delimit the study of *intergroup* relations to research on attitudes, emotions, and behavior that are influenced by the salience of an ingroup–outgroup differentiation. This is consistent with Sherif's (1966) classic characterization of intergroup situations: "Whenever individuals belonging to one group interact, collectively or individually, with another group or its members in terms of their group identification, we have an instance of intergroup behavior" (p. 12). In line with this definition, this chapter discusses theories and research on intergroup relations under conditions in which awareness of ingroup membership and intergroup differentiation is a salient factor.

The Role of Mere Categorization in Intergroup Behavior

In a laboratory setting in Bristol, England, Henri Tajfel and his colleagues undertook initial experiments with the so-called "minimal intergroup situation" (Tajfel, 1970; Tajfel, Billig, Bundy, & Flament, 1971). The results provided a powerful demonstration that merely classifying individuals into arbitrary distinct social categories was sufficient to produce ingroup–outgroup discrimination and bias, even in the absence of any interactions with fellow group members or any history of competition or conflict between the groups.

These laboratory studies succeeded in confirming the power of we–they distinctions to produce differential evaluation, liking, and treatment of other persons

depending on whether or not they are identified as members of the ingroup category. The laboratory experiments with the minimal intergroup situation demonstrated that ethnocentric loyalty and bias clearly do not depend on kinship or an extensive history of interpersonal relationships among group members but can apparently be engaged readily by symbolic manipulations that imply shared attributes or common fate. What appears to be critical for ingroup attachment is that there be a basis for distinctive identification of who is "us" and who is "them"—a rule of exclusion as well as inclusion.

Differentiation between ingroups and outgroups appears to be a necessary condition for intergroup discrimination, but categorization alone does not necessarily carry evaluative implications. Acknowledging one's ingroup membership is not equivalent to identification with that social group. This is clear from Tajfel's (1981) definition of social identity as "that part of an individual's self-concept which derives from his knowledge of his membership of a social group . . . *together with* the value and emotional significance attached to that membership" (p. 255, emphasis added). Social identification, then, entails affective and evaluative processes that are above and beyond mere cognitive classification of the self and others into a shared social category. The affective significance of social identification arises from the felt attachment between the self and the ingroup as a whole (cf. Oyserman, Chapter 18, this volume).

Social identification represents the extent to which the ingroup has been incorporated into the sense of self and, at the same time, that the self is experienced as an integral part of the ingroup. With high levels of social identification, the group's outcomes and welfare become closely connected to one's own sense of well-being (Brewer, 1991). According to social identity theory, it is this engagement of the self that accounts for the positive valuation of the ingroup and positive orientations toward fellow ingroup members. Self-worth is both projected onto and derived from positive ingroup evaluation. The distinction between ingroup membership and ingroup identification implies that social identification is not an automatic by-product of categorization. Identification implies some *motivation* to define oneself in terms of that group membership and to achieve and maintain inclusion in the ingroup category. A deeper understanding of the nature and consequences of this attachment of individuals to their ingroups is essential to an understanding of relationships between groups.

PRINCIPLE 2: THE PRIMACY OF INGROUP IDENTIFICATION

> Although we could not perceive our own in-groups excepting as they contrast to out-groups, still the in-groups are psychologically primary. . . . Hostility toward out-groups helps strengthen our sense of belonging, but it is not required. . . . The familiar is *preferred*. What is alien is regarded as somehow inferior, less "good," but there is not necessarily hostility against it. . . . Thus, while a certain amount of predilection is inevitable in all in-group memberships, the reciprocal atti-

tude toward out-groups may range widely. (Allport, 1954, p. 42, original emphasis)

Allport's (1954) chapter, "Ingroup Formation" (from which the foregoing quotation is taken), is one of the less cited sections of his classic book *The Nature of Prejudice*, but it warrants closer attention as a precursor to later research on ingroup bias and intergroup discrimination. In this chapter, Allport postulated that ingroups are "psychologically primary" in the sense that familiarity, attachment, and preference for one's ingroups come prior to development of attitudes toward specific outgroups.

Recognizing that ingroup attitudes and intragroup relationships may be independent of attitudes and behavior toward outgroups leads to a new approach to research on intergroup relations. If we take Allport's insight about the primacy of ingroup orientations seriously, we must first come to a better understanding of how and why ingroups are formed and why individuals exhibit ingroup loyalty, identification, and attachment in the first place. The second question is why and under what conditions does the formation and maintenance of ingroups and ingroup loyalty lead to negative relationships with outgroups.

Ethnocentrism and Ingroup Positivity

Along with proclaiming the psychological primacy of ingroup membership as the foundation of intergroup behavior, Allport (1954) also noted that "a certain amount of predilection is inevitable in all in-group memberships" (p. 42). This idea that ingroups are inevitably positively regarded accords with the concept of "ethnocentrism" as introduced by Sumner (1906) several decades earlier. Ethnocentrism was described by Sumner as a universal characteristic of human social groups whereby

> a differentiation arises between ourselves, the we-group, or in-group, and everybody else, or the others-group, outgroups. The insiders in a we-group are in a relation of peace, order, law, government, and industry, to each other. . . . Ethnocentrism is the technical name for this view of things in which one's own group is the center of everything, and all others are scaled and rated with reference to it. . . . Each group nourishes its own pride and vanity, boasts itself superior, exalts its own divinities, and looks with contempt on outsiders. . . . (pp. 12–13)

Experimental evidence from research in the minimal group paradigm demonstrated just how powerfully mere social categorization can influence differential thinking, feeling, and behaving toward ingroup versus outgroup members. Upon social categorization of individuals into ingroups and outgroups, people spontaneously experience more positive affect toward the ingroup. They also favor ingroup members directly in terms of evaluations and resource allocations (Tajfel et al., 1971), as well as indirectly in valuing the products of their work (Dustin & Davis, 1970; Ferguson & Kelley, 1964). In addition, ingroup membership increases the psychological bond and feelings of "oneness" that facilitate the arousal of

promotive tension or empathy in response to others' needs or problems (Hornstein, 1976) so that prosocial behavior is offered more readily to ingroup than to outgroup members (Piliavin, Dovidio, Gaertner, & Clark, 1981). Moreover, people are more likely to be cooperative and exercise more personal restraint when using endangered common resources when these are shared with ingroup members than with others (Brewer & Kramer, 1986; DeCremer & van Dijk, 2002; DeCremer & van Vugt, 1999), and they work harder for groups they identify more as their ingroup (Worchel, Rothgerber, Day, Hart, & Butemeyer, 1998).

Engaging social identities also influences perceptions of social justice and justice motives in general. Recent research provides evidence that group identification bounds the scope of people's concerns for distributive justice. For instance, Wenzel (2000) found that only East and West Germans who strongly identified with the inclusive category "German" were likely to apply norms of equality to entitlements of all citizens (east and west) of the country. Similarly, Tyler and his colleagues have found that individuals who are highly identified with a group or organization are more likely to defer to authorities and to be concerned with procedural fairness (Huo, Smith, Tyler, & Lind, 1996; Tyler, Degoey, & Smith, 1996). And people appear to be *less* concerned about distributive or procedural justice for actions related to outgroups in intergroup contexts than they are in interpersonal contexts (Bruins, Platow, & Ng, 1995; Platow et al., 1997).

When a particular social identity is made salient, individuals are likely to think of themselves as having characteristics that are representative of that social category. Social identity, in other words, leads to self-stereotyping (Hogg & Turner, 1987; Simon & Hamilton, 1994). Group stereotypical traits that may not be particularly relevant to personal identity become central to the self-concept when social identity is activated. When a woman's female identity is not salient, she may think of herself in terms of personal traits that are not relevant to the masculinity–femininity distinction (e.g., as organized, neat, and politically conservative). When her identity as a member of the female category is made salient, however, this same woman may think about herself in terms of those characteristics that make her more like other women and distinct from most men (e.g., nurturant and dependent). When an ingroup identity is salient, traits for which the self-concept and the group stereotype overlap become particularly accessible (Coats, Smith, Claypool, & Banner, 2000; Smith & Henry, 1996).

The hallmark of ingroup identification is ingroup positivity. There is even ample evidence that positive affect and evaluation are activated automatically by an ingroup label or whenever a group (even a minimal group) is associated with the self (Farnham, Greenwald, & Banaji, 1999; Otten & Wentura, 1999; Purdue, Dovidio, Gurtman, & Tyler, 1990; Rudman, Greenwald, & McGhee, 2001). This does not mean, however, that ingroup evaluations are indiscriminately positive on all dimensions of assessment. When there is objective evidence of outgroup achievement or a consensual status hierarchy in which the outgroup is recognized to be of higher status than the ingroup, then some degree of outgroup positivity (relative to the ingroup) is frequently obtained (Jost, 2001). However, ingroup positivity is consistently found on traits or attributes that are self-defining or self-relevant (Otten, 2002), and on traits reflecting basic social values (e.g., warmth, trustworthiness, and cooperativeness) ingroup positivity appears to be essentially universal (Brewer, 2001; LeVine & Campbell, 1972).

Ingroup Formation: The Boundaries of Cooperation and Trust

Ingroup identification implies some *motivation* to define oneself in terms of that group membership and to achieve and maintain inclusion in the ingroup category. Because identification entails some sacrifice of an autonomous self-concept, the question arises as to why individuals would attach some measure of their self-worth and well-being to the fate of a collective.

Theoretical understanding of ingroup identification starts from the recognition that group living represents the fundamental survival strategy that characterizes the human species. In the course of our evolutionary history, humans abandoned most of the physical characteristics and instincts that make possible survival and reproduction as isolated individuals or pairs of individuals, in favor of other advantages that require cooperative interdependence with others in order to survive in a broad range of physical environments. In other words, as a species we have evolved cooperation rather than strength and social learning rather than instinct as basic adaptations (cf. Caporael, Chapter 1, this volume).

Given the morphology and ecology of evolving hominids, the interface between hominids and their habitat must have been a group process. Finding food, defense from predation, moving across a landscape—these matters of coping with the physical habitat—are largely group processes. Over time, if exploiting a habitat is more successful as a collective group process than as an individual process, then not only would more successful groups persist but so also would individuals better adapted to group living. The result would be a shift to cooperative groups as the selective context for uniquely human mental systems. The result of selection *in* groups would be the evolution of perceptual, affective, and cognitive processes that support the development and maintenance of group membership (Caporael, Dawes, Orbell, & van de Kragt, 1989). Without a group, the probability of reproduction and survival to reproductive age is lowered for humans.

The result is that as a species, human beings are characterized by *obligatory interdependence* (Brewer, 1997; Caporael, 1997). For long-term survival, we must be willing to rely on others for information, aid, and shared resources, and we must be willing to give information and aid and to share resources with others. At the individual level, the potential benefits (receiving resources from others) and costs (giving resources to others) of mutual cooperation go hand in hand and set natural limits on cooperative interdependence. The decision to cooperate

(to expend resources to another's benefit) is a dilemma of trust since the ultimate benefits depend on everyone else's willingness to do the same (Brewer, 1981). A cooperative system requires that trust dominate over distrust. But indiscriminate trust (or indiscriminate altruism) is not an effective individual strategy; cooperation must be contingent upon the probability that others will cooperate as well.

Social categorization and clear group boundaries provide one mechanism for achieving the benefits of cooperative interdependence without the risk of excessive costs. Ingroup membership is a form of contingent altruism. By limiting aid to mutually acknowledged ingroup members, total costs and risks of nonreciprocation can be contained (see Takagi, 1996, for a related argument). Thus, ingroups can be defined as bounded communities of mutual trust and obligation that delimit mutual interdependence and cooperation.

An important aspect of this mutual trust is that it is *depersonalized* (Brewer, 1981), extended to any member of the ingroup whether personally related or not. Psychologically, expectations of cooperation and security promote positive attraction toward other ingroup members and motivate adherence to ingroup norms of appearance and behavior that ensure that one will be recognized as a good or legitimate ingroup member. Symbols and behaviors that differentiate the ingroup from local outgroups become particularly important here, to reduce the risk that ingroup benefits will be inadvertently extended to outgroup members, and to ensure that oneself is recognized as a member of the ingroup and entitled to those benefits. Assimilation within and differentiation between groups is thus mutually reinforcing, along with ethnocentric preference for ingroup interactions and institutions.

A consequence of ingroup identification and intergroup boundaries is that individuals modify their social behavior depending on whether they are interacting with ingroup or outgroup members. Ingroup behavior is governed by norms and sanctions that reinforce expectations of mutual cooperation and trustworthiness. Depersonalized trust is supported by implicit understandings that ingroup members will monitor the behavior and interactions of other group members, sanctioning deviations from group expectations about appropriate ingroup attitudes and behavior. Thus, shared ingroup membership may be taken as prima facie evidence that other members of the group will live by the codes of conduct that bind them together as a group (Kramer, Brewer, & Hanna, 1996).

Optimal Distinctiveness Theory

Cooperative groups must meet certain structural requirements in order to exist, just as organisms must have certain structural properties in order to be viable. For community-sized groups these organizational imperatives include mobilization and coordination of individual effort, communication, internal differentiation, optimal group size, and boundary definition. The benefits to individuals of cooperative arrangements cannot be achieved unless prior conditions have been satisfied that make the behavior of other individuals predictable and coordinated. Group survival depends on successful solution to these problems of internal organization and coordination.

The advantage of extending social interdependence and cooperation to an ever wider circle of conspecifics comes from the ability to exploit resources across an expanded territory and buffer the effects of temporary depletions or scarcities in any one local environment. But expansion comes at the cost of increased demands on obligatory sharing and regulation of reciprocal cooperation and free riding. Both the carrying capacity of physical resources and the capacity for distribution of resources, aid, and information inevitably constrain the potential size of cooperating social networks. Thus, effective social groups cannot be either too small or too large. To function, social collectives must be restricted to some optimal size—sufficiently large and inclusive to realize the advantages of extended cooperation, but sufficiently exclusive to avoid the disadvantages of spreading social interdependence too thin.

Based on this analysis of one structural requirement for group survival, Brewer (1991) hypothesized that the conflicting benefits and costs associated with expanding group size would have shaped social motivational systems at the individual level. If humans are adapted to live in groups and depend on group effectiveness for survival, our motivational systems should be tuned to the requirements of group effectiveness. We should be uncomfortable depending on groups that are too small to provide the benefits of shared resources but also uncomfortable if group resources are distributed too widely. A unidirectional drive for inclusion would not have been adaptive without a counteracting drive for differentiation and exclusion. Opposing motives hold each other in check, with the result that human beings are not comfortable either in isolation or in huge collectives. These social motives at the individual level create a propensity for adhering to social groups that are both bounded and distinctive. As a consequence, groups that are optimal in size are those that will elicit the greatest levels of member loyalty, conformity, and cooperation, reflecting the fit between individual psychology and group structure.

The optimal distinctiveness model of social identity (Brewer, 1991) was based on this evolutionary perspective on the functions of ingroup formation and differentiation. The theory assumes that psychological mechanisms at the individual level (opposing needs for differentiation and inclusion) coevolved with structural requirements at the group level for successful group functioning and coordination (size and boundedness). The model posits that humans are characterized by two opposing needs that govern the relationship between the self-concept and membership in social groups. The first is a need for assimilation and inclusion, a desire for belonging that motivates immersion in social groups. The second is a need for differentiation from others that operates in opposition to the need for immersion. As group membership becomes more and more inclusive, the need for inclusion is satisfied but the need for differenti-

ation is activated; conversely, as inclusiveness decreases, the differentiation need is reduced but the need for assimilation is activated. These competing drives ensure that interests at one level are not consistently sacrificed to interests at the other. According to the model, the two opposing motives produce an emergent characteristic—the capacity for social identification with distinctive groups that satisfy both needs simultaneously.

The relative strength of inclusion and differentiation needs at the individual level interacts with group properties such as size and permeability to determine social identification and ingroup attachment and loyalty. The psychology of assimilation and differentiation limits the extent to which strong social identification can be indefinitely extended to highly inclusive, superordinate social groups or categories. Thus, one implication of optimal distinctiveness theory is that ingroup loyalty, and its concomitant depersonalized trust and cooperation, is most effectively engaged by relatively small, distinctive groups or social categories. Groups that satisfy these needs are those that provide the necessary boundaries on mutual obligation and trust. Optimal group identities become essential to a secure self-concept. Once group identification has been achieved, maintaining a secure sense of inclusion and boundedness becomes tantamount to protecting one's own existence. When optimal inclusion within a distinctive ingroup is not achieved, the sense of self is threatened and vulnerable.

Ingroup Preference Needs No Outgroups

The arguments in the previous sections make the case that there is no need to require intergroup conflict to account for ingroup formation and exclusion of outgroups. In fact, in light of both paleoanthropological and archaeological evidence, it makes little sense to see conflict as the source of ingroup formation. There is no reason to believe that early hominids lived under dense population conditions in which bands of people lived in close proximity with competition over local resources. Estimates of the total human population during the Middle Paleolithic are less than 1.5 million (Hassan, 1981). Group living was well established much earlier—2.5 million years ago by human ancestors—and complex sociality evolved early among primate ancestors (Foley, 1996). Early evidence of population packing occurs around 15,000 years ago (Alexander, 1989; Stiner, 2002), too recently to have been relevant to the origins of human sociality. As Alexander himself admits, there is no evidence of intergroup conflict in early human evolutionary history (Alexander, 1989). Given the costs of intergroup fighting combined with low population density, flight rather than fight would seem to be the strategy of choice for our distant ancestors.

The idea that ingroup cooperation is born of intergroup conflict is also inconsistent with contemporary research on social identity and intergroup relations (Brewer, 1999, 2001). Despite widespread belief that ingroup positivity and outgroup derogation are reciprocally related, empirical research demonstrates little consistent relation between the two. Indeed, results from both laboratory experiments and field studies indicate that variations in ingroup positivity and social identification do not systematically correlate with degree of bias or negativity toward outgroups (Brewer, 1979; Hinkle & Brown, 1990; Kosterman & Feshbach, 1989; Struch & Schwartz, 1989). For example, in a study of the reciprocal attitudes among 30 ethnic groups in East Africa, Brewer and Campbell (1976) found that almost all the groups exhibited systematic differential positive evaluation of the ingroup over all outgroups on dimensions such as trustworthiness, obedience, friendliness, and honesty. However, the correlation between degree of positive ingroup regard and social distance toward outgroups was essentially .00 across the 30 groups.

Experiments with the minimal intergroup situation also provided additional evidence that ingroup favoritism is prior to, and not necessarily associated with, outgroup negativity or hostility. Brewer (1979) reported that most minimal group studies that assessed ratings of the ingroup and outgroup separately found that categorization into groups leads to enhanced ingroup ratings in the absence of decreased outgroup ratings. Furthermore, the positive ingroup biases exhibited in the allocation of positive resources in the minimal intergroup situation (Tajfel et al., 1971) are essentially eliminated when allocation decisions involve the distribution of negative outcomes or costs (e.g., Mummendey et al., 1992), suggesting that individuals are willing to differentially benefit the ingroup compared to outgroups but are reluctant to harm outgroups more directly. In a more recent review of developmental studies on intergroup attitudes, Cameron, Alvarez, Ruble, and Fuligni (2001) similarly concluded that children tend to display a positivity bias toward their ingroup but no negativity toward the outgroup.

Subsequent research in both laboratory and field settings has come to acknowledge the important distinction between ingroup bias that reflects beneficence and positive sentiments toward the ingroup that are withheld from outgroups ("subtle" prejudice) and discrimination that reflects hostility, derogation, and intent to harm the outgroup ("blatant" prejudice) (Pettigrew & Meertens, 1995). This is not to say that ingroup-based discrimination is benign or inconsequential. Indeed, many forms of institutional racism and sexism are probably attributable to discrimination based on ingroup preference rather than prejudice against outgroups (Brewer, 1996). Nonetheless, the absence of positive regard and lack of trust for outgroups that is characteristic of most ingroup–outgroup differentiation can be conceptually and empirically distinguished from the presence of active hostility, distrust, and hate for outgroups that characterizes virulent prejudice.

PRINCIPLE 3: WHAT ACCOUNTS FOR OUTGROUP HATE?

In most social psychology textbook definitions of "prejudice," the concept is associated with negative attitudes or behaviors toward specific outgroups. In other words,

social psychological research on prejudice is focused on outgroup negativity, rather than ingroup positivity (though that is, too, a form of prejudice).

If ingroup identification and attachment does not inevitably entail disdain for or conflict with outgroups, then explaining outgroup hate and hostility requires processes that go beyond social identity per se (Turner & Reynolds, 2001). As Allport noted, although ingroup positivity appears to be inevitable, attitudes toward relevant outgroups can vary considerably—from generally positive to neutral to negative or hostile.

Systematic variation in the relationship between ingroup identification and outgroup attitudes has been demonstrated in recent survey studies of mutual attitudes among ethnic subgroups in South Africa (Duckitt, Callaghan, & Wagner, 2005) and New Zealand (Duckitt & Parra, 2004). The findings from these studies demonstrate clearly that the nature of the relationship between ingroup identification/positivity and outgroup negativity varies considerably depending on which outgroup is being assessed. Among ethnic subgroups, the ingroup positivity–outgroup positivity correlation ranged from positive (particularly between ethnic minorities) to zero to negative (particularly between dominant and subordinate groups). Furthermore, the nature of these correlations tended to be reciprocal for pairs of groups, suggesting that attitudes toward specific outgroups are shaped by the structure of intergroup relations within a particular societal context.

Types of Ingroup–Outgroup Relationships

Duckitt's findings are consistent with the idea that the relationship between ingroup identification and outgroup attitudes depends on the implications that the outgroup has for the ingroup. Consistent with the principle of primacy of the ingroup, attitudes toward specific outgroups should be shaped by the motivation to protect and enhance the ingroup. Within this framework we can distinguish three primary patterns of ingroup–outgroup relationships:

1. *Ingroup autonomy.* In some contexts, particular outgroups are essentially irrelevant to the well-being of the ingroup. Outgroups that are psychologically or physically very distant from the ingroup are a source of neither comparison nor threat. Under these circumstances, we would expect to find zero relationship between ingroup attachment and outgroup attitudes.

2. *Intergroup comparison.* When an outgroup is a relevant standard of comparison for ingroup evaluation, this gives rise to intergroup social competition (Turner, 1975). If ingroup worth is evaluated *relative to* an outgroup, then ingroup outcomes improve only as outgroup benefits decrease. In that case, it is not clear whether the motivation for discriminatory behavior is to benefit the ingroup (i.e., discrimination *for* us) or to disadvantage the outgroup (discrimination *against* them).

3. *Intergroup conflict.* Intergroup comparison and social competition provide an initial connection between valuing the ingroup and devaluing relevant outgroups.

In the literature on social motives (McClintock, 1972), however, a clear distinction is made between *competition*–the motivation to seek relative gain for the ingroup over others—and *aggression*–the motivation to harm the other as an end in itself. Following this distinction, we can distinguish between intergroup discrimination that is based solely on ingroup favoritism and discrimination or prejudice that entails an active component of outgroup derogation and aggression (Levin & Sidanius, 1999; Struch & Schwartz, 1989).

Social identity theory provides an adequate framework for understanding ingroup bias and intergroup discrimination of the positive types described earlier. Assimilation of the self to the ingroup accounts for ingroup positivity, and from there, the extension to relative enhancement of the ingroup over outgroups under conditions of intergroup comparison is not a big motivational leap. The story becomes more complicated, however, when one tries to use the same framework to account for more virulent outgroup hate and intergroup hostility. To justify aggression against outgroups in the interest of the ingroup, the very existence of the outgroup, or its goals and values, must be seen as a threat to the maintenance of the ingroup and to one's own social identity. Thus, understanding the relationship between ingroup identification and outgroup hostility requires understanding how the interests of the ingroup and those of the outgroup come to be perceived as in conflict.

One approach to conceptualizing how perceptions of ingroup–outgroup relations may lead to outgroup negativity is integrated threat theory (Stephan & Stephan, 2000). This model distinguishes four different sources of experienced threat from a specific outgroup: *realistic threats* (threats to the existence, power, or material well-being of the ingroup or ingroup members), *symbolic threats* (threats to the ingroup worldview arising from perceived group differences in morals, values, and standards), *intergroup anxiety* (personal fear or discomfort experienced in connection with actual or anticipated interactions with members of the outgroup), and *negative stereotypes* (beliefs about outgroup characteristics that imply unpleasant or conflictual interactions and negative consequences for the self or the ingroup). In a field test of this model, Stephan and colleagues (2002) found that ratings of realistic threat, symbolic threat, and intergroup anxiety were significant predictors of negative interracial attitudes and that these threat perceptions mediated the effects of other predictor variables such as ingroup identification, intergroup contact, and status differences.

Stephan's taxonomy of intergroup threat delineates the ways in which the very existence of a particular outgroup may be perceived as a danger to the ingroup, but it begs the question of how ingroup members come to see outgroups in this way. Except under conditions of realistic group conflict (i.e., life-and-death competition for scarce resources or open warfare), the perception that an outgroup constitutes a symbolic or reputational threat to the ingroup is highly subjective, and we still need more explicit theory of how these perceptions arise.

Next I suggest two factors that may promote or exacerbate the perception of outgroup threat.

Common Goals

The presence of realistic competition over scarce resources or other group goals is clearly a strong basis for intergroup conflict and hostility. In contrast, the presence of superordinate goals or common threat is widely believed to provide the conditions necessary for intergroup cooperation and reduction of conflict (e.g., Sherif, 1966). This belief is an extrapolation of the general finding that *intragroup* solidarity is increased in the face of shared threat or common challenge.

It may be true that loosely knit ingroups become more cohesive and less subject to internal factioning when they can be rallied to the demands of achieving a common goal. The dynamics of interdependence are quite different, however, in the case of highly differentiated social groups. Among members of the same ingroup, engaging the sense of trust necessary for cooperative collective action is essentially nonproblematic. In an intergroup context, however, perceived interdependence and the need for cooperative interaction makes salient the absence of mutual trust. Without the mechanism of depersonalized trust based on common identity, the risk of exploited cooperation looms large and distrust dominates over trust in the decision structure. It is for this reason that I have argued elsewhere (Brewer, 2000) that the *anticipation* of positive interdependence with an outgroup, brought on by perceptions of common goals or common threat, actually promotes intergroup conflict and hostility. When negative evaluations of the outgroup such as contempt are also already present, common threat in particular may promote scapegoating and blame rather than mutual cooperation.

Perceived positive interdependence with the outgroup also threatens intergroup differentiation (Branscombe, Ellemers, Spears, & Doosje, 1999; Jetten, Spears, & Postmes, 2004). To the extent that feelings of secure inclusion, ingroup loyalty, and optimal identity are dependent on the clarity of ingroup boundaries and intergroup distinctions, shared experiences and cooperation with the outgroup threaten the basis for social identification. Particularly for individuals who are exclusively vested in a single group identity, the threat of lost distinctiveness may override the pursuit of superordinate goals and lead to resistance to cooperation (collaboration) even at the cost of ingroup self-interest.

Power Politics

Moral superiority, distrust of outgroups, and social comparison are all processes that emerge from ingroup maintenance and favoritism and can lead to hostility and conflict between groups even in the absence of realistic conflict over material resources or power. When groups are political entities, however, these processes may be exacerbated through deliberate manipulation by group leaders in the interests of mobilizing collective action to secure or maintain political power. Social category differ-

entiation provides the fault lines in any social system that can be exploited for political purposes. When trust is ingroup based, it is easy to fear control by outsiders; perceived common threat from outgroups increases ingroup cohesion and loyalty; appeals to ingroup interests have greater legitimacy than appeals to personal self-interest. Thus politicization—an important mechanism of social change—can be added to the factors that may contribute to a correlation between ingroup love and outgroup hate.

Intergroup Emotions and Image Theory

The general idea that intergroup attitudes are shaped by the perceived relationship between the ingroup and outgroup (in particular whether the existence of the outgroup poses a threat to the ingroup or not) is consistent with recent theories of prejudice as intergroup emotion (Smith, 1993). It has long been recognized that intergroup attitudes are a complex mixture of affective, evaluative, and cognitive responses, but recent social psychological research has been dominated by a focus on the cognitive component (stereotypes) to the relative exclusion of the more emotional underpinnings of prejudice. Although feelings and emotions toward specific outgroups are certainly connected to beliefs about those groups, these components are conceptually and empirically separable (Esses, Haddock, & Zanna, 1993).

Zanna and Rempel (1988) have suggested that an attitude can be defined as an overall evaluation of a social group that is based on a combination of cognitive information (beliefs and stereotypes) and affective information (feelings and emotions). Attitudes toward different groups may reflect different weightings of affective and cognitive components. For some individuals, prejudice toward a specific group may be primarily emotion driven, whereas for other individuals or other groups, prejudice is primarily a matter of beliefs and values (Esses et al., 1993). Furthermore, emotional states may directly affect the beliefs and evaluations associated with an outgroup.

Emotional reactions to a particular outgroup can include positive emotions (e.g., admiration and respect) as well as a range of negative emotions (e.g., fear, disgust, anxiety, and hate). In Dijker's (1987) examination of the relation between emotions and attitudes toward two minority groups in the Netherlands, although both types of emotion predicted evaluation of the outgroups, positive emotions were more predictive of attitudes toward one group and negative emotions were more predictive of attitudes toward the other. Similarly, in an investigation of the relation between positive and negative emotional responses toward seven minority groups in the United States, both types of emotion predicted prejudice toward these groups (Stangor, Sullivan, & Ford, 1991, study 1).

Attitude Ambivalence

The emotional component of prejudice is made more complex when one realizes that positive and negative affect may be held independently (Cacioppo & Berntson,

1994; Larsen & Diener, 1992). If positive and negative emotions are potentially independent, the reduction of extreme negative affect toward a particular outgroup does not necessarily result in increased positive affect. Recently, Pettigrew and Meertens (1995) have suggested that, although "blatant" forms of prejudice against outgroups involve strong negative affect, more "subtle" forms of prejudice involve the absence of positive emotional reactions toward the outgroup rather than the presence of negative emotions. For many outgroups, prejudice comes in the form of relative indifference and exclusion from the benefits of positive affect and leniency accorded to ingroup members. Antipathy-based prejudice and discrimination occur only against outgroups that arouse strong negative emotions.

Prejudice may also be associated with emotional ambivalence when arousal of negative affect occurs in situations in which positive attitudes are desirable. The theory of ambivalence amplification (Hass, Katz, Rizzo, Bailey, & Eisenstadt, 1991; Katz & Hass, 1988) refers to a complex motivational state that applies particularly to the relation between a dominant, politically powerful group (such as Whites in the United States) and a less powerful or disadvantaged minority group (such as Blacks). It emphasizes the conflict between egalitarian values and antipathy toward the outgroup. On the one hand, for example, Whites hold pro-Black feelings that stem from the endorsement of egalitarianism and fairness as societal values and they simultaneously perceive that Blacks are disadvantaged. Concomitantly, these same Whites possess anti-Black feelings that arise from early socialization and stereotypes, including the perception that Blacks deviate from the traditional cultural values, such as the Protestant work ethic. In turn, these ambivalent feelings motivate exaggerated evaluations of Blacks. Thus, when a Black individual and a White individual exhibit the same positive behavior, the Black will be evaluated more positively than the White; conversely, a Black behaving negatively will be evaluated more harshly than a White who behaves in that same manner. And the more strongly a White American simultaneously holds these conflicting motives toward Blacks, the more extreme these evaluations will be.

The ambivalence associated with internal conflicts between egalitarian values and negative affect toward outgroups plays a role in a number of theories of prejudice and racism. Theories of "aversive" (Gaertner & Dovidio, 1986), "modern" (McConahay, 1986; McConahay & Hough, 1976), "symbolic" (Sears, 1988; Sears & Funk, 1991), or "regressive" racism (Rogers & Prentice-Dunn, 1981) argue that there is a conflict between egalitarian values and the emotional antipathy toward outgroup members that is often automatically activated. Among the propositions of aversive racism (Gaertner & Dovidio, 1986, 2000) is that the salience of egalitarian values influences the expression of racial bias. When the salience of egalitarian values is high, there will be no overt display of racial discrimination. When it is low, discrimination may appear, particularly in subtle forms. According to the model, prejudice influences behavior via an indirect process whereby the race of the other person enhances the salience of elements in a situation that would justify or rationalize a negative response to that individual. In interactions between ingroup and outgroup members, then, egalitarian values may typically exert pressure to behave in a nonprejudiced manner. However, when there is a justifying cause that can rationalize a negative response, that will legitimize negative behavior toward outgroup members, resulting in amplified negative responses and prejudice that is not recognized as such by the actor (see Dovidio & Gaertner, 2004, for review).

Another explanation for the consequences of ambivalence or aversive racism is that conflict of values affects resources available for cognitive processing (Richeson & Shelton, 2003). Devine (1989), for instance, argues that because prejudicial responses are well learned from early childhood, two processes are necessary for suppression of prejudiced behavior: (1) inhibition of automatically activated negative stereotypes and (2) activation of "controlled information processing" that makes salient those associations that are consistent with egalitarian values. Thus, circumstances in which egalitarian values are salient will allow an individual to inhibit negative associations and behave in a manner consistent with them. If, however, either time or processing capacity are limited or constrained, biased behavior emerges as a consequence of overlearned negative racial associations. This suggests that biased behavior can occur unintentionally, even in one who sincerely embraces egalitarianism.

Differentiating Negative Emotions: Appraisal Theory of Intergroup Emotions

In addition to distinguishing between positive and negative emotions as components of intergroup attitudes, researchers have begun to recognize the importance of distinguishing among different types of negative emotions in intergroup contexts. Distinct emotions reflect different underlying causes and lead to different types of behavior. Smith (1993) has suggested that five specific emotions are most likely to be aroused in intergroup situations: fear, disgust, contempt, anger, and jealousy. Of these, fear and disgust can be distinguished as emotions that imply avoidance or movement away from the outgroup, whereas contempt and anger imply movement against the outgroup (although fear can also elicit the attack response if the perceiver feels trapped or cornered and unable to effectively flee the source of fear). Attitudes that are driven by the former emotional states are likely to have different cognitive contents and behavioral implications than attitudes that are associated with the latter forms of emotion.

Mackie, Devos, and Smith (2000) demonstrated, across three empirical studies, that (1) for groups that are defined by a basic value conflict, anger and fear can be differentiated as distinct negative emotional responses to the outgroup, (2) appraisals of relative ingroup strength determine the degree of reported anger toward the outgroup, and (3) level of felt anger mediates the relationship between strength appraisals and participants' desire to confront, oppose, or attack members of the

outgroup. Based on these findings, Mackie and colleagues conclude that intergroup attitudes and behavior are channeled by the specific emotions that are elicited in response to appraisals of a particular outgroup in relation to the ingroup.

According to appraisal theories of emotion, the type of emotion directed toward outgroups may be a function of the degree of conflict of interest that is perceived to exist between the outgroup and the ingroup. When perceived conflict or threat is relatively low, negative emotions toward outgroups are likely to be associated with appraisals of status and legitimacy. The perception that the outgroup is different from the ingroup in ways that are devalued or illegitimate gives rise to feelings of moral superiority, intolerance, and concomitant emotions of contempt and disgust toward relevant outgroups. The emotions associated with moral superiority may justify some negative discrimination against outgroups but do not necessarily lead directly to hostility or conflict. In various contexts, groups have managed to live in a state of mutual contempt over long periods without going to war over their differences. The emotions of contempt and disgust are associated with avoidance rather than attack, so intergroup peace may be maintained through segregation and mutual avoidance.

As perceived conflict increases, avoidant emotions such as anxiety and disgust may be replaced by emotions such as anger, which instigate active hostility and aggression. This relationship was indicated by results of a study of the attitudes of Israeli citizens toward members of an ultraorthodox sect (Struch & Schwartz, 1989). Two types of intergroup attitudes were assessed, one measuring aggressive intent against the outgroup, the other measuring more conventional ingroup–outgroup evaluative ratings. The strongest predictors of ratings on the aggression measure were perceived conflicts of interests and values between the respondent's own religious group and the outgroup sect. However, these conflict measures did not predict the more traditional evaluative ratings, and these two measures of outgroup attitude were essentially uncorrelated.

Image Theory

One theoretical perspective that links perceptions and emotions in intergroup contexts is represented by "image theories" of international relations as developed by Cottam (1977) and Herrmann (1985). These theorists argue that images form as a *consequence* of strategic relationships between nations and serve a functional purpose. Working from Heider's (1958) balance theory, Herrmann suggested that images in international relations serve to balance a positive self-image and behavioral inclinations toward another nation. Herrmann argued that the nature of relationships between nations is represented in terms of perceived threats and perceived opportunities that give rise to emotions and associated behavioral implications. The cognitive system is balanced when the evaluative and behavioral implications of the image of the other nation matches the behavioral inclination generated from the threat or opportunity in a way

that maintains consistency with a positive, moral self-image (see also Sande, Goethals, Ferrari, & Worth, 1989). Thus, appraisals of the nature of the relationship between ingroup and outgroup (threat vs. opportunity) give rise to specific images of the outgroup nation that serve to account for and justify affective and behavioral orientations toward that group.

Herrmann (1985) identified three critical dimensions of intergroup relationships that give rise to sentiments and subsequent images of the other. These appraisal dimensions are (1) evaluations of competitive versus cooperative goal interdependence, (2) assessments of relative power, and (3) evaluations of relative cultural status. Together, these three assessments are the primary determinants of perceived threat and opportunity in intergroup relationships. When relationships are perceived to be characterized by extreme values on these three dimensions, emotions are aroused that determine both specific behavioral orientations toward the outgroup and specific content of the cognitive image of that group. Among the generic images that can arise from different configurations of intergroup relationship appraisals, five were identified as particularly relevant to international relations. These were labeled the "ally" image, the "enemy" image, the "barbarian" image, the "dependent (colonial)" image, and the "imperialist" image (Herrmann & Fischerkeller, 1995). Evidence from both laboratory experiments (Alexander, Brewer, & Herrmann, 1999) and field studies of interracial attitudes (Alexander, Brewer, & Livingston, 2005) support the hypothesis that relational appraisals can account for differences in outgroup perceptions and attitudes.

The influence of specific perceptions of the intergroup situation to create images and reactions is consistent with appraisal theories of intergroup emotions. In fact, the mediating role of emotions is implicit in the premises of image theory. First, the theory holds that appraisals of the pattern of intergroup relationships give rise to "sentiments" (Herrmann, 1985) that drive the behavioral orientations and consequent image activation. While the sentiments were not identified in terms of specific emotions, the idea that emotions correspond to specific action tendencies is integral to appraisal theories of emotion.

Based on this, a case can be made for incorporating an appraisal theory of emotions into image theory more formally (Brewer & Alexander, 2002). Information about the goals, status, and power relationships between ingroup and outgroup gives rise to appraisals along the dimensions of goal congruence, coping (relative ingroup strength and resources), and legitimacy (status evaluations). The resulting appraisal configuration elicits specific emotions (e.g., fear, anger, or resentment) that are associated with specific action tendencies (e.g., retreating, attacking, or resisting). In the context of intergroup relations, these emotional responses and associated action orientations are translated into cognitive representations of the outgroup (images) and preferences for behavior and policies toward that group. Table 30.1 summarizes this emotion appraisal model with respect to five specific intergroup configurations that have been drawn

TABLE 30.1. Image Theory of Intergroup Emotions

Relationship pattern	Intergroup emotion	Outgroup image	Action tendency
Goal compatibility Status equal Power equal	Admiration Trust	Ally	Cooperate
Goal incompatibility Status equal Power equal	Anger	Enemy	Contain or compete
Goal independent Status lower Power lower	Disgust Contempt	Dependent	Exploit or protect
Goal incompatibility Status lower Power higher	Fear Intimidation	Barbarian	Defend
Goal independent Status higher Power higher	Jealousy Resentment	Imperialist	Rebel

from image theory in international relations. By combining political theory with recent advances in the social psychology of intergroup emotions, we have a much more nuanced picture of the cognitive and affective underpinnings of different forms of intergroup behavior.

APPLYING THE PRINCIPLES: PREJUDICE REDUCTION THROUGH CONTACT AND COOPERATION

When ingroup identification leads to outgroup derogation, hostility, or overt conflict, principles for understanding the origins of intergroup prejudice must be turned toward the issue of how to reduce the negative consequences of ingroup–outgroup differentiation. Broadly speaking, there are two approaches to changing intergroup attitudes that have been derived from social psychological theory and research. One approach follows from principles of social categorization and focuses on altering ingroup–outgroup categorization. A second approach follows from intergroup emotion theory and involves changing appraisals of the outgroup vis-à-vis the ingroup.

Social Categorizaion and the Contact Hypothesis

The "contact hypothesis" is a general set of ideas about reducing intergroup prejudice and discrimination that developed among social scientists in the 1940s in the context of interracial relations in the United States (Allport, 1954; Watson, 1947; Williams, 1947). The basic idea behind the hypothesis is that hostility between groups is fed by unfamiliarity and separation and that *under the right conditions*, contact among members of different groups will reduce hostility and promote more positive intergroup attitudes. According to Allport (1954), the four most important of these qualifying conditions were that (1) integration has the support of authority, fostering *social norms* that favor intergroup acceptance; (2) the situation has high "acquaintance potential," promoting *intimate contact among members of both groups*; (3) the contact situation promotes *equal status* interactions among members of the social groups; and (4) the situation creates conditions of *cooperative interdependence* among members of both groups. Each of these conditions was derived from results of early research on racial desegregation and intergroup contact in the United States, on which the hypothesis was initially based.

Although the principle underlying the contact hypothesis was based on both empirical research and practical experience, research on the effects of contact tended to be largely atheoretical and driven by the exigencies of real-world desegregation settings. One advance toward a more integrative theory of prejudice reduction was achieved when contact research was combined with concepts of social categorization and social identity theory to provide a theoretical framework for understanding the cognitive mechanisms by which cooperative contact is presumed to work (see Brewer & Miller, 1984; Brown & Hewstone, 2005; Gaertner, Mann, Murrell, & Dovidio, 1989; Hewstone, 1996; Hewstone & Brown, 1986; Wilder, 1986). From the social categorization perspective, the issue to be addressed is how intergroup contact and cooperation can be structured to alter cognitive representations in ways that would eliminate one or more of the basic features of the negative intergroup schema.

Based on the premises of social identity theory, three alternative models for contact effects have been developed and tested in experimental and field settings, namely, decategorization, recategorization, and intergroup contact. Each of these models can be described in terms of (1) the structural representation of the contact situation that is recommended, (2) the psychological processes that promote attitude change within the contact setting, and (3) the mechanisms by which contact experiences are generalized to changed attitudes toward the outgroup as a whole. The first two models seek to change attitudes and perceptions by altering the salience of ingroup–outgroup social categorization in the contact situation. The third model addresses how intergroup attitudes can be changed while ingroup–outgroup differentiation remains salient.

Decategorization: The Personalization Model

The first model is essentially a formalization and elaboration of the assumptions implicit in the contact hypothesis itself (Brewer & Miller, 1984). A primary consequence of salient ingroup–outgroup categorization is the deindividuation of members of the outgroup. Social behavior in category-based interactions is characterized by a tendency to treat individual members of the outgroup as undifferentiated representatives of a unified social cate-

gory, ignoring individual differences within the group. The personalization perspective on the contact situation implies that intergroup interactions should be structured to reduce the salience of category distinctions and promote opportunities to get to know outgroup members as individual persons.

The conditional specifications of the contact hypothesis (equal status, intimate, cooperative interaction) can be interpreted as features of the situation that reduce category salience and promote more differentiated and personalized representations of the participants in the contact setting. Attending to personal characteristics of group members not only provides the opportunity to disconfirm category stereotypes but also breaks down the monolithic perception of the outgroup as a homogeneous unit (Wilder, 1978). In this scheme, the contact situation encourages attention to information at the individual level that replaces category identity as the most useful basis for classifying participants.

Repeated personalized contacts with a variety of outgroup members should, over time, undermine the value and meaningfulness of the social category stereotype as a source of information about members of that group. This is the process by which contact experiences are expected to generalize—via reducing the salience and meaning of social categorization in the long run (Brewer & Miller, 1988).

A number of experimental studies provide evidence supporting this perspective on contact effects (Bettencourt, Brewer, Croak, & Miller, 1992; Marcus-Newhall, Miller, Holtz, & Brewer, 1993). Miller, Brewer, and Edwards (1985), for instance, demonstrated that a cooperative task that required personalized interaction with members of the outgroup resulted not only in more positive attitudes toward outgroup members in the cooperative setting but also toward other outgroup members shown on a videotape, compared to cooperative contact that was task focused rather than person focused.

The personalization model is also supported by the early empirical evidence for the effects of extended, intimate contact on racial attitudes, reviewed previously. More recently, extensive data on effects of intergroup friendships have been derived from surveys in Western Europe regarding attitudes toward minority immigrant groups (Hamberger & Hewstone, 1997; Pettigrew, 1997; Pettigrew & Meertens, 1995). Across samples in France, Great Britain, the Netherlands, and Germany, Europeans with outgroup friends scored significantly lower on measures of prejudice, particularly affective prejudice (Pettigrew, 1998). This positive relationship did not hold for other types of contact (work or residential) that did not involve formation of close personal relationships with members of the outgroup. Although there is clearly a bidirectional relationship between positive attitudes and extent of personal contact, path analyses indicate that the path from friendship to reduction in prejudice is stronger than the other way around (Pettigrew, 1998).

Other recent research also reveals two interesting extensions of the personalized contact effect. One is evidence (again from European survey data) that personal friendships with members of one outgroup may lead to tolerance toward outgroups in general and reduced nationalistic pride—a process that Pettigrew (1997) refers to as "deprovincialization." A second extension is represented by evidence that contact effects may operate indirectly or vicariously. Although interpersonal friendship across group lines leads to reduced prejudice, even knowledge that an ingroup member befriended an outgroup member has potential to reduce bias (Wright, Aron, McLaughlin-Volpe, & Ropp, 1997).

Recategorization: The Common Ingroup Identity Model

The second social categorization model of intergroup contact and prejudice reduction is also based on the premise that reducing the salience of ingroup–outgroup category distinctions is key to positive effects. In contrast to the decategorization approaches described earlier, recategorization is not designed to reduce or eliminate categorization but rather to structure a definition of group categorization at a higher level of category inclusiveness in ways that reduce intergroup bias and conflict (Allport, 1954, p. 43). Specifically, the common ingroup identity model (Gaertner, Dovidio, Anastasio, Bachman, & Rust, 1993; Gaertner, Dovidio, Nier, Ward, & Banker, 1999) proposes that intergroup bias and conflict can be reduced by factors that transform participants' representations of memberships from two groups to one more inclusive group. With common ingroup identity, the cognitive and motivational processes that initially produced ingroup favoritism are redirected to benefit the former outgroup members.

Among the antecedent factors proposed by the common ingroup identity model are the features of contact situations (Allport, 1954) that are necessary for intergroup contact to be successful (e.g., interdependence between groups, equal status, and equalitarian norms). From this perspective, cooperative interaction, for example, enhances positive evaluations of outgroup members, at least in part, because cooperation transforms members' representations of the memberships from "us" and "them" to a more inclusive "we."

To test this hypothesis directly, Gaertner, Mann, Dovidio, Murrell, and Pomare (1990) conducted a laboratory experiment that brought two three-person laboratory groups together under conditions designed to vary independently the members' representations of the aggregate as one group or two groups (by varying factors such as seating arrangement) and the presence or absence of intergroup cooperative interaction. Supportive of the hypothesis concerning how cooperation reduces bias, among participants induced to feel like two groups, the introduction of cooperative interaction increased their perceptions of one group and also reduced their bias in evaluative ratings relative to those who did not cooperate during the contact period. Also supportive of the common ingroup identity model, reduced bias associated with introducing cooperation was due to enhanced favorable evaluations of outgroup members. In further support for the common ingroup identity model, this ef-

fect of cooperation was mediated by the extent to which members of both groups perceived themselves as one group.

Outside the laboratory, survey studies conducted in natural settings across very different intergroup contexts offered converging support for the proposal that the features specified by the contact hypothesis can increase intergroup harmony in part by transforming members' representations of the memberships from separate groups to one more inclusive group. Participants in these studies included students attending a multiethnic high school (Gaertner, Rust, Dovidio, Bachman, & Anastasio, 1994), banking executives from a wide variety of institutions across the United States who had experienced a corporate merger (Bachman, 1993), and college students who were members of blended families whose households were composed of two formerly separate families trying to unite into one (Banker & Gaertner, 1998). Results of these studies showed that the more the aggregate felt like one group, the lower the bias in affective reactions in the high school, the less the intergroup anxiety for the bankers, and the greater the amount of step-family harmony (Gaertner, Dovidio, & Bachman, 1996).

Challenges to the Decategorization/ Recategorization Models

Although the structural representations of the contact situation advocated by the decategorization (personalization) and recategorization (common ingroup identity) models are different, the two approaches share common assumptions about the need to reduce category differentiation and associated processes. Because both models rely on reducing or eliminating the salience of intergroup differentiation, they involve structuring contact in a way that will challenge or threaten existing social identities. Both cognitive and motivational factors conspire to create resistance to the dissolution of category boundaries or to reestablish category distinctions across time. Although the salience of a common superordinate identity or personalized representations may be enhanced in the short run, these may be difficult to maintain across time and social situations.

Preexisting social–structural relationships between groups may also create strong forces of resistance to changes in category boundaries. Cognitive restructuring may be close to impossible (at least as a first step) for groups already engaged in deadly hostilities. Even in the absence of overt conflict, asymmetries between social groups in size, power, or status create additional sources of resistance. When one group is substantially numerically smaller than the other in the contact situation, the minority category is especially salient and minority group members may be particularly reluctant to accept a superordinate category identity that is dominated by the other group. Another major challenge is created by preexisting status differences between groups, where members of both high- and low-status groups may be threatened by contact and assimilation (Mottola, 1996).

The Intergroup Contact Model: Changing Appraisals of the Ingroup–Outgroup Situation

These challenges to processes of decategorization/ recategorization led Hewstone and Brown (1986; Brown & Hewstone, 2005) to recommend an alternative approach to intergroup contact wherein cooperative interactions between groups are introduced without degrading the original ingroup–outgroup categorization. Specifically, this model favors encouraging groups working together to perceive complementarity by recognizing and valuing mutual superiorities and inferiorities within the context of an interdependent cooperative task or common, superordinate goals. This strategy allows group members to maintain their social identities and positive distinctiveness while avoiding insidious intergroup comparisons. Thus, the intergroup contact model does not seek to change the basic category structure of the intergroup contact situation but to change the intergroup affect from negative to positive interdependence and evaluation.

To promote positive intergroup experience, Hewstone and Brown recommend that the contact situation be structured so that members of the respective groups have distinct but complementary roles to contribute toward common goals. In this way, both groups can maintain positive distinctiveness within a cooperative framework. Evidence in support of this approach comes from the results of an experiment by Brown and Wade (1987) in which work teams composed of students from two different faculties engaged in a cooperative effort to produce a two-page magazine article. When the representatives of the two groups were assigned separate roles in the team task (one group working on figures and layout, the other working on text), the contact experience had a more positive effect on intergroup attitudes than when the two groups were not provided with distinctive roles (see also Deschamps & Brown, 1983; Dovidio, Gaertner, & Validzic, 1998).

Hewstone and Brown (1986) argued that generalization of positive contact experiences is more likely when the contact situation is defined as an *intergroup* situation rather than an interpersonal interaction. Generalization in this case is direct rather than requiring additional cognitive links between positive affect toward individuals and representations of the group as a whole. This position is supported by evidence that cooperative contact with a member of an outgroup leads to more favorable generalized attitudes toward the group as a whole when category membership is made salient during contact (e.g., Brown, Vivian, & Hewstone, 1999: Hewstone et al., 2005; van Oudenhoven, Groenewoud, & Hewstone, 1996).

Although ingroup–outgroup category salience is usually associated with ingroup bias and the negative side of intergroup attitudes, cooperative interdependence is assumed to override the negative intergroup schema, particularly if the two groups have differentiated, complementary roles to play. Because it capitalizes on needs for distinctive social identities, the intergroup contact model

provides a solution that is highly stable in terms of the cognitive–structural aspects of the intergroup situation. The affective component of the model, however, is likely to be more unstable. Salient intergroup boundaries are associated with mutual distrust (Insko & Schopler, 1987), which undermines the potential for cooperative interdependence and mutual liking over any length of time. By reinforcing perceptions of group differences, the differentiation model risks reinforcing negative beliefs about the outgroup in the long run and intergroup anxiety (Greenland & Brown, 1999; Islam & Hewstone, 1993), and the potential for fission, and conflict along group lines remains high.

Hybrid Models: An Integration of Approaches

As reviewed previously, each of the cognitive–structural models of intergroup contact and prejudice reduction has its weaknesses and limitations, particularly when one seeks to generalize beyond small group interactions in laboratory settings. These criticisms have led a number of writers to suggest that some combination of all three models may be necessary to create conditions for long-term attitude change (e.g., Brewer, 1996; Brown & Hewstone, 2005; Gaertner et al., 2000; Hewstone, 1996; Pettigrew, 1998).

More integrative models of intergroup contact take advantage of the fact that individuals are members of multiple social groups, which imply different social identities and ingroup loyalties. Traditionally, social identities have been treated as if they were mutually exclusive, with only one social categorization (ingroup–outgroup differentiation) salient at any one time. New research has begun to challenge this assumption of exclusivity and to explore the implications of holding multiple group identities, or identities at different levels of inclusiveness, simultaneously.

Hierarchical Dual Identities

In recent work regarding the development of a common ingroup identity, it has been proposed that embracing a more inclusive superordinate identity does not necessarily require each group to forsake its original group identity completely (Gaertner et al., 1990, 1994). In many contexts this may be impossible or undesirable. In some intergroup contexts, however, when members simultaneously perceive themselves as members of different groups but also as part of the same team or superordinate entity, intergroup relations between these subgroups are more positive than if members only considered themselves separate groups (Brewer & Schneider, 1990). For example, minority students in the multiethnic high school who identified themselves using both a minority subgroup and an American superordinate identity had lower intergroup bias than those students who identified themselves using only their minority group identity (Gaertner et al., 1994). Also, the greater the extent to which majority and minority students perceived the study body as "different groups . . . all playing on the

same team" (the dual identity item), the lower their degree of intergroup bias. By contrast, the more they conceived of the student body as "belonging to different groups" the higher the intergroup bias.

Other research also supports the value of a dual identity for reducing bias and improving intergroup relations. Two studies further suggest that the intergroup benefits of a strong superordinate identity remain relatively stable even when the strength of the subordinate identity becomes equivalently high (Huo et al., 1996; Smith & Tyler, 1996). This suggests that identification with a more inclusive social group does not require individuals to deny their ethnic identity. In addition, a dual identity can also lead to even more positive outgroup attitudes than those associated with a superordinate identity alone (Hornsey & Hogg, 2000). In terms of promoting more harmonious intergroup interactions, a dual identity capitalizes on the benefits of common ingroup membership as well those accrued from mutual differentiation between the groups.

On the other hand, dual identities are not always associated with positive relations between subgroups within the superordinate category. Mummendey and Wenzel (1999) make a convincing case that under some circumstances, making a shared superordinate category salient can lead to enhanced derogation of other subgroups when both subgroup and superordinate group identities are salient. This can happen if the values and attributes of the ingroup are projected onto the superordinate group, in which case subgroups that differ from these attributes come to be seen as *deviant* (rather than just "different") and a potential source of symbolic threat to the ingroup and the superordinate. In studies of national groups in the European Union, Mummendey and Waldzus (2004) have demonstrated that individuals who profess dual identification also exhibit higher ingroup projection, which in turn mediates negative attitudes toward other subgroup nations.

Cross-Cutting Identities

Embedded categories at different levels of inclusiveness represent only one form of multiple ingroup identities. Individuals may also be members of social categories that overlap only partially, if at all. Many bases of social category differentiation—gender, age, religion, ethnicity, occupation—represent cross-cutting cleavages. From the standpoint of a particular person, other individuals may be fellow ingroup members on one dimension of category differentiation but outgroup members on another. (For instance, for a woman business executive, a male colleague is an ingroup member with respect to occupation but an outgrouper with respect to her gender identification.) It is possible that such orthogonal social identities are kept isolated from each other so that only one ingroup–outgroup distinction is activated in a particular social context. But there are reasons to expect that simultaneous activation of multiple ingroup identities is both possible and has potential for reducing prejudice and discrimination based on any one category distinction.

Evidence from both anthropology (e.g., Gluckman, 1955) and political sociology (e.g., Coser, 1956) has long suggested that societies characterized by cross-cutting loyalty structures are less prone to schism and internal intergroup conflict than societies characterized by a single hierarchical loyalty structure. More recently, social psychologists have also begun to consider the implications of such multiple cross-cutting social identities for reduction of ingroup bias at the individual level (Brown & Turner, 1979; Deschamps & Doise, 1978; Marcus-Newhall et al., 1993; Vanbeselaere, 1991).

Experimental studies with both natural and artificial categories have demonstrated that adding a cross-cutting category distinction reduces ingroup bias and increases positive attitudes toward crossed category members compared to simple ingroup–outgroup differentiation (Vanbeselaere, 1991) or compared to situations in which category distinctions are convergent or superimposed (Bettencourt & Dorr, 1998; Marcus-Newhall et al., 1993; Rust, 1996). In these studies, cooperative interaction in the context of cross-cutting social identities and roles increases intracategory differentiation and reduces perceived intercategory differences, resulting in less category-based evaluations of individual group members. Furthermore, the benefits of cross-categorization may be enhanced when both category distinctions are embedded in a common superordinate group identity (Gaertner et al., 1999; Rust, 1996). Thus, crossed categorization and recategorization may work together to produce enhanced inclusiveness and reduced intergroup discrimination.

Cross-cutting category memberships, however, do not always result in reduced category salience and greater intergroup acceptance (Vanbeselaere, 1991). If one category distinction is more socially meaningful or functionally important than others, intergroup discrimination based on that categorization may be unaffected by the existence of cross-cutting memberships in other, less important groups. More important, multiple group identities may be combined into a single ingroup (e.g., categorization based on shared ethnicity *and* gender), which is more exclusive than either category membership considered separately. This possibility shifts the focus to the *phenomological* rather than the objective categorization structure. To understand when cross-cutting categories will be effective in reducing prejudice, we need to know how the individual subjectively represents his or her ingroups and the interrelationships among them.

As one step toward understanding the subjective structure of multiple social identities, Roccas and Brewer (2002) introduced the concept of *social identity complexity*. The idea behind the complexity construct is that it is not only how many social groups an individual identifies with that matters but, more important, how those different identities are subjectively combined to determine the overall inclusiveness of the individual's ingroup memberships. Specifically, Roccas and Brewer proposed that multiple social identities can be represented along a continuum of complexity and inclusiveness, reflecting the degree to which different identities are both differenti-

ated and integrated in the individual's cognitive representation of his or her group memberships. At the low end of the complexity dimension, the individual defines the ingroup as the *intersection* of all of his or her group identities, creating a single, highly exclusive identity category (e.g., female Republican college professors) whereby others who do not share all the same memberships are effectively outgroup members. At the high end of the social identity complexity dimension, the individual recognizes that each of his or her group memberships incorporates a different set of people as ingroup members and the combined representation is the *sum* of all of these group identities—more inclusive than any one ingroup identity considered alone.

Roccas and Brewer (2002) also speculated that social identity complexity (as represented by perceived overlap among ingroup memberships) would be associated with tolerance for outgroups in general. Social identity complexity is based on chronic awareness of cross-categorization in one's own social group memberships and those of others. A simple social identity is likely to be accompanied by the perception that any individual who is an outgroup member on one dimension is also an outgroup member on all others. In contrast, if an individual is aware that one of his ingroups only partly overlaps with any other of his ingroups, then we assume that he is also aware that some of his ingroup members have crossed group memberships: They are ingroup members on one dimension but are simultaneously outgroup members on others. Making salient that an outgroup member on one category dimension is an ingroup member on another decreases bias by comparison with instances in which the latter information is not available (Gaertner et al., 1993).

There are a number of theoretical reasons why a complex representation of ingroup categorization should influence intergroup attitudes and behavior in ways that reduce bias and discrimination. First, cross-cutting distinctions make social categorization more complex and reduce the magnitude of ingroup–outgroup distinctions. According to social categorization theory (Deschamps & Doise, 1978; Doise, 1978; Vanbeselaere, 1991), processes of intracategory assimilation and intercategory contrast counteract each other when categories are cross-cutting. Thus, the effects of intercategory accentuation are reduced or eliminated, and differences between groups are minimized (or no greater than perceived differences within groups). This undermines the cognitive basis of ingroup bias. Second, partially overlapping group memberships reduce the evaluative significance for the self of intergroup comparisons, thereby undermining the motivational base for intergroup discrimination (Vanbeselaere, 1991). Third, multiple group memberships reduce the importance of any one social identity for satisfying an individual's need for belonging and self-definition (Brewer, 1991), again reducing the motivational base for ingroup bias.

Finally, principles of cognitive balance (Heider, 1958; Newcomb, 1963) are also brought into play when ingroups and outgroups have overlapping membership. When another person is an ingroup member on one cat-

egory dimension but belongs to an outgroup in another categorization, cognitive inconsistency is introduced if that individual is evaluated positively as an ingroup member but is also associated with others who are evaluated negatively as outgroup members. In an effort to resolve such inconsistencies, interpersonal balance processes should lead to greater positivity toward the outgroup based on overlapping memberships. The processes here are similar to those underlying the "extended contact effect" (Wright et al., 1997). Having someone connected to the self (i.e., a friend or an ingroup member) associated with an outgroup should reduce negativity toward that outgroup.

In sum, both cognitive and motivational factors lead us to predict that complex social identities will be associated with reduced ingroup favoritism and increased tolerance and positivity toward outgroups in general. Results from a telephone interview survey of adult residents of the state of Ohio (Brewer & Pierce, 2005) supported this hypothesis. Individual differences in complexity of perception of their national, religious, occupational, political, and recreational social identities were systematically related to their attitudes toward ethnic outgroups and diversity. Individuals with a more complex representation of their own multiple ingroups were more tolerant of diversity and more accepting of outgroups in general than were individuals with less social identity complexity. Thus, both the actual complexity of the structure of the society and the individual's subjective representation of his or her networks of social group memberships contribute to the reduction of negative ingroup–outgroup relations.

CONCLUSIONS: IMPLICATIONS FOR MULTICULTURAL SOCIETIES

The principles of social categorization, ingroup favoritism, and outgroup prejudice discussed in this chapter have important implications for promoting positive intergroup relations within a context in which groups must live together interdependently. The same basic principles apply whether we are considering two nuclear families joining into a common household, departments or companies combined within an organization, diverse ethnic or religious groups within a nation, or nation-states within an international community. In any of these contexts, the goals of contact and cooperation compete with natural tendencies toward ingroup–outgroup differentiation, separation, and exclusion. Personalization across category boundaries and formation of common superordinate identities—processes that reduce the social meaning of category boundaries—are in tension with pluralistic values that seek to maintain cultural variation and distinct social identities.

The tension between differentiation and integration must be recognized and acknowledged in any complex social system. Exclusive focus on either assimilation or separation as the solution to intergroup discrimination and conflict is neither desirable nor realistic. Proponents of multiculturalism assert that alternatives to these extremes are possible, that groups can maintain distinct identities at the same time that their members participate in a shared, superordinate group structure. Berry (1984), for instance, has argued that there are four different forms of interethnic relations possible in a pluralistic society, depending on how members of the diverse ethnic groups relate to their own ethnic identity and to their role in the society at large. In Berry's classification system, integration is the form of intercultural relations in which identification with ethnic subgroups and identification with the larger society are both engaged. The reciprocal relations among processes of personalization, recategorization, and mutual differentiation discussed earlier are compatible with this view of social integration and constitute the necessary underpinnings for an equalitarian multicultural society.

CHAPTER 31

Social Psychology of Leadership

MICHAEL A. HOGG

Leadership is a huge, rambling behemoth of a topic. Because it so profoundly affects all of our lives, leadership is the focus not only of pure and applied academic disciplines such as philosophy, history, management and psychology but also of current affairs, literature and the arts, and of course the popular self-help and personal growth industry. Biography is frequently about leadership, and most classic accounts of history are mainly accounts of the actions of leaders. Our day-to-day life is pervaded by the impact of leadership—for example, leadership in the political, governmental, corporate, work, educational, and artistic spheres—and we all, to varying degrees, occupy leadership roles ourselves. Not surprisingly, people take a keen interest in leadership and we all have our own views on leaders and leadership. Incompetent leadership and leadership in the service of evil, in particular, are of great concern to us all (e.g., Kellerman, 2004). An excellent illustration of the scope of the topic of leadership is Goethals, Sorenson, and Burns's (2004) recent four-volume *Encyclopedia of Leadership*—1,927 pages, 1.2 million words, and 373 substantive (1,000–6,000 word) entries written by 311 scholars.

Because leadership has many facets and dimensions and occurs in many different contexts, it is a legitimate focus for many disciplines. For example, political science focuses on political and governance contexts (e.g., Gergen, 2000), philosophy focuses on the general principles of good leadership (e.g., Cawthon & Clark, 2002), history has often focused on the actions of "great people" (e.g., Simonton, 1994), and management science and or-

ganizational psychology, which are the main domains of leadership research, focus primarily on business leadership in corporate and organizational contexts (e.g., Avolio, 1999; Bass & Avolio, 1994; Bennis, 1989; Burns, 2003; Kellerman, 1999; Northhouse, 2004; Yukl, 2002).

Perhaps partly because of the dominance of research on business leadership, the scientific study of public leadership is somewhat less prolific—and yet public leadership has a huge impact on our lives. The Center for Public Leadership at Harvard University recently convened a 35-member committee of experts to name America's best currently living leaders (presidents and ex-presidents were excluded from the list). Published in *U.S. News & World Report* (October 31, 2005), the final list of 25 leaders included political leaders such as Colin Powell and Condolezza Rice; industry innovators such as Bill Gates, Steve Jobs, and Howard Schutz; media personalities such as Oprah Winfrey; and scientific leaders such as Francis Collins and Craig Venter, who mapped the human genome.

SOCIAL PSYCHOLOGY AND LEADERSHIP

Where does social psychology fit into all this? Historically, leadership was a significant and major focus of social psychology. This was the case through the glory days of research in the small-group dynamics tradition (e.g., Cartwright & Zander, 1968; Shaw, 1981). Indeed, leadership research has been a focus of some of social

psychology's classic research programs (e.g., Bales, 1950; Fiedler, 1964; Hollander, 1958; Lippitt & White, 1943; Sherif, 1966; Stogdill, 1974).

However, during the 1970s social psychology became preoccupied by an interest in social perception, social inference, and social cognitive processes (e.g., Devine, Hamilton, & Ostrom, 1994; Fiske & Taylor, 1991), and, in Europe, with large-scale intergroup relations and processes of social change (e.g., Moscovici, 1976; Tajfel, 1984). Research on small interactive groups lost its shine (e.g., Steiner, 1974) and there was an exodus of small-group research and small-group researchers to neighboring disciplines, notably organizational psychology and management science (Levine & Moreland, 1995; McGrath, 1997; Sanna & Parks, 1997; Tindale & Anderson, 1998).

Leadership research suffered the same fate—the third edition of *The Handbook of Social Psychology* featured a chapter on leadership, by Hollander (1985), but the most recent, fourth edition did not (Gilbert, Fiske, & Lindzey, 1998). For a period of almost a quarter of a century, since the mid-1970s most significant social psychological research on leadership has been conducted outside the social psychology mainstream—mainly in organizational and management disciplines where it found a natural and receptive home. This scientific focus on business leadership may have come at a cost—a somewhat restricted leadership research agenda, directing attention away from public leadership, nonprofit leadership, social movement leadership, celebrity leadership, scientific leadership, philanthropic leadership, and other manifestations of leadership as a general phenomenon in which individuals or groups are able to provide leadership to others.

Over the past 5–10 years things have changed. There has been a growing revival of interest within the mainstream of social psychology in leadership. This is attested to by many new empirical articles, and by handbook chapters (Chemers, 2001; Lord, Brown, & Harvey, 2001), an integrative position paper (van Knippenberg, van Knippenberg, De Cremer, & Hogg, 2004), a number of books (e.g., Chemers, 1997; Lord & Brown, 2004; Messick & Kramer, 2005; van Knippenberg & Hogg, 2003a), and of course this handbook chapter. There has also been a significant focus on gender and leadership (e.g., Eagly, Karau, & Makhijani, 1995; Eagly, Makhijani, & Klonsky, 1992).

One reason for this revival is that social psychology has once again taken an interest in studying groups—but this is a more wide-ranging and more cognitive interest in groups that incorporates both small-scale face-to-face groups and large-scale social categories and focuses on both what happens within and between groups (see Abrams & Hogg, 1998; Moreland, Hogg, & Hains, 1994).

DEFINING LEADERSHIP

The main reason, however, for this revival in interest in leadership is that leadership is a quintessentially social psychological phenomenon. Take Gordon Allport's (1968) classic definition of social psychology as "the scientific investigation of how the thoughts, feelings and behaviors of individuals are influenced by the actual, imagined or implied presence of others" (p. 3)—"influence" is the key term here, and what leaders do is influence other people. Chemers (2001) defines leadership as "a process of social influence through which an individual enlists and mobilizes the aid of others in the attainment of a collective goal" (p. 376). Leadership requires there to be an individual, or clique, which influences the behavior of another individual or group of individuals—where there are leaders there must be followers.

Not surprisingly, it is difficult to find a single simple definition of leadership that embraces all the research done on leadership—there are numerous definitions that reflect and are closely tied to the variety of different theories of, approaches to, and perspectives on leadership. From a social psychological point of view, however, leadership rests on the proximal or distal interaction between leader and follower that allows the former to influence the latter. The interaction is largely symbolic and is structured by an interaction of leader attributes and cognitions, follower attributes and cognitions, and properties of the immediate interactive context and wider sociostructural context.

This is a broad and complex characterization of the field that invites the question of what is *not* leadership. If I asked you to spend the weekend helping me clean my apartment and you agreed, either because you liked me or you were afraid of me, it would be influence but not leadership—this is a classic case of compliance (e.g., Cialdini & Trost, 1998). Related to this, the exercise of power is generally not considered to be leadership (e.g., Chemers, 2001; Lord, Brown, & Harvey, 2001; Moscovici, 1976; Raven, 1993). If you agreed because you knew that there was a neighborhood norm to clean at the weekend, that would be conformity to a norm (e.g., Turner, 1991)—not an example of leadership. If on the other hand I had first convinced you that we should develop a neighborhood cleaning norm, and you subsequently adhered to that norm, then that most definitely would be leadership. Leaders play a critical role in defining collective goals, and in this respect leadership is more typically a group processes than an interpersonal process—it is an influence process that plays out more noticeably in group than interpersonal contexts.

Another key question is, How do we evaluate leaders and leadership (e.g., Kellerman, 2004)? In answering this question it is useful to distinguish between the two evaluative dimensions of effective/ineffective leaders and good/bad leaders. An effective leader is someone who is successful in setting new goals and influencing others to achieve them. Here, the evaluation of leadership is largely an objective matter of fact—how much influence did the leader have in setting new goals and were the goals achieved? In contrast, evaluating whether the leader is good or bad is largely a subjective judgment based on one's preferences and perspective, and one's goals and group memberships. We evaluate leaders in terms of their character (e.g., nice, nasty, or charismatic), the ethics and morality of the means they use to influ-

ence others and achieve goals (e.g., persuasion, coercion, oppression, or democratic decision making), and the nature of the goals that they lead their followers toward (e.g., saving the environment, reducing starvation and disease, producing a commodity, combating oppression, waging war, and engaging in genocide). Here good leaders are those who have attributes we applaud, use means we approve of, and set and achieve goals we value. Thus, secular Westerners and supporters of al-Qaeda would disagree on whether Osama bin Laden is a good leader (they disagree on the value of his goals and the morality of his means) but may agree that he has been a relatively effective leader (agreeing that he has mobilized fundamentalist Muslims around his cause).

CHAPTER AIMS AND OUTLINE

Because leadership is such a huge subject it would be impossible to provide, in this single chapter, a comprehensive and detailed coverage of the entire field. I have had to be selective. In doing this I have tried to make sure that the main themes and ideas are covered, albeit sometimes briefly, but have focused more on social psychology than on management and organizational science, and I have tried to spend more time on some of the more recent contributions from and within social psychology.

I start by discussing the extent to which some people are more effective leaders because they have specific personalities that predispose them to leadership. This focus on personality and individual differences surfaces in a slightly different guise later when we discuss transformational and charismatic leadership. To counterbalance the personality perspective is a situational perspective that essential argues that we can all lead if the circumstances are right.

Generally, an interactionist perspective is most useful—particular kinds of leadership behavior are more effective in some situations, and other behaviors are more effective in other situations. This view spawned substantial research on the behavior of leaders, in an attempt to distinguish between different categories of leader behavior—one important distinction that surfaces in different guises is between behaviors that focus primarily on getting the task done and behaviors that focus primarily on how group members feel. The interactionist perspective finds its most elaborated form in contingency theories of leadership—the leadership effectiveness of certain types of behavior is contingent upon situational factors. I discuss Fiedler's contingency theory, normative decision theory, and path-goal theory.

Leadership involves interactions between leaders and followers. One perspective on these interactions is that they involve transactions in which both leaders and followers provide resources for each other—if the transaction is mutually beneficial then leadership is effective. I discuss Hollander's notion of idiosyncrasy credit, the vertical dyad linkage (VDL) model, and leader–member exchange (LMX) theory. Path-goal theory can also be classified as a transactional theory.

Undoubtably the most popular approach to leadership in recent years, particularly in management and organizational science, is the transformational model. Effective leaders are those who can instill in followers their vision for a new and better future for the group—effective leaders need to be able to transform groups. Charisma and charismatic leadership play a central role in transformational leadership.

Another, more social psychological, perspective on leadership is fueled by social cognition and what we know about the role of schemas in social perception. According to leader categorization theory, we all have schemas of leadership, and effective leaders are those whom we can categorize as a good fit to our schema of an effective leader in a particular situation. Schematic expectations also play a central role in expectations state theory, status characteristics theory, and role congruity theory.

I have dedicated a section to the social identity theory of leadership. Although only relatively recently formulated, this approach has attracted substantial attention (it crops up throughout the chapter), and because it links social cognition, self-conception, and group behavior, it represents a direct treatment of leadership as a group process. The basic idea is that where people identify with a group, leadership benefits if the leader is seen to embody the group's attributes—this builds popularity and trust and allows the leader latitude to be innovative.

The body of the chapter finishes with a discussion of trust and leadership, and gender and leadership. Trust is very basic to effective leadership. I discuss the role of justice perceptions and trust in leadership, and the role of leadership in building trust that may resolve social dilemmas. The study of gender differences in perceived leadership effectiveness has gathered momentum over the past 10 years—mainly through the work of Eagly and her associates. One of the main factors influencing gender and leadership is role incongruity—where gender stereotypes clash with leadership role schemas, leaders find it difficult to be effective.

The chapter concludes with a brief summary and overview in which in which I explicitly pull together some basic principles of leadership—things that we know pretty much for sure about leadership. I also identify some burgeoning directions for future leadership research in social psychology.

INDIVIDUAL DIFFERENCES
AND LEADERSHIP PERSONALITIES

In everyday life people tend to personify leadership—they focus on the person who leads rather than the context or process of leadership. We probably do this because the leader, as an individual, is figural against the background of the group and is therefore the focus of our attention. Under these conditions people are likely to explain the leader's behavior internally in terms of invariant personality dispositions (cf. Gilbert & Malone, 1995; Haslam, Rothschild, & Ernst, 1998; Ross, 1977)—there is evidence that this is indeed the case (e.g., Fiske & Dépret, 1996; Meindl, Ehrlich, & Dukerich, 1985).

Social psychologists are little different from people in everyday life and have therefore tried to explain leadership in terms of personality constellations that suit some people for effective leadership better than others. The "great person" analysis of leadership has a long and illustrious pedigree, going back to Plato and ancient Greece. One scholarly view, championed in the 19th century by Francis Galton (1892), was that leaders are born, not made. Most scholars, however, rejected the argument that leadership is innate, instead proposing that it was acquired very early in life, and therefore that an enduring constellation of personality attributes exists that imbues people with charisma and a predisposition to lead (e.g., Carlyle, 1841; House, 1977).

A prodigious amount of research has been conducted to identify reliable personality correlates of effective leadership. All that has been found is a handful of weak correlates, among which intelligence and talkativeness are the most reliable—leading Stogdill (1948), in his classic review, to conclude that leadership is not a "mere possession of some combination of traits" (p. 66), and others to proclaim that the search for a leadership personality is simplistic and futile (e.g., Conger & Kanungo, 1998). In general, correlations among traits, and between traits and effective leadership, are very low (Stogdill, 1974, reports an average correlation of .30).

Nevertheless, the belief that some people are better leaders than others because they have enduring traits that predispose them to effective leadership persists. This idea has reemerged, as we shall see later, in a different guise in modern theories of transformational leadership that place an emphasis on charisma (e.g., Avolio & Yammarino, 2003; Bass, 1985; Conger & Kanungo, 1998). Rather than focusing on specific traits, this tradition focuses on the wider Big Five personality dimensions of extraversion/surgency, agreeableness, conscientiousness, emotional stability, and intellect/openness to experience. A definitive meta-analysis by Judge, Bono, Ilies and Gerhardt (2002) reports a multiple correlation of .58 of these attributes with leadership—with extraversion/surgency, intellect/openness to experience, and conscientiousness as the best predictors of effective leadership.

SITUATIONAL PERSPECTIVES

In contrast to personality approaches that attribute effective leadership to possession of particular enduring trait constellations is the view that anyone can lead effectively if the situation is right. The most extreme form of this perspective is to deny any influence at all to the leader. For example, much of Tolstoy's epic novel *War and Peace* is a vehicle for his critique of the great person account of history: "To elicit the laws of history we must leave aside kings, ministers and generals, and select for study the homogeneous, infinitesimal elements which influence the masses" (Tolstoy, 1869, p. 977). Likewise, Karl Marx's theory of history places explanatory emphasis on the actions of collectivities, not individuals.

This perspective may be too extreme. For example, from an analysis of 300 military battles, Simonton (1980) found that situational factors did not account for all the outcomes—personal attributes of specific leaders were also significant correlates. In reality, effective leadership is a function of a match between one's behavioral style or personality attributes and the particular requirements of a specific leadership situation. Different situations call for different leadership properties, and therefore the most effective leader in a given context is the group member who is best equipped to assist the group in achieving its objectives (Bales, 1950). For example, Carter and Nixon (1949) had pairs of high school students perform three different tasks—an intellectual task, a clerical task and a mechanical assembly task. Those who took the lead in the first two tasks rarely led in the mechanical assembly task. In another example, Sherif, Harvey, White, Hood, and Sherif (1961; Sherif, 1966) documented in one of their boys' camp studies a change of leader in one of the groups when the situation changed to one of intergroup competition.

THE BEHAVIOR OF LEADERS

If effective leadership is an interaction between leader attributes and situational requirements, then we need to know about leader attributes. Based on dissatisfaction with the predictive reliability and utility of personality and on concerns about the validity of the construct of personality itself, another perspective on the study of leadership focuses on what leaders do—their actual behavior. This perspective spawned some of social psychology's classic leadership research.

One of the earliest studies was Lippitt and White's (1943) experiment on the effect of three different leadership styles (autocratic, democratic, and laissez-faire) on group atmosphere, morale, and effectiveness in afterschool activities clubs for young boys. They found that a democratic leadership style was most effective—it produced a friendly, group-centered, task-oriented atmosphere that was associated with relatively high group productivity, which was unaffected by whether or not the leader was physically present.

Another program of research, into interaction styles in groups (Bales, 1950), identified two key leadership roles: *task specialist* and *socioemotional specialist* (Slater, 1955). No one person could occupy both roles simultaneously, and the person occupying the task-specialist role was more likely to be the dominant leader. Task specialists tend to be centrally involved, often by offering opinions and giving directions, in the task-oriented aspects of group life, whereas socioemotional specialists tend to respond and pay attention to the feelings of other group members.

The Ohio State leadership studies constitute a third major leadership program (e.g., Fleishman, 1973; Stogdill, 1974). In this research, a scale for measuring leadership behavior was devised, the Leader Behavior Description Questionnaire (LBDQ) (e.g., Shartle, 1951), and a distinction was drawn between *initiating structure*

and *consideration*. Leaders rating high on initiating structure define the group's objectives and organize members' work toward the attainment of these goals: They are task oriented. Leaders rating high on consideration are concerned with the welfare of subordinates and seek to promote harmonious relationships in the group: They are relationship oriented. Unlike Bales (1950), who believed that task-oriented and socioemotional attributes were inversely related, the Ohio State researchers believed their dimensions to be independent—a single person could be high on both initiating structure (task-oriented) and consideration (socioemotional), and such a person would be a particularly effective leader. Research tends to support this latter view (e.g., Sorrentino & Field, 1986; Stogdill, 1974).

The general distinction between a leadership style that pays more attention to the group task and getting things done and one that pays attention to relationships among group members is quite pervasive in the leadership literature. For example, as we see later, it also appears in Fiedler's (1964) influential contingency theory of leadership, and in a slightly different guise in leader–member exchange (LMX) theory's emphasis on the quality of the leader's relationship with his or her followers (e.g., Graen & Uhl-Bien, 1995). Furthermore, it is a distinction that may hold across cultures, but with the caveat that what counts as task oriented or socioemotional leadership behavior may vary from culture to culture (e.g., Smith, Misumi, Tayeb, Peterson, & Bond, 1989)—for example, eating lunch with workmates is considered socioemotional leadership in some cultures but not others (Misumi & Peterson, 1985).

CONTINGENCY THEORIES

Contingency theories of leadership recognize that the leadership effectiveness of particular leadership behaviors or styles is contingent upon the properties of the leadership situation: Some styles are better suited to some situations or tasks than are others.

Fiedler's Contingency Theory

In social psychology the best known contingency theory is that proposed by Fiedler (1964, 1967). Fiedler, like Bales (1950), distinguished between task-oriented and relationship-oriented leaders—measuring leadership style in a rather unusual way with his Least Preferred Coworker (LPC) scale in which respondents rated their least preferred coworker on semantic differentials. High LPC scores meant that the respondent felt favorably inclined toward a fellow member even if he or she was not performing well (indicating a relationship-oriented style), and low LPC scores indicated a task-oriented style because the respondent was harsh on a poorly performing coworker.

Fiedler classified situations in terms of the quality of leader–member relations, the clarity of the structure of the task, and the intrinsic power and authority the leader had by virtue of his or her position as leader—good

leader–member relations in conjunction with a clear task and substantial position-power furnished maximal "situational control" (making leadership easy), whereas poor leader–member relations, a fuzzy task, and low position power furnished minimal "situational control" (making leadership difficult).

Fiedler's prediction was that low LPC, task-oriented, leaders would be most effective when situational control was low (the group needs a directive leader who focuses on getting things done) *and* when it was high (the group is doing just fine so there is little need to worry about morale and relationships within the group). High LPC, relationship-oriented leaders are more effective when situational control lies between these extremes. Against a background of some controversy and criticism (e.g., Peters, Hartke, & Pohlmann, 1985) focused, for example, on the measurement of situational control and on the characterization of leadership style as an invariant personal quality, Fiedler's predictions based on contingency theory have generally been supported (see meta-analyses by Strube & Garcia, 1981, and Schriesheim, Tepper, & Tetrault, 1994).

One troublesome finding, reported by Kennedy (1982), is that the 20% or so of leaders who have neither high nor low LPC scores are actually the most effective leaders of all, and their effectiveness is not affected by situational control. Another limitation of Fiedler's theory is that it is somewhat static—it does not focus on the dynamic interactive processes that occur within a group between leaders and followers and among followers, which characterize leadership situations.

Normative Decision Theory

Vroom and his associates have brought a contingency perspective to the explanation of leadership and the role of subordinate participation in group decision making (e.g., Vroom & Jago, 1988; Vroom & Yetton, 1973). Vroom's normative decision theory (NDT) identifies three decision-making strategies among which leaders can choose: autocratic (subordinate input is not sought), consultative (subordinate input is sought, but the leader retains the authority to make the final decision), and group decision making (leader and subordinate's are equal partners in a truly shared decision-making process). The relative efficacy of these strategies is contingent upon the quality of leader–subordinate relationships (which influences how committed and supportive subordinates are), and on task clarity and structure (which influences how much need the leader has for subordinate input).

In decision-making contexts autocratic leadership is fast and effective if subordinate commitment and support are high and the task is clear and well structured. When the task is less clear, greater subordinate involvement is needed and therefore consultative leadership is best. When subordinates are not very committed or supportive, group decision making is required to increase participation and commitment. Predictions from NDT are reasonably well supported empirically (e.g., Field & House, 1990)—leaders and managers report better deci-

sions and better subordinate ratings when they follow the prescriptions of the theory. However, there is a tendency for subordinates to prefer fully participative group decision making, even when it is not the most effective strategy.

Path-Goal Theory

Path-goal theory (PGT), developed by House and his colleagues (e.g., House, 1971; House & Mitchell, 1974), is another well-known contingency theory—although it can also be classified as a transactional leadership theory (see below). PGT is predicated on the assumption that a leader's main function is to motivate followers by clarifying the paths (i.e., behaviors and actions) that will help them attain their goals. It distinguishes between the two classes of leader behavior identified by the LBDQ, described earlier: *structuring* behaviors, whereby the leader directs task-related activities, and *consideration* behaviors, whereby the leader addresses followers' personal and emotional needs.

PGT predicts that structuring behaviors will be most effective when followers are unclear about their goals and how to reach them (e.g., when the task is new, difficult or ambiguous). When tasks are well understood structuring behaviors are less effective, or they can even backfire because they are viewed as undue meddling and micromanagement. Consideration behaviors are most effective when the task is boring or uncomfortable, but they can backfire when followers are already engaged and motivated because they are considered distracting and unnecessary.

Empirical support for PGT is mixed, and most scholars agree that tests of the theory tend to suffer from flawed methodology and from being incomplete and simplistic (Schriesheim & Neider, 1996). For these reasons research on PGT tapered off in the early 1980s. Recently, however, House (1996) has tried to reinvigorate the theory by addressing some of these concerns and by making it feel more contemporary—for example, the interpersonal focus of the original formulation has been expanded to include ways in which a leader can motivate an entire work group rather than just individual followers.

TRANSACTIONAL LEADERSHIP

One limitation of contingency theories is that in general they are somewhat static in not focusing on the dynamic interaction between leader and follower(s) that allows leaders to lead and encourages followers to follow. After all, effective leadership requires leaders and followers to provide support and gratification for one another (Messick, 2005). This lacuna is addressed by theories of transactional leadership.

Transactional leadership has been referred to as a "process of exchange that is analogous to contractual relations in economic life [and] contingent on the good faith of the participants" (Downton, 1973, p. 75). Leaders transact with followers to get things done, setting expectations and goals and providing recognition and re-

wards for task completion (Burns, 1978). Taking this idea further, Bass (1985) talked of contingent rewards and punishments—mutual benefits are exchanged (transacted) between leaders and followers against a background of contingent rewards and punishments that shape up cooperation and trust. Leader member transactions may also have an equity dimension (Walster, Walster, & Berscheid, 1978). Because effective leaders play a greater role in steering groups to their goals than do followers, followers may reinstate equity by rewarding the leader with social approval, praise, prestige, status, and power—in other words, with the trappings of effective leadership.

Although PGT, discussed above (e.g., House, 1971), is a contingency theory because of its focus on how the effectiveness of leadership behaviors is contingent upon situations, it can also be considered a transactional theory because it focuses on the transactions between leaders and followers that enhance motivation and lead to goal attainment.

Idiosyncrasy Credit

A well-known early approach to leadership that focused on leader–follower transactions is Hollander's (1958; Hollander & Julian, 1970) analysis of idiosyncrasy credit. Hollander argued that for leaders to be effective, they need to be allowed by the group to be innovative, to be able to experiment with new ideas and new directions—to be idiosyncratic. Drawing on the equity argument, Hollander wondered what circumstances of leadership would create a transactional relationship between leader and followers in which the followers would provide the leader with the resources to be able to be idiosyncratic. Hollander argued that leaders who had behaved in a highly conformist manner as they climbed the organizational ladder accumulated "idiosyncrasy credits" from the group. When the leader arrived at the top of the organization, followers would effectively hand over these credits (as a resource) to the leader, who could then "spend" them by behaving idiosyncratically, innovatively, and creatively.

Research provides some support for this analysis. Merei (1949) introduced older children who had shown leadership potential into small groups of younger children in a Hungarian nursery. The most successful leaders were those who initially complied with existing group practices and who only gradually and later introduced minor variations. In another study, Hollander and Julian (1970) found that leaders of decision-making groups who were ostensibly democratically elected enjoyed more support from the group, felt more competent at the task, and were more likely to suggest solutions that diverged from those of the group as a whole.

The idea that leaders who initially conform to group norms are ultimately allowed to be innovative and, paradoxically, nonnormative has recently been given a more group-oriented spin than allowed by a strictly interpersonal transaction approach. Drawing on the social identity approach in general (see Hogg, 2003, 2006, for an overview) and its more recent theory of leadership

(Hogg, 2001; Hogg & van Knippenberg, 2003; van Knippenberg & Hogg, 2003b; see below) it has been argued that group normative behavior on the part of a leader communicates to the group that the leader is "one of us"—a central member who identifies strongly with the group and embodies the norms and aspirations of the group and is therefore unlikely to do the group any harm (Platow, Hoar, Reid, Harley, & Morrison, 1997; Platow, Reid, & Andrew, 1998; Platow & van Knippenberg, 2001; van Knippenberg & van Knippenberg, 2005). If one identifies strongly with the group oneself, then such a person is to be trusted (e.g., Brewer, 1981; Hogg, in press; Tyler, 1997; Yamagishi & Kiyonari, 2000) and followed, because whatever he or she suggests or does is likely to be in the best interest of the group. The social identity analysis of leadership and the role of trust in leadership are both discussed more fully below.

Vertical Dyad Linkage Model and Leader–Member Exchange Theory

Leader–member transactions play a central role in the vertical dyad linkage (VDL) model of leadership (Dansereau, Graen, & Haga, 1975), which has evolved into leader–member exchange (LMX) theory (e.g., Graen & Uhl-Bien, 1995; Sparrowe & Liden, 1997). According to VDL researchers, leaders develop dyadic exchange relationships with different specific subordinates. In these dyadic relationships, the subordinate can either be treated as a close and valued "ingroup" member with the leader or in a more remote manner as an "outgroup" member who is separate from the leader.

As the VDL model evolved into LMX theory this dichotomous, ingroup versus outgroup, treatment of LMX relationships has disappeared and been replaced by a continuum of quality of exchange relationships ranging from ones that are based on mutual trust, respect and obligation (high-quality LMX relationships) to ones that are rather mechanically based on the terms of the formal employment contract between leader and subordinate (low-quality LMX relationships).

In high-quality LMX relationships subordinates are favored by the leader and receive many valued resources, which can include material benefits (e.g., money and privileges) as well as psychological benefits (e.g., trust and confidences). Leader–member exchanges go beyond the formal employment contract, with managers showing influence and support and giving the subordinate greater autonomy and responsibility. High-quality relationships should motivate subordinates to internalize the group's and the leader's goals. In low-quality LMX relationships subordinates are disfavored by the leader and receive fewer valued resources. Leader–member exchanges simply adhere to the terms of the employment contract, with little attempt by the leader to develop or motivate the subordinate. Subordinates will simply comply with the leader's goals, without necessarily internalizing them as their own.

LMX theory predicts that effective leadership hinges on the development of high-quality LMX relationships. These relationships enhance subordinates' well-being

and work performance and bind them to the group more tightly through loyalty, gratitude, and a sense of inclusion. Differentiated LMX relationships develop in groups because the leader usually has to relate to a large number of subordinates, and it is simply more efficient to select some subordinates in whom to invest a great deal of interpersonal energy and to treat the rest in a less intensive and personalized manner. The selection process takes time because it goes through a number of stages: role taking, in which the leader has expectations and tries out different roles on the subordinate; role making, in which mutual leader–member exchanges (e.g., of information and support) establish the subordinate's role; and role routinization, in which the leader–member relationship has become stable, smooth-running, and automatic.

Research confirms that differentiated LMX relationships do exist in most organizations; that high-quality LMX relationships are more likely to develop when the leader and the subordinate have similar attitudes, like one another, belong to the same sociodemographic groups, and both perform at a high level; and that high-quality LMX relationships are associated with (most studies are correlational, not causal) better performing and more satisfied workers who are more committed to the organization and less likely to leave (see Gerstner & Day, 1997; Graen & Uhl-Bien, 1995; Liden, Sparrowe, & Wayne, 1997; Schriesheim, Castro, & Cogliser, 1999). The stages of LMX relationship development are consistent with more general models of group development (e.g., Levine & Moreland, 1994; Tuckman, 1965).

The main general limitation of LMX theory is that it focuses on dyadic leader–member relations. It fails to consider that such dyadic relations are located in a wider context of shared group membership in which followers interact with one another as group members and are influenced by their perceptions of the leader's relations with other group members (Hogg & Martin, 2003; Hogg, Martin, & Weeden, 2004; Scandura, 1999). For example, from the perspective of the social identity theory of leadership (Hogg, 2001; see below), we would expect that when members identify strongly with a group they might find differentiated LMX relationships that favor some members over others to be uncomfortably personalized and fragmentary of the group and would not endorse such leaders. Instead, members might prefer a somewhat more depersonalized leadership style that treated all members relatively equally as group members—endorsing such leaders more strongly. This general hypothesis has recently been tested and supported in two field surveys of leadership perceptions in organizations in Wales and India (Hogg et al., 2005).

TRANSFORMATIONAL LEADERSHIP

Transactional theories of leadership represent a particular focus on leadership, but transactional leadership is itself a particular leadership style that can be contrasted to other leadership styles. In defining transactional leadership, Burns (1978) contrasted it sharply with transforma-

tional leadership. This contrast is put rather clearly by Judge and Bono (2000): Transactional leaders appeal to followers' self-interest, whereas transformational leaders inspire followers to adopt a vision that involves more than individual self-interest.

Three key components of transformational leadership are (1) individualized consideration (careful attention to followers' needs, abilities and aspirations, in order to help raise aspirations, improve abilities, and satisfy needs); (2) intellectual stimulation (challenging of followers' basic thinking, assumptions, and practices to help them develop newer and better mindsets and practices); and (3) charismatic/inspiring leadership, which provides the energy, reasoning, and sense of urgency that transforms followers (Avolio & Bass, 1987; Bass, 1985).

Transformational leadership theorists were quickly mortified that the charisma/inspiration component inadvertently admitted notorious dictators such as Hitler, Stalin, and Pol Pot into the hallowed club of transformational leaders—all were effective leaders insofar as they mobilized groups around their goals. So, a distinction was drawn between good charismatic leaders with socialized charisma that they use in a "morally uplifting" manner to improve society and bad charismatic leaders who use personalized charisma to tear down groups and society—the former are transformational, the latter are not (e.g., Avolio & Gibbons, 1988; Bass, 1990; O'Connor, Mumford, Clifton, Gessner, & Connelly, 1995).

In recent years the distinction between transactional and transformational leadership has been joined by a third type of leadership—laissez-faire (noninterfering) leadership, which involves not making choices or taking decisions and not rewarding others or shaping their behavior. Avolio and Bass (1991; Avolio, 1999) use laissez-faire leadership as a baseline anchor point in their full-range leadership model that has transformational leadership sitting at the apex (see Antonakis & House, 2003).

First published by Bass and Avolio in 1990, the Multifactor Leadership Questionnaire (MLQ) was designed to measure the components of transactional and transformational leadership. After revisions to address criticisms and problems, it is now in its fifth version, and it has been used in every conceivable organization, at every conceivable level, and on almost every continent. It has become the de facto leadership questionnaire of choice of the organizational and management research communities—producing numerous large-scale meta-analyses of findings (e.g., Lowe, Kroeck, & Sivasubramaniam, 1996; see also Avolio & Yammarino, 2003).

The Black Box of Transformation

One of the contemporary challenges for transformational leadership theory is to explicate what happens in the head of a follower to transform leader behavior into follower thought and behavior—what is the social psychology of transformation? Shamir, House, and Arthur (1993) suggest that followers personally identify with the leader and in this way make the leader's vision their own.

Dvir, Eden, Avolio, and Shamir (2002) suggest that the behavior of transformational leaders causes followers to identify more strongly with the organization's core values.

These ideas fit well with but are taken further by the more comprehensive social identity theory of leadership (e.g., Hogg, 2001) that is discussed later. Where group members identify strongly with a group, leaders who are considered central/prototypical group members are able to be innovative in defining a group's goals and practices. Strong identification is associated with internalization of group norms as one's own beliefs and actions. In this way leaders can transform groups.

Charisma and Charismatic Leadership

As we saw previously, the notion of charisma is so central to transformational leadership theory that a distinction was drawn between good and bad charisma, in order to distinguish between nontransformational villains (e.g., Hitler) and transformational heroes (e.g., Gandhi). Herein lies an initial problem with transformational leadership theory that can probably be traced to its grounding in organizational and management science (Jack Welch, former CEO of General Electric, is often held up as the apotheosis of a charismatic transformational leader) rather than social psychology or political science—one person's transformational leader can sometimes be another's war criminal or vice versa (much like one person's freedom fighter is another's terrorist). For example, whether Lenin and Mao are considered transformational leaders or not may rest more on one's political persuasion and ideological leanings than on transformational leadership theory's notion of good versus bad charisma (see earlier discussion of effective/ineffective vs. good/bad dimensions of leadership).

There is perhaps a more general issue concerning the role of charisma in transformational leadership. Scholars speak of charismatic leadership as a product of the leader's personal charisma and followers' reactions to the leader's charisma in a particular situation—personal charisma alone may not guarantee charismatic leadership (e.g., Bryman, 1992). However, it is difficult to escape the inference that charisma is a relatively enduring personality trait—in which case some of the problems of past personality theories of leadership may have been reintroduced (Haslam & Platow, 2001; Mowday & Sutton, 1993). Indeed, charismatic/transformational leadership has been linked to possession of the big five personality traits of extraversion/surgency, agreeableness, and intellect/openness to experience (e.g., Judge et al., 2002). Charismatic leadership is also linked to the related construct of visionary leadership (e.g., Conger & Kanungo, 1998) and the view that people differ in terms of how visionary they are as leaders. Visionary leaders are special people who are able to identify attractive future goals and objectives for a group and mobilize followers to internalize these as their own.

There is no doubt that charisma facilitates effective leadership; probably because charismatic individuals are emotionally expressive, enthusiastic, driven, eloquent, vi-

sionary, self-confident, and responsive to others (e.g., House, Spangler, & Woycke, 1991; Lindholm, 1990; Riggio & Carney, 2003). These attributes allow a person to be influential and persuasive and therefore able to make others buy their vision for the group and sacrifice personal goals for collective goals. Meindl and Lerner (1983; Meindl et al., 1985) talk about visionary leaders heightening followers' sense of shared identity, and how this shared identity produces a collective "heroic motive" that puts group goals ahead of personal goals.

The role of shared identity in charismatic leadership is given a different treatment by the social identity theory of leadership. Social identity researchers adhere to a meta-theory that views personality as playing at best a minor role in group processes (e.g., Abrams & Hogg, 2004; Billig, 1976). So, in the social identity theory of leadership (e.g., Hogg, 2001; Hogg & van Knippenberg, 2003; see below) charisma is seen more as a product of group processes than an ultimate cause of effective leadership. Social identity processes in salient groups that members identify strongly with render group prototypical (central) leaders influential and attractive, imbue them with trust, and allow them to be innovative. Followers attribute these qualities internally to the leader's personality—thus constructing a charismatic leadership personality. Empirical studies provide some support for the attributional construction of charisma (e.g., Fiske & Dépret, 1996; Meindl et al., 1985) and for the wider social identity perspective on charisma and leadership (see Haslam & Platow, 2001; Platow & van Knippenberg, 2001).

LEADER PERCEPTIONS AND LEADERSHIP SCHEMAS

Leader Categorization Theory

Keeping pace with the social cognition revolution in social psychology in the late 1970s (Taylor, 1998), and drawing on earlier work on implicit theories of leadership (Hollander & Julian, 1969), an approach to leadership has developed that focuses on the specific content of our leadership schemas and on the causes and consequences of categorization of someone as a leader. Leader categorization theory (LCT), or implicit leadership theory (e.g., Lord, Brown, Harvey, & Hall, 2001; Lord, Foti, & DeVader, 1984; Lord, Foti, & Phillips, 1982; Lord & Hall, 2003; Lord & Maher, 1991), assumes that leadership perceptions play a key role in leader selection decisions, in leader endorsement, and in a leader's power base, and thus in the extent to which people can effectively exercise leadership and influence others.

The theory rests on the notion that people have implicit leadership theories that shape their perceptions of (potential) leaders. In making leadership judgments, leadership schemas (called prototypes by Lord and colleagues) based on these implicit leadership theories are activated, and characteristics of the leader are matched against the relevant schema of effective leadership. Earlier conceptions of LCT (e.g., Lord et al., 1984) viewed leader schemas as relatively general and fixed. The contemporary version (e.g., Lord, Brown, Harvey, & Hall, 2001; Lord & Hall, 2003), which invokes a role for connectionist networks, views leadership schemas as flexible cognitive structures that are regenerated in situ to meet contextual demands.

The basic prediction, however, of LCT remains the same. The better the match between the leader's characteristics and the perceiver's leadership schema, the more favorable are leadership perceptions. For example, a perceiver whose leadership schema favors "intelligent," "organized," and "dedicated" as core leadership attributes is more likely to endorse a leader the more the leader is perceived to be intelligent, organized, and dedicated.

LCT focuses on categories and associated schemas of leadership and leaders (e.g., military generals, CEOs, outward bound leaders), not on social groups as categories (e.g., a psychology department, a corporation, a sports team). LCT's leader categories are tied to tasks and functions, and transcend groups—for example, a CEO schema applies similarly to companies such as Apple, Dell, GM, Toyota, Starbucks, Google, and so forth, whereas each company may have very different group norms and prototypes. LCT leaves unanswered the question of how schemas of group membership may influence leadership (but see Lord & Hall, 2003)—more specifically the role played by group identification and group prototypicality in effective leadership. This lacuna is addressed by the social identity theory of leadership (e.g., Hogg, 2001; see below)

Expectation States, Status Characteristics, and Role Congruity

Related to LCT are two other theories that also focus on leader categorization processes but do not go into social cognitive details quite so extensively—expectation states/status characteristics theory, and role congruity theory. Both theories suggest that the match between an individual's characteristics and abstracted conceptions of status and leadership affect leadership perceptions.

Expectation states theory or status characteristics theory (e.g., Berger, Fisek, Norman, & Zelditch, 1977; Berger, Wagner, & Zelditch, 1985; Ridgeway, 2001) attributes influence (and by implication leadership) within groups to possession of specific status characteristics (qualities that match what the group actually does) and diffuse status characteristics (stereotypical properties of high-status groups in society). Influence within an interactive group is a function of the extent to which a person possesses characteristics that suit him or her to effective task performance (i.e., specific status characteristics), and possesses characteristics that categorize him or her as a member of a high-status sociodemographic category (i.e., diffuse status characteristics). Influence, or leadership, is an additive function of perceived group task competence and perceived societal status (Ridgeway, 2003).

Role congruity theory focuses on gender and leadership (see below). According to Heilman (1983), gender-linked differential leadership potential may rest on a perceived congruity or incongruity between stereotype-based skills and attributes of an individual, and the per-

ceived nature of a job's requirements. In other words, because there is greater overlap between general leader schemas and male stereotypes than between leader schemas and female stereotypes, people tend to have more favorable perceptions of male leaders than of female leaders (Eagly, 2003; Eagly & Karau, 2002). Research provides some support for role congruity theory (e.g., Martell, Parker, Emrich, & Swerdlin Crawford, 1998; Shore, 1992).

SOCIAL IDENTITY AND LEADERSHIP

Leadership is a relationship in which some people are able to influence others to embrace, as their own, new values, attitudes, and goals and to exert effort on behalf of and in pursuit of those values, attitudes, and goals. The relationship is almost always configured by and played out within the parameters of a group—a small group like a team, a medium-size group like an organization, or a large group like a nation. Effective leadership inspires others to adopt group membership defining values, attitudes, and goals and to behave in ways that serve the group as a collective. Effective leaders are able to transform individual action into group action. Thus, leadership has an important identity function. People look to their leaders to express and epitomize their identity, to clarify and focus their identity, to forge and transform their identity, and to consolidate, stabilize, and anchor their identity.

Leadership is a core feature of social groups—it is difficult to think about groups without thinking about who leads or manages them, and about how well they are led and managed. Indeed, if one scratches below the surface of apparently leaderless groups a tacit leadership structure almost always emerges (e.g., Counselman, 1991). Given the pervasiveness and importance of leadership in group life, it seems odd that leadership is often not a core feature of the study of group processes and group processes are often not a core feature of the study of leadership (Chemers, 2001), and the identity function of leadership is very rarely center stage.

One way in which these issues have recently been addressed is through the development of the social identity theory of leadership (Hogg, 2001, 2005; Hogg & van Knippenberg, 2003; van Knippenberg & Hogg, 2003b). Firmly grounded in the social identity approach (e.g., Hogg & Abrams, 1988; Tajfel & Turner, 1986; Turner, Hogg, Oakes, Reicher, & Wetherell, 1987; see Hogg, 2003, 2006, for recent formulations), the social identity theory of leadership has, in a relatively short time, energized a significant amount of new leadership research in social psychology that focuses on the role of group membership and social identity (see Ellemers, de Gilder, & Haslam, 2004; van Knippenberg & Hogg, 2003a; van Knippenberg et al., 2004).

The central tenet is that as people identify more strongly with a group, they pay more attention to the group prototype and to what and who is more prototypical—this is because the prototype defines the group's membership attributes. In these salient group contexts being perceived to be highly prototypical makes one more influential. There are a number of social identity-related processes that cause this to happen. First, prototypical members best embody the group's attributes, and so they are seen to be the source rather than target of conformity processes—they are the ones to whom other members seem to align their behavior (e.g., Turner, 1991).

Second, prototypical members are liked as group members (a process of depersonalized social attraction), and, because there is usually significant agreement on the prototype, the group as a whole likes the leader—he or she is consensually popular in group terms (Hogg, 1993). This process not only facilitates influence (we are more likely to comply with requests from people we like—Berscheid & Reis, 1998) but also accentuates the evaluative (status) differential between leader and followers.

Third, prototypical leaders generally find the group more central and important to self-definition and therefore identify more strongly with it. They have a greater investment in the group and thus are more likely to behave in group-serving ways. They embody group norms more precisely, and they are more likely to favor the ingroup over outgroups, to treat ingroup members fairly, and generally to act in ways that promote the ingroup. These behaviors confirm their prototypicality and membership credentials and encourage group members to trust them to be acting in the best interest of the group even when it may not appear that they are—they are furnished with legitimacy (Tyler, 1997; Tyler & Lind, 1992; see Platow et al., 1998). One important consequence of this is that prototypical leaders are actually able to be innovative—they can, paradoxically, diverge from group norms and be less conformist than non- or less prototypical leaders. Innovation is, of course, a key component of effective leadership as it allows one to transform the group and steer it safely through the stormy waters of change (see earlier discussion of transformational leadership).

This analysis of how prototypical leaders can be innovative describes the processes that may account for Hollander's (1958) idea, discussed earlier, that to be effective a leader needs initially to conform to group norms to earn "idiosyncrasy credits" in order later to be able to diverge from such norms and be innovative. The social identity analysis is wider in that conformity and the temporal dimension are not always necessary—the key factor is that the leader behaves in ways that build trust based on shared identity and the perception that the leader is centrally invested in the group.

Finally, because the prototype is so central to group life, information related to the prototype is figural against the background of other information in the group. A prototypical leader is probably the most direct source of prototype information, and so is figural against the background of the group. Members pay close attention to the leader and, as in other areas of social perception and inference, attribute his or her behavior to invariant or essential properties of the leader's personality—they engage in the fundamental attribution

error (Ross, 1977), correspondence bias (Gilbert & Malone, 1995), or essentialism (Haslam et al., 1998).

This process readily constructs a charismatic leadership personality, because the behaviors that are being internally attributed include being the source of influence, being able to gain compliance from others, being popular, having higher status, being innovative, and being trusted. In this way charisma plays a role (cf. transformational leadership), but charisma is constructed by group processes rather than being a static personality attribute that is brought to the group (cf. Haslam & Platow, 2001). In any event, the construction of charisma further facilitates effective and innovative leadership on the part of a prototypical leader.

Social identity-based leadership processes confer on a leader considerable power to maintain his or her position of leadership. Because such leaders are invested with charisma, status, and so forth, they are very effective prototype managers. Largely through communication and talk they can construct, reconstruct, or change the group prototype in ways that protect or promote their highly prototypical central position in the group—a process that can be referred to as norm talk (Hogg & Tindale, 2005; see also Fiol, 2002; Gardner, Paulsen, Gallois, Callan, & Monaghan, 2001; Reid & Ng, 2000). Indeed, one of the key attributes of an effective leader is precisely this visionary and transformational activity—a leader is able to change what the group sees itself as being and can be considered an entrepreneur of identity (Reicher & Hopkins, 2003).

Specifically, prototypical leaders can talk up their own prototypicality and/or talk down aspects of their own behavior that are nonprototypical. They can identify deviants or marginal members to highlight their own prototypicality or to construct a particular prototype for the group that enhances their own prototypicality. They can secure their own leadership position by vilifying contenders for leadership and casting the latter as nonprototypical. They can identify as relevant comparison outgroups those outgroups that are most favorable to their own prototypicality—that is, they can manipulate the social comparative frame and thus the prototype and their own prototypicality. They can engage in a discourse that raises or lowers salience—if we are highly prototypical then raising salience will provide us with the leadership benefits of high prototypicality; if we are not very prototypical, then lowering salience will protect us from the leadership pitfalls of not being very prototypical. Research suggests that all these processes are used by leaders to manage their prototypicality (e.g., Reicher & Hopkins, 1996, 2001, 2003). Generally, leaders who feel they are not, or are no longer, prototypical, strategically engage in a range of group-oriented behaviors to strengthen their membership credentials (e.g., Platow & van Knippenberg, 2001).

As a final point on the social identity theory of leadership, it should be noted that social identity leadership processes only or more strongly occur in groups that members identify more strongly with. As group salience or strength of identification weakens, social identity leadership processes weaken and leadership becomes less based on group prototypicality and more based on other factors such as leadership schemas.

The social identity theory of leadership, although a relative newcomer to the leadership scene, has already attracted substantial empirical support from laboratory experiments and more naturalistic studies and surveys (for summaries of empirical work, see Hogg, 2001; Hogg & van Knippenberg, 2003; van Knippenberg & Hogg, 2003b; van Knippenberg et al., 2004).

TRUST AND LEADERSHIP

A key feature of leadership is trust (e.g., Dirks & Ferrin, 2002)—witness current concerns about corporate corruption and distrust of our business and government leaders (e.g., Boyle & Tkaczyk, 2004; Kellerman, 2004). Lack of trust in leadership is a matter of great concern and consequence—after all, if we are going to follow someone we certainly do need to be able to trust them to be acting in the very best interest of us all as a group, rather than in their own self-interest. The notion that trust in leaders allows them a sufficiently wide latitude of behaviors for innovative decisions and actions goes back a long way, for example, to the philosopher John Locke (1690/1988). More recent social psychological research on trust and leadership takes a group-oriented perspective that focuses on justice and fairness perceptions (can we trust our leader to be just and fair?) and is generally or more specifically informed by the social identity perspective (e.g., Hogg, in press; Tyler, 1997, 2003, 2005; Tyler & Blader, 2000; Tyler & Lind, 1992).

Justice and Fairness

One of the key tenets of Tyler's group value model (Lind & Tyler, 1988) and his relational model of authority in groups (Tyler, 1997; Tyler & Lind, 1992) is that fairness and justice perceptions are critical to group life. Because leaders make decisions that have important consequences for followers (e.g., promotions, performance appraisals, and allocation of duties), followers are concerned about how fair the leader is in making these decisions. In judging fairness, followers focus on both distributive justice (how fair are the outcomes of the leader's decisions) and procedural justice (how fair are the procedures that the leader has used to make a decision). Justice and fairness judgments affect reactions to decisions and to the authorities making these decisions and thus influence leadership effectiveness (see De Cremer, 2003; De Cremer & Tyler, in press).

One way in which justice perceptions, particularly procedural justice perceptions, may affect leadership is via social identity processes (e.g., Koper, van Knippenberg, Bouhuijs, Vermunt, & Wilke, 1993; Tyler, 2003; van Knippenberg & Hogg, 2003b). Procedural justice serves a social identity function because fair procedures convey a favorable social evaluation of followers as group members—the respect for group members conveyed by

procedural fairness builds member identification and thus feeds into cooperative and compliant behavior. Research shows that as members identify more strongly with the group they care more strongly that the leader is procedurally fair (e.g., Brockner, Chen, Mannix, Leung, & Skarlicki, 2000), and care less strongly that the leader is distributively fair—this asymmetry arises because with increasing identification, instrumental outcome-oriented considerations (distributive justice) become less important relative to intragroup relational and membership considerations (procedural justice) (e.g., Vermunt, van Knippenberg, van Knippenberg, & Blaauw, 2001).

Social Dilemmas

The fact that justice, particularly procedural justice, may facilitate effective leadership because it builds trust and strengthens group identification raises the possibility that leadership may be a way to resolve social dilemmas. Social dilemmas are essentially a crisis of trust—people behave selfishly because they do not trust others to sacrifice some immediate self-interest for the longer-term greater good of the collective (e.g., Dawes & Messick, 2000; Hardin, 1968; Liebrand, Messick, & Wilke, 1992).

Social dilemmas are notoriously difficult to resolve (Kerr & Park, 2001). However, they are not impossible to resolve if one can address the trust issue. One relatively successful solution is to build mutual trust among people by causing them to identify strongly as a group—people tend to trust ingroup members more (e.g., Brewer, 1981; Hogg, in press; Yamagishi & Kiyonari, 2000), and under these circumstances they are more likely to sacrifice self-interest for the good of all (e.g., Brewer & Schneider, 1990; De Cremer & van Vugt, 1999). One downside to this is that mutual ingroup trust and cooperation are typically balanced by intergroup distrust and competition—the interpersonal dilemma may be transformed into a destructive intergroup dilemma (e.g., Kramer & Jost, 2002; Kramer & Messick, 1998).

Nevertheless, building ingroup trust is one way to resolve a social dilemma. Leadership plays an often critical role in this process precisely because a leader can transform selfish individual goals into shared group goals by building a sense of common identity, shared fate, interindividual trust, and custodianship of the collective good (De Cremer, 2000, 2002; De Cremer & van Knippenberg, 2003; De Cremer & van Vugt, 2002; van Vugt & De Cremer, 1999).

GENDER AND LEADERSHIP

Throughout the world, leadership roles are dominated by men. If one restricts oneself to liberal democracies like the United States where more progressive gender attitudes have developed over the past 40 years, it is still the case that although women are now relatively well represented in middle management, they are still significantly underrepresented in senior management and "elite" leadership positions—there is a "glass ceiling" (e.g., Cejka & Eagly, 1999; Eagly & Karau, 1991; Eagly et al., 1992, 1995).

Perhaps this is because men and women differ in ways that suit men better for leadership. Research does not uphold this idea. Although women and men tend to adopt different leadership styles, women are usually rated as just as effective leaders as men—and in general they are perceived to be slightly more transformational, participative, and engaged in contingent reward behaviors (Eagly, Johannesen-Schmidt, van Engen, & Vinkenburg, 2002).

If women and men are equally capable of being effective leaders, why is there a gender gap in leadership? One explanation is in terms of role incongruity theory (Eagly, 2003; Eagly & Karau, 2002; Heilman, 1983), which argues that because there is greater overlap between general leader schemas and agentic male stereotypes than between leader schemas and communal female stereotypes, people tend to have more favorable perceptions of male leaders than of female leaders. These leadership perceptions facilitate or impede effective leadership. One implication of role incongruity theory is that the evaluation of male and female leaders will change if the leadership schema changes or if people's gender stereotypes change. For example, research has shown that men leaders are evaluated more favorably than women leaders when the role is defined in more masculine terms, and vice versa when the role is defined in less masculine terms (Eagly et al., 1995).

Related to role incongruity theory is a social identity analysis (see above) that argues that in high-salience groups with which members identify, male or female leaders are perceived to be and actually are effective if the group's norms are consistent with the members' gender stereotypes. So, people with traditional gender stereotypes will endorse a male not a female leader of a group with instrumental norms and a female not a male leader of a group with more expressive norms, whereas among people with less traditional gender stereotypes this effect may not be so pronounced and may be reversed (Hogg et al., 2006).

Bowles and McGinn (2005) attribute the gender leadership gap to a tendency for women to claim authority less effectively than men (men claim and hold a greater number of leadership positions than do women), not to any difference in how effective men or women leaders are once they achieve authority. Bowles and McGinn propose four main barriers to women claiming authority. The first is effectively role incongruity, as discussed previously. The second is lack of critical management experience. The third is familial responsibility that restricts a woman's ability to find the time commitment required by leadership positions.

The fourth obstacle is lack of motivation—women are simply not as "hungry" for leadership positions as are men. They shy away from self-promotion and take on less visible background roles with informal titles like "facilitator" or "coordinator." Although the link has not been made explicit, it is very possible that the underlying reason for women's reticence to claim authority is stereotype

threat (Steele & Aronson, 1995; Steele, Spencer, & Aronson, 2002)—women fear that stereotypes about women and leadership will be confirmed, and so they experience reduced motivation to take on leadership. In addition, self-promotion and leadership claiming are non-female-stereotypical behaviors that can be interpreted as "pushy" and can attract negative reactions from most group members (Rudman, 1998; Rudman & Glick, 1999).

SUMMARY AND CONCLUSIONS

This review of leadership has covered a lot of ground. I have tried to capture the breadth of the topic by including the main perspectives and approaches, but this has entailed some sacrifice of detail. I have tried to place more emphasis on social psychological research, in particular recent work, than on management and organizational science work.

It is important, however, to recognize that there is substantial overlap between social psychological research and research in management and organizational settings—this is because leadership is a topic that sits right on the boundary and people who do leadership research, of whatever discipline, are often social psychologists. One of the exciting and timely new opportunities for leadership research is a much closer and more concrete working relationship between social psychology and management/organizational science, and also political science and sociology. This integration will benefit social psychology because leadership plays out in organizations and society, and management/organizational science, political science, and sociology will benefit from the significant advances made in social psychology over the past 30 years in our understanding of social cognition and group processes.

Basic Principles

From a social psychological point of view the take-away message about leadership is that leadership is a group process and that effective leadership is the product of a complex interaction between, on the one hand, what a leader does and how this is perceived by the followers and, on the other hand, the expectations of and constraints imposed on leader behavior by societal norms, group norms, and group tasks. Leadership plays out through interactions, which are largely symbolic, between leaders and followers that are configured by the wider group that leader and followers belong to. Leadership has an important identity dimension. Effective leaders need to be innovative and transformational—they need to be able to influence group norms and persuade members to internalize those norms as their own guides to action. They need to be able to make members sacrifice self-interest for collective interest. They need to make members identify with the group. To accomplish all this, leaders need to be persuasive and perhaps viewed as charismatic and visionary. They need to be trusted to be acting in the interest of the group, not in their own self-interest.

This general message can be reframed and expanded into a set of basic principles about leadership—things that we know fairly certainly about leadership.

1. Leadership is a process of influence that does not require the exercise of coercive power over others—coercion may negate true leadership and merely produce compliance and obedience.
2. Leadership is predominantly a group process in which one person transforms other members of the group so that they adopt a vision (often a new vision) and are galvanized into pursuing the vision on behalf of the group—leadership is not simply managing a group's activities. Transformational leadership is facilitated by charisma, consideration of followers, and inspiring followers.
3. Leadership involves transactions between leader and followers—leaders do something for the group and the group in return does something for the leader to allow the leader to lead effectively.
4. Leadership often has an important identity dimension—followers look to their leaders to mould, transform, and express who they are, their identity. Being perceived to be "one of us" can often facilitate leadership.
5. Trust plays an important role in leadership—leaders have greater scope to be innovative if the group trusts them.
6. Effective and good leadership are not the same thing—effective leaders successfully influence the group to adopt and achieve (new) goals, whereas good leaders pursue goals that we value, use means that we approve of, and have qualities that we applaud.
7. Although some broad personality attributes tend to be associated with effective leadership (e.g., extraversion/surgency, intellect/openness to experience, and conscientiousness), personality alone is rarely sufficient.
8. There is a general distinction between task-focused (structuring) and person/relationship-focused (consideration) leadership style—their relative effectiveness and the effectiveness of other leadership styles depends on context (e.g., the nature of the group, the nature of the task).
9. Leadership effectiveness can be improved if the leaders' attributes and behavior are perceived to fit general or task-specific schemas we have of effective leadership, or the norms/prototype of a group membership/identity that we share with the leader.

Agenda for Leadership Research in Social Psychology

In terms of a concrete research agenda for social psychology, one thing that is badly needed, and was foreshadowed earlier, is a social psychological specification of what goes on in the social cognitive black box of transformational leadership—what happens in the head of a follower to transform leader behavior into follower thought and behavior? We cited research by Shamir and colleagues (1993) and Dvir and colleagues (2002) that quite

clearly suggests that processes of follower identification with the group may play a key role. The social identity theory of leadership may help flesh this out.

Related to this is a need to explore the notion of charisma more fully (cf. Haslam & Platow, 2001). Is it an enduring personality attribute that is brought to a leadership situation? Is it perceptually constructed for an effective leader by group members? Or is it a mixture of the two, and if so how are the two related and in what proportions? Social psychologists are often uncomfortable with explanations of group processes that rely too heavily on enduring personality attributes.

Leadership has a critical identity function that needs to be more fully explored. Not only are leaders often more effective if they are perceived to embody the group's identity, but in many leadership contexts followers actually look to their leaders to define and express and to consolidate or transform who they themselves are—their identity.

Trust also plays a key role in effective leadership. There is a strong strand of social psychology research on trust and leadership, mainly by Taylor and De Cremer and their colleagues. However, this is an area that would probably benefit from more extensive general social psychological research on trust, to link the general notion of trust to risk management, group life, identity, and leadership (Hogg, in press).

Leaders lead groups in the context of, or against, other groups. Intergroup relations impact leadership, and leadership impacts intergroup relations. This intergroup aspect of leadership is a core aspect of Eagly and colleagues' research on gender and leadership—intergroup perceptions, in the guise of gender stereotypes, impact leadership expectations and thus leadership effectiveness. This analysis could be expanded and integrated with a broad social identity analysis to focus more on intergroup behavior, as opposed to perceptions, and also widened to deal with other intergroup situations aside from gender relations. This wider intergroup analysis might help us understand intergroup leadership in the political sphere. It might also help us identify common reasons why many minorities may find it hard to lead—for example, as hinted previously, minorities may not take opportunities to lead because of stereotype threat processes (cf. Steele & Aronson, 1995).

Finally, by focusing on leadership as a basic influence process that involves people's identities as group members, social psychology may be able to speak to a wider conceptualization of leadership that moves beyond business leadership to address public leadership, nonprofit leadership, and so forth. This wider perspective may also make it important to move beyond a discussion of leadership effectiveness to incorporate a fuller causal analysis of good and bad leadership.

Dynamical Social Psychology

Finding Order in the Flow of Human Experience

ROBIN R. VALLACHER
ANDRZEJ NOWAK

Intuition is a double-edged sword for a social psychologist. The advantages are obvious. Particularly if the psychologist is a keen observer of the human condition and is sensitive to the nuances of his or her own experience, intuition can provide a head start on theory construction that is simply not available to a scientist attempting to identify the principles of, say, photosynthesis, radioactivity, or quasar formation. The psychologist's privileged access to his or her subject matter—the experience of humans—provides an abundance of raw data for identifying lawful regularities concerning emotion, motivation, social influence, and all manner of interpersonal behavior. Therein lies the other edge of the sword. There are no limits to the amount and diversity of insights forthcoming from introspection, observation, and empathy. The insights emanating on a continual basis from our private and social experiences can generate a dizzying amount of relevant data, expose an enormous range of important phenomena, and promote a bewildering array of explanations with unclear points of confluence and conflict. It is not surprising, then, that social psychology has developed into a discipline that is rich in insight but devoid of theoretical consensus, let alone explanatory coherence.

One could argue that the fragmented nature of contemporary social psychology simply mirrors the complexity of human experience. The intricacies of information processing, after all, seem to belong to a different theoretical realm than the passion and dependency associated with close relationships. With a topical landscape that runs the gamut from vascular processes to social movements, perhaps it is entirely reasonable that the explanatory landscape of social psychology should be correspondingly diverse. Indeed, this idea itself is represented in the intuitions of laypeople and psychologists alike.

Recent years, however, have witnessed the emergence of a new perspective on the relationship between surface and explanatory complexity in many areas of science (cf. Haken, 1978; Holland, 1995; Johnson, 2001; Schuster, 1984; Strogatz, 2003; Weisbuch, 1992; Wolfram, 2002). This perspective trades on the idea that any phenomenon can be conceptualized as a system of interacting elements, the dynamics of which give rise to new properties and processes at an aggregate level. In analyzing phenomena as nonlinear dynamical systems, the task of the scientist is to identify the rules of interaction among system elements and to investigate how these rules promote the emergence of macrolevel behavior. In fields as distinct as population ecology and organic chemistry, the dynamical systems perspective has revealed that highly complex behavior at the macrolevel can emerge from very simple rules of influence among the system's elements. The rules linking the micro and macro features of a system, moreover, have been found to be remarkably similar for otherwise highly distinct phenomena.

Our aim in this chapter is to outline the dynamical perspective and demonstrate its relevance to social psychology. Although in its infancy, this approach has already proven useful in highlighting many distinct phenomena

and providing the discipline with a new set of research tools. Social psychology covers a lot of ground, however, and there are many topics and issues that have yet to be addressed from an explicitly dynamical perspective. In addition to noting the accomplishments to date, then, we suggest how various phenomena of current interest might be reframed in dynamical terms and investigated with methods adapted from the study of nonlinear systems in other areas of science. In a concluding section, we describe dynamical minimalism, an approach to theory construction and research that mirrors the dynamical properties of human experience. Because dynamical principles characterize complex systems generally, the dynamical approach to investigating personal and interpersonal experience holds potential for bridging social psychology with other areas of science.

THE DYNAMICAL PERSPECTIVE

Over the past decade, theorists and researchers in the social sciences have come to recognize the relevance of the dynamical approach to their respective areas of concern. This recognition has fueled ambitious attempts to adapt the concepts and methods associated with nonlinear dynamical systems to various topics in social psychology, including attitudes (e.g., Eiser, 1994; Latané & Nowak, 1994; Shultz & Lepper, 1996; Simon & Holyoak, 2002), social judgment (e.g., Kunda & Thagard, 1996; Queller, 2002; Read & Miller, 1998; Smith, 1996; Vallacher, Nowak, & Kaufman, 1994), decision making (Kaplowitz & Fink, 1992; Richards, 1990; Townsend & Busemeyer, 1995), self-regulation (e.g., Carver & Scheier, 1999; Hsee, Abelson, & Salovey, 1991; Vallacher & Nowak, 1999), self-concept (e.g., Nowak, Vallacher, Tesser, & Borkowski, 2000; Vallacher, Nowak, Froehlich, & Rockloff, 2002), action (e.g., Newtson, 1994; Thelen & Smith, 1994; Turvey & Carello, 1995; Vallacher, Nowak, Markus, & Strauss, 1998), social interaction (e.g., Baron, Amazeen, & Beek, 1994; Buder, 1991; Newtson, 1994; Nowak & Vallacher, 1998b), social influence (e.g., Nowak, Szamrej, & Latané, 1990; Vallacher, Nowak, & Miller, 2002), group dynamics (e.g., Arrow, McGrath, & Berdahl, 2000), close relations (e.g., Gottman, Murray, Swanson, & Tyson, 2004; Kenrick, Li, & Butner, 2003; Tesser & Achee, 1994), organizational behavior (e.g., Guastello, 1995), and social systems (e.g., Goldstein, 1996; Nowak & Vallacher, 2001). This general approach has also been used to investigate and model personality development (e.g., Fischer & Bidell, 1997; Lewis, 1997; Nowak, Vallacher, & Zochowski, 2002) and personality dynamics (e.g., Carver & Scheier, 2002; Cervone, 2004; Mischel & Shoda, 1995; Read & Miller, 2002; Shoda, LeeTiernan, & Mischel, 2002). The various adaptations differ in crucial respects, but they share the assumption that personal and interpersonal phenomena can be profitably viewed as sets of interconnected elements that evolve due to the mutual influences among the elements (cf. Barton, 1994; Weidlich, 1991). Research within the dynamical perspective describes the connections among a system's elements and investigates the system-level properties and behaviors that these connections promote.

Below we highlight the primary features of nonlinear dynamical systems that are especially relevant for the subject matter of social psychology. We focus first on the tendency for systems to display internally generated dynamics and on the temporal patterns to which such dynamics conform. Building on this foundation, we develop the implications of nonlinear relations for the nature of complexity and the emergence of global properties and higher-order processes in human functioning. We develop these ideas in the context of specific personal or interpersonal processes of interest to social psychology. Our aim is not to be exhaustive but, rather, to illustrate the heuristic and integrative potential of the dynamical perspective.[1]

Intrinsic Dynamics

Dynamical systems are not new to science. This perspective, in fact, has been employed to investigate phenomena since the rise of modern science. Perhaps the most fundamental characteristic of a dynamical system is that it changes and evolves in time. Consider the proverbial falling apple that is said to have knocked insight regarding gravitation into Isaac Newton. The apple begins moving, continues moving for some time, eventually hits the ground (after bonking the hapless Newton), and finally stops moving. The state of the apple at any moment in time (i.e., its position, velocity, and angular momentum) determines its state in the next moment in time. The apple's motion can be described and modeled using differential or difference equations. The resultant model is deterministic in the sense that the future of the apple can be fully predicted from full knowledge of the apple's current state.

Clearly humans are not apples, nor should reducing complex human experience to differential equations be the goal of social psychology. Nonetheless, the experience gained in the investigation of dynamics in other systems in nature may provide important insights concerning the nature of processes occurring in people and social groups. People's thoughts, emotions, and actions can clearly evolve and change in the absence of external influence. Such patterns of "intrinsic dynamics," however, are rarely the focus of social psychological theory and research (cf. McGrath & Kelley, 1986). Research instead largely concentrates on trying to predict the values of some outcome variables (operationalized as dependent measures) from the knowledge of other variables (independent variables). External causation clearly characterizes social processes, of course, and this approach has generated enormous insight into personal and interpersonal phenomena. External forces, however, do not act on an empty or passive system. Rather, such factors interact with the intrinsic dynamics associated with the process in question. The concepts, principles, and methods developed within nonlinear dynamical systems thus may enhance our understanding of social psychological phenomena and how otherwise distinct phenomena are related in terms of common properties.

Personal Dynamics

The importance of intrinsic dynamics is apparent at different levels of social reality, from personal processes to interpersonal processes and even societal phenomena. At the individual level, the spontaneous activation and turnover of cognitive and affective elements in the stream of thought (James, 1890) may be more indicative of a person's mental makeup than the summary aspects of thought (e.g., overall attitude, final decision, and global self-evaluation) that are more commonly the focus of investigation (cf. Vallacher & Nowak, 1994b). Attention to the internal workings of the cognitive–affective system is apparent in several contemporary lines of theory and research. Theory and research on thought-induced attitude polarization, for example, has shown that when people simply think about an attitude object (e.g., another person) in the absence of external influence or new information, their evaluation of the object tends to be become more extreme over time (e.g., Tesser, 1978).

Research on the time course of social judgment has shown that internally generated thoughts and feelings about someone can reflect rich and elaborate patterns of change and that these patterns convey important information about the person's judgment. A seemingly neutral judgment of someone, for instance, can have quite different meanings and implications, depending on the intrinsic dynamics of the judgment process (Vallacher et al, 1994). If neutrality reflects little variation in evaluation occurring on a relatively slow time scale, the summary judgment might indicate detachment or a true neutral sentiment. But if neutrality reflects oscillation between highly positive and highly negative judgments, and this variation occurs on a rapid time scale, the summary judgment is likely to reflect heightened involvement and ambivalence rather than neutrality per se.

Similarly, knowing only a person's level of self-esteem may provide an unclear, potentially misleading indication of how the person processes self-relevant information, responds to social feedback, interacts with others, or forms social relationships (e.g., Baumgardner, 1990; Campbell et al., 1996; Kernis, 1993; Nowak et al., 2000; Pelham, 1991; Showers, 1992; Vallacher, 1978, 1980; Vallacher & Nowak, 2000). Insight into such issues is enhanced by tracking the moment-to-moment changes in self-evaluation in the stream of self-reflective thought (Vallacher et al., 2002). A person may express a highly positive assessment of him- or herself on a self-report measure, but the manifestation of the person's high self-esteem depends on the dynamic properties of his or her self-reflection. If the person's self-evaluative thought is relatively quiescent, with modest changes in self-evaluation occurring on a slow time scale, his or her level of self-regard is likely to be associated with high self-concept certainty, the maintenance of particular self-views despite contradictory incoming information, and a nondefensive orientation toward other people. But if the person's high self-esteem masks underlying volatility in self-reflection—the spontaneous expression of highly pos-

itive and highly negative self-relevant thoughts on a relatively fast time scale—he or she is likely to display lower self-concept certainty and heightened vulnerability to social feedback that challenges his or her positive self-image.

Contemporary models of personality also incorporate the potential for intrinsic dynamics into their conceptualizations and research strategies (e.g., Carver & Scheier, 1999; Cervone, 2004; Lewis, 1997; Mischel & Shoda, 1995; Read & Miller, 2002). These models differ in a number of important respects, of course, but they share an appreciation for the role of internal mechanisms in giving meaning to, and modulating the effects of, environmental cues and demands. In this perspective, the stability of personality does not refer to stable traits or to the control provided by a stable environment but, rather, to stable patterns of thought, emotion, and action in the context of goals, opportunities, pressures, and other situational parameters. Such models go beyond the recognition of personality by situation interactions to focus on the structures within a person that interpret, synthesize, and utilize incoming information.

Interpersonal Dynamics

Interpersonal behavior involves the temporal coordination of behavior at different levels, from motor movements and utterances to high-level action categories reflecting momentary goals or long-range plans. Actions as basic as talking or passing in a hallway require coordination in time (e.g., turn taking) to prevent individuals from stumbling over one another. As discussed previously, a person can be viewed as a separate system capable of displaying rich dynamics. Social coordination, then, involves the synchronization of partners' respective dynamics to produce a higher-order system with its own dynamic properties.

Several lines of research have explored the coordination of dynamics in social interaction with respect to speech (e.g., Condon & Ogston, 1967; Dittman & Llewellyn, 1969) and motor movement (e.g., Beek & Hopkins, 1992; Kelso, 1995; Newtson, 1994; Turvey, 1990). Two individuals, for example, might simply be asked to swing their legs. One person swings his or her legs in time to a metronome and the other person tries to match those movements. This simple paradigm reveals interesting coordination phenomena. First, synchronization may be in phase, with people swinging their legs in unison, or in antiphase, with people swinging their legs with the same frequency but in the opposite direction. Second, hysteresis is commonly observed. When participants are instructed to synchronize out of phase, they are able to do so only up to a certain frequency of movement, at which they switch to in-phase synchronization. When the tempo decreases, at some value they are able to coordinate out of phase again, but this tempo is significantly lower than the point at which they originally started to synchronize in phase. The appearance of hysteresis shows that movement coordination can be analyzed as a nonlinear dynamical system (Kelso, 1995). Yet more complex modes of coordination have been cap-

tured in this line of research (cf. Baron et al., 1994; Turvey, 1990).

Social relations go beyond the coordination of speech and motor movements to include the temporal coordination of higher-order actions and internal states (moods, judgments, etc.). The quality of a social relationship is reflected in the ability of partners to synchronize in this fashion (e.g., Baron et al., 1994; McGrath & Kelly, 1986; Nowak et al., 2002; Tickle-Degnen & Rosenthal, 1987). In everyday parlance, people who like one another are said to "be in synch" or "on the same wavelength." Dynamically speaking, the ebb and flow of sentiment, information exchange, and action may be more informative about the nature of a relationship than are the average sentiment, the amount of information exchanged, or the summary action tendencies.

In a close relationship, for example, the partners' mutual affect may alternate between intense passion and equally intense anger (e.g., Gottman, Swanson, & Swanson, 2002). If one assessed partners' feelings at a point in time dictated by measurement convenience or the needs of the experimenter, one would conclude that they experienced either positive or negative feelings, depending on which phase the partners were experiencing at that time. If, instead, one were to collapse partners' expressed feelings over time to obtain a summary measure (with temporal variance treated as noise), one would be left with the curious conclusion that the predominant affective tone was mutual neutrality—a state that is never experienced. What is important is the pattern of feelings over time, which may have a life of its own, independent of factors outside the dyadic system that are capable of promoting some feelings rather than others.

Societal Dynamics

At a societal level, tracking the temporal trajectory associated with the emergence of norms and public opinion may provide greater insight into the society's future makeup and likely response to external threat than simply knowing what the norms and public sentiments are (cf. Nowak et al., 1990). When norms and opinions develop slowly and incrementally, for example, society is likely to display resistance to external threats or even to new information that might promote better economic conditions. Societal change in political and economic ideology, however, can also occur in a rapid, nonlinear manner (e.g., Nowak & Vallacher, 2001; Nowak, Vallacher, Kus, & Urbaniak, 2005), with a trajectory that resembles phase transitions in physical systems (Lewenstein, Nowak, & Latané, 1993). Such nonlinear societal transitions can make society vulnerable to subsequent rebounds of the earlier ideologies and highly responsive to threats and new information, and they can promote a period of sustained oscillation between conflicting worldviews (Nowak & Vallacher, 2001).

Attractor Dynamics

The proclivity for intrinsic dynamics cannot be denied, but neither can the tendency for psychological systems to demonstrate stability and resistance to change. An enormous amount of diverse information relevant to self-understanding, social judgment, goal-directed action, and interpersonal relations is encountered on a daily basis, yet people manage to maintain relatively stable platforms for thought and action in each of these domains. Clearly, then, the flow of thoughts, feelings, and behavior is not random but, rather, converges on specific states or patterns of change between states. In reaction to negative life experiences, for example, a person is likely to experience sadness and perhaps even depression, but over time his or her self-regulatory mechanisms are likely to reinstate positive moods and a sense of personal control (e.g., Johnson & Nowak, 2002). Similarly, a person with high self-esteem may experience negative self-relevant thoughts, but these are likely to be unstable, giving way over time to a flow of self-evaluative thinking that converges on a positive state (e.g., Vallacher, Nowak, Froehlich, & Rockloff, 2002).

The constraints on psychological process can be couched in terms of *attractor dynamics*. An attractor is a state or a reliable pattern of changes (e.g., oscillation between two states) toward which a dynamical system evolves over time, and to which the system returns after it has been perturbed. In a system governed by attractor dynamics, a relatively wide range of starting points (initial states) will eventually converge on a much smaller set of states or on a pattern of change between states. In effect, an attractor "attracts" the system's dynamics, so that despite differences at the outset in one's thoughts, feelings, or behaviors, the process unfolds in the direction of the attractor. Attempting to move the system out of its attractor, moreover, promotes forces that reinstate the system at its attractor. Across different areas of science, research has identified three types of attractors (cf. Eckmann & Ruelle, 1985; Nowak & Lewenstein, 1994; Schuster, 1984): fixed-point attractors, periodic (including multiperiodic) attractors, and deterministic chaos (intrinsic dynamics characterized by very irregular, seemingly random temporal evolution).

Fixed-Point Attractors

A *fixed-point attractor* describes the case in which the state of the system converges to a stable value. In psychological systems, this tendency is similar to the notion of equilibrium or homeostasis (cf. Cannon, 1932; Miller, 1944). In some cases, the attractor may correspond a desired end state or goal (Vallacher & Nowak, 1997) that functions as a standard of self-regulation (Carver & Scheier, 1999). In the face of obstacles to goal attainment, a person's thought and behavior are configured (and reconfigured if necessary) in order to overcome the obstacles and ensure achievement of the goal or maintenance of the regulatory standard. Thus, people are described as motivated to bring about and maintain various psychological states, whether cognitive (e.g., a belief), affective (e.g., a judgment or an attitude), or behavioral (e.g., an action tendency or desire) in nature.

Attractors are not limited to goals, however, nor do they necessarily refer to intentions or desired states. A

person may display patterns of behavior that repetitively converge on hostility across his or her social relations, for example, even when he or she attempts to avoid behaving in this manner. In an intergroup context, meanwhile, warring factions embroiled in conflict may exhibit conciliatory gestures when prompted to do so but revert to a pattern of antagonistic thought and behavior if left to their own devices. In like manner, a person with low self-esteem may initially embrace positive feedback from someone, but over time he or she is likely to discount such feedback, displaying a pattern of self-reflective thought that converges on a negative state (Swann, Hixon, Stein-Seroussi, & Gilbert, 1990). A system governed by fixed-point attractor dynamics, in other words, will consistently evolve to a particular state, whether or not this state is hedonically pleasant, and will return to this state even when perturbed by outside influences that might promote a more pleasant state.

A system may have multiple stable states, each corresponding to an attractor for the system's behavior. The particular attractor that is reached depends on the initial states or starting values of the system's evolution. The set of initial states leading to each attractor represents the *basin of attraction* for that attractor. In a system with multiple fixed-point attractors, then, the system can display correspondingly different equilibrium tendencies, each associated with a distinct basin of attraction. Within a given basin, even quite different initial states will promote a trajectory that eventually converges on the same stable value. But by the same token, even a slight deviation in initial conditions has the potential to promote a dramatic change in the system's trajectory if the deviation represents a state that falls just outside the original basin of attraction and within a basin for a different attractor. In a high-threat situation, for example, there are two dominant responses, corresponding to fight versus flight. Minimal differences in the circumstances associated with the threat will thus lead to dramatically different behaviors, with virtually no option for a response that integrates the two tendencies.

The essence of the attractor concept and its relevance for personal and social processes can be illustrated with a simple metaphor. Figure 32.1 portrays a ball on a hilly landscape. The ball represents the current state of the system and the two valleys (A and B) represent different fixed-point attractors for the system. The ball will roll down the hill and come to rest at the bottom of a valley. Each attractor has its own basin of attraction—that is, a set of states that will evolve toward the attractor. The ba-

sin of attraction for attractor A is somewhat wider than the basin for attractor B. This means that a wider variety of states will evolve toward attractor A than toward attractor B. Attractors can also vary in their respective strength, which is depicted as the relative depth of the two valleys. Attractor B, then, is stronger than attractor A. This means that when a system is at attractor B, it is more difficult for it to be dislodged by external influence.

The potential for multiple fixed-point attractors captures the idea that people may have different (sometimes conflicting) goals, self-views, and behavior patterns. A person may have more than one self-regulatory standard, for example, each providing for behavioral direction and self-control under different conditions. His or her actions may be in service of an achievement standard under a range of conditions that promote this tendency but in service of affiliation standards under a different set of conditions. In similar fashion, a person may have multiple self-views (e.g., Markus & Nurius, 1986), each representing a stable way of thinking about him- or herself that comes to the fore when a specific set of self-relevant information is primed, made salient by virtue of context or role expectations, or otherwise brought to consciousness. Apparent inconsistency or conflict in personality, too, can be viewed as the existence of multiple attractors associated with different basins of attraction for thought and action (cf. Nowak et al., 2002). One set of conditions and initial states might promote a trajectory that evolves toward dominance and competition, but another might promote instead warmth and compassion.

Because an attractor's strength may be independent of the size of its basin of attraction, one can envision different combinations of these properties and consider their implications for psychological processes.[2] Attractors A and B in Figure 32.1 present contrasting combinations. Attractor A is relatively weak but has a wide basin of attraction. In this case, a small force may be sufficient to change the state of the system (i.e., move the ball up the gradual slope), but even if these changes are relatively large, the system will still have a tendency to return to the attractor (i.e., it will roll back into the valley). Attractor B is stronger but has a relatively narrow basin of attraction. In this case, considerable influence is necessary to have even a slight impact on the system (i.e., move the ball up the steep slope), but once such an effect is achieved, the system will lose its ability to return to the attractor (i.e., it will escape the valley).

To illustrate this difference, consider two people, A and B, who express equally flattering self-appraisals but whose attractors for positive self-evaluation differ in their respective strength and basin of attraction. Person A has a relatively weak attractor but a relatively wide basin of attraction (corresponding to attractor A in Figure 32.1). This person may entertain a broad range of evaluatively discrepant thoughts (e.g., reminders of past deeds, negative social feedback), but over time his or her trajectory of self-evaluation is nonetheless likely to converge on the positive attractor. Person B has a stronger attractor for positive self-evaluation but a narrower basin of attraction (corresponding to attractor B in Figure 32.1). Unlike per-
FIGURE 32.1. A dynamical system with two attractors (A and B).

son A, he or she may actively resist even mildly negative thoughts and immediately discount unflattering self-relevant information. If such thoughts and elements of information fail to be rejected, however, they may be sufficient to generate self-doubt and, if a potential negative attractor exists for the person, a trajectory of self-evaluation that converges on a considerably less flattering self-appraisal.

Differences in the properties of fixed-point attractors can be envisioned as well at an interpersonal level of functioning. Imagine a couple that has a strong attractor associated with positive feelings but also a weak attractor associated with negative feelings. The couple may consistently evolve toward positive feelings if the partners begin an interaction within a certain range of affective states (e.g., neutral to very positive) but just as consistently end up feeling negative about one another if they begin an interaction within a different range of affective states (e.g., mildly to highly negative). If the couple has a wider basin of attraction for positive feelings than for negative feelings, a broader range of initial states is likely to produce a communication trajectory that results in an exchange of warm sentiments. If the couple routinely starts out with negative feelings, though, the relatively narrow negative attractor may nonetheless dictate the predominant trajectory for feelings expressed in the couple's interactions. On the other hand, if the couple has a wider basin for negative feelings, anything short of a highly positive initial state could dissolve into a negatively toned exchange.

Latent Attractors

When a system is at one of its attractors, other attractors for the system's behavior may not be visible to observers, perhaps not even to the actors themselves. Indeed, the existence of these potential states of the system might not even be suspected. Such *latent attractors* are nonetheless important in the long run because they determine which states are possible for the system when conditions change. The concept of latent attractor thus goes beyond the traditional notion of equilibrium by specifying possibilities for a system that have yet to be observed or experienced. Important changes in a system might not be reflected in the system's observable state but, rather, in the creation or destruction of a latent attractor corresponding to a potential state that is currently invisible to all concerned.

The possibility of latent attractors has recently been explored in the context of social relations characterized by seemingly intractable conflict (Coleman, Vallacher, Nowak, & Bui-Wrzosinska, in press; Nowak, Vallacher, Bui-Wrzosinska, & Coleman, in press). In intergroup relations, for example, factors such as objectification, dehumanization, and stereotyping of outgroup members have been shown to be preconditions for the development of intractable conflict (Coleman, 2003; Deutsch, 1973), but their immediate impact may not be apparent. Rather, these factors may gradually create a latent attractor to which the system can abruptly switch in response to seemingly minor provocations. By the same token,

though, seemingly fruitless efforts at conflict resolution may have the effect of creating a latent positive attractor for intergroup relations, thereby establishing a potential relationship to which the groups can switch if other conditions permit. The existence of a latent positive attractor can promote a rapid deescalation of conflict, even among groups with a long history of seemingly intractable conflict.[3]

The concept of latent attractor resonates well with the concept of implicit attitude (cf. Greenwald & Banaji, 1995; Greenwald et al., 2002; Greenwald, McGhee, & Schwarz, 1998). In the course of socialization (through peer and parental influence, mass media, idiosyncratic experiences, etc.), some thoughts, beliefs, and attitudes may become integrated in a relatively coherent manner and thus constitute an attractor for thoughts and feelings concerning a person or group (or oneself). Such an attractor may become inaccessible, however, by virtue of control mechanisms that reject or suppress the cognitive and affective elements comprising it. In contemporary society, for example, racist attitudes are widely condemned and strongly rejected, yet they are potentially accessible in a prepackaged manner as an integrated belief system (cf. Devine, 1989).

Because access to this set of thoughts may be constantly blocked by self-regulation (e.g., controlled cognitive processes), this attractor for mental dynamics is unlikely to be experienced. Under conditions that disrupt self-regulation, however, the latent attractor may become manifest and shape the person's trajectory of thoughts, feelings, and actions. This perspective is consistent with research showing that such factors as stress, cognitive load, deindividuation, and heightened arousal may facilitate the expression of attitudes and emotions that are normally suppressed (cf. Macrae, Bodenhausen, Milne, & Jetten, 1994; Sherman, Stroessner, Loftus, & Deguzman, 1997; Wegner, 1994; Zimbardo, 1970).

Repellors

Social psychological dynamics can be described in terms of not only seeking and maintaining specific states (i.e., fixed-point attractors) but also avoiding or escaping various states. In classic and contemporary psychological theories, avoidance tendencies are accorded equal theoretical status to approach tendencies (e.g., Higgins, 2000; Lewin, 1936). Sometimes, in fact, stronger predictions can be made about actions people are likely to avoid than about actions they are likely to perform. It is difficult to predict who will marry whom in a society, for example, but it is often clear who will not become marriage partners (e.g., siblings).

From a dynamical perspective, states in which a system cannot stabilize and from which the system escapes are termed "repellors." It is possible to construct dynamical models in which specific states and their associated "basins of repulsion" can be specified (Nowak, Lewenstein, & Tarkowski, 1994). Although these models have not been developed in the context of social psychology, one might speculate that repellor dynamics are relevant to any aspect of human experience involving avoidance or repres-

sion. Negative standards of self-regulation, for example, may be represented as repellors (Carver & Scheier, 1999, 2002). This is not to suggest that repellors are synonymous with conscious efforts to avoid a state. In a multistable system, for instance, any two adjacent fixed-point attractors are separated by a repellor. Movement out of the basin of attraction for one attractor is avoided, but the person's subjective experience revolves around the state defining the attractor.

Periodic Attractors

Some systems display sustained rhythmic behavior rather than convergence on a stable value over time. This temporal pattern is referred to as a periodic or limit-cycle attractor. Periodic attractors capture the essence of many biological phenomena (cf. Glass & Mackey, 1988), such as circadian rhythms and menstrual cycles. There is reason to think that cyclicity is associated with psychological phenomena as well (Gottman, 1979). Moods, for example, have been shown to demonstrate periodicity, often corresponding to a weekly cycle (e.g., Brown & Moskowitz, 1998; Larsen, 1987; Larsen & Kasimatis, 1990). Individuals have been found to differ in this tendency, with some people reliably demonstrating greater temporal variation in mood than others (Penner, Shiffman, Paty, & Pritzche, 1994). Research into the intrinsic dynamics of social judgment (Vallacher et al., 1994) and self-evaluation (Vallacher, Nowak, Froehlich, & Rockloff, 2002), meanwhile, has found that the stream of thought often oscillates between positive and negative assessments, sometimes in accordance with remarkably fast time scales. Periodic structure also characterizes human action (Newtson, 1994) and is apparent as well in social interaction (Beek & Hopkins, 1992; Gottman, 1979; Nezlek, 1993).[4]

A periodic attractor may be difficult to distinguish from the existence of multiple fixed-point attractors. In both cases, the system has a tendency to move between different states over time. The distinction between these two forms of attractor dynamics centers on the regularity of the movement and the role of external factors in producing the movement between states. A periodic attractor is defined in terms of a repetitive temporal pattern, such that the values of the dynamical variable repeat after a time T, $x_i(t) = (t + T)$, where T is the period of motion. Thus, even in the absence of noise or external influence, the state of the system undergoes constant change. For a pattern of change to qualify as an attractor for a system, then, it must represent a pattern on which the system converges, and to which it returns after small perturbations. In a daily cycle of activity, for example, a departure (e.g., a sleepless night) might temporarily disrupt the pattern (e.g., oversleeping the next few days), but eventually the pattern will be restored.

In contrast, a system characterized by fixed-point attractors exhibits a tendency to stabilize on a particular state or set of states. Because such attractors capture all trajectories within their respective basins, a movement from one stable state to another necessarily reflects a disturbance, noise, or external influence operating on the system. A person with self-regulatory standards for both assertiveness and conciliation, for example, will display one of these tendencies as long as the context surrounding the person is within the basin of attraction for that tendency. If the two attractors differ in the size of their respective basins, and if contexts are avoided that attract the person's mental, emotional, or behavioral state toward the smaller basin, the person may operate for extended periods of time in accordance with the stronger attractor. Similarly, an intimate couple may have fixed-point attractors for both positive and negative affective states, but whether they display periodic movement between them will depend on the starting conditions associated with their interactions. Even if the couple demonstrates fairly regular change between positive and negative states, each of these states provides at least temporary stability. In periodic evolution, on the other hand, stability is not afforded by any particular state but, rather, by the pattern of changes between states.

The distinctiveness of fixed-point attractor dynamics was observed in a study exploring the temporal trajectories of affective states on the part of bipolar depressive individuals (Johnson & Nowak, 2002). Time-series analysis of mood and other symptoms revealed that patients whose temporal dynamics were not characterized by fixed-point attractor tendencies were at highest risk for suicide and were hospitalized more often for their depression. Interestingly, these risks were equally low for individuals whose moods oscillated around a single attractor, even one corresponding to a depressed state, and those whose moods switched between two distinct attractors representing a normal state and a depressed state. These results may be interpreted in light of the connection between attractor dynamics and self-regulatory tendencies. Self-regulation implies approach and stabilization regarding some states and avoidance and destabilization of other states. The stable states are manifest as fixed-point attractors for a person's dynamics. From this perspective, the absence of fixed-point attractors for one's affective state signals a breakdown in the capacity for self-regulation.

Deterministic Chaos

Perhaps the most popular insight concerning nonlinear dynamical systems involves *deterministic chaos*. Indeed, many researchers—especially those outside mathematics and physics—often discuss the primary insights from the work on nonlinear dynamics as chaos theory (cf. Gleick, 1987). It is true that only nonlinear systems can display chaos, but as we have seen, such systems are capable of displaying far less spectacular temporal patterns (e.g., fixed-point attractors) as well.

The fascination with chaos reflects the fact that although the behavior of a chaotic system is fully determined, it may be totally unpredictable in practice. This seeming paradox reflects the system's *sensitivity to initial conditions*. In modeling weather patterns, for instance, Lorenz (1963) found that even the most trivial changes in initial conditions, such as rounding the initial humidity and ambient temperature to the third instead of the sec-

ond decimal point, eventually led to entirely different weather patterns. In a chaotic system, anything short of infinite precision in the knowledge of a system at one point in time can undermine knowledge of the system's future states. This occurs because all initial inaccuracies are amplified by the system's intrinsic dynamics, so that the inaccuracies grow exponentially over time. Exponential growth, in turn, ensures that after some finite (often quite short) time, the size of the error will exceed the possible range of states of the system's behavior.

Of course, one can never specify completely the initial conditions for any real-world system, because there is always some error of measurement. It is a matter of time, then, before any initial imprecision grows to values that make prediction impossible. Beyond measurement error, slight and momentary perturbations of a system's dynamics can cause arbitrarily large effects after some time. In the popular literature, this aspect of chaotic systems is known as the "butterfly effect." Lorenz coined this phrase to capture the illusive nature of weather forecasting. He suggested that the flapping of a butterfly's wings in one location—say, Brazil—could generate a cascade of events culminating in a tornado in a distant location such as Texas.

Chaos is always a possibility in nonlinear dynamical systems and, in fact, has been demonstrated in many biological and physical phenomena. It is conceivable, then, that human thought and behavior may often follow a chaotic trajectory. Indeed, social psychology is replete with nonlinear phenomena, such as threshold functions, inverted-U relations, and complex interactions among causal variables (Nowak & Vallacher, 1998a; Vallacher & Nowak, 1997). Despite this potential, however, unequivocal evidence for deterministic chaos in human thought and behavior remains to be documented.

To be sure, human behavior often appears to be unpredictable. But the source of unpredictability in chaotic systems is different from that in random systems. When unpredictability reflects randomness, either no deterministic rules exist for dictating the system's behavior or so many factors influence the system that it is impossible to account for all of them except by treating their combined effects as random influences or noise. In a chaotic system, in contrast, unpredictability results from the nonlinear interactions among a small number of variables. Indeed, as few as three elements can interact in sufficiently nuanced fashion to produce a chaotic—hence, unpredictable—trajectory for the system as a whole (Poincaré, 1908/1952). Deterministic chaos may well play a role in human affairs, but it is also the case that human behavior is often the nexus of innumerable influences, so randomness must be seriously considered when a particular phenomenon proves difficult to forecast.

Nonlinearity, Complexity, and Emergence

Intuition leads us to believe that behavior conforms to two basic rules: one concerning cause and effect, the other concerning complexity. The intuition about causation is that there should be proportionality between cause and an effect. When we see a large effect, it seems reasonable to attribute the effect to a correspondingly large cause. Minor effects, in turn, are reasonably attributed to smaller, incidental causes. It is hard for people to accept that one insignificant disgruntled young man could command the world's attention, perhaps even change the course of history, by assassinating John F. Kennedy in 1963. And who could imagine that a slight peculiarity in the connection between names and punch holes on a voting card would determine the outcome of the U.S. presidential election in 2000—in essence, a "butterfly ballot effect."

The complexity intuition concerns the relation between surface and explanatory complexity. When something behaves in a complex or intricate fashion, we naturally assume that the behavior is a manifestation of complex processes involving multiple factors. We assume that simple thoughts, for example, represent simple assumptions and a paucity of relevant information, whereas complex or nuanced thoughts stem from multiple, perhaps conflicting, assumptions and an abundance of relevant information.

Prior to the advent of the mathematical theory of nonlinear dynamical systems, scientists tended to share these assumptions about the workings of reality. Generally speaking, it was assumed that causal relations were linear—that there was proportionality between cause and effect—and that the complexity of a system's behavior was a direct reflection of the number of interacting elements and the complexity of their mutual influences. Scientists recognized that many natural phenomena involved nonlinear relations, but they believed that such relations could be approximated with adequate precision by linear equations. The revolution in science during the late 1970s and early 1980s reflected a realization that even simple systems consisting of a few elements often exhibit behavior of enormous complexity when the interactions among elements are nonlinear as opposed to linear.

Nonlinearity means that the effects of changes in one variable are not reflected in a proportional manner in other variables. A variable may increase in magnitude with no change in the magnitude of another variable, for example, until a threshold is reached, beyond which even slight changes in the first variable can promote large changes in the second variable. In a nonlinear system, moreover, system-level behavior cannot be decomposed into separate additive influences. Rather, the relations among variables depend on the values of other variables in the system. Even if one's theoretical concern centers on the relation between two variables, one cannot ignore the influence of myriad other variables relevant to the phenomenon.

Nonlinear systems are capable of far richer behavior than can be generated in linear systems. Even a system consisting of a few elements can display highly complex macrolevel behavior if the elements interact in a nonlinear manner over time. The generation of macrolevel properties and behavior from the internal workings of a nonlinear system is referred to as *emergence* (cf. Holland, 1995). Emergence is reminiscent of pattern formation in Gestalt psychology and is captured by the phrase, "the

whole is greater than the sum of its parts." Emergence is due to self-organization among elements, such that each element adjusts to the current state of other elements. No higher-order agent is required for the emergence of such structures. Rather than being imposed on the system from above or from outside the system altogether, they emerge from the nonlinear relations among the system's elements. The higher-order properties that result from the mutual adjustment among lower-level elements provide coordination for the lower-level elements (cf. Haken, 1978; Kelso, 1995).

Emergence via self-organization has implications for the achievement of higher-order structure at different levels of social reality. At the individual level, specific movements and perceptions become coordinated to produce meaningful action (cf. Kelso, 1995; Newtson, 1994), detailed representations of behavior are integrated to form comprehensive representations of the action (Vallacher et al., 1998), and the cognitive and affective elements populating the stream of thought influence each other to promote the emergence of higher-order judgments (Vallacher et al., 1994) and self-concepts (Nowak et al., 2000). The emergence of system-level properties is apparent as well in interpersonal phenomena. Classic accounts of group and societal dynamics have noted that shared norms and beliefs often develop through the spontaneous coordination of group members' impulses and actions, without the intervention of a higher-level authority to impose rules and standards (Durkheim, 1938; Turner & Killian, 1957).

The self-organizing nature of groups and societies has been verified in recent empirical research and computer simulations on social influence and interdependence (e.g., Axelrod, 1984; Latané & Bourgeois, 1996; Messick & Liebrand, 1995; Nowak et al., 1990; Nowak & Vallacher, 1998b, 2001). This work shows that social interaction with one's neighbors is responsible for the emergence of public opinion, altruistic values, and other group-level properties. Thus, individuals become integrated into higher-order functional units such as dyads and social groups (e.g., Nowak et al., 2002), and social groups become coordinated with respect to larger goals and values that define the social system in which they are embedded (cf. Nowak & Vallacher, 2001).

PERSONAL VERSUS SITUATIONAL CAUSATION

Social psychology is preoccupied with the "person versus situation" issue. On the one hand, a variety of theories and research traditions emphasize internal forces that maintain a semblance of stability in thought, emotion, and action. Thus, people are said to maintain or protect their self-esteem (Tesser, Martin, & Cornell, 1996); verify a particular level of self-regard (Swann, 1990); act in accordance with personal standards of achievement, morality, and other values (e.g., Carver & Scheier, 1999; Higgins, 1996); resist attempts by others to dictate their behavior or change their beliefs (e.g., Brehm & Brehm,

1981; Knowles & Linn, 2004); and express a small handful of personality dispositions (e.g., McCrae & John, 1992). The power of the person is often characterized in positive terms such as self-regulation, self-control, self-efficacy, willpower, and ego strength, although it can provide fodder for a focus on dysfunction as well, as reflected in such pejorative (and sometimes clinical) notions as dogmatism, inflexibility, and obsessive–compulsive disorder.

On the other hand, social psychology emphasizes the power of the situation to shape people's internal states and overt behaviors. In this view, people are highly responsive to social norms, authority figures, the presence of others, social feedback, incentives and threats, social influence strategies, environmental conditions such as temperature and crowding, and a host of other general and localized factors. Such situational factors are commonly operationalized as independent variables in experimental research and are assumed to provide the proximate causes of human thought, affect, and action. Internal states are not denied in this perspective, but their purported role in directing thought and behavior is often marginalized when clear situational forces are at work. Some accounts emphasize person-by-situation interactions, in which the expression of personal characteristics (traits, motives, etc.) is either enhanced or minimized in different situations or takes on different forms as a function of variation in situational factors.

The dynamical perspective reframes the person-versus-situation issue somewhat. The basic idea is that external factors do not promote change directly but, rather, shape thought and behavior by influencing the person's intrinsic dynamics. This scenario is manifest in different ways depending on the magnitude of the situational influences and characteristics of the person's intrinsic dynamics. One is likely to observe the power of the person under some configurations of influence and intrinsic dynamics but the power of the situation under other configurations.

The Power of the Person

When intrinsic dynamics are constrained by an attractor, situational influences may have an effect on people's thought and behavior. However, this effect is likely to be transient in nature because when a system is at its attractor, it tends to counter any force that would move it out of the attractor and will return to the attractor if perturbed. The power of the person, then, represents both the ability to resist change despite situational influences and the ability to return to an unperturbed state once the influence subsides. This suggests that situational influences may be most visible directly after their occurrence but fade over time as personal properties, represented as attractor tendencies, regain their prepotence.

Evidence for this idea is provided by research examining the intrinsic dynamics of self-evaluation (Vallacher, Nowak, Froehlich, & Rockloff, 2002). Among participants with a relatively coherent self-concept—and thus presumably with a strong attractor for self-evaluation—

the flow of self-reflective thought initially showed the effect of a manipulation designed to prime either positive or negative thoughts about the self. Over time, however, the evaluative tone of participants' self-reflection increasingly conformed to their chronic self-evaluation tendencies. Participants with high self-esteem who were asked to recall past events that reflected negatively on themselves, for example, tended to express negative self-aspects at the outset, but these sentiments gave way over the course of self-reflection to positively toned self-relevant thoughts.

In a related vein, research on affective forecasting (e.g., Wilson, Wheatley, Meyers, Gilbert, & Axsom, 2000) has shown that people commonly overestimate how enduring a mood will be after experiencing a pleasant or an unpleasant event. Even major life events that would seem to alter one's view of the world—whether winning a lottery or experiencing a debilitating illness—typically have relatively short-term effects. Over time, the person's characteristic worldview and mood tend to overpower the mood-inducing effect of the event.

Research has identified various mechanisms that promote resistance to, and recovery from, situational influences that have potential to impact people's attitudes, beliefs, self-concepts, and response tendencies. Social cognition research, for example, has investigated biases in thought and memory (e.g., selective attention and confirmatory bias) that enable people to resist challenges to their judgments about other people and social groups (cf. Kunda, 1999). The work on self-esteem maintenance (Tesser et al., 1996), meanwhile, illustrates the interchangeability of various means for protecting self-esteem against incoming information (e.g., social feedback) that holds potential for undermining positive self-evaluation. Theory and research on self-verification (cf. Swann, 1990) has shown that self-protective tendencies operate to maintain any level of chronic self-regard, even a largely negative self-view that is presumably not consciously desired.

People often have different responses to the same external forces. Some people seem unaffected by information and social influence that contradicts their beliefs or self-concepts, whereas others may readily succumb to such perturbations. Yet others show an exaggerated and highly defensive response to the same factor. Such individual variation can be cast in terms of the strength and basins of attraction associated with the relevant attractors. The strength of an attractor determines the likelihood of rejecting perturbing influences, while the width of the basin of attraction determines the likelihood of the system returning to the attractor after being perturbed. Thus, a person with a strong attractor is likely to reject contradictory information, and someone with a wide basin of attraction is likely to return to his or her attractor after being influenced to think or act in a different manner. If a person has a weak attractor, on the other hand, relatively small influences may prove sufficient to dislodge a system, and if the basin of attraction is also narrow, the system will not return to its attractor. Under this configuration of attractor properties, the person may be especially vulnerable to inconsistent information or other perturbing influences.

Yet another configuration may be at work for people who react in a disproportionately strong manner to any information that challenges their predominant mode of thought or behavior. Such people may have a strong attractor, which promotes rejection, but a narrow basin of attraction, which reduces the potential for recovery from perturbing influences. This scenario, though clearly speculative pending empirical confirmation, is consistent with theory and research on threatened egotism (Baumeister, Smart, & Boden, 1996). The threatened egoist has inflated but insecure self-esteem and responds defensively, even aggressively, toward others who provide feedback challenging his or her self-appraisal. The same dynamics may underlie traits reflecting closed-mindedness, such as dogmatism and need for closure (cf. Kruglanski & Webster, 1996).

Rigid attempts to maintain a particular point of view while rejecting information and influences that challenge this view may promote a paradoxical effect. Imagine, for instance, a person who wishes to maintain a positive view of a close friend despite exposure to information that implies an unflattering assessment of the friend. By virtue of having a shared valence, the thoughts that are rejected are likely to provide mutual reinforcement for each other and thus hold potential for creating a latent attractor. Assuming the latent negative attractor is unwanted, its potential activation may promote increased effort at maintaining the preferred (positive) attractor. But this effort at mental control is likely to increase the number of rejected thoughts, which can then become organized with respect to the latent attractor. The result is further integration of the latent attractor, which augments its potential for capturing the person's trajectory of thoughts should his or her self-regulatory efforts be disrupted or weakened.

In effect, heightened mental control can initiate a tendency that works in opposition to the control effort. This tendency is particularly likely to become prepotent when cognitive resources are drained or mental control is otherwise undermined. This scenario is speculative at this point, of course, but it follows from the notion of latent attractor and its manifestation is consistent with the well-documented ironic effect of thought suppression (cf. Wegner, 1994).

The Power of the Situation

In a system governed by attractor dynamics, situational influences up to a certain magnitude may have only a transient effect because of the tendency for a system to return to its attractor after perturbation. Beyond a certain threshold (i.e., a magnitude that positions the system outside the attractor's basin of attraction), however, an external factor may have a lasting effect on the person's thought or behavior. In a system with multiple attractors, such an influence will dislodge the system from one attractor and position it in the basin of another attractor. This suggests that even when a strong force is experi-

enced, its manifestation may vary from one person to another, depending on the respective attractors available for each person. Thus, a strong provocation might undermine a person's tendency toward friendliness, but whether it promotes aggression or surrender will depend on which of these alternative behavioral tendencies represents an alternative attractor for the person. The person's attractor landscape, in other words, is critical in determining just what effect a situational force is likely to have.

Although strong influences are typically required to promote a lasting change in a person's thought and behavior, small influences may prove sufficient under some conditions. As noted previously, small external influences are likely to be countered by the system, whereas larger perturbations will be accommodated and even amplified in their effects. This suggests that a series of small effects are likely to have little impact on the long-term dynamics of the system. If these effects are concentrated in time, however, their combined effect may be sufficient to move the system into a basin of attraction for a qualitatively different state. Such a scenario was the emergent outcome of the model developed by Nowak and colleagues (2000) to simulate self-concept structure and process. The same amount of conflicting self-relevant information tended to be resisted if presented in small packets separated by time, but tended to promote noteworthy change in global self-evaluation if presented in a large packet in a short period of time. This result can be understood in terms of the system's ability to restore its state after each small perturbation but its inability to do so when a single massive perturbation is experienced.

Weak situational influences may also have effects on a person if his or her thought and behavior are not constrained by attractor dynamics. Research on action identification is relevant in this regard. This work has established that when people are engaged in unfamiliar, complex, or difficult actions, they are highly responsive to suggestions regarding the effects, meanings, or implications of what they are doing (Vallacher & Wegner, 1985, 1987). This vulnerability to influence reflects the lack of integration associated with unfamiliar and personally difficult actions. Such an action is identified in terms of independent low-level components rather than in terms of an integrated high-level identity that provides a stable and comprehensive interpretation. Isolated in this way, each low-level identity lacks the strength to resist social and situational cues regarding its larger meaning—in effect, it is each thought for itself.

If, however, lower-level action components are integrated into higher-level, meaningful structures, then each element receives support from related elements and the combined resistance of these integrated elements can effectively counter outside influence—in effect, one for all and all for one. This general scenario has been demonstrated in computer simulations of self-concept dynamics (Nowak et al., 2000). Contradictory information presented to clusters of self-relevant information that were poorly organized tended to disrupt the clusters, but the same information presented to well-integrated clusters tended to be rejected.

This reasoning suggests that some people may be more vulnerable to situational influences than others. Individuals differ in their characteristic level of action identification (Vallacher & Wegner, 1989), for example, and this difference has been shown to shape people's response to social influence. Thus, people who think about their behavior in low-level (fragmented) terms tend to embrace bogus feedback about the personality characteristics purportedly revealed in a recent action on their part (Wegner, Vallacher, Kiersted, & Dizadji, 1986). From a dynamical perspective, people who identify their action in low-level terms lack stable attractors for thinking about and regulating their behavior (Vallacher et al., 1998). Lacking such attractors, low-level agents are highly vulnerable to external influence.

People also differ with respect to dimensions of self-concept that are relevant to attractor dynamics. Considerable research in recent years has focused in particular on self-concept certainty (e.g., Baumgardner, 1990; Swann & Ely, 1984; Vallacher, 1978; Vallacher, Nowack, Froehlich, & Rockloff, 2002), self-concept clarity (e.g., Campbell et al., 1996), and self-concept stability (e.g., Kernis, 1993). People with an uncertain, unclear, or unstable sense of self have been shown to be highly responsive to social feedback, social comparison, and social influence (cf. Story, 2004). Two possible attractor configurations could be at work here. First, such people may have multiple and conflicting attractors with narrow basins of attraction. Even a slight change in the initial state induced by a social or situational factor might be sufficient to dislodge the system from one attractor and position it in the basin of another attractor. Alternatively, the uncertain person may have a paucity of fixed-point attractors for stabilizing his or her thought and behavior on specific states. In this view, uncertain people are not only responsive to influence but actively seek it out in an attempt to impose structure and clarity on their mental, affective, and behavioral processes (e.g., Vallacher & Nowak, 2000).

PSYCHOLOGICAL CHANGE

In the preceding discussion, the focus was how people change with respect to their location in an existing attractor landscape. Thus, situational forces were described as moving a person within an attractor or, under some conditions, dislodging the person from one basin of attraction and positioning him or her within the basin of another attractor. There is a more fundamental way, however, in which psychological change may occur. Rather than moving a person (or group) within an existing attractor landscape, change can instead involve reconfiguration of the attractor landscape itself. Change reflecting movement between existing attractors is reversible, at least in principle. Thus, if a person moves from attractor A to attractor B because of a specific influence, then an influence in the opposite direction could

reinstate the prepotence of attractor A. A change in the attractor landscape, however, may have lasting and irreversible consequences because it changes the set of possible stable states for the system.

The variables that control the qualitative features of a system—such as the number, location, and type of attractors—are *control parameters*. When developing a theoretical model, then, the central concern is determining which causal factors function as control parameters and have a qualitative effect on the system's dynamics and which factors have a quantitative effect, changing only the momentary state of the system. In modeling psychological change, the system's control parameters clearly are more important and of greater interest than are variables controlling the momentary state of the system.

Changing the attractor landscape of a system can take two different forms. In a system with fixed-point attractors, first of all, change may involve altering the number, position, and shape of the attractors. This type of change is described in topological terms by catastrophe theory (cf. Guastello, 1995; Thom, 1975). A more comprehensive account that incorporates periodic and chaotic attractors is described in dynamical terms by bifurcation theory (cf. Nowak & Lewenstein, 1994; Ruelle, 1989). The second form involves altering the entire pattern of intrinsic dynamics in a system and transforming the types of attractors available for constraining system dynamics. This type of change is often illustrated with the logistic equation, a simple model that captures important features of dynamical systems (cf. Feigenbaum, 1978; Schuster, 1984).

Changing Fixed-Point Attractors

The cusp catastrophe (Thom, 1975) exemplifies change in fixed-point attractors. In this model, two variables—a *splitting factor* and a *normal factor*—control the attractor landscape of the system. The splitting factor, functioning as the control parameter, decides whether the system reacts in a linear or nonlinear way to changes in the normal factor. For low values of the splitting factor, the system is characterized by a single attractor, the position of which changes in a monotonic fashion with changes in the normal factor. For higher values, the single attractor splits into two attractors whose values diverge with increases in values of the splitting factor.

A model of close relations proposed by Tesser and Achee (1994), recast and tested in dynamical terms by Kozlowska, Nowak, and Kus (cited in Nowak & Vallacher, 1998a), illustrates this scenario. The splitting factor in this model is social pressure regarding the formation and maintenance of close relations. The normal factor is the perceived attractiveness of the potential partner. For low values of social pressure (e.g., nonsalience of social norms), the desired closeness of the relationship was a direct function of perceived attractiveness. For high values of social pressure (e.g., against forming a relationship with a stranger but for maintaining a relationship once it is formed), however, there were two attractors corresponding to preferred closeness—

one for a distant relationship, the other for a close relationship.

This scenario is also illustrated in a model of attitudes that focuses on the relationship between the positivity of information concerning an issue and the person's resultant attitude regarding the issue (Latané & Nowak, 1994). The splitting factor in this model is the importance of the issue to the person. For low values (i.e., unimportant issues), there is an approximately linear relationship between information positivity and the attitude. For high values (important issues), however, the relation between information positivity and attitude takes a nonlinear form. When the information concerning an attitude object is predominantly negative, only a negative attractor exists for the person's attitude. When the information increases in positivity, a second attractor appears corresponding to a positive attitude. As the positivity of information increases yet further, the negative attractor disappears and only the positive attractor exists.

Changing Attractor Types

Control parameters can change not only the position and number of attractors but also the types of attractors for a system's dynamics. The simplest and most commonly employed example of this role of control parameters involves the *logistic equation* (cf. Schuster, 1984). The logistic equation involves one variable, x, whose values change in time, and one control parameter, r, which is a coefficient of the equation. The equation specifies what the next value of x will be depending on the current value of x. There are two opposing components of this dependence. First, the higher the value of x at a given moment, the higher the value of x at the next moment—specifically, x_{n+1} equals x_n multiplied by the value of r. Second, the higher the value of x at a given moment, the *lower* the value of x at the next moment—specifically, x_{n+1} equals $(1 - x_n)$ multiplied by the value of r. The combined effect of these two forces is expressed as $x_{n+1} = rx_n(1 - x_n)$, where x_n is the value of the dynamical variable at one moment, x_{n+1} is the value of a dynamical variable at the next moment, and r is the control parameter (the crucial variable influencing changes of x over time). The equation thus expresses conflicting tendencies in a phenomenon and has been employed as a model of many natural science phenomena.

Conflict involving the coexistence of two opposing tendencies is well recognized in social psychology. In the approach–avoid situation (Miller, 1944), for example, movement toward a goal increases both approach and avoidance tendencies. In analogous fashion, theory and research concerning achievement motivation have identified two concerns, the desire for success and the fear of failure, that combine in different ways to produce resultant motivation (e.g., Atkinson, 1964). Theory and research on thought and action suppression, meanwhile, suggest that attempts at suppression activate an ironic process that works at cross-purposes with the attempted suppression (Wegner, 1994). Many other phenomena in psychology can be framed in terms of conflicting tenden-

cies or forces (e.g., impulse vs. self-control, short-term vs. long-term self-interest, egoism vs. altruism, and autonomy vs. social identity).

The temporal pattern of the dynamical variable, x, is totally dependent on the value of the control parameter, r. For low values of r, x will always converge on a single value that represents a fixed-point attractor of the system. For a higher range of values of r, x will oscillate between a set of values, with the period (i.e., number of values through which x oscillates) increasing with the value r. In this case, x follows the scenario of a periodic attractor. For a yet a higher range of values of r, the evolution of x becomes very complex, with the exact sequence of values never repeating. In this case, the attractor for x becomes chaotic.

Exact empirical tests of the application of the logistic equation to social psychological phenomena have yet to be devised. Theoretical models, however, have been proposed in such domains as consumer behavior, close relationships, and the dynamics of approach–avoid conflict (cf. Nowak & Vallacher, 1998a). The dynamics of judgment and decision making might also conform to the logistic equation. In this application, the complexity of relevant information might function as the control parameter, with increases in complexity promoting systematic changes in the attractor defining a person's mental process. Relatively simple information might promote convergence on a stable value (e.g., a decision or judgment)—a fixed-point attractor. As the information becomes increasingly complex, however, the stable value may give way to periodic movement between alternative decisions or evaluative states, neither of which provides for stability in the cognitive–affective system. This pattern might be experienced as ambivalence or conflict between different assessments of the appropriate course of action. Yet further increases in information complexity might promote multiperiodic or even chaotic trajectories of thought and feeling. This dynamic pattern might be manifest as indecision or perhaps confusion, and experienced emotionally as heightened arousal, agitation, and anxiety.

The logistic equation, in sum, shows that the same system can display entirely different patterns of behavior (e.g., fixed-point, periodic, and chaotic attractors) depending on changes in the values of a control parameter. There is a clear distinction between external influences or perturbations that change of value of x and control parameters that change the pattern of the temporal evolution of x. The logistic equation also highlights the possibility that whenever the dynamics of a system are governed by opposing forces, the system has the potential for very complex dynamics, even if the system consists of a very small number of variables.

COHERENCE IN SOCIAL PSYCHOLOGICAL SYSTEMS

Despite the enormous complexity of human minds and social groups, psychological systems at different levels of social reality display self-organization and the emergence of higher-order properties and processes. Emergence, however, is not a one-step process. To the contrary, once global properties and higher-order processes come to characterize a system, they effectively become lower-level units that can become integrated with respect to yet higher-order properties. In principle, this process of progressive integration can proceed until the system as a whole can be characterized in terms of a single macro-level state that functions in accordance with a single process. In reality, the tendency toward progressive integration is likely to "stall" at a level that promotes differentiation rather than unification in the phenomenon at issue.

The critical factor dictating the level at which integrative processes stall is coherence (cf. Nowak et al., 2000; Simon & Holyoak, 2002; Thagard, 1989). A set of elements is coherent to the extent that they are consistent in their implications for thought, emotion, or behavior, depending on the phenomenon. Thus, a set of thoughts relevant to social judgment is coherent if they collectively convey an unequivocal evaluation of someone, whereas a set of low-level act identities is coherent if they are sufficiently coordinated to promote effective performance of the action under a higher-level (comprehensive) act identity. In both cases, the challenge of attaining higher-order coherence may stall the process at a level well beneath that of global evaluation or action mastery. Instead, social judgment will reflect a differentiated view of the target (cf. Kunda & Thagard, 1996) and action identification will be characterized by the prepotence of various lower-level act identities (Vallacher & Wegner, 1985, 1989).

Coherence and the potential for progressive integration may have a wide range of application in social psychology, providing a principle that links otherwise distant phenomena. To date, however, research designed to illuminate the building of psychological structures in this fashion is limited to a few domains. Next, we discuss how coherence is relevant to emotion, the emergence and maintenance of self-concept, and the formation of public opinion.

Emotion and Affective Experience

Perhaps the most basic and widely accepted division of psychological processes is the tripartite distinction among action, cognition, and emotion. Numerous and diverse accounts have been forwarded to depict how these systems interact, but to a large extent these accounts all suggest that emotion serves to signal the state of the other systems or the quality of coordination between them (e.g., Carver & Scheier, 1999; Csikszentmihalyi, 1990; Festinger, 1957; Heider, 1958; Higgins, 2000; Kruglanski & Webster, 1996; Mandler, 1975; Simon, 1967; Thagard & Nerb, 2002; Vallacher & Nowak, 1999; Vallacher, Wegner, & Somoza, 1989; Winkielman & Cacioppo, 2001). In general, negative emotion signals incoherence: poor processing fluency in perception, inconsistency or uncertainty in judgment, discrepancy between mental representations (e.g., goals, attitudes) and behavior, and poor coordination between mind and action. Depending on the theoretical account

and the system or systems at issue, the negative emotional states are sometimes diffuse (e.g., arousal and agitation) and sometimes fairly specific (e.g., guilt, disliking, and self-consciousness).

The flip side of the notion that incoherence promotes negative emotion is that systems strive for coherence (e.g., Kruglanski & Webster, 1996). Insight into the dynamic underpinnings of this scenario is provided by Lewenstein and Nowak (1989a, 1989b), who introduced self-control mechanisms in attractor neural networks (Hopfield, 1982). Attractor neural networks (a subclass of connectionist models) are programmable dynamical systems. In this approach, familiar (previously experienced, overlearned, etc.) stimuli are encoded as attractors of the network. In the vicinity of an attractor (i.e., when a familiar stimulus is perceived), the signals arriving at a given neuron from other neurons are consistent in dictating the state of the neuron. Coherent signaling, in other words, signifies an energy minimum (equilibrium) in the network. When the network is far from an attractor, however, the system is characterized by incoherence—the signals arriving a given neuron from other neurons dictate conflicting states of the neuron.

Network incoherence is used to construct a self-control feedback loop. The control parameter is the level of "noise" in the network, corresponding to the random component of neuron firing. Self-control is established by making the noise level dependent on the degree of network incoherence. With increasing levels of incoherence, the network increases its noise level, which in turn decreases the coherence of the network, and so on, in a self-perpetuating manner. This has the effect of making progressively stronger attractors inaccessible, until at some point no attractor can capture the system's dynamics. On the other hand, because familiar stimuli are coherent and hence produce low levels of noise, the feedback loop results in their correct recognition. This feedback loop, in sum, enables the network to regulate its own recognition process. The recognition process is maintained when the network is characterized by coherence (produced by familiar patterns) but is interrupted by high levels of noise when the network detects its own incoherence (produced by unfamiliar patterns).

This scenario can be used to interpret the nature of coherence in different psychological systems (Vallacher & Nowak, 1999). The units in an attractor network are not restricted to neurons but can take on a variety of identities, from cognitive elements (in the case of judgment) to individuals (in the case of group dynamics). Noise, in turn, corresponds to negative emotion signaling incoherence. Depending on the phenomenon, noise could thus represent a wide variety of emotional states, including diffuse arousal, acute anxiety, self-conscious emotions such as embarrassment or guilt, or negative affect toward a stimulus. The detection of incoherence, signaled by negative emotion, engages the self-regulation feedback loop to restore coherence.

Consider, for example, the operation of action systems. In a malfunctioning system or one that has been destabilized by external influences, the action elements are no longer coherent (i.e., they provide conflicting signals to one another) and thus cannot be coordinated into an effective pattern. This can happen, for example, when cues to action are ambiguous or conflicting, or when novel circumstances disrupt the normal course of action. This promotes negative emotion (e.g., anxiety and self-doubt) and has the effect of disassembling the action system into its lower-level elements, which can then be reassembled in a different configuration that restores coherence (and effectiveness) to the action.

This scenario does not imply that a person's affective state goes flat when coherence is achieved in a psychological system. Rather, the attainment of system coherence is associated with positive emotion. When an action system, for example, functions autonomously and has the potential for continuing self-organization, it may produce a special affective state commonly referred to as "flow" (Csikszentmihalyi, 1990). Because positive emotions signal coherence and effective self-regulation at a given level, moreover, they free up consciousness from monitoring the functioning of the system and thus allow attention to move upward to assemble higher-level systems. This perspective is interesting in light of recent consideration of independence and asymmetry with respect to positive and negative emotions (cf. Cacioppo, Gardner, & Bernston, 1997; Carver & Scheier, 1999; Higgins, 2000). Whereas negative emotions focus attention on the internal workings of an incoherent system, positive emotions are associated with progression of consciousness to higher levels of integration. In the context of action, for example, effective self-regulation at a basic level of mental representation (e.g., hitting a tennis ball) not only feels good but also directs attention to the action's more comprehensive meanings, such as its purpose, consequences, and implications (Vallacher & Wegner, 1987). Positive emotions, in effect, provide the hedonic basis for progressive integration in psychological systems.

Considered together, the progressive assembly of lower-order systems into higher-order systems and the repair of disrupted systems impart a dynamic quality to affective and cognitive experience. Each time one's attention is diverted from a higher-order system to lower-level elements and systems, there is a press for consciousness to reassemble the elements into a higher-order system. To the extent that the resultant coordination differs from the earlier pattern of interelement connections, the emergent higher-order system may be qualitatively different from the original system. With each enactment of the disruption-repair pattern, then, there is potential for the creation of a new higher-order system of self-regulation. From a dynamical perspective, the content of mind is open-ended and ever-changing, representing a constructive process that fosters adaptation to changing demands and conditions.

Self-Reflection and the Emergence of Self-Concept

The self is arguably the largest and most chronically accessible structure in a person's mental system. Every facet of personal experience is potentially relevant to a person's self-understanding, from the details of his or

her physical appearance to his or her self-perceived traits, values, and personal aspirations. The voluminous information relevant to the self that is encountered on a daily basis is highly diverse in content and valence, ranging from incidental events to consequential feedback from significant others and success versus failure in personal pursuits. The nonstop exposure to distinct, often inconsistent, pieces of self-relevant information would seem to undermine the formation of a stable and coherent sense of self. Yet people somehow manage to develop relatively certain and coherent conceptions of themselves with respect to higher-order constructs such as traits, skills, and goals.

In addressing this issue, Nowak and colleagues (2000) conceptualized the self-structure as a complex system composed of cognitive elements representing self-relevant information, with mechanisms of self-organization promoting coherence and stability in self-concept in much the same way that that such mechanisms promote social consensus among autonomous agents in society (Nowak et al., 1990). Although the elements of self-structure are diverse by many criteria, they can all be scaled with respect to evaluation. Nowak and colleagues assumed that the elements do not have a fixed valence but, rather, that they influence each other to adopt a common evaluative state. An element incongruent with neighboring (thematically related) elements may change its valence or change the valence of its neighbors, to establish evaluative coherence with the related elements. The recognition that one is distractable, for example, may take on positive rather than negative valence in the context of other self-perceived qualities that together convey an image of oneself as a creative scientist. This press for integration generates subsets of self-relevant information that have a shared evaluation. The self-structure thus becomes differentiated, with different regions stabilizing on different values of self-evaluation (e.g., Showers, 1992). A person may have a coherent and positive view of him- or herself as a scholar, for example, and an equally coherent but negative view of him- or herself as an athlete.

Nowak and colleagues (2000) developed a cellular automata model to simulate the emergence of local coherence in self-structure. In this model, the self-system consists of n elements, each reflecting a specific aspect of the self, which are represented as cells arranged on a two-dimensional grid (see Figure 32.2). The physical proximity of any two elements represents their degree of relatedness. Each element is characterized with respect to its current evaluation, which is either positive (denoted by light gray) or negative (dark gray). Some elements are more important than others and have greater weight in self-evaluation. An element's importance, which remains constant in the course of simulation, is denoted by its height. Each element influences and is influenced by its eight neighboring elements (four on the adjacent sides and four on the connecting diagonals).

In the course of simulation, an element chosen at random tries to adjust to its neighboring elements by checking how much influence it receives from them. This process involves weighting the valence of each neighbor by the neighbor's importance. The result of this computation is the weighted sum of evaluations of the neighboring elements. This result is then compared to the current valence of the element. If the element's valence agrees with the overall evaluation suggested by its neighbors, the valence does not change. If the valence of the element differs from the overall evaluation suggested by its neighbors, the element changes evaluation only if the combined weight of evaluation from the neighboring elements is greater than the element's own weighted evaluation. It is relatively easy for neighboring elements to change the evaluation of a relatively unimportant element, in other words, but it is difficult to change the evaluation of a more important piece of self-relevant information.

This process is repeated for another randomly chosen element, and then again for another element, and so on, until each element has been chosen. In the next simulation step, each element has a chance to adjust its state again. The simulation steps are repeated the system reaches an asymptote, indicating no further changes in the state of elements (i.e., static equilibrium) or a stable pattern of changes in the system (i.e., dynamic equilibrium).

As Figure 32.2 illustrates, the process of mutual adjustment among elements of self-relevant information promotes the emergence of clusters. Self-relevant information that is randomly distributed at the outset (top picture) forms well-defined domains composed of elements that share a common valence (bottom picture). The emergence of evaluatively coherent clusters is due to the local nature of influence among elements. The self-system also becomes more polarized in overall evaluation, with more negative elements switching to positive valence than vice versa. In a disordered system, the proportion of positive and negative elements in a region roughly corresponds to the proportion of positive and negative elements in the entire structure. Hence, any given element is likely to be surrounded by more positive than negative elements and thus is likely to experience greater influence in the positive direction. Once the self-
FIGURE 32.2. The emergence of coherence in self-structure (Nowak et al., 2000).

structure has become clustered, however, most elements are surrounded by elements of the same valence, so that only the elements on the border of a cluster are subjected to conflicting influences.

The emergence of locally coherent regions tends to stabilize the self-system. This is because each element in a coherent region supports the current state of the other elements. A change in one element results in joint influence of the other elements for the element to return to its original value. In effect, coherent regions function as attractors, where the value of each element is anchored in the value of the other elements. The joint influence of all the elements in a region promotes resistance to change, and enables an element to return to its original value if it is changed. In an incoherent region, in contrast, the current state of an element is supported by some elements but undermined by others. Hence, when an element is influenced from the outside, some of the surrounding elements help the element resist the influence, whereas other elements work in the direction of the influence. If an element is overwhelmed by outside influence, there will be little tendency for it to return to its original state because some of the neighboring elements are likely to support the new state.

Computer simulations provided support for coherence as a basis for the attracting tendencies of clusters. Integrated self-structures could withstand external influence and were able to rebound to their original state after being perturbed. Unintegrated self-structures yielded more readily to influence and displayed weaker tendencies toward restoration of their original state. Figure 32.2 also shows that although the proportion of positive elements increased, the negative elements that manage to survive tended to be more important and hence resistant to subsequent changes. This is consistent with research on the negativity effect in judgment (e.g., Cacioppo et al., 1997; Pratto & John, 1991; Skowronski & Carlston, 1989). Although positive information tends to be more prevalent than negative information in cognitive structures, the relatively few elements of negative information tend to be more important and hence more salient.

Despite the press for integration, evaluative coherence with respect to higher-order constructs such as traits, competencies, and roles may be difficult to achieve and maintain. An aspect of self-concept such as "honesty," for instance, may consist of conflicting self-views that render a unified self-evaluation impossible. Rather than having a global coherent self-view with respect to honesty, a person might differentiate this dimension into more basic dimensions, such as academic versus interpersonal honesty. If each of these lower-level assessments also prove to be internally inconsistent, the person's self-concept will be correspondingly more fragmented.

Specificity in self-assessment may reflect reality constraints and suggest precision in self-understanding, but it is unlikely to be personally satisfying. Because of the press for higher-order coherence, the person might experience periods of rumination as he or she attempts to integrate the conflicting thoughts, or, alternatively, he or she might engage in a variety of self-defense mechanisms (e.g., reinterpretation, discounting, and denial) that pro-vide subjective coherence with respect to the higher-order dimensions (Tesser et al., 1996). These tendencies are likely to be reinforced by the demands and expectations of social life, which typically emphasize broader categories of self-understanding. People describe and judge one another in terms of motives and traits rather than specific acts (cf. Kunda, 1999), after all, and decision making often pertains to basic goals and values rather than narrowly defined concerns. Hence, someone with an evaluatively mixed view of him- or herself with respect to traits and goals is likely to report relatively low self-concept certainty (Baumgardner, 1990; Campbell et al., 1996; Pelham, 1991; Vallacher, 1980; Vallacher, Nowak, Froehlich, & Rockloff, 2002)—even if the person is certain of what he or she is like with respect to lower-level aspects of self (Vallacher & Wegner, 1989). Such a person is also likely to display instability in the stream of self-evaluative thought, as inconsistent self-relevant thoughts rise and fall in salience on a short time scale (Vallacher, Nowak, Froehlich, & Rockloff, 2002).

Social Interaction and the Emergence of Group Structure

One would think that putting individuals together in groups would create a breeding ground for chaos and conflict. Particularly in an individualistic society like the United States, the potential for self-interest to color one's interactions with others might promote highly complex trajectories of group sentiment and behavior as the group members express and try to promote their respective idiosyncratic and egoistic agendas. Several decades of research on group dynamics, however, have pointed to a very different dynamic scenario, one that is similar in form to the emergence of coherence in individual minds. Across a wide range of contexts, groups of interacting individuals tend to become increasingly uniform over time in their opinions, beliefs, and recommended courses of action (cf. Arrow et al., 2000; Festinger, Schachter, & Back, 1950).

People in groups certainly attempt to influence one another. But such attempts usually represent more than a concern with forwarding one's own agenda, centering instead on a concern with achieving a common psychological state and platform for action. In the process of social interaction, group members adjust their opinions, mood, or behavior to promote consensus with one another. Even if the members have diverse opinions and initially disagree with one another, there is nonetheless a tendency for uniform opinions to emerge over time. The group-level product of local social interactions, however, rarely reflects the central tendency of members' individual initial opinions. Rather, the opinion that emerges as a result of social interaction tends to be more extreme than the average of group members' opinions (e.g., Myers & Lamm, 1976).

The tendency for groups to develop a common psychological state is largely adaptive, as it provides the social coordination and consensus necessary for social life and group action. But the tendency for groups to achieve uniformity has downsides as well. Under some condi-

tions, for example, it can promote mindless conformity to inaccurate assessments of reality (cf. Asch 1955; Sherif, 1936). The press for coherence in groups can also produce decisions and recommendations for action that are guided more by a concern for reaching consensus than for developing the best policy. Rather than examining all possible courses of action, people in the grip of "groupthink" (Janis, 1982) expend their mental energy on achieving and maintaining group solidarity and opinion unanimity. Once a group has achieved a common psychological state, moreover, anyone who expresses a contrary view is likely to experience enormous pressure to change. If the person doesn't cave in to such pressure, he or she is likely to be rejected (Schachter, 1951). This has clear implications for a host of phenomena, from peer pressure among adolescents to jury deliberations in cases in which a guilty verdict carries the death sentence (e.g., Hastie, Penrod, & Pennington, 1983).

Insight into the dynamics of coherence in groups is provided by social impact theory (Latané, 1981) and the implementation of a dynamical version of this model (Nowak et al., 1990). The theory holds that influence in a group reflects two basic functions—one describing the combined effect of different people on a single person, the other describing how a single person's influence is divided across different people. Three variables are common to both functions: the number of people influencing or being influenced, the respective strength of these people, and the immediacy of the people to one another. The influence of a group grows as a power function of the number of people, usually with an exponent of approximately 0.5. In other words, the joint effects of the group's influence grows as a square root of the number of group members. Strength represents the potential for influence and refers both to stable individual characteristics (e.g., social status) and to topic-relevant variables (e.g., relevant knowledge). Finally, influence depends on proximity and tends to decrease as a square of the distance.

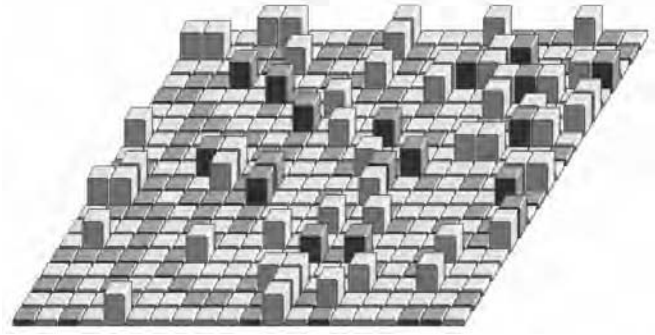
In the dynamical model (Nowak et al., 1990), each individual is characterized by his or her opinion on a topic, persuasive strength, and position in a social space. For simplicity sake, individuals are commonly assumed to have one of two opinions on an issue (e.g., pro vs. con). The social group is modeled as a cellular automata consisting of n individuals located on a two-dimensional grid (see Figure 32.3). Each box in Figure 32.3 corresponds to an individual. The color of the box (light vs. dark gray) denotes the individual's opinion (e.g., light gray denotes pro, dark gray denotes con), and the height of the box corresponds to the individual's strength. Each individual discusses the issue with other group members to assess the degree of support for each position. The opinions of those who are closest and have the greatest strength are weighted most heavily. An individual's own position is also taken into consideration and is weighted most heavily by virtue of immediacy. Each individual adopts the opinion that is most prevalent in the process of social interaction. The strength of influence of each opinion is expressed as follows:


FIGURE 32.3a. Initial distribution of opinions in the simulated group.

$$I_i = \left(\sum_1^N \left(\frac{s_j}{d_{ij}^2} \right)^2 \right)^{1/2}$$

where I_i denotes total influence, s_j corresponds to the strength of each individual, and d_{ij} corresponds to the distance between individuals i and j.

In the simulations, one individual is chosen (usually at random), and influence is computed for each opinion in the group. If the resultant strength for an opinion position is greater than the strength of the individual's current position, his or her opinion changes to match the prevailing position. This process is performed for each individual. This procedure is repeated until there are no further changes, which typically requires several rounds of simulation, because a person who had previously changed his or her position to match that of his or her neighbors may revert to the original position if the neighbors change their opinions. Figure 32.3 presents representative results of the computer simulations. In Figure 32.3a, there is a majority of 60% (light gray) and a minority of 40% (dark gray). The majority and minority members are randomly distributed, and each group has the same relative proportions of strong and weak members (high vs. low boxes). Figure 32.3b shows the equilibrium
FIGURE 32.3b. Final equilibrium of opinions in the simulated group.

reached after six rounds of simulated discussion. Now the majority is 90% and the minority is 10%. The minority opinion has survived by forming clusters of like-minded people, and these clusters are largely formed around strong individuals.

These two group-level outcomes—*polarization and clustering*—are commonly observed in computer simulations (cf. Latané, Nowak, & Liu, 1994) and are reminiscent of well-documented social processes. As noted earlier, the average attitude in a group becomes polarized in the direction of the prevailing attitude as a result of group discussion. Polarization in the simulations reflects the greater influence of the majority opinion. In the initial random configuration (Figure 32.3a), the average proportion of neighbors holding a given opinion corresponds to the proportion of this opinion in the total group. This means that the average group member is surrounded by more majority than minority members, which results in more minority members being converted to the majority position than vice versa. Some majority members are converted to the minority position, however, because they happen to be located close to an especially influential minority member, or because more minority members happen to be at this location.

Clustering is also pervasive in social life. Attitudes have been shown to cluster in residential neighborhoods (Festinger et al., 1950), for example, and pronounced clustering has been observed for political beliefs, religions, clothing fashions, and farming techniques. Clustering reflects the relatively strong influence exerted by an individual's neighbors. When opinions are distributed randomly, the sampling of opinions through social interaction provides a reasonably accurate portrait of the distribution of opinions in the larger society. When opinions are clustered, however, the same sampling process will yield a highly biased result. Because the opinions of those in the nearby vicinity are weighted the most heavily, the prevalence of one's own opinion is likely to be overestimated. Hence, opinions that are in the minority in global terms can form a local majority. Individuals who hold a minority opinion are therefore likely to maintain this opinion in the belief that it represents a majority position.

Clustering occurs despite the press for coherence that is responsible for progressive integration in psychological systems. Three factors have been identified that effectively stall the integration process, preventing complete unification and hence preserving minority opinions in groups (Latané & Nowak, 1997; Lewenstein et al., 1993; Nowak, Lewenstein, & Frejlak, 1996). Individual differences, first of all, are indispensable to the survival of minority clusters. By counteracting the sheer number of majority opinions, strong leaders stop minority clusters from decaying. As a result of social influence, moreover, individual differences in strength tend to become correlated with opinions. This is because the weakest minority members will most likely adopt the majority position, so that the average strength of the remaining minority members will grow over time at the expense of the majority. This scenario provides an explanation for why individuals advocating minority positions are often more influential than those advocating majority positions (cf. Moscovici, Lage, & Naffrechoux, 1969).

The second factor is nonlinearity in attitude change. Abelson (1979) showed that when individuals move incrementally toward the opinions of their interaction partners, groups invariably become unified in their support of the majority opinion. In the model of dynamic social impact, however, attitudes change nonlinearly in accordance with a threshold function. Thus, individuals hold their opinion until social influence reaches a critical level, at which point they switch from one categorical position (e.g., pro) to the other (con). So whereas a linear change rule, which implies a normal distribution of opinions, promotes unification of opinions, a nonlinear change rule, which implies a bimodal distribution, can prevent complete unification and enable minority opinion to survive in clusters. Latané and Nowak (1994) have shown that a normal distribution tends to develop for relatively unimportant attitudes, but that a bimodal distribution is more often observed for attitudes of high personal importance. This suggests that consensus in a group can be achieved by decreasing the subjective importance of the topic.

The third factor is the geometry of the space in which individuals interact (Nowak, Latané, & Lewenstein, 1994). People do not communicate equally with all members of a group, nor are their interactions often random. In the cellular automata model, different communication patterns can be approximated with different geometries of social space. In the limiting case, geometry is lacking altogether and interactions occur randomly between people. Under these conditions, minority opinion decays rapidly and the group converges on the majority position. Other geometries have been used to capture different communication patterns, and these have been shown to have predictable consequences for the fate of minority opinions. In real social settings, of course, several different geometries are likely to coexist and determine the emergence of opinion structure in groups. Even in a small town, the ready availability of telephones, email, shopping malls, and common areas for recreation add many dimensions to the effective geometry in which interactions take place. The combined features of these geometries are certain to play significant roles in shaping the distribution of public opinion.

TOWARD COHERENCE IN SOCIAL PSYCHOLOGY

Social psychology is an ambitious area of scientific inquiry that has attempted to capture every conceivable nuance of human experience. But although the field's wide-ranging agenda is commendable, it has had the unintended effect of creating a highly fragmented discipline. With a topical landscape ranging from cardiovascular processes and momentary feelings to intergroup relations and societal change, the field has become populated by myriad theoretical orientations

and research strategies that have few points of contact with each other or with other scientific disciplines. The lack of theoretical and paradigmatic coherence has generated concern from several quarters in recent years (cf. Buss, 1995; Krueger & Funder, 2004; Vallacher & Nowak, 1994a). But lamenting this state of affairs is one thing and fixing it is quite another. Is it possible to establish theoretical integration for the complexity and vagaries of human social experience? Can the fragmented field of social psychology be put back together in a coherent fashion?

At first blush, it is easy to reframe diverse social psychological processes in dynamical terms. Human experience qualifies as a complex system, in that any mental, affective, or behavioral process can be analyzed with respect to myriad genetic, hormonal, dispositional, familial, situational, and cultural causes. And because these factors interact with one another over time to promote sustained temporal trajectories of thought, feeling, and action, social psychological phenomena can be investigated as nonlinear dynamical systems. The earliest formulations of social psychological issues were remarkably prescient in this regard. Such pioneers as James (1890), Cooley (1902), Mead (1934), Lewin (1936), and Asch (1946) all emphasized the multiplicity of interacting forces operating in individual minds and in social groups, the potential for sustained patterns of change resulting from such complexity, and the tendency for individuals and groups to strive for mental and interpersonal coherence.

The dynamical perspective, in fact, may prove *too* appealing for those seeking an integrative paradigm for social psychology. Such notions as self-organization, emergence, bifurcation, and chaos have an intuitive resemblance to many personal and interpersonal phenomena. It is tempting to note the penchant for spontaneous coordination of sentiments and actions in social groups, for example, or to suggest that attitudes emerge from the self-organization of specific thoughts. Although such intuitions are compelling, the success of the dynamical perspective will depend on the ability of this approach to go beyond metaphors, intuitive similarity, and general statements to generate explicit theoretical statements and testable hypotheses. With this concern in mind, we outline an approach specifically developed to frame and test hypotheses concerning the dynamical properties of personal and interpersonal experience. To establish the integrative and predictive utility of this approach, we conclude the chapter by summarizing the basic principles (to date) of dynamical social psychology.

Dynamical Minimalism

The subject matter of social psychology is obviously very complex, and a good theory must be able to account for this complexity. In the traditional approach to theory construction, the complexity of human thought and behavior is reflected in the complexity of the model, with many variables and complex interactions among them providing the starting point for an explanation of a phenomenon. The approach of *dynamical minimalism* (Nowak, 2004), in contrast, tries to construct models in such a way that the observed complexity emerges from the simplest possible assumptions rather than being inherent in the model itself. The focus of this approach is on identifying the minimal set of realistic principles and mechanisms capable of producing the phenomenon under investigation. This perspective often assumes simple, almost trivial, assumptions at the level of individual elements yet tries to reproduce the complexity of the phenomenon at the system level. Because the resultant theories provide simple explanations that nonetheless capture the complexity of human thought and behavior, this approach aims to maximize parsimony in theory construction without trivializing the phenomenon in question.

As emphasized in this chapter, simple rules governing the interactions among individual elements can generate very complex properties at the system level. For complexity to emerge from simple rules, though, the rules must interact over time. Thus, a simple theory of a complex phenomenon is necessarily dynamic in nature. Dynamical minimalism is the approach of choice, then, when the relations among elements are nonlinear and the phenomenon displays self-organization and emergence. It is less essential for phenomena governed by linear dependencies, in which the potential for emergence is minimal. Of course, one can develop dynamical theories that do not propose emergence. Such a theory may be valid if one's interest is the nature of the dynamics per se and the theory's assumptions are verified empirically. However, many relationships in social psychology, such as threshold phenomena, inverted-U relations, and statistical interactions, reflect nonlinearity and thus have the potential for emergence if the variables are embedded in a larger system that evolves over time (cf. Vallacher & Nowak, 1997).

The minimalist approach provides a new perspective on the relation between micro- and macrolevels of description. From the perspective of reductionism, the properties at higher levels of description can be directly reduced to properties of elements at lower levels. The rules observed at one level, in other words, directly correspond to the rules observed at another level. The relation between poverty and crime on the social level, for example, may be reduced to the relation between frustration and aggression operating at the level of individuals. In dynamical models, in contrast, the rules operating at one level may generate wholly different rules at a higher level. In the *society of self* model (Nowak et al., 2000), for example, basic rules regarding the integration of basic elements of self-knowledge have many interesting but unanticipated consequences for higher-level self-representation. The model assumes simply that each basic element acquires the prevailing valence of related elements. Repeated iterations of this basic rule have been shown to generate several interesting consequences at the global level of self-representation, such as the differentiation of self-structure into local regions of contrasting valence, and global properties (e.g., self-esteem) that

are relatively immune to external influences and that can rebound after being challenged.

Building scientific theories that capitalize on emergence leads to an apparent paradox. By definition, emergence refers to principles on the system level that cannot be derived by reasoning about the knowledge of the system's elements. In a system characterized by emergence, then, how can the knowledge of lower-level elements serve as an explanation of higher-level properties? The answer highlights the crucial role played by computer simulations in the dynamical approach. Computer models enable one to specify properties of elements and the rules of interaction among them. When the elements interact according to the specified rules, dynamics may be observed at the system level that were not assumed on the level of individual elements. Indeed, a primary reason for constructing computer simulations is to identify the emergent consequences of basic rules. Computer simulations thus allow for a theory formulated under one level of psychological reality to be tested at a different level of psychological reality.

Computer simulations are essential for another reason. Many specific properties of individual elements and their interactions have only minimal effects on properties at the system level. Indeed, the basic elements themselves are typically uninteresting, even trivial in nature. What matters are some very basic properties of the elements and the patterns of interaction among the elements. Consider, for example, the emergence of public opinion modeled with cellular automata by Nowak and colleagues (1990). As noted earlier, this model characterizes each individual in terms of only three properties: his or her location on a two-dimensional grid, his or her attitude (e.g., pro vs. con) on some topic, and his or her persuasive strength. Clearly, any individual is far more complex than this. Many nuances of individual variability (e.g., idiosyncratic traits), however, have little if any impact on the dynamics of public opinion formation in a social group. So although this model hardly does justice to the complexity of individuals, it captures the essential features that are responsible for the emergence of public opinion.

The goal of dynamical minimalism is to build a model that incorporates only the variables that are critical for the emergence of macrolevel properties. In computer simulation models, one can systematically vary the assumptions concerning different properties of elements and their interactions and observe which assumptions result in important changes at the macrolevel. The characteristics that do not have consequences at the system level can be disregarded and omitted from the model. In effect, computer simulations function as a sieve that distills the minimal set of components and their interactions that constitute the essence of the phenomenon of interest.

Although computer simulations play a pivotal role in dynamical minimalism, they cannot substitute for empirical verification of a theory's assumptions. To the contrary, computer simulations are useful in delimiting the crucial assumptions of a theoretical model and thus provide a roadmap for empirical efforts. In a common scenario, computer simulations of processes assumed to operate a lower level may be used to investigate the consequences of these processes at a higher level. These consequences, in turn, may function as hypotheses to be tested in empirical research. Dynamic social impact theory (Nowak et al., 1990), for example, was used to derive predictions concerning spatial–temporal patterns of social change processes. The existence of these hypothesized patterns were then assessed in statistical data concerning patterns of entrepreneurship and voting patterns in Poland following the fall of Communism in the 1990s (Nowak et al., 2005). In addition to testing a model's assumptions, empirical tests can also be used to refine the model. The refined model, in turn, can then be implemented in computer simulations, the results of which can provide further hypotheses to be tested empirically. This reciprocal loop between theory, computer simulation, and empirical research is instrumental to the progress of scientific social psychology.

Principles of Dynamical Social Psychology

The dynamical approach serves as both a useful heuristic and an integrative platform for the diverse phenomena comprising social psychology. Both these functions are reflected in the following principles, which summarize the primary themes conveyed in this chapter.

- *Principle 1. Intrinsic dynamics are inherent in social psychological systems.* Intrinsic dynamics characterize all levels of personal and social reality, from neural function to societal processes. Intrinsic dynamics are produced by multiple influences among the elements comprising the personal or social system. External factors influence thought, feelings, and action by interacting with the system's intrinsic dynamics. In some cases, intrinsic dynamics are manifest as resistance to change and thus promote stability rather than change in behavior. The characterization of intrinsic dynamics is a central task for social psychological research.
- *Principle 2. There is a direct connection between structure and dynamics in social psychological systems.* The interdependency among the variables comprising a system is expressed in the system's pattern of temporal evolution. Nonlinear relationships among system variables, for example, are necessary for chaotic dynamics. Knowing the structure of the system thus enables prediction of the system's behavior, and conversely, knowing the system's dynamics provides insight into the structure of the system.
- *Principle 3. Attractor dynamics provide for stability while allowing for constant change in social psychological systems.* The unperturbed dynamics of personal and interpersonal systems converge on states, or patterns of change between states, that can be described as attractors. There are three basic types of attractors: fixed-point, periodic, and chaotic. Although thought, emotion, and behavior can change on a moment-to-moment basis, identifying the attractors governing their dynamics allows one to characterize psychological processes in terms of stable points or patterns on which the dynamics converge.

• *Principle 4. Latent attractors represent possible equilibrium states for a system that have yet to be manifest*. External influences that do not have an immediate effect on the state of the system may nonetheless have important consequences for the long-term dynamics of the system by creating a latent attractor. The existence of latent attractors creates the potential for rapid change in the state of a system in response to small external influences.

• *Principle 5. Change in social psychological systems can refer to changes in state or changes in attractors*. External factors that change the momentary state of the system are likely to have only a transient effect if they move the system within the basin of attraction of the system's current attractor. They have more lasting but nonetheless reversible effects if they move the system to the basin of a different attractor. Lasting and irreversible changes in a system reflect changes in the type, number, and position of the system's attractors. Such changes are achieved by changing the control parameters of the system.

• *Principle 6. Personal causation can be understood as patterns of intrinsic dynamics and constraints on the effects of external influences*. As a first approximation, personal dispositions can be couched in terms of attractor dynamics. Personal causation is reflected in the rejection of influences that would move the system out of its attractor and in the system's tendency to return to the attractor if it is perturbed. Processes of self-regulation result in the creation of attractors (or repellors) for system dynamics.

• *Principle 7. Structure and order at the system level can result from interactions among elements at a lower level in a process referred to as self-organization*. No supervision or control by a higher-order structure is necessary for this to occur. Self-organization underlies the process of emergence in social psychological phenomena at different levels of personal and social reality. Emergence can only occur in a dynamical system in which elements interact over time. Systems characterized by nonlinear relations among elements are especially likely to demonstrate emergence. The principle of self-organization provides for coherence in social psychological processes.

• *Principle 8. The approach of dynamical minimalism is essential for building and testing dynamical theories*. The goal of dynamical minimalism is the construction of the simplest possible theories of complex phenomena. Very simple elements and simple rules of interaction among elements can result in very complex properties at the system level. This can happen only if the elements interact in time. Many specific features of elements and their interactions do not have important consequences at the system level and thus can be ignored in the description of elements. Computer simulations provide the primary tool for investigating the emergent properties of social psychological systems and for determining which features of the elements must be included in a minimalist account of a phenomenon. They also provide a tool for investigating the relation between the structure and dynamics of the system. Empirical research is necessary for verification of the model. Because of the concentration on basic principles, dynamical minimalism has the potential for building models that are general across otherwise diverse phenomena in social psychology.

THE TRAJECTORY AHEAD

Theory construction in social psychology can itself be viewed in dynamical terms, with individual researchers influencing one another over time in an attempt to achieve consensus on the nature of human experience. Despite the progressive coherence that emerges over time by virtue of self-organization, complex systems rarely attain complete integration. Hence, one should not expect a discipline as diverse and multifaceted as social psychology to reach a stable equilibrium, with a single set of immutable principles capturing all the nuances of personal and interpersonal function. Complex systems are inherently dynamic, continually evolving, and undergoing transformations by virtue of their intrinsic dynamics and in response to incoming information and outside influences. At this point in time, then, the promise of theoretical coherence is simply that—an optimistic extension of a current temporal trajectory. So although we anticipate that dynamical principles and methods will emerge as the paradigmatic foundation for social psychological science, we also anticipate that the field will display repeated episodes of disassembly and reconfiguration with respect to specific theories and research strategies in the years to come. This trajectory provides ironic testament to the viability and generality of the dynamical perspective on human experience.

NOTES

1. For depictions of specific research agendas spawned by this approach, the interested reader is referred to a special issue of *Personality and Social Psychology Review* (Vallacher, Read, & Nowak, 2002) devoted to this topic.
2. See Nowak et al. (2002) for a detailed discussion of these and other properties of fixed-point attractors.
3. This scenario is exemplified by the rapid improvement in Polish–Ukrainian relations after the 2004 "orange revolution" in Ukraine (see Nowak et al., in press).
4. The dynamics of a system may be governed by the superimposition of different periods. This is referred to as *multiperiodic evolution*. Patterns of human activity, for example, vary on a daily basis (e.g., wake and sleep), on a weekly basis (e.g., weekends vs. weekdays), and on an annual basis (e.g., seasonal activities). At each moment, a person's state is determined by its position in each of these periods. His or her activity thus depends on the time of day (e.g., lunch at noon), the day of the week (e.g., Saturday), and the time of year (e.g., Spring). The most complex case of multiperiodicity is quasi-periodic evolution, in which each of the system's variables exhibit different periods and these periods are not multiples of a single basic period. The temporal dependence of a dynamical variable that displays quasiperiodic motion might be very complicated and difficult to identify, as the superimposition of waves can create very irregular and complex shapes (cf. Nowak & Lewenstein, 1994).

Inclusion and Exclusion

Implications for Group Processes

JOHN M. LEVINE
NORBERT L. KERR

Many efforts have been made to elucidate the fundamental motives underlying human emotion, thought, and behavior. Recently, Fiske (2004) identified five core social motives that enhance people's integration into groups and thereby their physical and psychological survival. One of these motives—belonging—is "first among equals" because it serves as the foundation for the remaining four (understanding, controlling, self-enhancing, and trusting). Fiske defines the motive to belong as the need for strong, stable relationships with other people (cf. Baumeister & Leary, 1995). She notes that in addition to enhancing individual survival, the motive to belong also benefits the group by increasing the likelihood that members will cooperate and engage in coordinated action.

Although belonging has been recognized as an important human motive for decades, there has been an explosion of recent theoretical and empirical work on this topic, much of it stimulated by Baumeister and Leary's (1995) influential paper. These authors argued that there is a fundamental need to belong that requires frequent positive interactions with one or more others in the context of stable, supportive relationships.

Current interest in the need to belong is high, as indicated by several recent conferences and edited volumes on inclusion/exclusion (e.g., Abrams, Hogg, & Marques, 2005b; Williams, Forgas, & von Hippel, 2005), as well as a large number of journal articles, chapters, and books focusing on this topic. Researchers from several disciplines, including psychology (social, developmental, per-

sonality), biology, ethology, and economics, are addressing the origins of the need to belong and the consequences of striving to satisfy this need. These issues include, among others, individual differences in sensitivity to rejection (Romero-Canyas & Downey, 2005); causes and consequences of familial rejection (Fitness, 2005); coping strategies for stigma-based exclusion (Major & Eccleston, 2005); prosocial and antisocial reactions to ostracism (Williams & Govan, 2005); impact of exclusion on aggression and cognitive activity (Twenge & Baumeister, 2005); bullying as a form of exclusion (Juvonen & Gross, 2005); self-regulation in coping with exclusion (Pickett & Gardner, 2005); inclusion and exclusion as means of managing group composition (Levine, Moreland, & Hausmann, 2005); consequences of marginally fitting the group's prototype (Hogg, 2005); and threat of exclusion as inducement to cooperation (Ouwerkerk, Kerr, Gallucci, & van Lange, 2005).

Although sizable, the contemporary literature on inclusion/exclusion is limited in at least two respects. One limitation concerns the tendency to favor some levels of analysis over others. Most of the work on inclusion/exclusion has involved either the intrapersonal, the interpersonal, or the intergroup level of analysis—that is, either the individual's response to inclusionary/exclusionary opportunities/threats, inclusionary/exclusionary relations between members of dyads, or inclusionary/exclusionary relations between members of different groups that are more or less hostile to one another. In contrast, the intragroup level of analysis has

been neglected, with relatively little attention given to how social processes within groups influence and are influenced by inclusion/exclusion.

The second limitation concerns the tendency to focus on one side of the inclusion/exclusion relationship (the target or the source) while neglecting the other. This is particularly true in the case of dyads. Research on dyads has sought to explain why relationship partners desire inclusion and how they respond to exclusion, with much less attention to how and why relationship partners include or exclude one another. Until recently, work on inclusion/exclusion in intergroup contexts had precisely the opposite bias. Research on intergroup relations assumed (explicitly or implicitly) that problems between groups are due to strong majorities excluding weak minorities, and hence the key to increasing intergroup harmony is identifying the origins of this exclusion and designing ways to transform it into inclusion. Not surprisingly, this perspective stimulated much more attention to the source of exclusion (the majority) than to its target (the minority). In the last few years, however, increased research has focused on how minorities cope with the exclusion they encounter (e.g., Crocker & Quinn, 2000; Major & Eccleston, 2005).

The central premise of this chapter is that inclusion/exclusion underlies a large and disparate set of small group phenomena. In the following pages, we review and extend prior analyses of inclusion/exclusion with the goal of clarifying the dynamics of small, task-oriented groups. Though both individuals and groups can—at least in certain senses—be sources as well as targets of inclusion/exclusion, we focus on the more common case in which the group is the source and the individual (member) is the target. This focus reflects the common asymmetry in power between the two parties, in which the group typically has more power to include/exclude than does the individual, and the individual typically is more sensitive to being included/excluded than is the group (Abrams, Hogg, & Marques, 2005a).

THE GROUP MEMBER AS THE TARGET OF INCLUSION/EXCLUSION

Humans strive for inclusion in small groups and, once included, seek to avoid exclusion. This assertion clearly reflects—but implies more than—the *need to belong* proposed by Baumeister and Leary (1995). They present a reasoned and persuasive argument that the need to belong is a fundamental human need. But they also suggest that this need is not simply for any kind of positive bond with others (like the positive unit relations of balance theory) but, rather, requires interpersonal bonds of both high quantity and high quality. That is, infrequent contacts or casual associations with others are not sufficient. There are indications that, for most of us, the need to belong can largely be satisfied through a few intimate personal relationships (Baumeister & Leary, 1995, pp. 513–515). However, this need can also be satisfied in other contexts. In particular, membership or inclusion in small

groups often provides interpersonal contacts that are both frequent and close enough (e.g., as in families) to satisfy the need to belong (Hornsey & Jetten, 2004). Interestingly, however, people also routinely worry about their inclusion/exclusion in groups that provide only infrequent contact (e.g., a high school graduating class) or relatively weak interpersonal bonds (e.g., an informal discussion group). In this chapter, our analysis of the individual's drive to obtain group inclusion (and avoid group exclusion) will thus incorporate both the need to belong, as defined by Baumeister and Leary, and other (perhaps less urgent) motivations to maintain group memberships.

Roots of the Drive for Group Inclusion

Why is being and remaining a group member so important to us? There are three general answers to this question, which should be viewed as complementary rather than mutually exclusive.

The Drive for Group Inclusion as a Residue of Evolution

It has become not only acceptable but fashionable in social psychology to suggest that patterns of human social behavior are, at least to some degree, the results of long-term evolutionary processes (Buss & Kenrick, 1998; Caporael, 2001; Neuberg, Smith, & Asher, 2000). In that vein, a number of scholars (e.g., Barchas, 1986; Baumeister & Leary, 1995; Caporael & Baron, 1997; Kurzban & Leary, 2001) have suggested that propensities to seek, maintain, and value group memberships have been strongly selected for during human evolution. The evidence for such claims—as for many assertions of evolutionary psychology—is by no means conclusive, but these claims remain intriguing nonetheless. Several arguments can be made for the role of evolution in the drive for group inclusion.

One argument stresses the likely adaptive value of group memberships for our early ancestors. A number of essential reproductive tasks (e.g., finding mates, caring for young) and survival tasks (e.g., hunting, defense, winning and holding territories) can be pursued more effectively by groups than by individuals, so it makes sense that a strong tendency to join and remain in groups was selected for during evolution. Other arguments are based on anthropological and comparative evidence. For example, there are no fossil records suggesting that *homo sapiens* ever lived other than in groups (Caporael, Dawes, Orbell, & Van de Kragt, 1989). Moreover, the fact that our closest hominid relatives (e.g., gorillas and chimpanzees) live in groups suggests that this preference for collective social organization may have predated the beginnings of our species. The apparent universality of collective social organization in modern (as well as primitive) human societies is likewise consistent with an innate drive to affiliate. Finally, there is evidence linking biological mechanisms to social affiliation and disaffiliation (e.g., opioid production and social bonding, Panksepp, Siviy, & Normansell, 1985; pain center activation in the brain following social ostracism, Eisenberger,

Lieberman, & Williams, 2003; MacDonald & Leary, 2005; see also Dickerson & Kemeny, 2004).

An interesting, although indirect, argument involves the relationship between the evolution of sociality (the tendency for members of a species to live, work, and associate with one another) and the existence and regulation of group boundaries. A long-standing puzzle for those interested in explaining human cooperation is how sociality evolved when so many environments have the structure of *social dilemmas* (cf. Orbell & Dawes, 1981), in which pursuing immediate self-interest and survival (e.g., not sharing one's catch with others, taking more than one's share of a dwindling resource) is inimical to collective survival (e.g., keeping the whole clan fed, stretching scarce resources as long as possible). A number of theoretical models (e.g., Boyd, Gintis, Bowles, & Richerson, 2003; Boyd & Richerson, 1992; Hayashi & Yamagishi, 1998; Kameda, Takezawa, & Hastie, 2003) suggest that the evolution of cooperative behavior is facilitated by creating and maintaining group boundaries and tying cooperative behavior to group membership. For example, a strategy that involves sticking with partners who cooperated in the past but abandoning partners who failed to cooperate does better than many alternative strategies in a selective-play environment, where individuals can choose with whom to affiliate (de Vos & Zeggelink, 1997; Yamagishi, Hayashi, & Jin, 1994). It has also been suggested that intragroup cooperation emerges more readily through group selection processes (1) when there are competing groups in the environment than when there are not (Boyd et al., 2003) and (2) when group members recognize and punish those who act uncooperatively than when they do not (Boyd et al., 2003; Kameda et al., 2003; Price, Cosmides, & Tooby, 2002). The ample evidence that humans are often cooperative (e.g., Dawes, Van de Kragt, & Orbell, 1990; Marwell & Ames, 1979; Van Vugt & Van Lange, 2006) supports (at least indirectly) the arguments that the collective value of cooperative behavior created selective pressures for humans to seek group membership, to maintain group boundaries, to value the welfare of fellow group members, to feel obligated to reciprocate cooperation, to be attentive to those who fail to cooperate, and to be highly punitive toward such defectors. As this analysis suggests, group membership has costs as well as rewards, and the need for inclusion thus stems, at least in part, from the competitive demands of group life.

The Drive for Group Inclusion as a Residue of Early Experience

The role of evolution in the drive for inclusion was also posited by Bowlby (1969), who argued for the existence of an evolutionarily adaptive attachment system that keeps infants and their caregivers in close proximity to one another. According to Bowlby, early attachment experiences are important because they affect children's perceptions of themselves (as worthy or unworthy) and others (as dependable or undependable), which in turn influence how they think, feel, and act toward others.

In recent years, increasing attention has been given to adult attachment in the context of romantic relationships and groups (Mikulincer & Shaver, in press). For example, Hazan and Shaver (1987) identified three adult attachment styles (secure, anxious–ambivalent, and avoidant) that predict people's thoughts, feelings, and behaviors in romantic relationships (Simpson & Rholes, 1998). Moreover, Smith, Murphy, and Coats (1999) used adult attachment theory to explain people's psychological ties to groups. Arguing that attachment to groups, like attachment to caregivers, has a strong evolutionary basis, Smith and his colleagues developed a questionnaire measure of group attachment with a two-dimensional structure: (1) Attachment Anxiety (how much a person fears group rejection) and (2) Avoidance (how much a person wants and values group closeness). They then demonstrated that this measure predicted several important group outcomes, including group-relevant emotions, perceived social support, and plans to leave.

Regardless of the utility of attachment theory as an explanation for the impact of early experience on reaction to later inclusion/exclusion, it is clear that social isolation and parental neglect are aversive and potentially lethal to children (cf. Bowlby, 1980; Harlow, Harlow, & Suomi, 1971). If the presence/absence of nurturant social contact is powerfully rewarding/punishing to children, then any stimuli consistently associated with such contact should acquire secondary reinforcing properties. Such conditioning could create strong connections between narrow but powerful needs for social attachment in early life and a variety of common social stimuli or situations. For example, if a parent were to withdraw attention and nurturance whenever a child was disobedient, then the act (or even the prospect) of disobedience might well acquire aversive properties, which in turn would lead to anxiety and to actions designed to reduce (or avoid) this unpleasant state (Baumeister & Tice, 1990). Through secondary conditioning processes, the act (or prospect) of disobedience in group settings may elicit very similar reactions. Recent research (Abrams, de Moura, Frings, & Rutland, 2005) nicely documents developmental trends in awareness of such relevant social stimuli and situations (e.g., social norms).

The Drive for Group Inclusion as a "Rational" Choice

The forgoing discussion suggests that the drive for group inclusion is based on primitive (unconscious) mechanisms, such as evolution or conditioning. However, inclusion can be important to group members for another reason as well, namely, because of a calculated decision that it facilitates their ability to achieve specific individual goals. Any number of such goals can only be achieved in group settings (e.g., winning a basketball championship, getting a team leadership award). Clearly, the more a person values such goals, the more he or she would want to obtain and maintain group membership.

One ubiquitous individual goal is obtaining social status or approval, and group inclusion is a clear indicator that one enjoys the esteem of fellow group members. Moreover, when standards of social evaluation link high

status to particular or multiple group affiliations (e.g., belonging to a particular fraternity or sorority; belonging to a large number of campus groups), such memberships can elicit esteem from those outside as well as inside the group. Consistent with this idea, Leary and Baumeister (2000) have argued in their *sociometer theory* that an individual's level of self-esteem is a subjective monitor of how much he or she is socially valued. From this perspective, the more functional group memberships are for obtaining positive social evaluations, the more important group inclusion/exclusion should be for self-regard.

Another perspective on the relationship between group membership and self-esteem involves the self-enhancement function of social comparison (e.g., Goethals & Darley, 1977; Tesser, 1988; Wills, 1991). The fundamental idea here is that the valence and intensity of people's feelings about themselves are affected by how they compare to others on valued dimensions. Although much of this work has focused on the affective consequences of interpersonal comparisons in dyadic settings, other work has dealt with self–other comparisons in group settings or with ingroup–outgroup comparisons (e.g., Levine & Moreland, 1987; Luhtanen & Crocker, 1991). This latter type of comparison has been emphasized by social identity theorists (e.g., Tajfel & Turner, 1986), who argue that people have high self-esteem to the extent that their ingroup is superior to outgroups on valued dimensions (see Abrams & Hogg, 2001). To exploit this potential source of self-esteem, people should seek to establish and maintain memberships in only certain groups, namely, those that are obviously "superior" to other groups. Absent the option for such memberships, people should try to produce ingroup superiority in other ways, such as encouraging intergroup competition that the ingroup is likely to win, perceiving the ingroup as superior to the outgroup on new dimensions, and so on (Jackson, Sullivan, Harnish, & Hodge, 1996; Tajfel & Turner, 1986).

Rather than focusing on the goal of self-enhancement, the original formulation of social comparison theory (Festinger, 1950, 1954) emphasized the goal of self-evaluation. According to Festinger, people want an accurate appraisal of their abilities and opinions, which, in the absence of objective standards, can only be obtained through social comparison (cf. Laughlin & Ellis, 1986). The general notion that people use information obtained from others to validate their perception of reality is widely held in social psychology (see Hardin & Higgins, 1996; Levine & Higgins, 2001; Tindale, Meisenhelder, Dykema-Engblade, & Hogg, 2001). A recent example of this emphasis is the *subjective uncertainty reduction hypothesis*, which posits that people self-categorize as group members in order to reduce uncertainty about the social world and their place in it (Hogg, 2000; Hogg & Abrams, 1993). The goal of reducing uncertainty, or gaining understanding (Fiske, 2004), is thus a powerful individual motive that, in most cases, can only be satisfied through group membership. For this reason, uncertainty reduction, like self-esteem, can be a "rational" reason for seeking group inclusion.

The Detection System for Inclusion/Exclusion

Our discussion so far has focused on why people seek inclusion (and avoid exclusion) in groups. We now turn to the question of how they behave to achieve these goals. Although much of our analysis is informed by Baumeister and Leary's (1995) treatment of the *need to belong* within high contact, caring relationships, our analysis also applies to other motives for group inclusion, such as "rational" efforts to attain individual goals.

According to Baumeister and Leary, the need to belong has several basic features. First, the need involves avoiding exclusion as well as seeking inclusion (although MacDonald & Kingsbury, 2006, have recently suggested that these might be independent motives). Second, one's level of success in fulfilling the need elicits strong emotional and cognitive responses (e.g., positive emotions to satisfaction and negative emotions to frustration). Third, need satisfaction is characterized by both satiation (i.e., satisfaction of the need diminishes motivation for additional relationships) and substitution (i.e., one relationship can replace another). Finally, the need energizes and directs behavior—one plans and acts to fulfill the need.

Leary and Baumeister (2000) suggest that the power of the need to belong has led to the development of an internal system—the *sociometer*–for monitoring satisfaction of this need. Three of the proposed properties of that system are crucial to our current analysis. First, humans are highly sensitive to information about their level of acceptance/rejection by others. Second, people are more sensitive to decrements than to increments of belongingness. "Granted, we feel good when we think we are valued or loved, but most people seem to feel far worse after learning that they are devalued or hated" (Leary & Baumeister, 2000, p. 41) This asymmetry in sensitivity to negative versus positive information appears to be a general phenomenon, with several possible origins (e.g., the survival value of avoiding danger, the relative novelty and diagnosticity of negative events; Baumeister, Bratslavsky, Finkenauer, & Vohs, 2001). Third, this monitoring system operates automatically (i.e., continuously, involuntarily, and unconsciously). Several recent findings by Williams and his colleagues support these claims (see Williams, 2007). They have shown that quite rudimentary cues of ostracism (e.g., being excluded in a ball toss game) activate the same regions in the brain that are activated for another primitive and automatic monitoring system, namely, physical pain (Eisenberger & Lieberman, 2005; Eisenberger et al., 2003). In addition, they have demonstrated that initial aversive reactions to cues of ostracism are not mediated by ostensibly relevant situational or personality factors (Williams & Zadro, 2005). For example, participants were just as upset by ostracism from members of a disliked group (viz. members of the Ku Klux Klan) as from a control group of liked ingroup members (Gonsalkorale & Williams, in press).

It is important to note that this monitoring system is not only sensitive to current signs of group exclusion but also to settings or behaviors associated with past in-

stances of exclusion. The confederates in Asch's (1956) classic conformity studies did not say or do anything overt to suggest that a deviant (but correct) response would result in exclusion. Nevertheless, participants reported that expressing disagreement with these confederates was uncomfortable—for many, sufficiently uncomfortable to prompt conformity. Thus, rather than being simply reactive, the individual's detection system is also proactive, seeking to identify and avoid settings or behaviors that are "dangerous" because of their association with past exclusion.

Responses to Threats of Exclusion

Assuming that (for whatever reason) an individual perceives that he or she is vulnerable to group exclusion, how might the person react to this threat? Unfortunately, there is no simple answer to this question. Some studies report reflexive behaviors, such as hostile and antisocial reactions to exclusion (see Twenge & Baumeister, 2005). Other studies report more planful behaviors, including acts of "behavioral supplication," such as prosocial behavior, greater effort at group tasks, and higher conformity (see Williams & Govan, 2005).

The latter category of responses is relatively easy to explain. If one's standing in a group is threatened, a rational actor would be expected to choose a course of action that is likely to reduce the threat. A major strategy for doing so is changing the self, for example, by altering the behavior that gave rise to the threat. In addition, an actor might try to change the group (e.g., by persuading members that one's actions are benign or even functional) or leave the group (e.g., by joining another group that is more likely to value one's contributions) (cf. Festinger, 1950). Which of these strategies one uses depends, of course, on a number of factors, including their availability in the situation, their perceived efficacy, one's habitual coping responses, and the attractiveness of alternative group memberships.

The former category of responses, hostility and antisocial behavior, is harder to explain, because it runs the risk of eliciting even more exclusion from the group. Hostile and antisocial responses to the threat of exclusion have been explained in several ways. Williams and Govan (2005), for example, suggest that the threat of exclusion endangers not only the need to belong but other fundamental needs as well (viz., the need to maintain positive self-esteem, the need for control, the existential need for a meaningful existence). From this perspective, behavior that is dysfunctional for reestablishing belongingness (e.g., aggressing against excluders) might well be functional for satisfying other needs (e.g., enhancing one's sense of control). An alternative explanation has been offered by Baumeister and DeWall (2005), who suggest that exclusionary acts or signals void an implicit social contract stipulating that the group will meet one's belongingness needs as long as one regulates one's behavior to satisfy group standards. If one receives feedback from the group suggesting that one's best efforts at self-regulation are not working, one may lose the motiva-

tion to self-regulate and instead act in an impulsive manner. It is also possible, of course, for hostile and antisocial behaviors to be used in a conscious and instrumental fashion to signal that the group may pay a price if it persists in acts of exclusion.

In an effort to explain both "positive" and "negative" responses to threats of exclusion, MacDonald, Kingsbury, and Shaw (2005) offer the interesting argument that responses to threats of exclusion derive from and mimic primitive responses to threats of physical pain (e.g., Gray & McNaughton, 2000). When a physical threat is not immediate and severe, the usual reaction is *fearful avoidance*, which involves attempts at supplication tinged with cautious, defensive distancing. However, when the threat is immediate and severe, *panic* ensues, which in turn prompts one of three basic survival responses—fight (e.g., aggression, verbal insult), flight (e.g., withdrawal, leaving the group), or freezing (lethargic unresponsiveness; cf. Twenge, Catanese, & Baumeister, 2003).

The ideas of MacDonald and colleagues (2005) and Williams and Govan (2005) suggest that when the threat of exclusion is mild and remote and the individual has both the motivation and ability to assess his or her behavioral options, responses to threat will be thoughtful attempts to avoid or reduce exclusion. In contrast, when the threat of exclusion is severe and immediate, impulsive, panic-like reactions may occur, some of which may involve hostility and antisocial behavior. Such reactions may also occur with relatively mild and remote threats, if the individual lacks the motivation and/or ability to engage in a thoughtful analysis of his or her options.

Threat of Exclusion and Group Processes

To this point, we have argued that individuals are acutely sensitive to inclusion and exclusion in group settings. In so doing, we have discussed the factors that cause individuals to desire group inclusion, the system that individuals use to detect inclusion/exclusion, and the responses that individuals make to threats of exclusion. In the following sections, we use the notion of inclusion/exclusion to analyze three important group topics—conformity, group decision making and problem solving, and behavior in mixed-motive settings.

Conformity: The Role of Normative Influence

That individuals desire inclusion and fear exclusion in group settings is consistent with a substantial amount of theoretical and empirical work on majority influence, or conformity. This phenomenon is typically studied by leading a lone participant to believe that several people unanimously disagree with his or her position on a factual or opinion issue and then assessing the extent to which the participant shifts toward the majority position. It has long been argued that conformity derives from two general motives—the desire to reduce uncertainty and the desire to be accepted (Deutsch & Gerard, 1955; Jones & Gerard, 1967; Kelley, 1952; Thibaut & Strickland, 1956). The best-known analysis of these motives was of-

fered by Deutsch and Gerard (1955), who defined informational influence as "influence to accept information obtained from another as *evidence* about reality" and normative influence as "influence to conform with the positive expectations of another" (p. 629). Informational influence is based on the desire to hold accurate beliefs or opinions, coupled with the majority's real or presumed ability to provide valid information. Normative influence is based on the desire to gain or maintain social approval, coupled with the assumption that the majority will respond more favorably to conformity than to deviance. Thus, desire for inclusion and fear of exclusion is a fundamental feature of normative influence.[1]

Consistent with the idea that individuals anticipate negative responses for deviance, evidence indicates that opposition from a majority on a judgment task is a stressful experience and that conformity can reduce this stress (Back & Bogdonoff, 1964; Costell & Leiderman, 1968; Gerard, 1961). In addition, a powerful mechanism for reducing conformity, namely, the presence of a social supporter who agrees with one's position, has been shown to reduce anxiety (Allen & Levine, 1968; Asch, 1952). These data, however, do not provide unequivocal evidence that anxiety in group pressure situations is based on fear of punishment for deviance. This anxiety may be attributable, at least in part, to participants' concern about the validity of their position—a concern that underlies informational (rather than normative) influence.

More convincing evidence is provided by research indicating that people who dissent from group consensus both expect to receive and actually do receive more negative evaluations from other members than do people who conform. Regarding anticipation of punishment, Gerard and Rotter (1961) found that 76% of participants who conformed very little or not at all on a line-judgment task expected negative group evaluation, whereas 71% of participants who conformed a great deal expected positive evaluation (see Jones & Gerard, 1967). Regarding actual receipt of punishment, many studies (reviewed below) demonstrate that people who dissent from group consensus are indeed disliked by other members (Levine, 1989; Marques, Abrams, Paez, & Hogg, 2001). And, after one has been rejected or ostracized by the group, subsequent conformity to the group has been shown to increase (Williams, Cheung, & Choi, 2000).

There is also reason to believe that the effectiveness of social support for attenuating the power of the majority is based, at least in part, on an ally's ability to reduce fear of majority retaliation for deviance. For example, Allen (1975) reported an unpublished study showing that 69% of participants who deviated alone from a group expected to be rejected, whereas only 30% of those who had social support held this expectation. Social support may decrease fear of majority retaliation for several reasons. First, even superficial and transitory relationships with supporters may produce feelings of "inclusion" that innoculate participants against the threat of majority retaliation. Second, participants may believe that their partners will siphon off at least some of the hostility that would otherwise be directed toward them alone. Finally, participants may believe that if they have a partner, the

majority will be more likely to attribute their nonconformity to the validity of their position than to a personal idiosyncrasy, which in turn will reduce the majority's anger at such behavior. Consistent with a normative explanation of social support, evidence indicates that supporters who are disliked by the majority are relatively ineffective in reducing conformity (at least on certain kinds of issues), presumably because they may increase, rather than decrease, the punishment directed toward participants (Boyanowsky & Allen, 1973). Moreover, supporters whose presence is unknown to the majority (and hence give the impression that participants are isolated) have little impact on conformity (Allen, 1975).

To the extent that fear of group punishment underlies conformity, we would expect conformity to be higher under some conditions than others. For example, conformity should be higher when group members are working for a common goal than for individual goals. This is because people in common goal (interdependent) groups should fear that deviance on their part will be seen as a threat to group goal attainment and hence will be severely punished, whereas people in individual goal (noninterdependent) groups should not have these expectations. Consistent with this reasoning, conformity is generally higher in interdependent than in noninterdependent groups (e.g., Deutsch & Gerard, 1955). As might be expected, people in interdependent groups are less likely to conform if their behavior reduces, rather than enhances, the group's probability of success (Sakurai, 1975).

Another factor that should increase normative influence is surveillance by other group members. Because others can only deliver rewards and punishments contingent upon one's behavior if they can somehow monitor this behavior, people ought to be more concerned about others' reactions (and more likely to show normative influence) when their behavior is public rather than private. Consistent with this reasoning, people conform more when their responses are known to other group members than when they are not (e.g., Asch, 1956; Deutsch & Gerard, 1955; Insko, Drenan, Solomon, Smith, & Wade, 1983).

Group attractiveness is also likely to affect normative influence, because both acceptance and rejection should be more potent reinforcers when one cares about the group than when one does not. Although some studies indicate that people conform more to attractive than to unattractive groups (e.g., Festinger, Gerard, Hymovitch, Kelley, & Raven, 1952; Lott & Lott, 1961), this finding is not always obtained (see Allen, 1965; Turner, 1991). Jones and Gerard (1967) argued that the impact of group attractiveness on conformity may depend on such factors as the individual's level of acceptance (i.e., status) in the group, the likelihood that conformity will be instrumental in increasing or maintaining acceptance, and the individual's alternatives outside the group (cf. Dittes & Kelley, 1956; Harvey & Consalvi, 1960; Hollander, 1958). Although the interactive effects of these variables have not been adequately tested, there is suggestive evidence that people conform to an attractive group primarily when they feel insecure about being accepted by the

group and believe that conformity will increase their acceptance (Walker & Heyns, 1962).

In discussing the role of normative influence in conformity, it is important to distinguish between public compliance (overt behavioral change toward the majority's position) and private acceptance (covert attitudinal change toward the majority's position). Although Deutsch and Gerard (1955) did not discuss the relationship between normative/informational influence and compliance/acceptance, subsequent authors have generally assumed that normative influence produces compliance but not acceptance, whereas informational influence produces both compliance and acceptance (e.g., Allen, 1965; Wood, 1999). This assumption is consistent with models of social influence in dyadic relationships proposed by Kelman (1958, 1961) and Raven and his colleagues (e.g., French & Raven, 1959; Raven & Kruglanski, 1970). For example, Raven posited six types of unilateral social influence—reward, coercive, expert, referent, legitimate, and informational. His reward and coercive power (which produce public but not private conformity and require surveillance by the influence source) closely parallel Deutsch and Gerard's normative influence. His informational power (which produces both public and private conformity and requires neither surveillance nor any particular perception of the influence source) closely parallels Deutsch and Gerard's informational influence. Raven's remaining three types of power are less clear-cut in this regard, although legitimate power has normative connotations, whereas expert and referent power have informational ones (cf. Eagly & Chaiken, 1993).

The relationship between normative/informational influence and compliance/acceptance is complicated by several factors. First, although the conceptual distinction between public compliance and private acceptance seems straightforward, methodological problems arise in operationally defining these two types of influence (Allen, 1965). For example, it is often assumed that a person who publicly agreed with a majority at time 1 but privately disagreed at time 2 was showing only compliance at time 1. However, it is possible that acceptance did in fact occur at time 1 but then dissipated, perhaps because of forgetting old information or receiving new information. In contrast, it is often assumed that a person who agreed with a majority at both time 1 and time 2 was showing acceptance as well as compliance at time 1. However, it is possible that the person was only complying at time 1 and subsequently came to believe what he or she said as a function of dissonance reduction or self-perception. Second, the binary distinction between compliance and acceptance greatly oversimplifies how individuals can respond to majority pressure (e.g., Allen, 1965; Nail, 1986; Willis, 1965). Nail (1986), for example, identified eight types of potential influence, based on crossing initial agreement–disagreement, final public congruence–noncongruence, and final private agreement–disagreement. Third, and most important, there are reasons to question the assumption that normative and informational influence produce qualitatively different types of conformity. As Chaiken, Wood, and

Eagly (1996) argued, "social influence theories need to de-couple the motives inducing change from the processes through which change occurs and from the kinds of influence outcomes obtained" (p. 724).

One challenge to traditional notions of normative/informational influence and compliance/acceptance was offered by self-categorization theorists (e.g., Abrams & Hogg, 1990; Turner, 1991; Turner & Oakes, 1989). In brief, they argue that social influence only occurs if a target person perceives that a member of the ingroup disagrees with his or her position and if the source's position represents (is prototypical of) the ingroup norm. This perspective differs from traditional analyses of social influence in several ways, for example, by suggesting that group formation is necessary for influence to occur and that subjective uncertainty is not based on stimulus ambiguity per se but, rather, on the unexpected disagreement with similar others. Most important for our purposes, self-categorization theory denies the distinction between normative and informational influence. Instead, this distinction "is replaced by the idea that the basic influence process is one where the normative position of people categorized as similar to self tends to be subjectively accepted as valid. The validity of information is (psychologically) established by ingroup norms" (Turner, 1991, p. 171). An implication of the self-categorization perspective is that the distinctions between public and private responding and between compliance and acceptance are less relevant for ingroup than for outgroup influence (cf. Abrams & Hogg, 1990).

This effort to merge informational and normative influence, while interesting, is not entirely convincing from our point of view. One reason is that the analysis does not apply to outgroup influence, in which the target and source belong to different groups. This point was acknowledged by Turner and Oakes (1989) in their discussion of the difference between "influence" and "compliance." They noted that, whereas ingroups produce influence, "outgroups produce compliance, i.e., it is people with whom one does not expect to agree, whom one cannot be influenced by, that must resort to coercion, force and power to change behavior (p. 254) (see also Mugny & Perez, 1991). In addition, the self-categorization analysis fails to acknowledge the possibility that, at least under certain conditions, ingroups use normative influence techniques (e.g., threats of sanction) to shape members' behavior. Based on our earlier discussion of factors that stimulate desire for inclusion and fear of exclusion, such techniques are likely to be particularly effective when employed by ingroups. Thus, although self-categorization theorists are correct that informational and normative influence are sometimes intertwined, we believe that maintaining the conceptual distinction between them is worthwhile.

Traditional conceptualizations of normative/informational influence and compliance/acceptance have also been questioned by Wood (1999). Regarding normative influence, Wood argued that outcomes provided by others can prompt *either* public change that is limited to situations involving surveillance by the source *or* private change that endures in the absence of surveillance. The

former type of influence, which occurs when outcomes that others provide are not highly important, involves limited cognitive processing of relevant information and transitory attitude change. The latter form of influence, which occurs when such outcomes are important, involves substantial processing and enduring attitude change. Because this relationship between level of processing and public/private change also obtains when other goals are salient (e.g., desire to hold a valid position), Wood concluded that "the distinction between public and private agreement is not a reliable indicator of the motives underlying participants' responses in social influence research" (p. 563).[2] Nevertheless, Wood argued for maintaining the distinction between normative and informational goals, because people in everyday settings behave differently when motivated by groups to obtain acceptance and to hold a valid position (see also Chaiken et al., 1996).[3]

Finally, it is worth considering the possibility that the desire for accuracy, which is assumed to underlie informational influence and plays an important role in many other phenomena (Hardin & Higgins, 1996; Levine & Higgins, 2001), may be a secondary motive that derives from the desire for acceptance. In other words, the motive to hold accurate views on factual and opinion issues, while very real, may be important precisely because it facilitates an individual's ability to adapt to group life and thereby attain inclusion and avoid exclusion. This perspective is consistent with evolutionary analyses of individual motivation for inclusion discussed earlier, which emphasize the critical importance of group membership for individual survival. To gain group acceptance and avoid rejection, an individual must behave in ways that other members see as instrumental to attaining collective goals. One such behavior is holding "accurate" views on issues of importance to the group—in most cases, views that agree with group consensus. Failure to hold such views elicits strong reactions from other members, including pressure to conform, negative evaluations, and various kinds of punishment (Festinger, 1950; Hogg, 2005; Levine, 1989). Given this reward structure, the desire to hold accurate (i.e., consensual) positions has adaptive *social* consequences for individuals (cf. Brewer, 2004).

In concluding this section, we do not wish to leave the impression that fear of group sanctions for deviance invariably leads to conformity. One exception, noted earlier, occurs when the presence of a social supporter reduces anxiety about punishment. In addition, fear of group sanctions can produce responses other than conformity. These include leaving the group, remaining in it but redefining one's group-relevant identity (e.g., by emphasizing simultaneous memberships in other highly valued groups), or engaging in collective action designed to protect oneself or alter the group via minority influence (Hart & Van Vugt, 2006; Hogg, 2005; Levine & Kaarbo, 2001; Sani & Reicher, 1998). While these strategies are often difficult to implement, for example, because of low intergroup permeability in the case of exit (Ellemers, 1993) or majority resistance in the case of minority influence (Wood, Lundgren, Ouellette, Busceme, &

Blackstone, 1994), they are nonetheless used. Finally, people are sometimes insulated from fear of group sanctions by other powerful motives, such as the desire to establish personal distinctiveness (Brewer, 1991; Hornsey & Jetten, 2004; Lemaine, 1974). Interestingly, this desire may be based, at least in part, on the assumption that the courage one shows by defying the group in the short run will elicit its approval in the long run.

Group Decision Making and Problem Solving

The preceding section focused on the reactions of an attitudinal or behavioral minority to the actions or mere existence of a corresponding majority. In this section, our focus shifts to group contexts in which there is genuine interaction between group members in the pursuit of some common goal (e.g., reaching a decision, solving a problem).

One clear implication of our analysis of inclusion/exclusion is that there should be a *strength-in-numbers* (i.e., majority influence) effect in such contexts (cf. Hastie & Kameda, 2005). As we noted earlier, small (minority) factions are more susceptible to threats of exclusion by large (majority) factions than vice versa. Hence, all else being equal, decision alternatives or problem solutions that enjoy high member support at the beginning of group interaction should have a disproportionately high likelihood of being adopted by the group during interaction. And, indeed, a substantial literature—much of it employing Davis's (1973) *social decision scheme* model—has documented that majority (or even plurality, cf. Kerr, 1992) factions are very likely to prevail in decision-making groups (for reviews, see Baron & Kerr, 2003; Stasser, 1999; Stasser, Kerr, & Davis, 1989). For example, in juries, one can accurately predict final verdicts most of the time from simply knowing the predeliberation preferences of group members (e.g., Kalven & Zeisel, 1966; Kerr, 1981).

But can such reliable strength-in-numbers effects be confidently attributed to normative pressure based on minority members' fear of exclusion for deviance? Clearly, other interpretations are possible. The most common (and plausible) alternative interpretation is that majorities exert informational influence (Burnstein, 1982; Stasser et al., 1989). This could occur because larger factions can muster a greater number of novel arguments for their position (Burnstein & Vinokur, 1977), can appropriate more "airtime" and thereby dominate group discussion (e.g., Hawkins, 1962), and/or can profit from a consensus heuristic, which presumes that majority positions are likely to be correct (e.g., Darke et al., 1998).

Although informational influence can certainly play a role in the strength-in-numbers effect (Stasser et al., 1989), several lines of evidence suggest that it is not the only, or even the primary, determinant of this phenomenon. It has been found, for example, that majorities actually use less than their proportional share of airtime (e.g., Hawkins, 1962) but nonetheless exert more than their proportional impact on group decisions. Stated differently, the relative size of majority factions "overpredicts"

majority members' speaking time and "underpredicts" their ability to exert influence (Stasser et al., 1989). In addition, at least on issues involving continuous response dimensions, positions that are relatively distant from other group members' positions (i.e., more deviant) are less influential (Davis, 1996).

Support for a normative (as opposed to informational) interpretation of the strength-in-numbers effect can also be gleaned from reports of people who held minority positions in decision-making groups. For example, work on "groupthink" (Janis, 1982) has shown that people who find themselves in a minority position often go along with the majority because of fear of sanctions for deviance. In describing the unsuccessful 1961 Bay of Pigs operation, Janis (1982) noted, "The sense of group unity concerning the advisability of going ahead with the CIA's invasion plan appears to have been based on superficial appearances of complete concurrence, achieved at the cost of self-censorship of misgivings by several of the members" (p. 39). In explaining his failure to dissent from administration policy during this period, Arthur Schlesinger (1965) said, "In the months after the Bay of Pigs I bitterly reproached myself for having kept so silent during those crucial discussions in the Cabinet Room, though my feelings of guilt were tempered by the knowledge that a course of objection would have accomplished little save to gain me a name as a nuisance" (p. 255). Additional anecdotal support for the pressures that deviates feel is provided by memoirs of jurors who took minority positions (e.g., Burnett, 2002; Thornton, Menendez, Wrightsman, Posey, & Scheflin, 1995; Timothy, 1975). In addition to lamenting the fatigue associated with long deliberations and the difficulties of developing counterarguments, holdout jurors complain about the implicit and explicit exclusionary messages they received in retaliation for blocking group unanimity.

Further evidence against an informational interpretation of majority influence is that features of group tasks moderate the impact of majorities in just the manner one would expect if that impact were based on normative influence (cf. Kerr, 2001). As Festinger (1950) noted (see also Laughlin, 1980; Laughlin & Ellis, 1986), for some judgments there exist nonsocial criteria for validation, which place such judgments in the realm of *physical reality*. Thus, deciding whether San Diego is the most populous city in California can be determined through objective ("physical") means, such as consulting census records. But other judgments (e.g., deciding whether San Diego is the most beautiful city in California) cannot be made using consensually accepted objective criteria, because such criteria do not exist. Instead, these kinds of judgments must be made on the basis of social consensus (i.e., what other people believe about the beauty of cities in general and San Diego in particular). It is precisely these kinds of judgments, which involve *social reality*, for which minority positions are most difficult to defend in the face of majority opposition, because the minority cannot appeal to objective criteria to bolster its position. Minorities holding deviant positions on issues of social (as opposed to physical) reality should therefore feel particularly vulnerable to exclusionary sanctions if they dis-

sent from majority opinion. If so, majorities should exert greater influence on issues of social than physical reality (i.e., on judgmental than on intellective tasks), and indeed they do (Laughlin, 1999; Laughlin & Ellis, 1986; see also Crano & Hannula-Bral, 1994; Wood et al., 1994).[4]

There is also reason to believe that majority influence on judgmental issues has normative (as opposed to informational) underpinnings. In a group decision-making study investigating the bases of social influence, Kaplan and Miller (1987) found that, whereas content analyses of discussions of an intellective issue showed evidence of more informational than normative influence, parallel analyses of discussions of a judgmental issue showed just the opposite pattern, namely, more normative than informational influence. This difference was stronger in groups using a unanimity than a majority decision rule, perhaps because it was harder to reach consensus in the former case and hence groups relied more heavily on their "default" influence mode. Kaplan and his colleagues have also identified other factors that increase the likelihood that normative (as opposed to informational) messages will be used in decision-making groups and will prove effective (for reviews, see Kaplan, 1989; Kaplan & Wilke, 2001). Two of the most important of these are the group's dominant goal and the personal orientation of its members. In general, normative messages are more prevalent and more influential when the group is motivated to achieve positive socioemotional relations (as opposed to high-quality decisions) and when members are oriented toward group harmony (as opposed to task performance).

It is also the case that group decision-making procedures that force members to take sides early and publicly (e.g., by asking for a show of hands before beginning discussion) alter the style of group deliberation from a rational exchange and weighing of information (evidence-driven deliberation) to a confrontation between antagonistic factions (verdict-driven deliberation) (Hastie, Penrod, & Pennington, 1983; Kerr & MacCoun, 1985). Likewise, all else being equal, groups are less likely to rely on informational argumentation (and more likely to rely on normative argumentation) when a clear majority position exists than when it does not (Parks & Nelson, 1999).

Of course, majorities do not always prevail in decision-making contexts, and the conditions under which they fail are revealing. On intellective tasks (e.g., simple arithmetic problems, semantic associations), one-person minorities holding positions that are deviant but clearly "correct" within the group's shared conceptual system do more than resist majority influence—they typically convince the majority to adopt their position (a *truth-wins* social decision scheme) (Laughlin & Ellis, 1986; Laughlin, Kerr, Davis, Halff, & Marciniak, 1975). One interpretation of this effect is that the minority member's strong conviction about the validity of his or her position reduces fear of group sanctions for deviance. Moreover, on tasks that contain both judgmental and intellective elements (e.g., vocabulary tests—Laughlin et al., 1975; memory tests—Hinsz, 1990), a person who advocates a deviant but "correct" position in the face of majority opposition also can prevail, as long as he or she receives

support from another group member (a *truth-supported wins* social decision scheme). Thus, just as social support can reduce susceptibility to majority pressure in conformity settings by reducing fear of exclusion for deviance, so the presence of a supporter in decision-making settings may blunt the power of the majority by weakening its normative impact. It is also noteworthy that even when a group member knows the demonstrably correct answer to a problem, he or she is less likely to prevail (because of failure to mention the answer or argue vigorously for it) when the costs of exclusion are raised (viz., when the member has low status in a group that must continue to work together; Torrance, 1954).

As noted earlier, an important condition for normative influence is the majority's ability to monitor (and punish) deviant behavior. The impact of surveillance on social influence in interacting groups has been studied by comparing (1) individuals' private opinions prior to discussion, (2) the group decision that emerges during discussion, and (3) individuals' private opinions following discussion. Many such comparisons have been made in group polarization studies (see, e.g., Kerr, Davis, Meek, & Rissman, 1975; Myers & Lamm, 1976), and a common pattern has emerged: In nearly all cases, a "rebound" effect occurs, such that prediscussion opinions become more polarized during discussion and then shift back toward moderation after discussion. For example, in jury settings, some jurors who initially think the defendant is innocent but nonetheless join a unanimous guilty verdict privately assert, after deliberation, that they still believe in the defendant's innocence (e.g., Kerr et al., 1976). This pattern implies that at least some of the group polarization effect (i.e., the increased extremitization from prediscussion to discussion) reflects compliance to those holding the more prevalent (guilty) position in the group, motivated by the desire to avoid exclusion.

Other aspects of the group polarization literature are also consistent with this conclusion. Although there is substantial evidence that informational influence contributes to polarization effects (e.g., Burnstein & Vinokur, 1977; Ebbesen & Bowers, 1974), many findings challenge the sufficiency of this process. For example, if polarization is motivated by a desire to avoid deviance and its social costs, then merely permitting the exchange of group member preferences—without the opportunity for discussion and mutual persuasion—should be sufficient to produce polarization. And, indeed, although omitting group discussion does attenuate the polarization effect somewhat, it does not eliminate it (e.g., Baron et al., 1996; Baron & Roper, 1976; Myers, 1982). Several social comparison models of group polarization have been advanced, all of which are broadly consistent with a normative, or deviance-avoidance, explanation of polarization. For example, the position that individuals take on risky-shift items appears to represent a compromise between their (bold and risky) ideals and what they perceive to be the group norm, as predicted by the *pluralistic-ignorance theory* of polarization. If and when they discover that others (making the same compromise) define a descriptive group norm that is actually more risky than they had presumed, they shift their preferences in the norma-

tively preferred direction (cf. Pruitt, 1971). And as we have seen in a number of paradigms, when individuals discover that at least one other group member takes a position closer to their own ideal, they feel liberated to take a position somewhat further from the group norm in the direction of that ideal (Pruitt, 1971).

To this point, we have assumed that the robust strength-in-numbers effect in groups is attributable—in large part—to compliance motivated by deviates' desire to avoid social exclusion. But another, more subtle, mechanism may also be at work. That is, the minority's fear of exclusion may increase the majority's ability to produce *informational*, as well as normative, influence. In other words, minority members' concern about exclusion may increase the likelihood that they will be genuinely persuaded by majority members' arguments. This could occur if fear of exclusion motivates minority members to attend to, elaborate, and value majority members' arguments. Although direct evidence for these processes is not available, several lines of research are consistent with them (e.g., Crano & Chen, 1998; De Dreu & De Vries, 1996; Mackie, 1987; Schulz-Hardt, Frey, Luethgens, & Moscovici, 2000; Tesser, Campbell, & Mickler, 1983).

Behavior in Mixed-Motive Settings

We now turn our attention to cases in which group members' individual interests are not wholly compatible with one another or with collective interests. This state of negative interdependence clearly characterizes settings with explicit intragroup conflict, such as social dilemmas. Perhaps less obviously, it also characterizes most group performance contexts. Even though group members typically share a common interest in achieving a high level of joint performance, the costs (in effort, time, and lost opportunities) required to achieve such performance can create (or exacerbate) conflicts of interest among members (e.g., how hard one should work on the group's behalf; cf. Kerr, 1986). We argue that motivation to avoid social exclusion can powerfully shape members' behavior in such settings. We discuss first the less obvious case of group performance and then the more obvious case of social dilemmas.

GROUP PERFORMANCE

There are pervasive social expectations about how group members should behave on collective tasks. In some cases, these expectations deal with members' effort, that is how hard they try. In other cases, these expectations deal with members' competence, that is how well they perform vis-à-vis some standard of quality. As discussed below, evidence of laziness or incompetence reduces a member's social desirability and value to a group. Hence, if concern about exclusion motivates behavior in group settings, we would expect people to work harder and perform better when their behavior can be evaluated by others than when it cannot.

One line of relevant work concerns social facilitation, or the finding that others' presence sometimes energizes

performance (Zajonc, 1965). Social facilitation is often explained in terms of evaluation apprehension. According to this explanation, the presence of others causes people to become concerned about how their performance will be evaluated, which increases their level of drive or arousal. This in turn increases their task-relevant motivation (Cottrell, 1972; see also Blascovich, Mendes, Hunter, & Salomon, 1999; Geen, 1989; Harkins & Szymanski, 1987). It is important to note that the enhanced arousal produced by others' presence only facilitates performance on simple (well-learned) tasks. On difficult tasks, it has just the opposite effect, namely, inhibiting performance.

Concern about evaluation also contributes to social loafing, or the finding that others' presence sometimes deenergizes performance (Latane, Williams, & Harkins, 1979; see also Karau & Williams, 1993). Research on social loafing shows that people often expend less effort when working collectively rather than coactively or individually. This effect is often explained by positing that the ability to "hide in the crowd" in collective situations reduces group members' feeling of evaluation apprehension, which in turn reduces their task-relevant effort. To the extent that apprehension-based arousal enhances performance on simple tasks but impairs performance on difficult tasks, as argued previously, group members who believe that their individual performance cannot be evaluated should perform relatively poorly on simple tasks (because they are too relaxed) but relatively well on complex tasks (because they are not too tense) (cf. Jackson & Williams, 1985). Evidence on the role of task complexity in social loafing provides some support for these hypotheses (Karau & Williams, 1993).

Other research is also consistent with the notion that performance in group settings is influenced by members' concerns about how others evaluate them. For example, the performance of workers in the classic Hawthorne studies (e.g., Landsberger, 1958) was affected more by the presence of observers per se than by all the workplace environment manipulations examined. In addition, the consistent failure of members of face-to-face brainstorming groups to produce as many ideas as members of nominal groups can be attributed, at least in part, to evaluation apprehension. Anxiety that one's contributions may be negatively evaluated by others contributes to reluctance to speak up in brainstorming groups (e.g., Camacho & Paulus, 1995).

The impact of evaluation apprehension on performance in groups should, in principle, be moderated by members' dependence on one another for meeting their belongingness needs. Thus, we would expect stronger conformity to others' performance expectations in groups that are highly cohesive, elicit strong identification, and have high levels of member interaction or interdependence. Indeed, group productivity tends to be higher in groups that are more cohesive (Mullen & Copper, 1994) and elicit stronger identification (Haslam, 2004), especially when those groups have high levels of member interaction or interdependence (Gully, Devine, & Whitney, 1995). In a similar vein, tendencies to socially loaf are moderated by group valence (Karau & Williams,

1993), with less loafing in higher-valence groups. The occasional exceptions to these rules seem to occur when the group does *not* expect members to do their best. So, for example, when groups of workers hold antiproduction norms and punish "rate busters," high cohesiveness results in reduced, rather than enhanced, performance (Roethlisberger & Dickson, 1939; Schachter, Ellertson, McBride, & Gregory, 1951; Seashore, 1954).

Concern about others' evaluations can also influence how group members respond to common social interaction norms, such as the ubiquitous equity norm, which stipulates that group members' outcomes should be proportional to their inputs. Several studies show that when one member's contributions are not essential (i.e., are "dispensable") to the group's success, that person's task-relevant motivation is undermined (e.g., Kerr, 1983; Kerr & Bruun, 1983). But if group members expect to be rewarded equally, then the equity norm would prescribe that they contribute equally to the group product. Hence, those who contribute less than others (e.g., don't work as hard) would violate the equity norm and invite negative group sanction (and also produce guilt if the equity norm has been internalized). Thus, even when one's efforts are dispensable to the group's success, a person is unlikely to reduce his or her effort if others can monitor this effort and are likely to interpret low effort as failure to do one's fair share (Harkins & Petty, 1982). Conversely, when an ostensibly capable group member is clearly *not* doing his or her fair share, other group members will reduce their own efforts rather than tolerate the inequity of carrying a "slacker," even when such behavior produces costs for the self and the group (cf. Kerr, 1983). Such tendencies to match fellow members' effort levels are accentuated by conditions that increase concerns with social relations in the group (e.g., anticipated future interaction; Groenenboom, Wilke, & Wit, 2001).

SOCIAL DILEMMAS

Group members' decisions about how hard to work on group tasks are in many ways parallel to their decisions about how much to cooperate in mixed-motive situations, such as social dilemmas (Kerr, 1983, 1986). In social dilemmas, a personally beneficial or group-defecting choice yields higher outcomes to the individual than does a cooperative choice no matter what other members of the group do, yet universal defection produces worse outcomes for individuals and the group than does universal cooperation (Orbell & Dawes, 1981). Hence, it is not surprising that many of the behavior patterns identified earlier in the group performance literature are paralleled in the social dilemma literature. Just as effort in performance settings is enhanced by attraction to and identification with the group, so cooperation in social dilemmas varies positively with attraction to and identification with the group (e.g., Kramer & Brewer, 1984; Sattler, 1998), as well as the publicness (i.e., surveillance potential) of one's behavior (e.g., DeCremer & Bakker, 2003; although see Kerr, 1999). Moreover, just as there is a general expectation that group members should work hard on group tasks, so there is a general expectation

that group members should sacrifice self-interest when the welfare of the group is at stake. (As noted earlier, such group-serving norms could well have evolutionary roots.) And such sacrifice indeed occurs. Striking anecdotal evidence indicates that members of military units sometimes sacrifice their personal safety, and even their lives, to aid their comrades (e.g., Fussel, 2003; Stouffer, 1949). More prosaic experimental evidence confirms the power of (often implicit) cooperative norms (e.g., Hertel & Kerr, 2001; Van Vugt & Hart, 2004; Zdaniuk & Levine, 2001). Uncooperative group members are punished in one way or another (Dawes, McTavish, & Shaklee, 1977; Fehr & Gächter, 2002), and removing the threat of such exclusion for uncooperative behavior increases the likelihood of such behavior (Kerr, 1999; Masclet, Noussair, Tucker, & Villeval, 2003; Ouwerkerk et al., 2005), as does reducing a person's relative concern for the group as a whole versus some particular member of the group (Batson et al., 1995).

Other studies suggest that cooperative behavior is shaped by compliance with more specific social interaction norms (Kerr, 1995). One example is the powerful positive effect of group discussion on cooperation in social dilemmas. This effect stems, at least in part, from commitments to cooperate that group members make during discussion and then feel bound to honor (Chen & Komorita, 1994; Kerr & Kaufman-Gilliland, 1994). Likewise, evidence indicates that many patterns of cooperative choice reflect the prescriptions associated with norms of fairness or reciprocity (e.g., Komorita, Parks, & Hulbert, 1992; van Dijk & Vermunt, 2000; Wit, Wilke, & Oppewal, 1992).

We are not suggesting, of course, that group members never act selfishly, putting their own interests above the group's interests and violating normative expectations. There is no question that group members have other concerns besides inclusion (e.g., minimizing effort, maximizing short-term personal payoffs). But at least some of these violations of normative expectations may be reactions to the group's perceived violation of the implicit contract that conformity will be rewarded by inclusion. For example, if a member feels that the group (or its leadership) is not treating him or her in a respectful manner (e.g., by acting autocratically, by refusing to listen to his or her concerns), then the individual will no longer feel obligated to meet the group's expectations (e.g., Branscombe, Spears, Ellemers, & Doosje, 2002; De Cremer, 2002, 2003; Tyler & Degoey, 1995; Van Vugt, Jepson, Hart, & De Cremer, 2004). Likewise, a member's willingness to work for or contribute to the group will be undercut if the individual is convinced that his or her inclusionary needs will not be met by the group (Kerr, Harris, Messe, Poulsen, & Seok, 2005; Twenge, Baumeister, De Wall, Ciarocco, & Bartels, in press).

THE GROUP AS THE SOURCE OF INCLUSION/EXCLUSION

In the previous section, we focused on the group member as the *target* of inclusion/exclusion. In this section, we turn our attention to the group as the *source* of inclusion/exclusion. First we discuss the impact of collective goals on the monitoring system that groups use to assess individuals' contributions to collective goals, as well as the nature of this system. Next we consider the consequences of this monitoring system for how groups behave toward individuals, focusing primarily on exclusive reactions.

Collective Goals and Group Monitoring Systems

A fundamental property of groups is that they seek to achieve collective goals. Many typologies of group goals have been offered over the years. For example, Mackie and Goethals (1987) suggested that groups (as well as individuals) want to attain (1) utilitarian goals involving tangible outcomes, such as food and shelter; (2) knowledge goals involving valid information about how the world works; and (3) identity goals involving accurate self-knowledge and positive self-concept. In addition to such general goals, groups may seek to achieve a variety of specific task goals. Extrapolating from McGrath's (1984) circumplex model of group tasks, these latter goals include generating ideas or plans, solving problems with correct answers or deciding issues involving preferences, resolving conflicts of viewpoint or interest, and performing tasks that have objective standards and resolving conflicts of power. Moreover, to attain collective goals of any sort, groups need to satisfy a variety of "maintenance goals" that are critical to group survival (Cartwright & Zander, 1968). These include gaining and retaining members, managing role assignments, facilitating cohesion, enforcing norms, and so on.

Given that groups have goals, it is hardly controversial to suggest that they will pay attention to factors that facilitate and inhibit the attainment of these goals. Of the many potential determinants of group goal attainment, members' behaviors are typically quite important. Therefore, groups are likely to spend substantial time and energy monitoring these behaviors. In our earlier discussion of individuals' need for group inclusion, we noted that the monitoring system people use to assess their social status is asymmetrical (i.e., more sensitive to rejection than acceptance) and automatic (i.e., continuous, involuntary, and unconscious). We would argue that groups use a similar system to monitor individuals, although this similarity is greater in regard to system asymmetry than to automaticity. Just as individuals are particularly sensitive to group rejection, so groups are more sensitive to individuals' negative than positive contributions to collective goal attainment (Blanton & Christie, 2003). However, whereas groups are typically highly vigilant in monitoring individuals' contributions, their monitoring systems frequently do not fulfill the criteria of automaticity. Instead, these systems often have "controlled" features, such as routinized performance reviews carried out by designated group representatives. As discussed below, the outcome of the group monitoring system influences the form, valence, and magnitude of group responses to individuals (typically some form of

exclusion in the case of negative contributions and some form of inclusion in the case of positive contributions).

This analysis is consistent with recent evolutionary explanations of why and when groups exclude members (e.g., Kurzban & Leary, 2001; Neuberg et al., 2000). According to these explanations, because humans live in interdependent, cooperative groups, various forms of exploitative, or "selfish," behavior pose serious threats to group (and ultimately individual) welfare. These threats, in turn, have caused humans to evolve "mechanisms to identify individuals who threaten or hinder successful group functioning, to label them as such, to motivate group members to withhold group benefits from them, and to separate such individuals from the group if necessary" (Neuberg et al., 2000, p. 36).[5]

This evolutionary perspective suggests that certain kinds of individual behaviors may operate as "generic" threats, eliciting exclusion from a wide range of groups (cf. Neuberg et al., 2000; Stangor & Crandall, 2000). Of particular importance are behaviors that directly undermine the group's ability to function effectively. Some of these behaviors reflect lack of task-relevant knowledge or skills, as when new members do not understand the requirements of the overall group task or cannot perform the subtasks they are assigned. Other behaviors reflect lack of task-relevant motivation, as when individuals fail to work hard (socially loaf) because they believe others will take up the slack (Kerr, 1983). Social loafing is just one of several "misbehaviors" that undermine a group's ability to achieve its goals because they violate the implicit (sometimes explicit) social contract stipulating that group members should behave cooperatively to achieve shared goals. Other behaviors that undermine group effectiveness include being an "imposter," that is, publicly claiming a group identity while violating the expectations associated with this identity (Hornsey & Jetten, 2003), and failing to honor generic social norms such as reciprocity, promise/commitment keeping, property rights, and fair exchange (Kerr, 1995). It is difficult to think of cases, for example, in which cheating and stealing within the group are not punished (Kurzban & Leary, 2001; Neuberg et al., 2000). Of particular importance are violations of the norms prescribing that group members should sacrifice personal welfare in favor of group welfare (at least up to a point) and should show loyalty to their ingroup, especially when intergroup conflict is high (cf. Hertel & Kerr, 2001; Van Vugt & Hart, 2004; Zdaniuk & Levine, 2001). Disloyalty is typically viewed as the worst form of deviance and hence elicits the harshest penalties (Hogg, Fielding, & Darley, 2005; Levine & Moreland, 2002).

Other normative violations pose indirect but still potentially real threats to group effectiveness. These include acting in an unpredictable fashion (Kurzban & Leary, 2001) and violating implicit "residual rules" regarding appropriate dress, speech, cleanliness, interaction distance, and so on (Scheff, 1966), Whereas these examples (and the ones mentioned previously) deal with violations of behavioral norms, exclusion can also be triggered by various "abnormal" bodily conditions, such as physical disabilities or deformities and skin disorders (e.g., Neuberg et al., 2000; Thornhill & Gangestad, 1993). According to evolutionary explanations of exclusion, these conditions elicit negative responses because they imply inability to reciprocate benefits or produce viable offspring (in the case of disabilities or deformities) or danger of parasitic infection (in the case of skin disorders).

Social psychologists have been particularly interested in one kind of indirect threat to group effectiveness, namely, deviations from group consensus on opinion issues. In an influential early formulation, Festinger (1950) argued that group members want to attain opinion uniformity for two reasons: (1) desire to validate opinions that are not based on physical reality (social reality motive) and (2) desire to move toward (i.e., achieve) group goals (group locomotion motive). These two motives bear some resemblance to those that underlie informational and normative influence, respectively (Deutsch & Gerard, 1955). However, as discussed in more detail later, Festinger argued that both the social reality and group locomotion motives have a normative component in that individuals who impede the group's ability to satisfy either motive are perceived as "dangerous" and hence elicit some form of exclusion.

Although certain behaviors on the part of an individual may have generic threat-inducing properties, this does not mean that a given behavior is equally threatening to all groups at all times. Instead, the perceived threat value of a behavior varies as a function of the perceived probability that it will seriously undermine the group's ability to achieve a valued goal, and this probability judgment, in turn, can be influenced by numerous features of the behavior itself, the individual who emits the behavior, and the group context in which the behavior occurs (Levine, 1989; Levine & Moreland, 2002). For example, holding constant the value of the group goal, violation of a norm is likely to be perceived as more threatening if the violation is seen as directly (rather than indirectly) inhibiting goal attainment, if it is clear-cut (rather than ambiguous), and if it occurs repeatedly (rather than once). In addition, violation of a norm is likely to be perceived as more threatening if it is done by a member who has high (rather than low) status, has been in the group for a long (rather than a short) time, and seems unmotivated (rather than motivated) to achieve the group goal. Finally, violation of a norm is likely to be perceived as more threatening if the group is performing poorly (rather than well), is understaffed (rather than adequately staffed), and is in a competitive (rather than cooperative) relationship with an outgroup.

This line of argument has two important implications. First, it suggests that the nature of norm violations is often not "perceptually given" but, rather, is constructed during an inferential process.[6] That is, the group uses information about the violation itself, the person who commits the violation, and the group context in which the violation occurs to make attributions about the person and to judge the likely impact of his or her behavior on group goal attainment (Levine, 1989; see also Hogg et al., 2005; Stangor & Crandall, 2000). This inferential process can

be more or less complex, depending on the amount and clarity of information that the group has access to and decides to use. Second, because the inferential process occurs at the group level, it can involve a range of social processes, including majority and minority influence, group polarization, leadership, coalition formation, negotiation, and so on (Levine, 1989). The complexity of these processes makes it difficult, if not impossible, to predict the outcome of the group inferential process simply by knowing what individual members think about the norm violation prior to group interaction. Because these same processes operate when groups make decisions about how individuals should be treated, it is also useful to adopt a group-level perspective when analyzing the nature of exclusive responses.

A similar analysis is relevant to cases in which individuals adhere to, rather than violate, group norms and hence elicit inclusive, rather than exclusive, reactions. Evidence indicates, for example, that group members (1) believe a slider (who shifts from disagreement to agreement with the majority position) has less genuine belief in the correctness of his or her final position and more desire to be liked than does a mode (who always agrees with the majority position) and (2) evaluate the slider more negatively than the mode (Levine, Saxe, & Harris, 1976). Recent research in which a minority faction becomes a majority faction as the result of majority members' conversion to the minority position yields consistent findings (Prislin, Levine, & Christensen, 2006). Here, former minority (current majority) members expressed more liking for converts who changed their position for genuine reasons (i.e., because they were convinced by persuasive arguments) than for superficial or unexplained reasons. Thus, it appears that group members make attributions about the motives of conformers, as well as deviates, and these attributions influence their reactions to these individuals (cf. Morris & Miller, 1975).

This is not to say, of course, that group members do not sometimes appraise and respond to norm violations (and norm adherence) on their own. If, as we have suggested, individual group members are very alert to risks of exclusion, then deviation by others may often be deterred or reversed by exclusionary actions or signals (e.g., commenting on the deviant behavior) from members acting on their own (e.g., Fehr & Gächter, 2002). Such independent individual actions can invoke group norms, identify behavior as deviant, and remind the deviate of the potential for more concerted group action. Such individual-level appraisals and responses may be more or less consistent across members, depending on the degree to which they share appraisal biases and response preferences. To the extent members differ on these dimensions, norm violators can receive "mixed messages" about the appropriateness of their behavior.

Group Inclusion and Exclusion

As suggested earlier, the outcome of the group monitoring system—a judgment about the individual's contribution to group goal attainment—plays an important role in determining the form, valence, and magnitude of the

group's behavior toward the individual. In general, negative contributions elicit some form of exclusion, and positive contributions elicit some form of inclusion (Festinger, 1950; Levine et al., 2005; Mackie & Goethals, 1987). It is not the case, however, that deviance from group norms is always perceived negatively and hence elicits exclusion. Although groups have a default assumption that conformity to norms enhances, and deviance inhibits, collective welfare, they often desire (though do not require) that some members violate these norms by performing exceptionally well (Blanton & Christie, 2003). In such cases, positive deviance (i.e., norm violation in the "right" direction) can facilitate group goal attainment and hence elicit strong inclusion (cf. Schmitt, Silvia, & Branscombe, 2000).[7] Reactions to positive deviance have also been analyzed from the perspective of social identity theory and the Subjective Group Dynamics (SGD) model (e.g., Abrams, Marques, Bown, & Dougill, 2002; Abrams, Marques, Bown, & Henson, 2000; Hogg et al., 2005). This line of research, which is discussed in more detail later, indicates that reactions to positive ingroup deviates (who take a position consistent with, but more extreme than, the modal ingroup position) are most favorable when an intergroup context is salient and the ingroup's positive self-image is threatened.

Because social psychologists have devoted most of their attention to how groups respond to opinion deviance, it is appropriate to begin our discussion of group inclusion/exclusion by reviewing work on this topic. According to Festinger (1950), regardless of whether the social reality or group locomotion motive is dominant, differences of opinion among group members produce pressures toward uniformity, which in turn produce communication designed to reduce these differences. Communication can resolve opinion differences in two ways—either the group convinces the deviate to move toward its position or the deviate convinces the group to move toward his or her position. In addition, the group can redefine its boundaries by rejecting the deviate. Festinger made several predictions about the determinants of communication pressure in groups, the likelihood of communication to particular members, the amount of opinion change that communication produces, and the rejection of deviates. For example, he suggested that the likelihood of communication to particular individuals increases as a function of their perceived disagreement with the group, the group's desire that they remain members, and the group's belief that communication will alter their opinions. In addition, he suggested that group rejection of deviates increases as a function of their perceived disagreement with the group, the relevance of the issue to group function, and the group's cohesiveness. These and related hypotheses received partial support in studies conducted by Festinger and his colleagues (see reviews by Levine, 1989; Turner, 1991).

Perhaps the best known of these studies is Schachter's (1951) experiment on reaction to opinion deviance. In this study, participants were assigned to small groups that were either high or low in cohesiveness and then asked to discuss a topic that was either relevant or irrele-

vant to the group's purpose. Each group contained several naive participants and three confederates. The mode agreed with participants throughout the discussion. The slider began by disagreeing but gradually shifted to agreement. And the deviate consistently disagreed throughout the discussion. Results indicated that the deviate received the most overall communication, the slider received the next most, and the mode received the least. Moreover, the temporal pattern of communication to the three confederates differed. Communication to the mode remained uniform over the course of the discussion, communication to the slider decreased, and communication to the deviate tended to increase in all conditions except one (high-cohesive-relevant), where a final decrease occurred. Surprisingly, however, the greatest total communication to the deviate occurred in the low-cohesive-irrelevant condition. After the discussion, the three confederates were evaluated by the rest of the group. In general, the deviate was rejected more than the slider and mode, who were liked about equally. Finally, group cohesiveness and issue relevance affected deviate rejection as predicted, although their impact varied as a function of how rejection was measured (sociometric responses vs. committee nominations).

A number of more recent experiments have also investigated factors that affect rejection of opinion deviates in small groups (see Levine, 1989; Levine & Thompson, 1996). Evidence indicates that both the extremity and content of the deviate's position influence group reactions. Extreme deviates receive more communications and less favorable evaluations than do moderate deviates (e.g., Hensley & Duval, 1976; Levine & Ranelli, 1978). Moreover, the reasons that deviates give for taking their position influence how they are evaluated (e.g., Levine & Ruback, 1980), and deviates taking positions that are consistent with the wider Zeitgeist are liked better than those taking positions that are inconsistent (Maass, Clark, & Haberkorn, 1982; Paicheler, 1976). In addition, when deviates change their position over time, those shifting toward the majority position are generally liked better than those shifting away (e.g., Levine & Ranelli, 1978; Levine et al., 1976). Evaluation of shifting deviates is also affected by the social pressures ostensibly acting on them (e.g., the number of other people who support their position), presumably because these pressures affect the attributions that are made for their behavior (e.g., Levine, Sroka, & Snyder, 1977).

We have focused so far on studies in which group members' responses to deviates presumably were influenced by their desire to validate or evaluate the correctness of their opinions. Other studies have investigated how group members respond to deviates who interfere with group locomotion toward valued goals. These studies have operationalized deviance as either opinion disagreement or overt disruption of group performance (e.g., failure to follow instructions). It has been found, for example, that the greater the deviates' interference with group locomotion and the greater their perceived responsibility for this interference, the less they are liked (e.g., Berkowitz & Howard, 1959; Jones & deCharms, 1957; Miller & Anderson, 1979; Wiggins, Dill, &

Schwartz, 1965). Deviates' status within the group has also been shown to be important. Hollander (1958, 1960) argued that people who conform to group norms and demonstrate task-relevant competence gain status, or idiosyncrasy credit, which in turn allows them to deviate from group norms (but see Bray, Johnson, & Chilstrom, 1982). Other studies indicate that a deviate's status and degree of interference with group locomotion interact in determining majority members' reactions. High-status deviates tend to be severely punished for major interference with group locomotion toward valued goals, mildly punished for minor interference, and highly rewarded for facilitating locomotion toward these goals (e.g., Alvarez, 1968; Suchner & Jackson, 1976; Wiggins et al., 1965). In general, high-status persons who interfere with group locomotion are less likely to be defined as deviates than are low-status persons. However, if they are identified as deviates, they often receive severe punishment (e.g., Giordano, 1983; Hollander & Willis, 1967; Wahrman, 1970).

To understand reaction to deviance, it is important to consider the group context in which deviance occurs. Three potentially important features of this context are the group's norms regarding deviance, the group's desire for consensus, and social influence among majority members. Most groups have norms that prohibit deviance (e.g., Janis, 1982; Roethlisberger & Dickson, 1939). But some groups tolerate or even encourage deviance. These latter reactions can occur for several reasons, including members' desire to uphold a value system fostering freedom of expression, develop creative solutions to group problems, or demarcate the boundaries of tolerable behavior within the group (cf. Coser, 1962; McAuliffe, Jetten, Hornsey, & Hogg, 2003). Evidence indicates, for example, that deviates are liked better when the group has a norm favoring originality rather than objectivity (Moscovici & Lage, 1978). In addition to explicit norms regarding the acceptability of deviance, group members' desire for consensus, or collective cognitive closure, can affect reaction to deviance. Thus, Kruglanski and Webster (1991) found more rejection of deviates (and more acceptance of conformers) when the group's costs for failing to attain consensus were high rather than low. Finally, social influence among group members can affect how deviates are treated. Evidence indicates that people who see a fellow member react negatively toward a deviate are more likely to react negatively themselves than are people who do not have this experience (Wheeler & Caggiula, 1966; see also Dedrick, 1978), suggesting that exclusion itself can emerge as a group norm.

In recent years, substantial theoretical and empirical attention has been devoted to clarifying how reaction to opinion (and other forms of) deviance is influenced by the intergroup context in which it occurs. This work, which adopts a social identity approach, differs from that discussed above in a fundamental way, namely, by downplaying the importance of group members' face-to-face interaction and behavioral interdependence and focusing instead on their collective self-definition as members of social categories (Marques, Abrams, Paez, & Hogg, 2001). Initial work on reaction to deviance from

this perspective focused on the "black sheep effect," the finding that unlikable ingroup members are evaluated more negatively, and likable ones more positively, than similar outgroup members (e.g., Marques, Yzerbyt, & Leyens, 1988). Researchers working in this tradition interpret negative evaluations of unlikable ingroup members as a group protection strategy designed to maintain positive group identity by rejecting those who threaten this identity (Marques & Paez, 1994; but see Eidelman & Biernat, 2003).

Current social identity research on reaction to deviance is framed in terms of the SGD model (see reviews by Abrams, de Moura, Hutchison, & Viki, 2005; Marques, Abrams, Paez, & Hogg, 2001). This model is based on the assumption that group members are motivated to maximize both the positive distinctiveness of their ingroup vis-à-vis outgroups and the relative validity of their ingroup's norms. These goals, in turn, are satisfied through a combination of intergroup differentiation (regarding descriptive norms) and intragroup differentiation (regarding prescriptive norms). In addition to the research on reaction to positive ingroup deviates described earlier, a substantial amount of work on reaction to negative ingroup deviates (who threaten one or both of the goals mentioned above) is consistent with the SGD model. Evidence indicates, for example, that such deviates are more likely to be rejected (1) by people who identify strongly with the ingroup (e.g., Branscombe, Wann, Noel, & Coleman, 1993; Coull, Yzerbyt, Castano, Paladino, & Leemans, 2001; Hutchison & Abrams, 2003), particularly when their own prototypicality is threatened (Schmitt & Branscombe, 2001); (2) when deviance occurs in an intergroup context (Matheson, Cole, & Majka, 2003; but see Marques & Yzerbyt, 1988); (3) when the status of the ingroup is insecure (Marques, Abrams, & Serodio, 2001); (4) when there is lack of perceived consensus among ingroup members (Marques, Abrams, & Serodio, 2001); (5) when ingroup members feel a sense of accountability to one another (Marques, Abrams, Paez, & Martinez-Taboada, 1998); and (6) when the deviate challenges prescriptive ingroup norms (Bown & Abrams, 2003; Scheepers, Branscombe, Spears, & Doosje, 2002). This and related work provides strong support for the notion that social identity threat (Branscombe, Ellemers, Spears, & Doosje, 1999) plays an important role in group reaction to deviance.

Group responses to deviance can vary in form, valence, and intensity. For example, Festinger (1950) distinguished between communication directed toward changing the deviate's opinion and redefinition of the group's boundary by rejecting the deviate (see also Marques, Abrams, & Serodio, 2001; Schachter, 1951). A similar distinction was made by Orcutt (1973), who distinguished between inclusive and exclusive reactions to deviates. In the former case, the group wants to change the opinion of a person who seems responsive to persuasion. In the latter case, the group wants to exclude a person who seems unresponsive. Orcutt argued that the more serious the deviate's dissent is perceived to be, the more likely it will elicit an exclusive reaction. Yet another typology of reaction to deviance was offered by Israel

(1956), who argued that overt hostility toward a deviate is different from rejection of that person. Whereas overt hostility is used as a sanction to produce conformity, rejection is a last-ditch response that occurs after efforts to produce conformity fail. According to Israel, rejection can take three forms: expelling the deviate from the group, isolating the deviate from all interaction within the group, and depriving the deviate of the normal privileges of group membership (cf. Eidelman, Silvia, & Biernat, 2006; Williams, 2001).

An interesting example of how groups seek to alter the public (but not necessarily private) opinions of deviates was reported by Janis (1982) in his book on groupthink. He noted that self-appointed "mindguards" urged members who disagreed with the dominant group position to keep their concerns to themselves. Dissenters who had the temerity to question the group's position were subjected to strong conformity pressures, including disparaging remarks about their loyalty and competence. For example, during the Johnson administration, "everyone in the hierarchy, including every senior official, was subjected to conformity pressures, which took the form of making those who openly questioned the escalation policy the butt of an ominous epithet: 'I am afraid he's losing his effectiveness' " (Janis, 1982, pp. 114–115). Events in the years since indicate that advisors to more recent presidents have also felt pressure to go along with official policy.

Responses to deviance can be clarified by considering how groups use inclusion/exclusion to mark individuals' role transitions across different phases of group membership (Levine et al., 2005). Rather than simply being members or nonmembers of groups, people can relate to groups in more differentiated ways (i.e., as prospective members, newcomers, oldtimers, and ex-members). Given that group membership varies along an ingroup–outgroup continuum, group inclusion/exclusion can involve not only managing transitions across the group's external boundary but also managing transitions across internal boundaries that demarcate different roles members can play.

Levine and colleagues (2005) discuss three psychological processes relevant to inclusion/exclusion—evaluation, commitment, and role transition (cf. Levine & Moreland, 1994; Moreland & Levine, 1982). Evaluation involves efforts by the group and the individual to assess the past, present, and probable future rewardingness of their own and alternative relationships. Thus, a group's evaluation of an individual is high to the extent that his or her past, present, and anticipated future contributions to group goal attainment are greater than those of other people who were, are, or might be associated with the group. Evaluation affects feelings of commitment between the group and the individual, which can rise or fall over time as a function of each party's assessment of the other's rewardingness. The greater the group's commitment to an individual, the more likely it will be to engage in inclusive behaviors and the less likely it will be to engage in exclusive behaviors.

Role transitions are an important consequence of commitment, because they signal major changes in the

group's and the individual's relationship. These transitions occur when the two parties' commitment levels rise or fall to their decision criteria, which are specific levels of commitment indicating that it is time for the individual to undergo a role transition (i.e., move from one phase of group membership to another). Four basic role transitions can be identified (entry, acceptance, divergence, and exit). Entry reflects promotion from prospective member to new member, and acceptance reflects promotion from new member to full member. Because these role transitions indicate the individual's movement toward the core of the group (full membership), they signal the group's inclusion of the person. In contrast, divergence reflects demotion from full member to marginal member, and exit reflects demotion from marginal member to ex-member. Because these role transitions indicate the individual's movement away from the core of the group, they signal the group's exclusion of the person.

Groups use a variety of behaviors to indicate their inclusion/exclusion of an individual. Whereas some of these behaviors explicitly communicate the group's desire that the individual undergo a specific role transition, others do not. Some of these latter behaviors signal the group's level of commitment to the individual, based on its evaluation of his or her contributions. Positive behaviors (e.g., praise, personal warmth, bestowal of resources) generally indicate high commitment and thereby inclusion. In contrast, negative behaviors (e.g., criticism, personal coldness, withdrawal of resources) generally indicate low commitment and thereby exclusion. An important way in which groups indicate inclusion is by paying attention to the individual's arguments and thereby enabling him or her to exert influence. This type of inclusion has been studied under the rubric of minority influence. Although space considerations preclude a review of the extensive literature on minority influence (see DeDreu & DeVries, 2001; Martin & Hewstone, 2001; Wood et al., 1994), two issues relevant to our present concerns are worth noting. First, minority influence is hard to produce, and minorities are influential only under certain conditions (i.e., compared to majorities, minorities produce less public and direct private influence, although they can produce more indirect private influence) (Wood et al., 1994). Second, even when minorities succeed in exerting influence, they are viewed by majorities with ambivalence at best and hostility at worst (Moscovici, 1976).

Other behaviors that indicate inclusion/exclusion of an individual involve the group's decision criteria for role transitions. Groups signal inclusion by adopting decision criteria that (1) facilitate promotion from prospective to new member and from new to full member and (2) inhibit demotion from full to marginal member and from marginal to ex-member. Conversely, groups signal exclusion by adopting criteria with the opposite consequences—inhibiting promotion from prospective to new member and from new to full member and facilitating demotion from full to marginal member and from marginal to ex-member.

We have argued that groups generally behave in an exclusive (and negative) manner toward those who retard the attainment of collective goals. This tendency was recently documented in a meta-analytic summary of the strength of a large number of social psychological phenomena (Richard, Bond, & Stokes-Zoota, 2003). A mean effect size of .60 was reported for the finding that "people who deviate from a group are rejected by that group," as compared to mean effect sizes of .32 for the category of 27 group phenomena and .21 for all 474 social psychological phenomena in the sample. Given this strong tendency to punish deviates, the question arises as to whether all group members are equally likely to play the role of "enforcer." The answer seems to be no. In fact, there appears to be a bimodal distribution of enforcers. In some cases, they are high-status people, such as leaders (Hogg et al., 2005). In other cases, they are low-status people, such as peripheral group members (cf. Noel, Wann, & Branscombe, 1995).

Exclusive reactions toward deviance can vary in intensity. Mild examples of exclusion include frowns, derisive laughter, disparaging remarks, and withdrawal of privileges and responsibilities. Extreme examples include pressure to wear humiliating symbols (e.g., the scarlet letter "A"), threats of physical injury, and expulsion from the group. It is plausible to assume that the intensity of exclusive behaviors depends on the deviate's perceived interference with group goal attainment. This relationship makes sense if groups are particularly motivated to punish individuals who cause major harm (and deter others who might be inclined to behave the same way). However, an alternative possibility should be considered, namely, that groups *generally* prefer strong exclusive behaviors, because such behaviors send clear signals about the group's negative evaluation of deviance and hence are likely to influence the target's (and others') future actions.

In evaluating this latter hypothesis, it is important consider some potential costs associated with strong exclusive behaviors. For example, strong behaviors are more time-consuming and expensive to produce than are mild behaviors (firing an employee is much harder than frowning when he speaks). This is true, in part, because strong behaviors typically require greater coordination of group members' actions than do mild behaviors. In addition, strong behaviors make a greater impression on recipients than do mild behaviors, and sometimes this impression is not the one the group intended. Thus, a group that publicly criticizes a member for poor performance in an effort to increase his motivation may instead increase his anxiety to the point that he (and, perhaps, others) cannot function at all. Strong exclusive behaviors may also undermine a member's intrinsic motivation to work on the group task and make the group less attractive (Darley, 2001). When the person's contributions are indispensable to the group, for example, when loss of the person would lead to understaffing, the risks of alienating her may exceed the benefits associated with altering her behavior (Hogg et al., 2005).

The costs associated with strong exclusive behaviors often lead groups to use a cautious strategy in which harsh actions are taken only if milder ones fail (Festinger, 1950; Hogg et al., 2005). In fact, however, such steady es-

calation is rare. Because of their experiences in groups, people carry a set of expectations about how other members will behave toward them (e.g., regarding eye contact or personal greetings). Even small deviations from these expectations in the direction of reduced intimacy/acceptance (absent some benign attribution for such deviations) are likely to be interpreted as signaling exclusionary danger. Thus, the group rarely needs to make an overt threat to get a member's attention and prompt behavioral change—subtle and mild exclusionary signals will usually suffice. This argument is consistent with evidence, discussed earlier, regarding the sensitivity of individuals' monitoring system for detecting signs of group exclusion.

Notwithstanding the fact that groups generally respond to members' deviance with exclusive (and negative) behavior, it is not the case that negative behaviors are always used to punish negative contributions to group goal attainment and positive behaviors are always used to reward positive contributions. Groups sometimes use positive responses as "carrots" for individuals making negative contributions and negative responses as "sticks" for individuals making positive contributions. For example, carrots may be used when a group fears alienating an unproductive, but potentially useful, member, whereas sticks may be used when a group seeks to motivate a productive, but seemingly complacent, member. In addition, groups sometimes "pull their punches" with individuals making negative contributions for other reasons, including the desire to foster innovation or demonstrate tolerance (Levine, 1989; see also Alvaro & Crano, 1997; Crano & Chen 1998).

Our analysis to this point has assumed that a group's inclusive/exclusive reaction to an individual (1) is based on a (more or less rational) calculation of the person's contribution to group goal attainment and (2) has the instrumental goal of maintaining or increasing the group's ability to reach its goals. While these assumptions are plausible in many cases, they do not explicitly consider the role of emotion in influencing the direction and magnitude of the group's behavior. In particular, they do not address the possibility that inclusive/exclusive reactions to an individual may be attributable, in whole or in part, to the group's affective responses to the person or his or her actions. These responses may arise for several reasons. For example, a group may have a strong negative emotional response to a person because his behavior closely resembles an evolutionarily wired threat (cf. Kurzban & Leary, 2001; Neuberg et al., 2000). Several current models of sociality (e.g., Boyd & Richerson, 1992; Price et al., 2002) suggest a strong punitive reaction to behavior that can hurt the group or violates its norms, and experimental work demonstrates that people are willing to bear an extra cost simply to punish such behavior (Fehr & Gächter, 2002). Alternatively, a group may have a strong positive emotional response to a person because she was merely present when the group received a reward or possesses some valued trait. Such affective responses may influence the group's behavioral reactions to the individual by altering or even overriding

behavioral tendencies based on the "rational calculus" model proposed previously.

Emotional responses can influence a group's behavior toward an individual in another way as well. That is, emotions arising from the social dynamics of the group can affect how the person is treated by increasing the intensity of the inclusive or exclusive reaction that he or she elicits via one of the mechanisms discussed earlier, or, when no reaction tendency exists, by creating one. Examples include cases of extreme group adulation (e.g., responses to Hitler at Nazi rallies) as well as extreme group hostility (e.g., lynchings in the American South). Several mechanisms may underlie such effects, including social facilitation (Bond, 2000; Zajonc, 1965), emotional contagion (Hatfield, Cacioppo, & Rapson, 1994), behavioral contagion (Wheeler, 1966), and deindividuation (Diener, 1980; Postmes & Spears, 1998). These mechanisms illustrate additional ways in which group-level processes can influence inclusion/exclusion.

CONCLUSIONS

In this chapter, we used the notion of inclusion/exclusion to explain a range of small-group phenomena. In so doing, we adopted two different but complementary perspectives—one focusing on the individual member as the target of inclusion/exclusion, and the other focusing on the group as the source of inclusion/exclusion. Although there are differences in how groups and individuals deal with inclusion/exclusion (e.g., groups generally have more power to include/exclude than do individuals, and individuals generally are more sensitive to inclusion/exclusion than are groups), there are also striking parallels between the two perspectives. It may be useful, therefore, to suggest some general principles that help to integrate these perspectives.

First, there are strong commonalities in key motives that underlie individuals' desire for inclusion and groups' desire that individuals adhere to normative standards. In both cases, evolutionary factors are probably important. In addition, rational self-interest, based on previous experience, plays a critical role. Because of the rewards typically associated with inclusion and the costs typically associated with exclusion, individuals believe that inclusion generally facilitates personal goal attainment. Similarly, because of the rewards typically associated with normative behavior and the costs typically associated with deviant behavior, groups believe that normative behavior generally facilitates collective goal attainment.

Second, given that these motives produce strong desires for inclusion and normative behavior, both individuals and groups are acutely sensitive to information relevant to the satisfaction of their needs. This sensitivity, in turn, is reflected in similar kinds of monitoring systems by which individuals and groups assess their need satisfaction. One feature of these systems is asymmetry, that is, greater sensitivity to negative than to positive information. A second feature is automaticity, that is, continu-

ous, involuntary, and unconscious operation (although this is clearer in the case of individuals than groups).

Third, notwithstanding the fact that individuals generally desire to be included and groups generally desire that individuals behave normatively, the strength of these motives can vary across situations. Critical determinants of motivational strength are the salience and importance of momentary goals and the perceived impact of inclusion (from the individual's perspective) or normative behavior (from the group's perspective) on these goals. Thus, the more the individual wants to attain a particular personal goal and the more he or she believes that group inclusion is instrumental for doing so, the more motivated he or she will be to achieve or maintain inclusion. Similarly, the more the group wants to attain a particular collective goal and the more it believes that normative behavior is instrumental for doing so, the more motivated it will be to ensure that members engage in such behavior. This analysis suggests that, at least under certain conditions, individuals and groups make cognitive appraisals of one another's likely contributions to goal attainment rather than only responding in an automatic manner to evolutionarily wired cues.

Finally, this distinction between automatic and controlled processes in perception of the benefits of inclusion and normative behavior (and the costs of exclusion and deviance) is mirrored by a similar distinction regarding the processes underlying individuals' and groups' behavioral responses to these perceptions. As we argued earlier, the perceived benefits/costs of inclusion/exclusion for the individual and normative/deviant behavior for the group energize and direct both parties' behavior. For example, an individual who perceives that he or she is (or might be) excluded will be motivated to act, as will a group that perceives that its collective goal is (or might be) thwarted by a deviate. In both cases, these threat-induced behaviors will vary along a continuum from automatic/reflexive to controlled/planful. Factors that influence where a particular behavior falls on this continuum include the perceived intensity of the threat, the accessibility of habitual coping responses, and the availability of cognitive (and other) resources for selecting and producing responses.

We believe that our analysis of group processes in terms of inclusion/exclusion is distinctive in at least two ways. First, it seeks to provide a conceptual framework for understanding a wide range of small-group phenomena. With the notable exception of investigators working within the social identity tradition, contemporary researchers have been reluctant to offer integrative accounts of group processes, preferring instead to develop circumscribed explanations of specific phenomena. Although such analyses are often very insightful, their narrow scope has had the unfortunate consequence of fragmenting the field of group processes into seemingly unrelated subfields (Levine & Moreland, 1998). The disadvantages of such fragmentation are many (cf. De Dreu & Levine, 2006), and hence efforts to develop broader conceptual frameworks for understanding groups are worthwhile. Second, our perspective emphasizes the role of social needs in explaining group processes. Over the last few decades, research in social psychology has been dominated by a focus on how cognitive needs (e.g., to reduce uncertainty, to maintain consistent beliefs) influence people's thoughts, feelings, and actions (e.g., Kruglanski, 1989). This general perspective has yielded a wealth of important insights and will no doubt continue to generate interesting research. In the last few years, however, social psychologists in general and group researchers in particular have begun paying more attention to social needs, which include "the needs to be accepted by, connected with, and of value to other persons and social groups" (Brewer, 2004, p. 108). We applaud this increasing balance in how group processes are conceptualized and hope that our analysis will stimulate further work on the role that social needs (in conjunction with cognitive needs) play in such processes.

In closing, a few caveats are in order regarding the theoretical analysis we proposed and the empirical work we cited. As implied in the previous paragraph, we are not suggesting that inclusion/exclusion provides a simple and sovereign explanation of group processes. However, we are suggesting that by taking this perspective seriously, researchers will gain substantial leverage in predicting and explaining how groups and their members behave. In citing empirical work relevant to our arguments, we were selective rather than exhaustive. In addition to the literatures we discussed (conformity, group decision making and problem solving, behavior in mixed-motive settings, reaction to deviance), several other lines of work are also amenable to analysis emphasizing inclusion and exclusion. These include research on coalition formation (e.g., the fact that larger-than-necessary coalitions sometimes form because of the desire not to exclude people) and negotiation (e.g., the fact that outcome distributions sometimes reflect negotiators' concerns about their present and future relationships with their opponents). It is also important to acknowledge that whereas the studies we cited were consistent with our conceptualization, many were not designed to provide direct tests of the role of inclusion/exclusion in group processes. Because control conditions needed to rule out alternative explanations were usually not included in these studies, the evidence cited for many of our arguments should be viewed as suggestive rather than definitive. Finally, in some cases, there is little or no research bearing on our arguments. For example, neither the specific cues that individuals use to detect group exclusion nor the social dynamics that underlie group decisions about how to handle deviates have been systematically investigated. Although the absence of such research leaves several facets of our theoretical perspective untested, we believe this perspective suggests many interesting questions for future research.

ACKNOWLEDGMENTS

NOTES

1. Although Deutsch and Gerard specified that "another" can refer to a group, a person, or the self, analyses of normative influence have generally assumed that the source of influence is a group (Wood, 1999).

2. Mackie and her colleagues make the related point that group-mediated persuasion can involve either superficial or intensive cognitive processing (e.g., Mackie & Queller, 2000).

3. Wood (1999) distinguished between two forms of "normative" influence, one based on desire to obtain others' approval and the other based on desire to align oneself with valued reference groups and against derogated groups. We focus on the former kind of normative influence in this chapter. (See also Cialdini & Goldstein, 2004.)

4. Notwithstanding these findings, it is important to note that the distinction between social and physical reality may be more apparent than real. Perhaps matters of "physical reality" are thought to have objectively correct answers only because people assume that everyone perceives them in the same way (cf. Hardin & Higgins, 1996; Moscovici, 1976).

5. It is also possible, of course, for individual group members to exclude others who do not directly undermine the attainment of group goals, because doing so yields personal benefits, such as self-enhancement, cognitive simplicity, and anxiety management (Crocker, Major, & Steele, 1998). These individual-level explanations for exclusion are not the primary focus of our present discussion.

6. As noted earlier, violation of some "generic" norms may elicit immediate and strong reaction that does not depend on the sort of inferential process described here.

7. This is not to say, of course, that high achievers are always liked. When their accomplishments threaten perceivers' self-esteem or induce envy, they may be disliked (e.g., Feather, 1994; Schmitt, Silva, & Branscombe, 2000; Tesser, 1988).

CHAPTER 34

Cultural Processes

Basic Principles

CHI-YUE CHIU
YING-YI HONG

Culture exhibits the way people interpret their biology and environment. In public discourse, "culture" has also been given a tremendous amount of authority over people's act and thought (Rothstein, 1999). In anthropology, the concept of "culture" has been compared to the concepts of gravity in physics, and disease in medicine (Kroeber, Kluckholm, & Untereiner, 2001). Recently, psychologists have invoked the concept of "culture" to understand national and regional differences in a wide range of phenomena, from attention (Masuda & Nisbett, 2001) to categorization (Ji, Zhang, & Nisbett, 2004), thinking style (Peng & Nisbett, 1999), attributions (Menon, Morris, Chiu, & Hong, 1999; Morris & Peng, 1994), self-construals (Heine, Lehman, Markus, & Kitayama, 1999), self-regulatory focus (Lee, Aaker, & Gardner, 2000), prediction of future events (Ji, Nisbett, & Su, 2001), choice and motivation (Iyengar & Lepper, 1999), emotion (Cohen & Gunz, 2002), and life satisfaction (Oishi, Wyer, & Colcombe, 2000; Suh, Diener, Oishi, & Triandis, 1998). Contemporary reviews of the extant literature (Fiske, Kitayama, Markus, & Nisbett, 1995; Lehman, Chiu, & Schaller, 2004; Markus, Kitayama, & Heiman, 1996) have produced an impressive catalog of cultural differences in psychological processes and their outcomes.

However, a social psychology of culture is at best incomplete if it deals with cultural differences only. Studying cultural differences in psychological processes and their outcomes provides a litmus test of the generality of the basic principles in social psychology—basic principles should be able to accommodate and explain cul-

tural variations in behavior (Norenzayan & Heine, 2005). Nonetheless, culture does not explain cultural differences (see Bickhard & Campbell, 2000); what needs to be explained is culture itself. Principles of cultural processes are needed to account for the production, reproduction, and evolution of culture.

In this chapter, instead of providing a catalog of cultural differences, we attempt to construct a social psychology of cultural processes. We take a knowledge perspective to culture, and define culture as a network of distributed knowledge that is produced and reproduced among a collection of interconnected individuals. Our goal is to explicate the basic principles underlying how cultural knowledge is represented in the mind and applied in concrete situations, and how it emerges, spreads, and evolves. We begin with an overview of the key questions and basic premises in the knowledge perspective and proceed to expound on the specific principles.

KEY QUESTIONS AND BASIC PREMISES

By taking a knowledge perspective to culture, we seek to answer four interrelated questions. First, what is the nature of culture? As noted, we define culture as a network of distributed knowledge. However, how does cultural knowledge differ from personal knowledge? Is culture a coherent knowledge system? What forms can cultural knowledge take? Second, what are the social cognitive principles that govern the use of cultural knowledge in concrete situations? Third, what is culture for? What are

the societal and psychological functions of culture? Finally, how does culture spread and change? In this chapter, we address each question in turn.

We acknowledge that there are profound cultural differences in human behaviors. However, our goal is to explain cultural variations in terms of universal cultural processes. In psychology, it is customary to treat culture as contents (e.g., different kinds of self-construal, values, and beliefs). Researchers generally agree that individuals adhering to different cultural knowledge traditions may exhibit markedly different behaviors. However, there is disagreement over whether the same psychological principles can account for such cultural variations (see Hong & Chiu, 2001). Cultural relativists hold that because culture shapes the fundamental schemas used for grasping experiences, qualitatively different systems of psychological knowledge are needed to understand behaviors in specific cultures. We accept the premise that behaviors vary across cultures but reject the notion that culture creates incommensurate psychological systems. Most social psychologists believe in the power of situation. However, few see the need to develop different systems of social psychology for different kinds of situations. Instead, a common goal in social psychology is to uncover basic principles that explain situational variations in behaviors. Following the intellectual tradition in social psychology, we seek to identify the basic principles that underlie cultural variations in psychological phenomena.

We submit that this course of inquiry can contribute to the construction of a more complete body of social psychological knowledge. On the one hand, this course of inquiry may extend the generality of *some* existing psychological principles (e.g., principles of knowledge activation; Higgins, 1996) by illustrating how these principles also account for cultural variations in certain social psychological phenomena. On the other hand, this course of inquiry may also identify the boundary conditions of and suggest modifications to other principles (e.g., principles of self-enhancement). Furthermore, individuals have at their disposal both personal and cultural knowledge. These two kinds of knowledge differ in many respects (see below). Studying how cultural (vs. personal) knowledge is called out in concrete situations may inspire construction of new basic principles.

In short, our primary goal is not to advocate a distinct body of knowledge to account for behaviors in a particular cultural group but to use cultural variations as a source of inspirations for uncovering and revising basic principles, and as a litmus test for the generality of existing principles. Table 34.1 provides a summary of what we consider to be the basic principles of cultural processes.

WHAT IS CULTURE?

A Knowledge Perspective to Culture

We take a knowledge perspective to culture, and define culture as *a network of knowledge shared (albeit incompletely) among a collection of interconnected individuals*. Knowledge refers to all the ways of understanding that we use to make up our experienced, grasped reality. It consists of a

TABLE 34.1. DEFINITIONAL ISSUES AND BASIC PRINCIPLES

Definition: *Culture consists of a network of knowledge shared (albeit incompletely) among a collection of interconnected individuals.*

D.1 Cultural knowledge is distributed in a group of interconnected individuals, and is instantiated or communicated in one or several media, and distributed or communicated within a series of instituted social relations.

D.2 Items of cultural knowledge are domain-specific with loose interconnectedness.

D.3 Two major types of cultural knowledge are procedural knowledge and declarative knowledge; declarative knowledge can be further subdivided into person representations, event representations, and norm representations.

D.3 Cultural knowledge is conceptually different from cultural identification.

Describing cultural differences

P.1 Cultural differences can be understood in terms of the differing contents of the widely circulated and highly accessible procedural and declarative knowledge in different cultures.

P.1a Procedural knowledge: A learned response sequence (procedural knowledge) becomes automated through frequent practices; once a production is automated, its performance requires little cognitive deliberation.

P.1b Declarative knowledge: Chronic declarative cultural knowledge provides premises for subsequent judgments and behaviors.

P.2 Cultures also differ in how basic psychogenic needs, cultural knowledge, and personal experiences work together. Some cultures emphasize personal experiences, whereas others emphasize conformance to cultural norms. A behavior mediated by personal attitudes in one culture may be mediated by cultural norms in another culture. Self-motives and cultural norms may act in concert to produce the same behavior in some cultures, and push behaviors into opposite directions in others.

Cultural knowledge activation

P.3 People in every culture have constructed different cognitive representations of the people, events and norms. Cultural experiences determine the relative accessibility of these representations. Prevalence of cultural practices supporting certain representation renders it highly accessible.

P.4 Cultural knowledge items that have been frequently used in a group are usually widely shared, more frequently reproduced in communication, widely represented in external or public carriers of culture, and cognitively accessible to members of the group.

P.5 Contextual cues may increase the temporary accessibility of a body of knowledge, and momentarily raise the probability that this body of knowledge will be applied.

P.6 The probability that a knowledge item will be applied also depends on its applicability in the immediate context.

P.7 People are likely to use cultural knowledge when the situation calls for a readily available or conventionalized solution, or when the problem solver lacks the capability, motivation, or resource to consider alternative solutions.

P.8 People who are primed with a social category tend to assimilate their response into the primed category. However, if the individuals feel that they do not belong to the primed culture, culture priming may lead to contrastive responses.

TABLE 34.1. *(continued)*

Production, maintenance, and reproduction of culture

P.9   Cultural knowledge was originally developed to solve coordination problems in collective living.

P.10 The shared physical, social, and motivational environment in a culture affords opportunities to develop procedural knowledge through repeated practices of certain cognitive procedure.

P.11 Instantiation of cultural knowledge in external media enables ratcheting, and turns these media into effective means for the acquisition, transmission, activation, and maintenance of cultural knowledge.

P.12 Interpersonal communication may lead to spatially differentiation and clustering of attitudes and beliefs, and correlation of previously unconnected values and beliefs.

P.13 Through interpersonal communication, cultural knowledge that is widely shared among group members would likely be reproduced and consolidated in communication.

P.14 A cultural knowledge tradition is maintained partly because Individuals need culture to reduce uncertainty in social living, to manage existential terror, and fulfill the need for belongingness.

P.15 Culture change may occur because of endogenous and exogenous reasons. Endogenous culture change may take place through the processes of differentiation. Exogenous culture change often results from intercultural contacts.

set of learned routines of thinking, feeling, and interacting with other people, as well as a corpus of substantive assertions and ideas about aspects of the world (Barth, 2002).

For decades, anthropologists have debated what culture is. Some anthropologists (Braumann, 1999; Shore, 1996; Sperber, 1996) now believe that culture is a complex web of shifting meanings that connect people in a physical or virtual locale. Early 20th-century scholars understood culture to refer to a pattern of fixed traits (e.g., national or modal personalities) and assumed that such fixed traits had clear bounds. In the 1990s, some anthropologists became critical of the common practice of treating culture as a static monolith and using it synonymously with a demarcated population. In their opinion, through this practice, an inordinate degree of boundedness, homogeneity, coherence, and stability is attributed to the concept of culture (Appadurai, 1996; Friedman, 1994). In addition, the search for discrete cultural patterns may lead to reification of cultures and essentialism (Keesing, 1994). Similar objections were registered in psychology (Bandura, 2002). To escape from the predicament their discipline is facing, some anthropologists declared that "the culture concept has served its time" (Clifford, 1988, p. 274), while others even rallied their colleagues to write against culture (Abu-Lughod, 1991).

Unlike the fixed-trait approach, the knowledge perspective to culture highlights the dynamical, contextualized, and agentic aspects of culture. First, as Barth (2002) puts it, "knowledge is distributed in a population, while culture [traditionally defined] makes us think in terms of diffuse sharing" (p. 1). Because knowledge is distributed, the patterns of distributions and their determi-

nants cannot be taken for granted. Instead, they merit systematic investigations.

Second, items of cultural knowledge, like items of personal knowledge, are cognitive structures. Accordingly, basic principles of knowledge activation can be applied to understand when a cultural knowledge item is evoked to grasp experiences in concrete situations, hence permitting researchers to predict when response differences between two cultural groups may appear, disappear, or reverse (Hong & Chiu, 2001).

Third, cultural knowledge is *conceptually* different from cultural identification (Chiu & Chen, 2004; Kashima, 2000). Individuals who have inherited the knowledge tradition in their culture may identify with this tradition, be indifferent about it, or even reject it. Accordingly, it is important to examine the joint psychological effects of cultural knowledge and cultural identification (Hong, Wan, No, & Chiu, in press).

Finally, knowledge provides people with premises for judgment and action (see Kruglanski & Thompson, 1999). Thus, culture may also be compared to a toolkit that can be put to manifold uses (DiMaggio, 1997), and people in a cultural group can sample knowledge items from their cultural toolkit to fulfill their valued goals (Chiu & Chen, 2004; Chiu & Hong, 2005).

In short, the knowledge perspective offers some advantages over a fixed-trait approach. To exploit these advantages, it is important to clarify the nature of cultural knowledge. In the next two sections, we discuss (1) how cultural knowledge differs from personal knowledge, and (2) whether the items in a cultural knowledge tradition are organized around a small number of central themes or dimensions.

Cultural Knowledge and Personal Knowledge

Like items of personal knowledge, items of cultural knowledge are cognitive structures. However, unlike personal knowledge, cultural knowledge is not idiosyncratic knowledge that resides primarily in the head of the individual. Aside from its rich symbolic contents, culture also has material contents (e.g., strategy of subsistence; see Harris, 1964) and social contents (e.g., kinship terms; see Keesing, 1974) that are exhibited in various public forms. Oftentimes, the same cultural theme can be discerned in a social group's symbolic, material, and social culture. Indeed, the research literature is richly furnished with illustrations of how cultural knowledge is externalized in a variety of media and social relations, including childrearing practices (Miller, Wiley, Fung, & Liang, 1997), popular songs (Rothbaum & Tsang, 1998; Rothbaum & Xu, 1995), architecture (Miyamoto, Nisbett, & Masuda, 2006), language (Kashima & Kashima, 1998, 2003), news media (Cohen & Nisbett, 1997; Hallahan, Lee, & Herzog, 1997; Lee, Hallahan, & Herzog, 1996; Menon et al., 1999; Morris & Peng, 1994), proverbs (Ho & Chiu, 1994), advertisement (Aaker & Schmitt, 2001; Han & Shavitt, 1994; Kim & Markus, 1999), consumption symbols (Aaker, Benet-Martinez, & Garolera, 2001), cultural icons (Hong, Benet-Martinez, Chiu, & Morris, 2003; Hong, Chiu, & Kung, 1997; Hong, Morris, Chiu, &

Benet-Martinez, 2000; Verkuyten & Pouliasi, 2002; Wong & Hong, 2005), role models (Lockwood, Marshall, & Sadler, 2005), life practices (Kitayama, Markus, Matsumoto, & Norasakkunkit, 1997; Morling, Kitayama, & Miyamoto, 2002), and law and social policies (Cohen, 1996). In short, cultural knowledge is distributed in a group of interconnected individuals, instantiated or communicated in one or several media, and distributed or communicated within a series of instituted social relations (Barth, 2002).

In fact, instantiation of cultural knowledge in external media is what makes rapid accumulation of cultural knowledge possible. Unlike animal culture, human culture is cumulative: When humans discover a piece of knowledge, they start from there, and go on. Once the wheel was invented, the new generations do not need to invent it again. Instead, they build on it and invent the carriage, and then the automobile (Tomasello, 2001). This process is known as *ratcheting*. Because human memory has limited capacity and can be assessed by one individual only, if social transmission of knowledge relies exclusively on individual memory, the rate of ratcheting would have been slow. In contrast, many external memory devices (e.g., paintings, books, and the Internet) have virtually unlimited capacity and many retrieval paths and can be accessed by multiple users. Thus, they are more efficient tools than personal memory for storing and transmitting cultural knowledge (Donald, 1993).

Instantiation of cultural knowledge in external media turns these media into effective means for the acquisition, transmission, activation, and maintenance of cultural knowledge. For example, individuals can directly access cultural knowledge encoded in the external media (e.g., scriptures, fictions, and folktales). Cultural values (e.g., human rights) are transmitted through folklores (e.g., stories of the Civil War). The presence of some external carriers of culture (e.g., the picture of the Statue of Liberty) in the environment can call out the cultural knowledge encoded in the media. When a cultural idea is instantiated in many different external carriers, individuals in the culture are frequently exposed to the idea. As a consequence of frequent activation, this idea becomes chronically accessible in the cultural group.

Coherence of Cultural Knowledge

We posit that culture consists of a set of *loosely organized* distributed knowledge. This view stands in sharp contrast to the *systemic* view of culture, which maintains that culture is a *coherent* system of meanings with an identifiable central theme around which all cultural meanings are organized (see Shore, 2002). For example, in psychology, the dimension of individualism–collectivism has received most research attention. Individualism emphasizes individual achievement, individuality, and individual rights. Collectivism emphasizes collective achievement, close ties between individuals, and responsibility for fellow members of the group (Hofstede, 1980, 2001). Some writers (Greenfield, 2000) consider individualism–

collectivism as the "deep structure" of cultural differences, from which all other differences evolved.

However, there is only limited evidence for the view that individualism–collectivism is the central theme that underlies the deep structure of cultural differences. In a comprehensive meta-analytic review of the extant literature on country differences in individualism and collectivism, Oyserman, Coon, and Kemmelmeier (2002) found that contrary to popular assumptions in cross-cultural and cultural psychology, "European Americans were not more individualistic than African Americans, or Latinos, and not less collectivistic than Japanese or Koreans" (p. 3). In addition, there are remarkable interdomain variations in country differences in individualism and collectivism. For example, in the case of U.S.–Japanese differences, North Americans are *more collectivist* than Japanese in most domains, including accepting hierarchy, striving to maintain group harmony, and defining oneself contextually, as well as sense of belonging to groups. Japanese are more collectivist than North Americans only in the domain of preference for working in a group. Comparisons of North Americans with other national groups point to the same conclusion: The nature of the difference between North Americans and other regional groups depends on which aspect of individualism or collectivism is being assessed.

In another review, after surveying the literature in six major areas of cross-cultural research (perception, cognition, language, personality, emotions, and social behaviors), Poortinga (2003) reached a similar conclusion: "The evidence for a system of values or meanings in one culture that differs in essential ways from the systems of other cultures appears to be rather limited." He urged researchers to stop explaining cultural differences in behavior in terms of broad and inclusive concepts, and instead consider culture as "a loose set of mentifacts with incidental interconnectedness" (p. 275).

Furthermore, inconsistent and contrastive cultural ideas are often present in the same external carrier of cultural meanings. For example, popular sayings and idioms carry widely shared evaluative, prescriptive, or proscriptive beliefs and are embedded in many conversation scripts. In a content analysis of over 2,000 Chinese popular sayings and idioms, Ho and Chiu (1994) found that ideas supporting individualism and ideas supporting collectivism are both prevalent in Chinese sayings. Likewise, Zhang and Shavitt (2003) analyzed the values promoted in Chinese advertising and found that ideas pertinent to modernity and individualism predominate in current Chinese advertising. They also discovered that individualism and modern values are more pervasive in magazine advertisements than in television commercials, whereas collectivism and traditional values are more pervasive on television than in magazine advertisements.

These findings do not undermine the theoretical importance of individualism and collectivism. Compared to many other cultural ideas, these two ideas seem to have a broad range of convenience and mediate a wide range of cultural differences (Triandis, 1995). However, in light of these findings, it seems justified to try to understand cul-

tural differences in terms of specific cultural knowledge (Shore, 2002).

FORMS OF CULTURAL KNOWLEDGE

If culture consists of a coalescence of knowledge items, can these items be classified into theoretically meaningful categories? Borrowing insights from the knowledge representation literature, we classify cultural knowledge into two major categories: Procedural knowledge and declarative knowledge. We further subdivide declarative knowledge into person representations, event representations, and norm representations. Aside from providing a taxonomic classification of cultural knowledge, this categorization also sheds light on how a specific cultural knowledge item is cognitively represented in an individual's head, and when and how it will be activated.

Procedural Knowledge

Two major types of knowledge representations are *procedural* knowledge (knowing *how*) and *declarative* knowledge (knowing *that*; Wyer, 2004). Procedural knowledge consists of procedural representations of how to achieve a particular result. It consists of a learned sequence of responses to situational cues. Once the learned response sequence is automated through frequent practices, its performance requires little cognitive deliberation.

Cultural experiences can lead to the development of procedural knowledge in at least two ways. First, the physical and social environment in a culture affords opportunities to practice a certain response repeatedly. Second, a certain culture may emphasize a particular goal. As members of the culture pursue this goal routinely, the procedure used to attain the goal is automated and can be activated in response to the controlling stimuli without the individual's conscious awareness.

Procedural knowledge may underlie some universal cultural processes. As an illustration, consider the decoding of emotions from facial expressions. In a typical emotion recognition experiment, perceivers view emotion faces on slides or photos and identify the emotion each face is intended to portray by selecting an emotion term from several alternatives. In most studies, perceivers are more accurate in judging the emotions of expressors from their own culture than emotions of foreign expressors (Elfenbein & Ambady, 2002).

The seemingly universal ingroup advantage in recognizing facial expressions of emotions may arise from more frequent practices in decoding facial expressions of one's cultural members (vs. foreign cultural members). For example, Chinese in China have greater exposure to emotion faces of Chinese people than do Chinese Americans and non-Asian Americans. Conversely, non-Asian Americans and Chinese Americans have greater exposure to emotion faces of Americans than do Chinese in China. Consistent with the "practice makes perfect" idea, Chinese in China are faster and more accurate in recognizing emotions from facial expressions of Chinese pos-

ers than from those of American posers, and the reverse is true for non-Asian Americans and Chinese Americans. In addition, among Chinese Americans, the advantage for recognizing American over Chinese expressions is greater among second-generation Chinese Americans than among immigrant generation Chinese Americans. Finally, Tibetans residing in China are faster and more accurate when they decode emotions from Chinese faces than from American faces. Likewise, Africans residing in the United States are more proficient in recognizing emotions from American faces than from Chinese faces (Elfenbein & Ambady, 2003). In short, proficiency (as measured by accuracy and speed) in recognizing the facial expressions of emotions of a certain group increases with the amount of opportunities to practice the skill.

Procedural knowledge may also underlie many cross-cultural differences, ranging from visual scanning (Braine, 1968; Hoosain, 1986) to language comprehension (Ishii, Reyes, & Kitayama, 2003; Kitayama & Ishii, 2002), attention (Kitayama, Duffy, Kawamura, & Larsen, 2003; Masuda & Nisbett, 2001), categorization (Ji et al., 2004), reasoning (Norenzayan, Smith, Kim, & Nisbett, 2002), and problem solving (Kim, 2002). For example, American undergraduates often use internal speech to keep track of their thoughts during problem solving. Requiring them to think aloud while solving reasoning problems does not affect their performance on the problem-solving task. However, thinking aloud is not an automated cognitive strategy for most East Asian undergraduates. To these East Asian undergraduates, thinking aloud requires cognitive effort and may lead to impaired performance in problem solving (Kim, 2002).

As another example, for most people, the preferred direction of visual scanning is left to right. One exception is found among Israelis. Israelis' preferred visual scanning direction is right to left, and Hebrew is written from right to left (Braine, 1968). Likewise, Chinese characters are sometimes read from left to right and sometimes read from top to bottom. The habitual way Chinese characters are read influences Chinese readers' preferred visual scanning direction. Unlike Americans, Chinese do not display lower visual acuity in vertical scanning than in horizontal scanning (Freeman, 1980). Furthermore, Chinese American children who do not have any experience with written Chinese have poorer acuity in vertical scanning than in horizontal scanning, just as the American adults do (Hoosain, 1986).

Procedural knowledge may also underlie cultural differences in attention and perceptual strategy. Compared to each other, European Americans attend to focal objects more spontaneously, and East Asians attend to contextual information more spontaneously. For example, East Asians (compared to European Americans) spend more time looking at the background in a visual display (Chua, Boland, & Nisbett, 2005), mention contextual information more frequently when they describe an animated scene, have better performance in detecting changes in background information (Masuda & Nisbett, 2004), and recognize previously seen objects more accurately when the objects are seen in their original settings

than in novel settings (Masuda & Nisbett, 2001). By comparison, European Americans spend more time looking at the focal object in a visual display (Chua et al., 2005), and have better performance in detecting changes in focal objects (Masuda & Nisbett, 2004). East Asians are also more accurate in processing contextual information (the length of the line relative to the height of a squared frame) than absolute information (the length of a line), and the reverse is true for European Americans (Ji et al., 2001; Kitayama, Duffy, Kawamura, & Larsen, 2003). Finally, when responding to an oral presentation of an emotional word, Japanese respond automatically to its vocal tone (contextual information), whereas European Americans respond automatically to its verbal contents (Ishii et al., 2003; Kitayama & Ishii, 2002).

A set of recent studies links some of these cultural differences to the perceptual environment in East Asia and North America. Based on a detailed textural analysis of city scenes in Japanese and American cities, Miyamoto and colleagues (2006) found that in U.S. cities, objects are usually distinctive and stand out from the background. Thus the experience of living in the American environment tends to direct one's attention to the distinctive and focal objects rather than to the background. Conversely, in Japanese cities, objects are more ambiguous and difficult to distinguish from the background. The experience of living in the Japanese environment may direct one's attention to the relationship between the focal object and the background.

To test the connection between environmental affordances and attention strategies, Miyamoto and colleagues (2006) had Japanese and European American undergraduates view either Japanese or American scenes. Subsequent to this manipulation, both Japanese and American participants in the Japanese scene condition displayed increased sensitivity to changes in the background, whereas those in the American scene condition displayed increased sensitivity to changes in the focal objects.

Aside from environmental affordances, pursuit of culturally important goals also affords opportunities to practice the procedures for attaining these goals. Compared to Westerners, Easterners are more worried about being isolated. They also tend to pay more attention to contextual information. In a series of studies, Kim and Markman (2006) linked the East–West difference in attention strategy, described earlier, to cross-cultural variation in the fear of isolation. According to these researchers, when individuals fear being isolated, they attend to the social context. Because fear of isolation is a chronic concern in East Asian contexts, East Asians have plenty of opportunities to practice the attention strategy connected to this social concern. As expected, in these studies, cultural differences in fear of isolation mediated East–West difference in attention strategies. Furthermore, among European Americans, those primed with fear of isolation exhibited greater sensitivity to contextual information than did control participants.

Taken together, these findings suggest that the shared physical, social, and motivational environment in a culture affords opportunities to develop procedural knowledge through repeated practices of a certain cognitive procedure.

Declarative Knowledge

Declarative knowledge is knowledge that is either true or false. It describes objects and events by referring to the characteristic properties of the events but does not specify the actions needed to obtain a result (Turban & Aronson, 1988). When a piece of declarative representation is activated, it may constrain subsequent inferences and decisions. The three types of declarative knowledge that have received the most attention in culture and psychology research are representations of persons, events, and norms.

Person Representations

A person representation is a network of associations between a central concept and a number of individual features. The referent of the central concept can be the self, a person other than the self, a group, or a social category. The features that are associatively linked to the referent may include alternative labels of the referent, traits, prototypical behaviors, or physical characteristics. The associations between individual features and the central concept differ in associative strength and may be specific to a particular type of situation.

Several different representations may be constructed for the same referent, each with a different set of associated features. For example, a person can construct a personal self that is associatively linked to a set of personal attributes, a social self that is linked to a set of social roles and role expectations, and a collective self that is linked to a set of collective memberships (Triandis, 1989). Moreover, each person representation is a separate cognitive unit that can be independently retrieved from memory (Wyer, 2004).

Cultural differences in person representations can be seen from the way individuals describe the referent of a person representation. When individuals retrieve a person representation from memory and report the features that are associatively linked to the referent, although several different representations of the same referent are available in memory, description may depend on which representation is most accessible in memory and, therefore, is most likely to be retrieved and used. Accordingly, although people in every culture may have constructed several different cognitive presentations of a person, cultural experiences determine the relative accessibility of these representations.

Consistent with this idea, research has shown that for European Americans, the most cognitively accessible mental representation of other people consists of general traits, whereas the one for Asians includes social roles and situation-specific behaviors. For example, compared to Asians, European Americans are more likely to use abstract traits to describe others, and less likely to use social role descriptions and situation-specific behaviors (Miller, 1984). They are more likely to attribute situationally induced events to the actor's dispositions

(Choi & Nisbett, 1998; Masuda & Kitayama, 2004; Miyamoto & Kitayama, 2002) and attribute the causes of social events to the actor's internal factors (Miller, 1984; Morris & Peng, 1994). In addition, they are less aware of the influence of the situation on behavior (Morris & Peng, 1994), and they make stronger predictions of trait-relevant behavior based on previous trait-relevant behavior (Norenzayan, Choi, & Nisbett, 2002). By comparison, East Asians are more affected by information about situational constraints when predicting trait-relevant behavior in a particular situation (Norenzayan, Choi, & Nisbett, 2002).

The same principle can also be applied to understand cultural variations in the representation of the self. According to Triandis (1989), all individuals can include in their self-representations three kinds of features: the private self (knowledge about one's own traits, states, or behaviors), the public self (knowledge about the generalized other's view of the self), and the collective self (knowledge about some collective's view of the self). Individuals in different cultural groups sample these three kinds of self with different probabilities. How likely the private self and the collective self will be sampled depends in part on the relative emphasis on personal versus collective goals in the cultural context. Some cultures (e.g., Western cultures) value independence of the self from others (Triandis, Bontempo, Villareal, Asai, & Lucca, 1988). In these cultures, the private self (self-reliance, independence, self-esteem, self-concept clarity, and self-realization) is likely to be sampled. Other cultures (e.g., East Asian cultures) value interdependence with ingroup members. In these cultures, the widely accepted view is that people should avoid pitting their personal goals against the collective goals. If a conflict between personal and group goals is inevitable, people should subordinate their personal goal to the group goal (Triandis et al., 1988). In such cultural contexts, higher rates of sampling the collective self are expected.

Consistent with this idea, some studies have shown that Chinese Americans are more likely than European Americans to describe themselves spontaneously in terms of attributes that reference group memberships rather than personal attributes (Bond & Cheung, 1983; Cousins, 1989; Trafimow, Triandis, & Goto, 1991). Other studies have shown that East Asians use more interdependent or group-related statements to describe themselves, whereas European North Americans use more independent self-statements (Hong, Ip, Chiu, Morris, & Menon, 2001; Rhee, Uleman, Lee, & Roman, 1995; Triandis, 1989; Wang, 2001, 2003). In a similar vein, Markus and Kitayama (1991, 2003) reported that European Americans are more inclined to view the self as a self-contained entity, whereas Japanese are more disposed to view the self as being embedded in social relations. These cultural differences may reflect differences in the chronic accessibility of the independent and interdependent self-representations.

Chronic representations of the self provide premises for subsequent judgments and behaviors. First, there is evidence that when the self is seen as being interdependent of others, individuals seek closeness with ingroup members. For example, the interdependent self-representation has higher chronic accessibility among Turks than European Canadians, and Turks have a stronger desire for closeness with family members and acquaintances than do European Canadians (Uskul, Hynie, & Lalonde, 2004). Second, the interdependent self is more widely shared and accessible in Eastern cultures, whereas the independent self is more widely shared and accessible in Western cultures (Markus & Kitayama, 1991). Under the influence of the interdependent self, compared to Westerners, Easterners have a greater tendency to see the group as agentic (Kashima et al., 2005); relational information (the target's interpersonal network, or community memberships) versus individuating information as useful in making social predictions (Gelfand, Spurlock, Sniezek, & Shao, 2000); commercial advertisements that appeal to ingroup benefits, harmony, and family integrity as persuasive; and those that appeal to personal preferences and benefits as unconvincing (Han & Shavitt, 1994). Furthermore, relative to North Americans, East Asians have better memory of other people's perspective on the self (Cohen & Gunz, 2002) and of the information encoded in relation to the collective self (Wagar & Cohen, 2003), are more likely to take other people's perspective when reading other people's emotions (Cohen & Gunz, 2002), pay closer attention to the common ground in communication (Haberstroh, Oyserman, Schwarz, Kuehnen, & Ji, 2002), feel more obliged to justify their choice for others (Fein, Hoshino-Browne, Davies, & Spencer, 2003), and have a greater tendency to mimic other people's behaviors (van Baaren, Maddux, Chartrand, de Bouter, & van Knippenberg, 2003).

By comparison, Westerners who see the self as being independent of others are motivated to make the personal self the nucleus of their social cognitive activities. They rely more on individuating (vs. relational) information in making social predictions (Gelfand et al., 2000). In addition, compared to Easterners, Westerners have higher self-esteem (Heine et al., 1999; Hetts, Sakuma, & Pelham, 1999), place heavier emphasis on self-consistency (Choi & Choi, 2002; Kashima, Kashima, et al., 2004; Suh, 2002), have a greater tendency to project one's own emotions to others (Cohen & Gunz, 2002), have better memories of information encoded in relation to the personal self (Wagar & Cohen, 2003), are more likely to make choices to highlight personal uniqueness (Aaker & Schmitt, 2001; Iyengar & Lepper, 1999; Kim & Drolet, 2003; Kim & Markus, 1999), feel more obliged to justify their personal choices (Heine & Lehman, 1997b), and are more likely to display egocentric biases in self-appraisals such as self-enhancement on individualist traits (viewing themselves as being more intelligent, unique, and independent than they really are; Gelfand et al., 2002; Heine & Lehman, 1997a; Hetts et al., 1999) and unrealistic optimism (perceiving the self as more invulnerable and more likely to experience positive events than it really is; Chang, Asakawa, & Sanna, 2001; Heine & Lehman 1995).

Finally, pursuit and attainment of interdependent goals and quality of interpersonal relationships are

better predictors of life satisfaction for East Asians than for European Americans, whereas self-esteem, identity consistency, personal freedom, pursuit and attainment of individual goals, and personal affect are better predictors of life satisfaction for Westerners than for Easterners (Diener & Diener, 1995; Kwan, Bond, & Singelis, 1997; Oishi & Diener 2001; Schimmack Radhakrishnan, Oishi, Dzokoto, & Ahadi, 2002; Suh, 2002; Suh et al., 1998).

Unlike procedural knowledge, which consists of automated productions resulting from repeated performance, person representations are propositional representations of people (including the self) abstracted from cultural experiences (see Koo & Choi, 2005). Such experiences provide materials for reflections on the self, other people, and the society and its norms. Furthermore, prevalence of cultural practices supporting a certain representation renders it highly accessible. In line with this principle, there is evidence that cultural practices that promote personal agency and self-esteem are more prevalent in the United States than in Japan (Kitayama et al., 1997; Morling et al., 2002), whereas cultural practices that promote adjustment to social constraints are more prevalent in Japan than in the United States (Morling et al., 2002). Furthermore, after individuals of a particular cultural group have engaged in a new culture for a prolonged period of time, their new experiences may render a previously inaccessible person representation accessible (Hetts et al., 1999).

Indeed, when an individual has constructed for the same referent several representations, each with different implications for a judgment or decision, the response that is made will depend on which representation is retrieved and used (see Wyer, 2004). Priming a particular self-representation can increase the temporary accessibility and hence the probability of retrieving and using this representation. As mentioned, the representation of the self as an independent entity is more accessible to Westerners than to Easterners. However, subsequent to being primed with an interdependent self, Westerners use group memberships rather than personal attributes to describe oneself (Trafimow et al., 1991; Trafimow, Silverman, Fan, & Law, 1997), adhere more strongly to collectivist values than individualist values (Gardner, Gabriel, & Lee, 1999), exhibit a greater tendency to mimic the interaction partner's behaviors (van Baaren et al., 2003) and a lesser tendency to assert one's uniqueness (Kim & Drolet, 2003), and attend more closely to the common ground in communication (Haberstroh et al., 2002).

In summary, person representations are propositional knowledge of people abstracted from cultural experiences. Although people in every culture may have constructed several different cognitive presentations of a person, the prevalence of cultural practices supporting certain person representations renders these representations more accessible than others. Chronic representations of the self provide premises for subsequent judgments and behaviors. Priming a particular self-representation can also increase the temporary accessi-

bility and hence the probability of retrieving and using this representation.

Event Representations

People spontaneously construct mental representations of temporally and thematically related sequences of events. An event representation allows individuals to picture in their mind a state of affairs or an event in a specific situation and how it transforms into another state or event. To capture the gist of the event sequence, a caption or header (e.g., "visiting a restaurant") can be attached to the event representation (see Wyer, 2004).

When an event representation becomes widely shared in human group, it becomes a cultural script. One widely studied cultural script in the United States is the culture of honor that persists in the American South (Cohen, 1996, 1998; Cohen & Nisbett, 1997). In the United States, Caucasian Americans in the South are thrice as likely as Caucasians in the North to commit conflict-, argument-, or brawl-related homicides (Cohen, 1998; Nisbett, 1993; Nisbett & Cohen, 1996). In addition, compared to Caucasians in the North, those in the South are more accepting of the use of violence for self-protection, to answer an affront, or to socialize children (Cohen, 1996). In the Old South where the law was weak, citizens had to depend on themselves to protect their own life, families, and wealth. Tolerance of insults became a symbol of vulnerability to predation, whereas violence in response to aggression and insults was an indication of one's determination to get even with the aggressor. Although the need for the use of violence as a means of self-protection has diminished, pockets of the culture of honor still persist in the South.

A cultural script consists of sequentially connected frames. When a frame is activated, the subsequent frames are activated as well. The script for the culture of honor contains the following frames:

Frame 1: A man receives negative remarks on himself and his family.
Frame 2: He interprets the remarks as an insult and an attack on his honor.
Frame 3: This thought infuriates him, and he wants to retaliate.
Frame 4: He uses or threatens the use of violence to coerce submission from the perpetrator as a means to restore his honor.
Frame 5: Regardless of the outcome, he feels proud for standing up against an attack on his honor and sees defending one's honor with violent acts as justified and honorable.

In societies in which the culture of honor prevails (e.g., the American South, Brazil, and Chile), violence in response to an attack on one's honor is often seen as justified and not blameworthy (Cohen & Nisbett, 1997; Vandello & Cohen, 2003). In addition, men who feel that their honor has been damaged would feel angry, display dominant behaviors, and be physically prepared to use

aggression (as revealed in an increase in cortisol and testostereone level; Cohen, Nisbett, Bowdle, & Schwarz, 1996).

Prototypical event representations are representations of events that routinely occur in a certain type of situation. A prototypical event representation can function as an "implicit theory" about the events that occur in a particular type of situation (Wyer, 2004). Cross-cultural differences in implicit theories have been reported. Two types of implicit theories have received the most attention in cultural psychology.

A widely researched implicit theory is the belief in the fixedness or malleability of people and the world. Cultures differ in the nature of these representations. Su and colleagues (1999; Norenzayan, Choi, & Nisbett, 2002) found that East Asians are substantially more likely to believe that the world is relatively fixed and individual persons relatively malleable (Chiu, Dweck, Tong, & Fu, 1997). If these implicit theories are used as guides for relating the self to the social environment and as premises for making causal inferences, East Asians should be more inclined to adjust to their social environment than to influence it, whereas North Americans should have the reverse preference. In addition, East Asians should be less inclined than North Americans to explain social behavior with the actor's global traits but relatively more inclined to reference external forces (dispositions of the group and situational constraints) in their social explanations. Both predictions have received clear empirical support (Chiu, Morris, Hong, & Menon, 2000; Menon et al., 1999; Miller, 1984; Miyamoto & Kitayama, 2002; Morling et al., 2002; Morris & Peng, 1994; Norenzayan, Choi, & Nisbett, 2002; Peng & Knowles, 2003).

People in different cultures also construct different implicit theories of change. For example, a widely held belief in Confucian societies (e.g., China and South Korea) is that two opposing forces, manifest in various forms in nature (the weak vs. the strong; evil vs. divine, illness vs. health, coldness vs. warmth, darkness vs. light, bad vs. good fortune), push themselves into the place of the other, resulting in changes. According to this view, similar to how the sun and moon continually emit their light, good fortune and ill are continually prevailing each against the other by an exact rule. This exact rule mandates a cyclical trajectory of changes. The continual prevailing of opposing forces gives rise to a stable reality, because all transient changes engendered by one force will be canceled out by the changes instigated by its opposing force. Thus, these beliefs about the trajectory of change may reinforce the belief in a fixed reality (Chan et al., 2001; Peng & Nisbett, 1999).

In contrast, since the beginning of the industrial revolution, optimism and the belief in incremental change and progress have dominated the social philosophy in Western Europe and the New World. The intellectuals witnessed how their world was being transformed into one of iron, coal, and steam; of machinery and engines; and of railroads, steamships, and telegraph wires. They were optimistic about the future; they believed that a better world lay just around the corner, and the making

of it was in people's own hand (Burchell, 1966). Theories of biological evolution and economic development that surfaced at that time forecast the extinction of unfit species, the decline of maladaptive social systems, the domination of the superior species, and the rise of more advanced social systems. These beliefs about the trajectory of change support a malleable view of the world and its institutions.

These culture-characteristic beliefs about the trajectory of change continue to have authority over Chinese and North American students. When things are moving in a particular direction, compared to their American peers, Chinese undergraduates are more likely to anticipate change in direction of movement. For example, they believe more strongly that a couple who have been dating each other for 2 years will break up, someone who has been a chess champion for 3 years will lose in the next game, a student from a poor family will become rich one day, two kindergarten children who have been fighting will become friends one day, and a trend in the growth rates of the world economy or the worldwide death rate for cancer will reverse in the future (Ji et al., 2001). Furthermore, individuals who expect the development of events to change course should be less surprised by unexpected events than those who expect events to develop following a linear trend. Consistent with the idea that East Asians subscribe to a cyclical theory of change and Americans a linear theory, Korean undergraduates exhibit a stronger hindsight bias than do their U.S. counterparts (Choi & Nisbett, 2000).

The belief that opposing forces operate together also increases the sensitivity to competing concerns in conflict situations and the motivation to reconcile them. In one study, Peng and Nisbett (1999; Cheung et al., 2003) had Chinese and American students analyze everyday life situations that involve intrapersonal conflicts (e.g., a conflict between having fun and going to school) or interpersonal conflicts (e.g., a conflict between mothers and their daughters). Consistent with the idea that the Confucian theory of change is more widely distributed in Asia than in the United States, Chinese responses tended to focus on the reconciliation of contradiction by considering merit and fault on both sides ("both the mothers and the daughters have failed to understand each other"). In contrast, American responses tended to come down in favor of one side or the other ("mothers should respect daughters' independence").

Norm Representations

A norm representation is an implicative proposition consisting of three elements: the antecedent circumstances, the norm, and the consequent conditions (Lindahl & Odelstad, 2000). The antecedent conditions specify the activation circumstances of the representation. They include the range of concrete situations where the norm is applicable. The norm refers to the state of affairs that is generally believed to be the case (e.g., the shared belief that the needy will receive help). In constructing a norm representation, individuals need to have access to the dis-

tribution of social knowledge in the society (e.g., they need to know the extent of agreement in the group with the idea of helping the needy—Ho & Chiu, 1998; Lau, Chiu, & Lee, 2001; Wan et al., in press; Wan, Chiu, Peng, & Tam, in press). Finally, the consequent conditions specify the behavioral implications of the norm. When the antecedent circumstances are present in a given situation, a certain state of affairs is designated as the norm, and the individual is expected to see to it that this state of affairs will take place. Because norm representations are implicative propositions, they have direct authority over behavior.

Cultural norms are widely distributed norm representations. For example, a highly uniform norm in the United States is one for experiencing emotions—Americans agree that they *should* feel happy (Eid & Diener, 2001). Americans who can live up to cultural expectations for experiencing positive emotions have higher levels of life satisfaction (Schimmack et al., 2002).

Different cultures have different norms. For example, in resolving conflicts, the prevailing norms in East Asian societies prescribe the use of mediational and accommodating strategies to minimize interpersonal animosity. In contrast, the prevailing norms in Western countries prescribe the use of more direct, confrontational strategies to win the negotiation game (Adair, Okumura, & Brett, 2001; Derlega, Cukur, Kuang, & Forsyth, 2002; Gelfand et al., 2001; Ohbuschi, Fukushima, & Tedeschi, 1999).

In summary, cultural differences can be understood in terms of the differing contents of the widely circulated and highly accessible knowledge structures in different cultures. Defining a culture tradition in terms of its component knowledge items (procedural knowledge, person representations, event representations, and norm representations) invites researchers to articulate clearly the type and nature of each knowledge item, as well as its range of applicability, activation circumstances, and inferential and behavioral implications. For example, environmental affordances support the development of procedural knowledge, which is activated automatically in the presence of the controlling situational cues. Activation of a particular self-construal (e.g., interdependent self) will call out its associated behaviors (e.g., behavioral mimicry). The applicability of a norm is augmented in situations in which cultural identities are salient (Jetten, Postmes, & McAuliffe, 2002), and when people are accountable to their cultural group for their behaviors (Briley, Morris, & Simonson, 2000; Gelfand & Realo, 1999).

THE INDIVIDUAL AND THE CULTURAL

Cultural knowledge, once activated, constrains subsequent behaviors. However, not all behaviors are expressions of cultural knowledge. Aside from cultural knowledge, every individual has some idiosyncratic personal experiences. In addition, regardless of their cultural background, all individuals have some basic psychogenic needs (such as the need for positive self-regard). Behaviors are the result of the dynamic interaction of basic psychogenic needs, cultural knowledge, and personal experiences.

Cultures also differ in how these three elements work together. First, some cultures emphasize personal experiences, whereas others emphasize conformance to cultural norms. For example, conformity is more emphasized in Asia than in North America. Indian adolescents value conformity more than do U.S. adolescents (Sundberg, Rohla, & Tyler, 1970). Hong Kong Chinese students are more likely to shift their opinions in the direction of the majority than are U.S. undergraduates (Meade & Barnard, 1973). In a quiz, compared to their U.S. peers, Taiwan Chinese are more likely to conform to their coparticipant's answer, particularly when the coparticipant seems to be knowledgeable about the topic (Huang & Harris, 1973). In the United States, people who have higher satisfaction have more intense positive affect and less intense negative affect. By comparison, in collectivist countries (e.g., China, Indonesia, and Colombia), both emotional experiences and norms regarding life satisfaction (how satisfied the ideal person would feel about his or her life) predict life satisfaction. In these countries, people who have high life satisfaction have pleasant emotional experiences, *and* expect the ideal person to have high life satisfaction (i.e., they view having a high level of life satisfaction to be a socially desirable characteristic cherished by the ideal person in their culture; Suh et al., 1998).

Second, a behavior mediated by personal attitudes in one culture may be mediated by cultural norms in another culture. Joan Miller and her colleagues (Baron & Miller, 2000; Miller & Bersoff, 1992, 1994, 1998; see also Janoff-Bulman & Leggett, 2002) reported that in North America, individual rights and freedom form the ultimate criteria for judging the moral correctness of social actions. Reciprocal helping is more often categorized as a personal choice rather than as a moral duty, and whether one feels the obligation to help another person is often affected by how likable the target is. According to Miller and Bersoff (1998), the American's tendency to consider liking for the target in assessing moral responsibilities to help may reflect a voluntaristic view of social relationship in U.S. culture. In contrast, in India, duties form the ultimate criterion for evaluating the moral rightness of social action. Helping is morally required, and reciprocal prosocial behavior is seen as a moral obligation instead of a social exchange.

Finally, cultures may also differ in the relationship between self-motives and cultural norms. Self-motives and cultural norms may act in concert to produce the same behavior in some cultures and push behaviors into opposite directions in others. In the United States, both the need for self-esteem and the dominant cultural norm lead individuals into self-enhancement (Bond, Leung, & Wan, 1978), and research has found consistent self-enhancement biases among European Americans on a wide variety of measures (Davis & Stephan, 1980; Miller & Ross, 1975). In contrast, in Asian cultures, unbridled expression of the positive self goes against the norm of mod-

esty (Bond, Leung, & Wan, 1978; Kim, Kim, Kam, & Shin, 2003), and overt expressions of the positive self are permissible only under certain circumstances. As a consequence, in these cultures, self-enhancement is relatively infrequent (Akimoto & Sanbonmatsu 1999; Gelfand et al., 2002; Heine & Renshaw, 2002; Oishi et al., 2000; Ross, Heine, Wilson, & Sugimori, 2005), particularly in public situations (Kanagawa, Cross, & Markus, 2001). The seeming lack of self-enhancement in public arenas among Japanese has led some researchers (Heine et al., 1999; Kitayama, Takagi, & Matsumoto, 1995) to conclude that the Japanese may not have the need for positive self-regard.

However, a closer examination of the empirical evidence reveals that like Americans, Asians also have the need for positive self-regard; they do not self-enhance as much as their American peers do because of the relatively heavy emphasis on conformance to the modesty norm in Asian contexts (Kurman, 2001, 2003; Kurman & Sriram, 1997). In situations in which the norm of modesty is not enforceable, as when all responses are completely anonymous, Japanese also self-enhance (Kudo & Numazaki, 2003). In addition, Japanese display self-enhancing responses when self-enhancement is measured via implicit or indirect measures (Kitayama & Karasawa, 1997; Kobayashi & Greenwald, 2003; Muramoto, 2003). Japanese also exhibit self-enhancement biases (feel confident in their performance, and review the performance feedback when they outperform their competitor) in a competitive situation, where the goal of winning is more important than the goal of being modest (Takata, 2003). Finally, although Asians feel compelled to display humility when presenting their agentic qualities, they feel comfortable in exaggerating their positive communal qualities (e.g., cooperation). Several studies have shown that while European American undergraduates self-enhance more on agentic traits than do their Asian peers, Asian undergraduates self-enhance *more* on communal traits (Kobayashi & Brown, 2003; Kurman, 2001; Lalwani, Shavitt, & Johnson, 2006; Sedikides, Gaertner, & Toguchi, 2003).

In short, to understand behaviors in cultural contexts, it is not enough to just describe the relative distributions of individual knowledge items. It is also important to consider the dynamic interactions of universal motives, cultural knowledge, and personal experiences. In some cultures, these elements may be unrelated. In other cultures, they may reinforce each other, or compete with each other for authority over behavior.

PRINCIPLES OF CULTURAL KNOWLEDGE APPLICATION

Taking the knowledge perspective to culture allows researchers to apply basic principles of knowledge application to predict how culture works in concrete situations. Application of knowledge activation principles to cultural knowledge has shed light on how cultural knowledge impacts behaviors in concrete situations.

Chronic Accessibility

A body of cultural knowledge gains chronic accessibility when it has been used frequently. Cultural knowledge items that have been frequently used in a group are usually widely shared (Lau et al., 2001; Sechrist & Stangor, 2001), more frequently reproduced in communication (Lyons & Kashima, 2001, 2003), widely represented in external or public carriers of culture (Menon & Morris, 2001), and cognitively accessible to members of the group (Hong et al., 2000). We have illustrated with many examples how chronic accessibility in procedural and declarative knowledge may mediate a wide range of cultural differences.

Temporary Accessibility

Contextual cues may increase the temporary accessibility of a body of knowledge and momentarily raise the probability that this body of knowledge will be applied. We have described how priming a specific representation of the self calls out its associated cognitive and behavioral responses. Recently, researchers have applied the principle of temporary accessibility to illuminate the process of cultural frame switching.

Flexible switching of cultural frames is an experience familiar to people with multicultural background. When individuals who have engaged in both Chinese and American cultures (e.g., Chinese Americans and Westernized Hong Kong Chinese undergraduates) are primed with either Chinese cultural icons (e.g., the Chinese dragon) or American cultural icons (Mickey Mouse), they assimilate their responses into the primed culture (Hong et al., 1997, 2000). When primed with Chinese (vs. American) cultural icons, these bicultural individuals make more group attributions and fewer individual attributions. Analogous culture priming effects have been found on spontaneous self-construal (Ross, Xun, & Wilson, 2002), perception of physical events (Peng & Knowles, 2003), encoding and memory of person information (Sui, Zhu, & Chiu, in press), spontaneous inference of cultural values (Fu, Chiu, Morris, & Young, in press), and cooperative behavior (Wong & Hong, 2005). In addition, the culture priming effect has been reported in studies that used different bicultural samples (Chinese–Canadian, Dutch–Greek bicultural children), and a variety of cultural primes (e.g., language and experimenter's cultural identity; Ross et al., 2002; Verkuyten & Pouliasi, 2002).

Applicability

The probability that a knowledge item will be applied also depends on its applicability in the immediate context. Knowledge applicability is defined in terms of the extent of mapping between "the features of a stored construct and the attended features of a stimulus" (Higgins & Brendl, 1995, p. 220). In a series of culture priming experiments, Hong and colleagues (2003) found that among Chinese American bicultural individuals, culture priming affects the likelihood of making group attribu-

tion or individual attribution only when the tension between group agency and individual agency in the stimulus event is highlighted, rendering the cultural theory of group versus individual agency applicable in the judgment task. Furthermore, previous research has shown that in Chinese societies, the norm of cooperation applies to friendship but not to interactions with strangers (Ho & Chiu, 1994). Consistent with the principle of applicability, Hong Kong Chinese primed with Chinese (vs. American) culture icons make more cooperative choices when they play a prisoner's dilemma game with friends, but not when they play it with strangers (Wong & Hong, 2005).

Motivation and Cognitive Load

Culture is like a collection of chronically accessible cognitive tools (DiMaggio, 1997). Consistent with this analogy, research has shown that people are likely to use these tools when the situation calls for a readily available or conventionalized solution, or when the problem solver lacks the capability, motivation, or resource to consider alternative solutions (Knowles, Morris, Chiu, & Hong, 2001).

Cultural differences also tend to accentuate when people have high chronic need for cognitive closure (the need for a certain answer). For the Chinese, high need for cognitive closure is positively related to the tendency to make group attributions, whereas for European Americans, high need for cognitive closure is positively related to the tendency to make individual attributions. Situational inducement of the need for cognitive closure by manipulating time pressure produces a similar effect. Putting the Chinese under time pressure and thus increasing their need for cognitive closure increases their tendency to make group attribution. Conversely, putting European Americans under time pressure increases their tendency to make individual attribution (Chiu et al., 2000; Fu et al., in press).

This finding has important implications for understanding the acculturation pattern of new immigrants. Individuals with a high need for cognitive closure rely on readily available knowledge to resolve interpretive ambiguity. However, when the readily available knowledge is no longer seen as applicable, they will eagerly seize new knowledge from their surrounding to reduce interpretive ambiguity. Consistent with this idea, Kosic, Kruglanski, Pierro, and Mannetti (2004) found that immigrants who are surrounded by other members of their ethnocultural group perceive the knowledge of their home culture as applicable. For them, a higher need for cognitive closure is associated with a stronger motivation to adhere to the culture of origin. Conversely, immigrants who are surrounded by members of the host country no longer perceive the knowledge of their home culture as applicable. For them, a higher need for cognitive closure is associated with a stronger motivation to assimilate into the host culture.

People rely on readily accessible knowledge when they lack cognitive resources. If cultural knowledge is chronically accessible knowledge, people will use it particularly when they are cognitively busy. Consistent with this hypothesis, European Americans have a greater tendency to make individual attribution than do Chinese, but only when they are under cognitive load. When individuals are not cognitively busy, this cultural difference is significantly attenuated (Knowles et al., 2001; Lieberman, Jarcho, & Obayashi, 2005).

Self and Contrast Effect

People who are primed with a social category tend to assimilate their response into the primed category. For example, university students walk more slowly than they normally do after they have been subliminally primed with the "elderly" stereotype (Bargh, Chen, & Burrows, 1996). However, activation of social stereotypes can also result in automatic behavioral contrast if a comparison of the self to the stereotyped group is provoked. For example, when university undergraduates are primed with the self and the elderly stereotype, a comparison intention is activated. They may feel that they do not belong to the elderly category and display a behavioral contrast (see Dijksterhuis et al., 1998; Dijksterhuis, Spears, & Lepinasse, 2001; Schubert & Hafner, 2003; Spears, Gordijn, Dijksterhuis, & Stapel, 2004).

As noted, priming a culture often leads to assimilative responses. However, if the participants feel that they do not belong to the primed culture, culture priming may lead to contrastive responses. Bond and his colleagues have reported contrast effects in a study that used languages as culture primes. In this study (Yang & Bond, 1980), Chinese–English bilingual participants responded to a Chinese value survey. They showed stronger adherence to Chinese values when the survey was in English than in Chinese. In this case, the presence of an outgroup language reminded the participants that they did not belong to the primed cultural group. As a consequence, a contrast effect was found. In another study (Bond & Cheung, 1984), Cantonese-speaking Hong Kong Chinese undergraduates filled out a survey of traditional Chinese beliefs. Mainland Chinese are generally seen as more traditional than Hong Kong Chinese. Participants who received oral instructions in Putonghua (the spoken language in Mainland China) responded more like Westerners, compared to those who received instructions in Cantonese (a dialect used in Hong Kong).

Some bicultural individuals view their dual cultural identities as oppositional (I cannot be both a Chinese and an American at the same time), while others see them as independent or complementary (e.g., I am both a Chinese and an American; Benet-Martinez, Leu, Lee, & Morris, 2002; Tsai, Ying, & Lee, 2000). Variations in how dual identities are managed are related to bicultural individuals' responses to cultural priming. Those who view their dual identities as independent or complementary tend to assimilate their responses to primed culture. Those who view their dual identities as oppositional may feel ambivalent about either cultural identity and thus respond reactively to the cultural primes, displaying contrastive responses (Benet-Martinez et al., 2002). In

summary, activation of cultural knowledge follows the basic principles of knowledge activation, which govern the dynamic interactions between cultural knowledge, the situation, the individuals' current cognitive and motivational states, and cultural identities.

WHAT IS CULTURE FOR?

Cultural knowledge is a collective resource accumulated over time. This resource is used to attain collective and individual goals. A major research objective in the social psychology of culture is to identify the societal and psychological functions of culture and to explain how culture evolves.

Societal Functions of Culture

It is widely accepted that culture is a collectively constructed device to solve coordination problems (Cohen, 2001; Fiske, 2000; Heylighen & Campbell, 1995; Kashima, 1999). To ensure that individuals facing coordination problems will make joint decisions that produce optimal outcomes to all parties involved, several major types of social control mechanisms have evolved in human societies. The most rudimentary type is mutual monitoring. Through informal face-to-face transmissions, the involved parties agree on some common beliefs and practices, and those with deviating beliefs or patterns of behaviors are held in check by different forms of ostracism. Individuals may also internalize and identify with these beliefs and practices. Indeed, according to Heylighen and Campbell (1995), in human societies, beliefs spread through conformist transmission and internalization are often the predominant mechanisms of social control. These beliefs are then crystallized into cultural knowledge.

Successful solution of complex coordination problems also requires coordination of plans and actions. In addition to being a social control mechanism, culture also provides the shared, standard operating procedures, unstated assumptions, tools, norms, and values for grasping experiences (Triandis, 1996). As such, by virtue of culture, individuals are capable of constructing shared representations of their experiences, and coordinating their plans and actions (Kashima, 1999).

Furthermore, culture provides conventionalized solutions to recurrent coordination problems (Kashima, 1999). Culture is to society as what memory to individuals (Kluckhohn, 1954). Culture encodes collective memories of schematized approaches to solving coordination problems (Kashima, 1999). These conventionalized solutions are widely accepted solutions in the community. Competent members of the culture can retrieve such conventionalized solutions to solve emergent coordination problems.

In short, coordination problems arise in all human communities in which people need to make joint decisions on problems with more than one possible optimal solution. Culture provides different means for solving such coordination problems.

Psychological Functions of Culture

Culture also serves several psychological functions. First, it serves to reduce uncertainty in social living. Because cultural knowledge is widely distributed in a human group, it serves an epistemic function by offering individuals a socially validated perspective for grasping experiences (Kosic et al., 2004). Knowing that others share one's own knowledge increases confidence in the knowledge. For example, individuals who learn that others share their attitudes increase their confidence in the attitudes and the likelihood of using these attitudes to guide their behavior (e.g., Sechrist & Stangor, 2001). Accordingly, cultural knowledge, as a kind of socially validated knowledge, has greater authority over behaviors, compared to personal knowledge.

Because cultural knowledge affords a sense of epistemic security, or the feeling of having certain answers to questions in life, when people need certain answers, they may tend to rely on cultural knowledge. For this reason, cultural knowledge is particularly likely to be used when people are under cognitive load or time pressure (Chiu et al., 2000; Knowles et al., 2001).

Second, cultural knowledge may provide a buffer against the anxiety arising from the vulnerability of the individual. According to the terror management theory (Greenberg, Solomon, & Pyszczynzki, 1997), the thought of death is anxiety provoking. Because cultural knowledge is reproduced across generations, it outlasts the individual. By identifying with their cultural tradition, individuals may feel that they are a part of the imperishable cultural tradition and hence feel not as terrified by the thought of death. The idea that culture may offer a psychological buffer against existential terror has received some support. Making salient the threat of mortality strengthens adherence to individualist values among Australians and weakens it among the Japanese (Kashima, Halloran, Yuki, & Kashima, 2004). In addition, among Aborginal Australian bicultural individuals, mortality salience increases adherence to Aborginal values when the Aborginal identity is primed, and adherence to Australian values when the Australian identity is primed (Halloran & Kashima, 2004).

Finally, individuals need culture when they need to feel that they belong to a group. By identifying with the group and its culture, individuals fulfill their need for belongingness. The knowledge tradition of a group is a defining feature of the group (D'Andrade, 1987). When the need to belong to a group is activated, people who identify strongly with their ingroup will be motivated to adhere to the group's knowledge tradition (Heaven, 1999; Heaven, Stones, Simbayi, & Le Roux, 2000; Hong, Chiu, Yeung, & Tong, 1999; Lam, Lau, Chiu, Hong, & Peng, 1999) and will defend their cultural identity by affirming their cultural knowledge tradition (Jetten et al., 2002).

The need to belong may change across situations. The need to belong to the ingroup will be stronger either when people realize that they are different from other members of the ingroup or when they realize that they are not different from members of an outgroup (Brewer,

1991; Pickett & Brewer, 2001; Picket, Bonner, & Coleman, 2002). In addition, when people see visual icons of their group, they tend to see themselves as members of a group rather than as individuals (Briley & Wyer, 2002). When the need to belong is induced, people tend to adhere to the group's cultural tradition. In summary, people need culture to satisfy basic social and psychological needs, including the needs to reduce uncertainty in social living, to manage existential terror, and to fulfill the need for belongingness.

HOW DOES CULTURE SPREAD?

Culture is a shared phenomenon. Through communication, people make the contents of their mind accessible to others. Not surprisingly, dynamical systems theorists have attempted to explain how culture spreads through interpersonal communication. For example, Kashima, Woolcock, and Kashima (2000) have developed a connectionist model to account for the reproduction and stabilization of cultural meanings in a group. The model assumes that cultural ideas are not evenly distributed across members of a group. Individuals in a group resemble simple processing units in a network. These units receive information from each other and reproduce the information through the network. The network of connections is updated as serial reproductions proceed. Due to memory decay and schema-driven distortions, errors are introduced in the reproduced messages. In addition, to overcome the cognitive limits of the individual processing units, cognitive division of labor and externalization of memory are implemented. Through self-organization processes, cultural knowledge that is widely shared among group members (e.g., stereotypical knowledge) will have a high likelihood of being reproduced and consolidated in communication.

This kind of connectionist models has several conceptual advantages. First, it explains how cultural knowledge and meanings are reproduced and maintained in everyday interpersonal communication. Second, it relies on a set of self-organizational processes to produce and maintain shared meanings spontaneously. Thus, it does not require a homunculus-like agent or a collective will to oversee or manage the reproduction of cultural meanings. Third, the model is specific enough to permit precise simulation of the postulated cultural meaning reproduction processes in controlled experiments. Findings from such experiments have lent support to the proposed model (Lyons & Kashima, 2001, 2003).

Communication theories have also been recruited to explain spatial distribution of shared attitudes and beliefs. According to dynamic social impact theory (Latane, 1996), people influence and are influenced by the proximal people with whom they communicate. Through interpersonal communication, a set of values and beliefs become spatially differentiated (or clustered), and previously unconnected values and beliefs become correlated (see also Brauer, Judd, & Jacquelin, 2001). These self-organization processes have been demonstrated in computer simulations (Latane & Bourgeois, 1996; Latane & L'Herrou, 1996), in computer-mediated communication games, and in a longitudinal study of college students' political socialization in their academic discipline (Guimond & Palmer, 1996).

HOW DOES CULTURE CHANGE?: A FUTURE RESEARCH AGENDA

Culture is constantly being reproduced, but culture also changes. In a recent review of the extant literature in culture and psychology, Lehman and colleagues (2004) noted a lopsided emphasis on cultural differences in the psychological research and concluded that consideration of how societies adapt to globalization and culture change will become more and more important in the coming years.

Culture change may occur because of endogenous and exogenous reasons. Endogenous culture change may take place through the processes of differentiation. According to Triandis (2004), a cultural idea that works well may be replaced by an idea that works slightly better, but frequently both tools are retained in the culture. Accordingly, random variation and selective retention result in different dimensions of cultural variation.

Exogenous culture change often results from intercultural contacts, through which people from a culture are incidentally exposed to knowledge from another culture. With rapid development of electronic communication, people find themselves increasingly enmeshed in global symbolic environments (Bandura, 2002). As cultural boundaries become increasingly permeable and fuzzy, intercultural contacts could take place without face-to-face contacts with members of other cultures.

Culture change often involves complex transactions between old and new cultural knowledge in the society. In many developing countries, the arrival of the global culture has also brought forward cultural identity issues that are intertwined with complicated socioeconomic and political issues (Hong et al., in press). Some of these issues have caught psychologists' attention. For example, Arnett (2002) noted that with globalization, people worldwide now face the issue of relating to their local culture and the global culture. How would individuals react and relate to the confluence of the local and global cultures? What would the resulting bicultural identity be like (Orr, Mana, & Mana, 2003; Tafarodi, Kang, & Milne, 2002)? How can people navigate multiple cultures competently (Chiu & Hong, 2005)? How do people manage knowledge from different cultural traditions (Arends-Toth & Van De Vijver, 2003)? What are the implications of individuals' responses to multiculturalism for psychological well-being (Downie, Koestner, ElGeledi, & Cree, 2004)? The field of culture change is one with many questions and few answers. Yet, answers to these questions are of foremost importance as they will connect cultural psychology to the psychology of social identification, political psychology, and other social science disciplines.

CONCLUDING REMARKS

> Every science passes through a phase in which it considered
> its basic subject matter to be some sort of substance or
> structure. Every science has passed beyond that phase,
> recognizing its subject matter as being some sort of process.
> —Bickhard (2003, p. 122)

Similar historical shift is beginning to take place in the social psychology of culture. The current focus in the social psychology of culture is still on some sort of substance or structure: How do cultures differ? What are the deep structures of cultures? However, there is increasing recognition that to explain culture, we need to understand cultural processes. Bickhard (2003) submits that causality resides in process, not substances. A paradigmatic shift in physics occurred when physicists recognized that there are no particles. What appear as particle interactions are actually quantized oscillatory processes. Unlike particles, which are supposed to take on some irreducible forms, quantum fields are organized processes. In quantum physics, all causal power is resident in process organizations, and new organizations of process give rise to higher-level phenomena (Bickhard, 2003). Extending this view to the social psychology of culture, explaining culture involves identification of basic principles that give rise to organized cultural processes.

In this chapter, we adopted a knowledge perspective to culture, which places a strong emphasis on organized cultural processes. From the knowledge perspective, culture consists of a collection of loosely organized shared knowledge constantly being created, maintained, reproduced, and transformed by a collection of interconnected individuals. Cultural differences in behavior are understood not with reference to differing deep structures in different cultures but in terms of specific knowledge structures. Each knowledge structure has a specified range of applicability. Thus, instead of focusing on global cultural differences, our analysis focused on the social psychological consequences when specific knowledge structures are activated in concrete situations. In addition, cultural meanings are created, maintained, reproduced, and transformed for adaptive purposes. Thus, explaining cultural processes also demands attention to culture's social and psychological functions.

PART VI

APPLICATIONS OF SOCIAL PSYCHOLOGY

Psychology and the Law

Reconciling Normative and Descriptive Accounts
of Social Justice and System Legitimacy

Tom R. Tyler

John T. Jost

> The fundamental problem of a correct psychological doctrine is not why a hungry man steals
> but the exact opposite: Why doesn't he steal?
>
> —Reich (1934/1989, p. 158)

The legal system is a codified set of rules developed to regulate interactions and exchanges among people. The authorities who make and implement legal rules draw on a fairly wide range of sources in seeking to understand, predict, and control human behavior. Some of these sources are purely cultural, in the sense that they reflect received wisdom that is passed down within specific traditions, including philosophical, civil, and political traditions. These traditions contain commonsense explanatory frameworks for understanding and regulating human behavior—"folk psychologies" in which behavior is caused by individual beliefs, desires, and intentions (e.g., Dennett & Haugeland, 1987). The extent to which folk psychology is accurate is a matter of persistent debate among philosophers, cognitive scientists, and others (Greenwood, 1991; Wegner, 2002), but there can be little doubt that it is pervasive and influential in legal contexts and countless other social situations (e.g., Malle, 2004).

In addition to cultural sources of knowledge concerning the putative causes of human behavior, there are also scientific sources that may be considered (to varying degrees) by legislators, judges, juries, and other legal decision makers when they are creating and implementing laws. The possibility exists, therefore, that current scientific opinion about the "facts" of human nature can influence the legal system (see Blasi & Jost, 2006). Research on core topics in law and psychology—including the accuracy of eyewitness testimony, the fairness of police lineups, jury decision making, and attitudes toward the death penalty—has affected legal practice, at least to some degree (e.g., Ellsworth & Gross, 1994; Hastie, Penrod, & Pennington, 1983; Heuer & Penrod, 1989; Köhnken,

1996; Loftus, 1979; Monahan & Loftus, 1982; Wells, Leippe, & Ostrom, 1979). There is also the possibility that psychology can motivate attempts to reform the legal system (i.e., to make laws more just), at least in part because it can provide a more accurate set of facts about the causes and consequences of human behavior (e.g., Carson, 2003; Haney, 1993; Kang, 2005; Krieger, 1995). In this way, psychology can contribute to the actual (as well as perceived) legitimacy of the legal system, although this process may be very slow indeed because of obstacles to interdisciplinary collaboration in general as well as the institutional conservatism inherent in legal and other social and political systems (e.g., Blasi & Jost, 2006; Meyer & Rowan, 1977; Zucker, 1977).

THE AIMS AND ACHIEVEMENTS
OF PSYCHOLOGICAL JURISPRUDENCE

Psychology can contribute to the field of law by providing legal scholars with the most accurate and up-to-date understanding of scientific knowledge possible in those areas of psychology that are most relevant for the legal system. We refer to this endeavor as *psychological jurisprudence*—the effort to shape law through knowledge of human psychology (Darley, Fulero, Haney, & Tyler, 2002). As has already been suggested, psychology as a discipline is always centrally relevant to the law, whether or not legal authorities recognize it. This is because, as Haney (1982) put it, "Laws embody theories of behavior. Legal rules, doctrines, and procedures necessarily reflect basic assumptions about human nature" (p. 191).

Psychological jurisprudence thus reflects a distinctly empirical perspective on the problems presented by the law. From this perspective, the legal conception of human action and responsibility should be based on scientific research addressing cognition, motivation, and behavior (see also Darley et al., 2002; Kang, 2005; Krieger, 1995). Much like proponents of the *legal realism* movement, we argue that the roots of effective legal doctrine must lie in an accurate understanding of the nature of the social world. Psychological jurisprudence carries this basic premise further by exploiting the methodological tools of psychology, including experimentation, in order to achieve *behavioral realism* (see also Blasi & Jost, 2006; Kang & Banaji, 2006; Krieger & Fiske, 2006). From this perspective, legal doctrines should have a strong empirical basis and should be linked explicitly to scientific evidence concerning the principles of human nature.

The Scope of This Chapter

The goal of psychological jurisprudence, as we have suggested, is to make legal assumptions about human nature as consistent with contemporary psychological knowledge as possible, that is, to close the gap between folk and scientific theories of the person. At the same time, it must be acknowledged that psychology is an evolving discipline, and scientific consensus about specific determinants of human behavior will change as new research results emerge. It is quite possible that a chapter on psychology and law 25 years from now will endorse different psychological principles than the ones that we emphasize today. What presumably will not change is the underlying value of shaping law with some attention to empirical conclusions drawn from contemporary psychological research.

In this chapter, we make no attempt to cover all the areas in which psychology is relevant to the field of law. Topics such as violence and the media, mental illness and criminal responsibility, the battered woman syndrome, eyewitness memory, effectiveness of polygraph tests, jury instructions and decision making, group profiling, and attitudes toward sentencing and capital punishment are reviewed comprehensively by Ellsworth and Mauro (1998) and are not revisited here. Instead, we focus on the implications of basic social psychological research for understanding human motivation in general and the specific types of motivation that lead people to obey the law and comply with legal authorities. Legal scholars and decision makers, we submit, would benefit considerably by reconceptualizing their approaches to regulation and taking into account a wider variety of instrumental and symbolic motivations, including the genuine desire to adhere to moral principles that are espoused by legitimate authorities on behalf of a just social system.

LAW AND THE PSYCHOLOGY OF HUMAN MOTIVATION

One of the main functions of the law is to regulate the behavior of the citizenry by maximizing the likelihood that people will comply with normative standards of conduct—that is, with socially shared definitions of acceptable conduct as they are enshrined in rules, norms, and laws. If the law is to be effective in fulfilling its regulatory role, most citizens must obey most laws most of the time (Easton, 1975; Tyler, 2006b). The need for legal authorities to secure compliance has been widely noted by legal scholars and social scientists. Fuller (1969), for instance, observed that "the lawgiver must be able to anticipate that the citizenry as a whole will . . . generally observe the body of rules he has promulgated" (p. 201). Decisions made by police officers and judges mean little if people fail to take them seriously, and laws lack importance if they do not affect public behavior (Tyler, 2006b; Tyler & Huo, 2002).

Although widespread behavioral compliance is necessary to the effective functioning of society, obtaining compliance cannot be taken for granted (e.g., Sherman, 1993). Because many laws restrict the ability of individual citizens to behave as they wish, people sometimes resist them. Mastrofski, Snipes, and Supina (1996) note that "although deference to legal authorities is the norm, disobedience occurs with sufficient frequency that skill in handling the rebellious, the disgruntled, and the hard to manage—or those potentially so—has become the street officer's performance litmus test" (p. 272). Their observational study of police encounters with the public in Richmond, Virginia, provides useful evidence concerning the frequency of noncompliance. Mastrofski and colleagues estimated an overall noncompliance rate of 22%. Citizens failed to comply with police requests 18% of the time when they were told to cease illegal behavior, 19% of the time when they were told to leave another person alone, and 33% of the time when they were instructed to stop some form of disorder. Similar results were obtained in a replication by McCluskey, Mastrofski, and Parks (1998) in Indianapolis and St. Petersburg. The overall noncompliance rate was 20%. Citizens resisted 14% of the time when asked to leave another person alone, 21% of the time when ordered to cease illegal behavior, and 25% of the time when told to stop engaging in disorder.

These studies investigated short-term compliance—that is, whether the person behaved as instructed—and not whether people willingly accepted the decisions made by the authorities, bought into their resolution of a problem, or believed that the restrictions on their behavior were reasonable or appropriate. However, as Mastrofski and colleagues (1996) note, "citizens who acquiesce at the scene can renege" (p. 283). In other words, if citizens fail to internalize legal restrictions, further police intervention will eventually be required. An important contribution of psychological jurisprudence, therefore, is to shed light on the question of how to best motivate public rule-following behavior, both in general and with respect to specific encounters with authorities (Darley, Tyler, & Bilz, 2003; Tyler, 2006b). The legal system depends on obedience, and the law and police officers and judges generally expect public deference. The power of the legal system to gain cooperation is substantially increased when strategies for obtaining deference

are based on an accurate and relatively complete model of human motivation.

PERSPECTIVES ON SOCIAL CONTROL

An underlying assumption of the legal system is that public deference is a desirable attribute. This view fits well with a "consensus" view of society (Dahl, 1956, Easton, 1965; Lipset, 1959; Parsons, 1967; Sears, 2003; Tyler, 2006a). From this perspective, all members of society benefit from stability and social order of the type produced by an effectively administered rule of law. Hence, it is beneficial when people obey the law, and facilitating such an outcome through legal authorities and institutions is an important goal.

In contrast to this perspective, "conflict"-based views of society, such as those associated with Marxism, realistic group conflict theory, social identity theory, and social dominance theory, look at society as composed of competing groups. Group distinctions may correspond to economic classes (e.g., rich vs. poor), or they could be based on ethnic or national group memberships (White vs. minority; native born vs. immigrant). However a given society is constituted, those groups that dominate through their control of cultural and economic institutions tend to establish rules that are designed to benefit their own group and recruit authorities (e.g., police) to enforce those rules. From this perspective, the rules are created and administered to benefit particular groups and will be only marginally likely to produce justice for the members of disenfranchised groups (in the best case scenario). In legal scholarship, the conflict view is reflected in the writing of Edelman and Scheingold, among others. To the degree that such a view of society is adopted, it is not unambiguously good to maintain social order. In fact, it would be better if people were to become more sensitive to injustice in the system and more resistant to the status quo; they would then be more mobilized to create social change.

The ways in which these perspectives diverge can be demonstrated by considering one legal procedure in particular—dispute mediation. It is often difficult within the legal system to produce dispute resolution decisions that are mutually acceptable to the parties who come to court. Mediation has become popular among legal authorities because it is found to produce more acceptable decisions, as reflected in both expressions of satisfaction on the part of disputants and long-term adherence to those agreements. Hence, the use of mediation is viewed by consensus theorists as a desirable way to manage everyday disputes involving landlords and tenants, merchants and customers, and many other parties.

However, from a community-organizing perspective that is sensitive to the presence of conflict in society, mediation is not so favorably evaluated. Mediation provides a mechanism by which the most highly motivated complainants can receive some measure of justice and satisfaction for their disputes. At the same time, it "cools out" those individuals who are most likely to be socially aware and committed members of the community. Once their individual level grievance has been settled, they have less motivation to join with others to work at a collective level to rectify injustices. So, for example, a merchant may engage in unfair pricing practices but resolve grievances individually only with those who are most angered by their actions. This saps energy from politically motivated collective action aimed at establishing regulations that would constrain the merchant to act more ethically. While we recognize that the consensus and conflict perspectives provide very different normative perspectives on issues of compliance and settlement, our focus is on the effectiveness of different approaches for motivating compliance, setting aside the ultimate desirability of being able to obtain widespread compliance.

THE DETERRENCE MODEL

In recent decades the exercise of legal authority has become increasingly associated with the use of threat and punishment aimed at deterring people from engaging in criminal behavior (e.g., Kahan, 1999; Nagin, 1998). From this perspective, the focus is (and should be) on the power of legal authorities and institutions to shape behavior by threatening to deliver (or by actually delivering) negative sanctions for rule breaking. Within legal circles, this way of viewing the relationship between legal authorities and citizens is referred to as the deterrence or social control model, and it is this model of human behavior that—for better or worse—currently dominates law and public policy.

Motivational Assumptions of the Deterrence Model

To implement deterrence strategies police officers carry guns and clubs, and they are empowered to threaten citizens with physical injury and incapacitation, among other penalties. The goal is to establish legal authority and, as Reiss (1971) points out, "The uniform, badge, truncheon, and arms all may play a role in asserting authority" in the effort to "gain control of the situation" (p. 46). The police thereby seek to gain control over the individual's behavior "by manipulating an individual's calculus regarding whether 'crime pays' in any particular instance" (Meares, 2000, p. 396). More generally, agents of the legal system who are charged with producing compliant behavior concern themselves with shaping environmental contingencies in such a way that citizens will be faced with the prospect of heavy losses (e.g., incarceration) that are intended to outweigh the anticipated gains of engaging in criminal behavior. Judges, for example, attempt to influence people's acceptance of their decisions by threatening fines or jail time for failure to comply. The deterrence model dictates that the responsibility of lawmakers is to decide which acts should be prevented and then to specify sufficiently strict penalties—generally fines or prison terms—so that the prohibited behavior is rarely enacted.

The notion that people's behavior with respect to the law is shaped by calculations of expected gains and losses is a core premise of rational choice theory, as derived

from neoclassical economics (Blumstein, Cohen, & Nagin, 1978; Nagin, 1998). It is assumed that most people will calculate expected utilities by multiplying the probability of an outcome (e.g., getting caught for armed robbery or drunk driving) by its valence (very, very bad). If the laws are well calibrated, people will arrive at the desired conclusion that they should follow the law. Thus, rational self-interest is the motivational engine of the deterrence/social control model. To regulate behavior, this model suggests that decision makers should adjust criminal sanctions to the needed level so that the expected losses associated with lawbreaking will minimize the likelihood that people will break the law.

Research supports the notion that variations in the perceived certainty and severity of punishment do affect people's compliance with the law, at least to some degree. In particular, people's behavior is often, though not always, shaped by their estimate of the likelihood that if they disobey the law, they will be caught and punished (see Nagin & Paternoster, 1991; Paternoster, 1987, 1989; Paternoster & Iovanni, 1986; Paternoster, Saltzman, Waldo, & Chiricos, 1983). At the same time, however, perceptions of the likelihood of being caught and punished seem to have a relatively minor influence on people's behavior, as we will see (MacCoun, 1993; Robinson & Darley, 1995, 1997; Ross, 1982). Consequently, social control strategies based exclusively on a deterrence model of human behavior have had at best limited success (see also Tyler, 1997a, 1997b, 1997c, 1998).

Problems with the Deterrence Model

The deterrence model, with all of its motivational assumptions, has had dramatic effects on the nature of American society. Consider the case of the U.S. prison population (Haney & Zimbardo, 1998). Because of the widespread belief that crime is deterred by the threat of punishment and/or the experience of punishment, a massive number of citizens have been convicted and sentenced to serve time in prison. Today, the United States is a world leader in the proportion of citizens it holds in prison. In the year 2000 there were over 2 million Americans in jail or prison, a large percentage of the adult population (U.S. Department of Justice, 2001), far surpassing incarceration rates in Europe and elsewhere (Garland, 2001). Given the heavy costs of imprisonment to individuals and communities (especially members of racial and ethnic minority groups, which are overrepresented in the prison system), it is crucial to ask whether the deterrence model is based on sound psychological principles.

Costs of Surveillance

Assuming unlimited resources on the part of law enforcement officials, there is probably nothing inherently untenable (from a purely pragmatic point of view) about controlling people's behavior through threats of punishment. One of the key problems with sanctioning systems, however, is that they require near-constant surveillance of individual behavior. For obvious reasons, people are strongly motivated to hide their behavior from authori-

ties to avoid punishment; authorities must therefore develop surveillance systems for detecting rule-breaking behavior. Sometimes surveillance is easy, because the structure of the situation makes it easy. For example, wage earners' incomes are easy for the government to monitor, because businesses withhold percentages from each paycheck and send the withheld amount to the government. This makes tax violations among this group relatively easy to prosecute. In other cases, however, surveillance can be quite difficult. The police, for example, have tremendous difficulty monitoring public behavior in order to identify people who are using illegal drugs, just as tax authorities have trouble monitoring the incomes of street vendors, waiters and waitresses, and small business owners.

For all these reasons, as Meares (2000) notes, the effectiveness of "instrumental means of producing compliance always depend[s] on resource limits" (p. 401). The relevant questions are how much in terms of financial and other resources are authorities willing to expend in order to control crime, and how much power to intrude into citizens' lives are people willing to allow the authorities to have?

Furthermore, resources must be deployed in strategic and cost-effective ways. Sherman (1998), for example, notes that within the United States, police resources are typically used more in response to political pressures than to actual crime threat levels. As a result, police officers do not most heavily patrol the highest crime areas, so the ability of the police to deter crime is typically suboptimal. Sherman suggests that a greater effort is needed to put surveillance where the crime problem lies. Current deployments reflect the reality that public resources are allocated in ways that respond to political pressures, and the effective implementation of social control strategies often conflicts with those pressures.

The deterrence model probably works best in the case of crimes that are committed for instrumental reasons. For example, car theft, burglary, and crimes of this type are at least to some extent motivated by calculations about the costs and benefits expected from lawbreaking behavior. Thus, deterrence approaches work best in affecting the occurrence of instrumentally motivated crimes. They are significantly less effective in controlling criminal behavior that is motivated by factors other than economic gain.

Ross (1982) focuses on the problem of drunk driving to outline some of the problems associated with using deterrence to shape law-related behavior. He suggests that raising risk estimates to a level that is high enough to lower the rate of lawbreaking behavior, while not necessarily impossible, involves prohibitively high costs in terms of police manpower and citizen willingness to accept state intrusions into their personal lives. Interestingly, Ross finds that changes in laws can lead to short-term declines in lawbreaking because the high level of media exposure to police activities leads people to temporarily overestimate the risks of being caught and punished for lawbreaking behavior. Ross further points out that even the intensive efforts of Scandinavian authorities to create high estimates of risk using random road-

blocks and other similarly expensive and intrusive law enforcement measures are insufficient to create and maintain subjective risk estimates that are high enough to deter drunk driving over the long term.

As we have noted, many of the problems associated with deterrence-based strategies identified by Ross (1982) and others are structural in nature and involve variations in the degree to which the police are able to monitor citizens' behavior. This suggests that there should be situations in which deterrence strategies will be more or less effective in deterring lawbreaking behavior. From a deterrence approach, the two key variables determining the extent to which such strategies will be effective are (1) the ease of behavioral surveillance and (2) the level of resources that society is willing to devote to the task of surveillance.

Insensitivity to the Magnitude of Punishment

Deterrence works reasonably well in at least some cases of murder, mainly because society has devoted considerable resources to preventing murder and enforcing penalties for it. The objective risk of being caught and punished for murder is relatively high: approximately 45% (Robinson & Darley, 1997). The likelihood of being caught for committing a murder is high enough for deterrence to be effective in lowering the murder rate. Even in this case, however, criminals are not as sensitive to the magnitude of the penalty as they are to the estimated probability of being apprehended. As a result, capital punishment does not serve to deter murder more effectively than does life imprisonment (Ellsworth & Mauro, 1998).

Studies consistently find that the most important issue to people who are deciding whether or not to break the law is their estimate of the likelihood of being punished for their actions and not the expected severity of their punishment (e.g., Nagin & Paternoster, 1991). Consequently, societies cannot enforce rules simply by developing more and more draconian punishments. To be effective, authorities must engage in extensive surveillance strategies that increase the likelihood of detection. In other words, they must increase the number of supervisors who are watching employees or increase the size of the police force that is watching citizens. Effective strategies are, therefore, inevitably costly. There are no deterrence-based quick fixes that can be gained cheaply—despite the frequent suggestion among policymakers that a few instances of dramatically severe punishment will depress crime.

With regard to less serious crimes, the deterrence model is even less effective. Despite the expenditure of significant societal resources in the form of increased police efforts in the "War on Drugs," deterrence strategies have failed to improve rates of public compliance with drug laws. MacCoun (1993) estimates that only about 5% of the variance in people's use of illegal drugs is attributable to their perceptions of the likelihood of being caught and punished for rule breaking. For most people, and especially for addicts, the decision to obtain or con-sume controlled substances is simply not based on a rational calculation of prospective legal costs.

Subjectivity and Bias in Risk Estimates

There are many other crimes that are motivated not by instrumental concerns but by temporary emotional states—what Loewenstein, Prelec, and Shatto (1998) refer to as a "hot state." For example, crimes such as rape, assault, and many murders occur on the "spur of the moment" and in the "heat of passion." In such cases, the assumption that rational calculations of costs and benefits enter into the perpetrator's "decision" about whether or not to commit such crimes is naive in the extreme. In part, this is because of intrapersonal "empathy gaps": The person who is in a "hot state" cannot access or identify with how he or she will think or feel later upon returning to a "cold state" (Loewenstein et al., 1998). Thus, crimes of passion as well as crimes committed under states of intoxication are relatively unaffected by deterrence strategies, regardless of the actual or even perceived likelihood of being caught and punished for wrongdoing.

The lack of a direct correspondence between objective and subjective risks leads to another problem with the psychology of the deterrence model, namely, its failure to take into account "threshold effects." That is, to influence people's behavior at all, risk estimates need to be high enough to exceed some threshold of being psychologically meaningful (Ross, 1982; Teevan, 1975). In most situations the objective risk of being caught and punished is quite low. For example, the approximate objective risk of being caught, convicted, and imprisoned for rape is 12%; for robbery it is 4%; and for assault, burglary, larceny, and motor vehicle theft the incarceration rate is approximately 1% (Robinson & Darley, 1997). Of course, psychologists know that subjective estimates of risk are stronger determinants of people's behavior than are objective risks. However, research suggests that subjective risk estimates for infrequent events are, if anything, even lower than objective risks (e.g., Bazerman, 1990). Furthermore, it is reasonable to assume that people's estimates of whether or not they will be apprehended by the police are subject to egocentric biases and the "illusion of invulnerability" (Dunning, 1999; Taylor & Brown, 1988).

Limits of Extrinsic Motivation

There are still other reasons to think that the deterrence model is based on flawed motivational assumptions. For most crimes, the resources devoted to law enforcement are low and the opportunities for cheating are high. This is as true of white-collar crime and corporate wrongdoing as it is of other crimes (e.g., Moore & Loewenstein, 2004). In many cases, imposing monetary penalties can paradoxically *decrease* rather than increase rates of compliance, because of the fact that people construe the fine as a price and determine that they are willing to pay the cost in order to benefit from rule-breaking behavior (Gneezy & Rustichini, 2000; Tenbrunsel & Messick, 1999).

An analysis in terms of general principles of human motivation further suggests that if people comply with the law only in response to coercive power, they will be less likely to obey the law in the future because acting in response to external pressures diminishes internal motivations to engage in a behavior (e.g., Brehm, 1966; French & Raven, 1959; Tyler & Blader, 2000). This follows from the well-known distinction in social psychology between intrinsic and extrinsic motivation. Research on intrinsic motivation shows that when people are motivated solely by the prospect of obtaining external rewards and punishments they become less likely to perform the desired behavior in the absence of such environmental reinforcements (e.g., Deci, 1975). On the other hand, if people are motivated by intrinsic reasons for behaving in a certain way, their compliance becomes much more reliable and less context dependent.

Studies of regulatory authorities indeed demonstrate that seeking to regulate behavior through the use of threat serves to undermine people's commitment to rules and authorities, compared to other methods of regulation (Frey, 1994; Frey & Oberholzer-Gee, 1997). From a motivational perspective, instrumental approaches are not self-sustaining and require the maintenance of institutions and authorities that can keep the probability of detection for wrongdoing at a sufficiently high level to constantly motivate the public through external means (i.e., the threat of punishment). Over time it becomes more and more important to have external constraints in place, for whatever intrinsic motivation people originally had is gradually "crowded out" by extrinsic concerns.

Distrust and Suspicion

The use of surveillance systems also has deleterious effects on the social climate of groups. The use of surveillance implies distrust, which decreases people's ability to feel positively about themselves, their groups, and the system itself (e.g., Kramer & Jost, 2002; Kramer & Tyler, 1996). Furthermore, people may experience intrusions into their lives as procedurally unfair, leading to anger and other negative emotions often associated with perceptions of injustice (e.g., Gurr, 1970; Tyler & Smith, 1998). Whether surveillance works or not, it is often demotivating and introduces new costs in terms of distrust and perhaps even paranoia in subsequent social interaction. Such costs are borne by groups, organizations, and societies to which people belong, as they lose the gains that occur when people are willing to cooperate with each other. Research suggests that the increasing use of deterrence strategies and social control has exerted precisely this type of negative influence on the U.S. social climate. It has created an adversarial relationship between legal authorities and members of the communities they serve, especially with respect to racial and ethnic minority group members (Tyler & Huo, 2002), leading the public to grow less compliant with the law and less willing to help the police to fight crime (Sunshine & Tyler, 2003b).

Achieving a better understanding of the psychology of human motivation should be of paramount interest to le-

gal authorities, to members of the legal profession, and to those working within legal institutions such as the courts, the police, and prisons. The problems inherent in implementing many laws—and the inadequacy of the deterrence model in general—have led to widespread calls from legal authorities and scholars for social science to help in understanding how to secure the effective rule of law. Their concerns suggest that current models of the determinants of human behavior are not providing legal authorities with an adequate basis for effective social regulation. This presents an important opportunity for psychologists to put forward a new and more empirically grounded perspective on the relationship between the individual and society and the following of social rules. Taking psychological jurisprudence seriously means linking our understanding of motivation and social influence in legal contexts to a broader psychological understanding of the person (e.g., see Cohn & White, 1990; Krislov, Boyum, Clark, Shaefer, & White, 1966; Melton, 1985; Tapp & Levine, 1977).

AN ALTERNATIVE MODEL BASED ON SOCIAL PSYCHOLOGICAL PRINCIPLES

Most legal scholarship, as we have seen, addresses issues of motivation and rule following in the context of deterrence and social control (i.e., by imposing external constraints on people largely through the threat of punishment). Social psychologists can contribute to a more sophisticated understanding of compliance. Specifically, a good deal of research indicates that self-regulatory motivations are activated when people believe that the law reflects their views about right and wrong and that it is therefore a moral responsibility and even an obligation to conform to the law. Consequently, people who identify with legal authorities and imbue the legal system with legitimacy will voluntarily abide by laws and defer to authorities (Darley et al., 2003; Jost & Major, 2001; Tyler, 2006a; Tyler & Blader, 2000). We develop this position in more detail in the remainder of this chapter.

Commitment Based on Legitimacy and Moral Values

Ever since Kurt Lewin's (1936) field theory, social psychologists have assumed that behavior is determined by two main forces. The first is the pressure of the situation or the environment, and the second includes the motives and perceptions that the person brings to the situation. In Lewin's famous equation, behavior is understood to be a function of the person and the environment: $B = f(P, E)$. An expanded conception of the person term includes the set of social and moral values that shape the individual's thoughts and feelings about what is ethical or normatively appropriate to do. We focus on two such values: (1) the conviction that following the rules of the community is (in most cases) the morally appropriate thing to do, and (2) commitment to the notion that if the rules are fair and legitimate, they ought to be obeyed.

From a social psychological perspective, the first step is to recognize that the legal system depends at least in part

on the willingness of citizens to consent to the operation of legal authorities and to actively cooperate with them. Second, willing acceptance comes most quickly and completely to the extent that people view the law as (1) determined and implemented through procedurally fair means, and (2) consistent with cherished moral values.

These notions are consistent with the proposals of Ayres and Braithwaite (1992), who suggest that legal authorities should approach citizens by appealing to their moral values. The idea is that if authorities are successful in joining legal and moral concerns, it will be much easier to isolate the relatively small number of citizens who do not share the values of the community. Third, if the overwhelming majority accepts that the law is based on sound moral principles carried out by legitimate authorities, the majority is likely to exert strong social pressure on deviants to conform to normative standards. This is a kind of social self-regulation that enhances the effectiveness of legal authorities by freeing them to pay attention to those problems or people who, for various reasons, are not amenable to self-regulation (Ayres & Braithwaite, 1992).

The Concept of Legitimacy

Modern discussions of legitimacy are usually traced to the writings of Weber (1968) on authority and the social dynamics of authority (e.g., Zelditch, 2001). Weber, like Machiavelli and others before him, argued that successful leaders and institutions use more than brute force to execute their will. More specifically, they strive to win the consent of the governed so that their commands will be voluntarily obeyed (Tyler, 2006a). As Kelman (1969) put it: "It is essential to the effective functioning of the nation-state that the basic tenets of its ideology be widely accepted within the population. . . . This means that the average citizen is prepared to meet the expectations of the citizen role and to comply with the demands that the state makes upon him, even when this requires considerable personal sacrifice" (p. 278). Widespread voluntary cooperation with the state and the social system allows authorities to concentrate their resources most effectively on pursuing the long-term goals of society. The authorities do not need to provide incentives or sanctions to all citizens to get them to support every rule or policy they enact.

Legitimacy, according to this general view, is a quality that is possessed by an authority, a law, or an institution that leads others to feel obligated to accept its directives. It is, in other words, "a quality attributed to a regime by a population" (Merelman, 1966, p. 548). When people ascribe legitimacy to the system that governs them, they become willing subjects whose behavior is strongly influenced by official (and unofficial) doctrine. They also internalize a set of moral values that is consonant with the aims of the system, and—for better or for worse—they take on the ideological task of justifying the system and its particulars (see also Jost & Major, 2001).

Although the concept of legitimacy has not featured prominently in recent discussions of social regulation with respect to law-abiding behavior, there is a strong intellectual tradition that emphasizes the significance of developing and maintaining positive social values toward cultural, political, and legal authorities (Easton, 1965, 1975; Krislov et al., 1966; Melton, 1985; Parsons, 1967; Tapp & Levine, 1977). This work builds on the sociological tradition associated with Weber and others. According to "consensus" theories such as these, the smooth functioning of society depends on the existence of supportive attitudes and values among members of the population in general. Presumably, attitudes and values that support the social system begin to develop during childhood and adolescence as part of the process of political (and legal) socialization (e.g., Cohn & White, 1990; Niemi, 1973).

The value of cultivating system legitimacy consists in its enabling the effective (and, ideally, fair) exercise of social authority. While authorities can exercise power directly through the promise of rewards or the threat of punishment, such approaches to deterrence are expensive, inefficient, and psychologically naive. They may be especially problematic during times of instability or crisis, when authorities need the support of the people at a time in which they lack control over resources. An organization or society whose governance is motivated only by incentives and sanctions is at risk of disintegrating during times of trouble or change. In contrast, if a system enjoys widespread legitimacy, authorities can appeal to members based on their shared purposes and values, providing the system with much-needed stability. From this perspective, legitimacy is a highly desirable feature of social systems (see also Tyler, 2006b; Tyler & Huo, 2002).

Underlying this generally positive view of the role of legitimacy and social values in motivating cooperation with the social system is the tenet of consensus theories that there is a mutual benefit that comes from voluntarily accepting societal norms. According to this view, the rulers and the ruled alike gain from having "a stable social and political order" that is helped by widespread shared beliefs that the system is legitimate and consistent with people's moral values (Sears, 2003, p. 322). Clearly, legitimacy and stability facilitate regulation—the process whereby authorities seek to bring the behavior of individuals into line with system rules. The police and courts depend very heavily on the widespread voluntary compliance of most of the citizens most of the time (Tyler, 2006b). This compliance presumably allows authorities to focus their attention on those individuals and groups whose behavior seems to be responsive only to threats of punishment. The legal system would be overwhelmed immediately if it were required to regulate the behavior of the majority citizens solely through sanctioning or the threat of sanctioning.

Legitimacy, as we have suggested, has many appealing features as a possible basis for the rule of law. On its face it appears to be an all-purpose mechanism of social coordination, insofar as people feel obligated to obey whatever laws or decisions authorities make, within some realm of legitimacy. Much as studies of confidence and trust in government focus on people's overall evaluations of the government, its institutions, and its authorities (Citrin & Muste, 1999), studies of "legal consciousness" focus on whether people have "trust and confidence" in

the legal system, whether they think that the law works to help everyone, and how and when people have duties and obligations to legal institutions and authorities (Ewick & Silbey, 1988; Finkel, 1995; Flanagan & Longmire, 1996; Hamilton & Sanders, 1992; Merry, 1990).

Research by Tyler (2006b) demonstrates that perceptions of system legitimacy do shape everyday compliance with the law, which is a conclusion that is also supported by other studies (Sunshine & Tyler, 2003b; Tyler & Huo, 2002). Furthermore, perceived legitimacy seems to have more influence on compliance than do subjective assessments of the likely risk of punishment. When people perceive the system as legitimate, they feel an intrinsic moral obligation to comply with its demands.

Internalization of Moral Values

Moral values are influential because they are based on internalized feelings of responsibility to follow certain principles (see Robinson & Darley, 1995; Tyler & Darley, 2000). A key feature of moral values is that people feel personally obligated to adhere to them, and they feel guilty when they fail to do so. Hence, moral values—once they exist—are self-regulatory in nature; people who possess them are strongly motivated to bring their conduct into line with normative standards. The internalized sense of morality is central to the work of, among others, Freud, Weber, and Durkheim (e.g., see Sunshine & Tyler, 2003a). Hoffman (1977) writes:

> The legacy of both Sigmund Freud and Emile Durkheim is the agreement among social scientists that most people do not go through life viewing society's moral norms as external, coercively imposed pressures to which they must submit. Though the norms are initially external to the individual and often in conflict with [a person's] desires, the norms eventually become part of [a person's] internal motive system and guide [a person's] behavior even in the absence of external authority. Control by others is thus replaced by self control [through a process labeled internalization]. (p. 85)

The idea is that internalized values become self-regulating, so that people accept and act on the basis of values that produce respect for societal institutions, authorities, and rules. Public standards are taken on as private values that are associated with a moral responsibility to act in accordance with ethical judgments about what is right and wrong. Presumably, this occurs during childhood as part of the socialization process (Cohn & White, 1990; Greenstein, 1965; Hess & Torney, 1967; Hyman, 1959; Merelman, 1966; Niemi, 1973). Robinson and Darley (1995) conclude that people's moral values form during childhood socialization and are not easy to change later in their lives.

The significance of morality is illustrated by research on punishment. Studies demonstrate that people's views about appropriate sentencing decisions in criminal cases are driven by moral judgments about deservingness rather than by instrumental judgments concerning how to deter future criminal conduct (Carlsmith, Darley, & Robinson, 2002; Darley, Carlsmith, & Robinson, 2000).

People accept that a punishment is appropriate when it accords with their moral sense of what is appropriate given the level and type of wrong committed. More generally, research shows that people are more willing to comply with the law to the extent that they view it as consistent with their moral values (e.g., Robinson & Darley, 1995; Tyler, 2006b). As a consequence, an important question for the law is the degree to which it is congruent with public moral values. If people correctly understand the law, and if the law truly reflects moral standards of the community, then the internalized sense of morality acts as a force for law-abidingness.

Justice as Intrinsically Motivating

Our value-based model of motivation to obey the law is also consistent with two additional principles of human behavior that should be made more explicit. One is that people, as a general rule, desire justice; that is, they are motivated by fairness concerns. In summarizing decades of research, Lerner (2003) refers to this as the "justice motive," and he suggests that it cannot be reduced to considerations of self-interest. There is indeed evidence that people experience unfair advantages (as well as disadvantages) to be psychologically aversive and that they are happier when justice is served (e.g., Boll, Ferring, & Filipp, 2005; Loewenstein, Thompson, & Bazerman, 1989; Walster, Walster, & Berscheid, 1978). This work provides a reasonably strong basis for assuming that people *want* to follow the law and that they want others to follow the law—*provided that they also believe that the law is fair and just*. To draw on the justice motive as a source of legal obedience, therefore, authorities must pursue policies that are generally consistent with people's sense of right and wrong (Sunshine & Tyler, 2003a).

A second and related fact about human behavior, to which we have alluded already, is that people are more consistently motivated by intrinsic than extrinsic considerations (e.g., Deci, 1975; Frey & Oberholzer-Gee, 1997). Thus, to the extent that social values become internalized, they become a part of the person and lead him or her to exercise self-regulation so that their behavior is consistent with the principles and values that define their sense of themselves. Under such circumstances, people may be expected to follow the rule of law not out of a temporary fear of surveillance but because they have internalized the values that are codified by the legal system. Deference, then, will not be experienced as a cost but as the kind of benefit that comes from doing what is defined as morally right.

A value-based perspective on human motivation suggests the importance of developing and sustaining a civic culture in which people abide by the law because they feel that it is morally required. For this model to work, society must create and maintain public values that are conducive to following justice norms. Political scientists refer to this set of values as a "reservoir of support" for government and society (Dahl, 1956). Although it may not always be easy for authorities to maintain high reservoir levels, a value-based model is consistent with a social psychological understanding of how authorities can ef-

fectively regulate citizen behavior, maintain social order, and promote an effective, well-functioning society by developing and maintaining a culture of supportive social values that will be internalized by the citizenry.

The value-based model we have outlined in this section avoids many of the pitfalls of the deterrence model. Specifically, it does not require extensive surveillance efforts, is more sophisticated concerning the genuine causes of human behavior, engages intrinsic (and not just extrinsic) motivation, and fosters a positive social climate based on a shared commitment to moral values rather than a negative social climate based on suspicion and distrust. But there is yet another important advantage of our value-based model to which we have only alluded thus far. To the extent that people are in fact internalizing appropriate moral values, deferring to legal authorities who implement fair procedures, and obeying laws that are truly just, then the model of human behavior we have sketched will lead not only to an efficient and well-ordered society but also to one that has a profoundly legitimate basis for regulating the behavior of its citizenry.

SYSTEM JUSTIFICATION AND THE PROBLEM OF FALSE CONSCIOUSNESS

Up to this point, we have assumed that fostering perceptions of system legitimacy is uniformly desirable, especially from the standpoint of legal authorities. Astute readers will have realized, however, that the power of legitimacy to motivate compliance can be abused. That is, Machiavellian leaders can use their influence to lend legitimacy to immoral as well as moral causes and to maintain consensual support for oppressive as well as beneficent forms of social control (e.g., Jost & Major, 2001). And, as we have noted, conflict models of society suggest that elite individuals and groups are highly motivated to wield their power and the legitimacy they possess in order to achieve ends that suit their own interests. The social psychological processes that we describe, therefore, are morally ambiguous. We return later to the question of whether it is possible to reconcile descriptive accounts of how and why people actually perceive systems and authorities as legitimate and normative accounts of whether people *ought* to perceive them as legitimate and therefore worthy of compliance.

Legitimacy, Authorization, and Obedience to Authority

Legitimacy, we have suggested, is the property of a rule or authority that leads people to feel morally obligated to voluntarily defer to that rule or authority. From a social influence perspective, a legitimate authority is a person or group that is regarded by others as being entitled to have its rules accepted and followed (e.g., French & Raven, 1959). In this way, ascriptions of legitimacy play a key role in persuasion and motivation, especially to the extent that legitimate authority figures can lead people to suspend considerations of self-interest and to ignore personal goals and values that are at odds with officially sanctioned values. This capacity for systems and authorities that are perceived as legitimate to influence and motivate others is a double-edged sword. It means that people will be loyal and committed to following the norms and rules of the system, but it also means that they can be made to obey unjust laws and pursue cruel objectives in the name of the system.

In their study of obedience to authority, Kelman and Hamilton (1989) use the term "authorization" to capture the process by which followers license their leaders to define what counts as appropriate behavior in a given situation. In this way, citizens, employees, soldiers, and others abdicate moral responsibility and follow orders conscientiously. Kelman and Hamilton note "Behaviorally, authorization obviates the necessity of making judgments or choices. Not only do normal moral principles become inoperative, but—particularly when the actions are explicitly ordered—a different type of morality, linked to the duty to obey superior orders, tends to take over" (p. 16).

Imbuing institutions and authorities with legitimacy has the consequence of "authorizing" certain behavior that might not otherwise be seen as normatively appropriate. In fact, people often view their own moral values as irrelevant when a legitimate authority figure is present. An example is provided by Milgram's (1974) famous experimental studies of obedience to authorities. As Kelman and Hamilton (1989) note:

> It is interesting that, in the postexperimental debriefing, he [a participant who shocked the confederate at the maximum level] seems unable to understand a question about whether there are any conditions under which he might have stopped administering shocks to [the confederate]. As far as he is concerned, he did stop—and he seems dismayed to learn that some participants did not stop. He stopped; it was the [authority] who continued. His hand may have been on the switch, but the decision and the responsibility were clearly the experimenter's. (p. 155)

Thus, under some (perhaps exceptional) circumstances, granting legitimacy to authorities and internalizing the moral values that are encouraged by any given system can lead good people to engage in horrific activities (see also Darley, 2004). The problem of obedience to a legitimized authority figure, however, is only one of several related problems that can result from idealizing the system and its authorities.

False Consciousness and the Legal System

As we have noted, consensus theorists influenced by Weber and his intellectual heirs assume that virtually everyone benefits from a stable and effective social system. This assumption is not shared by conflict theorists inspired by Marx and his followers (see Zelditch, 2001). Rather, a Marxian perspective suggests that members of elite or dominant groups have an ideological interest in maintaining the existing social system, whereas the objective interests of subordinated groups lie in opposing the status quo (e.g., Parkin, 1971). However, due to socialization pressures, members of subordinated groups often

develop ideological beliefs that are supportive of the system rather than of their own needs and interests.

The dominant class, in other words, uses its control over cultural institutions—including churches, schools, and the mass media—to promulgate an image of society that obscures the oppression of the subordinate class and legitimates the status quo by portraying existing institutions as fair, appropriate, and just. From a Marxian perspective, then, internalized social values may reflect distortions of the true social situation. They may reflect, in other words, "false consciousness" (e.g., Jost, 1995; Tyler & McGraw, 1986). Members of disadvantaged groups, according to this view, are often made worse off by acquiescing to dominant ideologies and accepting existing authorities and institutions as legitimate.

It has been argued that citizens' relatively widespread acceptance of the legitimacy of legal authorities and institutions reflects some degree of false consciousness (e.g., Fox, 1999). Scheingold (1974), for instance, proposed that at a system level of analysis, the function of the courts is to provide disadvantaged people with symbolic satisfaction rather than to make rulings that create substantive justice. And in an article that was subtitled "Let Them Eat Due Process," Haney (1991) further suggested that many litigants are manipulated into believing that they are receiving procedural justice from the court system when in fact they are being hoodwinked into accepting poor outcomes.

An even stronger indictment of the legal system comes from the work of Sidanius and Pratto (1999), who argue that the law is in fact an instrument of oppression that is wielded by elite members of society against those who are disadvantaged, especially members of racial and ethnic minority groups. From these perspectives, legal institutions do not deserve the degree of legitimacy that they currently enjoy.

System justification theory, which builds on Marxian analyses of ideology and false consciousness and Lerner's (1980) work on the belief in a just world, among other influences, focuses on the social psychological tendency to rationalize the status quo and to see "what is" as "what ought to be" (Jost & Banaji, 1994). The theory suggests that people are apt to exaggerate the legitimacy of existing institutions, in part because they have little choice but to live with and adapt to them (Jost & Hunyady, 2002). Because it is psychologically aversive to feel as if one is subject to unjust treatment, capricious authorities, and oppressive institutions, people tend to believe that the status quo is fair and just. Thus, they develop stereotypes and ideologies—some of which may be operating at a nonconscious level of awareness—that bolster existing institutions and narrow the range of conceivable and acceptable alternatives to the status quo (e.g., see Jost, Banaji, & Nosek, 2004).

System justification—defined as the tendency to justify the status quo—is often observed in the economic realm. People tend to uncritically accept meritocratic explanations for inequality (Jost, Pelham, Sheldon, & Sullivan, 2003; Tyler & McGraw, 1986) and to blame individuals rather than systems for the existence of poverty (Hochschild, 1981; Kluegel & Smith, 1986). Further-

more, research by Jost, Blount, Pfeffer, and Hunyady (2003) suggests that people who live under capitalist systems are motivated to believe in "fair market ideology," according to which market-based outcomes and exchanges are not only efficient but also inherently fair and legitimate. Consistent with this general theoretical perspective, Tyler (2004) showed that people who endorsed free-market procedures as fair were more likely to resist governmental intervention in the economic sphere and less likely to support social change aimed at increasing economic justice.

Why would people engage in system justification, especially when it is contrary to their own individual and collective interests? Jost and Hunyady (2002) proposed that system-justifying ideologies serve a palliative function in that they decrease anxiety, uncertainty, guilt, frustration, and dissonance and increase people's satisfaction with their own situations and with the status quo in general. Research by Wakslak, Jost, Tyler, and Chen (in press) provides support for these affective benefits of system justification. Specifically, they demonstrated that increased system justification—either measured in terms of strength of ideological endorsement or experimentally manipulated by activating a "Horatio Alger" rags-to-riches mindset—produces a significant reduction in emotional distress, which in turn leads to a significant reduction in support for social change and the redistribution of resources.

Although system justification theory has only recently been applied to the law (Blasi & Jost, 2006; Greenwald & Krieger, 2006; Hanson & Yosifon, 2004; Kang, 2005; Travis, 2005; see also Jolls & Sunstein, 2006), there are numerous consequences of the theory for the legal system and its legitimacy. For one thing, the fact that people come to believe that the system is fair and legitimate does not in any way mean that it actually is. Researchers have shown that are a number of cognitive and motivational biases that lead people to rationalize outcomes and procedures that are neither favorable nor inherently just (see Jost et al., 2004, for a review). This work integrates and builds on earlier evidence that people evince a remarkable capacity to acquiesce in the face of injustice (e.g., Crosby, 1982; Major, 1994; Moore, 1978; Tyler & McGraw, 1986). Thus, system justification theory suggests that, for a wide range of psychological reasons, false consciousness about legal and other institutions may be relatively widespread (see also Jost, 1995; Jost & Banaji, 1994).

Is there a way out of this predicament? How can citizens and their leaders increase the likelihood that system legitimacy is genuine rather than illusory? There may be no way of guaranteeing that legal institutions will deliver substantive justice, but it seems to us that adhering to normatively defensible standards of procedural fairness maximizes the likelihood of obtaining outcomes that are objectively (and not just subjectively) fair (see also Jost & Ross, 1999). In other words, efforts to attain system legitimacy should be based not merely on bringing about consensus *per se* but on establishing and protecting standards that are likely to guarantee genuine or substantive fairness.

NATURALIZING JUSTICE: RECONCILING NORMATIVE AND DESCRIPTIVE ACCOUNTS OF LEGITIMACY

The social psychological principles we have described throughout this chapter are morally ambiguous. That is, they can be used equally to win compliance for just and unjust systems and authorities. However, for our model to contribute to genuine (rather than merely apparent) system legitimacy, there must be congruence between subjective and objective justice considerations. That is, the system that seems morally justified must in fact *be* morally justified, according to normative theories of justice as developed, for example, in the philosophical traditions of Kant, Mill, Marx, Rawls, and others. The issue we are raising here is how normative and descriptive accounts of social justice and system legitimacy can be reconciled.

To some readers, it may seem like an impossible task to distinguish between "true" and "false" consciousness or, relatedly, between social systems that provide genuine, substantive justice rather than merely the subjective appearance of justice. We readily acknowledge that this is a challenging problem that may require the active collaboration of philosophers, legal scholars, sociologists, psychologists, and others in order to solve it. At the same time, the problem is similar to the one facing students of *rationality*. By juxtaposing descriptive psychological data concerning the ways in which people actually make decisions under ambiguity and uncertainty with normative accounts of rationality derived from philosophical and economic theories, scholarship on judgment and decision making has advanced considerably (e.g., Kahneman, Slovic, & Tversky, 1982; Thaler, 1994). Just as we can ask whether a person is acting rationally, we can ask whether a system is just. In either case, the key issue is to create a normative model against which psychological findings can be compared.

Within legal research, the attempt to reconcile normative and descriptive approaches has spawned the influential and productive "behavioral law and economics" movement (e.g., Sunstein, 2000). In general, such efforts to "naturalize" the study of traditionally philosophical questions by bringing scientific evidence to bear on them have been quite successful.

A similar opportunity exists for behavioral realists who are interested in reforming legal code to make it more just in light of social psychological principles involving stereotyping, bias, and discrimination (e.g., Blasi & Jost, 2006; Kang & Banaji, 2006; Krieger & Fiske, 2006). For example, current discrimination law falls short of protecting members of disadvantaged groups against automatic, unintentional biases that likely harm their chances in a variety of employment and educational contexts. The question is how the law can and should be changed to prevent disparate treatment of minorities and women in light of scientific evidence demonstrating that implicit stereotyping and prejudice can produce discriminatory effects (e.g., Ayres, 2001; Fazio & Olson, 2003; Greenwald & Krieger, 2006; Kang, 2005; Krieger, 1995).

On an even grander scale, it may be possible to bring descriptive sociological and psychological research to bear on normative questions of what constitutes a truly just social system. Probably the most progress has occurred with respect to empirical assessments of John Rawls's (1971) theory of justice as fairness. In the Kantian philosophical tradition, Rawls argued that the most just social system would be the one chosen by rational decision makers under a "veil of ignorance," that is, without knowing anything about their own status or position within the resulting social system. Drawing at least in part on psychological theory and research, Rawls reasoned that under such circumstances people would choose a social system that (1) minimized the degree of inequality in social and economic outcomes, and (2) maximized the social and economic outcomes of those who would occupy the worst position in the new system.

Although there is a limited sense in which empirical research can be said to approximate what Rawls's hypothetical rational decision makers would choose under the "veil of ignorance" as he described it, studies have shown that actual decision makers do tend to favor at least some of the justice principles Rawls advocated (e.g., Bond & Park, 1991; Frohlich & Oppenheimer, 1992; Jost & Ross, 1999; Mitchell, Tetlock, Mellers, & Ordonez, 1993). That is, in evaluating the fairness of various distributional schemes, people who lack information that would enable them to act on self-interest motives tend to behave in a manner that is at least somewhat related to how Rawls theorized they *should* behave. We suggest that similarly useful points of contact exist between normative (i.e., legal and philosophical) and descriptive (sociological and psychological) approaches to issues of *procedural* fairness. The important point is that it is—at least in principle—possible to investigate whether certain normative conceptions of justice and morality fit with empirical data in psychology and other social and behavioral sciences (see also Doris, 2002; Flanagan, 1991; Harman, 1999).

Procedural Fairness as the Basis of Legitimacy

For system legitimacy to be genuine, effective, and long lasting, it needs to be based on more than consensus alone. Aristotle linked the stability of the state to the voluntary acceptance that occurs when resources are actually being fairly distributed across society, that is, to objective distributive justice (Zelditch, 2001).

Authorities also gain a great deal in terms of legitimacy when they follow clear norms of procedural justice, including impartiality, transparency, and respect for human dignity (e.g., Miller, 2001; Tyler, 2001a). Thus, implementing fair procedures as well as outcomes can provide a solid basis for establishing system legitimacy. And, as with distributive justice, procedural justice can be viewed as an objective property of a procedure. For example, in their classic work on procedural justice Thibaut and Walker (1975) compared the procedural justice of inquisitorial and adversary procedural justice using objective criteria. One such criterion was the ability to combat prior bias. They experimentally induced prior bias for or against the defendant and then had cases tried

using one of the two procedures. They reasoned that a just procedure should wash away the effects of prior bias, leading the proportion of guilty verdicts to be the same irrespective of the direction of prior bias. When evaluated against this objective criterion of justice, the adversarial procedure was more just than the inquisitorial system. Such evaluations had nothing to do with how the participants evaluated the justice of the procedures. Rather, they were linked to objective criteria defined by the experimenters.

We want to argue for the particular benefits that come from basing legitimacy on specific mechanisms that communicate and deliver substantive procedural fairness as defined by legal philosophers and scholars who are concerned not only with what people are likely to perceive as just (the descriptive question) but also with what *is* just (the normative question). In other words, we suggest the value of using procedures that both *are* just when evaluated in relationship to objective criteria and *are experienced as being just* by those involved in them.

The legitimacy of authorities is an especially promising basis for the rule of law because research suggests that it is not yoked to agreement with the decisions rendered by legal authorities. If people view as legitimate only those authorities who make decisions with which they agree, it would be difficult for legal authorities to maintain their legitimacy insofar as they are required to make unpopular decisions and to deliver unfavorable outcomes. Fortunately, from the perspective of legal authorities, studies suggest that ascriptions of legitimacy are tied to the perceived fairness of the procedures used by authorities to make decisions rather than to the favorability of outcomes per se (Lind & Tyler, 1988; Thibaut & Walker, 1975; Tyler, 1990; Tyler, Boeckmann, Smith, & Huo, 1997; Tyler & Smith, 1998). These results suggest that legal authorities may be able to maintain their legitimacy in the long term by making decisions in an ethically defensible manner.

People are more likely to regard the police as legitimate if they believe that the police exercise their authority through fair and impartial means (Sunshine & Tyler, 2003b; Tyler, 2001b). Indeed, the evidence suggests that procedural justice judgments are more central to judgments of legitimacy than are such factors as the perceived effectiveness of the police in combating crime. To the extent that people perceive law enforcement officials as legitimate, they are significantly more willing to defer to individual authorities (Tyler & Huo, 2002), and they are also more likely to be in compliance with the law in general (Sunshine & Tyler, 2003b; Tyler, 2006b). These observations hold true when people are reporting on their own personal experiences with legal authorities (Tyler, 2006b; Tyler, Casper, & Fisher, 1989) and also when they are evaluating system-level authorities such as the Supreme Court (Tyler, 1994; Tyler & Mitchell, 1994).

Perhaps most important, from the perspective of the legal system, a number of recent studies link judgments about procedural fairness to the willingness to accept particular legal decisions (Kitzman & Emery, 1993; Lind, Kulik, Ambrose, & de Vera Park, 1993; Wissler, 1995) and to generally follow laws and legal rules (Kim &

Mauborgne, 1993; Sparks, Bottoms, & Hay, 1996; Tyler, 2006b). Procedural justice cues play an especially important rule in securing compliance over time (Paternoster, Brame, Bachman, & Sherman, 1997; Pruitt, Peirce, McGillicuddy, Welton, & Castrianno, 1993). It is by now very clear that people's reactions to law and legal authorities are heavily influenced by their assessments of the fairness of legal procedures.

The procedural basis of legitimacy is especially strong with respect to public opinion concerning political and legal institutions. Studies of the presidency (Tyler, Rasinski, & McGraw, 1985), the legislature (Hibbing & Theiss-Morse, 1995, 2002), and the Supreme Court (Tyler & Mitchell, 1994) all suggest that when citizens are evaluating government institutions, they focus primarily on the fairness of the procedures by which the institutions make policies and implement their decisions. Research on work organizations also suggests that perceived legitimacy has a strong procedural basis (Elsbach, 2001; Tyler & Blader, 2000, 2005).

The procedural basis of legitimacy on an institutional level is consistent with the argument that support for the rules of governance (i.e., procedures and institutions) is theoretically and empirically distinguishable from support for particular individuals or their policies. Studies suggest that reactions to individual leaders and policies are more strongly linked to outcome desirability than are reactions to institutions (Rasinski, Tyler, & Fridkin, 1985). In general, however, it is support for the rules of governmental operation—what Easton (1965) referred to as "diffuse system support" (p. 444)—that is seen as crucial to long-term governmental stability.

Our thesis is that the most reliable way of attaining real as well as ostensible legitimacy and maintaining diffuse system support for legal institutions and authorities is by establishing and protecting procedural safeguards. Indeed, the need for procedural safeguards is one of the strongest arguments for the constitutional separation of executive, representative, and judicial branches of government. To the extent that procedures for ensuring genuine fairness are compromised, the system will begin to lose legitimacy and—over time—fail to inspire the kind of cooperation and deference that is often taken for granted during periods of stability.

The fact that, as system justification theory holds, people tend to perceive the status quo as relatively fair and legitimate means that perceptions of *injustice* should be taken very seriously by anyone who is committed to maintaining genuine system legitimacy. In the case of law, issues of distributive injustice are linked to questions about the appropriate or fair response to violations of the law ("just deserts"). To the extent that a wide rift develops between public opinion and legal doctrines about appropriate punishments in response to wrongdoing (e.g., concerning the severity of drug laws or the desirability of capital punishment), this can be an important sign that the legal system may be lacking in substantive justice and, over time, that it may eventually suffer in terms of perceived legitimacy and capacity for motivating widespread compliance with the law (Robinson & Darley, 1995, 1997).

IMPLICATIONS OF THE VALUE-BASED MODEL

Now that we have laid out the basic tenets of our value-based model, which emphasizes (1) system legitimacy as the basis of social influence and motivation to comply with the law and (2) genuine procedural fairness as the basis of system legitimacy, we are in a position to consider some further legal implications of the model. We focus on three areas of application in particular: reactions to rule breaking, restorative justice, and corporate wrongdoing. In each of these cases, our model makes different recommendations from those that are commonly derived from the deterrence model, which currently dominates scholarly and professional thinking about both criminal justice and business ethics.

Reactions to Rule Breaking

In this section, we return to the central question posed by the deterrence model, namely, what to do with people who break the rules so that neither they nor others will repeat the offense. A frequent justification of incarceration as a common method of deterrence is the notion that once in prison, people who have broken the law can be rehabilitated into citizens who will comply with the law in the future. Unfortunately, there is little evidence that the legal system in its present state effectively changes the future behavior of those who come before the law because of past illegal actions (i.e., to "reform" criminals; see Ellsworth & Mauro, 1998). Much of the fault, no doubt, lies with prison conditions, which are extremely unlikely to create the social and psychological circumstances necessary for learning and self-improvement to occur (e.g., Haney & Zimbardo, 1998).

The work of Darley and colleagues (2000) on rule breaking suggests that the same social values that can help to motivate rule following are also useful for understanding reactions to legal transgressions (see also Carlsmith et al., 2002). They find that people respond to rule breaking by seeking to restore a moral balance between the rule breaker and society. The focus of this work, however, is on how other members of society react to wrongdoing, and not on changes in the rule breakers themselves. If, as we have suggested, legitimacy and moral values are central to rule following, then one guiding concern with regard to rehabilitation should be with how to reconnect the offender to their original moral values.

Consider an example from a recent study of citizen–police encounters (Paternoster et al., 1997). In this study researchers examined what transpired when the police were called to homes to deal with issues of domestic violence. The concern of the study was with subsequent compliance to the law on the part of the abusive men whose behavior led to the initial call. The deterrence model would predict that compliance would be increased by threats and/or punishments meted out by the police. From a social psychological perspective, however, we would argue for the value and effectiveness of more constructive police efforts designed to create and maintain respect for the law on the part of the abuser.

The results of Paternoster and colleagues' (1997) study were consistent with our model of legitimacy and motivation. When the police treated abusers in a procedurally fair manner during their encounter, those abusers were more likely to comply with the law afterward. Fair treatment increased feelings of respect for the law and led abusers to be more willing to obey the law in the future. The influence of procedural fairness was greater than that of threatened or enacted punishments.

This study illustrates one of the core premises of psychological jurisprudence, as we understand it—that legal authorities should be concerned with fostering the shared commitment of citizens to overarching moral principles. To do this, authorities must be aware of citizens' values, their experiences with the legal system, and their judgments about the practices and policies of legal authorities. From this perspective, the key to successfully implementing the rule of law lies in an understanding of procedural fairness as the basis of legitimacy rather than in efforts to more effectively deploy coercive tactics.

Restorative Justice and Reintegrative Shaming

The most comprehensive attempt to reconnect offenders to societal norms and to their own sense of moral values is through *restorative justice* (Braithwaite, 1989; Roberts & Stalans, 2004). During a restorative justice conference the rule-breaking behavior is recognized and punished, but an effort is also made to encourage the rule breaker to recognize that his or her behavior violates social and moral codes that partially constitute the perpetrator's own self-image. As a consequence, his or her criminal behavior should be personally upsetting. Thus, an effort is made to use the incident of rule breaking as a way of encouraging the perpetrator to redouble his commitment to obeying the rules in the future.

To achieve these goals, the restorative justice movement advocates sentences such as formal acknowledgement of wrongdoing, public apologies, and acts of restitution that connect people with the wrongfulness of their actions. From a restorative justice perspective, transgressions and disputes arising from them should be resolved through "reintegrative shaming" techniques (Braithwaite, 2002). Reintegrative shaming combines strong moral disapproval of the offense with respect for the person who committed the offense.

The goal is to bring about reconciliation among victims, offenders, and the community at large. With regard to offenders, the primary goal is to encourage feelings of shame regarding one's crimes, accepting responsibility, and sincerely apologizing for them; this is intended to restore the dignity of offenders. Essential to this process is the social connection that perpetrators feel to their family, friends, and community, so these parties are present at restorative justice hearings, along with the victim and his or her family and friends. All those present are involved in reconnecting the offender to a sense of moral responsibility in relation to the community as a whole. This reconnection, it is hoped, will enhance intrinsic motivation to engage in self-regulatory actions that will work against future transgressions of the law. The restorative

justice argument mirrors the concern in procedural justice research with developing both formal and informal legal procedures that strengthen the influence of social and moral values on people's law-related behavior (Tyler & Darley, 2000).

Research results support the facilitative role of restorative justice conferences (Roberts & Stalans, 2004; Sherman, 1999). Studies suggest that, at least with regard to some types of crime, participating in a restorative justice conference leads to greater cooperation with the law in the future (Nugent, Williams, & Umbreit, 2003; Poulson, 2003). Such conferences, it seems, do increase the motivation to accept the law and the decisions of legal authorities and to be a law-abiding citizen. Work on restorative justice and reintegrative shaming provides further evidence that internal moral values play a pivotal role in motivating compliance with the law (Sunshine & Tyler, 2003b; Tyler, 2006b; Tyler & Huo, 2002). This work also suggests future directions for the rehabilitation of criminals that is based on sound social psychological principles.

Corporate Wrongdoing and Organizational Legitimacy

As with regard to criminal conduct in general, the dominant approach to the problem of corporate crime has been to focus on increasing penalties aimed at deterrence (Tyler, 2005). These efforts have encountered many of the same problems that deterrence efforts have encountered in other domains, including major difficulties with regard to surveillance and the tendency for corporations to accept possible risks associated with being caught for accounting fraud, environmental abuses, and other crimes as costs of doing business (e.g., Moore & Loewenstein, 2004). Another approach to ethical scandals at Enron, Arthur Andersen, WorldCom, Adelphi, Tyco, and many other corporations has been to blame wrongdoing on a "few bad apples," when the reality is that much of the fault lies with the barrel itself (e.g., Bazerman & Banaji, 2004; Tenbrunsel & Messick, 2004).

In this section, we focus on two types of values that have ramifications for the problem of business corruption. The first is the conviction by employees that their organization's rules and authorities are *legitimate*. Legitimacy in this context refers to the view by employees that they are responsible for obeying organizational rules (e.g., that the organization is entitled to have its rules and policies obeyed). Thus, issues of legitimacy apply not only to perceptions of government and law (Tyler, 1999), but also to perceptions of work organizations (Elsbach, 2001; Selznick, 1969; Suchman, 1995; Tyler & Blader, 2005). In work settings, legitimacy refers to the judgment that "the actions of an entity are desirable, proper, or appropriate within some socially constructed system of norms, values, beliefs, and definitions" (Suchman, 1995, p. 574). If people feel that their organization has legitimacy, they will be motivated to defer to its rules and policies.

The second value is the conviction by employees that corporate policies are congruent with their own personal *moral values*. Because of relatively widespread corporate wrongdoing, this congruence is often missing. If an employee believes that personal and corporate value congruence exists, then their own moral values motivate them to follow corporate rules because they see those rules as being consistent with—and developed from—a set of moral values that they have internalized. In legal settings, research shows that an important motivation that encourages people to bring their behavior into line with the law is their belief that many behaviors that are illegal are also immoral (Carlsmith et al., 2002; Robinson & Darley, 1995, 1997; Tyler, 2006b). Similar moral values shape cooperation within experimental games (Kerr, 1995; Kerr, Garst, Kiehle, & Harris, 1997; Kerr & Kaufman-Gilliland, 1994). When people feel that their organization acts in ways that are consistent with their own social and moral values, they will be more strongly motivated to support their organization. Serious problems arise when business leaders fail to define illegal activity as morally unacceptable and to foster organizational norms that are consistent with that definition.

Recent calls for greater attention to ethics in business school curricula and for more attention to ethical issues in work cultures follow from the notion that employees' values can be developed and activated within organizational settings (Bowie, 1999; Schminke, 1998; Trevino & Weaver, 2003; Tyler, 2005; Tyler & Blader, 2005). Because internalized moral values strongly affect employee rule following, the challenge is to create organizational climates that foster genuinely ethical goals and then harness the motivational power of employees' values to attain those goals. Fair market ideology and other system-justifying beliefs pose a threat to these efforts to the extent that they minimize ethical scandals, lead to system undercorrection, and rationalize rule-breaking behavior in the name of profit-related goals (Jost, Blount, et al., 2003).

The efficacy of drawing on genuine organizational legitimacy and internalized moral values is suggested by the results of research. While the use of sanctions remains a traditional (but not very effective) management strategy to secure employee compliance with organizational rules and policies, recent studies directly examine whether activating employees' ethical values can be an effective management strategy for securing compliance. The use of a self-regulatory model such as the one we are proposing was advocated long ago in the context of discussing the legal regulation of business (Selznick, 1969), and it has been advanced with increasing frequency in recent years (Darley et al., 2003; Gunningham & Rees, 1997; King & Lenox, 2000; Rechtschaffen, 1998; Suchman, 1995; Tyler, 2001b; Tyler & Darley, 2000).

Research shows that ethical concerns do indeed motivate self-regulatory behavior in organizational settings (Aalders & Wilthagen, 1997). This includes work focused on legitimacy (Human & Provan, 2000; Suchman, 1995; Tyler, 2006b; Tyler & Blader, 2000, 2005; Zimmerman & Zeitz, 2002), morality (Paternoster & Simpson, 1996; Tyler, 2006b; Tyler & Blader, 2000, 2005), and the general role of fairness in shaping social behavior (Lerner, 2003; Rabin, 1993; Tyler & Blader, 2000; Vandenbergh, 2003).

Ethical values shape behavior when people believe that the rules of their organization are legitimate and hence ought to be obeyed, and/or that the values defining the organization are congruent with their own moral values, leading people to feel that they are morally obligated to support the organization.

At the organizational level, studies show that companies are reluctant to use their market power by lowering employee wages during recessions because they believe such an action will be viewed by employees as unfair (Bewley, 1999). In addition, companies often relinquish opportunities to press their market advantages when dealing with their customers due to concerns that they will be perceived as behaving unfairly (Kahneman, Knetsch, & Thaler, 1986). Ethical concerns also shape wage determination (Rees, 1993) and other parameters of employment relationships (Jolls, 2002). These studies suggest that companies are motivated to respond to serious ethical concerns because they believe that judgments of fairness shape people's reactions and behavior (Estreicher, 2002). Indeed, there is evidence suggesting that companies that are regarded as more ethical by employees, customers, and other constituencies also tend to be more profitable (Huselid, 1995; Margolis & Walsh, 2001) and, conversely, that more profitable companies tend to be perceived as more ethical (Jost, Blount, et al., 2003). Because, as we have suggested with regard to system justification and false consciousness, subjective appraisals of legitimacy can be wrong, the key to developing long-term ethical commitments is to maintain genuine rather than apparent organizational legitimacy that is based on normatively defensible standards of fairness.

CONCLUDING REMARKS

Our goal has been to demonstrate several ways in which psychological jurisprudence can inform a set of legal questions, especially those pertaining to the legitimate exercise of legal authority and the motivation of individuals and groups to adhere to the tenets of the legal system. It would be impossible for any review to consider all the relevant issues in the heterogeneous field of law and psychology, and we have not even tried to do so. Nor would it be possible to handle all of these issues within a single conceptual framework, especially given that the concerns of the legal system are what determine the agenda for the application of psychology to the law (e.g., Carson, 2003). We have opted for a more modest approach. We have considered a specific set of theoretical and empirical developments in social psychology that we think are broadly relevant to several areas of the law. These developments pertain to human motivation, social influence, procedural fairness, and system legitimacy and the relations among these constructs.

More specifically, we have suggested that the deterrence model makes a number of assumptions concerning human motivation to comply with the law and that at least some of these assumptions are untenable. A more realistic model takes as its starting point the notion that people are intrinsically motivated to follow internalized moral values that are supportive of a system that is perceived as legitimate. Because perceptions of legitimacy can be inaccurate due to a number of system-justifying biases, a legal system that delivers substantive justice (and not just the appearance of justice) must be based on something other than consensus. We have suggested that one of the most solid foundations for such a system is a genuine commitment to normative standards of procedural fairness. This formulation suggests a number of consequences for reactions to rule breakers, restorative sentencing, and corporate malfeasance. Our hope is that by taking seriously both subjective (i.e., social and psychological) and objective (i.e., normative) factors with regard to justice and the law—as well as the relationship between subjective and objective factors—it is possible to develop a more sophisticated understanding of how citizens in a society like ours can be motivated to follow norms for appropriate conduct and, indeed, why they should.

The Reciprocal Relation
between Principles and Practice
Social Psychology and Health Behavior

ALEXANDER J. ROTHMAN
PETER SALOVEY

From 1990 to 2003, the percentage of obese individuals in the United States has increased dramatically. In 1991, four states reported that between 15% and 19% of their population was obese and not a single state reported rates of obesity equal to or greater than 20%. By 2001, these numbers had increased to 20 and 29 states, respectively (Mokdad et al., 2001, 2003). These data offer a stark illustration of a daunting practical problem. Although the observed increase in rates of obesity reflect the interplay of myriad factors, fundamentally they are rooted in the consequences of people's behavior—the amount and type of food people eat and the amount and type of physical activity in which people are engaged. Efforts to reduce rates of obesity thus depend on strategies that can effectively elicit changes in diet and physical activity. These initiatives can take the form of structural initiatives that modify the physical environment to promote physical activity, improve access to healthier food, or reduce the cost of healthy foods in schools or other settings (Brownell & Horgen, 2004; French et al., 2001; Stokols, Grzywacz, McMahan, & Phillips, 2003) as well as behavioral initiatives that target individuals directly and provide them with a diet or exercise plan (Wadden, Vogt, Andersen, & Bartlett, 1997; Wing, 2002). Regardless of the focus of the initiative, its design is predicated—either implicitly or explicitly—on assumptions regarding the processes that regulate people's behavioral decisions. Thus, the design and implementation of initiatives to address obesity critically depend on the state of scientific knowledge regarding the basic principles that shape how people process and respond to information about their behavior.

The premise that theoretical principles afford invaluable guidance in the design and implementation of interventions is not unique to efforts to slow rising rates of obesity. The opportunities afforded by theoretical innovations underlie Miller's (1970) call to "give psychology away" and Kurt Lewin's (1951) often quoted assertion "that there is nothing so practical as a good theory" (p. 169). Although we share Lewin and others' confidence in the value of theory, we must not forget that such value is predicated on the existence of *good* theories (Rothman, 2004).

What makes for a good theory? Theory development is a dynamic process that involves the specification of relations between constructs, the testing of those relations, and then, in light of the obtained evidence, the respecification, if needed, of the initial proposition (Noar & Zimmerman, 2005; Weinstein & Rothman, 2005). The efforts of basic behavioral scientists typically focus on elucidating whether a predicted relation between two constructs *can* be observed and thus theory testing is typically conducted in a controlled setting that affords the social and behavioral version of a Petrie dish (Mook, 1983). However, from the perspective of an applied behavioral scientist, good theories must articulate not only what *can* happen but also what *does* and *does not* happen when basic principles operate in more complex social environments. Theory development depends on answers to questions regarding both what can and what does happen, and initiatives that rigorously test the ability of basic principles to specify the determinants of practical problems provide invaluable opportunities to pursue answers to these questions. The process of applying

basic principles sheds light on both what is known and well specified and what is not known or poorly specified. Yet, too often theories are treated—both by theorists and by practitioners—as fixed entities that need only to be disseminated. What is needed instead is a system comprised of an ongoing exchange between basic and applied behavioral scientists in which theory is treated as a dynamic entity whose value depends on it being not only applied and tested rigorously but also refined based on the findings afforded by those tests.

In this chapter, we explore how the interplay between basic and applied behavioral scientists has advanced not only our understanding of health behavior but also our ability to develop initiatives that can promote healthy behavioral practices effectively. Specifically, we examine how social psychological principles have informed the understanding of how people think and reason about their health and how efforts to analyze people's health practices have, in turn, enriched our understanding of basic social psychological principles. It is our hope that this perspective serves to illustrate what can be gained when we challenge our theoretical principles and seek to discern their scope, power, and applicability and to shed light on those areas in which investigators have successfully pursued the interplay between basic and applied behavioral science and those areas where work of this type remains sorely needed.

Our organization of the material in this chapter is grounded in the observation that the process by which people manage and change their behavior can be differentiated into a series of different phases, each of which involves a critical set of psychological and behavioral processes (Prochaska, DiClemente, & Norcross, 1992; Rothman, Baldwin, & Hertel, 2004; Weinstein, 1988). Specifically, we have chosen to focus on three phases. First, we examine how people *gather and interpret* health information and determine whether there is a health problem. Second, we examine how people *decide* whether to take action and the processes that regulate the implementation of their decision. Third, we examine the processes that underlie people's efforts to *initiate and maintain* their behavioral decisions. We believe that differentiating between these phases illustrates a fundamental social psychological perspective in that it reveals how the decision-making processes people rely on are sensitive to the situations in which they find themselves. Finally, in light of the present state of the science, we consider what investigators can do to capitalize on the opportunities emanating from collaborations between basic and applied behavioral scientists.

HEALTH INFORMATION PROCESSING: RECOGNIZING A HEALTH PROBLEM

Given the significant costs associated with unhealthy behaviors, one might expect that people would readily take advantage of opportunities to modify them. Yet, it has become increasingly clear that most people are neither ready nor willing to change their health behavior (Prochaska et al., 1992) and that a critical aspect of en-

couraging people to modify their behavior is to first draw their attention to a given health issue and then, when appropriate, help them to recognize its personal relevance. It is this phase of the behavior change process that we examine in this section.

Weinstein (1988; see also Prochaska et al., 1992) has proposed that there is value in recognizing the informational and psychological needs of people who have yet to consider whether to take action. Specifically, some individuals may not be aware of the health issue (e.g., "I've never heard of the avian flu"), whereas others may be aware of the issue but not see it as personally relevant ("I've heard of the avian flu, but it is not a problem where I live"). Weinstein has proposed that this distinction is best represented by two discrete stages and thus suggests that there are a discrete set of factors that facilitate the transition out of each stage (see Weinstein, Rothman, & Sutton, 1998, for a discussion of what defines a stage). Although there is not yet sufficient evidence to accept this premise, we feel it is worth considering the distinction between efforts to help people become aware of a health issue and efforts to help people recognize the personal relevance of a health issue.

Are You Aware of the Health Problem?

What is known about getting people to recognize the existence of a health problem? Although research has shown consistently that information alone is not enough to promote changes in behavior, awareness of a health issue is a critical first step in the behavior change process. Basic health information provides people with a cognitive framework or schema that helps them to monitor for and integrate new information about the issue (Cameron & Leventhal, 2003). In thinking about educational efforts, it may be important to distinguish between providing information about a new, emerging health issue (e.g., avian flu) and a health issue that has been around for a while but for which what is known about it has changed. People have been shown to be attentive to novel, particularly negative, information (Taylor, 1991), suggesting that information about a new threat will stand out. However, in the absence of any continued pressure to think through the issue, people may have little motivation to elaborate on and gather more information about it and thus will take advantage of available opportunities to minimize any potential danger afforded by this issue. One consequence of this may be that people find that they have heard of a health issue, but when pressed find they know little or nothing about it.

Yet, it may be even more challenging to get people to attend to information about a health problem of which they are already aware. A general feeling of familiarity with the issue may be taken as a sign that they have already considered the issue and thus have little need to look for more, new information. For example, in a recent survey 94% of smokers answered "yes" to the question, "Do you consider yourself adequately informed about the health risks of smoking?" (Cumming et al., 2001). It would be interesting to examine how beliefs such as these affect decisions about information seeking.

People may also be less responsive to information when they perceive a continual shift in what is known about an issue. The perception that there is uncertainty regarding what is understood about a health issue may undermine the value people attribute to new information and, in some cases, may induce a sense of overload. For example, the repeated onslaught of information regarding the impact of diet and exercise on cancer may induce the belief that everything causes cancer and, in turn, may lead people to pay less attention to cancer information. Under these circumstances, people may actively resist attending to new information. Although researchers in the area of health communication continue to examine where and how people gather health information (e.g., Dutta-Bergman, 2004), there is a need for further work that specifies the processes that regulate people's willingness to seek out and evaluate new health information.

Do I Need to Be Concerned about This?

Perceptions of personal risk are thought to play a critical role in shaping the choices people make about their health (Salovey, Rothman, & Rodin, 1998; Weinstein, 1993). Although people are exposed to health risk information repeatedly—for example, that a specific pattern of behavior (e.g., smoking) will lead to a specific health problem (e.g., lung cancer)—this information does not always have a systematic effect on perceptions of personal risk. People appear to be consistently more willing to recognize the existence of a health problem than to recognize their own personal vulnerability (Weinstein, 1998) and to report that their own risk is below that of the average person (Klein & Weinstein, 1997; see Chambers & Windschitl, 2004, for a discussion of the processes that may underlie this effect).

The observation that people may not always recognize the risk posed by their behavior is thought to reflect the fact that people are not passive, unbiased processors of information about their health status (Kunda, 1990; Taylor & Brown, 1988). They respond to health information strategically and are generally receptive to favorable information about their health but often engage in strategies that minimize or discount unfavorable health information (e.g., Ditto & Lopez, 1992; Liberman & Chaiken, 1992; see Rothman & Kiviniemi, 1999, for a review).

Investigators have utilized a range of paradigms to illustrate the ways in which people can resist the unfavorable implications of health information. Laboratory studies have shown that when people review information that may indicate they are at risk for a health problem (e.g., when a heavy coffee drinker reads an article about the potential health risks associated with caffeine intake), they actively counterargue the information provided and are quick to recognize any potential problems with it (Kunda, 1987; Liberman & Chaiken, 1992). The same information is given limited scrutiny when it poses little risk (e.g., when read by someone who does not consume much caffeine). In a similar manner, people emphasize differences between themselves and others who have developed a health problem (e.g., HIV; Gump & Kulik,

1995). The more readily people are able to differentiate themselves from someone with a health problem, the less at risk they consider themselves to be. In a similar manner, the belief that a health problem is consistently associated with a particular social group to which one does not belong can facilitate the inference that it "cannot happen to me." The strategic reliance on social comparison information, in particular the reliance on comparisons to people worse off than themselves, may similarly offer people a way to manage the potential threat posed by a health problem (Taylor & Lobel, 1989).

Potentially threatening health risk information can also lead people to seek out additional information that might undermine its implications (Ditto & Lopez, 1992). For example, in an innovative paradigm that has provided investigators the opportunity to study people's reactions to a diagnostic test, people are asked to screen themselves for an enzyme deficiency that could lead to a mild but irritating pancreatic disorder (Croyle & Ditto, 1990). When people discover that they have tested negative for the enzyme deficiency, they are quick to accept the results. However, when people learn they have tested positive for the deficiency, they spend significantly more time scrutinizing the test result, question the accuracy of the test, and seek out opportunities to retest themselves (Ditto & Lopez, 1992; Ditto, Munro, Apanovitch, Scepansky, & Lockhart, 2003). People have also been shown to alter their beliefs about the health issue selectively in order to minimize its negative implications for the self. For example, when faced with information indicating that they may have a health problem, people reduce their perceptions of the severity of the problem and increase their perceptions of the prevalence of the problem (e.g., Croyle, Sun, & Louie, 1993; McCaul, Thiesse-Duffy, & Wilson, 1992). People have also been shown to shift the perceived importance of health-threatening information. For example, as adolescents engage in risk behaviors more frequently (e.g., smoking and drinking) they recognize that they have put themselves at greater risk for adverse outcome, but at the same time they lower the perceived importance of this information for their behavioral decisions (Gerrard, Gibbons, Benthin, & Hessling, 1996).

People may also have selective memory for health information. When people are faced with evidence of a potential health problem, they selectively recall prior experiences that might render the diagnostic test unreliable (e.g., I haven't slept much the last few days), which could represent a memory bias or a reporting bias (Ditto & Lopez, 1992). Do people have better memory for information that places their behavior in a favorable light? For example, if smokers who eat a healthy diet heard two news reports on the radio, one on the dangers posed by smoking and a second on the dangers posed by eating an unhealthy diet, might they have better memory for one report over the other? In a recent study, Kiviniemi and Rothman (2006) provided people with a series of health recommendations (e.g., eat at least five servings of fruit and vegetables a day) and then conducted a surprise memory test for the recommendations. Participants demonstrated a pronounced bias in their memory for

the recommendations. They were more likely to recall recommendations that indicated that their current behavior was healthy than those that indicated that their current behavior was unhealthy. Returning to the smokers in the prior example, one would expect them to have better memory for the report on diet than the one on smoking. Taken together with the findings from a second study that demonstrated that people's attitudes toward regular alcohol consumption affected their memory for arguments either in favor of or against consuming alcohol (Kiviniemi & Rothman, 2006), there would appear to be evidence of a congeniality bias in people's memory for health information (see Eagly, Chen, Chaiken, & Shaw-Barnes, 1999, for a meta-analysis regarding the effect of attitudes on memory).

There are two dominant explanations for the observation that people are strategic in their response to favorable and unfavorable health information. One perspective emphasizes the motivational concerns that may underlie the observed effects and asserts that because people are motivated to maintain a favorable sense of self, they actively strive to avoid or discount threatening health information. The second perspective emphasizes the degree to which people process information inconsistent with their prior expectations (Ditto, Scepansky, Munro, Apanovitch, & Lockhart, 1998; Ditto et al., 2003; Renner, 2004). When people receive information that is inconsistent or unexpected, it is processed systematically, whereas information that is consistent with one's prior expectations is processed heuristically. Because unfavorable health risk information is generally unexpected, it typically will receive extensive scrutiny. However, according to this framework, unexpected favorable health information would also be scrutinized and, in fact, there is some evidence to support this premise (Renner, 2004). Although investigators typically have approached people's responses to health information from either a motivational or a cognitive perspective, in the end these views are more likely to represent integrated parts of an explanation than two alternative accounts (see Ditto et al., 1998 and 2003, for a thoughtful discussion of these issues). The cognitive activity identified by investigators such as Ditto and his colleagues may provide a description of the mechanisms by which people act on the goals or motives that regulate their preferences.

Although it is clear that motivational concerns have a significant effect on how people respond to potentially unfavorable health information, the failure to appropriately or systematically respond to health information may also reflect the fact that people have difficulty understanding the information, especially statistical information about health risks. There is considerable evidence that people fail to appreciate the fundamental assumptions that impart meaning to numerical estimates of risk (e.g., Black, Nease, & Tosteson, 1995; Shaklee & Fischhoff, 1990) and are sensitive to the specific number used to describe a risk (e.g., 1:10 vs. 10:100; Denes-Raj, Epstein, & Cole, 1995; Slovic, Fischhoff, & Lichtenstein, 1982). In fact, not only are people's understanding of basic probability and numerical concepts quite poor, but their ability to interpret numerical information regard-

ing breast cancer and mammography accurately is systematically dependent on their general ability to deal with numerical information (i.e., numeracy; Schwartz, Woloshin, Black, & Welch, 1997).

One challenge posed by people's innumeracy is that they find it difficult to assign meaning to a given level of risk. Although informing a 40-year-old pack-a-day smoker that quitting will reduce his risk of dying from lung cancer from 131 of 10,000 to 56 of 10,000 is quite precise (see http://cancercontrol.cancer.gov/tcrb/smokersrisk), how people react to that information may not be equally precise. There is some evidence that people spontaneously transform numerical information into discrete categories (e.g., high or low risk; Bottorff, Ratner, Johnson, Lovato, & Joab, 1998) and that the labels assigned to the risk are the best predictors of people's responses to numerical information (Windschitl & Wells, 1996). The difficulty people have assigning meaning to numerical information about their health may help to explain their sensitivity to comparison information (Festinger, 1954). A range of studies has demonstrated that available comparison information regulates how people react to information about their health risk or their health behavior (e.g., Klein, 1997; Rothman, Haddock, & Schwarz, 2001; Sandman, Weinstein, & Miller, 1994; Windschitl & Weber, 1999; see Klein & Weinstein, 1997, for a review). Moreover, when possible, people may selectively recruit comparison standards that place them in a favorable light (Wood, Taylor, & Lichtman, 1985).

Finally, how people respond to health information may be affected by the features they believe characterize a specific health problem. One particularly interesting feature of people's mental model of a health problem (Leventhal, Nerenz, & Steele, 1984) is the social group they associate with the problem. To the extent that people associate an illness with a specific group, they may be less likely to recognize signs of that illness when presented by someone not in that group and may be too quick to recognize signs of that illness when presented by someone who does fit the stereotype. Across a series of studies, Martin and her colleagues have provided a compelling case that the belief that coronary heart disease is more strongly associated with men than women affects the likelihood that lay people and health professionals recognize signs of a heart attack when presented by a woman (Martin, Gordon, & Lounsbury, 1998; Martin & Lemos, 2002). Based on interviews conducted with men and women who had recently been hospitalized due to myocardial infarction (MI), they observed that women were more surprised than men to find that they had an MI and that prior to seeing a doctor, women were less likely to have attributed their initial symptoms to an MI (Martin et al., 2004). In a parallel line of work, Hunt and her colleagues have observed that illness stereotypes regarding who develops eating disorders affect how both lay people and doctors respond to diagnostic information (Hunt, McGorty, Iyer, & Rothman, 2005; Hunt & Rothman, 2004, respectively). Despite the presentation of the exact same symptom information, people are more likely to infer the presence of an eating problem when it is reported by a patient who is Caucasian and/or

a woman. Moreover, a separate set of studies has shown that the presentation of words that cue an illness automatically activates thoughts about members of social groups stereotypically associated with the illness and inhibit thoughts about members of social groups unassociated with the illness (Hunt, Rothmann, Rothman, Iyer, & McGorty, in press). Findings such as these not only illustrate how information about social category membership may regulate responses to health information but also point toward a potential set of mechanisms that might contribute to the disparities in clinical care that have been consistently observed (Smedley, Stith, & Nelson, 2003; van Ryn & Fu, 2003).

Do People Always Resist Health Risk Information?

Given the observation that people may resist unfavorable health information, it is critical to consider what is known about the factors that may facilitate or undermine resistance. Perhaps the first thing that should be noted is that people's hesitancy to accept or recognize unfavorable health information is bounded by rationality (Kunda, 1990). People may capitalize on uncertainties or weakness in evidence that indicate the presence of a health problem but generally do not make up weaknesses that are not present. Similarly, people may take longer to accept an unfavorable than a favorable test result, but when faced with consistent evidence of a health problem, they will generally accept it.

As noted earlier, one factor that may facilitate people's resistance to health risk information is the difficulty they have processing and understanding the information. To the extent that people need to work actively to infer the meaning of new health information, there is greater opportunity for them to engage in biased processing. This would suggest that there is particular value in ensuring that initial messages about a health risk are clear and easy to understand.

Beliefs about and interactions with similarly minded peers may also serve to reinforce the tendency to either discount the health risk information or augment the perceived value of a particular unhealthy behavior (Crandall, 1988; Prentice & Miller, 1993; Suls & Green, 2003; Suls, Wan, & Sanders, 1988). In fact, people may choose to rely on the real or perceived attitudes of their peers rather than thinking through the implications of an issue for themselves. This might be particularly true for people who are dispositionally inclined not to elaborate on information (Cacioppo, Petty, Feinstein, & Jarvis, 1996).

Another factor that may facilitate resistance to health risk information is that concerns about health and illness may not always be the primary motive that guides people's health decisions (McGuire, 1991). As Leary, Tchividjian, and Kraxberger (1994) have noted, people's health behaviors are often regulated by interpersonal, self-presentational concerns. For example, young adults think about tanning more in terms of the social benefits it affords (e.g., enhancing physical appearance) than its associated health risks. Although these concerns may render people less receptive to health risk information,

they may afford other opportunities to convince people that unprotected sun exposure is a problem. For instance, Jones and Leary (1994) found that a pamphlet that describes how the sun can harm one's appearance elicited lower interest in tanning than did a pamphlet describing the health risks posed by sun exposure. In a different study, an ultraviolet photo that revealed evidence of sun damage was able to increase intentions to use sunscreen but elicited behavior change (i.e., a reduction in the number hours spent sunbathing over the next month) only when combined with a brochure on photoaging (Mahler, Kulik, Gibbons, Gerrard, & Harrell, 2003).

Are there factors that render people more receptive to threatening health information? Prior experience with a health problem has a pronounced effect on perceptions of future risk (Weinstein, 1989). Although for health problems that arise as independent acute events (e.g., cavities and warts), people can capitalize on the lessons afforded by their earlier behavior or the lack thereof, in most cases this is not a satisfying solution. There is some evidence that people who are optimistic may be more willing to attend to potentially threatening health information (Aspinwall & Brunhart, 1996). Optimism may help minimize the feelings of distress elicited by consideration of the information or may help people maintain a sense of confidence or control that should they conclude that there is a health problem, they will be able to do something about it. More generally, positive affect may offer a similar set of psychological resources that enable them to confront potential challenges more effectively (see Aspinwall, 1998; Fredrickson, 2001; Trope & Neter, 1994), although the manner with which it influences the processing of health risk information has not been clearly elucidated.

Several studies have also shown that when people are provided an opportunity to affirm their self-worth, they are more open to health-threatening information (Reed & Aspinwall, 1998; Sherman, Nelson, & Steele, 2000). For example, Reed and Aspinwall (1998) adapted a paradigm that had previously been used to demonstrate that people will resist information that might indicate that their behavior is risky (Kunda, 1987; Liberman & Chaiken, 1992) and observed that when people had initially affirmed their self-worth, they were quicker to attend to information that confirmed that their behavior was risky and perceived this information to be more convincing than information that indicated their behavior was *not* risky. As with optimism, self-affirmation may provide people with the psychological resources to cope with and confront distressing information and may afford them the self-confidence that they can deal with these challenges.

Interpreting How People Respond to Health Information: The Importance of Assessing Multiple Indicators

Across a broad array of studies, investigators have reported evidence regarding people's resistance to accepting health information. Although these findings offer a

compelling picture of an individual who, when possible, strives to minimize or undermine the implications of threatening health information, there has been little discussion of what measures are needed to provide a comprehensive assessment of how people respond to health information (Rothman & Kiviniemi, 1999). Should investigators focus on people's knowledge of a risk factor, their perception of personal risk, feelings of concern or worry, or perceptions of the prevalence and the severity of a health problem? Should they assess people's interest in additional information about the issue? How important is the time course of people's reactions? If people's initial reaction is to derogate the information, does this negative view persist over time? The answers to these questions are critically important as the outcome criteria an investigator chooses to emphasize will affect what conclusions are drawn.

For example, think back to an earlier finding we discussed regarding the cognitive consequences elicited by changes in adolescent risk behavior (Gerrard, Gibbons, Benthin, & Hessling, 1996). In this study, Gerrard and her colleagues assessed several distinct beliefs (i.e., perceptions of personal risk, perceived prevalence of the behavior, and impact of health and safety concerns). However, imagine that the investigators had assessed only perceptions of personal risk. Because they found that participants' risk perceptions shifted in line with changes in their behavior, the authors might have concluded that adolescents do not respond defensively to health risk information. However, because they also assessed the perceived prevalence of the risk behaviors and the impact that health and safety beliefs have on decision making, it became clear that how people respond to changes in their risk behavior is quite complex. Although the adolescents acknowledged that their actions placed them at greater risk, they altered other beliefs that served to undermine the implications of the risk information for future behavioral decisions.

To develop a comprehensive understanding of how people respond to threatening health information, it may be critical for investigators to assess a broad range of outcome measures. As discussed earlier, there is considerable evidence that people actively work to minimize the implications of threatening health information (e.g., Ditto & Lopez, 1992; Jemmott, Ditto, & Croyle, 1986). However, a few of these studies included indicators of not only whether people minimized the threat posed by the problem (e.g., measures of severity and prevalence) but also whether they were interested in future opportunities to address the problem (e.g., how the problem could be treated). These studies revealed that even though people minimize the threat posed by the problem, this does not preclude them from being interested in how to deal with the problem (e.g., Croyle & Hunt, 1991; Croyle et al., 1993; McCaul, Glasgow, & O'Neill, 1992). For example, people who learned that they had borderline high cholesterol perceived high cholesterol to be a *less* serious health problem than did those told they had low cholesterol, but they still expressed greater interest in taking steps to lower their cholesterol (Croyle et al., 1993). There is also evidence that potentially threatening

health information can affect people's behavioral intentions, even in the absence of changes in perceived personal risk (e.g., Evers, Bishop, Gerhan, & Weisse, 1997; Gump & Kulik, 1995). For example, heterosexual students increased their perceptions of personal risk for HIV infection in response to a presentation by an HIV+ speaker, but only when the speaker was said to be heterosexual. Yet, they increased their intentions to be HIV tested regardless of the speaker's sexual orientation (Evers et al., 1997).

The observation that people can both minimize and be responsive to threatening health information is consistent with the parallel response model (Leventhal, 1970; Leventhal et al., 1984), which suggests that people independently regulate their affective and behavioral response to a health threat. Specifically, when faced with threatening health information, people may respond in ways that alleviate the distress elicited by the information—thereby attenuating any change in perceived risk and/or perceived severity—and in ways that serve to reduce the likelihood that they might develop the health problem—thereby eliciting changes in behavior. By reducing feelings of distress, people may find themselves in a better position to deal with the challenges posed by the health issue and, in fact, possess the same psychological resources that allow people who are optimistic or have a strong sense of self-worth to be more receptive to health-threatening information (Aspinwall & Brunhart, 1996; Reed & Aspinwall, 1998; Sherman et al., 2000).

Yet, the broader implications of these findings remain uncertain. If people are able to alleviate the feelings of distress elicited by a health problem, will this serve to undermine their motivation to take corrective actions? In situations in which the steps people need to take are relatively simple and require only a single course of action (e.g., being vaccinated for a health threat), there may be little downside to reducing felt distress. However, in situations in which people need to engage in a sustained series of behaviors (e.g., changes in diet or physical activity), the absence of distress may serve to undermine the perceived value of engaging in these new behaviors.

Recent research by Klein and his colleagues also indicates the importance of assessing the interrelationships between people's health beliefs (Klein, 2005; Klein, Blier, & Janz, 2001). Klein has suggested that self-affirmation may allow people to more readily examine threatening health information but that the nature of this examination may not be as thoughtful as one might have hoped. Specifically, Klein and colleagues found that the risk perceptions reported by people who had self-affirmed prior to receiving threatening health information were associated with their self-esteem but not with their standing on relevant risk factors (Klein et al., 2001). People who had not affirmed prior to receiving the threatening information reported risk perceptions that were correlated with their risk factor scores. Thus, self-affirmation may help people pay attention to threatening health information but may lead them to form poorly structured beliefs about the issue. To date, the implications of these findings are uncertain. A critical issue for future research will

be to examine the immediate and long-term consequences of self-affirmation, in particular, the manner in which the beliefs that self-affirmed people form predict subsequent behavioral decisions.

Generally, research in this area would benefit from a closer examination of the structure of the relationships among the thoughts and feelings people hold about a health issue. Research on mental representations of illnesses (Lau & Hartman, 1983; Leventhal et al., 1984) may provide a useful starting point for these investigations as researchers have identified a set of themes that consistently characterize these representations (e.g., identity, cause, consequence, time line, and cure). Although considerable work has gone into describing these themes and developing measures that can assess them reliably (Moss-Morris et al., 2002), tests of the predictive value of these constructs are much more limited and when conducted have primarily examined how beliefs within a particular category are related to outcomes (see Hagger & Orbell, 2003, for a recent review). Greater consideration needs to be paid to the dynamic nature of these beliefs—how are these beliefs formed? How do they affect people's receptivity to new information about an illness? How does change along one dimension (e.g., time line) affect beliefs about another dimension (e.g., consequences)? And, how do beliefs affect and how are they affected by changes in behavior? For example, people's beliefs about the time line of an illness (i.e., acute, cyclic, or chronic) have been shown to be associated with how people treat their condition (Meyer, Leventhal, & Guttman, 1985) and how they feel about their condition (Rabin, Leventhal, & Goodin, 2004). To date, this work has focused exclusively on people with the relevant health problem. Yet, there may be a reason to predict that people's construal of the time line for a health problem, for example, might affect how healthy people process and respond to information about a potential health problem. For example, people who construe an illness as an acute condition may be quite receptive to information about screening for the condition but feel less of a need to learn about how it can be prevented, whereas those who construe an illness as a chronic condition may be quite interested in information about prevention but see little value in information about screening.

Taken together, it is clear that health beliefs are multifaceted and moderated by characteristics of the individual as well as his or her social environment. Should it surprise us, then, that the relation between health beliefs and health behavior is more complex than might be anticipated? It is to these issues that we turn next.

MOVING FROM THOUGHT TO ACTION

People may find that a health issue elicits a rich array of thoughts and feelings. They might know that regular exercise is associated with a range of health benefits and affords an important way to manage one's weight but find that thinking about exercise elicits feelings of boredom and discomfort. At a certain point, though, these thoughts and feelings need to be integrated, and people

need to decide whether or how to act. In this section, we first examine the processes that shape how people make behavioral decisions (e.g., should I test my home for radon?) and then turn to those that influence the transition from intention to action. Because a fundamental practical challenge is designing initiatives that promote healthy behavioral decisions, we conclude this section with an overview of several communication strategies (e.g., message tailoring and message framing) that appear to be effective.

There are presently a substantial number of models that purport to elucidate how people determine whether to adopt a given behavior (health belief model [Rosenstock, Strecher, & Becker, 1988]; precaution adoption process model [Weinstein, 1988]; protection motivation theory [Maddux & Rogers, 1983]; social cognitive theory [Bandura, 1986]; theory of planned behavior [Ajzen, 1991]; theory of reasoned action [Ajzen & Fishbein, 1980]; transtheoretical model of behavior change [Prochaska et al., 1992]). Although these models differ in assumptions regarding how health decisions are structured (e.g., some rely on a stage-based framework, whereas others rely on a continuum-based framework; Weinstein et al., 1998) and in the specific set of beliefs thought to be most closely associated with a decision to take action (see Sutton, 2002b, and Weinstein, 1993, for insightful comparisons of theories), they all rely on some version of a utility-based framework such that the decision to adopt a given behavior is predicated on an analysis of the relative costs and benefits associated with different courses of action (Salovey et al., 1998; Weinstein, 1993). In this chapter, we do not provide a systematic overview of each of the dominant models but instead refer the reader to several recent narrative and meta-analytic reviews (e.g., Albaracin, Johnson, Fishbein, & Mullerleile, 2001; Armitage & Conner, 2001; Conner & Norman, 1996, 2005; Milne, Sheeran, & Orbell, 2000; Sutton, 1998).

Deciding Whether to Take Action

What determines whether a person decides to engage in a new behavior? A critical assumption of nearly all models is that people conclude that the outcomes afforded by engaging in the new behavior (e.g., exercising at the gym 3 days a week) are more desirable than those afforded by one's current behavior (e.g., no regular exercise) (Bandura, 1997; Rothman, 2000; Salovey et al., 1998). Although there is considerable variability in the potential outcomes people consider, one consistent theme is the risk of unwanted health problems. The opportunity to reduce one's risk of a health problem is believed to be a critical motivation to adopt a health behavior. Although risk perceptions are explicitly identified in some models (e.g., the protection motivation theory), they can be readily integrated into other models that do not explicitly reference them (e.g., theory of reasoned action) (Weinstein, 1993).

The premise that people decide to take precautions to reduce the risk of adverse outcomes is widely shared, but it has received surprisingly inconclusive empirical sup-

port. This state of affairs primarily reflects the difficulty of capturing the causal effect of perceived risk on behavioral decisions (Gerrard, Gibbons, & Bushman, 1996; Weinstein, Rothman, & Nicolich, 1998). Because people's behavioral decisions affect their level of risk (e.g., having quit smoking for a year, I conclude that my risk of developing lung cancer has dropped), investigators need to be careful to differentiate between the effect that perceptions of risk have on behavior and the effect that behavior has on perceptions of risk (see Brewer, Weinstein, Cuite, Herrington, & Hayes, 2004, for an excellent empirical example of both of these effects).[1]

It has been suggested that people assess their risk for an unwanted event based on their ability to imagine it happening to them (Armor & Taylor, 1998; Kahneman & Tversky, 1982; Raghubir & Menon, 1998; Rothman & Schwarz, 1998; Sherman, Cialdini, Schwartzman, & Reynolds, 1985). To this end, people may be particularly responsive to information that facilitates this process, such as how the actions they do (or do not) take can affect the onset of a health problem (i.e., antecedents) and what it would be like to experience the health problem (i.e., consequences; for a more comprehensive discussion of this issue, see Rothman & Kiviniemi, 1999). Fear appeals have been one approach to providing people with vivid information about both how a health problem may arise and its severe, unpleasant consequences (Leventhal, 1970). Appeals that elevate feelings of concern about a health issue are effective as long as they provide people with an effective means to reduce their risk (Witte & Allen, 2000).[2] Although investigators have at times predicted that at a certain point elevating feelings of risk or concern about an issue can be counterproductive (e.g., Janis, 1967), there has been little evidence of a curvilinear relation between perceptions of risk and people's behavioral decisions (McCaul, Branstetter, Schroeder, & Glasgow, 1996). In fact, fear appeals lead people to be favorably biased in their evaluation of potential solutions to their health problem (Das, de Wit, & Stroebe, 2003; de Hoog, Stroebe, & de Wit, 2005). Once people recognize that they must deal with a personally relevant health problem, they may be motivated to believe that there is something that can be done about it.

Research on fear appeals would appear to suggest that action is predicated on people recognizing the existence of a significant personal health risk and believing that there is something they can do to effectively reduce their risk. However, the predictive power of these two constructs is almost always assessed simultaneously, and there has been little reason to consider the timing of these effects as well as whether these two classes of beliefs make unique contributions to the behavior change process. The precaution process adoption model (PPAM) (Weinstein, 1988) challenges this view and has argued that investigators need to differentiate between deciding whether to take action and implementing the decision to act (or not act as the case may be), a distinction that is consistent with the perspective offered by several other investigators (Gollwitzer, 1999; Sheeran, 2002). According to the PPAM, information about personal risk is a critical determinant of whether people decide to take ac-

tion, but once someone has decided to do so, additional risk information has limited impact. The availability of information on how, when, and where to take action—and the resulting inference that one is able to perform the desired behavior (i.e., self-effficacy) (Bandura, 1997)—is the critical determinant of whether people move from decision to action. Evidence for the premise that different types of information (i.e., about personal risk or about one's ability to take action) have more impact at specific points in the behavior change process was obtained in an informational intervention designed to promote home radon testing (Weinstein, Lyon, Sandman, & Cuite, 1998).

The observation that as people make their way through the behavior change process they shift from a consideration of the potential outcomes (e.g., the likelihood that one might develop cancer) to a consideration of the potential solution (e.g., the confidence in one's ability to perform the behavior) is strikingly similar to several predictions generated by construal state theory (Trope & Liberman, 2003). According to this theory, when people are considering an event in the future—which may be analogous to deciding whether or not to take action—they focus on its desirability, but when the are considering an event that may soon occur—which may be analogous to formally implementing one's decision—they focus on its feasibility (Liberman & Trope, 1998). This shift in focus from desirability to feasibility is consistent with the premise that beliefs about one's ability to take action become critical as the time for action gets closer. Furthermore, the notion that people initially focus on the desirability of the potential outcome serves as an important reminder that the risk of an unwanted outcome may not always be the critical determinant of the decision to take action.

Because Weinstein chose to focus on decisions regarding precautionary behaviors, he emphasized personal risk and the opportunity to reduce one's risk as the primary way to assess a behavior's value. The perceived value of other classes of behavior may rest not on their ability to avoid or reduce unwanted outcomes (i.e., reduce one's risk of cancer) but, rather, on their ability to afford or approach desirable outcomes (i.e., improve one's appearance). For example, weight loss efforts appear to be motivated more by a desire to improve one's appearance and physical fitness than to avoid health problems (Foster, Wadden, Vogt, & Brewer, 1997). To the extent that we can specify the factors that regulate the perceived value of a behavior, or ideally classes of behaviors, this information could be used to generate a more refined set of predictions regarding the determinants of the behavioral decision-making stage identified in the PPAM.

Generally, what is striking about the conceptual framework generated by Weinstein is that rather than providing a list of constructs that predict a behavioral outcome, it offers a series of predictions regarding the specific conditions under which a construct will or will not facilitate behavior change. By specifying when a construct has an effect, investigators should find it easier to describe the processes that underlie its impact, in turn stimulating the

development of a more comprehensive theoretical framework. This type of information should also enhance the ability of practitioners to develop theoretically grounded intervention strategies (Jeffery, 2004; Rothman, 2004).

Moving from Intention to Action

According to the dominant models of health behavior, once people decide to take action, their decision, perhaps represented by a stated intention to act, produces a pattern of action. Yet, there is considerable empirical evidence that intentions do not always translate into behavior, and a common complaint is that the process by which intentions lead to actions is not well articulated (Bagozzi, 1992; Sheeran, 2002).

What factors might regulate the observed relation between intentions and behavior? From a methodological perspective, it is critical that there is a clear correspondence between the stated intention and the observed behavioral outcome (Ajzen & Fishbein, 1980). Investigators need to be thoughtful from the outset regarding the behavioral outcome they are primarily interested in—is it a specific behavior (e.g., eating fruits and vegetables for snack when at work), a broad class of behaviors (e.g., eating a healthy diet), or a goal or consequence of behavior (e.g., losing weight) (Sutton, 2004)? Because investigators are frequently interested in the consequences of the behavior, they test whether a set of beliefs predict a desired outcome (e.g., change in weight). Yet, in doing so, they frequently fail to consider the behavioral practices that underlie the desired outcome. For example, Linde, Rothman, Baldwin, and Jeffery (2006) have illustrated how the impact of self-efficacy on weight loss outcomes critically depends on the ability of self-efficacy to predict effective weight loss practices (i.e., changes in diet and physical activity).

By adding perceived behavioral control to the theory of reasoned action, Ajzen (1991) strove to better specify the relation between intentions and behavior. Perceptions of behavioral control are thought to represent the degree to which people believe they have control over their actions and thus their confidence in their ability to turn their intentions into actions. Although perceived behavioral control has been shown to enhance investigators' ability to predict behavior, the specific manner by which it is expected to affect behavior is uncertain (Armitage & Conner, 2001). It could have a direct effect on behavior, an indirect effect on behavior through its effect on intentions, a moderating effect on the relation between intention and behavior, or perhaps some combination of effects (see Sutton, 2002a and 2004, for an excellent discussion of these issues)? The premise that control would regulate people's ability to act on their intentions would seem to be consistent with viewing its status as a moderating factor, but when effects have been observed, they almost always have taken the form of a direct effect of control on behavior. Interestingly, a study of the determinants of behavior change in patients with coronary heart disease revealed that patients' perceptions of behavioral control regarding exercise and smok-

ing cessation predicted objective changes in behavior (i.e., increases in exercise and decreases in smoking), whereas their stated intention to change did not predict behavior (Johnston, Johnston, Pollard, Kinmonth, & Mant, 2004). Although one must be cautious in drawing strong conclusions from a single study, this pattern of results might suggest that once people have decided to make a change (e.g., quit smoking), the degree to which they want to change may be less important than their confidence that they can act on their desire.

A particularly active line of inquiry regarding the relation between intentions and behavior has been to examine what characterizes intentions that people are more likely to carry out as compared to those they are less likely to act on. In particular, investigators have been examining the stability or strength of people's intentions (e.g., Conner, Norman, & Bell, 2002; Conner, Sheeran, Norman, & Armitage, 2000; Sheeran, Orbell, & Trafimow, 1999; see Cooke & Sheeran, 2004, for a review). Consistent with research on attitude strength (Petty & Krosnick, 1995), strong intentions are thought to be better predictors of behavior. Intention strength has been operationalized by assessing its stability over time (Sheeran et al., 1999), and empirical evidence has consistently found strong intentions to be a better predictor of behavior. In fact, Conner and colleagues (2002) demonstrated that, controlling for initial behavior, strong intentions regarding food choices (which were based on assessments of stability over a 6-month time window) were associated with healthy eating habits 6 years later.[3]

What is particularly striking about research on intention strength is that it may help to explain why a diverse set of factors moderate the relation between intentions and behaviors. Specifically, Sheeran and Abraham (2003) have shown that the moderating effect of factors such as intention certainty, self-schemas, and anticipated regret on the intention–behavior relation is mediated by intention strength. Thus, people who are certain about their intentions, who see a behavior as important to their sense of self, or who anticipate feelings of regret if they do not act, all form intentions that are strong and stable. The observation that the same mechanism underlies a disparate array of moderated effects provides a reassuring sense that it may be possible to develop parsimonious explanations for the relation between intentions and behavior. Moreover, it suggests there may be value in intervention strategies that can promote stable intentions. The challenge to future endeavors will be to delineate the processes that promote the formation of strong intentions.

One method that augments the translation of intention into actions is the use of implementation plans (Gollwitzer, 1999; Gollwitzer, Bayer, & McCulloch, 2005). Several studies have shown that asking people to specify how, when, and where they will implement their intentions increases the likelihood that they will perform the behaviors such as making healthy food choices, taking a vitamin supplement, or screening for cervical cancer (e.g., Armitage, 2004; Sheeran & Orbell, 1999, 2000). Implementation plans are thought to affect people's

sense of control over their behavior, but not their motivation to act. Consistent with this view, Sheeran, Webb, and Gollwitzer (2005) demonstrated that the beneficial effect of implementation plans is contingent upon people having initially endorsed the relevant behavioral goal.

One thing that an implementation plan does is render salient the structural and behavioral factors that may underlie people's ability to take action. For example, if people formulate a plan to eat fruits and vegetables as an afternoon snack at work, they are more likely to recognize what they need to do in order to act (e.g., buy fruits and vegetables and prepare and pack them each morning). The formulation of an implementation plan may also help people better specify their initial intentions. For example, a smoker might shift from the general intention of cutting down on the number of cigarettes she smokes to the more specific intention of not smoking any cigarettes after dinner. The principle of correspondence that helps investigators detect the effect of beliefs on behavior at the sample level should similarly help an individual maximize the chance he or she will act on his or her intention.

In a recent application of the theory of planned behavior, Bryan, Fisher, and Fisher (2002) reported that the model fit the data best when intentions to use condoms were allowed to predict a set of preparatory behaviors (i.e., buying condoms, carrying condoms, and discussing condoms with partner), which in turn predict condom use. What is particularly noteworthy about this study is that it illustrates an attempt to unpack the intervening steps that underlie behavioral decisions. To the extent that a behavioral outcome depends on a series of behavioral decisions, investigators need to consider how the experiences afforded by the initial set of behaviors may affect the beliefs that, in turn, predict subsequent behavioral decisions. For example, after forming an intention to use condoms, someone might attempt to purchase condoms in his or her neighborhood grocery store. If he or she finds purchasing condoms to be difficult or embarrassing, this is likely to affect the status of the initially stated intention.

Are All Actions Intentional?

Up to this point, we have implicitly assumed that all behavioral decisions reflect intentional, planned choices. Although this assumption is likely appropriate for decisions about most health behaviors, Gibbons and Gerrard have proposed that it may not provide an accurate account of the decisions adolescents and young adults make to engage in risky behaviors (Gibbons, Gerrard, & Lane, 2003). According to the prototype/willingness model, there are two paths that guide people's behavioral decisions (Gibbons, Gerard, Blanton, & Russell, 1998). People's behavior may reflect their intentions as specified by models such as the theory of planned behavior, but they may also reflect their willingness to engage in a particular behavior under particular circumstances. Measures of behavioral willingness tap the fact that people may not intend to engage in a given behavior (e.g., people don't leave the house intending to drive home drunk

at the end of the evening) but may respond favorably to the presence of situational factors that afford that behavior (e.g., at the end of a night out, faced with limited options, people may be willing to drive drunk). According to the model, behavioral willingness is predicated on the perceived acceptability of the relevant behavior, which is typically assessed as people's perception of the prototypical person who engages in the risky behavior (Gibbons & Gerrard, 1995).

Across several studies, Gibbons, Gerrard, and their colleagues have demonstrated that measures of behavioral willingness are significant predictors of the onset and increases in risky health behaviors such as drinking, substance use, smoking, and unsafe sexual behaviors, even when controlling for behavioral intentions (see Gibbons et al., 2003, for a review). Consistent with the broader model, the impact of behavioral willingness is particularly pronounced in samples of adolescents (e.g., Gibbons et al., 2004). As people age, patterns of risky behavior, such as those noted above, appear to be more strongly a function of their behavioral intentions (Gibbons, Gerrard, Pomery, & Reimer, in press). Yet, this does not necessarily mean that the behaviors of older adults are always the result of intentional, planned choices. Behavioral willingness may prove to be an important predictor of a new set of adult-oriented risk behaviors such as adultery, tax evasion, or insider trading.

The impact of behavioral willingness has also been shown to be more sensitive to context than the impact of behavioral intentions. For example, in a sample of young adolescents, behavioral willingness predicted changes in substance use, but this effect was particularly strong when those kids lived in high-risk neighborhoods that provided the situational affordances for the kids to respond to (Gibbons et al., 2004). The effect of behavioral intentions on substance use was the same across high- and low-risk neighborhoods.

COMMUNICATION STRATEGIES

A primary method for motivating people to change their behavior has been to provide them with information that will persuade them to alter it (Eagly & Chaiken, 1993). To be effective, communication strategies are needed that get people not only to attend to the message but also to process it in a manner that maximizes its impact on how they think and feel about the issue (Petty & Wegener, 1998). In this section, we consider two communication strategies, message tailoring and message framing, that have been shown to motivate behavior change effectively.

Message Tailoring

Message tailoring is based on the premise that people will pay more attention to and be more persuaded by information that speaks directly to their own personal concerns.[4] For example, a smoker who is worried about the social stigma of smoking would receive information on that topic, whereas a smoker who is worried about how secondhand smoke may affect her family's health would

receive information about that topic. Tailored health messages have been shown to be more effective than generic messages that provide all individuals with the same information (Brug, Glang, van Assema, Kok, & van Breukelen, 1998; Dijkstra, De Vries, & Roijackers, 1998a, 1998b; Kreuter, Oswald, Bull, & Clark, 2000; see Skinner, Campbell, Remer, Curry, & Prochaska, 1999, for review).

Why might tailored messages be more effective? Contemporary models of attitude change and persuasion offer a framework for understanding how and when tailored messages are maximally effective (Petty, Barden, & Wheeler, 2002). To the extent that tailored messages are perceived to be personally relevant, the message will be processed more extensively, which, in turn, should increase its influence on people's thoughts and feelings about the health issue. All else being equaled, greater elaboration of a strong, health message is desirable, as well-reasoned attitudes are more stable over time and better predictors of behavior (Petty & Wegener, 1998). Consistent with this perspective, studies have demonstrated that tailored messages are more likely to be read and remembered than are nontailored messages (e.g., Skinner, Strecher, & Hospers, 1994), are more likely to be discussed with others (e.g., Brug, Steenhuis, van Assema, & de Vries, 1996), and are perceived as more interesting and engaging (e.g., Brug et al., 1996; Kreuter, Bull, Clark, & Oswald, 1999).

The principle of tailoring messages is consistent with several lines of research in social psychology that have demonstrated the benefits of matching a message to an aspect of a person's personality or motivational concerns (e.g., Williams-Piehota, Pizzaro, Navarro, Mowad, & Salovey, 2006; Williams-Piehota, Pizzaro, Schneider, Mowad, & Salovey, 2005; Williams-Piehota, Schneider, Pizzaro, Mowad, & Salovey, 2004). Higgins (2000) has proposed that messages that correspond to a person's dominant self-regulatory concern—the tendency to be preoccupied moreso with accomplishments than safety or vice versa—benefit from the subjective experience of fit. Moreover, people appear to enjoy working on tasks that are structured to match their self-regulatory concerns (e.g., Freitas & Higgins, 2002) and may even perform better (Spiegel, Grant-Pillow, & Higgins, 2004). It may be that when people receive a tailored message they are more likely to construe their motivation to modify their behavior as reflecting intrinsic concerns, which have been shown to be predictive of behavior change (e.g., Williams, Ryan, Rodin, Grolnick, & Deci, 1998).

A critical challenge to further advances in tailoring is the development of a conceptual framework that can help determine or prioritize the dimensions along which information should be tailored. Theories of health behavior could potentially guide decisions regarding the type of information that should be tailored. For example, as discussed earlier, there may be benefits to tailoring message content (e.g., information about personal risk vs. information about self-efficacy) based on where people are in the decision-making process (Dijkstra, De Vries, Roijackers, & van Breukelen, 1998; Weinstein, Rothman, & Sutton, 1998). To the extent there is an ad-

vantage to matching information to where people are in the decision-making process, consideration could be given to whether there is any added advantage to tailoring the presentation of that material to an individual's unique concerns.

To date, investigators of tailored health messages have assumed that people's motivations or goals for changing their behavior are all equally effective. However, there is a substantial body of research in academic settings that has shown that approach goals (i.e., goals that are characterized by a desire to reach a favorable goal state) are more strongly associated with desirable outcomes than are avoidance goals (i.e., goals that are characterized by a desire to stay away from an unfavorable goal state; Elliot & Church, 1997; Elliot & McGregor, 1999). This would suggest that tailoring messages to an approach goal (e.g., dieting to improve one's appearance) might prove to be more effective than tailoring a message to an avoidance goal (e.g., dieting to avoid future health problems).

Only one study has tested the differential impact of approach and avoidance goals on health behavior change (Worth, Sullivan, Hertel, Jeffery, & Rothman, 2005). Although the type of goal people generated at the outset of a smoking cessation program predicted their ability to quit smoking, smokers who had generated more *avoidance* goals were more likely to initiate a quit attempt. The observation that avoidance goals were beneficial is quite striking and may be due to two critical factors. First, the avoidance goals that predicted behavior change were those that focused on curing a current problem (e.g., getting rid of the smell in one's car), a subset of goals that have not been considered in prior research. Consistent with prior findings, avoidance goals that focused on preventing a future unwanted outcome (e.g., not developing cancer) did not predict success. Second, the behavioral task at hand may affect the relative impact of different goals. For example, smoking cessation is typically construed in terms of trying not to be a smoker rather than to be a nonsmoker (Gibbons & Eggleston, 1996). This construal may lead avoidance goals to better fit the task at hand, a finding that would be consistent with other demonstrations of correspondence. This is clearly an area that needs further investigation.

Finally, tailoring initiatives may benefit from consideration of how the broader social context affects the perceived value of information about a given health practice. According to deviance regulation theory (DRT; Blanton & Christie, 2003), people will be more responsive to information about deviant than normative behavioral practices. Because health messages can emphasize either engaging in a particular behavior (e.g., smoking) or not engaging in the behavior (e.g., not smoking), DRT predicts that people will be more responsive to messages regarding the behavior that is not considered normative. For example, when students believe that getting a flu shot is normative, they are more responsive to information about people who do not get vaccinated, but when they believe that getting a flu shot is not normative, they are more responsive to information about people who do get vaccinated (Blanton, Stuart, & VandenEijden, 2001). This framework would suggest that efforts to tai-

lor messages to people's dominant concerns (e.g., their thoughts and feelings about dieting) would benefit from considering people's normative beliefs about the behavior.

By definition, tailored messages provide people with information that addresses their personal needs and concerns. The value of such an approach would appear to be self-evident. Yet, any evaluation of tailoring must weigh the implementation costs associated with assessing people's personal profiles as well as the reliability and validity of the instruments used to identify a person's needs. Interestingly, Dijkstra (2005) has observed that the benefits of tailoring may be obtained with only minimal information. He found that a personalized smoking cessation message (which included the participant's name and some basic smoking history information) was as effective as one that provided tailored feedback, and both messages were more effective than a generic message. It may be that the relative utility of different levels of tailoring may depend on the goal of the researcher. If the researcher needs only to heighten how engaged someone is when reading a brochure, personalization may be sufficient. However, if the researcher needs to provide people with strategies that can help them overcome barriers to action, more extensive tailored feedback may be necessary. Delineating the dose–response relationship between tailored information and behavioral outcomes may be an important next step in this area.

Message Framing

Messages designed to promote a health behavior can be constructed to focus on the benefits of performing the behavior (a gain-framed appeal) or the costs of failing to perform the behavior (a loss-framed appeal). For example, a gain-framed brochure designed to promote mammography would emphasize the health benefits afforded by screening, whereas a loss-framed brochure would emphasize the health costs of failing to be screened. According to prospect theory (Tversky & Kahneman, 1981), people act to avoid risks when considering the potential gains afforded by a decision (they are risk averse in their preferences) but are more willing to take risks when considering the potential losses afforded by a decision (they are risk seeking in their preferences). This premise has led investigators to assess the relative impact of gain- and loss-framed health messages have on people's behavioral practices.

The relative impact of gain- and loss-framed messages is thought to be based on how people construe the risk posed by performing the targeted behavior (Rothman, Kelly, Hertel, & Salovey, 2003; Rothman & Salovey, 1997). If performing a behavior is perceived to involve some risk, loss-framed appeals should be more persuasive, but if a behavior is perceived to afford a relatively certain outcome, gain-framed appeals should be more persuasive. Rothman and Salovey (1997) observed that the function served by a health behavior can operate as a reliable heuristic to predict whether people perceive engaging in a behavior to be risky. Specifically, detection behaviors serve to detect the presence of a health prob-

lem, and because they can inform people that they may be sick, initiating the behavior may be considered a risky decision. In contrast, prevention behaviors such as the regular use of sun screen or condoms forestall the onset of an illness and maintain a person's current health status. In fact, these behaviors are risky only to the extent that one chooses *not* to take action. Taken together, this distinction suggests that loss-framed appeals would be more effective in promoting the use of detection behaviors but gain-framed appeals would be more effective in promoting the use of prevention behaviors.

Empirical evidence obtained across both laboratory and field studies have provided strong support for this framework. Loss-framed messages have been shown to elicit greater interest in or performance of detection behaviors (e.g., Banks et al., 1995; Meyerowitz & Chaiken, 1987; Schneider et al., 2001; but see Lauver & Rubin, 1990; Lerman et al., 1992), whereas gain-framed messages have been shown to elicit greater interest in or performance of prevention behaviors (e.g., Detweiler, Bedell, Salovey, Pronin, & Rothman, 1999; Rothman, Salovey, Antone, Keough, & Martin, 1993; see Rothman, Stark, & Salovey, 2006, for a more comprehensive review of this literature). Moreover, systematically manipulating whether people believed a behavior prevented or detected a health problem has been shown to moderate the relative influence of gain- and loss-framed appeals (Rothman, Martino, Bedell, Detweiler, & Salovey, 1999).

Despite the fact that the observed distinction between prevention and detection behaviors rests on how people construe the behavior, investigators have paid limited attention to variability along this dimension. A few studies have examined whether people's perceptions of a screening behavior moderate the influence of framed appeals and have obtained results consistent with the guiding framework (Apanovitch, McCarthy, & Salovey, 2003; Meyerowitz, Wilson, & Chaiken, 1991). Some initial experimental work designed to manipulate how people construe a behavior—for example, is the test designed to detect a favorable or an unfavorable outcome?—has also provided supporting evidence (for a more complete discussion of these findings, see Rothman, Bartels, Wlaschin, & Salovey, 2006). Future work in this area would benefit from a better understanding of the factors that shape how a behavior is construed. For example, Orbell, Perugini, and Rakow (2004) have observed that people who are inclined to focus on the future consequences of a behavior will tend to think about the long-term benefits of a screening test (i.e., that it affords one the opportunity to treat a health problem), whereas those who are inclined to focus on more immediate consequences will tend to think about the immediate costs of a screening test (i.e., the possibility of learning one has a health problem).

Although research on message framing has primarily focused on the correspondence between the frame of the message and features of the targeted behavior, differences in individual's sensitivity to favorable and unfavorable outcomes has been shown to moderate people's response to gain- and loss-framed messages (Cesario, Grant, & Higgins, 2004; Lee & Aaker, 2004; Mann,

Sherman, & Updegraff, 2004). The primary assumption that underlies this work is that a message will prove to be more persuasive to the extent it fits or is compatible with how the recipient thinks and reasons about his or her environment. For example, gain-framed appeals will be more effective for people whose primary self-regulatory strategy is to focus on hopes and aspirations (i.e., a promotion focus), whereas loss-framed appeals will be more effective for people whose primary self-regulatory strategy is to focus on duties and obligations (i.e., a prevention focus) (Cesario et al., 2004; Lee & Aaker, 2004).

An important challenge for future research will be to integrate these recent findings with prior evidence that the function of the behavior moderates the influence of framed appeals. We have recently suggested that these findings may be based on a similar set of processes (Rothman, Bartels, et al., 2006). Specifically, performing a screening behavior may be considered a duty or obligation and may serve to induce people into a prevention-focus mindset (facilitating the impact of loss-framed messages), whereas performing a prevention behavior may be considered a choice rather than an obligation and may serve to induce people into a promotion-focus mindset (facilitating the impact of gain-framed messages). Although the premise that health behaviors can systematically invoke a promotion or a prevention mindset is compelling, further research is clearly needed to specify the predicted associations.

Evaluating Effectiveness

The impact of the communication strategies we have examined is typically determined by assessing changes in people's beliefs about the health issue (people's attitude toward or intention to get a mammogram become more favorable) or changes in people's behavior (rates of mammography utilization increase). Although these measures have clear and important value, it may be wise for investigators to begin to consider using a broader set of indicators. In particular, there is growing evidence that structural features of people's beliefs have important behavioral implications. As was reviewed earlier, the strength of a person's behavioral intention was a critical determinant of whether it led to a change in behavior (e.g., Sheeran & Abraham, 2003). This would suggest that messages need to be able to elicit both favorable and strong beliefs. Research on the consequences of resistance to persuasion also suggests that investigators need to attend to more than just the overall evaluation of a person's attitude. When people feel they have resisted the influence of a strong persuasive message, they become more certain about their initial attitude, which leads them to be more resistant to subsequent persuasive efforts (Tormala & Petty, 2002, 2004). This finding would suggest that health messages that appear to have no meaningful impact on respondents' beliefs might in fact have had more negative effect than had previously been thought.

Investigators may also want to consider how responses to messages unfold over time. The persistence of an individual's response to a health message has not received much systematic attention as investigators have primarily relied on between-subjects comparison strategies (see Sutton, 2004, for a broader discussion of the how an overreliance on between-subjects comparisons has constrained progress in health behavior theory). If people's responses to a health message are tracked over time, investigators will have to consider how their subsequent experience with the health issue, and perhaps the targeted health behavior, affects their response to the initial message. This is likely to be a particularly critical issue when a message is developed to promote a behavior that requires an ongoing series of actions (Rothman et al., 2004; Rothman, Hertel, Baldwin, & Bartels, in press). Recent work by Albaracin, Cohen, and Tumkale (2003) illustrates how the actions people take after having been exposed to a message can have dramatic effects on their response to the initial message. Specifically, people who engaged in a behavior (e.g., trying a new alcoholic beverage) after having been exposed to an abstinence-based message subsequently held more favorable attitudes toward the behavior than did those who had initially received a message promoting moderation or those who had not engaged in the behavior.

SUSTAINING PATTERNS OF BEHAVIOR

If changes in people's behavior are to afford improvements in health outcomes, those changes need to be sustained over time. People not only must lose weight or start a program of regular exercise but also must maintain their lower weight or continue to exercise regularly. Similarly, screening behaviors typically involve standardized regimens. Yet, behavioral maintenance remains discouragingly elusive. Even people who have successfully initiated a new pattern of behavior more often than not fail to sustain it over time (e.g., diet and exercise to produce weight loss [Jeffery et al., 2000], smoking cessation [Ockene et al., 2000]; substance abuse [Hunt, Barnett, & Branch, 1971; Marlatt & Gordon, 1985]).

To date, researchers have primarily focused on predicting a single behavioral outcome such as whether a woman has obtained a mammogram (e.g., Aiken, West, Woodward, & Reno, 1994), a smoker has quit (e.g., Norman, Conner, & Bell, 1999), or a man has modified his diet (e.g., Conner et al., 2002). Although these outcomes may include assessments of a series of behaviors (e.g., food choices over a 4-week period), very limited attention has been paid to the psychological experiences and decision-making processes that underlie behavioral patterns. To a certain extent, this reflects the fact that the dominant theoretical models assume either implicitly or explicitly that the factors that underlie a decision to initiate a behavior are the same as those that underlie the decision to maintain it (Rothman, 2000; Rothman et al., 2004).

Even models that were developed to describe how the behavior change process unfolds over time (e.g., Prochaska et al., 1992; Weinstein, 1988) offer little insight into the processes that might guide the ongoing performance of behavior. Although these models in-

clude a distinction between initial and maintained behavior, it rests on the length of time a behavior has been performed rather than the possibility that the decision to maintain a new behavior is distinct from the decision to implement the change in the first place (Prochaska & Velicer, 1997). In a similar manner, investigators have provided thoughtful descriptions of habits as a sequence of successfully enacted behaviors (Ajzen, 2002; Ouellette & Wood, 1998) but have not delineated the processes that determine whether or how an initially enacted behavior becomes a habit.

Several studies have revealed that it is difficult to account for certain patterns of behavior with current models of behavioral decision making. For example, Norman and colleagues (1999) observed that predictors from the theory of planned behavior were able to predict smokers' intentions to quit and whether they subsequently quit but were unable to explain how long smokers were able to sustain their abstinence. Similarly, in a study of predictors of attendance at a regular yearly physical over a 2-year period, constructs from the theory of planned behavior were able to predict whether or not people ever sought a physical but were unable to differentiate between different patterns of attendance (i.e., people who went the first year but not the second, people who went the second year but not the first, and people who went both years; Sheeran, Conner, & Norman, 2001). Intervention studies have also observed that methods that are effective at helping people initiate changes in their behavior do not have a similar effect on efforts to maintain those changes (e.g., McCaul, Glasgow, & O'Neill, 1992; Perri, Nezu, Patti, & McCann, 1989).

Rothman and colleagues (Rothman, 2000; Rothman et al., 2004, in press) have proposed that there is theoretical and practical value to more precisely delineating the processes that guide the transition from behavioral initiation to behavioral maintenance and that, in doing so, investigators will be able to discern factors that facilitate (and inhibit) initial behavioral efforts and those that facilitate (and inhibit) sustained behavioral efforts. To this end, they have proposed distinguishing between the following four phases of the behavior change process: *initial response*, *continued response*, *maintenance*, and *habit*. These phases capture the behavioral processes that begin once someone implements a decision to take action (e.g., enrolling in a smoking cessation program), transitioning out of what Prochaska and colleagues (1992) have characterized as the preparation stage.

The initial response phase captures the translation of an intention into an initial successful action (e.g., a smoker successfully remains smoke-free for a week) and thus the dominant issues regarding this phase have been discussed in a prior section of this chapter. The continued response phase represents the period of time in which people must sustain their initial beliefs about the benefits of the new behavior and their ability to perform the behavior in the face of the experiences—both pleasant and unpleasant—afforded by their actions. The length of time people remain in this phase is likely to differ across both behavioral domain and person. Some people may find it easy to master the new pattern of behavior, whereas others may find it a continual struggle. Similarly, some behavioral domains such as dietary change involve a complex series of behavioral modifications—which should lengthen this phase, whereas other domains such as taking a medication daily involve a more limited set of challenges—which should shorten this phase.

The maintenance and habit phases capture the processes that determine whether a successfully enacted change in behavior is sustained. During the maintenance phase, the decision to maintain a behavior is based on a regular assessment of whether the behavior is worth the effort, whereas during the habit phase the behavior is maintained without any consideration of a behavioral alternative (for a more comprehensive discussion of these phases, see Rothman et al., 2004, in press). We have chosen to use these phases to organize the issues reviewed in this section of the chapter.

Continued Response

Given that successfully initiating a change in behavior is predicated on people's confidence in their ability to execute the behavior and their belief that engaging in the new pattern of behavior will meaningfully improve their lives (Bandura, 1997; Salovey et al., 1998), the primary challenge to continuing these initial efforts is sustaining these beliefs in the face of their experiences with the new behavior. To the extent that people find the new behavior to be unpleasant or feel that it demands substantial mental and/or physical energy, their commitment to and confidence in the behavior may weaken, thereby undermining the likelihood that the behavior will be sustained (Baumeister, Heatherton, & Tice, 1994; Schmeichel & Baumeister, 2004). Thus, how the costs and rewards afforded by a given behavior unfold over time affects people's ability to negotiate this phase of the behavior change process. For example, because the costs associated with a behavior are often tied to performing the behavior (e.g., having to continually monitor what one eats or having to get up early to exercise), they tend not only to appear with the onset of the behavior but also to continue as long as the behavior is performed (Jeffery, Kelly, Rothman, Sherwood, & Boutelle, 2004). These salient, persistent costs may challenge the optimism that motivated people to initiate a change in behavior.

What factors might help people sustain their motivation and confidence in their ability to continue a new pattern of behavior? There is reason to believe that people need to possess sufficient psychological resources to maintain their beliefs. Baumeister and his colleagues (Baumeister et al., 1994; Schmeichel & Baumeister, 2004) have consistently shown that deficits in self-regulatory strength contribute to failures to regulate one's behavior. Thus, individual differences in the ease with which people can generate and sustain favorable expectations may be important. People who score high on self-esteem and those who score high on dispositional optimism have been shown to be more likely to generate positive expectations (e.g., Affleck et al., 2001; Aspinwall & Taylor, 1993; Gibson & Sanbonmatsu, 2004; Helgeson,

2003) and, moreover, are better able to sustain those beliefs in the face of difficult experiences (e.g., Campbell & Fairey, 1985; Gibson & Sanbonmatsu, 2004). At the same time, people who have difficulty not attending to thoughts or images associated with their prior (unwanted) behavior may have considerable difficulty negotiating their way through this phase of the process. For example, Waters and colleagues (2003) observed that the extent to which smokers, after having quit for a day, exhibited a Stroop-based bias for smoking-related stimuli predicted whether they subsequently lapsed and the time to the lapse.

Models of relapse prevention have proposed that people's attributions for any difficulties they have changing their behavior will regulate the transition from a lapse to a relapse (Marlatt & Gordon, 1985; Witkiewitz & Marlatt, 2004). Although the premise that people might cope better with a lapse that can be attributed to a controllable, external event is compelling, there is little evidence that people's attributions predict their response to a lapse in their behavior (Shiffman et al., 1996). However, Shiffman and his colleagues (2000) have shown that after a lapse, temporal shifts in smokers' confidence in their ability to quit do predict whether a lapse progressed into a relapse. Although not directly linked to people's ability to cope with difficulties, there is considerable evidence that people are more likely to change their behavior if their efforts are intrinsically or autonomously motivated (e.g., Williams, Gagne, Ryan, & Deci, 2002; Williams, McGregor, Zeldman, Freedman, & Deci, 2004). Moreover, Williams and colleagues (2004) have shown that autonomous motivation promotes behavior change due to its ability to enhance people's confidence in their ability to perform the desired behavior.

Taken together, there are a number of factors that likely regulate people's ability to sustain the beliefs that underlie the change in their behavior. Yet, greater consideration needs to be given to the patterns of change over time, in both behavior and beliefs, which are associated with these factors. Further research should also examine the interrelations between these factors, with a particular emphasis on whether the effects attributed to different constructs such as dispositional optimism and self-esteem are, in fact, distinct. Finally, consideration should be given to how features of the behavior in question affect the ease or difficulty with which people are able to successfully continue a new pattern of behavior. A rich description of how the rewards and costs afforded by a behavior typically unfold over time would be particularly valuable.

Maintenance and Habit

What determines whether a successfully initiated pattern of behavior is maintained? Rothman and colleagues have proposed that the decision criteria that underlie behavioral maintenance are distinct from those that underlie behavioral initiation (Rothman, 2000; Rothman et al., 2004, in press). Specifically, whereas decisions regarding behavioral initiation are based on expectations about future outcomes, decisions regarding behavioral mainte-

nance involve a consideration of the experiences afforded by the new pattern of behavior and a determination of whether those experiences are sufficiently satisfying to warrant continued action. The feeling of satisfaction indicates that the initial decision to change the behavior was correct, and it serves to justify people's efforts to sustain the behavior. Given that people who have reached this phase in the behavior change process have shown they can successfully perform the behavior, they may pay less attention to questions regarding their ability to engage in the behavior (i.e., "Can I do it?") and more attention to questions regarding their evaluation of the behavior (i.e., "Do I want to do it?").

Although it seems intuitive that the more satisfied a person is with a behavior, the more likely he or she will continue to perform it; the prospective effect of satisfaction on behavior has received only limited empirical attention. Dijkstra and Borland (2003) reported that the more ex-smokers missed experiences from when they smoked, the more likely they were to relapse (especially when they were low in self-efficacy). Evidence that perceived satisfaction with behavior change predicts sustained behavior change has also been obtained in two intervention studies designed to promote weight loss (Finch et al., 2005) and smoking cessation (Hertel et al., 2005). What is particularly noteworthy about these studies is that they have disentangled predictors of behavioral maintenance from predictors of behavioral initiation. Typically, claims regarding the determinants of behavioral maintenance are based on testing whether a psychological state (e.g., self-efficacy at baseline) predicts a distal behavioral outcome (e.g., smoking status 12 months later). However, this analytic model cannot determine whether, in the current example, people's initial feelings of self-efficacy contribute to their willingness to maintain their behavior over and above its effect on their initial behavioral efforts. To test the premise that the predictors of behavioral initiation and behavioral maintenance are distinct, investigators must attend to where people are in the behavior change process. For example, Baldwin and colleagues (2006) examined predictors of behavior in a sample of smokers who had just participated in a smoking cessation program. Among those smokers who had failed to quit during the program, perceived self-efficacy predicted whether they were able to initiate another quit attempt, whereas among those who had successfully quit during the program, perceived satisfaction with being tobacco free (and not perceived self-efficacy) predicted whether someone maintained smoking cessation.

What determines whether people are satisfied with their behavioral experience? Although some experiences may prove easy to evaluate (e.g., severe side effects from a treatment), in many cases people may find it difficult to determine how much of a change is sufficient to feel satisfied? For instance, if a man enrolls in a weight loss program in order to be able to wear clothes in a smaller size, what size does he need to reach to be satisfied with his efforts? There is considerable laboratory evidence that people often examine their experiences in light of their expectations (Gollwitzer, 1996; Schwarz & Strack, 1991). Thus, how one feels about being able to wear pants with a

30-inch waist depends on whether you initially expected to reach a 28-inch or a 32-inch waist. One implication of this framework is that while raising people's expectations regarding the benefits of behavior change will help motivate them to initiate a change in their behavior, it will make it much more difficult for them to meet those expectations, which serves to undermine their motivation to maintain the behavior (Rothman, 2000). Although there is evidence in the consumer behavior literature that people's satisfaction with a product is predicated on their experiences meeting their expectations (Szymanski & Henard, 2001), to date, two intervention studies designed to promote healthy behavior have failed to support the predicted, ironic effect of expectations on feelings of satisfaction (Finch et al., 2005; Hertel et al., 2005).

There are a number of other factors that may shape people's feelings of satisfaction. For instance, given that many health behaviors afford myriad outcomes, some people—perhaps those high in self-esteem or in dispositional optimism—may be better able to selectively or strategically monitor for desirable outcomes. For example, when some people find that weight loss did not improve their social life in the way that they had hoped it would, they are able to alter their priorities and derive satisfaction from the improvements in physical health they experienced. People may also find a behavior more satisfying to the extent that the process of engaging in the behavior fits their dominant self-regulatory orientations (Higgins, 1999). To the extent that satisfaction with behavior change is a critical determinant of behavioral maintenance, a priority for future research will be to delineate the processes that shape people's experience of satisfaction (see Rothman et al., in press, for a more complete discussion of this issue).

During the behavioral maintenance phase, people will engage in a sustained pattern of behavior. How is this distinct from a habit, which is similarly represented by a sustained pattern of behavior? According to the present framework, an important distinction is that people in the maintenance phase continue to monitor the value of the behavior, whereas those in the habit phase do not. This would suggest that people in the habit phase will be less sensitive to new information or new experiences regarding the behavior (e.g., Ferguson & Bibby, 2002). It is important to note that this does not mean that people in the habit phase do not value the behavior. They just no longer need to verify or test its value (Wood, Quinn, & Kashy, 2002). Habits are likely to persist as long as there is not a significant shift in the environment in which the habit is operating. Consistent with this perspective, Wood, Tam, and Guerrero-Witt (2005) found that students transferring to a new school will sustain their exercise habits if they are able to preserve continuity in the environment (e.g., they can exercise at the same time of day), but if there is a change in the environment (e.g., they have to exercise at a different time of day), the likelihood that they continue to exercise is strongly dependent on their intentions to exercise. One might speculate that the need to restructure when to exercise led these students to reassess their satisfaction with regular exercise, thereby modulating their intention to continue to exercise. Efforts such as this that elucidate the factors that regulate habitual behaviors not only have important theoretical implications but also can inform the design of interventions to help people sustain healthy behavioral practices (as well as undermine stable, unhealthy behaviors).

WITH AN EYE TO THE FUTURE: OPPORTUNITIES FOR INNOVATION AND INTEGRATION

The scope of research that examines issues at the intersection of social psychology and health extends considerably beyond the domains examined in the present chapter. For example, we have not attempted to cover the vast literatures on stress and coping (e.g., Martin & Brantley, 2004), psychoneuroimunology (e.g., Marsland, Bachen, Cohen, Rabin, & Manuck, 2002), social relationships and health (e.g., Cohen, 2004), or socioeconomic status and health (e.g., Adler & Snibbe, 2003). In fact, there are important issues in these areas that have implications for understanding the determinants of people's health practices, especially actions that are taken in order to care for a health problem (an area of study we have not emphasized). For example, people's physiological response to their psychological states and to their behavior likely provides critical information that shapes how people think about a health issue and their willingness to change or continue with a behavior.

Despite the volume of research activity concerning people's health practices, a number of investigators have expressed concern that these efforts have not been as productive or innovative as hoped (Noar & Zimmerman, 2005; Rothman, 2004; Sutton, 2004; Weinstein, 2004; Weinstein & Rothman, 2005). Too many findings are constrained by the limitations posed by cross-sectional as well as prospective correlational data and investigators have not adequately pursued opportunities to test, refine, and if need be refute theories of health behavior. In this final section, we consider these challenges with an eye toward several issues that we believe should be kept in mind as investigators pursue the next generation of research activity on the social psychological determinants of health and health behavior.

Expanding the Use of Experimental Methods

Although experimental methods have been used extensively to examine how people process health information, research on the determinants of health behavior has relied primarily on nonexperimental data to inform our understanding of the processes that regulate people's behavioral decisions. In several recent papers, both Sutton (2002, 2004) and Weinstein (2004) have thoughtfully reviewed how an overreliance on nonexperimental data constrains the conclusions that investigators are able to draw. Although nonexperimental data afford opportunities to make inferences regarding factors that predict behavior, conclusions regarding causal mechanisms rest on investigators being able to satisfy a strong

set of assumptions (e.g., that a regression coefficient for a predictor is an unbiased estimate of its causal effect on an outcome; see Sutton, 2004, for a thorough discussion of these issues). A greater reliance on experimental methods is needed to complement the nonexperimental research activities currently under way (Salovey & Williams-Piehota, 2004; Sutton, 2004; Weinstein, 2004). The observed impact of an experimentally manipulated variable can provide critical, converging evidence for the impact of predictors observed in correlational data sets. Thus, theory-based interventions provide an invaluable opportunity to clarify the strengths and weakness of a proposed theoretical model (Rothman, 2004).

Although we strongly endorse a greater reliance on experimental manipulation, in doing so investigators need to remain mindful of several issues. First, an experimentally induced belief (e.g., a smoker is led to hold an optimistic view of smoking cessation) may not prove as influential as a naturally occurring belief (e.g., a smoker who enrolls in a program with an optimistic view of smoking cessation). In our own work, we have observed that naturally occurring variation in people's expectations about the benefits of weight loss had a more pronounced effect on people's weight loss practices than did experimentally induced variation in expectations (Finch et al., 2005). Williams and colleagues have similarly observed stronger effects for measured as opposed to manipulated levels of autonomous motivation (Williams et al., 2002, 2004). One explanation for these findings is that it is difficult to induce a set of beliefs that are sufficiently strong and stable to motivate behavior (we elaborate on this point later). Alternatively, these findings may indicate that investigators need to better specify the defining features of the construct hypothesized to motivate behavior change. For example, the observed variation in people's expectations about weight loss may merely be a marker for the critical underlying factor or it may be that a facet of a belief's underlying structure—such as its degree of accessibility—could determine whether it affects behavior.

Second, investigators may find that experimentally manipulating how people think and reason about their health or their health behavior can prove to be a challenge when operating outside the controlled environment of the laboratory. Shifting the relative salience of beliefs about an attitude object (e.g., heightening the salience of the benefits of cessation) may prove to have a greater impact on participants' beliefs when implemented in a laboratory setting where participants' have limited experience or involvement with the issue at hand than when implemented as part of a smoking cessation program where participants have extensive experience and are quite involved with the issue at hand. Knowing that an intervention strategy can work may not necessarily mean that it does work in more complex settings (cf. Mook, 1983). This is not to suggest that such methods cannot be of value but, rather, that their effectiveness may prove to be contingent upon factors such as people's prior experience with the issue. For example, we observed that an intervention designed to focus people's attention solely on the benefits of cessation made smokers more optimistic about cessation, but only if they had previously had some prior success quitting. For those smokers who had never been able to quit previously, the optimistic intervention actually made them more pessimistic in their outlook. In fact, these latter smokers were more optimistic when they were instructed to focus their attention on both the benefits and the costs of cessation (Hertel et al., 2005).

Finally, as presently formulated, nearly all models of behavioral decision making provide limited guidance regarding the processes that shape the factors that are thought to predict behavior change (Rothman, 2004; Sutton, 2004). For example, we proposed that satisfaction with the outcomes afforded by a pattern of behavior is a critical determinant of behavioral maintenance, but we have offered minimal guidance as to what can be done to heighten the satisfaction people derive from changes in their behavior (Rothman et al., in press). The failure to address this issue is a frequent complaint that interventionists have regarding theories of health behavior (Jeffery, 2004). In fact, given these practical needs, it is not surprising that interventionists are more likely to rely on theories that provide guidance as to how to construct an intervention protocol (e.g., social cognitive theory; Bandura, 1997).

Theory Testing in Ecologically Complex Contexts

Most theories of health behavior specify a list of factors that inform people's behavioral decision but offer limited guidance as to the conditions that might moderate the applicability of these factors (cf. McGuire, 2004). For example, from the outset the theory of reasoned action (Ajzen & Fishbein, 1980) explicitly stated that the degree to which people's intentions rest on their attitudes and/or their perceived social norms will vary across setting and from domain to domain. It is striking that more than 25 years later, researchers have yet to refine further our understanding of the parameters that regulate the impact of attitudes and subjective norms on intentions. More generally, there has yet to be a systematic effort to clarify how features of health behaviors and the setting in which they are performed moderate the applicability of principles that are derived from our theories. Can we delineate how features of a behavior, or the setting in which it is most likely elicited, inhibit or facilitate the impact of particular antecedents or decision rules? For example, do people have a particularly difficult time maintaining behaviors that at the outset are normatively characterized with a high degree of optimism (e.g., weight loss behaviors) (King, Rothman, & Jeffery, 2002)? The proposition by Gibbons and Gerrard (Gibbons et al., 2003) that intentions may not guide the performance of adolescent risk behaviors offers an excellent example of how specifying an aspect of the behavioral domain can improve investigators ability to identify the determinants of behavior.

To specify the contexts in which a theoretical principle may operate, investigators need a much more comprehensive understanding of people's experiences engaging in different health practices. Such work will not only pro-

vide information about how people's experiences of the rewards and costs of the behavior shift over time (e.g., Jeffery et al., 2004) but also advance our understanding of the time lag between when people come to a decision about an issue (e.g., a person decides they are at high risk of getting the flu) and when they take action (e.g., get a flu shot) (Sutton, 2004). Although our proposition is consistent with calls for more descriptive research (e.g., Rozin, 2002), we believe it is critical that investigators attend to how gathering this descriptive information can advance our ability to apply, test, and refine our theoretical models. The challenge will be to identify a core set of parameters that can be used to organize these descriptions.

Because people's health is regulated by ongoing behavioral decision making, time is a critical issue in the study of health behavior. Although investigators may be interested in whether a particular communication strategy can promote the use of a screening behavior such as mammography, it is important that investigators not lose sight of the fact that the final outcome assessed in the study (e.g., rates of mammography utilization) is but a step in a sequence of behavioral decisions. For example, several years ago we demonstrated that providing women with a message that affirmed it was their responsibility to take care of their health increased the likelihood that they would get a mammogram (Rothman, Salovey, Turvey, & Fishkin, 1993). Although encouraging women to take personal responsibility for their health increased screening, the downstream consequences of this message was never considered. In particular, could heightening a woman's sense of personal responsibility for having a mammogram affect her reaction to learning that the mammogram has found an abnormality that might be cancer? Would it cause her to feel more responsible for her situation and more distressed about the possibility of cancer? The overall value of this communication strategy clearly depends on the answer to this question. Thus, in conducting our work we need to be mindful of the broader context in which our study operates. In particular, we need to develop a better understanding of people's psychological reactions to the consequences of their health behaviors (e.g., Andrykowski, Boerner, Salsman, & Pavlik, 2004; Gibbons, Eggleston, & Benthin, 1997) and the longer-term psychological and behavioral consequences of these reactions.

Stimulating Innovation

We believe that the opportunities afforded by using social psychological theory and the method to explore important health decisions can stimulate significant advances in theory construction and methods development, while stimulating innovations in methods to promote health and prevent illness. In many ways, the programs of research described in this chapter represent wonderful examples of the Lewinian ideal of moving between theory and practice in social psychology. However, as research and practice in this area continue, it is critical that investigators continue to refine, revise, and, when needed, reject the theoretical principles derived from our models of health behavior. We need to determine whether new perspectives are needed as investigators grapple with issues such as the nonlinear combination of variables, the role of "irrational" processes in decision making, and the scope of conditions that limit the applicability of general principles. However, the traditional tools of social psychology—and the new emphasis on translational research within the various funding agencies supporting health research—should stimulate just this kind of effort. There has never been a better time to reassert the relevance of theory, experimental research, and the addressing of important social problems, the three-legged stool on which our field was built.

NOTES

1. How investigators operationalize risk perceptions is another critical issue. Estimates of the likelihood of an event may not be sufficient indicators of whether an event is something they want to avoid (Slovic, 1987). Reports of how worried or concerned people are about a potential outcome may reveal the meaning people ascribe to a given level of risk and thus might serve as a better predictor of behavior (e.g., McCaul, Schroeder, & Reid, 1996).
2. It would appear that the label "fear appeals" is a bit misleading as there has been minimal evidence that the beneficial effects of these messages are due to increase in fear per se.
3. Several studies have observed that when intentions are not stable, prior behavior proves to be a better predictor of future behavior (e.g., Conner et al., 2002). Questions concerning the processes by which prior behavior influences future behavior are considered later in this chapter.
4. Messages can also be matched to information about group-level characteristics (e.g., why women resist exercising), an approach that has been labeled "message targeting."

CHAPTER 37

Contributions of Social Psychology to Clinical Psychology

Three Views of a Research Frontier

Timothy J. Strauman
Philip R. Costanzo
Neil P. Jones
Amy Noll McLean
Kari A. Merrill

The vast expanse of conceptual territory adjoining the disciplines of clinical psychology and social psychology remains a largely uncharted world. Although previous edited volumes have provided important summaries of the social/clinical interface (e.g., Leary & Kowalski, 1999; Ruble, Costanzo, & Oliveri, 1992), most scholars in each field remain largely unaware of important developments in the corresponding field (Strauman & Merrill, 2004). The extent of unexplored territory is particularly ironic because the flagship journal for many social psychologists, the *Journal of Personality and Social Psychology*, was once entitled the *Journal of Abnormal and Social Psychology*. Nonetheless, what may be most intriguing about the surprising scarcity of explicitly acknowledged connections between these two fields is that both claim a kinship with personality psychology (Snyder, Tennen, Affleck, & Cheavens, 2000). The linkage of social and clinical psychology through their mutual emphasis on understanding individual variation is a theme that has yet to be fully explored, but psychologists have been at least implicitly aware of such a mutual kinship since the very beginnings of clinical psychology. This chapter considers recent contributions of social psychology to clinical psychology and in doing so draws heavily on this often-implicit pathway between the two disciplines as a basic translational principle, with an eye on the clinical implications of social psychology's emerging understanding about "what matters in the social world" (Higgins, 2000).

The translation of the situational idiom and focus of social psychology into the language of individual variability often obscures the intimate connection between so-cial and clinical research but also allows social psychology to be highly relevant for clinical psychologists. In turn, the dominant questions within clinical psychology (particularly those related to the study of psychopathology and psychotherapy broadly construed) become relevant to the interests of social psychologists when they are "backtranslated" from an individual differences framework into the language of situational reasoning. For example, it is not only the case that individuals who are prone to anxiety are reliably distinguishable from other individuals less prone to such disruptive phenomena, but it is also clear that such vulnerability can be understood in situational as well as characterological terms (Tennen & Affleck, 2002). Situations that generate anxiety, such as those in which the perceived controllability of behavior is limited, are precisely the kinds of situations that elicit the chronic lack of control experienced by those who struggle with anxiety disorders. In this instance, articulating characteristics of people vulnerable to anxiety draws heavily on social psychological research and, in turn, allows for effective theory-based intervention (Bitran & Barlow, 2004).

This chapter considers the advances that might be achieved by an appreciation of the conceptual, theoretical, and empirical kinship between clinical and social psychology. A better understanding of this kinship is particularly critical given the unfortunate tendency for contemporary research in psychopathology and treatment to take a reductionistic neurobiological perspective (Fuchs, 2004; Millon, 2004). Ironically, as theories of psychopathology have become more dimensional and less

strictly categorical, they increasingly draw situational factors into the diagnostic equation (Widiger, 2005). Psychopathology does not solely lie under the skin, in the brain, or in each individual's unique past; it also is manifest in reactivity to ordinary and extraordinary circumstances, in how people are differentially exposed to pathogenic situations, and in tendencies to engage in activities that do not fit well with an individual's underlying proclivities (Caspi, 2000).

Although clinicians still contend over which psychotherapeutic interventions are most efficacious, they are coming to realize that different structures of intervention might best fit different people (Beutler, Alomohamed, Moleiro, & Romanelli, 2002). To match people to therapies, it is most important to understand not only differences between people but the differential impact of the kinds of situations in which they live. Without an understanding of the ways in which a focus on individual variability links social and clinical psychology, public health problems such as matching psychological interventions to the needs of different individuals will not be solved.

Social psychology's exploration of clinically relevant issues demands a systematic examination beyond the scope of what a single chapter could provide. Although we are selective by necessity, we return repeatedly to a discipline-level analysis to illustrate how the two fields continue to be drawn together—the basic principle of translation that allows social psychology to have a continuous productive influence on clinical psychology. What is critical in this movement is the tendency for social psychologists to frame theories and hypothesis of situational impact in ways that are equally compatible with describing distinctions among people (Higgins, 1990). Hence the assertion with which we began: that the two disciplines are linked by their mutual compatibility with an individual differences perspective that, in turn, facilitates the application of social psychological principles to diagnosis, intervention, and prevention. We also wish to note that due to space limitations we are not able to focus on health psychology, a domain in which social psychology has been enormously influential (Strobe, 2000).

Social psychologists have been particularly adept at discerning maladaptive behavioral styles by noticing how they deviate from typical behavior in well-characterized situations. Thus, for instance, while individuals generally tend to inflate the magnitude of personal control they believe they exert over the good things that happen to them, the subset of people who do not evidence such a pattern tend to experience dysphoric affect and to be differentially vulnerable to episodes of depression (Roberts & Monroe, 1999). In essence, they are the exceptions to the "rule" of positive self-illusions that both highlight the importance of the basic social psychological insights and raise the question of whether such illusions are paradoxically adaptive. This reciprocal pattern illustrates the best of what has become known as *translational* research, and social psychologists have been leaders in the effort to bring basic science to bear on the diagnosis, treatment, and prevention of mental disorders (National Institute of Mental Health, 1999).

To present a representative survey of the frontier that lies between social psychology and clinical psychology, we use three distinct lenses. The first lens is one through which social psychologists might peer; the second, another through which clinical psychologists might peer; and the third is speculative. To be more explicit:

• From the perspective of social psychologists, what have been their field's most important contributions to clinical psychology? This perspective can be illuminated by examining the many clinically relevant hypotheses tested by research in social psychology. We already have alluded to several, but more are examined in subsequent sections. We note that this first lens has a particularly critical diffracting property—that is, viewing social psychology as a level of analysis neither reducible to nor dependent upon other equally valid levels.
• From the perspective of clinical psychologists, what have been the most important contributions of social psychological research to their own models, theories, and practices? To identify these contributions, we examine relevant clinical literatures that have directly, or indirectly, deployed social psychological concepts or models. We expect that social psychologists will be pleasantly surprised with regard to how these contributions have influenced clinical theorizing and practice.
• From our own perspective on the yet-uncharted lands between the two fields, what developments in theory and research are likely to be most influential in the near future? New ideas in the psychology of self-regulation and social neuroscience represent potentially important facets of this third lens.

In all three instances, we attempt to define principles underlying the conjunction of the two fields by examining the translational space between the situational "common person" models of social psychologists and the individual-differences-based process models of clinical psychology (Ruble, Costanzo, & Higgins, 1992). Although we acknowledge that a number of research literatures might be viewed equally productively from all three lenses, we limit our discussion of those literatures to a single perspective, recognizing that the same territory can be viewed from multiple vantage points.

CONTRIBUTIONS TO CLINICAL PSYCHOLOGY: SOCIAL PSYCHOLOGY'S VIEW

This chapter is being written at a time when social psychology's contributions to the public health missions of the National Institutes of Health (including, but not limited to, the diagnosis, treatment, and prevention of mental disorders) appear to be underappreciated (Holden, 2004). There are many reasons for this unfortunate state of affairs, including the current popularity of reductionistic approaches to brain science (Cacioppo, Berntson, Sheridan, & McClintock, 2000) and the reluctance of social psychologists to demand the spotlight on their contributions to public health (Muehrer et al., 2002). While the "decade of the brain" has been valuable

for advancing knowledge of the neurobiological aspects of psychiatric disorders (National Advisory Mental Health Council, 1988), social psychology provides complementary and equally critical levels of analysis in understanding and treating such disorders (Cacioppo & Gardner, 1999). It also is worth noting that numerous other critical problems in our society, such as violence, sexual assault/abuse, cults, and terrorism, likewise will require a social-psychological analysis as part of a comprehensive understanding (Beck, 2002).

In this section, we review some of the most important social-psychological contributions to clinical psychology from the perspective of social psychologists. These contributions span several diagnostic categories and involve both etiology and treatment but have a common element: that social psychologists are more widely aware of their bases in the study of social cognition and behavior than are clinicians (Widiger, 2001).

Depression and Self-Esteem

Social psychology has had its greatest impact on clinical psychology in the domain of depression (Dodge, 1993). Of all facets of social psychology with potential relevance to depression, *self-esteem* has been the most extensively studied. Clinical, epidemiological, social, and personality researchers have long theorized that inadequate or fragile self-esteem can lead to (Roberts & Monroe, 1994; Southall & Roberts, 2002), exacerbate (Kernis et al., 1998; Roberts & Gotlib, 1997), and result from (Hayes, Harris, & Carver, 2004; Roberts & Gamble, 2001) episodes of unipolar depression. Although the origins of self-esteem are complex and not completely understood (Hoyle, Kernis, Leary, & Baldwin, 1999), the implications of self-esteem for psychopathology and health are undeniable (Kemeny, Gruenewald, & Dickerson, 2004).

It should be acknowledged that over the past century, self-esteem has been claimed as a causal explanation for a wide variety of social ills, including violence, delinquency, teenage pregnancy, eating disorders, and marital discord (Dawes, 1994). In many cases, decreased self-esteem is more likely to be a consequence of negative social or health outcomes than a causal factor (Baumeister, 1998). In contrast, recent research has criticized the emphasis in earlier theorizing on trait self-esteem, suggesting instead that self-esteem is a dynamic phenomenon that cannot be understood simply as a trait (Dweck, Higgins, & Grant-Pillow, 2003; Gramzow, Sedikides, Panter, & Insko, 2000). For example, Crocker and Wolfe (2001) discussed the importance of both trait and state self-esteem in general and perceived contingencies of self-worth in particular. In this model, fluctuations in self-esteem occur depending on successes and failures within specific domains in which the individual's self-worth is contingent, such as appearance, academic achievement, or popularity.

There is substantial empirical evidence that low self-esteem constitutes a significant risk factor for depression, beginning with the groundbreaking work of Brown and Harris (1978). In a series of retrospective and prospective surveys, Brown and his colleagues demonstrated that chronic low self-esteem was a statistically and clinically significant factor in vulnerability to depression (e.g., Andrews & Brown, 1993, 1995). Brown proposed that self-esteem was a critical *proximal* (immediate) causal locus for the indirect effects of *distal* vulnerability factors on affective vulnerability, including childhood loss or abuse experiences, temperament, and socioeconomic factors (Brown, Andrews, Harris, Adler, & Bridge, 1986). Roberts and Monroe (1994) argued that overall level of self-esteem was not a robust predictor of the onset of depression. They proposed a multidimensional model of self-esteem in depression that included an emphasis on structural deficits within the self (such as few, rigid, or externally based sources of self-worth), low levels of self-esteem exacerbated by dysphoric mood, stressful events, or schema-congruent experiences, and temporal instability of self-worth. This model, in turn, was elaborated by Crocker and Wolfe (2001) and other investigators.

The assertion that self-esteem processes are proximal influences on mental health that can carry risk from distal factors is consistent with much current research at the social/clinical interface (Moretti, Higgins, & Feldman, 1990; Strauman & Segal, 2001). Subsequent investigations using larger community samples and more sophisticated statistical modeling lead to similar conclusions. Kendler, Gardner, and Prescott (2002) found that among women, low self-esteem was associated with risk for depression in the period following a significant life event (usually, but not necessarily, negative), though the same group also reported that self-esteem was a less robust predictor of depression than neuroticism (Roberts & Kendler, 1999). Continued study of how individuals are motivated to maintain their self-worth and how self-worth becomes contingent upon certain domains would greatly improve clinical assessment and inform treatment planning (Showers, Limke & Zeigler-Hill, 2004; Strauman & Kolden, 1997).

Depression and Attributional Style

Personality and clinical psychologists have long noticed that variability in explanatory style was associated with psychopathology. Social psychologists, in turn, have determined that people explain their outcomes through reference to a wide variety of causal factors. A vast body of evidence indicates that Heider's (1958) classic four factors (ability, effort, luck, and task difficulty) are among the most frequently offered explanations for positive or negative outcomes. Weiner's theory of attribution (Weiner, 1985) has been a dominant model of how individuals interpret their successes and failures for the past 30 years. Attribution theorists emphasize that individuals' interpretations of their outcomes determine subsequent strivings (or lack thereof) as well as the psychological consequences of perceived success and failure (Anderson, Krull, & Weiner, 1996). Weiner's model classified attributions into three causal dimensions: locus of control, stability, and controllability. In turn, each of these causal dimensions has identifiable influences on motivation, behavior, and affect. Some degree of self-serving attributional bias (a tendency to attribute posi-

tive, but not negative, outcomes to one's own efforts, ability, etc.) appears to be universal (Mezulis, Abramson, Hyde, & Hankin, 2004), and greater positive bias is associated with greater psychological and physical health (Peterson & Seligman, 1987). Social-psychological theories of explanatory style and attributional biases have been enormously influential in the development of cognitive models for depression, anxiety, and related psychological problems (Bell-Dolan & Anderson, 1999).

The hopelessness theory of depression (Abramson, Metalsky, & Alloy, 1989) takes an explanatory style approach to the psychological processes associated with vulnerability to depression. Hopelessness theory proposes that specific attributional styles predispose individuals to depression when they encounter negative events. The theory focuses on three distinct depressogenic explanatory styles: attributions about the self (the tendency to draw negative inferences about one's worth, desirability, abilities, etc.), about consequences of one's actions (the tendency to catastrophize the consequences of negative events and to view these consequences as important, unlikely to change, and as affecting many areas of one's life), and about causes (the tendency to attribute negative events to global and stable causes). According to Abramson and colleagues, individuals with depressogenic attributional styles are more likely than individuals without such tendencies to make depressogenic inferences about negative events they encounter, which increases the likelihood that hopelessness (and subsequent depression) will result. The hopelessness theory is a powerful conceptual framework for predicting vulnerability to depression with substantial empirical support (Gibb, Alloy, Abramson, Beevers, & Miller, 2004). Along with Beck's cognitive theory of depression (Clark, Beck, & Alford, 1999), itself borrowing heavily from social cognition research, hopelessness theory represents a major success story in the social/clinical interface.

Thought Suppression and Psychopathology

The paradoxical tendency for unwanted suppressed thoughts to return to consciousness with increased frequency is a phenomenon that has ignited a plethora of research since the first research demonstration of the postsuppression rebound effect (Wegner, Schneider, Carter, & White (1987). Since its identification, researchers have identified three classes of suppression-related effects: (1) the immediate occurrence of target thoughts after a period of suppression; (2) an immediate suppression-induced surge in target thoughts; and (3) an intensification of intrusions during suppression when under cognitive load (Wenzlaff & Wegner, 2000).

Theoretical accounts exist that shed light on aspects of the process of mental control; however, to date, no single theory explains all the empirically observed results. The theory of ironic processes of mental control (Wegner & Wenzlaff, 1996) proposes that two processes are used when exerting mental control: (1) an intentional operating process that searches for mental contents that will yield the desired mental state and (2) an ironic monitoring process that searches for mental contents that signal

failure to achieve the desired state. For example, an intentional operating process may search for thoughts unrelated to romantic relationships, while the ironic monitoring process searches for mental contents that are related to romantic relationships. The operating process is described as effortful and requiring conscious thought, whereas the monitoring process is unconscious and does not require significant mental effort. This monitoring process is considered ironic because it is actively searchers for cues related to the thoughts to be suppressed. The theory goes on to state that even when the operating process is voluntarily terminated or is altered by increasing cognitive load, the monitoring process continues its vigilance for unwanted thoughts. This account explains the tendency to experience immediate unwanted thought intrusions and the increase in these intrusions while under high cognitive load (the postsuppression rebound effect).

Thought suppression research has the potential to influence both understanding and treatment of various forms of psychopathology, including obsessive–compulsive disorder, posttraumatic stress disorder, mood disorders, eating disorders, and borderline personality disorder. For example, Hardy and Brewin (2005) reported that efforts at thought suppression lead to an increase in obsessional thinking and symptoms, and Purdon, Rowa, and Antony (2005) noted a reliable effect of thought suppression on the frequency of unwanted thoughts (as well as associated distress) in individuals meeting criteria for obsessive–compulsive disorder according to the *Diagnostic and Statistical Manual of Mental Disorders* (DSM). Thought suppression has a demonstrable negative impact on eating behavior among dieters, restrained eaters, and individuals with eating disorders (Boon, Stroebe, Schut, & Ijntema, 2002; Mann & Ward, 2001). Similarly, Cheavens and colleagues (2005) observed that thought suppression moderates the impact of perceived criticism and distress on maladaptive behavior in borderline personality disorders. Studies of risk for unipolar depression suggest that thought suppression can be beneficial under some circumstances but is associated with greater symptoms in the presence of high levels of life stress (Beevers & Meyer, 2004; Rude & McCarthy, 2003).

Many of the effective treatments for these disorders focus on identifying and challenging cognitions that are maladaptive, distressing, intrusive, and perceived as uncontrollable. Research taking into account ironic mental processes has suggested that interventions focus on assisting patients in identifying effective distractors, pursuing alternate goals, and practicing acceptance of unwanted intrusive thoughts. For example, Roemer and Salters (2004) explored the effects of teaching rape victims to actively suppress intrusive thoughts on the short-term incidence of those thoughts. Dialectical behavior therapy and the associated skills training modules is an example of a second-generation cognitive-behavioral treatment that focuses on practicing acceptance of unwanted thoughts and feelings as a way of teaching distress tolerance and emotion regulation skills (Linehan, 2000; Robins, 2002).

Social-Cognitive Aspects of Body Image Disturbance and Eating Disorders

The emergence of body image dissatisfaction, maladaptive eating behaviors, and frank eating disorders ranks as one of the most challenging public health crises of the past century (Currin, Schmidt, Treasure, & Jick, 2005). With the exception of models focusing on metabolic abnormalities and physiological sequelae of disordered eating (e.g., Siegfried, Berry, Hao, & Avraham, 2003), the theoretical models that dominate the body image, eating disorders, and obesity literatures are social-cognitive in nature. In particular, three themes originating with social psychology pervade these literatures: social-cognitive and interpersonal influences on body image, social/interpersonal influences on food intake, and disordered eating as a means for coping with self-esteem, identity, and control issues.

In an influential review article, Polivy and Herman (2002) noted that social psychological principles were essential to understanding the intrapersonal and sociocultural causes of eating disorders. We endorse their conclusion and proposed to expand on it as follows. Any of the social-cognitive processes that influence self-perception and self-evaluation have the potential to lead to a distorted internal representation of one's body and appearance and/or a chronic sense of dissatisfaction with one's appearance. Other social-cognitive processes influence food intake and thus may be implicated in the development of disordered eating. Although genetic and biological factors have a role to play in vulnerability to eating disorders, the critical causal factors are predominantly social.

Social-Cognitive and Interpersonal Influences on Body Image

The psychology of body image formation, maintenance, and disturbance incorporates many of the most popular theories in social psychology (Cash, 2004). Individual differences (and intraindividual variation) in body image, along with gender differences in the determinants of body satisfaction, have been the focus of literally thousands of studies in the laboratories of social and clinical psychologists (Brownell, 1991). Given the enormous influence of symbolic interactionism and social constructionism on contemporary social psychology, it is hardly surprising that in order to understand body image, theorists have considered the role of the society (and its internalized representations) in determining how individuals perceive and evaluate their bodies (Reischer & Koo, 2004). In turn, body image distortion and dissatisfaction represents a major risk and maintenance factor for eating disorders, including bulimia, anorexia, binge eating disorder, and obesity (Stice & Shaw, 2002).

Body image can be conceptualized as a multidimensional construct that represents how individuals think, feel, and behave with regard to their own physical attributes (Muth & Cash, 1997). Body image is undoubtedly a social and cultural construction, and both historical and contemporary data indicate that self-esteem is greatly influenced by the extent to which the individual perceives his or her body as congruent with societal and local ideals (Van Wolputte, 2004). Beginning in childhood and extending into adolescence, both boys and girls come to evaluate their bodies in reference to cultural standards; however, in general, the data suggest that body image tends to be more critical for girls' self-esteem than for boys (Frost & McKelvie, 2004). Interestingly, recent studies suggest that social comparison theory, a mainstay of social psychology, is useful in explaining the dynamics of body image evaluation by the time children reach adolescence (Morrison, Kalin, & Morrison, 2004). Those dynamics include a tendency for girls and women to adopt observers' perspectives on their bodies and appearance, resulting in a greater vulnerability to distress and body shape/size distortion (Frederickson, Roberts, Noll, Quinn, & Twenge, 1998).

In turn, although both boys and girls can experience body dissatisfaction, the observed gender differences in body image tendencies predicts that more adolescent girls and adult women will report significant dissatisfaction with their bodies and appearance (Thompson, Heinberg, Altabe, & Tantleff-Dunn, 1999). Body dissatisfaction appears to be pervasive in American culture and constitutes a risk factor for eating disorders, depression, and substance use (Polivy & Herman, 2002). For both genders, behaviorally and clinically significant body dissatisfaction typically begins after puberty; a combination of biological, interpersonal, and sociocultural factors predicts dissatisfaction with appearance but does so more strongly for girls (Stice & Whitenton, 2002).

Both cross-sectional and longitudinal studies indicated that attitudes toward one's appearance are both influenced by and influence the individual's interpersonal context. In addition to the continuous presence of socially sanctioned ideal body types as presented by mass media, children's and adolescents' attitudes toward their appearance are substantially influenced by their parents and peers (Stice & Shaw, 2002). The belief that one is unattractive (in general) or overweight (in particular) significantly impairs the development and maintenance of intimate relationships and leads to an attachment style that reflects both negative self-evaluation and excessive concern with evaluation by others (Cash, Theriault, & Annis, 2004). Interestingly, the act of comparing one's appearance or body characteristics with those of others may constitute a critical psychological mechanism by which the influence of social and cultural factors is translated into body dissatisfaction, excessive dieting, and maladaptive eating habits (van den Berg, Thompson, Obremski-Brandon, & Coovert, 2002). Further support for this assertion comes from studies in which exposure to more realistic body images protects individuals from the negative consequences of thinness and restricted-eating expectancies (Fister & Smith, 2004).

Social and Interpersonal Influences on Food Intake

Anecdotal evidence and common sense both suggest that the presence of others influences how much people eat, but it has been social psychologists who have done much

of the research on these influence processes. As summarized by Herman, Roth, and Polivy (2003), that research supports three conclusions: (1) when people eat in groups, they tend to eat more than they do when alone (a social facilitation effect); (2) when individuals eat in the presence of others who consistently eat a lot or a little, those individuals likewise tend to eat a lot or a little (a modeling effect); and (3) when people eat in the presence of others whom they believe are evaluating or observing their eating, they tend to eat less (an impression management effect). Herman and colleagues proposed an inhibitory norm model to account for the social circumstances under which the same individuals would eat less or more than what they otherwise would eat when alone. It is interesting to note that this model incorporates both situational factors and individual differences, providing a clear illustration of how general social psychological principles are applicable to fundamental human activities.

Indeed, a broad range of social psychological processes have been implicated in food intake, including self-efficacy (e.g., Steptoe et al., 2003), regulatory focus (e.g., Förster, 2003), self-enhancement (e.g., Mills, Polivy, Herman, & Tiggemann, 2002), and conformity (e.g., Herman, Fitzgerald, & Polivy, 2003). This area of research provides a particularly powerful and salient demonstration of the importance of "the actual, imagined, or implied presence of others" (Allport, 1985, p. 3) on behavior. For instance, Herman, Fitzgerald, and Polivy (2003) found that hunger ratings of research participants were significantly altered by the availability of information regarding ratings of fictitious others. Similarly, Mills and colleagues (2002) observed that the impact of thin media images on individuals prone to restrained eating was mediated by self-enhancement motives—providing a much more powerful model (in both conceptual and statistical terms) for the impact of distal factors like media depictions of ideal body types on eating behavior.

Disordered Eating as a Coping Mechanism

Beginning with the hypothesis proposed by Heatherton and Baumeister (1991) that certain individuals seek to "escape" from a state of aversive self-awareness through binge eating, there has been an enormous amount of research on the causes, nature, and consequences of disordered eating. In addition to continued development of that and related eating-as-coping models, research in this area has documented that the same social-cognitive stresses implicated in stress reactivity also predict disordered eating (Bennett & Cooper, 1999) and that sociocultural messages (carried by family, peers, and media) combine with self-evaluation, expectancies, and related cognitive processes to create and maintain maladaptive eating patterns (Stice, 1994).

The study of disordered eating has become an integrative enterprise. Individual-differences variables such as coping (Freeman & Gil, 2004), attitudes (Garcia-Grau, Fuste, Miro, Saldana, & Bados, 2002), self-perception (Vohs, Heatherton, & Herrin, 2001), and ego involvement/strength (Heatherton, Herman, & Polivy, 1992;

Vohs & Heatherton, 2000) all appear to mediate/moderate the impact of situational cues on eating. In turn, situational factors such as modeling (Rotenberg, Carte, & Speirs, 2005), behavioral norms (Thome & Espelage, 2004), and peer pressure (Fischer, Anderson, & Smith, 2004) all exert influences on eating behavior. Of particular interest is the possibility that the particular mechanisms underlying disordered eating may vary substantially across different ethnic and racial groups (e.g., Vander Wal & Thomas, 2004).

Summary

In sharp contrast to the apparent misconception that social psychological research is not critical to the nation's public health, social psychology has made broad and deep contributions to the understanding of several highly prevalent forms of psychopathology. The contributions reviewed in this section represent trends in social psychology that the researchers themselves see as critical for the science and practice of clinical psychology. As we commented in the introduction to this chapter, social psychological principles are both powerful concepts for understanding psychopathology in their own right and are, when translated into the language of individual differences, often critical mediating variables in the link between environmental and cultural forces and distress. It is worth noting that the application of social psychology to clinical psychology has progressed far beyond simple translation. Rather, clinical investigators have extended and combined individual models to construct more complex and realistic models of etiology that take both distal and proximal contributory factors into account. In turn, constructing such models allows for more creative translation into therapeutic and preventive intervention (Cuthbert, 2002; Strauman & Merrill, 2004).

CONTRIBUTIONS TO CLINICAL PSYCHOLOGY: THE CLINICIAN'S PERSPECTIVE

It may surprise social psychologists to know that theories regarding social influence, social cognition, and other social processes have been incorporated into research on the etiology and treatment of disorders as diverse as schizophrenia, substance use, and generalized anxiety. Our impression is that clinical researchers and practitioners who work with these disorders are much more aware of the contributions of social psychology to these literatures. In some cases, the social psychological models are so integral to an understanding of the disorders that they may no longer be recognized as having those origins (at least among social psychologists); nonetheless, the contributions are impressive and we summarize a subset of them below. Due to space limitations, we focus on two disorders (schizophrenia and substance abuse) and refer the reader to excellent available summaries of social psychological processes in generalized anxiety disorder and social anxiety disorder (for reviews, see Alden & Taylor, 2004; Coles & Heimberg, 2002; Leary, 2001; Stanley & Beck, 2000). As in the previous section, we find

it useful to contemplate these literatures simultaneously in terms of the social/interpersonal forces involved and the ways in which those models have been translated into the language of individual differences in order to account for vulnerability to psychopathology.

Social Information Processing in Schizophrenia

One of the refreshing aspects of the recent emphasis in psychopathology research on understanding brain circuitry and its abnormalities is the recognition that there can be no real understanding of the neural basis of a psychological process without sufficient attention to the process itself (Adolphs, 2003). In fact, impairments in social functioning are among the defining characteristics of schizophrenia according to DSM-IV (American Psychiatric Association, 1994), and so schizophrenia researchers have borrowed liberally from models of social information processing to explore the psychological and neural mechanisms that account for deficits in social functioning (Lee, Farrow, Spence, & Woodruff, 2004). Most recently, a group of schizophrenia researchers is working to develop a standard battery of measures of cognitive functioning that includes assessment of social cognition (Green et al., 2004).

It has been argued that deficits in social cognition are at least as central to thought disorder syndromes such as schizophrenia as are deficits in non–social cognitive processes, in part because social cognition deficits are better predictors of symptoms and functional impairment in schizophrenic patients (Penn, Corrigan, Bentall, Racenstein, & Newman, 1997). Research on the development of social cognition also is of value in schizophrenia research, because it allows investigators to determine which processing deficits are characteristic of vulnerability to the disorder (i.e., are necessary but not sufficient precursors that may reflect a genetic, epigenetic, or environmental risk factor) and which reflect progression into clinical disorder (Carter & Flesher, 1995; Walker, 1994). We review several of the most influential lines of research in the schizophrenia literature that reflect social psychological models of information processing. The reader should note, however, that numerous other phenomena studied by social psychologists are relevant to understanding the cognitive and interpersonal deficits that characterize psychosis proneness and schizophrenia spectrum disorders (e.g., autobiographical memory; see Klein, German, Cosmides, & Gabriel, 2004).

Theory of Mind

Beginning with nonhuman primate research (Premack & Woodruff, 1978) and extending into human studies (Wimmer & Perner, 1983), behavioral scientists have been intrigued by the problem of understanding how people explain the behaviors of others. "Theory of mind" (ToM) refers to the observation that people believe other people have minds like theirs and that they can understand the behaviors of others in terms of the same kinds of mental contents they use to understand their own behavior, including knowledge, beliefs, and desires (Baron-Cohen, Tager-Flusberg, & Cohen, 2000). Frith (2004) noted that ToM had been applied to the study of autism, leading to the observation that performance on ToM tasks could be impaired even though other seemingly related social and intellectual abilities remained intact. Because impairment in social interaction (particularly a tendency to withdraw from others into oneself) is also characteristic of schizophrenia, Frith and colleagues hypothesized that a similar social-cognitive deficit was characteristic of schizophrenia (Frith & Frith, 1991).

Recent studies of ToM in schizophrenia have had a substantial impact on understanding of the disorder as well as on the larger research question of how human social interactions communicate knowledge, beliefs, and intent. Consistent with the observation that discrete areas of the brain appear to underlie ToM (e.g., Saxe & Kanwisher, 2003), impairments in other aspects of cognitive functioning (such as executive function and emotion recognition) found in schizophrenia do not account for deficits in ToM (Brune, 2005). Researchers taking a developmental perspective have been investigating whether ToM-type deficits can be detected prior to the onset of schizophrenia spectrum disorders. Schiffman and colleagues (2004) reported deficits in perspective-taking skills among children who later developed schizophrenia as compared to controls, indicating that such deficits may contribute to the development of such disorders. In a related investigation, Kelemen, Keri, Must, Benedek, and Janka (2004) found no evidence for impaired ToM skills in unaffected first-degree relatives of schizophrenia patients. As such, ToM is unlikely to be a necessary characteristic of an inherited vulnerability to schizophrenia.

Social Perception

Even the earliest descriptions of schizophrenia noted the inaccurate and often bizarre ways in which such individuals interpreted the behaviors of others, including paranoid delusions (Kraepelin, 1893, as cited in Ban, 2004). The study of social perception abnormalities in schizophrenia has proceeded in both bottom-up (Insel & Fernald, 2004) and top-down (Pinkham, Penn, Perkins, & Lieberman, 2003) directions. Just as important, insights gleaned from applying social information-processing models to the social perception and interpersonal abnormalities characteristic of schizophrenia spectrum disorders suggest avenues for adjunctive and perhaps even preventive interventions, as described below (Penn et al., 2004).

A number of investigations suggest that social cognition deficits may mediate the relationship between neurocognitive and behavioral/experiential aspects of schizophrenia. Wynn, Sergi, Dawson, Schell, and Green (2005) found that social perception deficits in schizophrenia were associated with a measure of neurocognitive impairment, sensorimotor gating. The same research group reported that social perception deficits were linked with visual processing abnormalities (Sergi & Green, 2002). Combs and Penn (2004) observed that college-age individuals manifesting subclinical paranoia (and who therefore were at risk for developing

schizophrenia spectrum disorders) performed significantly worse than matched controls on an *in vivo* social perception task and sat further away from the examiner during the task. Based on this emerging literature, it appears that the deficits in social cognition associated with schizophrenia spectrum disorders are central rather than peripheral aspects of vulnerability and clinical manifestations (Higgins & Moretti, 1988; Lancaster, Evans, Bond, & Lysaker, 2003).

Cognitive Remediation

The reliable association between social-cognitive processing abnormalities and other signs and symptoms of schizophrenia raises the obvious question of whether those processing deficits could be reduced or eliminated through treatment. It may surprise social psychologists to learn that models and methods developed in the social cognition literature are now routinely used in the process of antipsychotic drug development (Green & Braff, 2001). Although until recently treatments for schizophrenia were targeted almost exclusively at symptoms such as hallucinations and delusions, a consensus has emerged that treatments also need to reverse the cognitive and social-cognitive deficits summarized previously (Harvey, Green, Keefe, & Velligan, 2004).

Penn and colleagues (2004) have suggested that, at minimum, treatment for schizophrenia needs to include efforts at remediation of, or at least compensation for, social information-processing deficits and abnormalities. Although such interventions are too new to be in widespread use, there already is solid evidence that cognitive-behavioral techniques can effectively reduce deficits in executive function, attention, and memory. Kurtz, Moberg, Gur, and Gur (2001) reported a meta-analysis of intervention studies testing cognitive remediation strategies in schizophrenia and found a large average effect size ($d = 0.96$), with particularly robust effects observed in studies using encoding elaboration strategies and vigilance training to enhance social cue recognition accuracy.

Given the success of cognitive-behavioral interventions for treatment of depression, it was inevitable that such techniques would be adapted for use in adjunctive treatment of schizophrenia (Turkington, Dudley, Warman, & Beck, 2004). However, cognitive interventions in schizophrenia were intended primarily to reverse deficits in social and nonsocial information processing, rather than symptom reduction (Hogarty & Flesher, 1999). In the past 5 years alone, more than a dozen controlled clinical trials of cognitive-behavioral therapy for schizophrenia have been published, providing compelling evidence that interventions to improve social cognition can provide substantial benefits for patients over and above the effects of antipsychotic medications (which do not show reliable effects on social information processing) (e.g., Hogarty et al., 2004). Similarly, combining cognitive-behavioral therapy with social skills training leads to clinically and statistically significant improvement in interpersonal functioning among individuals with chronic schizophrenia (Granholm et al., 2005). Additional bene-

fits of these interventions include enhancing compliance with medication regimens, improving tolerance of hallucinations and other altered perceptions, and decreased likelihood of relapse (Trower et al., 2004). And perhaps the most exciting work in this field has just begun—intervention trials to determine whether targeting social information-processing abnormalities in at-risk individuals can prevent the onset of the disorder itself (e.g., Newton et al., 2005).

The Social Psychology of Substance Use

For most individuals who use illicit substances, taking drugs is a social event. Their knowledge of and exposure to drugs comes from their social contexts, their initial drug use occurs with peers, and their drug-use decision making occurs with reference to peer norms and feedback (Dishion, Capaldi, Spracklen, & Li, 1995). Association with drug-using peers is the single most potent predictor of drug-use initiation (Warr, 1996). Furthermore, diffusion of drug use across neighborhoods and communities may well follow contagious processes, with one critical pathogenic agent being peer interaction. Unfortunately, current drug-use prevention programs and practices do not benefit sufficiently from basic science knowledge of processes in social decision making, peer influence, and social diffusion (Miller-Johnson & Costanzo, in press). Ironically, recent findings indicate that many current policies and practices may even inadvertently exacerbate drug use by aggregating high-risk youth with deviant peers who provide a drug-use training ground. When peers do receive the attention of practitioners, they are the "enemy" that is the focus of peer-resistance skills training programs, rather than an ally.

In this section, we focus on two of the many contributions of social psychology to the understanding, treatment, and prevention of substance use. First, we briefly discuss peer norms and their influences on use during adolescence, with particular attention to the implications of these processes for intervention. Second, we examine the role of social information processing in laboratory and applied studies of "choosing to use." There are many other perspectives on substance use that could be included here (e.g., Gibbons, Gerrard, & Lane, 2003). We have selected these two simply in order to illustrate how critical social psychological variables are for understanding addiction—as demonstrated in the growth of social psychology research within the funding portfolio of the National Institute of Drug Abuse (NIDA; 1999).

Peer Influences on Substance Use

Recent theoretical accounts, empirical studies, and prevention trials have made clear that social influences are the primary factors in initiation of drug-using and -abusing behaviors (Donaldson et al., 1996; Flom, Friedman, Jose, & Curtis, 2001; Harrison, Fulkerson, & Park, 2000; Kandel & Adler, 1982; Olds & Thombs, 2001). Among the multiple sources of social influence, peer influence appears to have the most profound and lasting effects on beliefs about substance abuse outcomes and on the drug-

use behaviors that ensue from these beliefs. For example, in a 15-year, follow-back retrospective study, Flom and colleagues (2001) found that drug abuse in adulthood was strongly related to peer approval norms associated with drug use at age 15. Similarly, Olds and Thombs (2001), in a survey-based study of over 2,000 7th- to 12th-grade students, found that perceived "close friend" peer norms with regard to cigarette and alcohol consumption accounted for six to eight times the variance in substance use, as did supportive parent involvement in the life of the adolescent. Research by Seiving, Perry, and Williams (2000) convincingly demonstrates that the strong effect of peer influence on substance use is not simply an artifact of selecting similar peers as friends. Instead, their results reveal that substance use follows directly from the influence of peer norms, and that relationships and cliques solidify around such norms subsequent to friendship formation.

Given the critical role of peer norms in the onset of substance use during adolescence, numerous preventive interventions have targeted peer processes in middle and high school. However, the need to focus social influence-based programming on issues of adolescent social choice that range beyond narrow conceptions of peer pressure resistance is illustrated by Lynam and colleagues' (1999) comprehensive longitudinal evaluation of the D.A.R.E. program, the most frequently employed model of peer resistance training. Lynam and colleagues found that school-based peer resistance programming had *no* effect on either drug attitudes or illicit drug use assessed 10 years after the program. Many programs appear to primarily or exclusively target "refusal" or resistance skills, whereas the social development literature suggests the ubiquity of peer influences and the potential merits of using peer leaders in prevention rather than asking individuals to defy them (Perry, Williams, Veblen-Mortenson, & Toomey, 1996; Price, Gioci, Penner, & Trautlein, 1993).

A number of investigators have begun to examine the implications of peer leadership among adolescents for substance use attitudes and behaviors. Luthar and McMahon (1996), in their sample of inner-city teens, found two contrasting patterns of admired, well-liked teens. The first group was characterized by conventionally valued behavior, such as prosocial behavior and academic achievement. By comparison, the second group was characterized by disruptive/aggressive behaviors and poor school performance. Similarly, Rodkin, Farmer, Pearl, and Van Acker (2000) found two subtypes of well-liked peers: popular-prosocial ("model") and popular-antisocial ("tough") boys. The "tough" group rated themselves as being aggressive, "cool," and athletic, whereas the "model" group described themselves as also being cool and athletic but at the same time non-aggressive and academically competent. Both groups of these well-liked boys were highly central in their peer groups. These findings suggest that youth who are admired among peers are a heterogeneous group, and highly aggressive youth may be among the most influential and prominent among their peers.

Social Information Processing and Vulnerability to Substance Use

Social psychologists have been integral in the development and validation of conceptual models for understanding how substance use behaviors develop and are maintained. Using the language and concepts of social cognition, two main questions are being pursued within this broader framework: what types of social situations most commonly lead to drug use, and what social-cognitive processes mediate decision to use. Each question leads directly to translational research for preventive intervention, including school-based programs intended to prevent or delay first use.

Substance use is particularly likely when individuals are seeking relief from life stress and the tensions and struggles of living (e.g., Greeley & Oei, 1999). As a result, it has been hypothesized that risk for first use (and development of substance abuse behavior) will be greatest in situations characterized by high levels of distress. In this way, emotional distress serves as a key mediating variable in the prediction of substance use, and the substance use itself is seen as a concrete manifestation of inadequate coping skills. A number of preventive interventions have been developed that not only target behaviors directly associated with drug and alcohol use but also provide instruction in anger management and stress reduction techniques (e.g., Webb, Scudder, Kaminer, & Kaden, 2002).

The search for psychological variables that act as mediators in the onset and maintenance of substance use has led to adoption of social information-processing models developed for the study of other kinds of behavioral problems. Consider a hypothetical 14-year-old boy who is with a group of friends who bring out a marijuana cigarette and try to cajole the boy into trying it. Theory and research in antisocial behavior indicates that this decision is highly influenced by the individual's relationship with peers, schemas, and scripts about drugs and peer interaction and the manner in which the stimulus is processed online (Dodge & Pettit, 2003). Online processing can be conceptualized as occurring in sequential steps of encoding, interpretation, response accessing, response decision, and response enactment (Crick & Dodge, 1994). Patterns in processing can be measured reliably and have been found to predict growth in aggressive behavior across development (Dodge et al., 2003). Furthermore, cognitive-emotional processes have been found to mediate the effects of other distal risk factors in maladjustment outcomes (Graziano, Jenson-Campbell, & Finch, 1997). The intervention potential of this line of research is implicated in findings that parental and school supports for individual self-regulation and appropriate autonomy are correlated with successful adolescent outcomes (Eccles, Early, Frasier, Belansky, & McCarthy, 1997). A small but growing literature has suggested that individual differences in social cognition are correlated with drug-use behavior (Schmid, 2001; Wagner, Myers, & McIninch, 1999). A large prospective study indicates that social-cognitive processes in elementary school

predict initial drug use in middle school (Kaplow, Curran, Dodge, & Conduct Problems Research Group, 2002).

Summary

We presume that our convictions regarding the importance of the social/clinical psychology interface are evident to the reader by now. Nonetheless, we wish to emphasize that the contributions of social psychology are particularly evident within the context of disorders such as schizophrenia and substance abuse that are widely viewed as biologically based. In contrast to the popular belief that psychological theory and practice are increasingly irrelevant to treatment and prevention of mental disorders (Flanagan & Blashfield, 2000), we suggest that researchers and clinicians working in these two fields are as convinced of the importance of the social psychological level of analysis as we are (Holtzman, 2003). That is, even (and we are tempted to say *particularly*) in disorders with a clearly established neurobiological basis, social processes are implicated in the onset, persistence, and consequences of those disorders.

We asserted at the start of this section that the contributions summarized here are better known among clinical psychologists than their social psychologist colleagues. In a critical respect, that is indeed the case; a quick examination of the journals in which the aforementioned studies appeared makes clear the distinction between the first two "lenses" of this chapter. Whereas most of the social psychological research on depression (for instance) appears in social psychology journals, social information processing studies of schizophrenia are almost exclusively found in the journals of clinical psychology and psychiatry. However, there is no doubt that social psychologists would recognize the phenomena, theories, and methods that our clinical colleagues have borrowed. Likewise, both the clinical psychologists engaged in this research and the social psychologists viewing them from a distance would agree that combining a focus on social/interpersonal factors with an individual differences approach provides a critical level of analysis for understanding the etiology, treatment, and prevention of mental illness.

CONTRIBUTIONS TO CLINICAL PSYCHOLOGY: A GLIMPSE INTO THE FUTURE

What developments at the interface of social and clinical psychology are likely to be influential in the near future? This final lens requires us to stick our collective necks out a bit further, but we hope to convince the reader that there are indeed several research areas in social psychology that have clear, and we believe imminent, implications for clinical psychology. As we have argued throughout, this influence will likely occur through translating social psychological research into the language of individual differences. For reasons of convenience and familiarity, we focus on research related to depression, but we suggest that their ultimate impact on clinical research and practice is likely to extend beyond that particular disorder.

Self-Regulation, Repetitive Thought, and Depression

Current theories of self-regulation provide robust and thoughtful accounts of how individuals pursue personal goals and the kinds of motivational and emotional states they experience when they see themselves as attaining, or failing to attain, such goals (Carver & Scheier, 1999). A number of investigators have attempted to link problems in self-regulation with vulnerability to depression and other disorders (e.g., Karoly, 1993; Strauman, 2002). However, self-regulation theories have not yet adequately articulated how the experience of *acute* emotional distress following failure to attain important goals becomes the *chronic* emotional distress characteristic of mood and anxiety disorders. Because only a subset of individuals experiencing chronic difficulties attaining personal goals ever become depressed, there may be other factors that determine whether a particular individual responds adaptively in the face of continued failure feedback or becomes mired in a downward spiral of negative self-evaluation, doubt, and distress. One candidate for such a factor is maladaptive repetitive thought, also known as rumination.

Repetitive thought (RT) can be defined as "the process of thinking attentively, repetitively, or frequently about oneself and one's world" (Segerstrom, Stanton, Alden, & Shortridge, 2003, p. 909). Both theory and research suggest that the tendency to engage in specific types of RT in response to goal blockage predicts the likelihood of self-regulatory failure (Carver & Scheier, 1990; Pyszczynski & Greenberg, 1987). In this context, self-regulatory failure refers to an inability to make progress toward important goals and a subsequent inability to reprioritize or disengage these goals from the regulatory system (Emmons, King, & Sheldon, 1993). RT can lead to continued activation of a perceived discrepancy between the current state of being and the chosen goal, causing the goal to remain salient and distressing.

Martin and Tesser (1996) proposed a theory of rumination, which they defined as a "class of conscious thoughts that revolve around a common instrumental theme and that recur in the absence of immediate environmental demands requiring the thoughts" (p. 7). They posited that rumination is instigated by a failure to make progress toward a desired goal, and that attaining or disengaging from the blocked goal will terminate the ruminative process. However, redirecting thoughts away from the distressing content or reducing negative affect associated with the goal blockage is likely to only temporarily halt the process, because the continual cuing of goal-related thoughts by features of the social environment make continued distraction difficult. Other theorists have proposed that an unfavorable assessment of the expectancy of succeeding at goal-directed action instigates the process of rumination—especially if the blocked goal is central to the self (Carver, 1996).

While Martin and Tesser's theory of rumination is elegant, there is a critical distinction between problem solving and rumination. Problem solving refers to the process of recognizing that a problem exists, defining and representing the problem mentally, developing a solution strategy, organizing current knowledge about the problem, allocating mental and physical resources needed to solve the problem, monitoring progress toward the goal, and evaluating the quality of the solution (Pretz, Naples, & Sternberg, 2003). In contrast, rumination is better conceptualized in this context as "repetition of a theme in thoughts, without progression toward choice of a solution and a commitment to that solution" (Nolen-Hoeksema, 1996, p. 137).

Nolen-Hoeksema has studied rumination as a coping mechanism in depression (e.g., Nolen-Hoeksema, 2000). She defines ruminative coping "behaviors or thoughts that focus an individual's attention [on] the possible causes and consequences of that mood" (Nolen-Hoeksema, Morrow, & Fredrickson, 1993, p. 20). In this account, rumination is not instigated by a self-regulatory failure but is instead a maladaptive response to dysphoric mood. Indeed, dysphorics who ruminate demonstrate lower problem solving and less ability to generate effective solutions to interpersonal problems when compared to nondysphorics and dysphorics who use distraction (Lyubomirsky, Tucker, Caldwell, & Berg, 1999). We suggest that these findings could be integrated within the self-regulatory perspective taken by Martin and Tesser (1989) to create a more elaborated theory accounting for how acute failure feedback (which everyone experiences) becomes transformed over time into chronic failure feedback (which many people experience) and ultimately into a clinically depressed state (which most people receiving failure feedback do *not* experience).

Consider the following preliminary example of such an integrative approach. In the ongoing process of self-regulation, the individual evaluates his or her progress by monitoring the magnitude of perceived discrepancy between actual behavior and a particular goal or standard (Higgins, 1987, 1997) and the perceived rate of discrepancy reduction or enlargement (Carver & Scheier, 1990). Specifically, when using promotion (Higgins, 1997) as a means of self-regulating behavior, dysphoric emotions occur when the individual detects a discrepancy and subsequently evaluates that insufficient progress is being made. The intensity of the emotional discomfort resulting from this monitoring process is directly related to the magnitude, accessibility, and contextual relevance of the detected self-discrepancy, as well as the centrality of the discrepancy to a person's self-concept. A large self-discrepancy that is highly accessible, contextually relevant, and central to a person's self-concept is associated with a more intense emotional response.

The monitoring also generates a sense of expectancy (optimism or doubt) that influences subsequent motivation (Carver & Scheier, 1990). Under conditions that signal difficulties in goal attainment, a sense of optimism or doubt is generated that causes the person to initially respond by increasing the degree of persistence and effort of the initial instrumental behavior (Martin & Tesser,

1996). Detection of a large discrepancy generates doubt, whereas detection of a small discrepancy generates optimism that determines the degree of effort placed into repeating the instrumental behavior. At this stage, the evaluation that insufficient progress is being made causes the individual to disengage from the initial instrumental behavior to engage in a full evaluation of the likelihood of success (Carver & Scheier, 1998). In parallel with the expectancy evaluation, an individual may engage in problem solving: defining and representing the problem mentally, developing a solution strategy, organizing current knowledge about the problem, and allocating mental and physical resources needed to solve the problem (Pretz et al., 2003). Problem solving may entail attempts to specify alternate pathways that lead to attainment of the higher-order goal, redefining the goal at lower level of specification, or engaging in a process of redefinition of the self.

One of the most critical issues in developing this kind of integrative model is, how does acute failure/distress evolve over time into chronic failure and distress? Existing theories help to specify some of the conditions for such an evolution. Disengagement from a goal may not be possible due to the centrality of the goal to a person's self-concept; that is, the goal may reside at high levels within a person's goal hierarchy. This inability to disengage would lead to further attempts to attain a goal that are imbued with doubt, creating the conditions for further failure experiences as well as maladaptive rumination. In turn, maladaptive rumination results in continued activation of a perceived discrepancy, causing the goal to remain salient (Martin & Tesser, 1996). This begins a cyclical process where continued indirect and direct cuing of the discrepancy generate more intense negative affect and increasing levels of maladaptive rumination. The rumination prolongs existing negative affect and generates more negative affect as individuals begin to engage in secondary appraisals that their rumination is uncontrollable, harmful, and likely to produce detrimental interpersonal as well as social consequences (Papageorgiou & Wells, 2004). In this state, the individual is no longer actively producing solution strategies but is likely to be thinking about the goal object and his or her feelings regarding the object. This process can cause polarization of existing affect, which intensifies the negative experience (Martin & Tesser, 1989).

Combining this cognitive perspective on self-evaluation with the affective and motivational mechanisms proposed in regulatory focus theory suggests that a particular sequence of events would be discriminantly associated with depression. Over time, the repeated failure to attain promotion goals could result in disengagement from attempts to pursue them, that is, a downregulation in the active pursuit of concerns related to advancement and growth (Kasch, Rottenberg, Arnow, & Gotlib, 2002). Furthermore, appraising maladaptive rumination as aversive and uncontrollable could create a prevention goal of stopping the rumination (i.e., keeping bad things from happening), causing an upregulation in prevention concerns. As individuals enter a prevention-focused state, the strategic inclination to use vigilance to monitor for potential mistakes may generate a need to continue

searching the environment for ways to reduce the discrepancy or understand why they keep failing. Paradoxically, this vigilance also would make a person more likely to confront cues in the environment associated with existing discrepancies related to both promotion and prevention concerns that trigger further maladaptive rumination (Wenzlaff & Wegner, 2000).

Integrating models of self-regulation with models of repetitive thought would enhance the current understanding of cognitive processes underlying self-regulatory failure. In addition, this kind of integrative model suggests possible targets for cognitive, behavioral, and interpersonal interventions in the treatment of depression. To the extent that perceived goal failure, individual differences in regulatory focus, and rumination contribute to the onset and maintenance of a depressive syndrome, they could be addressed directly via existing therapeutic techniques (such as are common in cognitive therapy for depression [Beck, 1995]).

Biased Information Processing in Depression

In the past 15 years, social neuroscience has emerged as a distinct branch of social psychology that has far-reaching implications for clinical psychological research (Cacioppo & Berntson, 2004). Social neuroscience incorporates methodological advances in social psychology, cognitive psychology, and cognitive neuroscience to study social processes from a range of perspectives. The methods of social neuroscience, in combination with social psychological theory, can shed important new light on the nature of depression. In particular, we suggest that using functional imaging techniques to test theories about changes in information processing associated with depression could help to increase our knowledge about how depression emerges and could ultimately provide an empirical basis for treatment selection. We illustrate this proposal by discussing a current controversy in the depression literature: the nature of the cognitive changes observed as part of a depressive episode.

As stated originally in Akiskal and McKinney's (1973) "unified hypothesis" and observed in subsequent research that has combined biological and behavioral approaches to depressive disorders, depression emerges from a psychobiological "final common pathway" that produces an array of different depressive symptoms, such as memory impairment, negative cognitions, and depressed mood (Akiskal & McKinney, 1973, p. 290). There is a large but inconsistent literature documenting changes in performance on memory tasks among clinically depressed individuals (e.g., Barry, Naus, & Rehm, 2004; Blaney, 1986; Williams & Scott, 1988). Much of that literature is based on an implicit (and occasionally explicit) assumption that depression is an illness that leads to irreversible structural changes in the brain (e.g., Rompre, Stip, & Trudeau, 2004). However, Akiskal and McKinney (1973) had hypothesized that the core of depression was a "reversible functional derangement of the mechanisms of reinforcement" (p. 291), so that at least in early episodes, depression was more accurately characterized as a downregulated motivational state rather than

as an "illness." Consistent with Akiskal and McKinney's hypothesis, a recent review of relevant neurophysiological and cognitive research proposed that biased information processing is the primary cause of the memory deficits observed in depression (McLean & Strauman, 2006). From a clinical standpoint, determining whether cognitive changes associated with depression are functional (i.e., biased versions of "normal" processing) or structural (i.e., actual changes to the central nervous system) has important implications, because cognitive biases, unlike structural deficits, can at least potentially be altered to restore the individual's capacity for more adaptive information processing strategies. Consequently, strategies designed to reinstate premorbid social information processing may be a key component in successful treatment for depression.

Given the nature of this research question—does depression involve functional or structural changes in the central nervous system (CNS)—combining cognitive, behavioral, and functional neuroimaging techniques can provide essential information regarding the psychobiological changes that have been hypothesized to underlie depression. There are at least two sets of research findings that are relevant to this question: how emotional states affect memory encoding in depressed individuals (see Davidson, 1999, for a review), and how self-referential information is initially processed and/or recalled (Macrae, Moran, Heatherton, Banfield, & Kelley, 2004). To date, there are no neuroimaging studies that have explored the effects of combined negative emotional and self-referential processing in nondepressed individuals on memory (by examining encoding or retrieval), much less compared these findings with those of depressed individuals. This is unfortunate because insight into the cognitive and neurophysiological mechanisms that underlie a preference toward negative and negative self-referential information in depression may suggest new and more effective treatments for the disorder.

Despite the apparently inconsistent findings regarding memory in depressed individuals, a large body of research has shown that negative information is remembered better than positive and neutral information in depressed individuals, and that negative information is remembered especially well when it refers to the self (see Symons & Johnson, 1997, for review). Other research has shown that negative cognitions and negative self-referential information are remembered better in depressed compared to nondepressed individuals, which is hypothesized to create and maintain over time a bias toward negative self-referential information (Dent & Teasdale, 1988). This information processing bias is significant because an overemphasis on negative cognitions and negative self-referential information can lead to or maintain symptoms that in turn perpetuate depression (Williams, 1997). The persistence of negatively distorted cognitions maintains depressed mood and thereby predicts episode severity and duration as well as likelihood of relapse (Ingram & Holle, 1992).

Based on the available literature, we hypothesize that depressed individuals remember negative and negative

self-referential information more frequently than other kinds of information because they have developed a bias toward this information. We also predict that this bias is a manifestation of a functional change (i.e., a down-regulated motivational and emotional state), not an indication of a structural change in the CNS. While acknowledging the possibility that chronic recurrent depression could indeed lead to permanent changes in cortical and subcortical structures, we believe that this is the exception rather than the rule. We note in particular that our prediction implies that under certain conditions, depressed individuals will show better memory performance than nondepressed individuals—a finding that would be inconsistent with a structural or "disease" model. However, we also acknowledge that the mechanisms underlying this bias remain unknown.

One way to test this hypothesis would be to use neuro-imaging techniques to observe the activation patterns associated with negative versus positive and self-referential versus non-self-referential social information. In particular, patterns of activation in the anterior cingulate cortex (ACC) are likely to be informative, given the emerging literature implicating the ACC as underlying the processing of both emotionally valenced and self-referential information (Drevets, 2000). We would predict that depressed and nondepressed groups (when appropriately matched on age and other variables that can influence performance on cognitive tasks) would not manifest an overall difference in memory performance. Rather, whereas nondepressed individuals would show better recall or recognition for positively valenced self-referential stimuli, their depressed counterparts would better remember self-referential stimuli that were negatively valenced. In turn, these behavioral differences would likely be associated with detectable differences in location and intensity of cortical activation within the ACC. This kind of research illustrates how social psychological models, translated into an individual differences framework, can be applied to studies of the etiology, diagnosis, and treatment of major mental disorders.

Social Psychology and Psychotherapy

We close with a topic that may represent wishful thinking more than a definitive prediction. As researchers with identities as both social and clinical psychologists, we find it disappointing that contemporary social psychology has not been more closely involved with the study of psychotherapy outcome and process. With occasional exceptions (e.g., Cacioppo, Claiborn, Petty, & Heesacker, 1991; MacDonald, Nail, & Levy, 2004), social psychologists have not concerned themselves with studying how psychotherapy works—despite the fact that in previous eras, social psychological knowledge was considered essential to a thorough understanding of patient–therapist interactions (Frank & Frank, 1993). We propose that the efficacy of psychotherapy (particularly, but not limited to, cognitive-behavioral interventions) can be enhanced by taking into consideration the tools and models of social cognition (Merrill & Strauman, 2004). Several examples relating to depression are offered below to illustrate

how social psychologists can enhance both the efficacy of psychotherapy and clinician's understanding of how it works.

From the perspective of a therapist, what kinds of models or theories of behavior are most likely to be useful? Certainly one that incorporates individual differences, integrates the various components of an individual's personality system, takes into account situational variation, provides explanatory/predictive power for an individual's behavior, and, ultimately, provides information about the individual that could be applied within the framework of the therapy (e.g., identifying targets for change or compensation, contributing to better understanding of change processes, and predicting short-term and longer-term treatment outcome). Trait-based theories have not provided a useful framework for selecting or designing psychotherapeutic interventions. However, knowing what beliefs and attitudes typically influence that individual's interpretation of everyday life situations and trigger problematic conclusions or behaviors, or how affectively laden memories can influence change processes, *would* be of value in psychotherapy (Cacioppo & Berntson, 1992; Libby, Eibach, & Gilovich, 2005).

Social psychology has a long tradition of research in the area of *cognitive style*, and although several investigators have discussed the parallel development of cognitive theories in social, cognitive, and clinical psychology (e.g., Hollon & Garber, 1990), there has been relatively little crossover from these areas. One potential mechanism underlying poor outcomes seen in patients with personality disorders is an overly simplistic and rigid cognitive style. Social psychologists have explored constructs such as *need for cognition* (Cacioppo & Petty, 1982) that address stylistic differences in information processing. Understanding the interplay between the individual's cognitive style and other components of the personality system and the social environment should improve the therapist's understanding of the patient's problems as well as difficulties that arise in therapy. Individual differences in cognitive style also may influence the choice of therapeutic interventions and provide a basis for treatment matching.

Another example of an important aspect of social cognition applicable to psychotherapy is the individual's characteristic self-regulation. People differ in their customary styles of self-regulation, the ongoing cognitive process of evaluating oneself in relation to one's goals, and changing behaviors in an effort to attain goals (Carver & Scheier, 1990). One model of depression proposes that self-regulation plays an important role in the development and maintenance of the disorder (Strauman, 2002). Underlying an individual's self-regulatory processes are two hypothetical cognitive-motivational systems, which are focused on attaining positive outcomes or "making good things happen" (promotion) and on avoiding negative outcomes or "keeping bad things from happening" (prevention), respectively (Higgins, 1997). The prevention and promotion systems are hypothesized to have neural underpinnings associated with the behavioral inhibition system (BIS) and the behavioral approach system (BAS), respectively. Depres-

sion is thought to be characterized by decreased goal-directed behaviors, coupled with low levels of positive affect, which are associated with a deficit in the BAS (Watson, Weise, Vaidya, & Tellegen, 1999). Studies using brain-imaging techniques have shown that approach motivation (a BAS function) and positive affect may be associated with left frontal activation (Tomarken & Keener, 1998). Application of a self-regulation framework could offer a new means of assessing how treatments lead to symptom improvement and behavior change (Merrill & Strauman, 2004).

The inclusion of a self-regulation focus in therapy is the topic of ongoing investigation. Strauman and colleagues have developed self-system therapy (SST) (Vieth et al., 2003) a brief structured treatment for depression derived from theories of individual differences in self-regulation. In an initial randomized clinical trial, SST was more effective than a standard treatment for the subset of depressed individuals with significant problems in self-regulation such as high levels of self-discrepancy (Strauman et al., 2006). Future studies in this area aim to determine whether self-regulation may be a useful factor for treatment matching, by developing methods to identify which depressed individuals have significant problems in self-regulation.

A final area of overlap between social psychology and psychotherapy research is *person × situation interactions*. Both researchers and therapists share an interest in understanding the situational specificity of affective responses and behavioral tendencies. The interaction between situation and person is likely to be complex, dynamic, and mediated by a number of social-cognitive variables. The situation itself is a much less powerful predictor of clinically relevant behavior than the interaction between the situation and within-person variables such as beliefs, expectancies, and attitudes (Cervone, 1997). This notion of a dynamic process linking situational, cognitive, affective, and behavioral factors is consistent with the clinical literature. For example, the importance of cognitive variables in mediating the association between life events and depression has been acknowledged (Robins & Block, 1988).

CONCLUSION

Contrary to the unfortunately narrow and reductionistic worldview that dominates current headlines, social psychology is alive and well, particularly as it enriches clinical psychology. We hope that this chapter has illustrated both the critical translational principle by which social psychology influences the study of psychological disorders and the individual-differences pathway by which that influence often occurs. Clearly no single "lens" or perspective can do justice to this active research frontier; clinical psychologists will continue to pick and choose from the social psychological literature, and social psychologists will continue to develop models of the etiology, treatment, and prevention of mental disorders. If our brief glimpse of the future has any validity, there is much to be excited about.

The principles of social psychology that are summarized in this volume are all, in theory, both conceptually and empirically sound bases for understanding human distress. We have presented here three perspectives on how social psychology has been applied to clinical issues. All three perspectives translate the "common person" framework that characterizes social psychological research into an individual-differences structure to explain why some people, under certain circumstances, will experience significant distress. Clinical psychologists are to be congratulated on their willingness to borrow liberally from the social literature—or even simply for their opportunistic appropriation of interesting models. In turn, social psychology should be recognized for the extensive contributions it has made to the nation's public health. Individually and together, social and clinical psychologists are sure to continue their productive and occasionally surprising exploration of human behavior.

Consumer Behavior and Marketing

Eric J. Johnson
Michel Tuan Pham
Gita Venkataramani Johar

Whenever we make a decision to buy—or not to buy—something, there are short-term and often long-term consequences. In the short-term, we may consume a sandwich, go to a movie, or buy some clothing. We also have made a short-term decision to allocate resources, such as time and money, to that acquisition. That purchase may have long-term benefits and costs: That sandwich may contribute to being overweight; the movie may change the way we look at some aspect of the world; and the clothing may earn us a compliment or help us get a new job. Less obvious is that this decision involves trade-offs. For example, the resources required to make the purchase will prevent us from pursuing other opportunities with the same resources, what economists call *opportunity costs.*

These kinds of decisions are at the heart of consumer behavior. Because they are not made in isolation, we must also be concerned how that environment is influenced by firms and marketing managers. Although this chapter concentrates on *consumers*, we also talk about *managers* because they help design the products, allocate the advertising budget, and shape the messages that influence consumers. Their lay and expert theories of consumer choice help establish the environment in which consumers behave. In addition, one important role of consumer behavior research is to help managers develop better theories and make better decisions. Finally, many of the principles we discuss have relevance to public pol-

icy and, in fact, social marketing, a field that would like to employ these principles in not-for-profit arenas.

CONSUMER BEHAVIOR AS AN ACADEMIC FIELD

Consumer research is located at the nexus of theory and practice and at the intersection of several different research traditions. Two of the primary source disciplines are psychology and economics, although methodology, particularly quantitative modeling from statistics and management science, also plays an important role.

One way of portraying the field and its relationship to social psychology is to look at the pattern of citations among major journals. Figure 38.1 shows the pattern of cross citation for three psychology journals and four of the leading journals in marketing. The numbers are the percentage of all citations in that journal that refer to papers published in another. For example, 7% of the citations in the *Journal of Consumer Research* (JCR) are to papers in the *Journal of Personality and Social Psychology* (JPSP), while 20% of JCR's citations are to its own papers. For clarity, we eliminated cross citations with frequencies of less than 2%.[1]

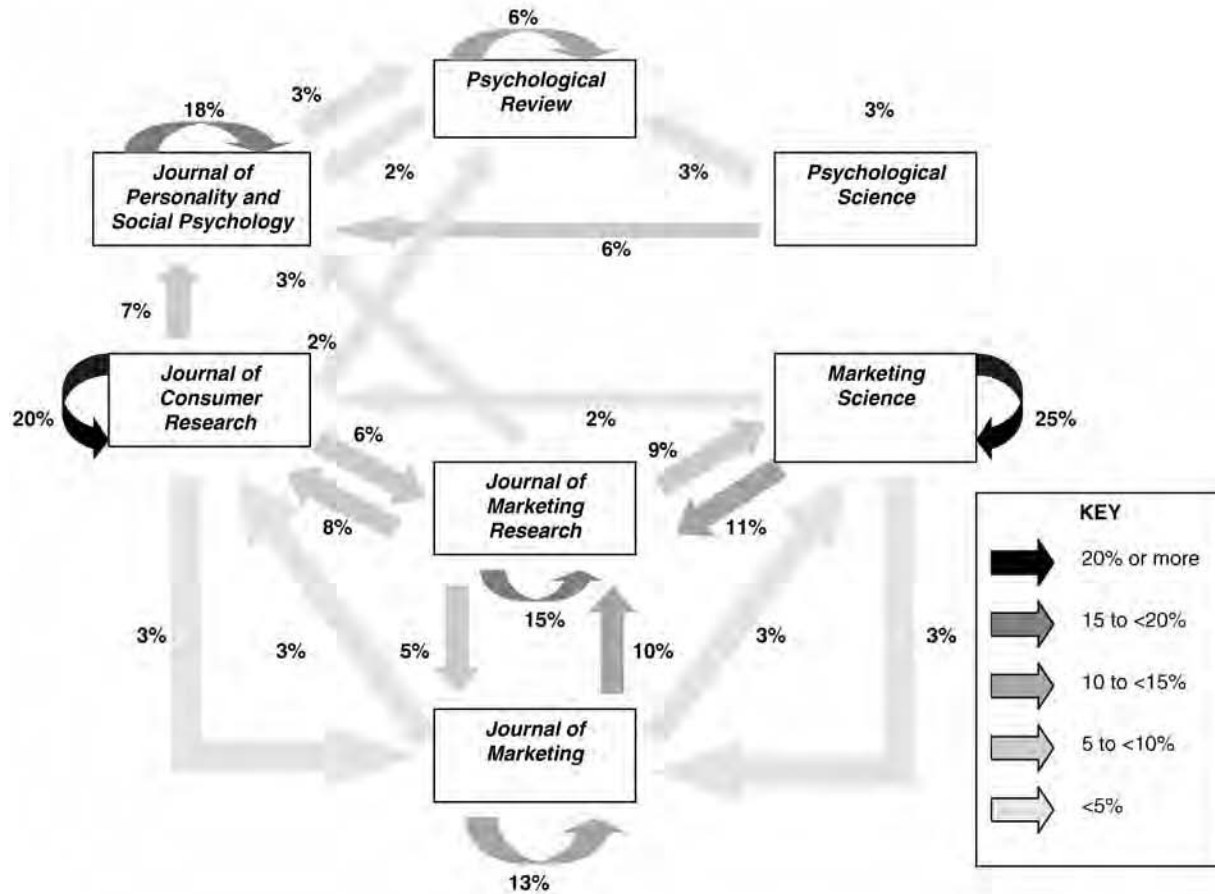
One strong conclusion that can be drawn is that the central journal in consumer research is a large consumer of social psychology: Seven out of every 100 citations are


FIGURE 38.1. Cross-citations of journals, psychology and marketing, based on *ISI Web of Knowledge* data, 2004. Arrows indicate citations from one journal to papers published in another. Any cross-citations less than 2% have been deleted for clarity.

to JPSP. That is even more than to any of the marketing journals other than itself. A second conclusion is that authors in JPSP find little to cite in any marketing journal. It is as if the phenomena and findings of the world of commerce are of little relevance to social psychology. While that may be the fate of any applied discipline, we are convinced that this should not be the case. Many of the questions in consumer research are, in fact, of great relevance to social psychology, and many important empirical results should be of interest to students of fields such as persuasion and decision making. Consumer behavior provides an ideal laboratory, not just for the application of theories but also for the extending existing theoretical ideas and the development of new ones.

A third conclusion that might be drawn from this diagram is that consumer research and marketing have their own schisms. Roughly speaking, there is a limited flow of citations to and from the more quantitative journals, such as *Marketing Science*, and one might conclude that consumer research is fairly distant from either *Marketing Science* or the *Journal of Marketing*, the latter often seen as the most applied journal in the discipline. In sum, Figure 38.1 shows the reader that what may appear a monolithic field is, in reality, like many outgroups, less homogeneous than it appears, and that social psychology is an important source for, but not a user of, consumer-oriented research.

GOALS OF THE CHAPTER

Our goal in this chapter is to review for social psychologists some of the interesting research done in consumer behavior and marketing. This review must be incomplete in the usual sense, that is, many good papers and many worthwhile research areas are not covered because of space constraints and the lack of fit to a relatively arbitrary structure. However, it is incomplete in a more intentional and strategic way. Because many excellent chapters in this handbook describe the basic research underlying consumer and marketing research, we do not review those basic ideas and results here. Our goal, instead, is to review the results of the application of psychological ideas to consumer behavior and marketing and to highlight data and ideas that should inform social-psychological research. The emphasis is on research published outside the traditional mainstream of social psychology but within the mainstream of consumer research

and marketing, and it addresses concepts, theories, and methods relevant to social and cognitive psychology.

To organize this literature, and to give the reader a sense of the last few decades of the field, we have chosen to concentrate on four topics: two representing classic areas of inquiry, and two representing developing ones. Our "old school" classics are topics that have been central to consumer research for at least the last 50 years: decision making and persuasion. This is not to say that they are not hotbeds of current research but rather that they have a longer traditional history and more established methods. Our "new school" topics are affect and implicit processing, areas that have grown rapidly in consumer research, paralleling trends in social psychology.

DECISION PROCESSES

Consumer Decision Making: A View from Economics

Imagine a consumer in front of a typical American supermarket aisle, choosing a breakfast cereal. There are, by most counts, at least 120 different options in a typical American supermarket. How does a consumer choose? We start by introducing an "as-if" model, termed "value maximization," from economics (see Deaton & Muellbauer, 1980, for a classic perspective; Tversky & Kahneman, 1991, and Tversky & Simonson, 1993, for a psychological view; and Varian, 1992, for a more recent view). We do this both because (1) it stands as a normative benchmark for other decision processes, and (2) it is the source, in spirit at least, of many of the models that managers use to predict consumer choice and design new products. In this model, consumers behave as if they were examining all relevant attributes for all the cereals. That is, they choose as if they knew all available relevant information. Not only do they pick the "best" cereal according to these criteria from this large set, but they are also maximizing their choice across all possible consumption choices they are making, both now and given their best predictions about what will happen in the future. This maximization is not limited to the supermarket, but to *all possible* consumption decisions!

However unrealistic this may sound, the basic idea of value maximization has generated many useful tools such as discrete choice modeling, which managers use to design, price, and position products. Most attempts to make these models more realistic involve modifications to the idea of value maximization rather than the use of alternative frameworks that are based on other principles or assumptions.

Choice Heuristics and Representations

Heuristics for Choice

In response to the apparently unrealistic demands of value maximization, many scholars have developed descriptions of choice processes that simplify the decision process. These simplifications from value maximization, or *choice heuristics*, try to maintain the ability to make

good choices at substantial savings of effort. One example of a choice heuristic in our cereal example would be if the consumer were to eliminate any cereal with added sugar. This corresponds to an elimination by aspects heuristic (Tversky, 1972), and it simplifies the choice because the brands that are eliminated are not examined further. Heuristics save effort by ignoring information. This savings comes with a potential cost because it is possible, if unlikely, that one of the eliminated cereals is so much better on the remaining attributes (e.g., lots of vitamins and very inexpensive) that it is better than the one finally chosen.

Many heuristics have been described (Svenson, 1979), including those that are based on comparisons of the alternatives, such as the lexicographic and additive differences heuristics, and those, like elimination by aspects (Tversky, 1972), that are based on the comparison of the alternatives to a standard, which are related to Simon's notion of satisficing (Simon, 1955). Do people use these heuristics? An extensive literature examines how people make choices, many using process tracing methods, such as talk-aloud protocols (Bettman, 1970), recording of consumers' head and eye movements (Russo & Leclerc, 1994; Russo & Rosen, 1974), and other ways of observing information acquisitions (Bettman & Kakkar, 1977; Jacoby, 1975; Jacoby et al., 1994). This literature clearly indicates that a large number of heuristics are used, that they depend on the characteristics of the choice, and that people switch heuristics, even in the course of a single decision. In fact, it has been argued that the research on choice processes should be conducted at a finer level of analysis, and that the concept of heuristics is too broad to use to understand consumer choice (Payne, Bettman, & Johnson, 1991) and that a lower level of analysis is appropriate. This plethora of potential strategies, while descriptively more accurate, poses a challenge for modeling consumer behavior: How can we try to predict what a consumer would want when we do not know how they will make a choice? This represents an active area of research in consumer choice modeling.

Mental Accounting

Recall that our shopper not only maximized, according to theory, across all breakfast cereals but across all choices. Thus, according to theory, shoppers are deciding between buying the brand-name corn flakes and the store-brand flakes in light of its implications for other purchases that may occur years in the future, such as buying a retirement home. A more psychologically realistic view is that people have much more restricted "mental" accounts in which trade-offs are made (Thaler, 1984, 1999; Thaler & Johnson, 1990). For our hypothetical cereal consumer, they may be making trade-offs within their mental accounts for breakfasts, trying to find the best possible combinations *within* that category, including hot breakfasts, the bagel bought at a corner kiosk, and so on.

While this psychologically plausible assumption markedly simplifies the consumer's task, it is not without its costs. One major concern is that consumers might be

maximizing within that account, but that this leads to over- or underconsumption in other accounts and that the quality of consumer's mental accounting depends on their ability to remember to "post" expenditures into each account and whether they compare expenditures in different accounts (Heath & Soll, 1996). One particularly nice application of this idea is studying how consumers make trade-offs between time and money (Leclerc, Schmitt, & Dube, 1995; Soman, 2001).

Another way in which mental accounting affects consumer choices is that mental accounting, like "real" accounting, occurs over time. That is, inflows of consumption and outflows of resources (like money) can occur at different times. We pay for cars over many years after we initially purchase them but usually pay for vacations before we take them. An interesting growth area in consumer research tries to understand how consumers would want these transactions framed, and how they might be manipulated by frames. Thus, studies have examined whether decision makers like to have the costs and benefits of decisions put together (integrated) or kept apart (segregated) (Prelec & Loewenstein, 1998; Read, Loewenstein, & Rabin, 1999; Thaler & Johnson, 1990).

An important application of this kind of mental accounting research is to look at how the way people pay for transactions affects their spending. The concept of payment decoupling (Soman & Gourville, 2001) suggests that if expenditures are in different accounts than consumption, consumers will spend more. This has been demonstrated in recent studies (Prelec & Simester, 2001; Soman, 2003) that show, for example, that people are willing to pay up to 100% more to purchase tickets to a basketball game when using a charge card than when paying in cash, and that people remember how much they spend better when they pay with cash than with a credit card. Soman and Cheema (2002) look at how mental accounting affects consumers' use of a line of credit.

Recent findings by Zhou and Pham (2004) suggest that nonprofessional consumer investors use two separate mental accounts to manage their investments: one account, associated with promotion-focused regulation (Higgins, 1997), is used to for the achievement of financial gains, and another account, associated with prevention-focused regulation, is used to for the prevention of financial losses. Because consumers learn to associate various financial products with either the achievement of gains or the prevention of losses, they tend to evaluate different investment products using different criteria, which violate standard finance and economics principles.

A major challenge in introducing the idea of mental accounts is identifying the boundaries of mental accounts. Does our hypothetical consumer include the bagel bought at work in the same account as the one for breakfast cereal, or maybe in an account of things bought to get to work early? Some initial work has looked at using natural categories as a starting point (Henderson & Peterson, 1992; McGraw, Tetlock, & Kristel, 2003), but much work remains to be done, particularly if mental accounting is to influence quantitative models of consumer choice.

Reference Dependence and Loss Aversion

Once consumers are seen as making decisions in more narrow accounts, it seems natural to adopt a different view of how they interpret attributes. Under value maximization, when our cereal consumer was judging calories, he or she was making trade-offs against all possible consumption decisions. For example, the calorie consumption of bagel might be compared to a crème brûlée the consumer might consume 2 weeks from Sunday. A more natural and cognitively economical assumption is to see the consumer as comparing the calories of a potential new cereal relative to the calories accompanying his or her current favorite brand.

This basic idea of a reference point is reflected most famously as the value function of prospect theory (Tversky & Kahneman, 1991). Along with the idea of loss aversion, the idea of reference dependence has had a major impact on consumer research. For example, imagine that our cereal consumer now sees that his favorite cereal has had a price increase (to him, a loss) of $0.10. How does that compare to a price decrease (to them a gain) of $0.10? According to the value function of prospect theory, the loss (price increase) will have much more impact; on average twice as much of an impact as would the same size price increase. In terms of economics, we would expect the *elasticity* to change: The decrease in consumption caused by the price increase should be twice the size of the increase in consumption caused by a price decrease.

Early work in studying consumer choice first examined, like our example, whether reactions to price were reference dependent (Kalyanaram & Little, 1994; Mayhew & Winer, 1992; Winer, 1986) and whether they exhibited loss aversion (Hardie, Johnson, & Fader, 1993; Putler, 1992). They provided evidence that reference dependence and loss aversion were useful in explaining the effect of price in consumer choice (see Mazumdar, Raj, & Sinha, 2005, for a recent review). Following the multiattribute extension of the prospect theory value function, Hardie and colleagues (1993) showed that there was loss aversion for both price and, to an even greater extent, quality (see also Bell & Lattin, 2000; Heath et al., 2000; Sen & Johnson, 1997). Subsequent work has looked at the amount of loss aversion for various attributes and whether there are systematic differences across individuals (Chernev, 2004; Erdem, Mayhew, & Sun, 2001; Klapper, Ebling, & Temme, 2005; Van Dijk & Van Knippenberg, 2005). Research has also examined how the pattern of purchases affects the reference point and preference (Sood, Rottenstreich, & Brenner, 2004; Wathieu, 2004). One interesting application examines reference effects and loss aversion in online auctions (Dholakia & Simonson, 2005).

Context Effects

Perhaps the best evidence against value maximization is the existence of context effects. A context effect occurs when adding alternatives to a choice set changes what is chosen, even when the added option seems largely irrelevant. To explore this, consider a website offering two air-

fares to the same city. One is a direct, more expensive flight, and the second a flight requiring a change of planes but significantly cheaper. Depending on one's tastes, one flight or the other might be chosen. Consider what happens if that site added another flight—one that is almost identical to the one-stop in every way but more expensive. Should this change peoples' choices?

Both common sense and value maximization say that choices should not change, but empirically they do. Adding the option that is the same in every way but more expensive typically increases the share of the better one-stop flight. This observation, termed "asymmetric dominance," or the *attraction effect* (Huber, Payne, & Puto, 1982), is one of the findings in consumer choice with the greatest impact throughout the social sciences. Other context effects exist, most notably a *compromise* effect. Here the option between two extreme options gets a greater share of choices than would be predicted by value maximization (Simonson, 1989). In our example, adding a fast, more expensive flight to our Web site would increase the share of the now less expensive nonstop flight. People have speculated whether these techniques could be used to manipulate consumers (Hamilton, 2003; Stewart, Chater, Stott, & Reimers, 2003).

What causes these rather bizarre effects? Answering this question seems to be particularly challenging as these effects have been found in other species such as honeybees and gray jays (Shafir, Bechar, & Weber, 2003; Shafir, Waite, & Smith, 2002). One common set of explanations makes use of loss aversion (Tversky & Simonson, 1993), suggesting that unfavorable comparisons have more impact on choice. Thus, the middle or compromise option has smaller disadvantages, relative to the two options. This leads to the middle option being more attractive, because its losses are smaller. In a very provocative paper, Kivetz, Netzer, and Srinivasan (2004a) develop several different models for the compromise effect and show one in which the middle option serving as a reference point provides a better account for the observed data. Importantly, they also generalize the result, extending it to choices where there are more than two alternatives and two attributes (Kivetz, Netzer, & Srinivasan, 2004b). While this is a major step forward, in part because it presents a managerially useful model of this particular context effect that can be estimated, the real challenge for further research is to develop theoretical mechanisms that unite a growing number of effects.

Task Effects

While context effects refer to the kinds of options presented to the consumer, task effects refer to the way in which the consumer must make these choices. One example might be the time pressure in the supermarket caused by an impatient young child; another might be the need to justify the decision to one's supervisor. The options remain the same, but the conditions of evaluation are different.

The classic task effect in psychology is the preference reversal between pairs of options, often two gambles. Here respondents will choose one option but be willing to pay more for the other, violating economic ideas of stable preferences (Lichtenstein & Slovic, 1971). Its close relative in consumer choice is the difference between joint and separate evaluations (Hsee, 1996; Hsee & Leclerc, 1998). In joint evaluation, two options are judged at the same time, while in separate evaluation, they are presented and judged one at a time. However, the mechanisms involved in both joint and separate evaluations are different than those involved in the classic reversal among gambles. For this type of reversal, the critical variable is the ease with which an attribute can be evaluated. Joint evaluation can make variables that are hard to evaluate easy to compare, thereby increasing their weight. One important question raised in this research is which gives better predictions of future experience? Hsee and Zhang (2004) argue that because most options are experienced in isolation, joint evaluation can yield to errors.

Another task factor that has a significant effect is the need to justify one's choice to others. This can change attribute weights for some attributes (Okada, 2005) and affects the frequency of some kinds of context effects and decision errors (Simonson, 1989, 1992; Simonson & Nye, 1992). Similarly, and somewhat counterintuitively, there are conditions in which being more thoughtful can increase a context effect (Priester, Dholakia, & Fleming, 2004). Thus, working harder does not mean working smarter.

WHERE DO VALUES COME FROM?: INFERENCE AND MEMORY

Until now, we have rather blithely assumed that consumers get the information needed to make a decision directly and immediately from the world around them, for example, from store shelves, or from websites. Of course, this is a gross simplification. In this section, we look at two very important sources of information about the options chosen by consumers—memory and inference. A third important source of value results from the fit between the decision maker and the choice process. We do not discuss this in depth here, because it is presented in the excellent review in this volume

Memory-Based versus External Search

It is clear that the use of the external environment can be expensive, in terms of effort, compared to retrieving information from memory. This has led consumer researchers to distinguish between information that comes from internal and external search (Alba & Hutchinson, 1987; Biehal & Chakravarti, 1986a; Johnson & Russo, 1984; Sanbonmatsu & Fazio, 1990)—a distinction that has close relations in the social cognition literature (Hastie & Park, 1986; Srull & Wyer, 1989). A significant literature in consumer research parallels similar queries in the social-psychological literature on person memory and social cognition more generally (e.g., Fiske & Taylor, 1991; Higgins, Kuiper, & Olson, 1981). Among the significant results in this area are the ideas that consumer knowl-

edge is organized mostly around brands (Biehal & Chakravarti, 1986b; Johnson & Russo, 1978) rather than attributes; that task goals play an important role in the encoding of information (Biehal & Chakravarti, 1982; Sujan, 1985); and that consumers tend to remember the results of decisions rather than the data on which they are based (Johnson & Russo, 1978; Park & Hastak, 1994). Research has also asked a question about the form of consumer's recall of chosen products: Is recall biased in favor of the chosen alternative? The data seem clear that such biases exist, and they follow from both cognitive and, perhaps, motivational factors. Because consumers often use heuristics like elimination by aspects, which focus on a few alternatives (Grether & Wilde, 1984; Wright, 1975), recall will naturally be better for chosen alternatives (Biehal & Chakravarti, 1986; Costley & Brucks, 1992; Dick, Chakravarti, & Biehal, 1990; Johnson & Russo, 1984). However, as it appears that choice often creates distortions in the valuation of the chosen alternatives (Posavac, Sanbonmatsu, Kardes, & Fitzsimons, 2004; Russo, Meloy, & Medvec, 1998; Simon, Krawczyk, & Holyoak, 2004) , memory is subsequently distorted as well (see Ross & Sicoly, 1979, for an analogy in the social psychological literature).

Category Inference

What happens when information needed to make a choice is not available, either in the environment or in memory? This can occur, for example, when one encounters a new product—for example, a new sport utility vehicle from a known manufacturer, say Saab. One stream of research in consumer behavior examines whether consumers use inferences in these situations. Consumers seem quite comfortable inferring characteristics of the product based on their categorization of the product. Early work in this area concentrated on potentially ambiguous new products, which could be characterized as belonging to two or more categories: Is a new fruit-flavored carbonated children's drink a healthy juice, or a soft drink? This work (Sujan & Dekleva, 1987) showed that consumers used two stages in inference, the first to determine how to categorize the new product ("It's a soft-drink") and the second to infer values ("The fruit flavor is probably artificial"). Similarity between the product and category seems to be an important mediator in determining how a product is categorized (Park, Milberg, & Lawson, 1991; Viswanathan & Childers, 1999), and it differs across age groups (John & Sujan, 1990). Sometimes these inference processes can lead us astray, when, for example, marketers add features that differentiate a product in a way that is meaningless to product performance but changes the way products are categorized (Carpenter, Glazer, & Nakamoto, 1994).

Brand Inference

A special type of inference that has attracted much attention is how consumers think about brands. Because brands are an important organizing principle in consumers' product knowledge, they would also seem to play an important role in product inference. In fact, a major theme of the last two decades of consumer and marketing research concerns the values of brands, termed "brand equity." Much work attempts to assess the economic value to the firm of consumers' awareness and associations with a brand (Aaker & Keller, 1990; Keller, 1993).

Brand Personality

One approach to conceptualizing consumers' knowledge about brands employs the notion of a brand personality, adapting many concepts, such as the Big 5 typology of personality, and applying them to brands (Aaker, 1997). Research here has also been concerned with people's relationships with brands (Fournier, 1998), how brand personalities might differ across cultures (Aaker, Benet-Martinez, & Garolera, 2001; Sung & Tinkham, 2005), and how they are updated (Aaker, Fournier, & Brasel, 2004; Johar, Sengupta, & Aaker, 2005). While this area of research remains a provocative metaphor, an open question is how closely processing of brand information, which evolutionarily must be a relatively recent event, resembles the processing of person information. A very recent functional magnetic resonance imaging (fMRI) study indicates that the areas usually associated with the identification of individuals are not used in identifying brands (Yoon, Gutchess, Feinberg, & Polk, 2006).

Brand Extensions

A specific type of inference is required when a known brand introduces a product in a new product class, as in our Saab SUV example earlier. These *brand extensions* are particularly important to managers because they can reduce the cost of a new product introduction (Aaker & Keller, 1990; Boush & Loken, 1991). However, a major theme in this literature is that there must be a "fit" between the two. In fact, a bad brand extension not only fails but can hurt the core brand (John, Loken, & Joiner, 1998; Loken & John, 1993). The accessibility of the brand and the category also determine the success of a brand extension (Meyvis & Janiszewski, 2004).

The area of consumer inference and categorization continues to grow, and readers who want to pursue this area are directed to the excellent recent reviews by Kardes, Posavac, and Cronley (2004) and Loken (2006).

PERSUASION

Persuasion research has been a central concern to consumer and marketing research for decades. There seems to be a natural application of ideas from attitude research to advertising, and research in the area actively adapts paradigms and concepts from social psychology (for a review, see Eagly & Chaiken, 1993) to questions that are raised by advertising as a marketing instrument. Typical of these are questions about frequency of advertising, the kind of message, execution, and medium that advertisers should use, and how to deal with competitive

advertising. The fact that the persuasive intent of advertising is known to consumers suggests that advertisements may be processed differently from other types of messages typically studied in social psychology; this "schemer schema" or "marketplace metacognition" has formed the focus of a compelling body of literature in consumer behavior (Friestad & Wright, 1995).

Most research on persuasion in marketing has used a dual-process approach, such as the elaboration likelihood model (Petty, Cacioppo, & Schumann, 1983), the MODE (Fazio, 1990), or the heuristic–systemic model (Chaiken & Maheswaran, 1994; Ratneshwar & Chaiken, 1991). Consumer research has challenged the prevailing view that peripheral cues are used blindly in the absence of motivation and ability and has shown that consumers sometimes (e.g., under high arousal) perform a check on the cue and use it if it is found to be diagnostic in the decision-making context (Pham, 1996).

The critical question addressed by persuasion research that is most relevant to consumer behavior concerns whether a less thorough and effortful process or a more thorough and effortful process will be used to process the message and the consequences of such processing. Consequences such as attitude persistence and resistance to future persuasion are especially meaningful in a consumer behavior context given the competitive nature of the marketplace. Because this volume contains excellent reviews of these theoretical issues, we concentrate on the application of these ideas to consumer and marketing settings. In essence, we concentrate on variables that determine the kind and level of processing an incoming communication will receive. These particularly relevant set of antecedents and their consequences are the focus of our review.

Antecedents of Message Processing

Clearly consumers face many decisions, some important ("which car to buy"), some truly trivial ("how would you like that burger?"). In some areas they may be more able to process information than others. But how do we measure and conceptualize motivation and ability, two important antecedents of our reactions to persuasive messages? Most research has organized around two themes: what message characteristics lead to more elaboration, and what person characteristics engender elaboration?

Message Characteristics

There is a long list of message characteristics that influence processing. For example, Ahluwalia and Burnkrant (2004) have examined the role of rhetorical questions on elaboration. Priester, Godek, Nayakankuppum, and Park (2004) have shown conditions under which comparative advertising (ads that compare one product to another) can lead to elaboration. The effect of message framing, emphasizing the product's advantages or the competing product's disadvantages, interacts with the amount of elaboration (Meyers-Levy & Maheswaran, 2004). Advertisements can mention the country of origin of a product, and Gurhan-Canli and Maheswaran (2000a) have examined how these effects might differ across different cultures. Similarly these authors (Gurhan-Canli & Maheswaran, 2000b) have examined how country of origin for products may change the consumer's motivation to process.

Person Characteristics

Among other factors that have been hypothesized to affect motivation to process and elaboration are a person's commitment to prior positions (Ahluwalia, 2000), involvement in the brand or product category (Johar, 1995), and his or her cognitive capacity (Johar & Simmons, 2000). Relating the communication to one's self can increase elaboration (Burnkrant & Unnava, 1995), but such effects are moderated by other variables that increase elaboration. Maheswaran and Sternthal (1990) examine the role of both knowledge and message type in the type of processing performed by a consumer.

Other person characteristic research examines how persuasive messages may be processed differently by those who are bilinguals (Luna & Peracchio, 2001), and gender differences appear to exist in processing strategies (Meyers-Levy, 1988; Meyers-Levy & Maheswaran, 1991). Given the evidence of individual differences, one might wonder whether standard dual-process theories generalize across cultures. However, an alternative perspective is that the theory itself may well be predictive but there may be differences in the perceptions of consumers about the inputs to the process. Most research suggests that dual-process models of persuasion are robust, once differences in perceptions are included. For example, Aaker and Maheswaran (1997) showed that advertising appeals that are compatible with the self-constructs (e.g., independent vs. interdependent) that are chronically accessible in a given culture are more effective. Advertising may also be effective if it reflects self-constructs that are made temporarily accessible via priming, as long as consumers have low levels of commitment to the brand (Agrawal & Maheswaran, 2005).

Message and Person Factors

A combination of person and message characteristics, such as the fit between the message and the current orientation of the consumer, can also influence persuasion: increasing persuasion when message recipients have positive thoughts about a message and decreasing persuasion when they have negative thoughts (Cesario, Grant, & Higgins, 2004). Appeals that urge consumers to imagine the product experience can similarly increase persuasion when consumers are high on imagery ability but can decrease persuasion when consumers are low on imagery ability (Petrova & Cialdini, 2005).

Competitive Effects

One situation that marks advertising as a unique environment for persuasion is the vast quantity of messages and the low level of attention in which exposure occurs. Researchers have suggested that these ingredients may lead

to circumstances in which ads will interfere with one another, leading to reduced recall for the entire product class. Nice empirical demonstrations of these effects (Burke & Srull, 1988) have shown that it is not just the number of ads but the share of advertising for a product that increases recall. Keller (1987) provides demonstrations that unique elements of advertising can be used to generate recall of ad content at the point of purchase. Under some conditions, however, such interference in memory can be helpful to some brand (Jewell & Unnava, 2003) by making some brands *relatively* easier to recall. Meyvis and Janiszewski (2004) examine the role of competitive interference in brand extending brand names to new products.

Consequences of Message Processing

Persuasion research in consumer behavior has typically examined effects of message processing on attitude valence and extremity. More recent research examining the role of consumers' goals has shown that messages may be selectively processed in the service of ego-defensive and impression-management goals (Agrawal & Maheswaran, 2005; Ahluwalia, 2002; Jain & Maheswaran, 2000; Sengupta & Johar, 2001). Focus on motivated processing has resulted in the study of elaboration quality as a consequence of processing, rather than simply the amount or quantity of processing emphasized by early versions of the dual-process models.

Attitude Strength: Attitude–Behavior Correspondence

Sengupta and Johar (2002) showed that consumers who have the goal of forming an integrated attitude at the time of exposure to inconsistent information form strong attitudes that are predictive of later product choices. On the other hand, the goal of minimizing later embarrassment decreases attitude strength in terms of attitude-choice correspondence by increasing attitudinal ambivalence. Importantly, both goals result in the same high amount of elaboration; only elaboration quality differs.

Outcomes such as attitudinal ambivalence are important because they can in turn guide future information processing. For example, Zemborain and Johar (in press) found that consumers with ambivalent attitudes tend to be more susceptible to interpersonal influence (even from potentially unreliable sources) than less ambivalent consumers. This finding is particularly relevant given the plethora of information regarding others' opinion and attitudes that consumers have access to in today's marketing environment. The variety of recommendations and gratuitous advice on the Internet is just one example.

Attitude Persistence and Resistance

Other aspects of attitude include how long-lasting the attitude is and how resistant it is to future attack (Sengupta, Goodstein, & Boninger, 1997). These aspects are particularly relevant in the competitive marketing environment where devices such as comparative advertising are used to change consumers' attitudes positively toward the advertised brand and negatively toward the comparison brand. For example, Ahluwalia (2002) demonstrated that negative information about a brand has less impact on consumers committed to that brand than others. Sengupta and Fitzsimmons (2004) found that thinking about reasons why a consumer likes or dislikes a brand does not necessarily disrupt the formation of attitudes and reduce attitude persistence and predictive power, as has been suggested in the past. Instead, attitudes formed by a reasons analysis can be strong in the sense of being persistent if the cues underlying attitude formation are also present at a later point in time.

Summary

One observation that can be made about the consumer literature on persuasion is that it is theoretically quite sophisticated, with most studies typically showing interactions between the variables of interest and their combined impact on attitude extremity as well as strength. A shared theoretical framework has allowed researchers to produce predictions that are highly interactive in nature, suggesting that multiple factors *must* be taken into account to understand the effectiveness of a persuasive marketing communication. However, from a manager's perspective, this complexity may be a bit daunting. Research in this area seldom generates simple advice and suggests instead that answers will depend on the interaction of message, person and competitive factors.

Another observation concerns the separation of work in persuasion and decision making. Interestingly, these two established research areas in consumer research have not been tightly integrated. As much as the decision making and attitudinal literatures have remained apart in social psychology, so have they in consumer research. There are some exceptions (Priester, Nayakankuppam, Fleming, & Godek, 2004), but this separation in an applied field such as consumer research is unfortunate.

AFFECT

Research on affect and consumer behavior has grown dramatically. A search of the ISI Web of Knowledge (a social science database) for the terms "consumer" and "affect" returned 136 articles for the 1985–1994 period and 841 articles for the 1995–2004 period. This interest in affect, of course, parallels the one observed in social psychology. It also reflects the fact that marketing and consumption stimuli (e.g., products, services, and TV commercials) are often emotionally rich. For example, over half of the advertisements appearing on American television contain no facts at all about the product advertised (Resnik & Stern, 1977). Advertisers instead often rely on emotionally arousing cues (attractive models, pleasant music, powerful imagery, etc.). Not surprisingly, consumers' descriptions of their consumption experiences often reveal a substantial degree of emotional richness (Derbaix & Pham, 1991; Havlena & Holbrook, 1986; Richins, 1997).

Types of Affect

It is useful to distinguish among three types of affect in consumer judgment and decision making: integral affect, incidental affect, and task affect (Bodenhausen, 1993; Cohen, Pham, & Andrade, in press). *Integral affect* refers to affective responses that are directly linked to the object of judgment or decision. These include momentary feelings experienced through direct exposure to the object itself (e.g., the pleasant feeling of tasting a fine wine) and those experienced in response to some representation of the object—representation that may be externally provided (e.g., viewing a TV commercial for a product) or internally generated (e.g., thinking about a product). *Incidental affect* refers to affective experiences whose source is clearly unrelated to the object to be evaluated. These include mood states, emotional dispositions (e.g., chronic anxiety or depression), and contextual stimuli that are affect eliciting (e.g., background music and pleasant scent). Finally, *task affect* refers to affective responses that are elicited by the judgment or decision task itself. For example, a choice between two integrally pleasant alternatives, such as two attractive vacation destinations, may generate negative task affect because one of the options must be forgone.

Integral Affect

INTEGRAL AFFECT INFLUENCES JUDGMENT AND BEHAVIOR

A major theme of research in social psychology has been that integral affective responses to various objects (e.g., people, issues, and messages) predict judgment, choice, and behavior toward these objects over and above more descriptive ("cognitive") bases of judgments such as beliefs, stereotypes, base rates, prior attitudes, and so on (e.g., Abelson, Kinder, Peters, & Fiske, 1982; Breckler & Wiggins, 1989). In marketing and consumer research, this theme was pursued most extensively in the advertising domain. A large number of studies have documented that affective responses to advertisements have direct effects on consumers' attitudes toward the ad (A_{ad}) and at least indirect effects on consumers' attitudes toward the brand (A_b) through the effects on A_{ad} (e.g., Aaker, Stayman, & Hagerty, 1986; Brown, Homer, & Inman, 1998; Edell & Burke, 1987; Holbrook & Batra, 1987). Some studies suggest that integral affective responses to the ad may also influence A_b directly, independently of A_{ad} (Burke & Edell, 1989; Derbaix, 1995; Stayman & Aaker, 1988).

Conceptually related results have been obtained in a variety of other consumption domains. For instance, Bodur, Brinberg, and Coupey (2000) found that affect toward various AIDS prevention behaviors such as abstinence or condom usage predicted attitudes and intentions toward these behaviors over and above personal beliefs about these behaviors. Similarly, MacGregor, Slovic, Dreman, and Berry (2000) found that investment banking students' feelings toward various industry sectors (e.g., electronics and managed health care) were strongly predictive of their intentions to invest in these sectors, independent of the sectors' financial fundamen-

tals. Integral affective responses have also been found to have direct effects on product satisfaction (Oliver, 1993), blood donation behavior (Allen, Machleit, & Kleine, 1992), and pricing of gambles (Peters, Slovic, & Gregory, 2003).

Two main explanations have been proposed for these direct effects of integral affect. The first is simple evaluative conditioning (De Houwer, Thomas, & Baeyens, 2001). A close proximity between a target and an integral feeling experience may result in the evaluative meaning of the feelings (mostly their valence) being carried over to the target—a mechanism sometimes called "affect transfer" in consumer research and marketing (e.g., Mackenzie, 1986). The second mechanism is an affect-as-information process (Schwarz & Clore, 1983, 1996). A number of studies (Pham, 1998; Pham, Cohen, Pracejus, & Hughes, 2001) indicate that consumers often evaluate objects by monitoring and interpreting their integral feeling responses to these objects, a process known as the "how-do-I-feel-about-it?" heuristic (Schwarz & Clore, 1988). Regardless of the actual explanation, there is substantial evidence that integral affect has a marked influence on judgments and decisions (see also Finucane, Alhakami, Slovic, & Johnson, 2000). For example, the mere fact of being lightly touched on the arm by a waiter or waitress in a restaurant results in dramatic increases in tipping and restaurant satisfaction, presumably because being touched makes the patron feel good toward the waiter or waitress and restaurant (Hornik, 1992).

AFFECT-BASED JUDGMENTS ARE DIFFERENT

Judgments based on integral affect seem to differ from judgments based on descriptive inputs in systematic ways. Because integral affective responses often arise quickly (LeDoux, 1996; Zajonc, 1980), can enter evaluations through simple associations, and usually have unambiguous interpretations (Strack, 1992), judgment and decisions based on integral affect tend to be reached more rapidly, whether online (Pham et al., 2001) or memory based (Verplanken, Hofstee, & Janssen, 1998). Similarly, because affect-based judgments and decisions seem to require less processing resources, consumers tend to rely on integral affect more when their processing resources are constrained (Pham et al., 2001). For example, when given a choice between a tempting piece of chocolate cake (an affectively attractive option) and a healthier fruit salad (a "cognitively" attractive option), consumers whose cognitive resources were not constrained tended to choose the healthier fruit salad. However, when cognitive resources were constrained, consumers tended to choose the more tempting cake, presumably because affective drivers of preference still operated while the more cognitive drivers could not (Shiv & Fedorikhin, 1999).

Judgments and decisions based on integral affect also seem to be myopic in that immediate affective rewards and punishments are weighted much more heavily, compared to delayed affective consequences (see Loewenstein, 1996). This property is very obvious in impulse control situations where people have to trade off

the immediate hedonic consequences of an option (e.g., the pleasure of eating junk food or the pain of visiting the dentist) against its long-term consequences (e.g., high cholesterol and obesity; healthy teeth and gums). According to Loewenstein (1996), the myopia of affect-based judgments and decisions is caused by the differential accessibility of current and delayed affective states. Whereas the experience of immediate integral affect has strong drive properties, it is very difficult to vividly picture future affective states. Consistent with this proposition, recent brain-imaging studies indicate that preferences for immediate rewards are associated with greater activation in parts of the limbic system associated with affect (McClure, Laibson, Loewenstein, & Cohen, 2004).

Contrary to popular beliefs that affect is highly subjective, a growing body of evidence suggests that affective judgments are, in fact, quite consensual, sometimes even more so than cognitive judgments. For instance, it has been found that consumers are more likely to agree on their affective responses to various stimuli (e.g., magazine pictures and television commercials) than they are to agree on their reason-based assessments of the same stimuli (Pham et al., 2001). According to Pham and colleagues (2001), affect-based judgments will be highly consensual whenever they are based on hardwired programs involved in bioregulation or emotional schemas acquired through socialization. The inherent consensuality of affective responses explains why juries can agree strongly on how outraged they feel in response to legal cases even when they disagree widely on the amount of punitive damages they are willing to award (Kahneman, Schkade, & Sunstein, 1998).

Affect-based judgments and decision also seem to be insensitive to quantity. In an interesting study, Hsee and Rottenstreich (2004) manipulated the number of pandas that might be saved by donations to a rescue effort and how this number was represented. In one condition, the number of saved pandas was simply represented by one or four dots; in the other, it was represented by one or four cute pictures of pandas. As predicted, respondents' donations were much more sensitive to the number of pandas saved in the affect-poor (dot) condition than in the affect-rich (picture) condition. In a similar vein, it has been observed that affect-based evaluations are insensitive to probabilities (Loewenstein, Weber, Hsee, & Welch, 2001). For example, it was found that people were willing to pay much more to avoid a high probability of losing a certain amount of money than to avoid a low probability of losing the same amount, consistent with economic theory. However, people were *not* willing to pay much more to avoid a high probability of receiving an electric shock (a prospect rich in negative affect) than to avoid a low probability of receiving the same shock (Rottenstreich & Hsee, 2001).

A final property of evaluations and decisions based on integral affect is that they tend to have a *high degree of internal coherence* (Pham, 2004). This is because integral affective responses to a target, which are often immediate and highly accessible, usually trigger a confirmatory search for information that supports or helps explain the initial feelings (Pham et al., 2001; Yeung & Wyer, 2004).

This confirmatory search results in a strong correlation between the immediate affective response elicited by a target and the spontaneous thoughts that people associate with the target.

Incidental Affect

As in social psychology (e.g., Isen, Shalker, Clark, & Karp, 1978; Johnson & Tversky, 1983), numerous consumer research and marketing studies have shown that mood states and other forms of incidental affect generally have assimilative (affect-congruent) influences on evaluations, decisions, and behaviors (e.g., Adaval, 2001; Fedorikhin & Cole, 2004; Gorn, Goldberg, & Basu, 1993; Miniard, Bhatla, & Sirdeshmukh, 1992; Pham, 1998; Yi, 1990a). In fact, some of the earliest demonstrations of this phenomenon appeared in marketing. For example, Axelrod (1963) found that consumers who had viewed a depressing television documentary gave more negative evaluations to a variety of products than they had prior to seeing the documentary. Similarly, Dommermuth and Millard (1967) showed that viewing a pleasant or unpleasant movie later produced product ratings that were consistent with the mood induced by the film.

Consumer and marketing researchers have been particularly interested in studying marketplace implications of this phenomenon. There has been significant interest in assessing how consumers' responses to advertisements are influenced by the affective tone of the media context in which the ads appear (e.g., TV programs or magazines). It is generally found that incidental affect elicited by the media context has a congruent influence on evaluations of the ad but less influence on evaluations of the advertised brand (e.g., Goldberg & Gorn, 1987; Mathur & Chattopadhyay, 1991; Murry & Dacin, 1996). It has also been found that gift wrapping can enhance the recipient's evaluation of the gift by elevating the recipient's mood (Howard, 1992). Even browsing a series of attractive products may elevate a consumer's mood, which may become assimilated into subsequent evaluations (Raghunathan & Irwin, 2001). It has also been found that if a product that consumers find disgusting (e.g., hygienic napkins) incidentally touches another product in a shopping cart, consumers' attitudes toward the latter product become more unfavorable, even if the products are in their original, unopened packages with no real chance of physical contamination (Morales & Fitzsimons, in press).

The explanations offered for these assimilative effects of incidental affect are essentially the same as those offered to explain the direct effects of integral affect: evaluative conditioning (Gorn, 1982) and reliance on the "how-do-I-feel-about-it?" heuristic. Pham (1998) proposed that the "how-do-I-feel-about-it?" heuristic is a widely used decision strategy among consumers. His findings indicate that this strategy is more likely to be used when the consumers have experiential (hedonic) motives than when they have instrumental (utilitarian) motives. It is also more prevalent among consumers who favor a visual or sensory style of processing as opposed to a more verbal or propositional style. Pham and Avnet

(2004) observed that reliance on the "how-do-I-feel-about-it?" heuristic appears to be greater when consumers are under regulatory states of promotion focus as opposed to states of prevention focus (Higgins, 1997). Other studies suggest that incidental-affect-congruent evaluations are more likely when the target is evaluative as ambiguous and does not elicit strong integral affect (Miniard et al., 1992).

Because affective states are characterized not only by their valence but also by their arousal, consumer researchers have also examined the effects of incidental arousal on evaluations and decisions. When valence and emotional content are held constant, intense incidental arousal seems to increase risk seeking in decision making (Leith & Baumeister, 1996; Mano, 1992, 1994). Intense incidental arousal also increases consumers' reliance on diagnostic information in evaluations (Pham, 1996). Milder residual arousal has been found to interact with the integral affective tone of advertisements to amplify evaluations of these ads (Gorn, Pham, & Sin, 2001), a finding consistent with the excitation transfer hypothesis (Zillmann, 1971). It has also been found that consumers' states of relaxation versus activation are very sensitive to various retail environmental factors, which can then influence their judgments and behaviors. For example, fast-paced background music in a supermarket was found to increase in-store traffic flow and sales volumes compared to slow-paced music or no music, presumably because the fast-paced music increases the shopper's level of activation (Milliman, 1982). On the other hand, *slower*-paced music in a restaurant increased the amount of time patrons spent at the dinner table and how much they ordered from the bar, presumably because slower-paced music induces feelings of relaxation (Milliman, 1986). It has also been found that the use of blue colors in Web pages produces feelings of relaxation that decrease perceived download time, whereas the use of red colors produces feelings of tension that increase perceived download time (Gorn, Chattopadhyay, Sengupta, & Tripathi, 2004).

A recent theme both in consumer research and in social psychology has been to examine the differential effects of specific incidental emotions (e.g., Raghunathan & Pham, 1999; Tiedens & Linton, 2001). Raghunathan and Pham (1999) found that, in choices between high-risk/high-reward and low-risk/low-reward options, sad individuals consistently favor the former, whereas anxious individuals consistently favor the latter. This is presumably because, even though their states are incidental, sad individuals tend to infer that they have lost something of value (a typical cause of sadness), which activates a goal of reward acquisition that shifts preferences toward high-reward options. In contrast, anxious individuals tend to infer that the situation is uncertain and beyond control (typical causes of anxiety), which activates a goal of risk avoidance that shifts preferences toward low-risk options. Similarly, Lerner, Small, and Loewenstein (2004) found that incidental states of sadness amplify the endowment effect—the tendency to overvalue one's possessions—whereas incidental states of disgust attenuate this effect. This is presumably because sadness, even

if incidental, triggers an impulse to hold on to sources of rewards, whereas disgust triggers an impulse to expulse sources of discomfort. Raghunathan, Pham, and Corfman (2006) recently showed that the effects of specific incidental emotions are more pronounced if there is a surface similarity between the true source of the incidental emotion and the target decision—a phenomenon they call displaced coping. Finally, Mukhopadhyay and Johar (in press) found that feelings of pride or happiness engendered by recent shopping history (i.e., giving in vs. restraining from temptations) carry over to influence the effectiveness of advertising appeals viewed subsequently so that pride (happiness) appeals are more effective after restraint (giving in).

Task-Related Affect

Finally, the process of making a decision may itself induce affect. For example, difficult choices are often those that involve trade-offs on important attributes (Bettman, Johnson, Luce, & Payne, 1993), such as deciding how much quality to surrender in order to save money. One means of minimizing such negative affects is to maintain the status quo and not make an active choice (Luce, 1998; Nowlis, Kahn, & Dhar, 2002). Although one might expect consumers to work harder when faced with difficult choices, they instead seem to shift to simplifying choice heuristics that minimize task-related negative affect (Luce, Bettman, & Payne, 1997). Similar effects have been observed for another aspect of decision tasks that can generate negative affect: time pressure (Dhar & Nowlis, 1999; Payne, Bettman, & Johnson, 1988). It has also been found that the more consumers deliberate about their choices, the more they become emotionally attached to the options, which leads to decision-related discomfort once one option has been chosen (Carmon, Wertenbroch, & Zeelenberg, 2003).

A particularly important outcome of a task-related affect is the transfer of that affect to the valuation of the alternative chosen. Garbarino and Edell (1997) demonstrate that reducing the effort involved in selecting an alternative can increase the price respondents are willing to pay for that option. Similarly, Higgins and colleagues have shown that a fit between the manner in which a decision is made and the current orientation of a decision maker can produce positive task-induced feelings that increase the perceived value for a chosen object (Avnet & Higgins, 2003; Higgins, 2000; Higgins, Idson, Freitas, Spiegel, & Molden, 2003).

IMPLICIT PROCESSES

For decades, researchers have, almost by force of habit, asked participants whether they were aware of a given manipulation in an experiment. The lack of awareness of the manipulation was prima facie evidence that demand characteristics did not operate. More recently, questions surrounding consumers' awareness of the causes of their behavior have generated significant controversy and interest in consumer research.

Before proceeding, we need to clarify the meaning of "implicit processes," a term that is borrowed, at least in part, from memory research (Fazio & Olson, 2003). As our opening example suggests, one important characteristic attributed to implicit processes is a lack of awareness (Bargh, 2002), but the exact definition of awareness can be more complicated (Chartrand, 2005). Does awareness mean that a respondent is aware of the possibility that some factor may influence someone's behavior in some task, or does it require a respondent to know the exact influence in that task? A second characteristic associated with implicit processes is automaticity: requiring less effort or intentionality (Bargh & Chartrand, 1999). However, while automaticity is well defined in the cognitive literature (Shiffrin & Schneider, 1977), most studies in consumer behavior tend to assess this property more casually.

Priming

Priming is one of the earliest areas of consumer research to exploit the idea of implicit processes—an area that has received considerable attention from social psychologists (for a review, see Higgins, 1996). A particularly innovative study by Nedungadi (1990) manipulated the accessibility of brand names in memory and established an increased likelihood of choice, even when these effects were outside the awareness of the respondent. Herr (1989) showed that priming a category can change choices, while Yi (1990b) demonstrated that the priming of a product feature can increase the weight given to that feature.

Priming cultural knowledge has also been shown to affect choices. Mandel (2003) primed either independent or dependent identities by having Americans read a very simple description of others' motives changed by both hypothetical and actual purchases. Chen, Ng, and Rao (2005) demonstrated that priming one of two cultural identities in bicultural Singaporeans had a significant affect on their preference for accelerated consumption, which the authors attribute to cultural difference in regulatory focus. Johar, Moreau, and Schwarz (2003) used advertisements to prime cultural stereotypes of women as homemakers and found that these ads lead to stereotypical judgments of women encountered in a subsequent "study." Priming either cultural identity (Forehand & Deshpande, 2001) or particular goals (Strahan, Spencer, & Zanna, 2002) can also have an effect on the processing of subsequent persuasive communication. Even the presence of familiar objects can serve as a prime. Shrum, Wyer, and O'Guinn (1998) demonstrated that the mere presence of a television can prime beliefs that are consistent with most television content, such as increased perceptions of violence and crime.

Two studies demonstrated how priming can affect consumer behavior in actual consumption settings (North, Hargreaves, & McKendrick, 1997, 1999). The authors manipulated the background music in a store selling both German and French wine, predicting that pleasant music from the country of origin would increase sales of that country's products. Not only did this occur, but the background music accounted for about a quarter of the variance in choice between the two products. Similarly, Mandel and Johnson (2002) manipulated the background of a website, or wallpaper, using embedded designs shown to prime either quality attributes (safety for cars, comfort for couches) or price. They found marked differences in choice between the two products, cars and couches consistent with the prime, and that the prime affected both novices and experts in the product class, although through different mechanisms. In both studies, respondents specifically denied being influenced by the manipulation.

Mere Measurement

One application from social psychology that serves as an interesting case is the mere measurement effect. Using ideas from the social literature on the self-fulfilling nature of prediction errors (Greenwald, 1987; Sherman, 1980), Morwitz, Johnson, and Schmittlein (1993) hypothesized that merely asking questions about future behaviors could, in fact, change those behaviors. They examined data from two large commercial market research surveys and found that the mere asking of an intent question, such as "Do you intend to buy a personal computer in the next six months?" actually influenced purchases. Both those who answered yes and no behaved in ways that were more consistent with the request than groups that had not been asked. Subsequently, such effects have been shown to increase repurchases of one's current brand of car (Fitzsimons & Morwitz, 1996), and to accelerate purchases of supermarket goods for up to 3 months (Chandon, Morwitz, & Reinartz, 2004). In financial services, Dholika and Morwitz (2002) demonstrated the effect lasts up to a year when the question is asked as part of a consumer satisfaction survey. A similar effect has been shown in blood donation (Godin, Conner, Sheeran, & Germain, 2005) and can be shown to occur with mass communication requests (Spangenberg, Sprott, Grohmann, & Smith, 2003). Current explanations for these kinds of effects indicate that a general-intent question makes attitudes about specific items in the category more accessible (Morwitz & Fitzsimons, 2004), although some argue for a role of dissonance reduction (Spangenberg et al., 2003). However, because these effects last many months and occur without consumer awareness, they are unlikely to result from conscious processing of the question and its effect.

What makes this interesting as an implicit process is whether or not people are aware of the effect. Williams, Fitzsimons, and Block (2004) show that awareness of the persuasive nature of these effects can limit their effectiveness, but in experimental studies, it appears that such awareness is rare (Fitzsimons & Shiv, 2001). Thus, a particularly subtle interaction, occurring frequently as part of a market survey research encounter, seems to be able to have long-term behavioral consequences, which for the most part are unforeseen by both consumer and marketer.

Theoretical and Empirical Issues

One element of work in implicit processes has only started to impact consumer research—the idea of automatic goal activation. From a theoretical perspective, a study by Brendl, Markman, and Messner (2003) demonstrates an important point. In that study, the authors show that activating one need (e.g., the need to smoke) serves to lower the value of other objects, even when those objects are fungible, such as cash, and can be used to fulfill that need. The exact nature of goals, procedures for measuring their strength, and the relationships between goals will be an important item on the agenda for research into implicit processes (see Janiszewski & van Osselaer, 2005).

As a practical issue, in an applied area such as consumer research, much work in measurement and validation remains. Examination of the applicability of techniques such as the Implicit Attitude Test (Brunel, Tietje, & Greenwald, 2004; Maison, Greenwald, & Bruin, 2004) have started, but much more work needs to be done (Fazio & Olson, 2003).

An active, lively debate concerning the relative role of conscious and unconscious processes in consumer choice continues (see Dijksterhuis, Smith, van Baaren, & Wigboldus, 2005; Simonson, 2005, and other articles in this issue for examples).

Awareness and Subliminal Effects Reloaded

In 1980, a review of subliminal effects published in the *Journal of Marketing* (Moore, 1982) concluded, "The idea that subliminal directives can affect motives or actions is contradicted by much research and is incompatible with theoretical conceptions of perception and motivation. . . ." (p. 46). Has the research we have reviewed in this section done much to change this conclusion? Clearly, the focus has changed. The question no longer is whether stimuli are perceived or not but, rather, whether the effects of such stimuli, whether subliminal or supraliminal, are known to consumers. Awareness of the manipulations and a correct mental model of their effects seem necessary for any attempt by consumers to counteract their effects. As an applied area of research, questions do arise about the robustness and size of these effects, which, if answered, have implications for public policy and the ethics of marketing practice. Most important, a strong theoretical framework consistent with "conceptions of perception and motivation" would be useful.

CONCLUSION

Our goal in writing this chapter was to convince the reader that work in consumer behavior and marketing should be of great interest to social psychologists. In closing, it is then potentially helpful to outline some of the reasons social psychologists should be interested. The movement toward social cognition was motivated, in part, by the feeling that the same cognitive system that

categorized, learned about, and navigated the physical world also operated in the social world. Similarly, the same systems are involved in the world of transactions, goods, and services. Just as social cognition research hoped to be more than just a source of interesting examples and applications of cognitive concepts, consumer behavior and marketing should be more than a source of interesting examples of social psychological concepts. This realm should be, more fundamentally, a source of new ideas, concepts, and data. Much of what we have reviewed is research that, so far, has not been central to discussions in social psychology, but that, to us at least, seems to be quite relevant. It is our hope that this chapter will serve to change the picture in Figure 38.1 to one in which ideas flow more freely in both directions.

NOTE

1. While these data are from 2004, the picture would be similar for other recent years. Similarly, the inclusion of a more complete list of consumer research journals particularly the *Journal of Consumer Psychology*, or a more complete list of psychology journals, would only serve to make the same point.

Psychology and Politics

The Challenges of Integrating Levels of Analysis in Social Science

PHILIP E. TETLOCK

OVERVIEW

The stakes can be high in political–psychological debates—a factor that has undoubtedly contributed to political psychology's allure as a research specialty (Herrmann, 1986; Knutson, 1973; Sears, Huddy, & Jervis, 2003). The questions researchers pose tend to draw media and government attention: Are prejudice and racism still pervasive forces in American society? Are people inherently tribal creatures whose low thresholds for drawing invidious distinctions make nasty intergroup conflict inevitable? Are conservatives inherently more simple-minded than liberals? Are high-level officials subject to the same judgmental shortcomings as ordinary mortals? Do these officials, as a result, exaggerate the zero-sum character of international conflicts and overrely on competitive, threat-based influence tactics?

Of course, posing questions is one matter; answering them, quite another. Political–psychological questions are notoriously resistant to scientific consensus—in part, because key terms resist translation into precise manipulations and measures and, in part, because partisans of both the left and right are all too eager to reach ideological closure by claiming premature empirical vindication (Kruglanski, 2004; Tetlock, 2005).

This chapter examines four research programs in political psychology that illustrate, but far from exhaust, the theoretical and methodological diversity of the field: (1) attributions of implicit prejudice that rest on controlled laboratory experiments that explore the causes and consequences of millisecond differentials in reaction times to minority versus majority group stimuli; (2) attributions of irrationality in world politics that rest on mixtures of laboratory and field methods of assessing the pervasiveness of judgmental biases among political elites as well as among the mass public; (3) attributions of belligerence in international conflict that rest on mixtures of laboratory and field methods of assessing the relative efficacy of bargaining and negotiation tactics that vary along the deterrence–reassurance dimension; and (4) attributions of mental rigidity that rest largely on psychometric methods of assessing patterns of covariation between measures of cognitive style and political ideology.

This chapter also makes the case that even if we can agree on the basic psychological principles at work in each domain, there is no guarantee of agreement on the political–psychological principles at work. It is one thing to document millisecond differentials in reaction times toward a legally protected group, quite another to characterize that phenomenon as "prejudice." And it is one thing to document a human tendency to rely on low-effort heuristics to simplify choice tasks, quite another to show that public policy at a given moment is "deeply flawed."

It is crucial here to recognize that logically distinct principles govern the descriptive–explanatory and political–normative phases of such debates. In the descriptive–explanatory phase, researchers clash over the robustness of effects (is there something worth ex-

plaining?) and over whose first-order, psychological principles of cognitive and affective functioning best account for those empirical patterns worthy of theoretical attention. This phase is well captured by the phrase "normal science." By contrast, in the political–normative phase of the debate, researchers clash over the wisdom of moving from the relatively value-neutral, descriptive–explanatory language of science to the value-laden language of politics. This phase brings into play competing second-order principles that are ontological–epistemological and moral–ethical in character and that can be used either to trumpet or trivialize the political significance of psychological patterns. The first-order principles are typically spelled out; the second-order ones are typically slipped in. The result is often widespread conceptual confusion over where psychological claims end and political ones begin.

The principal barriers to bridging psychological and political-psychological principles are twofold: (1) contending views of the level-of-analysis problem and of whether the primary burden of proof should fall on advocates of psychological explanations (traditionally organized around intrapsychic processes) or of political explanations (traditionally organized around supraindividual, institutional and systemic, processes); (2) contending views of the fact-value problem and of the degree to which researchers should heed or ignore David Hume's famous is–ought distinction, which stipulates that one can never deduce a value-laden "ought" conclusion from factual or "is" premises. These philosophical fissures run so deep, and arise so frequently in political psychology, that it is worth sketching the canonical arguments in advance.

Level-of-Analysis Disputes

Although rarely articulated quite so baldly, the goal driving most research programs in political psychology is reductionist: reducing complex macropolitical phenomena to their constituent micropsychological processes. The inspirational precedents come from the physical and biological sciences: demonstrations that "heat" is nothing but kinetic energy, that the color "red" is nothing but photon emissions of 600 nanometers, and that DNA is the chemical structure that conveys hereditary information (Hempel, 1965; Suppe, 1977). Applied to political psychology, the reductionist syllogism begins with the major premise that psychology is the science of human behavior. The minor premise is that human beings are the proximal causes of all political behavior. In their role as citizens, they decide whether to treat "outgroups" contemptuously or respectfully; in their role as leaders, they decide whether to engage in ethnic cleansing or to build pluralistic polities. The conclusion is that insofar as psychology achieves its explanatory goals, it cannot avoid shedding light on the central problems of political life (Tetlock, 1998). In the strongest variant of this view, political psychology is merely psychology with political stimulus materials. The basic *processes*—of memory or judgment or emotion—are roughly invariant. All that varies—and sometimes dramatically—is the superficial

content on which those processes operate: Aryans or Jews, Hutus or Tutsis.

There is, of course, nothing wrong with reductionism per se. It has been associated historically with the greatest advances in scientific knowledge (Pinker, 1997). Reductionism does not, however, always work. And it is dangerous to assume automatically that the reductionist model is the most fruitful one to explore in a given domain. Antireductionists in the social sciences—from Durkheim (1925) to Waltz (1979)—have argued that psychological explanations have little to contribute to the explanation of macropolitical and economic regularities. Indeed, some variants of this view argue for putting reductionism in reverse: demonstrating that we only understand the psychological parts of political processes when we understand the (social) system within which the parts function. Relevant scientific precedents would be photosynthesis—a phenomenon that can be reduced to physicochemical processes but whose functional significance can be appreciated only when we situate these processes in their evolutionary context (Suppe, 1977)—or, as Searle (1984) has argued, consciousness—a "first-person" phenomenon that is utterly dependent on the physical workings of the brain but can never be fully captured using the "third-person" objectifying methods of cognitive neuroscience and artificial intelligence.

Applied to political psychology, this argument suggests that psychologists who fail to place their work in its broader cultural and political context are fated to commit fatal errors. One cannot understand foreign policy decision making without a prior grasp of the quasi-anarchic nature of world politics—how the absence of a sovereign (world government) creates security dilemmas for states that are only imperfectly solvable in a limited number of ways (Waltz, 1979). One cannot understand contemporary debates over distributive justice without a prior grasp of how globalization—the increasingly rapid flow of capital, information, and labor across borders—severely strains traditional employment contracts and welfare-state guarantees (Friedman, 1999; Mitchell, Tetlock, Newman, & Lerner, 2003). And one cannot understand the oft-observed faddishness of political psychology without grasping the critical role that wars, social movements, technological transformations, and economic booms and busts play in shaping what researchers deem to be worthwhile problems, how they go about investigating those problems, and where they set their standards of proof for judging competing solutions to those problems (Goldgeier & Tetlock, 2000).

The brusquest dismissals of political psychology by nonpsychologists have, however, traditionally been grounded in a Realpolitik brand of reductionism quite alien to psychologists, a hardball perspective that treats all political thought as an effort to advance the cause of one or another group in the endless struggle for social dominance (Tetlock, 2005). Politics is about "who will dominate whom?"—a point on which an illustrious array of thinkers agree: Thucydides, Hobbes, Marx, Nietzsche, Pareto, and Foucault (McClelland, 1996) and, now from inside political psychology, social-dominance and system-justification theorists (Jost, Pelham, & Carvallo, 2002;

Sidanius & Pratto, 1999). All systems of political thought are ultimately justifications of bids for power. Ideas—a popular microconstruct—are epiphenomenal, smoke to the fire of the real macrodrivers of history. To adapt Clausewitz's famous definition of war as the continuation of politics by other means, psychological research—be it on sex differences or intelligence or prejudice—reduces to the continuation of politics by other means—no matter how pure the avowed epistemic intentions of the scholar.

This chapter stakes out a contextualist position on the reductionism (cf. McGuire, 1983)—a position that acknowledges that the relative usefulness of micro versus macro interpretations of political behavior shifts over time and across topics. But it is only fair to alert readers that the conclusions they draw from the literatures examined here will be unavoidably colored by philosophical assumptions that they rarely have scientific occasions to give much thought. It is not unusual in political psychology for one observer's compelling *reason* for holding a position to be another's wafer-thin *rationalization*. Indeed, in the spirit of Harold Lasswell (1948) and C. Wright Mills (1959), we could elevate this reason–rationalization tension to the status of a cornerstone (second-order, meta-observational) principle. It is safest to assume that political psychologists are every bit as much political actors as are their research subjects—and as subject to the bias of naive realism and the resulting temptation to dismiss dissonant opinions by attributing them to ugly or selfish motives, attitudes, and values (Ross & Griffin, 1991).

Fact-Value Disputes

Research programs in political psychology generally have a moral as well as epistemological agenda. Although rarely articulated so baldly, the driving moral goal is to advance values such as racial equality, international understanding, political tolerance, and peace (cf. Deutsch, 1983; White, 1984). As Shelley Taylor (1998) observed in her history of "the social being in social psychology" (p. 61), some of our discipline's classic experiments from the 1930s, 1940s, and 1950s—such as the work on leadership styles by Lewin, Lippitt, and White (1939)—were driven by concerns "over the dictatorships of Hitler and Mussolini and the goal of demonstrating that "democracy was an inherently superior form of leadership that would produce higher morale and greater productivity than an autocratic style" (p. 61). There is, of course, nothing wrong with aspiring to make the world a better place. But there is potential for confusion, and mischief, when our moral evaluations of attitudes and behavior bleed into our political–psychological descriptions of the same phenomena. In Taylor's words, the findings of Lewin and colleagues "emerged as predicted, although a close examination of the methodology of the studies suggests that, given the guidelines offered to the democratic and autocratic leaders, one could not have expected any other results" (p. 61). It is instructive to pose a turnabout thought experiment: Would this venerable classic have the same status if the researchers had stacked the methodological deck in favor of an autocratic, philosopher-

king style of leadership, with instructions that trumpeted the advantages of decisive visionary leadership committed to achieving long-term goals requiring temporarily unpopular sacrifices? Or, would fame turn into infamy?

Positivists and their descendants have traditionally been the strongest advocates of a strict partitioning of facts and values (Boring, 1950). Within this philosophy-of-science tradition, researchers run afoul of Hume's famous is–ought syllogism when they start opining on the defensibility of research participants' opinions, of pronouncing them to be prejudiced, racist, irrational, belligerent, naively simplistic, or incorrigibly rigid. The researchers' expertise is "factual," and they overstep their professional competence when they blur the distinction between their views of what is and what ought to be (Suedfeld & Tetlock, 1991). As MacCoun (1998) noted in his review of political biases in social science, researchers also run afoul of Robert Merton's (1987) constitutive norms of science when they let their moral values creep into their characterizations of fact. Those norms include "universalism" (judge scientific accomplishments by impersonal criteria—the politics of the researcher should be irrelevant), "disinterestedness" (proceed objectively, with no regard for whose ox might be gored), and "organized skepticism" (organize yourselves into communities dedicated to rigorous peer review of all claims).

Nonetheless, many social scientists and philosophers now agree that a purely descriptive data language is an impossible ideal and that the fact-value distinction is neither as absolute nor as compelling as mid-20th-century positivists implied (Proctor, 1991; Putnam, 2002). There is no value-neutral vantage point for analyzing social phenomena (no view from nowhere, to use Nagel's [1986] felicitous phrase). Even the simplest scientific acts—such as setting a significance level for accepting or rejecting hypotheses—presuppose value judgments of the relative importance of making Type I versus Type II errors. It is inevitable—and some defiantly declare desirable—that the values of scientists seep into every facet of their work—from framing of hypotheses to choice of methodology to interpretation of findings.

This chapter stakes out a middle-ground position in the fact-value debate—one that concedes the impossibility of pure value neutrality but that stresses the importance of making good-faith efforts to disentangle factual from moral judgments of social phenomena (MacCoun, 1998). But, again, it is fair to alert readers that the conclusions they draw will be unavoidably colored by foundational assumptions they rarely see scientific reason to articulate. It is not unusual in political psychology for one observer's responsible contribution to a policy debate to be another's irresponsible politicization of the scientific process (Sears, 2004; Tetlock, 1994). Indeed, we should count such occurrences as special cases of the more fundamental reason–rationalization principle.

Point of Departure

Each of the four lines of work examined here raises messy mixtures of psychological, philosophical, and

moral–political issues. Scholarly assessments of the justifiability of attributions of racism or prejudice or irrationality or belligerence hinge not just on evidence but on level-of-analysis assumptions about what constitutes a plausible alternative explanation and on moral assumptions about the defensibility of particular attitudes (and when scholars are justified in letting their own moral views shape their characterizations of the views of others). Political psychology is arguably the only domain of psychology that *routinely* needs ideological subscripts for its dependent variables—subscripts to track the shifting labels that contending factions apply to our measures. Readers can take this state of affairs as evidence that political psychology is hopelessly relativistic and "perspectival," a field of interest only to anti-social-science constructivists and postmodernists (Gergen, 1978); or they can take this state of affairs as an indication that political psychology poses greater-than-usual scientific challenges that require us to model the mindsets not just of research participants but of the researchers themselves.

ATTRIBUTIONS OF IMPLICIT PREJUDICE TO MASS PUBLICS

Cognitive psychologists have used priming techniques for decades to explore fundamental associative laws of human memory (Higgins, 1996). In a typical priming experiment, a "prime" word is presented before a target word. The participant is instructed to react to the target word quickly, usually by pressing a key or pronouncing the target. The semantic relation between the prime and the target is of central interest in this study. To the extent that the prime influences the response to the target word, the two stimuli are deemed to be associated. Some primes facilitate the response to the target word, as when the prime is "bread" and the target is "butter." This facilitation is widely theorized to be due to the automatic activation of mental representations of the target by the earlier presentation of the closely related prime.

In a pioneering study, Fazio, Sanbonmatsu, Powell, and Kardes (1986) extended this priming technique to attitudes. For example, a prime might be a negatively valenced word such as "murderer." If the subsequently presented target is evaluatively congruent, such as "evil," the evaluation of the target would be accomplished more quickly than if the target were "happy." In another pioneering study, Fazio, Jackson, Dunton, and Williams (1995) extended this procedure to include pictures of White and African American faces as primes. The targets were adjectives with either a positive (e.g., wonderful) or negative (e.g., annoying) connotation. Participants had to push either the "good" key or "bad" key as quickly as possible. Fazio and colleagues (1995) found that among the White respondents, reaction time to good words was quicker following presentation of the White faces, and reaction time to bad words was quicker following the African American faces. Just as "bread" facilitated response times to the target "butter" due to their proximity in the associative network, Fazio and colleagues concluded that the participants in their study associated positivity more

closely with Whites and negativity more closely with Blacks—and that their technique might provide a bona fide (as opposed to bogus) pipeline into racial attitudes that people would rather not admit to having.

One critical feature of the affective-priming technique is the fleeting interval between the onset of prime and target. Because the interval is often as short as 300 msec, there is a strong implication that the cognitive processes underlying affective priming must be due to automatic semantic activation beyond conscious control. Even more decisive evidence for automaticity comes from the work of Wittenbrink, Judd, and Park (1997), who demonstrated subliminal priming effects.

Since the path-breaking studies of affective priming, and the parallel development of the Implicit Association Test (IAT; Greenwald & Banaji, 1995), there have been many efforts to assess the validity of claims that implicit-associative measures are indeed tapping into a construct that can be accurately labeled implicit prejudice. Banaji (2001) has stated the reductionist logic of her research program with exemplary clarity:

> If attitude is "a psychological tendency that is expressed by evaluating a particular entity with some degree of favor or disfavor" (Eagly & Chaiken, 1998, p. 269), and if implicit memory is "revealed when previous experiences facilitate performance on a task that does not require conscious or intentional recollection of these experiences" (Schacter, 1987, p. 501), then implicit attitudes are introspectively unidentified (or inaccurately identified) traces of past experience that mediate favorable or unfavorable feeling, thought, or action toward social objects (Greenwald & Banaji, 1995, p. 8). (p. 119)

Working from these first-order psychological principles, it is a short inferential step to conclude that the same methods that cognitive psychologists use in studying implicit memory should also prove useful in studying implicit attitudes. It requires, though, an inferential leap to conclude that the research community is justified in equating implicit attitudes and prejudice (as psychologists use those terms) with prejudice or racism (as ordinary people use those terms). Justifying that inference requires demonstrating that implicit-associative measures are reliably and strongly correlated with compelling criterion variables that capture discriminatory treatment (Tetlock & Arkes, 2004).

This rapidly growing literature has been ably reviewed elsewhere (Fazio & Olson, 2003) so there is no point in rereviewing it. The focal point of political–psychological controversy is over whether greater implicit negative affectivity toward Black-versus-White racial cues is sufficient evidence to indict large percentages of Americans as implicitly prejudiced (Redding, 2004). For when social psychologists use the politically charged language of prejudice and racism to characterize their findings, they enter—like it or not—the larger political battle over the tenacity of prejudice: Has racism lost most of its sting in the post–Civil Rights era or has it merely taken on new more subtle forms? The answers that policy elites reach to this question prove—perhaps not surprisingly—to be a potent predictor of how supportive those elites are of govern-

ment programs especially targeted at helping African Americans (cf. Kinder, 1998; Sniderman & Carmines, 1997).

Taken at face value, the self-report survey data suggest that although old-fashioned racism has not disappeared, it has been dramatically weakened as a political force. Overt White hostility toward African Americans declined precipitously in the 1960s and by the 1990s had reached historic lows. Whereas White Americans were once deeply divided over whether African Americans should be accorded the full rights of citizenship, there is now near consensus at the level of both mass and elite opinion that *de jure* segregation and doctrines of inherent racial superiority are unacceptable (Schuman, Steeh, Bobo, & Krysan, 1997).

These stylized facts are not in dispute, but there is dispute over their significance. Observers of race relations on the political left doubt that self-report surveys provide an accurate barometer of prejudice. They insist that racism still lies "at the center, not the periphery, in the permanent not in the fleeting, in the real lives of black and white people, not in the caverns of the mind" (Bell, 1992, p. 208). Claude Steele's research on stereotype threat is often taken to reinforce this worldview: African Americans have apparently so internalized negative societal stereotypes of themselves that even trivial reminders of their racial identity impair their academic performance (Steele, Spencer, & Aronson, 2002). By contrast, observers on the right tell a radically different story. Shelby Steele's (2006) writings imply that stereotype-threat effects arise because reminding African Americans of their racial identities on elite campuses makes salient SAT-admission differentials of racial groups, thus activating an ideology of victimology that reduces the need to try hard on academic tests. In a similar vein, Thernstrom and Thernstrom (1997) maintain that although African Americans have made large socioeconomic gains, the remaining pockets of inequality are best explained not by White racism but by racial gaps in achievement values, educational attainment, and family structure rooted in forces endogenous to Black communities.

Social psychologists have largely lined up with observers who stress the lingering power of prejudice and doubt. They are skeptical of the depth of the changes in racial attitudes documented in representative-sample surveys. Many Whites, they suggest, have learned to say the right thing, but they have not truly internalized the egalitarian ideals that would justify calling them non-racist (Greenwald & Banaji, 1995; Jackman & Jackman, 1983). Framed within the broader debate, though, the intense interest among social psychologists in implicit prejudice is inevitably viewed with suspicion among conservatives, as the efforts of a largely liberal research community to find evidence that bolsters government efforts to lend special assistance to Blacks because Blacks confront special obstacles to socioeconomic advancement (Redding, 2004; Stein, 2004).

Defenders of the implicit-prejudice research program counter that the burgeoning body of construct-validity research is already sufficient to sustain the prejudice in-

terpretation. They argue that research to date has revealed a lot about how implicit measures of prejudice correlate with a variety of criterion measures (for a recent meta-analysis of 60 IAT studies, see Poehlman, Uhlman, Greenwald, & Banaji, 2005). Particularly compelling in their view is evidence that:

1. Implicit-associative measures are positively correlated with explicit measures of prejudice such as the Modern Racism Scale, especially after correcting for attenuation due to measurement error, thus providing convergent validity across very different methods for the racism interpretation (e.g., Cunningham, Preacher, & Banaji, 2001).
2. Implicit-associative measures predict avoidance and awkwardness in interpersonal encounters with African American experimental confederates (nonverbal cues, such as interpersonal distance, eye blinking and gaze aversion, and paralinguistic cues, such as speech fluency and stuttering) and a preference for sitting beside and interacting with Whites, thus providing criterion-validity support for the racism interpretation (Dovidio, Kawakami, & Gaertner, 2002; Monteith, Voils, & Ashburn-Nardo, 2001; Poehlman et al., 2005).
3. Implicit-associative measures are associated with amygdala activation (taken by some as a neurological locus of hostility and aggression), thus further underscoring the power of the racism interpretation to unify findings across diverse methodologies (Chee, Sriram, Soon, & Lee, 2000; Phelps et al., 2000).

Defenders of implicit-prejudice interpretations of implicit-associative measures do not disguise their impatience with more benign shared-cultural-stereotype interpretations of the same measures (e.g., Karpinski & Hilton, 2001): the notion that African American stimuli prime negative associations more readily not because people hold such associations themselves but rather because they are aware that such associations have a long history in America. Banaji (2001) sees a false dualism at work, a tendency to distinguish too sharply between the true internal self and the external cultural environment. Our "selves" are the product of our social learning history and a racist culture inevitably leaves its imprint on our most readily accessible mental representations of the world. In Banaji's words:

> Perhaps the struggle to find a place to point the finger, to take the burden of possession off oneself, comes from the inherently political nature of such assessments. We certainly don't see the same agitation when we can't seem to remember a list of words for which we show intact priming. Individuals are the transducers of cultural experience—they provide the physical, social, and psychological shell through which culture speaks. Yet when revealed attitudes are not palatable, the reaction is to look for an answer elsewhere and pointing to culture (not as the environment in which the attitude is learned but rather as the thing whose attitude is being measured) is perfectly understandable and perfectly wrong. (p. 138)

Banaji's argument raises profound level-of-analysis questions about individual identity—and the meaningfulness of holding individuals (as opposed to political cultures) accountable for their attitudes—be they implicit or explicit. On a humbler empirical plain, though, it is worth noting that, in the spirit of signal-detection theory (Swets, 1982), there are two distinct sets of issues on which proponents and opponents of implicit-prejudice arguments might disagree:

1. Over the facts—the degree to which the construct-validity evidence convincingly shows that unconscious negative affect drives differential response times to minority-group stimuli in implicit-prejudice research paradigms.
2. Over values—the degree to which existing evidence passes their threshold for labeling people "prejudiced" or "racist." Researchers with different worldviews may attach different values to the risks of Type 1 errors (calling nonracists racists) versus Type II errors (calling racists nonracists) and these different values may lead them to set different thresholds for making accusations of racism.

It turns out, as is so often the case in political psychology, that the feuding camps disagree on both the facts and the values at stake (cf. Jervis, 1976). In a scholarly exchange with implicit-prejudice researchers, Tetlock and Arkes (2004) challenged whether the research community had given due weight to alternative, usually more benign explanations for the patterns of covariation between implicit-prejudice measures and various construct-validational indicators. These alternative explanations included:

1. The possibility, raised by Karpinski and Hilton (2001) and Fazio and Olson (2003), that implicit measures are picking up not racial animus but, rather, awareness of unflattering, media-amplified stereotypes of African Americans (or of particular subgroups, such as young, inner-city males) that participants would themselves disavow if those associations were called to their attention. As Judd, Blair, and Chapleau (2004) observe in their study designed to sort out why African American, relative to White, faces automatically facilitate the categorization of handguns: "It is one thing to believe that the tendency to misclassify weapons in the hands of young African Americans is part of a negative, prejudicial bias on the part of police officers. It is a rather different thing to believe that the officers are influenced by a widely shared stereotype of African-Americans as both violent and athletic, unreliable and possessing a good sense of humor, lazy and street-smart" (p. 77). For Judd and colleagues, these two assessments imply empirically distinguishable views of American society; for Banaji (2001), the distinction verges on meaningless, "perfectly understandable and perfectly wrong."
2. The possibility that the target construct, implicit prejudice, may be picking up on racial animus but animus that can be readily picked up by traditional self-report measures of prejudice and animus that is concentrated among relatively small numbers of bigoted outliers. If the goal is to enter the great American racism debate—on a grand societal scale—it is essential to show that the new prejudice is not reducible to the old—and that the effects are not being driven by isolated pockets of old-fashioned prejudice (Mitchell & Tetlock, 2006).
3. The possibility that the target construct is a multidimensional one that derives from a messy mix of affective associations, including anger at the injustices of racism, shame and embarrassment at past or current White mistreatment of Blacks, and sadness at missed opportunities to achieve fuller racial equality. In the parable of the "two Jesses," Tetlock and Arkes (2004) posit two respondents with markedly different associative networks for encoding information about African Americans. One, like Jesse Jackson, is sympathetic to a liberal policy agenda: He believes that racial discrimination is an ongoing, not just a past, problem and supports aggressive affirmative action to level the playing field. The other, like Jesse Helms, is sympathetic to a conservative agenda: He believes that, just as other minority groups had to work their way up the success ladder, so should African Americans. This respondent rejects affirmative action and believes the primary cause of racial inequality is now internal to the African American community: the breakdown of personal responsibility within inner-city communities. These eponymous figures agree that crime rates are too high and test scores too low, but they make different causal attributions for these facts and experience different mixtures of sorrow and anger. Is there compelling theoretical reason for expecting the IAT or other implicit associative measures of "negative affectivity" to differentiate these ideal-type belief systems, to differentiate people who have the same amount of negative affect but whose affect can be traced to qualitatively different emotional states and causal attributions for inequality (cf. Lerner & Keltner, 2001; for evidence that sympathy for underdogs can translate into negative implicit affect, see Uhlmann, Brescoll, & Paluck, 2006)?
4. The possibility that sizable fractions of the variance in IAT or other test scores might be attributable to individual differences that are neither associationist nor attitudinal, such as familiarity (Rothermund & Wentura, 2004), test anxiety (Frantz, Cuddy, Burnett, Ray, & Hart, 2004), general processing speed (Blanton & Jaccard, 2006), or cognitive dexterity (Fiedler, Messner, & Bluemke, 2006), and that these confounding influences undercut claims of natural zero points and ratio scales (Blanton & Jaccard, 2006).
5. The possibility that some component of the negative affectivity is traceable to realistic assessments of covariations between negatively valenced attributes—crime, out-of-wedlock births, school dropout rates—and racial categorizations (cf. Jussim, 2005). Tetlock and Arkes (2004) worry that implicit-prejudice research has set the threshold for labeling people prejudiced so low that most people will qualify as long as they live in societies in which intergroup inequalities exist on dimensions to which people assign evaluative significance (e.g., pov-

erty, crime) and they recognize, consciously or unconsciously, the existence of these inequalities. This argument implies that we need to control statistically for something no one has yet controlled: political knowledge. Implicit racism may be implicit awareness of depressing inequalities—a view consistent with experimental demonstrations of the power of positive social contexts to attenuate automatic negative affect in response to African Americans (Barden, Maddux, Petty, & Brewer, 2004). This possibility led Tetlock and Arkes to ask whether Jesse Jackson (who once confessed to relief on discovering that the young men walking behind him at night were White, not Black) would "fail" the IAT? It also led them to pose the corollary question: Is "Bayesian bigot" an oxymoron or is it reasonable to issue moral indictments for doing what decision theorists would call the right thing—using base-rate data?

These questions imply a further question: Is so politically charged a debate scientifically resolvable? Here we find a spectrum of views. At one end are those, such as Banaji and colleagues (2004) and Sears (2004), who believe the answer is an emphatic "yes": The scientific method is unfolding as it should and critics are just too impatient. It takes time to build up the requisite body of construct-validational evidence. At the other end, we find a perspective so philosophically extreme that no one in the debate has yet to endorse it: depoliticize the dispute by purging political hot-potato terms from our scientific vocabulary, abandoning all pretense of relevance, and replacing value-laden talk about "prejudice" and "racism," with dry technical talk about the "dimensionality of affectivity." From a history-of-psychology perspective (Boring, 1950), it is striking though that this proposal has so few advocates. Positivist traditionalists would be puzzled: Why should social scientists, in their roles as scientists and not citizens, be in the business of making pronouncements of racism and prejudice? Why can't researchers be content to say that they have documented a pattern of implicit affect, the behavioral correlates take certain forms, and the attentive public can now draw its own moral and legal conclusions about whether the correlates rise to actionable discrimination? Prejudice is more than a scientific judgment: It requires passing judgment on which aspects of public opinion (implicit or explicit) deserve our censure.

A middle-ground option is to accept that the dispute is inherently political and that special precautions may be necessary for ensuring reasonable ideological balance in the hypothesis-testing process. One path to this end is via Bayesian reputational bets and adversarial collaborations (cf. Mellers, Hertwig, & Kahneman, 2001). This process requires researchers from competing camps to agree, *ex ante*, on what would constitute fair tests of their respective positions and to update their beliefs in accord with the results.

Recent debates suggest that adversarial collaboration would reveal that different camps have markedly different views on the diagnosticity of the evidence—be it eye blinks or amygdala activation or factor analyses of response latency data. One tough test of the viability of ad-

versarial collaboration arises when we explore clashing views on the theoretical implications of correlations between implicit and explicit attitudinal measures. Fazio and Olson (2003) note that this is a messy literature: Correlations have ranged widely and there seem to be no theoretical constraints to prevent researchers from adopting a "heads-I-win-tails-I-do-not-lose" stance in which positive correlations suggest convergent validity, zero-order correlations suggest discriminant validity, and negative correlations suggest repression or overcompensation.

Banaji and colleagues (2004) make the convergent validity argument: after correcting for unreliability, the correlations between the IAT and certain explicit measures of prejudice can rise as high as 0.5. But skeptics are unpersuaded: Tetlock and Arkes (2004) point out that one of the most popular explicit measures—the Modern Racism Scale—is itself controversial, with some viewing it as a measure of prejudice and others viewing it as a measure of a political preference for the more conservative position that African Americans collectively should rely more on themselves and less on government (see the symbolic racism debate between Sniderman and Tetlock [1986] and Kinder [1986]. Should we conclude that slower responders to the IAT are implicit racists—as Banaji and colleagues suggest? Or does it just mean that these respondents believe, rightly or wrongly, that the primary obstacles to racial inequality now reside in the African American community?

Skeptics maintain that the data are insufficiently diagnostic with respect to whether the IAT is tapping implicit prejudice. But it is fair to ask: What would induce them to change their minds? It is also fair to ask what associations between implicit and explicit measures of prejudice would induce defenders of implicit-prejudice interpretations to change their minds. The answers are not obvious. For instance, when implicit measures predict explicit indicators of prejudice, investigators can construe such findings as construct-validation. But when such measures fail as predictors, investigators can interpret such findings as evidence of how skillful respondents are at cognitively overriding prejudicial impulses. Moreover, the most reliable individual-difference moderator of tendency to override—the motivation to control prejudice scale developed by Fazio and colleagues (1995)—does not break this impasse. This carefully constructed scale is also open to alternative interpretations. "Prejudice" is—it should now be clear—a term with ever-shifting political meanings. Are high scorers on the scale reining in raw bigotry or are they displaying hypersensitivity, even to matter-of-fact racial differences—exactly the hypersensitivity that one would expect if they feared that esteemed professors would label them as racist if they displayed even trace awareness of unpleasant facts of life in our society? Indeed, as Frantz and colleagues (2004) ask: Is the sinking sense that one is failing the IAT sufficient to induce stereotype threat among whites (fear that they fit the profile of the modern racist) and hence the oft-observed interpersonal awkwardness?

From a contextualist perspective, prejudice is not the epistemological equivalent of a rock—the true nature of

which we can ascertain if we only subject it to the right tests. Researchers need to acknowledge the wide spectrum of meanings that political observers assign to this popular conceptual variable. At one end are the most restrictive definitions of prejudice that require satisfying all three of Allport's (1954/1968) criteria: attitudes based on misinformation, charged with hostility, and unresponsive to evidence. Such definitions raise the risk of "missing" sneaky racists but lower the risk of false alarms. At the other end are the least demanding definitions that presume none of the three Allportian criteria. For Banaji and colleagues (2004), correlation with any form of disparate impact suffices. Such definitions raise the opposite risks. The dispute is thus as much about values as about facts, about where we should set our standards of proof for issuing indictments for prejudice. We have reached an epistemological, not just a disciplinary, boundary.

ATTRIBUTIONS OF IRRATIONALITY TO POLITICAL ELITES

From Lasswell (1948) to Janis (1982) to Suedfeld (1992), many political psychologists have subscribed to variants of the following reductionist syllogism: Policy elites are all too human (notwithstanding occasional efforts to promote themselves to deity status). Psychology is the science of human behavior. As such, psychology must shed light on why even the high and mighty think, feel, and act as they do.

Of course, reductionists need not agree on which first-order psychological principles confer the greatest explanatory leverage. The oldest tradition is the psychodynamic, which traces its lineage from Freud, Langer, and Erikson to contemporary scholars such as Etheredge (1980), Greenstein (1975), and Winter (1993). But the greatest activity in the last three decades has concentrated on applying first-order principles from the vast literature on errors and biases in human judgment at both the individual (Gilovich, Griffin, & Kahneman, 2000; Kahneman & Tversky, 2001) and group-dynamics levels (Aldag & Fuller, 1993; t'Hart, 1994). Whether working solo or in small groups, the recurring theme is how often people stray from key benchmarks of rationality. People, it is alleged, are too slow to change their minds in response to dissonant evidence, too quick to jump to conclusions from ambiguous evidence, loath to confront tough trade-offs, unaware of past mistakes, and excessively confident in their current predictions.

Cognitive Biases

Virtually all work in this tradition builds on three premises:

1. World politics is staggeringly complex—there are too many possible causes and interactions among causes, and not nearly enough observations to test these hypotheses, forcing us to rely on speculative counterfactual thought experiments (Tetlock & Belkin, 1996).

2. People—limited capacity information processors that we are—frequently resort to simplifying strategies to deal with this otherwise unmanageable ambiguity and complexity (Axelrod, 1976; George, 1980; Herrmann & Fischerkeller, 1995; Jervis, 1976; Mintz, 1993; Vertzberger, 1990). Although there is disagreement on how to characterize these simplifying strategies (proposals include the usual suspects: heuristics, schemas, scripts, cognitive maps, operational codes, associative networks, etc.), there is consensus on their indispensability. Decision makers need to feel they have reasonably firm answers to fundamental questions about the world. What are the basic objectives of other states? What should our own objectives be? Can conflict be avoided and, if so, how? If not, what form will conflict take?

3. There is, however, a price to be paid for the cognitive and political benefits of a simple, stable worldview. The price of cognitive economy in world politics is—as in other domains of life—susceptibility to error and bias (although there is disagreement over the price that must be paid, with a minority putting it startlingly close to zero) (Gigerenzer, Todd, & the ABC Research Group, 1999).

This argument runs into strong headwinds when the time comes to operationalize bias in real-world settings. In the laboratory, claims about deviations from rationality are hardly beyond dispute, but they at least rest on well-defined normative baselines (Kruglanski, 2004). Researchers can manipulate the order in which evidence is presented (assessing primary/recency effects), the directionality of the evidence (assessing double standards), the diagnosticity of the evidence (assessing whether people are good Bayesian belief updaters who live up to reputational bets), and the precise probabilities and monetary values of outcomes (assessing whether decision makers act in accord with expected utility theory or fall prey to arbitrary faming effects). It is a much tougher challenge to defend the same normative verdicts in the real world: When should the financial masterminds of Long-Term Capital Management have recognized that their hedging strategies were failing (Loewenstein, 2000) or when should Sovietologists have recognized that the Soviet Union was imploding (Breslauer & Tetlock, 1991), or when should policy elites stay the course in Vietnam, Iraq . . . or write off sunk costs?

Given the sheer bulk of laboratory and field evidence in support of the error-and-bias portrait of human nature, many psychologists might understandably conclude that relevance to policy elites has already been established (Gilovich, Griffin, & Kahneman, 2000). Relevance is not, however, enough to clinch the scientific case. Even within psychology, there are ongoing challenges to the empirical robustness of the error-and-bias portrait. Does the portrait hold up when data are presented in more naturalistic ways or when decision makers have incentives to become more thoughtful (Camerer, 1995; Gigerenzer et al., 1999)? Within psychology, there are also challenges that maintain that too much attention has been given to conditions under which simple heuristics lead us astray and not enough to conditions under which such heuristics perform surprisingly well (Gigerenzer

et al., 1999). Outside psychology, skeptics working at more macrolevels of analysis have advanced their own external-validity grounds for doubt, including (1) selection arguments (to make it into high-level political roles, one must be a lot more mature than the typical sophomore participant in laboratory studies); (2) motivational arguments (policymakers are especially motivated to learn from their mistakes and to make rational decisions because the stakes are so high); and (3) accountability-constraint arguments (even if policymakers were prone to the same effects as laboratory participants, they work within complex systems of checks and balances, and of elite debate and competition for power, that prevent psychological biases from being translated into policy) (see Druckman, 2004).

From McGuire's (1983) contextualist perspective, each argument highlights testable boundary-condition hypotheses. One strategy of testing them is to explore whether hypothesized threats to generalizability make a difference when manipulated in experiments. The results are reassuring to psychologists, if not to the rest of the world. Increasing the stakes is not a surefire method of checking biases such as belief perseverance and overconfidence (Camerer & Hogarth, 1999); more sophisticated subject pools also appear susceptible to basic biases and errors (Gilovich et al., 2000); and the only types of accountability that regularly attenuate bias are tricky to orchestrate in the political world (predecisional accountability to well-informed audiences with unknown views; Tetlock & Lerner, 1999).

Another strategy is to explore whether we obtain similar functional relationships between the conceptual independent and dependent variables studied in laboratory and real-world settings? The methodological division of labor seems straightforward: controlled experiments gauge the internal validity of the original causal claim whereas field methods—case studies, content analysis, codifying expert consensus—gauge how well the hypothesized process holds up in the hurly-burly of world politics. And when multimethod convergence arises in political psychology, it is understandably taken as an encouraging sign that reductionism works. The guiding assumption is that claims that pass radically different tests stand a better chance of being true than do claims whose support is confined to one genre of research.

By this standard also, the error-and-bias portrait holds up well in the political domain, with the caveat that most external-validational work would not pass muster among experimentalists. The work largely consists of comparative case studies, raising obvious concerns about selective sampling of cases (Do we even know how to draw a representative sample from the ill-defined population of decision-making episodes?) and about selective interpretation of cases (Are we giving "due" weight to alternative explanations?). The next sections illustrate the strengths and weaknesses of the evidence.

Heuristic-Driven Analogical Reasoning

People try to understand novel problems by reaching for familiar concepts. Frequently, these concepts take the form of metaphors and analogies that illuminate some aspects of the problem but obscure other aspects.

Lakoff and Johnson (1980) argue that metaphors are cognitive–linguistic structures that pervade all forms of discourse, and international politics is no exception. Moreover, metaphorical preferences are correlated closely with policy preferences. Consider the "ladder of escalation" and the "slippery slope" (Jervis, 1989). The former metaphor implies that just as we can easily climb up and down a ladder one step at a time, so we can control the escalation and deescalation of conventional or even nuclear conflicts; the latter metaphor implies that once in a conflict, leaders can easily lose control. In Cold War days, backers of the "ladder" metaphor supported a war-fighting doctrine that stressed cultivating counterforce capabilities; they believed that nuclear war could, in principle, be controlled and even won. By contrast, "slippery slopers" endorsed MAD (mutual assured destruction)—both as a policy and strategic reality—and they feared that, once initiated, conflicts would inevitably escalate to all-out war. They argued that nuclear powers need to avoid crises. Managing them once they break out is too risky. As President Kennedy remarked after the Cuban Missile crisis, "One can't have too many of these" (Blight, 1990).

People also bestow meaning on new situations by drawing on salient historical precedents (Gilovich, 1981; Neustadt & May, 1986; Vertzberger, 1990). But this essential strategy, too, can be abused. One mistake is to dwell on the most obvious precedent—a pivotal event early in one's career (Goldgeier & Tetlock, 2000) or perhaps the most recent crisis (Jervis, 1976; Reiter, 1996)—rather than survey a broader set of precedents. Consider the potpourri of conflicts that American observers in the elite press compared to Vietnam between 1975 and 2006: Lebanon, Israel's Vietnam (twice over); Eritrea, Ethiopia's Vietnam; Chad, Libya's Vietnam; Angola, Cuba's Vietnam; Afghanistan, the Soviet Union's Vietnam; Bosnia, the European Community's Vietnam; Kashmir, India's Vietnam; Nicaragua, Bosnia, Somalia, and Iraq (twice over) all new American Vietnams, and, of course, Kampuchea, Vietnam's Vietnam. To be sure, there are similarities, but the differences are also marked and often slighted.

Khong (1991) reports what is still the most elegant study of analogical reasoning in foreign policy. Coding high-level deliberations in the early 1960s, he documents how American policy in Vietnam was shaped by the perceived similarity of the Vietnamese conflict to the Korean war. Once again, a Communist army from the north had attacked a pro-Western regime in the south. This diagnosis led to a series of prescriptions. The United States should resist the aggression with American troops and could expect victory, albeit with considerable bloodshed. A side-constraint lesson drawn from the Korean conflict was that the United States should avoid provoking Chinese entry into the Vietnam war and practice "graduated escalation."

This example illustrates a second pitfall in analogical foreign policy reasoning: the tendency to neglect differences between the present and the preferred precedent.

In public but also in private, policymakers too rarely engage in balanced comparisons (Neustadt & May, 1986). From a psychological viewpoint, this result is reminiscent of laboratory research on the overweighting of hypothesis-confirming information (Klayman & Ha, 1987). To reinvoke Vietnam, American policymakers concentrated on surface similarities between the Vietnamese and Korean conflicts while George Ball—alone within Johnson's inner circle—noted the differences (e.g., the conventional vs. guerrilla natures of the conflicts, the degree to which the United States could count on international support). Whereas doves complained about this analogical mismatching, hawks complained about mismatching that led decision makers to exaggerate the risk of Chinese intervention. China had less reason to intervene in Vietnam in 1965 than in Korea in 1950, preoccupied as Beijing was in the late 1960s by the internal turmoil of the Great Proletarian Cultural Revolution and the external threat of the Soviet Union, which had just announced the Brezhnev Doctrine (claiming a Soviet right to intervene in wayward socialist states).

A third mistake is to permit preconceptions to drive the conclusions one draws from history. In the United States, hawks and doves drew sharply divergent lessons from the Vietnam war (Holsti & Rosenau, 1979). Hawks learned that the Soviet Union was expansionist and that the United States should avoid graduated escalation and honor alliance commitments. Doves learned that the United States should avoid guerrilla wars, that the press is more truthful than the administration, and that civilian leaders should be wary of military advice. No lesson appeared on both the hawk and dove lists (Zimmerman & Axelrod, 1981).

Belief Perseverance

Extending laboratory demonstrations of cognitive conservatism and belief perseverance (Nisbett & Ross, 1980), students of foreign policy often find that policymakers resist changing their minds (George, 1980). They also find that cognitive mechanisms, such as selective attention to confirming evidence, source derogation, and biased assimilation, play key roles in buffering beliefs from refutation. And they find that, although foreign policy belief systems take many forms (Herrmann & Fischerkeller, 1995), one of the most resistant-to-change configurations of beliefs is the inherent bad-faith model of adversaries (Blanton, 1996; Holsti, 1967; Murray & Meyers, 2004). A state is believed to be implacably hostile: contrary indicators, that in another context might be regarded as probative, are ignored, dismissed as propaganda ploys, or interpreted as signs of weakness—for example, American and Soviet images of each in the Cold War, Israeli and Palestinian, and Indian and Pakistani views of each other up to the present (Kelman, 1983). Although such images are occasionally on the mark, they can produce missed opportunities for conflict resolution (Spillman & Spillman, 1991). More generally, belief perseverance can slow shifts from less to more successful strategies. World War I offers one of the more horrendous examples: Military strategists continued to launch infantry charges despite enormous losses, leading to the wry observation that men die more easily than beliefs (Art & Waltz, 1979, p. 13).

Recent postmortems of intelligence failures—with respect to 9/11 and Iraqi WMD (weapons of mass destruction)—highlight the conditions conducive to belief perseverance. Jervis (2006) shows that a theme running through critiques of intelligence agency estimates of Iraqi capabilities is the readiness with which experts see what they expect to see—and what they suspect their political masters want them to see. Jervis also notes a core irony of the Iraqi WMD controversy: to deter his enemies, Saddam Hussein wanted those enemies to suspect that he possessed WMD capabilities, thereby creating exactly the type of ambiguity that his powerful foe, the United States, could use to justify demolishing his regime. That said, postmortem critiques are themselves methodologically problematic. In an insightful critique of the 9/11 Presidential Commission's criticism of American preparedness of the terrorist attacks on 9/11, Posner (2005) notes how hindsight bias fosters the dangerous illusion that it should have been easy for analysts to have connected the dots and prevented the terrorist attacks.

Compelling real-world evidence for irrational belief perseverance is hard to get. It requires an unusually long investigative attention span: First, to persuade professional observers of the political scene to specify the *ex ante* conditional likelihood of each member of the set of all possible futures (conditional on their own vs. rival views of the world being correct); second, to wait several years to find out which views spawned more accurate expectations, and only then to be able to apply the Bayesian belief updating formula to identify who was willing to change his or her mind by the prescribed amounts. Tetlock (1999b, 2005) reports a batch of such studies and finds that (1) experts whose most likely futures fail to materialize rarely change as much as they should given the reputational bets those experts themselves endorsed *ex ante*, but experts whose most likely futures do materialize tend to increase their confidence to roughly the right extent; (2) experts who get it wrong resist changing their minds by invoking a formidable battery of dissonance-reduction strategies, including the close-call-counterfactual defense (what I predicted did not happen but it almost did), the off-on-timing defense (it has not happened yet but it will), and the Type I/II error defense (yes, I was wrong but I made the right mistake); and (3) experts with high needs for closure and a preference for parsimony (hedgehogs) were more likely to invoke belief system defenses and to resist changing their minds when they got it wrong. These results converge with experimental work (Kruglanski, 2004; Suedfeld & Tetlock, 2001).

It is dangerous, however, to overstate the power of belief perseverance. Policymakers do sometimes change their minds (Levy, 1994; Tetlock, 2005). The key questions are: Who changes? Under what conditions? And what forms does change take? Converging evidence from archival studies of political elites and experimental studies of judgment suggest at least four possible answers:

1. When policymakers do change their minds, they are constrained by the cognitive-consistency principle of least resistance and show a preference for tweaking cognitions with minimal connections to other cognitions (Abelson, 1959). Policymakers should thus abandon beliefs about specific tactics before giving up on a strategy and abandon strategies before jettisoning assumptions fundamental to their worldview (Breslauer & Tetlock, 1991; Spiegel, 1991).

2. Timely belief change is more likely in competitive markets (Smith, 1991) that provide quick, unequivocal feedback and opportunities for repeated play on similar problems so that base rates of experience can accumulate, thereby reducing reliance on theory-driven speculation about what would have happened if one had chosen differently. Policymakers should thus learn more quickly in currency and bond markets than, say, in the realm of nuclear deterrence (who knows what lessons we should draw from the nonoccurrence of a unique event such as nuclear war?).

3. Timely belief change is more likely when decision makers are accountable for bottom-line outcomes and are free to improvise solutions than when decision makers are bound by complex procedural–bureaucratic norms that limit latitude to improvise (Wilson, 1989).

4. Timely belief change is more likely when decision makers—for either dispositional reasons (Kruglanski, 2004) or situational reasons (Tetlock & Lerner, 1999)—display self-critical styles of thinking.

Overconfidence

The overconfidence literature is a methodological minefield. It is difficult, however, to dismiss the entire body of experimental demonstrations of overconfidence as due to regression artifacts (Dawes, 1998; Einhorn & Hogarth 1981; Fischhoff, 1991). And the same can be said for demonstrations of overconfidence in world politics. Tetlock (2005, Chapters 2 and 3) has found that (1) most political experts consistently assign too low subjective probabilities to events that occur and too high probabilities to events that fail to occur; (2) this effect is not just an artifact of regression toward the mean; and (3) this effect is most pronounced among experts with strong ideological commitments and high needs for closure who are making long-term predictions within their domains of expertise. This result fits snugly under an umbrella social cognition framework that portrays overconfidence as pumped up by both the motivation to generate reasons that one-sidedly favor certain predictions (high need for closure plus strong theoretical priors) and the ability to do so (the large knowledge base provided by expertise and unchecked by immediate reality constraints because of the long-term nature of predictions).

In the foreign policy realm, Levy (1989) has noted that overconfidence can lead decision makers to overestimate their ability to detect subtle clues to the other side's intentions and to overassimilate incoming information to their existing beliefs. Overconfident deci-sion makers in defender states are likely to misapply deterrence strategies—either by failing to respond to potential challenges because they are certain that no attack will occur (e.g., Israel in 1973) or by issuing gratuitous threats because they are certain that there will be an attack, even when no attack is planned (Levy, 1989). Overconfident aggressors are prone to exaggerate the likelihood that defenders will yield to challenges (Lebow, 1981). In addition, overconfidence can produce flawed policies when decision makers assess military and economic capabilities. For instance, the mistaken belief that one is militarily superior to a rival may generate risky policies that can lead to costly wars that no one wanted (Levy, 1989). By contrast, a mistaken belief that one is inferior to a rival can exacerbate conflict in either of two ways. First, such beliefs generate unnecessary arms races as the weaker side tries to catch up. The rival perceives this effort as a bid for superiority, matches it, and sets the stage for an action/reaction pattern of conflict spiral. Second, the weaker state will be too quick to yield to a rival's demands (Levy, 1989). At best, such capitulation produces a diplomatic defeat; at worst, it tempts aggressors to up the ante and ultimately produces wars that might have been avoided with firmer initial policies (a widely held view of Chamberlain's appeasement policy of 1938).

The Fundamental Attribution Error

People often gravitate toward dispositional explanations for others' conduct, and overlook plausible situational accounts exist (Gilbert & Malone, 1995; Jones, 1979; Ross, 1977). This proclivity can interact dangerously with the security dilemma at the heart of international relation theory (Jervis, 1976). To protect themselves in an anarchic environment (no world government), states must seek security either through costly defense programs of their own or by entering into entangling alliances that oblige others to defend them. Assessing intentions in such an environment is hard. There is usually no easy way to distinguish between defensive states responding to the competitive logic of the situation and expansionist states seeking to transform the status quo. If everyone assumes the worst, the stage is set for conflict-spiral-driven arms races that no one wanted (Downs, 1991; Kramer, 1988). The fundamental attribution error exacerbates matters by lowering the perceptual threshold for attributing hostile intentions to others. This tendency—in conjunction with the security dilemma—can lead to an inordinate number of "Type I errors" in which decision makers exaggerate the hostile intentions of defensively motivated powers. The security dilemma compels even peaceful states to arm; the fundamental attribution error then leads observers to draw incorrect dispositional inferences from decisions to arm. Both processes—combined with self-serving motivational biases (Heradstveit & Bonham, 1996)—set the stage for a self-righteous spiral of hostility in which policymakers know that they arm for defensive reasons, assume that others know this, and then conclude that those who insist on building up their

military capabilities must have aggressive designs. At best, the result is a lot of unnecessary defense spending; at worst, needless bloodshed (White, 1984).

The fundamental attribution error may encourage a second misperception in the international arena: the tendency to perceive governments as unitary causal agents rather than as complex amalgams of bureaucratic and political subsystems, each pursuing its own missions and goals (Vertzberger, 1990). Retrospective reconstructions of the Cuban missile crisis have revealed numerous junctures at which American and Soviet forces could easily have come into violent contact with each other, not as a result of following some carefully choreographed master plan plotted by top leaders but, rather, as a result of local commanders executing standard operating procedures (Blight, 1990; Sagan & Waltz, 1995). The organizational analog of the fundamental attribution error is insensitivity to the numerous points of slippage between the official policies of collectivities and the policies actually implemented.

Claims about the fundamental attribution error in world politics should, however, be subject to rigorous normative and empirical scrutiny. On the normative side, skeptics can challenge the presumption of "error." Deterrence theorists might note that setting a low threshold for making dispositional attributions can be adaptive. One may make more Type I errors (false alarms of malevolent intent) but fewer Type II errors (missing the threats posed by truly predatory powers). And theorists of international institutions note the value of pressuring states to respect the norms of the transnational trading and security regimes. One way of exerting such pressure is to communicate little tolerance for excuses for norm violations, thereby increasing the reputation costs of such conduct. A balanced appraisal of the fundamental attribution "error" hinges on our estimates of the risk of each type of error as well as on the value we place on avoiding each error—a standard signal detection problem. On the empirical side, skeptics can challenge the presumption of "fundamental" by pointing to collectivist cultures in which sensitivity to contextual constraints on conduct is common (Peng & Nisbett, 1999). Skeptics can also question what counts as a "dispositional" explanation when we shift from an interpersonal to an international level of analysis and the number of causal entities expands exponentially. One could code the domestic political system of one's adversary might be coded either as a situational constraint on leadership policy or as a reflection of the deepest dispositional aspirations of a "people."

Avoidance of Value Trade-offs

For a mutually reinforcing array of cognitive, emotional, and social reasons, politicians find value trade-offs unpleasant and frequently define issues in ways that bypass the need for such judgments (Jervis, 1976; Mintz, 1993; Payne et al., 1992). Trade-off avoidance can, however, be dangerous. Implementing a policy of deterrence, for example, raises tricky trade-offs between the need to resist exploitation and the need to avoid exacerbating the worst-case fears of adversaries. The first value calls for de-

terrence; the second, for reassurance. There are also more complex multipronged geopolitical trade-offs. Kennedy (1987) has noted how great powers over the centuries have mismanaged the trade-offs among defense spending, productive investment, and consumer spending. Although policymakers must allocate resources for defense to deter adversaries and for consumption to satisfy basic needs, too much of either type of spending cuts into the long-term investment required for the sustained economic growth that undergirds military capabilities.

Research suggests that policymakers often avoid trade-offs in a host of ways: (1) holding out hope that a dominant option (one superior on all important values) can be found; (2) resorting to dissonance reduction tactics such as bolstering (Festinger, 1964) and belief-system overkill (Jervis, 1976) that create the illusion that one(s preferred policy is superior on all relevant values to all possible alternatives; (3) buckpassing and procrastinating to diffuse responsibility or delay the day of reckoning (Janis & Mann, 1977; Tetlock & Boettger, 1994); and (4) relying on lexicographic decision rules—such as elimination by aspects (Tversky, 1972)—that initially eliminate options that fail to pass some threshold on the most important value and then screen options on less important values (Mintz, 1993; Payne et al., 1992). Whichever avoidance strategy they adopt, policymakers who fail to acknowledge the trade-off structure of their environment can get into serious trouble by slighting one or another set of affected values.

It would be a mistake though to imply that policymakers are oblivious to trade-offs. Although complex trade-off reasoning is rare in public speeches, policymakers may know more than they let be known. Acknowledging trade-offs can be embarrassing. In addition, some policymakers display an awareness of trade-offs even in public pronouncements. Content analysis of the political rhetoric of Gorbachev revealed much sensitivity to the multifaceted trade-offs that had to be made by the Soviet Union had to make if it were to survive, in Gorbachev's words, into the next century in a manner befitting a great power (Tetlock & Boettger, 1989). Gorbachev's career illustrates that holding a complex view of the trade-off structure of one's environment is no guarantee that one will traverse the terrain successfully.

It would also be a mistake to imply that trade-off avoidance invariably leads to disaster. Procrastination is sometimes prudent. An expanding economy or evolving international scene may eliminate the need for trade-offs that sensible people once considered unavoidable. Passing the buck may be an effective way to diffuse blame for policies that inevitably impose losses on constituencies. And simple lexicographic decision rules may yield decisions in many environments that are almost as good as those yielded by more exhaustive, but also exhausting, utility-maximization algorithms.

Framing Effects

Prospect theory asserts that choice is influenced by "framing" (Kahneman & Tversky, 1979). When we de-

scribe a problem as entailing a high probability of gain, people tend to be risk-averse; when we recast the same problem as entailing a high probability of loss, people tend to be risk seeking. This prediction has been supported in numerous experiments (Bazerman, 2005; Tversky & Kahneman, 1981) as well as in case studies of policy decisions (Farnham, 1992; Levy, 1992; McDermott, 1998).

Framing effects can create severe impediments in negotiations (Bazerman, 2005; Jervis, 1989). When negotiators view their own concessions as losses and concessions by their opponent as gains, the subjective value of the former will greatly outweigh that of the latter. Both sides will therefore perceive a "fair" deal to be one in which the opponent makes many more concessions—hardly conducive to reaching agreements. Reactive devaluation makes matters even worse. When both sides distrust each other, concessions by the other side are often minimized for the simple (not inherently invalid) reason that the other side made them (Maoz, Ward, Katz, & Ross, 2004; Ross & Griffin, 1991). For instance, in 1981, President Reagan unveiled his zero-option proposal calling for Soviet dismantling of intermediate-range missiles (SS-20s) in eastern Europe while the United States would refrain from deploying new missiles in western Europe. The Kremlin initially rejected this proposal, but in 1986, the new Soviet leadership embraced it. Gorbachev's concessions stunned many Western observers, who now assumed that the zero option must favor the Soviets because of their conventional superiority and urged the United States to wiggle out of the potential agreement.

As prospect theory in one or another of its variations (Kahneman & Tversky, 2001) has emerged as the leading alternative to expected utility theory, its influence has proliferated throughout international relations. Levy (1992) notes a host of real-world observations on bargaining, deterrence, and the causes of war that are consistent with the spirit of prospect theory: (1) it is easier to defend the status quo than to defend a recent gain; (2) forcing a party to do something ("compellence") is more difficult than preventing a party from doing something (deterrence); (3) conflict is more likely when a state believes that it will suffer losses if it does not fight; (4) superpower intervention will be more likely if the client state is suffering; and (5) states motivated by fear of loss are especially likely to engage in risky escalation.

Although prospect theory fits these observations, much has been lost in translation from the laboratory literature (in which researchers can manipulate the framing and likelihood of outcomes) to historical accounts of world politics (Boettcher, 1995; Tetlock, 1999a). One critical issue for nontautological applications of prospect theory is "renormalization"—the process of adjusting the reference point after losses or gains. McDermott (1998) speculates that decision makers renormalize more rapidly for gains (recent acquisitions quickly become part of their endowment) than for losses (they may grieve for centuries over their setbacks, nurturing irredentist dreams of reconquest). The pressing need remains, however, for valid research methods—such as content analysis of group discussions (Levi & Whyte, 1997)—for determin-

ing when specific actors are in a loss or gain frame of mind. Without such methods, there is a danger of retrospective data fitting, *post hoc ergo propter hoc* reasoning: Because decision makers behaved rashly, we know they must have been in the losses.

To generate predictions from prospect theory (expansively interpreted) about whether decision makers will pursue risky or cautious policies, we need to know what is presently unknowable. For example, if decision makers have recently suffered losses, have they made peace with those losses (incorporated them into new reference points), or do they nurture grudges and dreams of dramatic recovery—as, for example, Hitler did with respect to the Treaty of Versailles? All other things equal, the latter, a loss frame of mind, should be more conducive to risk taking than the former. Conversely, if decision makers have recently enjoyed a string of triumphs, have they incorporated these new acquisitions into their reference point endowment of power, wealth, and status or has the novelty of fresh acquisitions yet to wear off? All other things being equal, the latter "gain" frame of mind, should be much more conducive to caution. But all other things are never equal in the real world. Moreover, much also hinges on decision makers' perceptions of the likelihood of the consequences of alternative courses of action. The probability-weighting function of prospect theory suggests that decision makers will often insure themselves against low-probability losses (risk aversion) and gamble for low-probability gains (risk seeking).

Another critical issue concerns how the risk preferences of individuals are amplified or attenuated by group processes such as diffusion of responsibility, persuasive arguments, cultural norms, and political competition for power (Druckman, 2004; Vertzberger, 1995). This argument reminds us of the need to be vigilant to the ever-shifting dimensions of value on which people may be risk averse or risk seeking. Leaders may suddenly become recklessly obdurate when issues of honor and identity are at stake. Saddam Hussein, just prior to the annihilation of his army in Kuwait, reportedly invoked the old Arab aphorism that "it is better to be a rooster for a day than a chicken for all eternity" (Post, 1991).

Do Psychologists Have Pro-Bias?

Although researchers have emphasized the role of cognitive biases in creating conflicts that might have been avoided had decision makers sized up situations more accurately, it is worth noting that these biases can attenuate as well as exacerbate conflicts. Much depends on the geopolitical circumstances. The fundamental attribution error can alert us to predatory powers; simplistic analogies are sometimes apt; belief perseverance can stop us from abandoning veridical assessments in response to skillful "disinformation" campaigns; and high-risk policies can yield big payoffs. Indeed, efforts to eliminate these "biases" through institutional checks and balances are likely to be resisted by skeptics who argue that such cognitive tendencies are often functional. Consider overconfidence. Some psychologists have made a strong case that when this "bias" takes the form of infectious "can-

do" optimism, it promotes occupational success and mental health (Seligman, 1990; Taylor & Brown, 1988). Moreover, there is the flip-side risk that self-critical thinkers may dilute justifiably confident judgments by heeding irrelevant or specious arguments (Tetlock & Boettger, 1989)—a severe threat to good judgment in environments in which the signal-to-noise ratio is unfavorable and other parties are trying to confuse or deceive the perceiver.

Such arguments strike resonant chords among those in the policy community who stress the dangers of "analysis paralysis" (Tetlock, 2000). Advice that strikes some academic observers as obviously sound strikes some policy elites as obviously flawed. Decision analysts face an uphill battle in convincing skeptics that the benefits of their prescriptions outweigh the costs. Whether or not they acknowledge it, policymakers must decide how to decide (Payne et al., 1992) by balancing the estimated benefits of complex, self-critical analysis against the psychological and political costs. What increments in decision quality is it reasonable to expect from seeking out additional evidence? Some observers see enormous potential improvement (e.g., Herek, Janis, & Huth, 1987; Janis, 1989); others suspect that policymakers are already shrewd cognitive managers skilled at identifying when they have reached the point of diminishing analytical returns (e.g., Suedfeld, 1992). These strong conclusions rest, however, on weak evidentiary foundations. In the spirit of Robert Merton's (1987) observation that the most rapidly advancing sciences are those that are most explicitly specify their domains of ignorance, we are well advised to admit both how poorly experts predict real-world trends and how little we know about the correlates of what systematic variation there is in judgmental accuracy (Tetlock, 2005).

Motivated Biases and Errors

Assumptions of rationality can be challenged not only on "cold" cognitive grounds but also on "hot" motivational grounds. Examples of such challenges arise in the literature on crises (high-pressure settings in which decision making may be driven by the ebb and flow of human emotions), on escalating commitment to sunk costs, and on the impact of deep-rooted personality needs.

Crises

Policymakers rarely have a lot of time to think. They frequently work under stressful conditions in which they must process large amounts of inconsistent information under severe time pressure, always with the knowledge that miscalculations may have serious consequences for both their own careers and vital national interests (Holsti, 1989). This combination of an imperative demand for crucial decisions to be made quickly, with massive information overload, is a form of psychological stress likely to reduce the information-processing capacity of the individuals involved (Suedfeld & Tetlock, 1977).

Both experimental studies and content-analytic studies of archives yield support for this hypothesis. The laboratory literature has repeatedly shown that stress—beyond the inflection point on the inverted-U curve—impairs complex information processing (Streufert & Streufert, 1978; Svenson & Maule, 1994). Impairment can take many forms, including a lower likelihood of discriminating among unfamiliar stimuli, a higher likelihood of relying on simple heuristics, greater reliance on old, now inappropriate, problem-solving strategies, and reduced curiosity in new, potentially dissonant evidence (Janis & Mann, 1977; Staw, Sandelands, & Dutton, 1981).

Archival studies reinforce these pessimistic conclusions, most notably, the work of Suedfeld and colleagues on declining integrative complexity in response to international tension (Koh, Han, & Kim, 2004; Maoz & Shayer, 1987; Raphael, 1982; Suedfeld & Tetlock, 1977). These downward shifts are especially pronounced in crises that culminate in war. It is tempting here to tell a causal story in which crisis-induced stress impairs the capacity to identify viable complex compromises, thereby contributing to the violent outcome. But it is wise to resist temptation until two issues are resolved. First, falling integrative complexity may be a sign not of simplification of mental representations but rather of a self-conscious hardening of bargaining positions. Policymakers may decide to lower their integrative complexity (closing loopholes, eliminating qualifications, denying trade-offs, and disengaging from empathic role taking) as a means of communicating firmness of resolve to adversaries (Tetlock, 1985). Here, we need more studies that trace shifts in integrative complexity in both private and public documents (Guttieri, Wallace, & Suedfeld, 1995; Levi & Tetlock, 1980; Walker & Watson, 1994). Second, there are exceptions to the generalization that high stress produces cognitive simplification. Decision makers have sometimes risen to the challenge and responded to intensely stressful circumstances in thoughtful ways (Brecher, 1993). For instance, during both the Entebbe crisis (Maoz, 1981) and the Six-Day War of 1967 (Stein & Tanter, 1980), Israeli officials managed—despite great stress—to consider numerous options, assess consequences in a probabilistic manner, trade off values, and remain open to dissonant information.

The challenge is identify when crisis-induced stress triggers simplification and rigidification. One approach is to look for quantitative variables that influence where the hypothetical optimum for the effects of stress lies (Streufert & Streufert, 1978). Another approach is to look for qualitative moderator variables that activate simple or complex coping strategies. For instance, the Janis and Mann (1977) conflict model predicts simplification of thought (defensive avoidance) only when decision makers confront a dilemma in which they must choose between two equally unpleasant alternatives and are pessimistic about finding a more palatable alternative in the time available. Under these conditions, decision makers are predicted to choose and bolster one of the options, focusing on its strengths and the other option's weaknesses (thereby spreading the alternatives). By contrast, when decision makers are more optimistic about finding

an acceptable solution in the available time but still perceive serious risks, they will shift into vigilant modes of information processing in which they balance conflicting risks in a reasonably thoughtful way.

Postdecisional Bolstering

Another motivated bias has been identified by research on escalating commitment to sunk costs. Experimental work suggests (Brockner & Rubin, 1985; Staw, 1980; Tetlock, 1992), and case studies corroborate, that policymakers who feel accountable for hard-to-reverse decisions often concentrate more on justifying what they have done than on figuring out what needs to be done next. These exercises in retrospective rationality—whether viewed as dissonance reduction or impression management—tend to be especially intense to the degree that earlier decisions cast doubt on decision makers' integrity or ability.

Situations of this sort—military quagmires such as Vietnams and Afghanistans or financial quagmires such as unpromising World Bank projects with large sunk costs—are common in political life. Indeed, the primary job of opposition parties in democracies is to find fault with the government and to refute the justifications and excuses that the government offers in its defense. The psychodrama becomes politically consequential when it extends beyond verbal sparring at press conferences and begins to bias policy appraisals. After all, if one convinces oneself and others that a bad decision worked out well, it starts to seem reasonable to channel even more resources into the same cause. Such sincerity can be deadly when decision makers must choose among courses of action in international confrontations under the watchful eyes of judgmental domestic constituencies.

Personality Needs

Lasswell (1948) famously defined political behavior as a function of private motives displaced onto public objects and rationalized in terms of the common good. By mixing laboratory and naturalistic methods, researchers have built a rather convincing case for this proposition (Etheredge, 1980; Greenstein, 1975; Herrmann, 1988; Walker, 1983; Winter, 1993).

In their analyses of disagreements among makers of American foreign policy elites between 1898 and 1984 over the use of force, Etheredge (1980) and Shephard (1988) found that policy preferences were closely linked to personality variables. Working from biographical data on personal relationships, coders rated leaders on interpersonal dominance (strong need to have their way and tendency to respond angrily when thwarted) and extroversion (strong need to be in the company of others). As predicted, dominant leaders resorted more to force than their less dominant colleagues and extroverted leaders advocated more conciliatory policies than their more introverted colleagues. Laboratory work suggests causal pathways for these effects, including perceptual mediators (dominant people see high-pressure tactics as more efficacious) and motivational mediators (dominant peo-

ple try to maximize their relative gains over others, like neorealists, whereas less dominant people try to maximize either absolute gains, like neoclassical economists, or joint gains, like good team players) (see Brewer & Kramer, 1985; Sternberg & Soriano, 1984).

In a cumulative series of studies, Winter (1993) adapted the content-analysis systems for assessing motivational imagery in the semiprojective Thematic Apperception Test (TAT) to analyze the private and public statements of world leaders. He has also proposed a psychodynamic conflict-spiral model that posits that combinations of high power motivation and low affiliation motivation encourage resort to force in international relations. Winter tested this prediction against archival materials drawn from several historical crises. In each case, Winter observed the predicted correlations between motives and war versus peace. In another study, Peterson, Winter, and Doty (1994) linked their motive theory to processes of misperception hypothesized to occur in conflict spirals (cf. Kelman & Bloom, 1973). In this integrative model, international conflicts escalate to violence when three conditions are satisfied: (1) there is high power motivation in the leadership of both countries; (2) each side exaggerates the power imagery in messages from the other side; and (3) each side expresses more power motivation in response to its exaggerated perceptions of the other side's power motivation. In ingenious simulations, Peterson and colleagues used letters exchanged in an actual crisis as stimulus materials and showed that subjects with high power motivation were especially likely to see power motivation in communications from the other side and to recommend the use of force.

The motive-imagery explanation is parsimonious. The same content-analytic method yields similar relationships across experimental and archival settings. But the interpretive difficulty is the same as in integrative complexity research: the possibility of spurious multimethod convergence. Political statements cannot be taken as face-value reflections of intrapsychic processes. Leaders use such statements both to express what they think and to influence what others think they think. There are good reasons for supposing that people can strategically raise and lower their integrative complexity (Tetlock, 1981), and it would be astonishing if motivational imagery were not also responsive to shifts in impression management goals.

Group-Induced Biases and Errors

Accountability to colleagues is often trotted out as an all-purpose solution to decision errors; accountability can, however, become intellectually incestuous when policymakers expect to answer only to like-minded colleagues and constituencies. This concentration of accountability to an ingroup is a defining feature of groupthink (Janis, 1982). The combination of opinionated leadership, insulation from external critics, and intolerance of dissent often appears sufficient to amplify already dangerous tendencies in individual judgment. Groupthink decision makers are more prone to

jump to premature conclusions, to dismiss contradictory evidence, to deny trade-offs, to bolster preferred options, to suppress dissent within the group, and to display excessive optimism.

Janis's case studies are the best-known effort to apply work on group dynamics to elite political settings. The groupthink model does, however, have serious limitations (t'Hart, Stern, & Sundelius, 1995). First, the evidence—from case studies to experiments—is mixed. Close inspection of case studies underscores the ambiguity of many diagnoses of (groupthink(in foreign policy contexts. For example, comparing Berman's (1982) and Janis's (1982) accounts of Johnson's decision to intervene in Vietnam, one needs to be a mindreader to determine whether (1) a manipulative Johnson had made up his mind in advance and used group deliberations merely to justify a predetermined policy; or (2) an uncertain Johnson leaned heavily on a cliquish advisory group for cognitive and emotional support. Also mixed is the content-analytic and Q-sort evidence (Tetlock, 1979; Tetlock, Peterson, McGuire, Feld, & Chang, 1992; Walker & Watson, 1994). These studies support some aspects of the model (rigidity and self-righteousness in hypothesized cases of groupthink) but not others (there is little evidence that cohesiveness alone or in interaction with other antecedents contributes to defective decision making). And laboratory studies have been even less supportive of the hypothesized preconditions for defective decision making (Aldag & Fuller, 1993; Turner, Pratkanis, Probasco, & Love, 1992)—although defenders of the model can always invoke the external-validity argument that experimental simulations pale next to their dramatic real-life counterparts.

Second, the groupthink model oversimplifies process-outcome linkages (Tetlock, Peterson, McGuire, Feld, & Chang, 1992; t'Hart, 1994). It is easy to identify cases in which concurrence seeking has been associated with outcomes that most observers now applaud (e.g., Churchill's suppression of dissent in cabinet meetings in 1940–1941, when some ministers flirted with the now unthinkable: a negotiated peace with Hitler) and cases in which vigilant decision making has been associated with outcomes that left group members bitterly disappointed (e.g., Carter encouraged rather vigorous debate over the wisdom of the hostage-rescue mission in Iran in 1980, even though the Secretary of State was eventually shunted out of the loop). The correlation between quality of process and of outcome was perfectly positive in Janis's (1982) carefully chosen case studies and positive correlations can be engineered to hold lab settings (Postmes, Spears, & Cihangir, 2001), but it is likely to slip in representative samplings of naturally occurring decision-making episodes (Bovens & t'Hart, 1996). We need contingency theories that identify (1) the distinctive patterns of group decision making that lead, under specified circumstances, to political success or failure (t'Hart et al., 1995; Vertzberger, 1995); and (2) the diverse functions that leadership groups serve. Groups do not just exist to solve external problems; they provide symbolic arenas in which bureaucratic and political conflicts can be expressed, support for shared values reaffirmed, and potentially divisive trade-offs concealed

(t'Hart et al., 1995). As with cognitive biases (Tetlock, 2002), patterns of group decision making judged maladaptive within a functionalist framework that stresses analytic problem solving appear reasonable within frameworks that stress other imperatives, such as acting decisively, forging a united front and mobilizing external support. At the risk of sounding repetitiously relativistic, much hinges on the value perspective of the scientific observer. Does the observer deem these alternative functions "good reasons"?

ATTRIBUTIONS OF EXCESSIVE COMPETITIVENESS, EVEN BELLICOSITY

The reductionist syllogism here rests on the first-order principle that laboratory and field studies have already taught us a great deal about the factors that promote or impede successful negotiation and conflict resolution at the interpersonal level (Bazerman, 2005; Kleiboer, 1996; Pruitt, 1998; Pruitt & Rubin, 1986; Thompson, 1990). The minor premise asserts process invariance: the same basic psychological processes at work in the interpersonal sphere drive international relations. It follows that explanatory frameworks developed at the microlevel can be readily applied at the macrolevel.

Many international relations scholars are not convinced. The most influential theory within this discipline remains some variant of deterrence theory (Schelling, 1966). Although deterrence theory comes in many forms (from thoughtful prose to game-theoretic models), it rests on a clear set of alternative first-order principles—principles for which prominent political psychologists have not concealed their disdain (Deutsch, 1983; White, 1984), even characterizing them as paranoid (Mack, 1985). First, the world is posited to be a dangerous place. Opportunistic opponents will seize every chance to expand their influence at one's expense. Whenever the expected utility of defecting or attacking exceeds that of other options, the risk of defection or aggression rises to an unacceptably high level. It follows that to deter defection or aggression—be it in a trade or military dispute—one must issue retaliatory threats that convince one's opponent that the expected utility of defection or aggression is lower than that of the status quo. Deterrent threats must therefore be potent and credible. Would-be aggressors must believe that the defender possesses the resolve and capability to implement the threat.

Deterrence theorists accept these principles in the abstract but disagree vigorously over how to implement them in policy. During the Cold War, for instance, some argued that in a MAD world, nuclear weapons could deter attacks only on one's territory whereas others argued that nuclear threats could also deter attacks on allies. More recently, deterrence theorists have split over the wisdom of launching preemptive attacks on countries suspected of providing havens for terrorists or developing weapons of mass destruction.

Any serious evaluation of deterrence theory must grapple with the deep problems of determining from the historical record whether deterrence actually worked

(Danilovic, 2004). To be sure, dramatic failures of deterrence as a policy are easy to identify. One country sought to prevent an attack on another, but the attack occurred nonetheless. The historical data are, however, sufficiently ambiguous to allow endless arguments over whether individual cases also represent failures of deterrence theory (as opposed to failures of implementation). An equally imposing obstacle is presented by alleged deterrence successes. When crises do not occur, is it because of the credibility of threats (successes for deterrence theory) or because other states never intended to attack in the first place? Causal inference requires assumptions about what would have happened in the missing counterfactuals cells in the contingency table in which the defender issued no threats. Research on counterfactual reasoning shows that the dominant tendency among sophisticated observers is to plug in ideological assumptions about what would have happened into the missing data cells. Moreover, this tendency is especially pronounced among observers who have high needs for closure (Tetlock, 2005) and a preference for integratively simple reasoning (Suedfeld & Tetlock, 2001).

These issues are of more than idle intellectual interest. The same policy elites who disagreed over the role that strong deterrence threats played in ending the Cold War also disagreed over the wisdom of dislodging Iraq from Kuwait in 1991 and of invading Iraq in 2003 and of using military threats to induce North Korea to abandon its nuclear weapons program. The hawk–dove personality distinction is fundamental in all debates over the use of force (Etheredge, 1980; Herrmann, Tetlock, & Visser, 1999).

One way out of this impasse is to turn to the laboratory literature on bargaining and negotiation for guidance on the relative utility of threats versus other influence tactics. This literature suggests that deterrence theory needs to be seriously qualified. For instance, laboratory studies of bargaining showed long ago that threats can impede cooperation and lower joint outcomes by triggering anger, competitiveness, and reactance (Deutsch, 1983; Kelley, 1965). And work on negotiation processes suggests a rather pervasive tendency for people, especially those in competitive mindsets or under accountability pressure from key constituencies, to exaggerate the zero-sum character of disputes (the fixed-pie fallacy; Bazerman, 2005; Thompson, 1990) and to overlook positive-sum integrative solutions (Pruitt, 1998).

The obvious alternative to threats of punishment is promises of reward. But, since Munich gave appeasement a bad name, scholars have slighted the role of positive inducements. The most outspoken proponents of positive inducements have been conflict-spiral theorists who warn of escalating action–reaction cycles in international conflict (Deutsch, 1983; White, 1984). And even these theorists have not advocated unilateral disarmament—and for good reason: Experimental evidence indicates that in mixed-motive games, such as Prisoner's Dilemma, unconditional cooperation is ruthlessly exploited (McClintok, Stech, & Beggan, 1987). Archival work on international disputes points to similar conclu-

sion: Nations adopting an appeasement strategy managed to avoid war but almost always suffered a diplomatic defeat (Leng, 1993). Positive inducements such as financial rewards for compliance can also be very expensive if the other side complies (particularly if it quickly becomes satiated and increases its demands for compensation) and they can foster unwanted dependency and a sense of entitlement. Finally, just as deterrence theorists face difficulties in operationalizing threats, so "reward" theorists encounter problems in operationalizing positive inducements, which may be perceived as condescending, presumptuous, manipulative, or insultingly small or large (Patchen, 1987).

The most attractive options appear to be mixed-influence strategies. Inspired by Robert Axelrod's (1984) "the evolution of cooperation," many researchers have focused on firm but fair strategies of resolving conflicts. The most famous is tit-for-tat. One begins by cooperating and thereafter repeats one's opponent's previous move. Although there are boundary conditions on the efficacy of tit-for-tat (e.g., misperception of intent behind moves can wreak havoc; Bendor, 2001), considerable research demonstrates that tit-for-tat is as effective as it is simple. In Axelrod's round-robin Prisoner's Dilemma computer tournaments that pitted expert nominated strategies against one another, tit-for-tat—the simplest entrant— earned the highest average number of points. Axelrod argued that tit-for-tat works because it is nice (never defects first), perceptive (quickly discerns the intent of the other), clear (easy for the other side to recognize), easily provoked (quickly retaliates), forgiving (willing to abandon defection immediately after the other side's first cooperative act), and patient (willing to persevere). Numerous archival studies have also shown that strategies of a tit-for-tat character tend to be more effective than either pure threat or pure appeasement strategies in averting both war and diplomatic defeat (Leng, 1993).

One could also argue that one of psychology's most ambitious contributions to the policy debate, Charles Osgood's graduated and reciprocated initiatives in tension reduction (GRIT) is much in the spirit of tit-for-tat (Lindskold, 1978; Patchen, 1987). Both are designed to resist exploitation and to shift the interaction onto a mutually beneficial, cooperative plane. Unlike tit-for-tat, however, GRIT does not assume that the game has yet to begin. Rather, GRIT assumes that the parties are already trapped in a costly conflict spiral. To unwind the spiral, Osgood proposed that one side should announce its intention to reduce tensions and then back up its talk with unilateral conciliatory gestures. These actions are designed to convince the opponent of the initiator's peaceful intentions but not to weaken the military or economic position of the initiator. The opponent is then invited to respond with conciliatory gestures but warned that attempts to exploit the situation will force the initiator to return to a hardline posture. GRIT is a softer, more liberal brand of tit-for-tat: It is nicer (it cooperates even in the face of defection) and less easily provoked (it continues to cooperate even when the opponent ignores what one has done. A good deal of evidence suggests that GRIT stimulates cooperation. The most cumulative ex-

perimental program—that of Lindskold (1978)—has repeatedly shown that GRIT leads to more integrative agreements than do competitive and no-message strategies and, moreover, that GRIT elicits more cooperation when initiated from a position of strength than from one of weakness (a finding that could be invoked as support for a mixed hawk–dove strategy of defense buildup as prelude to GRIT).

In sum, any policy-relevant conclusions we draw should be complex and tentative ones. An exclusive deterrence-based emphasis on threats can trigger otherwise avoidable conflicts. But so too can calls for unilateral disarmament, albeit via a different mechanism—by tempting aggressors. Encouraging, though, is the multimethod convergence suggesting that in many situations variants of a firm but fair strategy does a good job of both protecting vital interests and preventing conflicts from spiraling out of control. The challenge is translating this abstract causal principle into normative prescriptions in specific conflicts. There will always be a big element of guesswork in figuring out the optimal policy blend for dealing with specific régimes, and this will be especially true in dealing with régimes that we find profoundly alien in their practices and values (witness the old debates over Cold War strategy (Tetlock, McGuire, & Mitchell, 1991) as well as more recent debates over dealing with Islamic suicide attacks or with the North Korean nuclear program).

ATTRIBUTIONS OF SIMPLE-MINDEDNESS, DOGMATISM, AND RIGIDITY

Since the pioneering work on the authoritarian personality (Adorno, Frenkel-Brunswick, Levinson, & Sanford, 1950), psychologists have taken an active interest in treating political beliefs as dependent variables. The reductionist syllogism here rests on the first-order principle that all attitudes serve shifting blends of basic psychological functions: appraising reality, claiming social identities, preserving self-esteem motives, and expressing core values (Smith, Bruner, & White, 1956). The minor premise is that political attitudes are, by definition, attitudes. The conclusion is that functionalist psychological theories can help us to explain political attitudes.

The most influential functionalist hypotheses have posited that conservative beliefs tend to be especially rigid and dismissive of counterarguments because such beliefs help holders to (1) cope with unresolved childhood conflicts by identifying with esteemed authority figures; (2) suppress complexity and ambiguity by squeezing reality into procrustean categorization schemes; and (3) adjust to the intolerant norms of their community (cf. Altemeyer, 1996; Lane, 1973).

For over 50 years now, researchers have explored these conjectured linkages between cognitive styles and political ideology, between how people think and what people believe. This work has used a wide range of methods—ranging from self-report scales to content analyses of interviews and speeches—and has explored a wide range of samples—from college undergraduates to politi-cal activists to British parliamentarians and U.S. senators (Putnam, 1988; Stone, 1980; Tetlock, 1984).

A recent meta-analysis of this literature has sparked controversy by concluding that right-wing conservatism is related to dogmatism and intolerance of ambiguity; uncertainty avoidance; fear of threat, loss, and death; system instability; and epistemic needs to achieve order, structure, and closure as well as negatively related to openness to experience, integrative complexity, and (to a lesser extent) self-esteem (Jost, Glaser, Kruglanski, & Sulloway, 2003a, 2003b). The authors do, though, add a critical caveat: This does not mean that liberals crave uncertainty and risk. There can be rigidity of the left as well as of the right. Their claim is simply that rigidity of the left is markedly less common than that on the right.

Greenberg and Jonas (2003) challenge the meta-analysis on a mixture of empirical and conceptual grounds. They see far more exceptions to the rigidity-of-the-right hypothesis than do Jost and colleagues (2003a). For instance, Tetlock (1984)—drawing on Putnam's (1973) dataset on British parliamentarians—found support for the ideologue hypothesis: Hard-core socialists within the British Labor Party were as prone to dichotomous reasoning as hard-core conservatives. Greenberg and Jonas also point to Tetlock and Boettger (1989), who found, by content-analyzing statements by Soviet Politburo members, that more orthodox communists were less integratively complex than the reformist, pro-Gorbachev, Politburo members. These findings underscore the definitional ambiguity shrouding the concept of conservatism: Do hard-core "lefties" in the British Labor Party count as radicals or "conservative" upholders of the Party tradition? And do hard-line Soviet Communists in the late 1980s count as Bolshevik radicals or as conservative restorationists?

If we opt for the latter interpretations, it is easy to assimilate the Parliamentary and Politburo data to the Jost and colleagues (2003a) preference for the rigidity-of-the-right hypothesis (Tetlock, 1984). But Greenberg and Jonas also challenge definitions of conservatism that emphasize commitment to upholding the status quo. When the status quo is welfare-state liberalism or social democracy, conservatives can plausibly be portrayed—and sometimes are by adversaries—as radicals who want to change basic institutions: advocating the abolition of affirmative action, widespread privatization of state-controlled sectors of the economy, deregulation of business, and implementing dramatic cuts in taxation. Jost and colleagues (2003b) reply that these conservative positions should be viewed as reactionary efforts to preserve long-standing patterns of group dominance. This controversy also underscores the definitional murkiness of the ideology/cognitive style debate. The Mertonian injunction to specify scientific ignorance requires conceding that neither Jost and colleagues (2003a) nor Greenberg and Jonas (2003) have evidentiary warrant for claiming to know why "conservatives"—far from a homogeneous group—take the policy positions they do.

In a contextualist spirit, Tetlock and Mitchell (1993) proposed a taxonomy of flattering and unflattering cognitive and motivational portraits of liberalism and con-

servatism—each almost certainly true at particular times and places. Jost and colleagues (2003) favor one of the less flattering motivational possibilities: the desire to preserve the existing hierarchy of group dominance. Greenberg and Jonas (2003) flirt with the more flattering possibility that conservatives believe that the long-term well-being of society could be promoted by market mechanisms that stimulate economic growth and technological innovation.

These possibilities are, however, neither exclusive nor exhaustive. One could be a committed opponent of wealth-redistribution schemes that most liberals feel are essential for achieving equality of opportunity and a committed proponent of free-market economics—and view the two positions as mutually reinforcing. It is also worth noting that either of the two belief sets could play the role of independent or dependent variable vis-à-vis the other. And one could come to a conservative worldview via a variety of other cognitive-emotional paths, including—among other possibilities listed in Tetlock and Mitchell (1993)—a prospect-theory-grounded aversion to takings (imposing losses on those who are better off and transferring income to those worse off; Mitchell et al., 2003), a belief in the debilitating effects of generous welfare and entitlement programs, and a pessimistic view of human nature that leads one to suspect the readiness of others to exploit weakness and loopholes. Finally, there is evidence—certainly at the elite level and possibly at the level of the mass public as well—that conservatism is a multidimensional construct and that, at minimum, we need to distinguish more authoritarian from more libertarian conservatives (Kinder, 1998).

There are, however, potential methodological paths out of this scientific morass. One route is via hypothetical society paradigms that, artificial though they are, bring some causal clarity (Mitchell, Tetlock, Mellers, & Ordonez, 1993; Mitchell et al., 2003). In the real political world, there is a hopeless confounding of conservative beliefs about how meritocratic society is (answers to "why are the poor so poor and the rich so rich?") and conservative resistance to redistribution of wealth. It could be that conservative beliefs about meritocracy are merely justifications for maintaining existing hierarchies. Or, it could be that conservatives endorse existing patterns of group dominance because they honestly believe that society operates in a reasonably meritocratic fashion. Mitchell and colleagues (2003) cannot cut this Gordian Knot but they can show that when people are experimentally led to believe that socioeconomic status is determined purely by chance (zero meritocracy) or determined entirely by effort and ability (100% meritocracy), liberals and conservatives respond remarkably similarly to proposals to redistribute wealth. Both tend to support redistribution in the zero-meritocracy society and oppose it in the perfect meritocratic society. It was only in the ambiguous 50/50 world, where socioeconomic outcomes are partly determined by chance and partly by personal qualities, that pronounced ideological polarization emerged, with conservatives more opposed to redistri-

bution and liberals more supportive. Beliefs about meritocracy thus have some independent causal force.

In addition to clarifying causal relations among content components of belief systems, experiments can explore cognitive content/cognitive style linkages more effectively than the traditional reliance on psychometric approaches. On the one hand, researchers have shown that they can—via manipulations such as sociotropic threat and mortality salience—influence the conservatism of the policy preferences that people endorse (in particular, the punitiveness of their responses to norm violations (Gibson, 2006; Greenberg, Solomon, & Pyszczynski, 1991; Tetlock et al., in press). On the other hand, it is also possible to manipulate the flexibility and complexity of the reasoning that underlies policy preferences. This can be done, for example, by varying the degree to which issues bring core values into conflict, thus shifting the cognitive-dissonance-predicted preference of people for low-effort strategies of resolving intrapsychic conflict (such as denial and bolstering) toward more effort-demanding strategies (such as differentiation and integration) (Abelson, 1959; Tetlock, 1986). Neither the explanans (cognitive style) nor the explanandum (ideology) in the dispute between Jost and colleagues (2003a, 2003b) and Greenberg and Jonas (2003) is a static trait entity. Each has a dynamic component that permits it to vary across contexts, issues, and time. There are settings in which the linkages between cognitive style and ideology are powerful and in the direction posited by Jost and colleagues (e.g., McClosky, 1967; Tetlock, 1983) and other settings in which the relationships vanish (Gruenfeld, 1995; Tetlock, 1986, 2005). Much hinges on the issues under examination (some value-conflict problems "pull" more complex thinking from liberals; others "pull" more complex thinking from conservatives) (Tetlock, Peterson, & Lerner, 1996), the political balance of power (liberals cease to be more integratively complex than conservatives when liberals lose majority control of Congress) (Tetlock, Hannum, & Micheletti, 1984), and the range of views within the sample (if one goes far enough to the left, one finds a fierce contempt for alternative views that rivals anything found on the right) (Tetlock, 2005).

All that said, it is noteworthy that although the main effect revealed in the Jost and colleagues (2003a, 2003b). meta-analysis can be neutralized, it never seems to reverse direction so that, across issues, conservatives as a group score as more flexible and multidimensional than liberals. But should this result be disturbing to conservatives? Much hinges on the value spin that scientific observers put on the facts: the correlations between our measures of cognitive styles and of political orientations.

There is a common presumption in academic circles that complexity of thought is inherently superior—both as a means to ends and as an end in itself—to simplicity. Many conservatives, however, take issue with this value-laden premise: They subscribe to a different set of epistemological and moral ideals from those upheld by liberals. Tetlock (2000) found that conservative and libertarian business executives were more likely than their lib-

eral counterparts to rise to the defense of judgmental biases such as overconfidence (essential for getting things done and avoiding the analysis–paralysis trap), the fundamental attribution error (essential for communicating to employees that one has limited tolerance for situational justifications and excuses), and the severity effect (essential for motivating people to try to exert more control over the possible accidental consequences of acts of negligence; Tetlock et al., in press). Indeed, there are also settings in which liberal observers favor the integratively simple side of historical debates over the integratively complex side. For instance, Tetlock and Tyler (1996) demonstrated that Churchill used substantially less complex rhetoric to justify his antiappeasement policy stance toward Nazi Germany than did Chamberlain to justify his policy of identifying an integrative, mutually beneficial set of understandings with Hitler (although Churchill quickly loses liberal sympathy when the debate shifts to self-government for India and Churchill takes colonialist positions widely deplored as reactionary, even racist, today). Tetlock, Armor, and Peterson (1994) showed that, when one examines patterns of argumentation in antebellum America (1850s), one finds the least tolerance for trade-offs and willingness to acknowledge the legitimacy of alternative perspectives on both the extreme left (abolitionists) and right (Southern secessionists). The extreme left of that time and place are now widely portrayed as principled, not dogmatic. More generally, Tetlock (1986; Tetlock et al., 1996) showed that it is dangerous to make sweeping generalizations about immutable tendencies of one or another group to think in a particular fashion. Ideology-by-issue interactions in flexible trade-off reasoning are quite common. Much hinges on the degree to which an issue domain activates countervailing values. The value pluralism model, for instance, predicts that integrative complexity peaks when a policy problem activates two values that are approximately equally important, that point in opposite policy directions, and when the social context closes the door to buck passing and procrastination.

In this author's view, political psychology needs more disagreements of the sort represented in the exchange between Jost and colleagues and Greenberg and Jonas. The net result was clarification. Jost and colleagues (2003) close on a fittingly undogmatic note:

> To be clear, we never argued that it is intrinsically good to be tolerant of uncertainty or ambiguity, low on the need for cognitive closure, or even high in cognitive complexity. In many cases, including mass politics, "liberal" traits may be liabilities and being intolerant of ambiguity, high on the need for closure, or low in cognitive complexity might be associated with such generally valued characteristics as personal commitment and unwavering loyalty. (p. 374)

CONCLUDING THOUGHTS

It is a mistake to dismiss political psychology as just another applied subfield in which we can safely assume that the first-order, cognitive and affective principles developed elsewhere in this volume apply with no need for modification. But it is also a mistake to conclude that political psychology is lawless, that its scare-quote-bracketed "truths" are totally contingent upon the quirky cultural–historical contexts in which we find ourselves ideologically embedded. There are principles of political psychology. It is just that those principles are inherently more complex than those in mainstream social psychology. Political psychological principles require taking into simultaneous account the social psychology of the research participants and the political priorities and labeling rules of the researchers. Let us revisit each of the four lines of work featured in this chapter:

1. Prejudice toward outgroup members is a widespread phenomenon for an assortment of basic process, cognitive and affective reasons (Brewer & Brown, 1998). But the decision to label an attitude, implicit or explicit, a manifestation of prejudice is a politically charged one that reflects the prevailing norms and values of the research community. And that decision, in turn, is a lawful phenomenon, driven by a mixture of factual beliefs and value priorities—and subject to systematic modeling that uses conceptual tools such as signal detection and decision theory. How do researchers judge the risk of under- versus overestimating the tenacity of prejudice in shifting political environments? How do they weigh the clashing risks?

2. Cognitive biases—deviations from academic norms of rationality—reach into many spheres of life. But the decision of a researcher to label a point of view biased is a politically charged one that reflects value-laden assumptions about the goals that political actors should be pursuing in particular situations as well as extrapsychological assumptions about the world with which they are struggling to cope. And that decision, in turn, merits political–psychological analysis in its own right. For instance, how do researchers go about judging the relative risks of overconfidence versus underconfidence, of persisting too long with failing policies or prematurely abandoning fundamentally sound policies at the first sign of trouble, and so on?

3. Negotiation blunders are not unusual (Bazerman, 2005) and advocates of the fixed-pie fallacy argument may well be right that the more common error is to be excessively suspicious and competitive and to fail to ferret out integrative agreements (Thompson, 2005). But negotiators can also make the opposite mistake of trusting the untrustworthy. Claims about errors in international negotiation strategies rest on speculative leaps of faith about the researcher's superior ability to read the true intentions of other players. Is it not scientific hubris—even 20 years later—to claim to know whether Kelman (1983) offered a correct political–psychological assessment of Yasser Arafat as a negotiating partner, or whether White (1984) had an accurate read on the mindset of the Soviet Politburo?

4. Conservatives do seem to have different cognitive styles from liberals. But we know, from classic work on

implicit personality theory (Peabody, 1967), that it is easy to reverse the positive or negative connotative spins on the opposing ends of virtually any denotative personality dimension. Risk seekers may be bold or rash; risk avoiders may be cautious or timid. The big question thus remains: Under what conditions should the research community decide that the greater conservative affinity for simpler worldviews, with clear-cut good and bad guys, is a cognitive liability (a sign of rigidity, dogmatism, ignorance, ethnocentrism, etc.) or a cognitive strength (a sign of principled conviction, determination, resolve, decisiveness, etc.)?

The first-order principles of political psychology may well eventually prove quite similar to those of mainstream social psychology, with the important proviso that mainstream work needs to recognize boundary conditions highlighted by independent variables operating in political settings: game-theory pressures to keep up with the competition; role-theory and accountability pressures to take alternative perspectives into consideration; and the impact of periodic dramatic crises (Tetlock, 1998). Political actors are indeed human beings subject to the same basic process laws as ordinary mortals. But the second-order principles of political psychology will prove unsettlingly self-referential to the research community, requiring rigorous scrutiny of how its own ideological preconceptions and values shape its standards of evidence and proof for making pronouncements of irrationality or prejudice or miscalculation. Mapping political psychological principles will require understanding the workings of the minds not just of the research participants but also of the scientific observers. Our ability to rise to that challenge, without getting sucked into a tendentious infinite regress of impugning each other's motives, will ultimately determine the scientific viability of this intellectual enterprise.

CHAPTER 40

Organizational Behavior

LEIGH THOMPSON
JO-ELLEN POZNER

Organizational behavior (OB) is the study of how people think, feel, and act in organizations and similarly, how they are affected by the activities within organizations. OB is interested in the behavior of people embedded in specific contexts of organizational systems. Within this definition, there are three important levels of analysis that guide the field: the individual, the team, and the organization. Not surprisingly, OB has much in common with social psychology; however, the context of application—the organizational environment—is much more defined than it is in social psychology.

In this chapter, we highlight the key themes and principles that guide the study of OB, paying particular attention to the ways in which OB has been influenced by social psychology. We organize our chapter around the three key levels of analysis that undergird the study of OB. The first level of analysis within OB is that of the organizational actor as an independent decision maker or leader. Within this section, we focus on decision making, psychological contracts, justice and fairness, and, of course, leadership. We appreciate that all the concepts just listed do not occur in a social vacuum and therefore might very well occur in the context of teams and decision making in organizations; what is common among these phenomena, however, is that they are considered properties or characteristics of the organizational actor.

A second level of analysis considers the organizational actor as a team member. Within this section, we delve into perhaps what is considered to be the fundamental building block of most organizations and companies: the team. We are careful to draw a clear distinction between groups as they are commonly studied in the social psychology literature and teams as they are studied in the OB literature. In this section, we analyze the key processes of negotiation and teamwork. A final level of analysis is that of the organization in which actors are embedded. More than any other section, this is where social psychology and organizational behavior often part company.

Threaded throughout our discussion of these key themes in organizational behavior, we articulate the two key considerations facing the OB researcher: methodology and application. In terms of methodology, we argue that in contrast to social psychology, wherein there is near universal agreement that the laboratory method is necessary and (perhaps) sufficient, that considerably more methodological variety exists in OB. Accordingly, we are careful to point domains in which field researchers have placed a "flag" and domains in which lab researchers have claimed territory. In some cases, the subject matter necessitates a field study (e.g., organizational downsizing, social networks, and, often, leadership). In terms of application, we argue that in contrast to social psychology, wherein application is often an afterthought, it is a crucial consideration in organizational behavior research. Thoughtful application of principles of OB requires careful consideration of the realities of organizational life, including cost–benefit analysis, reorganization, globalization, and industry developments.

We conclude by considering the future of OB. To that end, we review some of the topics and themes that do not fit neatly into the aforementioned basic processes. We

suggest that in the future, OB will grow more divergent from social psychology, and we explain why we make this prediction using both theory and paradigmatic logic.

THE ORGANIZATIONAL ACTOR AS INDEPENDENT THINKER AND DECISION MAKER

The fundamental unit of analysis in OB, like social psychology, is the individual. Whereas OB privileges individual cognition, emotion, and behavior, it pays particular attention to the social and organizational contexts in which they are situated, as well as the consequences of those contexts on social life and social interaction.

One well-developed and highly influential area of research is individual decision making, which is inspired by the seminal work of Kahneman and Tversky (1979). Another important area of OB research is procedural justice—people's reaction to events based on their perceptions of the fairness of relevant processes and outcomes—as well as the behavioral consequences that follow. Finally, OB is interested in how individuals as leaders can understand and manage the cognitive and emotional reactions of their subordinates; thus we also review several theories on leadership.

Decision Making

Within the topic of decision making, there are three identifiable streams of research, including (1) flawed and biased decision making; (2) justification processes and pressures; and (3) organizational boundary effects.

Flawed and Biased Decision Making

This area of research in OB is a direct descendant of the seminal research of March and Simon (1958, 1993) and Kahneman and Tversky (1979). The fundamental theme is that organizational decision makers, despite being intelligent and presumably motivated by noble and benevolent reasons, are hopelessly victimized by their own nonrational thought processes (for an overview, see Bazerman, 2006). Consequently, although decisions often deviate from what is strictly rational, according to economists, they are somewhat predictable in light of OB decision-making research.

BEHAVIORAL DECISION RESEARCH TRADITION

With their seminal publication, *Judgment under Uncertainty: Heuristics and Biases*, Kahneman, Slovic, and Tversky (1982) changed the future of management and psychology by ushering in an era of experimental research on descriptive biases. Their book neatly outlined seven types of biases, including representativeness, causality and attribution, availability, covariation and control, overconfidence, multistage evaluation, and risk perception that served as the stage for the next 20 years of research on bias. Whereas bias approach primarily focused on cognitive biases for several years (availability

heuristic, representativeness heuristic, anchoring heuristic, framing bias, endowment effects, etc.), more recent treatments of bias implicate human motivation as a primary source of bias. Examples of biases that have a motivational core include the positive illusion bias, self-serving bias, and judgments that are affected by mood (for a review, see Bazerman, 2006).

The metaphor of the hopelessly "biased" decision maker within micro-organizational behavior has almost exclusively been applied to the individual. Moreover, the great body of research in micro-organizational behavior has relied on the individual as the fundamental unit of analysis. For example, Bazerman's (2006) sixth edition of his book, *Judgment in Managerial Decision Making*, nearly exclusively relies on the individual manager as the source of bias in organizational decision making. However, among macro-organizational theorists, bias occurs at the level of the organization.

BOUNDED RATIONALITY

The concept of bounded rationality was proposed by Herbert Simon (1947) and developed by the Carnegie School (Cohen, March, & Olsen, 1972; Cyert & March, 1963; March, 1962; March & Simon, 1958). Simon's fundamental insight is that the extent to which decision making can be rational is limited, or "bounded," by the fact that decision makers never have access to all the information they need about their alternatives or the consequences of any given decision. Actors therefore satisfice, rather than optimize, and focus their limited attention on a small, rather than expansive, range of issues, which are generally more salient to themselves. Because the situationally and structurally determined attention structures within an organization (Ocasio, 1997) lead the actor to focus on a unique set of issues, which often conflict with those of other actors, and because of the interdependence inherent within organizations, actors are forced to seek coalitions to achieve their goals (March, 1962). Arguing that information-processing capabilities prevent individuals from behaving perfectly rationally, the Carnegie School built a behavioral theory of the firm, dubbed the "garbage can model" of organizational choice.

GARBAGE CAN MODEL

An important implication of bounded rationality at the individual level is that organizational decision making—the outcome of many interdependent individual decisions—cannot itself be rational. Cyert and March (1963) sought to analyze ambiguous behaviors, or behavior that appears to contradict classical theory, at the organizational level. Underlying the garbage can model is the understanding that, when aggregated, bounded rationality leads to extremely uncertain decision environments, where it is impossible to employ classical decision theory.

In addition to bounded rationality, the presence of political coalitions of organizational subunits, conflicting goals, problematic preferences (i.e., the organization as a whole does not have a clear preference ordering), un-

clear technology (i.e., organizational processes are not fully understood by all participants), and fluid participation (i.e., sequential and selective attention to issues leads to different actors being involved in decisions over time) characterize the organizational decision-making environment, which can be termed "organized anarchy" (Cohen et al., 1972). Organizational choice is therefore the result of unique and somewhat unpredictable combinations of problems and solutions facing unique combinations of decision makers at a given point in time. Problems and choices are therefore partially decoupled from one another, and decisions are made only when the combination of problems, solutions, and decision makers facilitates action (Cohen et al., 1972; Cohen, March, & Olsen, 1976; March & Olsen, 1976). Grounded in theory as well as in field studies and computer simulations, the garbage can model and the Carnegie School represent a rich tradition in organizational behavior, which has influenced a wide array of literatures, from more microlevel views of decision making to the study of groups, learning, power, and leadership.

Justification Processes and Pressures

Accountability is generally assumed to have a positive effect on the quality of decision making. Tetlock's (1983) theory of accountability suggests that the decision maker who was effectively responsible for her decision would be more vigilant than the decision maker who was under no particular pressure to justify a decision. In a series of investigations, Tetlock and his colleagues (Tetlock, 1985; Tetlock & Kim, 1987) manipulated accountability, typically by informing decision makers at the outset of a judgment task that they would have to present their findings to a panel of experts or be otherwise reviewed and evaluated. Under such accountability conditions, decision makers were more accurate (Tetlock, 1985; Tetlock & Kim, 1987) and took longer to make decisions than when not under accountability pressure.

Tetlock distinguished different types of accountability, most notably process accountability (the extent to which a person or group must answer questions about how they came to a decision) and outcome accountability (the extent to which a person or group must account for the outcome or conclusion of their decision). Tetlock reasoned that process accountability was more effective than was outcome accountability in producing better decisions. Outcome accountability might lead a decision maker to arrive at a decision that would meet the approval of the organization; process accountability, on the other hand, presumably motivates decision makers to review the evidence without regard for the outcome that it might suggest.

Organizational Boundary Issues That Shape Decision Making

In recent years, the study of decision making has become decidedly more informed by an understanding of the organizational actor's relationship to the company.

INSIDER VERSUS OUTSIDER VIEWS

Kahneman and Lovallo (1993) suggest that organizational decision makers have a strong tendency to consider the organizational problems they face as unique, when in fact problems in organizations reoccur with some regularity. Managers tend to view current problems in isolation, while discounting or neglecting past experience and statistics, which might in fact be helpful in evaluating current decisions. Kahneman and Lovallo refer to this tendency to forget the past as an "insider view" of problems, which anchors predictions about the future on plans and scenarios. Kahneman and Lovallo argue that decision makers should adopt an "outsider view" of problems, which would bring relevant data and information to bear, and allow the decision maker to disassociate him- or herself from a problem.

KNOWLEDGE VALUATION

Menon and her colleagues (Menon & Blount, 2003; Menon, Choi, & Thompson, 2005; Menon & Pfeffer, 2003) find that decision makers' valuations of knowledge affecting their decision making are highly influenced by whether the information is perceived to emanate from organizational insiders or outsiders. Whereas traditional group research in social psychology posits a near law-like ingroup favoritism effect, Menon argues that within the organization, actors battle for status and distinctiveness (see also Sutton & Hargadon, 1996), making the use of knowledge contributed by an insider tantamount to career suicide. In controlled, empirical investigations of insider versus outsider knowledge, Menon finds that people tend to ignore, discount, and devalue knowledge that is presumably sourced from insiders, whereas the same knowledge sourced from an outsider is more carefully attended to and more highly valued. Menon and colleagues (2005) reveal that managers who have an opportunity to affirm themselves are less likely to experience status threat and therefore more likely to make use of valuable insider knowledge.

Prescriptive Approaches in Judgment and Decision Making

The question of how to mitigate or eliminate human bias in organizational decision making has received relatively short shrift in comparison to descriptive accounts of how biases emerge and operate. One explanation for this dearth of prescriptive treatments is that it is very difficult to reverse or mitigate fundamental human bias. Indeed, investigations of expert decision makers reveal that experts often fall prey to the same biases that befall novices (for a review, see Arkes & Hammond, 1986). Bazerman (2006) outlines six strategies for combating bias in individual decision making: (1) acquiring experience and expertise; (2) debiasing techniques, that often involve consciousness raising about biases; (3) analogical reasoning that involves highlighting biases that occur across a range of situations, allowing decision makers to induce a common theme (cf. Loewenstein, Thompson, & Gentner,

1999); (4) taking the outsider view; (5) using linear models; and (6) understanding biases in others.

Justice and Fairness

Pay and access to resources are critical concerns for most organizational actors. Not surprisingly, rewards and resource allocation, as well as actors' reactions to allocation decisions, are therefore central topics in OB. Research that sheds light on the processes by which organizational actors assess fairness, as well as the consequences of those assessments, is important for two reasons. First, it presents a limitation to the traditional economic perspective of individuals as atomistic, self-interested actors from a microperspective. In addition, it contrasts sharply with research on interpersonal decision making (e.g., Messick & Sentis, 1985; Ross & Sicoly, 1979), which focuses on individuals' egocentric preferences for maximizing their own utility relative to others. By placing the study of individual judgments into the contexts in which people interact, we get deeper insight into socially situated decision-making processes.

Although OB is interested in the factors that affect our assessments of what is just, and the consequences of those judgments on organizational outcomes, it also goes beyond the individual level of analysis to consider the effects of social context on justice assessments, as well as the implications of those assessments for organizational systems. This literature therefore considers the effect of the perceiver's relative position within the social system on his judgments (e.g., Kray & Lind, 2002; Mossholder, Bennett, & Martin, 1998). It also considers the implications of individual perceptions of fairness on the social system itself (e.g., Ambrose, Seabright, & Schminke, 2002; Greenberg, 1993; Johnson, Korsgaard, & Sapienza, 2002; Sapienza & Korsgaard, 1996). We deal with both of these topics, paying special attention to the negative consequences of procedural justice assessments in the workplace: sabotage and revenge.

Assessing Procedural Justice

Because most OB research is situated within organizational contexts, it is not surprising that the implications of the organization as a social context are primary to OB studies of procedural justice assessments (Cropanzano & Greenberg, 1997). Inasmuch as organizational structure shapes patterns of interaction and relative participation in decision making, it has clear implications for procedural justice assessments. Actors in highly centralized, vertically complex organizations, where individuals participate less in decision making and face more levels of hierarchy, generally feel a lower sense of distributive and procedural fairness (Schminke, Ambrose, & Cropanzano, 2000; Schminke, Cropanzano, & Rupp, 2002). Similarly, actors within larger and more formalized organizations—those marked by lower levels of social integration and fewer relationships based on intimate personal contact, and where decision making may be more political—also feel less distributive and procedural fairness (Randall, Cropanzano, Bormann, & Birjulin, 1999; Schminke et al., 2000, 2002). These effects are not felt across all levels of an organization, however. Because more control and higher returns accrue to those in higher echelons, higher-ranking actors feel a greater sense of justice than do those in the lower ranks. Likewise, those at higher levels are more forgiving of structural impediments to fairness, so that rank moderates the effects of structure on assessments of justice (Schminke et al., 2002).

Within a given organizational setting, actors' assessments of justice and fairness are likely to be often influenced by those with whom they interact on a daily basis. Thus organizational actors' assessments of justice are moderated by both the context in which those assessments are made as well as their relationships with the other actors involved in the event or process being scrutinized (Cropanzano & Greenberg, 1997). Coworkers' assessments of procedural and distributive justice often influence individuals' own assessments (Folger, Rosenfield, Grove, & Corkran, 1979; Steil, 1983), just as the treatment of other employees during the process of being laid off affects survivors' assessments of fairness (Brockner & Greenberg, 1990; Brockner, Grover, Reed, DeWitt, & O'Malley, 1987; Brockner et al., 1994), perhaps because actors focus on the potential implications for themselves of processes they see affecting others (James & Cropanzano, 1990).

In contrast, assessments are often based, at least in part, on prior personal experience (Lind, Kray, & Thompson, 1998; Lind & Tyler, 1988). Consequently, organizational actors are more likely to feel empathy when they have experienced injustice themselves (Kray & Lind, 2002). Similarly, the degree to which an actor has interacted with those involved in the focal event, particularly the authority figure perceived to be the source of the injustice, moderates perceptions of fairness (Folger & Cropanzano, 2001; Kray & Lind, 2002; Lind, Kray, & Thompson, 2001; Van den Bos, Lind, & Wilke, 2001).

Because much work within organizations focuses on the work group, the dynamics of interaction within such small groups have significant consequences for justice assessments. When organizational actors identify strongly with their work unit, their individual reactions are often filtered through group identification. This effect can be so strong that when authority figures violate neutrality or trust relative to individual team members, other members of the team perceive those actions as violations against the entire work group (Tyler & Lind, 1992). Similarly, perceptions of decision fairness are more associated with the degree to which the decision represents the interests of all group members than of individual group members (Miller, Jackson, Mueller, & Schersching, 1987). Consequently, members of work units are likely to share assessments of justice, affecting other types of employee attitudes, as well: work-unit-level procedural justice assessments explain more variance in individual job satisfaction than do individual perceptions of justice (Mossholder et al., 1998).

Consequences of Procedural Justice Assessments

Assessments of procedural justice at the group level affect the level of individual, self-reported job satisfaction.

Job satisfaction is not the only motivational outcome affected by perceptions of fairness, however; procedural and distributive justice assessments are relevant to an actor's evaluations of many and varied aspects of his organizational environment. Distributive justice, for example, accounts for more variance in satisfaction with compensation than does procedural justice (Folger & Konovsky, 1989). In contrast, perceptions of fairness regarding the performance appraisal process have a direct impact on an actor's trust in his supervisor, whereas perceptions of fairness regarding pay determination, performance appraisal and communication regarding compensation directly impact an actor's commitment to his or her employing organization (Folger & Konovsky, 1989; Scarpello & Jones, 1996). Similarly, the interaction of distributive and procedural justice moderate the effects of each, such that high procedural justice assessments reduce the effects of distributive justice on employee organizational commitment but heighten the effect of distributive justice on employee self-evaluation or self-esteem, implying that actors use information on procedural fairness to make self-attributions for their own outcomes (Brockner et al., 2003).

At the intraorganizational level, Kim and Mauborgne (1991, 1993a, 1993b, 1995, 1996, 1998) find that managers of foreign subsidiaries judge the strategic decision-making process to be fair when bilateral communication exists between the head office and subsidiary involved; subsidiaries are able to challenge and refute the strategic views of managers in the head office; managers in the head office are well informed regarding local conditions of the subsidiaries; subsidiaries are given a full account of the strategic decisions of the head office; and the head office applies decision-making procedures consistently across subsidiaries (Kim & Mauborgne, 1991, 1993b). Not only do these factors influence subsidiary managers' perceptions of procedural justice, they also increase subsidiary managers' willingness to comply (Kim & Mauborgne, 1993a), as well as to engage in extra-role behavior (Kim & Mauborgne, 1996).

Sapienza and Korsgaard (1996) find that the same cognitive and motivational processes that operate in individual perceptions of justice are also at work in interorganizational relationships. Because entrepreneurs cannot build high-potential businesses without the financing and participation of outside investors, harmonious entrepreneur–investor relations are paramount (Bygrave & Timmons, 1992; Larson, 1992). When entrepreneurs provide timely feedback, reducing the need for investor vigilance, investors' perceptions of procedural justice increase, particularly when investors' influence over organizational decisions is relatively low (Sapienza & Korsgaard, 1996).

*The Dark Side: Negative Assessments
of Procedural Justice*

Although organizational justice research has long identified revenge or retaliation as a means of restoring justice (e.g., Adams, 1965), only recently have OB researchers sought to test this assertion empirically. These studies demonstrate the moderating mechanisms that determine whether and how retaliation will be delivered, as well as the importance of interpersonal interaction in assessments of justice. Perhaps the most important question regarding the dark side of justice is *when* actors will take revenge. Retaliation appears to depend on the assignment of blame, and the type and degree of perceived injustice. When they assign blame, actors are more likely to take revenge against the perceived offender and less likely to reconcile with the perceived offender (Aquino, Tripp, & Bies, 2001). Sabotage is a specific type of retaliation in which a person actively tries to destroy another person's character, property, personal effects, and so on. The type of injustice actors feel also determines the type of sabotage they engage in and their goals in doing so: Those who feel distributive injustice are more likely to engage in sabotage to restore equity, whereas sabotage resulting from interpersonal injustice aims to retaliate against the transgressors. Although interpersonal injustices engender the most severe forms of sabotage or revenge, severity increases with perceived distributive, procedural, and interactional injustice (Ambrose et al., 2002; Greenberg, 1993).

In addition to the perceived source of injustice, the target of revenge affects the type and degree of retaliatory behavior in which an actor will engage. In general, wronged actors seem to use revenge to restore their feelings of justice, not to perpetuate the cycle of injustice. Thus the target of sabotage is most often the source of the perceived injustice, such that retaliatory action is seldom taken against individuals when the roots of the injustice are perceived to be structural (Ambrose et al., 2002; Greenberg, 2002). This reluctance is partially in the interests of self-preservation; low-status actors are less likely to take revenge on higher-status actors than are high-status actors on lower-status actors, although the tendency to take revenge decreases with the victim's absolute status (Aquino et al., 2001). Similarly, revenge is judged less harshly when its consequences are symmetric with the instigating injustice, whereas judgments are harsher when the method of revenge is similar to that by which the initial injustice was enacted (Tripp, Bies, & Aquino, 2002). Because revenge is often visible and subject to third-party evaluation, victims focus on aesthetic principles in deciding when and how to retaliate.

Both assessments of justice and fairness and the consequences of those reactions are highly salient to organizational functioning and outcomes. By supplementing the findings of laboratory research with participant observation, interviews, and surveys, organizational behavior is able to understand the interaction of these phenomena with other organizational processes and relationships much more deeply than it could if study were limited to the laboratory. The same is true of organizational behavior's treatment of the related topic of leadership; by moving the study of leadership, and particularly its consequences, out of the laboratory and into the field, we get a much clearer picture of how and why leadership matters.

Leadership

Perspectives on leadership in organizational behavior draw heavily on social psychology and industrial and or-

ganizational psychology. In OB, the focus of leadership studies is the individual actor within the organizational context, rather than individual differences. Therefore, we ultimately look to a discussion of social capital and networks and organizational power and influence—topics we address systematically in subsequent sections—to understand leaders in their organizations fully. In this section, however, we focus primarily on individual leadership styles and their consequences. We do not take up the age-old question of whether leaders are born or made (see Bryman, 1996, for a summary), but we outline three or streams of research on leadership within organizational behavior: leadership style, the consequences or impact of leadership, and leadership biases and blind spots.

Leadership Style

The study of styles of leadership in organizational behavior can be traced to Lewin, Lippitt, and White's (1939) studies of children's reactions to different leaders' approaches. Since then, research has gone in many different directions, from social-exchange theories to individual trait theories (see Judge, Bono, Ilies, & Gerhardt, 2002, for a review). OB researchers generally leave these issues aside, however, to focus primarily on how leadership shapes subordinate performance and satisfaction. Pearce and Sims (2002), building on Manz and Sims's (1991) and Bass and Avolio's (1993) models of leadership behavior, provide a model of five primary leadership types: directive leadership, aversive leadership, transactional leadership, transformational leadership, and empowering leadership. Here we focus on the latter three.

Transactional leadership can be understood as developing and fulfilling a contract with subordinates. Grounded in expectancy theory (Vroom, 1964), equity and exchange theory (Adams, 1963; Homans, 1958, 1961), and reinforcement theory (Luthans & Kreitner, 1985; Scott & Podsakoff, 1982), transactional leadership is associated with personal and material rewards conditional on performance, providing clarification and feedback relating to goals and managing by exception. Because expectancy theory suggests that individuals attempt to maximize expected returns to performance, transactional leadership focuses on clarifying the effort–reward relationship to maximize motivation, giving rewards equitable to input, and motivating higher subordinate input through the provision of higher rewards. Finally, transactional leadership emphasizes reinforcement through rewarding desired behavior.

Transformational leadership, in contrast, highlights the benefits of inspiration, charisma and overarching values in maximizing subordinate performance and satisfaction (Bass, 1985; Bass & Avolio, 1990). Transformational leaders elevate their subordinates' goals and give them confidence to exceed leaders' expectations. This tradition is rooted in charismatic leadership (House, 1977) and transforming leadership (Burns, 1978) and suggests that managers engage in impression management, articulate ideological goals, define subordinate roles in terms of ideological values, engage in role modeling, communicate high expectations and confidence in subordinates,

and arouse appropriate follower motives. Transformational leaders provide vision, express idealism, communicate inspiration and high performance expectations, challenge the status quo, and set high performance expectations (Bass, 1998). Although it aims to help subordinates realize their potential, subordinates often see transformational leaders as exceptional and thus become dependent on the leader for inspiration and guidance (Yukl, 1998).

Building on transformational leadership and the "new leadership approach" (Bryman, 1996), Manz and Sims (1980, 1987, 1989, 1991, 2001) describe empowering leadership. This leadership style involves developing follower self-leadership and self-management skills, and can be called "SuperLeadership" or "leading others to lead themselves" (Sims & Lorenzi, 1992, p. 295). The roots of empowering leadership lie in behavioral self-management (Thorenson & Mahoney, 1974), social cognitive theory (Bandura, 1986), participative goal setting (Erez & Arad, 1986; Locke & Latham, 1990), and cognitive-behavioral modification research (Meichenbaum, 1977). Fundamentally, this school holds that by modeling self-leadership behavior, leaders induce their subordinates to become similar self-leaders. Thus empowering leaders often reconceptualize obstacles as opportunities for learning (Manz & Sims, 1989, 2001) and set specific and difficult goals to stimulate performance (Locke & Latham, 1990). They emphasize independent action, teamwork, self-development, and self-reward and encourage participative goal setting, transforming followers into leaders (Bryman, 1996).

Consequences of Leadership

Although some OB scholars argue that organizational outcomes are marginally, if at all, affected by leadership (House & Aditya, 1997; Yukl, 1999), there is evidence of a causal link. Using archival statistics for professional baseball, Kahn (1993) finds that there is a strong correlation between the quality of managers' transactional leadership, team success, and player performance. Not only do higher-quality managers—measured by predicted pay relative to salary based on overall market trends—achieve better winning percentages, controlling for player skills, but also, players tend to perform better relative to prior performance the higher the manager's quality (Kahn, 1993). This study also suggests that transactional leadership, although often treated as problematic by OB scholars, can be quite consequential in certain contexts; further research regarding the limits of transactional leadership may therefore be merited.

Similar findings emerge not only for professional sports but also in more typical organizational settings. Transformational leadership, in particular, has a positive impact on subordinate performance. In a field study in which army officers were given training in either exclusively transformational or a variety of leadership techniques, transformational leaders had a more positive impact on direct follower development and indirect follower performance than did the control group (Dvir, Eden, Avolio, & Shamir, 2002). Although transforma-

tional leadership leads subordinates to identify with and become dependent on their leaders, it also leads to subordinate empowerment in terms of individual and collective self-efficacy and organization-based self-esteem (Kark, Shamir, & Chen, 2003); this relationship is partially mediated by subordinates' social identification with the group.

The relationship between transformational leadership and organizational outcomes seems to be linked to subordinate self-concordance, or the degree to which subordinates' own goals and values are aligned with those articulated by the leader (Bono & Judge, 2003; Sheldon & Elliot, 1999). By presenting work in terms of values and ideology that transcend individual interests, transformational leadership leads subordinates to internalize their leader's and group's goals, giving them internalized motivation, which is associated with more extra-role behavior and lower intention to leave (Bono & Judge, 2003; O'Reilly & Chatman, 1986). Employees see their work as more self-expressive, thus consequently perform better, and are more motivated, committed to their organizations, and satisfied with their leaders (Bono & Judge, 2003).

Even transformational leadership does not improve organizational outcomes under all conditions. For example, CEOs with transformational leadership styles improve organizational performance only when actors across the organization perceive environmental uncertainty (Waldman, Ramirez, House, & Puranam, 2001). Uncertainty appears to make actors more receptive to charismatic leadership and gives CEOs more discretion in their actions and behavior toward subordinates, with consequences for firm profitability, controlling for external influences. CEOs with transactional leadership styles, in contrast, do not improve firm performance, even under uncertainty (Waldman et al., 2001). Similarly, although transformational leadership is associated with improved future performance, it does not have a relationship to prior firm performance, suggesting a strong causal relationship between leadership and future performance (Waldman, Javidan, & Varella, 2004).

Leadership is clearly critical to the success of self-leading or self-managing teams (Barry, 1991). Often without a formal leadership position, self-managing teams may flounder if team members have previously experienced only aversive, directive, or transactional leaders in the past, as may those who have become dependent on transformational leaders (Bryman, 1996). Self-leadership is positively related to performance when teams are engaged in conceptual tasks and when team member interdependence is either very high or very low; in contrast, self-leading teams engaged in productive or behavioral tasks increase performance at moderate levels of team member interdependence (Stewart & Barrick, 2000).

Because empowered teams are almost forced to share leadership, distributing leadership roles and influence across team members (Pearce, Perry, & Sims, 2001; Yukl, 1998), they are better equipped to self-manage. In such shared leadership teams, the agents and targets of influence are peers. Pearce and Sims (2002) find that shared leadership is more closely associated with team effective-

ness than vertical leadership, particularly in teams with transformational and empowerment leadership styles. Shared leadership is a significant predictor of self-managing teams, particularly when engaged in complex tasks (Pearce & Sims, 2002). Self-managing teams are most successful when they have external leaders who span boundaries to build relationships, interact with outside constituencies, build internal and external support, and empower their teams (Druskat & Wheeler, 2003). External leaders of self-managing teams are less effective, however, when engaging in traditional leadership behaviors (Manz & Sims, 1987).

Despite evidence to the contrary, some OB researchers argue that the impact of leaders on organizational outcomes, particularly unexpected success, is overemphasized or "romanticized" (Meindl & Ehrlich, 1987; Meindl, Ehrlich, & Dukerich, 1985). Because individuals need to comprehend causally ambiguous, yet significant, organizational events, to attribute outcomes to human causes, and to validate their belief that organizations are effective, they give credit for unexpectedly positive outcomes to leadership (Meindl et al., 1985). This suggests that the value of leadership lies in the ability to control the meanings and interpretations that important stakeholders assign to events. This line of research points to an important consideration: that leadership may comprise both real effects, as indicated previously, as well as the interpretational effects suggested here.

Leadership and Biases

Because leaders are in both formal and informal positions of power and control, they may rely excessively on heuristics and mental models and may thus be subject to distorted perceptions, particularly in regard to their subordinates. The approach/inhibition theory of power (Keltner, Gruenfeld, & Anderson, 2003) argues that the experience of control increases the tendency to approach and decreases the tendency to inhibit. Because they experience subjective feelings of power, leaders are likely to feel more positive and less negative emotion, and are thus more attuned to rewards than threats (Anderson & Berdahl, 2002), suggesting that leaders may neglect subordinates' grievances. Similarly, leaders are likely to pay less attention to subordinates and thus more susceptible to stereotyping (Fiske, 1993). Moreover, those experiencing power are more likely to act, regardless of consequences (Galinsky, Gruenfeld, & Magee, 2003).

Those evaluating leaders may also show systematic biases, which are investigated in field studies and surveys by industrial and organizational psychologists and OB researchers. Implicit leadership theory holds that, over time and through personal perceptions and expectations, employees develop implicit leadership theories (ILTs), or personal assumptions about the skills, abilities, and personal characteristics of an ideal business leader (Kenney, Schwartz-Kenney, & Blascovich, 1996) that are stored and activated when they interact with people in a leadership position. Unless actors are perceived as conforming to those characteristics, they will not be per-

ceived as leaders (House & Aditya, 1997). Because ILTs are relatively constant across individuals, work contexts, and personal characteristics, as well as over time, not conforming to ILTs (Epitropaki & Martin, 2004) may hinder a leader's effectiveness.

Women leaders are particularly affected by biased attributions. Although evaluations of women leaders overall are only slightly less favorable than those of male leaders, meta-analysis shows that women tend to suffer more significant devaluation when their leadership styles are perceived as masculine (Eagly, Makhijani, & Klonsky, 1992). Similarly, women experience more devaluation when they occupy male-dominated roles and when their evaluators are men (Eagly et al., 1992). Women are evaluated more negatively than men even when their behavior meets the needs of a leadership role because of perceived incongruity of leadership and female gender roles, making it more difficult for women to achieve success as leaders than for men (Eagly & Karau, 2002). Evaluations of women are likely misguided, however, as meta-analysis shows that women display more transformational leadership behaviors positively related to effectiveness and fewer transactional leadership behaviors than do men (Eagly, Johannesen-Schmidt, & van Engen, 2003).

The study of leadership—similar to the study of decision making and justice and fairness—is clearly grounded in social psychology. Nevertheless, it often seeks to understand processes and consequences particular to organizational contexts, which cannot be replicated exactly in the laboratory. By measuring and controlling for outside influences, these studies are able to isolate and analyze the unique contributions and effects of leadership on organizational outcomes.

ORGANIZATIONAL ACTOR AS TEAM PLAYER

Within OB, teams are analyzed at several levels, including the nature of the intrateam relationships (also referred to as group dynamics) as well as the relationship between the team and the rest of the organization (commonly referred to as social networks).

Groups and Teams

It is nearly impossible to talk about organizations without mentioning or understanding teams. Not surprisingly, OB has borrowed and built on social psychology's groundbreaking studies of groups. Most of the research that OB has leveraged has been prior to 1990.

Many scholars (and certainly people in the business world) use groups and teams interchangeably when they should not. A *group* is an aggregate or collection, whose participants may or may not have a (shared) goal and may or may not be interdependent; a *team* is a group of people who share a goal and are interdependent. Thus, a team is a specific type of group—ideally composed of fewer than 10 people—working toward a shared goal that has organizational relevance (Hackman, 1990). The social psychology of groups is largely descriptive; the orga-

nizational study of teams is both descriptive and prescriptive. Key OB research on groups that derives from social psychology but has been claimed by OB includes transactive memory, the common information effect, minority influence, and conflict.

Transactive Memory

A transactive memory system is a group-level information-processing system that is an extension of the individual information-processing system (Wegner, 1986; Wegner, Giuliano, & Hertel, 1985). Whereas Wegner (1986) first measured and identified transactive memory systems in couples, Moreland, Argote, and Krishnan (1998) extended the concept to teamwork. In their investigation, teams were asked to assemble AM radios as part of a training experience (Moreland, Argote, & Krishnan, 1996). Teams were randomly assigned to either individual training sessions or group training sessions. In the training phase, everyone—both individuals and groups—received the same information; groups were not given any explicit instructions on how they should organize themselves. One week later, the participants were asked to assemble the radios again without the benefit of written instructions. The groups that had trained as a team performed better, in terms of successfully completing the assembly and with fewer errors. Most notably, the transactive memory effect has been examined in actual work teams, including hip and knee replacement surgery teams (doctors who have performed surgery as a team have patients with faster recoveries and fewer complications; Moreland & Argote, 2003) and coal-mining injuries and deaths (Goodman & Garber, 1988).

Common Information Effect

The common information effect, or the tendency for groups to discuss information that is common to everyone, as opposed to information that is unique to individuals in the team, has been demonstrated with a variety of paradigms and group tasks (cf. Christensen et al., 1998; Gigone & Hastie, 1996; Stasser & Titus, 1985). The common information effect is regarded to be dysfunctional for groups and, in most investigations, the optimal group answer can only emerge if group members are fully sharing all information. OB researchers quickly focused on two critical implications of the common information effect: practical solutions and the interface between the type of information and the type of team members (Phillips, Mannix, Neale, & Gruenfeld, 2004). Practical solutions to avoid excessive focus on common information have included instructing groups to rank rather than choose (Gigone & Hastie, 1996; Hollingshead, 1996), spend an equal amount of time discussing each alternative (Larson, Foster-Fishman, & Keys, 1994), define the goal as a "problem to be solved" rather than a "judgment to be made" (Laughlin, 1980; Stasser & Stewart, 1992), suspend initial judgment (Schulz-Hardt, Frey, Lüthgens, & Moscovici, 2000), and record facts during the discussion that justify their decision (Larson, Christensen, Franz, & Abbott, 1998).

Phillips and her colleagues (Gruenfeld, Mannix, Williams, & Neale, 1996; Phillips, 2003; Phillips & Loyd, 2004; Phillips, Mannix, et al., 2004) have examined not only how the distribution of information affects the likelihood that members will consider information but also the way that friendships among group members impact the common information effect. In this way, Phillips has linked the cognitive-information-processing aspects of teamwork with the sociorelational aspects. For example, team members who are familiar with one another are less likely to make poor decisions resulting from the common knowledge problem than are teams whose members are unacquainted (Gruenfeld et al., 1996). According to Gruenfeld and colleagues (1996), this result stems from the fact that teams that are more familiar with one another tend to pool their unique information to find the best choice, while unfamiliar teams tend to aggregate their preferences and adopt the choice of the majority; this suggests that familiarity prevents teams from adopting dysfunctional responses to normative influence. Moreover, Phillips and colleagues have shown that when the distribution of unique versus shared information is congruent with the relationship status of group members, such that the unfamiliar team member possesses the unique information and the previously acquainted team members share information, teams are more likely to discuss unique and shared information and exhibit superior performance (Phillips, 2003; Phillips, Mannix, et al., 2004). Phillips, Mannix, and colleagues (2004) found that when a familiar member who was in the numerical majority held unique information, groups performed worse than when that information belonged to a stranger. Likewise, Phillips (2003) argued that it is members' assumptions of similarity (e.g., Allen & Wilder, 1975) that lead them to alter their behavior when they find that they do not agree with whom they expect to agree. For instance, individuals express greater surprise and irritation with a differing perspective when it is expressed by a socially similar other than when it is expressed by someone who is socially different (Phillips, 2003; Phillips & Loyd, 2004). Thus, the sharing of unique information and performance of groups that face hidden profile situations is also affected by who agrees with whom in the group, which is frequently a function of the social relationships among group members and the decision-making strategies they employ as a consequence.

Minority Influence

Minority influence focuses on the extent to which people that hold nondominant opinions in a group can influence a group's ultimate decision. The mere presence of a minority stimulates more thorough information and more thoughtful group decision making (Gruenfeld, 1995). Minority opinions can arise from one of two sources—from a member of one's own work team (i.e., an ingroup member) or a member of another group (an outgroup member). Both can be effective; however, a minority opinion offered by an ingroup member is often more influential (David & Turner, 1996). People in work teams are often reluctant to express divergent views and

disagreement with outgroup members is more tolerable than disagreement with ingroup members (Phillips, 2003).

Intensive examinations of actual organizations reveal that members in the majority exhibit greater integrative complexity than do members in the minority (Gruenfeld, 1995). For example, the authors of majority opinions in the U.S. Supreme Court who are exposed to members who hold a minority point of view show increases in their own levels of integrative thinking (Gruenfeld, 1995). In contrast, people exposed to majority opinions or unanimous groups actually experience a decrease in integrative thinking (Gruenfeld, Thomas-Hunt, & Kim, 1998).

One type of minority influence hinges on the length of time a person has been a member of a group. Because reorganizations are so prevalent in businesses, OB researchers have been particularly interested in how the changing composition of a group affects its productivity. Gruenfeld, Martorana, and Fan (2000) investigated the consequences of temporary membership changes for itinerant members (i.e., members who leave their core group to visit a new work group, and then subsequently return) and indigenous members of those foreign and native groups. Although it would seem that itinerant members would learn new ideas that would transfer back to their native group once they returned, this was not observed. Members of all groups produced more unique ideas after itinerant members returned to their native group than before they left or during the temporary change period. However, indigenous group members were less likely to want to include them in a group project designed to draw on knowledge of the work team. Moreover, indigenous group members regarded the itinerant members to be more argumentative than they were before their new assignment, and their contributions were perceived as less valuable. Thus, itinerant group members had less direct influence after their reorganization than before. In this sense, groups benefit from their "worldly" members, but they do not appreciate them.

Conflict

The study of conflict in teams has been almost exclusively the domain of management theorists, such as Jehn (1995; Jehn & Mannix, 2001; Shah & Jehn, 1993; see also Amason, 1996; Guetzkow & Gyr, 1954). Jehn (1995) proposed that three types of conflict occur in teams: relationship conflict (also known as emotional conflict, A-type conflict), task conflict (conflict about the substance of an issue or project), and process conflict (conflict about how to do a project). Many research investigations measured the types of conflict within laboratory teams as well as actual work teams; several investigations reported that relationship conflict was negatively related to task performance, whereas task conflict was positively related to task performance (cf. Jehn, 1997). Recently, De Dreu and Weingart (2003) performed a meta-analysis of the three types of conflict; in all cases, both relational as well as task conflict was negatively related to group perfor-

mance. Behfar, Peterson, Mannix, and Trochim (2004) examined 51 work teams and found that three factors were associated with enhanced performance: members focus on content, rather than style; members assign work to others in the team based on expertise, not convenience; and members communicate about factors that affect their ability to carry out assignments, something that Behfar and colleagues call communicating about work and quirks.

Brainstorming and Creativity

Research on team brainstorming and creativity has a strong hold in psychology as well as management science. Whereas the social psychological approach to brainstorming focuses nearly exclusively on the question of why groups are inferior to individuals (or nominal groups; for a review, see Paulus, Brown, & Ortega, 1999; see also Diehl & Stroebe, 1987), the OB approach assumes that teams must be creative and consequently concerns itself with improving the effectiveness of intact brainstorming teams (cf. Sutton & Hargadon, 1996). Three subareas of research have been remarkably influential in this area: intrinsic versus extrinsic motivation, psychological safety, and boundary spanning.

PSYCHOLOGICAL SAFETY

Edmondson and Mogelof (2006; see also Edmondson, 1999) explain how the presence of psychological safety in a team provides a critical foundation for creativity. Psychological safety encompasses the taken-for-granted beliefs that others will respond positively when a person takes a risk. Because the creative process involves divergent thinking, it is a risky behavior. Edmondson and Mogelof investigated several project teams and measured psychological safety at key points in time during a project. Importantly, individual differences in terms of two of the "big five" personality factors—neuroticism and openness to experience—were positively associated with greater psychological safety in teams.

CREATIVITY AND BOUNDARY SPANNING

According to Ancona (1990; Ancona & Caldwell, 1988, 1990, 1992a), for teams to be creative, they need to navigate organizational boundaries and divides. Ancona and Caldwell's (1992a) groundbreaking investigation of 45 teams reveals four prototypical patterns: ambassadorialism, task coordination, scouting, and isolationism. Ancona and Bresman (2006) suggest that creative teams, called, X-teams, "beg, borrow, and steal" best practices across the company. They distinguish the process of creative idea generation from the organizational tightrope of winning support for ideas and ultimately receiving organizational buyin. They argue that the most innovative teams have a marked disrespect for traditional teams and even organizational boundaries, and that this fluidity drives the innovative process. They identify five key components of X-teams with respect to the innovative process: external activity, extensive (network) ties, expand-

able tiers (managing up and out), flexible membership, and coordination among ties.

Hargadon (2006) argues that creativity involves two complementary but seemingly opposing processes: bridging and building. Bridging, according to Hargadon, requires that two previously distinct worlds or domains be brought together via pattern recognition or making a new connection. To this end, Hargadon provides compelling case examples from physics to rock and roll. The building process, according to Hargadon, requires that new patterns be built involving both understanding and action within those social groups that serve as the arbiters of the creative output. Hargadon bases his theory in the microsociology of creativity.

Negotiations

Negotiation research is the child of at least three literatures: Morton Deutsch's (1973) seminal work in social psychology; Raiffa's (1982) work in applied game theory; and, oddly enough, Kahneman and Tversky's (1979) work in decision making. Negotiation takes front and center stage in OB, in part because organizational actors routinely find themselves involved in intra- and interorganizational conflict and exchange. Modern negotiation research in OB has dominated the micro-OB journals for over two decades, beginning in the 1980s when Bazerman and Neale redefined the study of negotiation as a joint decision-making process that contained the same flaws as individual decision making. We outline three central themes in negotiation research: judgment and decision making; relationships and reputation; and social perception and social identity. These themes are highly interrelated, but we distinguish them here to focus on how cognitive and motivational processes affect decision making in negotiation; how social relationships affect negotiation; and, finally, how subtle changes in context can affect negotiated outcomes.

Judgment and Decision Making

The great majority of research in negotiation focuses on the shortcomings that befall negotiators. The key finding is that negotiators are rather poor at negotiating. In one investigation, more than 40% of negotiators failed to realize when their interests were completely compatible (i.e., aligned) with others, and nearly 25% of these negotiators reached lose–lose outcomes (Thompson & Hastie, 1990; Thompson & Hrebec, 1996). Negotiation biases fall into biases that are general in nature and negotiation-specific biases that include the framing effect, anchoring and adjustment, and overconfidence (for reviews, see Neale & Bazerman, 1991). For example, several investigations have examined the impact of framing (gain vs. loss frame) on negotiation outcomes. The general finding is that negotiators who are led to adopt a gain frame are more likely to reach settlement than are negotiators who are led to adopt a loss frame (cf. Bottom & Studt, 1993; Neale & Bazerman, 1991).

The second set of biases is negotiation specific, such as the fixed-pie perception (Bazerman & Neale, 1983;

Thompson & Hastie, 1990), coercion bias (Rothbart & Hallmark, 1988); attribution bias (Morris & Larrick, 1995; Morris, Larrick, & Su, 1999), and concession aversion (or the grass-is-greener bias; Ross & Stillinger, 1991). Perhaps of all the negotiation-specific biases, it is the fixed-pie perception that has garnered the most attention. The fixed-pie perception, coined by Fisher and Ury (1983), refers to the often faulty belief that people's interests are fundamentally and directly opposed, such that a gain for one party represents a loss for the other party. Numerous research programs have established the presence and persistence of the fixed-pie perception in producing suboptimal negotiation agreements, preventing negotiators from reaching mutually beneficial agreements (cf. Bazerman & Neale, 1983). The implications of the fixed-pie perception for the quality of negotiated outcomes are serious; when negotiators believe that their interests are completely opposed, they cannot dovetail their interests.

Another well-documented general bias that has been studied in context of negotiations is overconfidence. Overconfidence refers to unwarranted levels of confidence in people's judgments of their abilities and the occurrence of positive events and underestimates of the likelihood of negative events. For example, in negotiations involving third-party dispute resolution, negotiators on both sides of the table believe that a "neutral" third party will adjudicate in their favor (Farber, 1981; Farber & Bazerman, 1986, 1989). Obviously, the third party cannot rule in favor of both parties. Similarly, in final-offer arbitration, wherein parties each submit their final offer to a third party, who then makes a binding decision between the two proposals, negotiators consistently overestimate the probability that a neutral arbitrator will choose their own offer (Bazerman & Neale, 1982; Neale & Bazerman, 1983). Whereas overconfidence about potential outcomes is a detriment to effective negotiation, evidence suggests that overconfidence about the value of the other party's walkaway point might serve the negotiator well. Specifically, negotiators who are optimistically biased (i.e., they think that their counterpart will concede more than he or she really can) have a distinct bargaining advantage (Bottom & Paese, 1999). Whereas negotiation research had initially been exclusively cognitive, the research tide turned and investigations of mood and emotion in negotiation grew in popularity (for a review, see Barry, 1999; Barry, Fulmer, & Goates, 2005). For example, several investigations have explored the implications of Forgas's (1995) affect infusion model on negotiated outcomes.

Relationships and Reputations

Somewhere in the late 1980s and early 1990s, a small rebellion took place against the overly cognized view of the negotiator. Rather than picturing him or her as a biased information processor, people began to focus on the context of the negotiation and the relationship among organizational actors. Pruitt and Rubin's (1986) dual-concern model, derived from Thomas and Kilman's (1974) concept of people and task focus, suggests that integrative agreements result when negotiators are concerned about themselves and the other party (Pruitt & Carnevale, 1993; Pruitt, Carnevale, Ben-Yoav, Nochajski, & Van Slyck, 1983). Several investigations have examined the impact of friendship and relationships on negotiator effectiveness (for a review, see Valley, Neale, & Mannix, 1995). Another aspect of relationships is the social-organizational network. Several investigations of networks in negotiations were conducted and, recently, the study of reputations in negotiation communities has become an important topic (Tinsley, O'Connor, & Sullivan, 2002). For example, Tinsley and colleagues (2002) find that negotiators who perform well in an organizational community but who then gain a reputation for being a tough negotiator encounter opponents who behave more aggressively toward them.

Glick and Croson (2001) argue that negotiators' reputations are built fairly quickly in negotiation communities and affect how others deal with them. They found that investigations of reputations in a community of MBA students yielded four profiles: liar-manipulators (who will do anything to gain advantage), tough but honest (negotiators who don't lie, but make very few concessions), nice and reasonable people (who make concessions), and cream puffs (who always make concessions). People act much tougher when dealing with someone who has a reputation for being a liar but are much more reasonable with other profiles. And, most notably, people are more likely to use tough strategies with liars for defensive reasons but might use tough strategies with cream puffs for opportunistic reasons.

Somewhat paradoxically, while people may expect that they will act tougher around those they expect to be tough, these same individuals also may be likely to cave in. Diekmann, Tenbrunsel, and Galinsky (2003) recently demonstrated that during negotiations, there can be a disconnect between individuals' intended reaction to a competitive opponent and how they actually behave. For example, MBA students reported that they would negotiate more aggressively with a competitive opponent relative to a noncompetitive opponent. However, when these same individuals conducted a negotiation 5 weeks later, the same participants who claimed they would be more aggressive when facing a competitive opponent set less aggressive expectations and ultimately agreed to worse outcomes than participants who believed they were facing a noncompetitive opponent. Why? When negotiators forecast how they believe they might behave, they fail to consider their motivation to reach an agreement.

The rise of the Internet era ushered in a new area of research on the impact of communication modality (face-to-face, telephone, email, etc.) on negotiation outcomes (for a review, see Nadler & Shestowsky, 2006). In general, it is believed that the richer the communication medium, the better the negotiated outcome (cf. Moore, Kurtzberg, Thompson, & Morris, 1999); however, negotiators who are not prepared or are in a relatively weak bargaining position are best advised to negotiate via email (Loewenstein, Morris, Chakravarti, Thompson, & Kopelman, 2005).

Social Perception and Social Identity

The classic study of social perception in negotiation is that of Kelley and Stahelsski (1970) who found that the outcomes of a multiround Prisoner's Dilemma Game depended on the parties' perceptions of one another as well as their social stereotypes in general. Kramer and Brewer (1984) used social identity theory to predict how negotiators would behave in a social dilemma task. They hypothesized that negotiators might be more cooperative if they shared a common identity. They examined the incidence of competitive and cooperative behavior in a social dilemma task. Although the stakes and payoffs were exactly the same across conditions, when group members were told to focus on a superordinate identity, they behaved more cooperatively (donated more to a common pool of resources) than when they were instructed to focus on their individual identities. In a similar sense, Ross and Ward (1996) found that people playing a Prisoner's Dilemma Game, titled "the Wall Street game," were much more competitive than people playing the same game when it was titled "the community game."

Morris and colleagues (1999) examined how people develop impressions of others in negotiations based on their behaviors. Morris and colleagues reasoned that negotiators would fall prey to the fundamental attribution error when attempting to explain the behavior of a demanding counterpart. The situational explanation for a demanding counterpart would attribute excessive demands to the quality of that person's alternatives (best alternative to negotiated agreement, or BATNA), whereas a dispositional explanation would invoke a personality attribution. Morris and colleagues found that negotiators with attractive options outside their negotiation were indeed labeled as more demanding (dispositional attribution) than negotiators who did not have as attractive outside options.

The tidal wave of unconscious processes in social psychology was not lost on OB research. Several investigations of below-conscious-awareness information processing and negotiator behavior have been conducted. For example, Kray, Thompson, and Galinsky (2001) applied stereotype threat to the study of negotiation. They found that when gender is "primed," women perform less well than do men (Kray, Thompson, & Galinsky, 2001). However, they also found evidence for a "stereotype reactance" effect, wherein when gender is explicitly primed, women are less likely to identify with traditional gender roles and perform even better than do males (Kray, Galinsky, & Thompson, 2002).

Research on cross-cultural negotiation differences has burgeoned in recent years (cf. Brett, 2001). One subarea within this research stream focuses on cultural differences as a personality difference among members of different cultures; another subarea in this research stream focuses on cultural differences that can be temporarily activated in people of different cultures. As an example of the first type of research, Brett and her colleagues (1998) find that direct information sharing about interests is not normative in collectivistic cultures; rather, collectivistic cultures share information indirectly, which

can be just as effective in reaching optimal outcomes. As an example of the second type of research, Seeley, Thompson, and Gardner (2003) temporarily primed negotiators to be either interdependent (similar to collectivistic) or independent (similar to individualistic) and found that interdependently negotiators are more cooperative in one-on-one negotiations, but more competitive in team-on-team negotiations.

Demography and Diversity

One of the contextual factors that influences work-team processes is the demography of the team itself, particularly the diversity of its composition. Not only does composition affect team processes and outcomes, it also affects the way team members feel about each other and their work. These effects are generally found to result from social categorization (Kramer, 1991), similarity/attraction (Byrne, 1971), and information sharing in decision making (Gruenfeld et al., 1996). The effects of work-team diversity are not limited to those created by gender or race but, rather, can stem from any characteristics used to identify others as different, which are often context specific (Williams & O'Reilly, 1998).

Organizations implement teams based on the assumption that decisions made by groups with diverse expertise and experience will be better than those made by individuals. Some, following the "value-in-diversity" school (Cox, Lobel, & McLeod, 1991), believe that diversity can improve organizational performance. Others, in contrast, show that diversity impedes group functioning (see Brewer, 1979; Messick & Massie, 1989) and argue that homogeneity might improve group performance, because similar people tend to like each other more than dissimilar people (Byrne, 1971) and undergo relatively little conflict in the course of completing a task. We review the effects on group process and performance of both task-oriented diversity (group tenure and background) and relations-oriented diversity (gender and race and ethnicity).

Task-Oriented Diversity

GROUP TENURE DIVERSITY

As argued by Pfeffer (1983, 1985), homogeneity in group tenure is generally found to lead to increased communication, social integration, and cohesion (Good & Nelson, 1971; Lott & Lott, 1965; O'Reilly, Caldwell, & Barnett, 1989). Social integration may be affected by heterogeneity in tenure indirectly, through decreased, less open communication and more distortion of messages (O'Reilly, Snyder, & Boothe, 1993; Smith et al., 1994). Similarly, tenure diversity is associated with increased conflict and political activity (O'Reilly, Williams, & Barsade, 1997; O'Reilly et al., 1993; Pelled, 1993).

These findings do not necessarily indicate that tenure diversity is detrimental to team performance. Heterogeneous groups are more likely to have access to nonredundant information because their networks do not overlap (Burt, 1997). Generally, diverse groups are

better able to identify and understand multiple external cues and thus may recognize subtle changes in task demands sooner than homogeneous group members (Thompson, 1967). Similarly, diverse teams may enjoy the benefit of diverse experience in attacking complex tasks (Ancona & Caldwell, 1992b; O'Reilly et al., 1997). In addition, the conflict engendered by diversity may lead to disagreements—such as those regarding minority opinions mentioned earlier—that improve decision making (Amason, 1996; Eisenhardt, Kahwajy, & Bourgeois, 1997; Pelled, 1996a). Nevertheless, heterogeneity in tenure increases turnover by creating conflict and poor social integration (O'Reilly et al., 1989, 1993; Pfeffer & O'Reilly, 1987). Together, these results suggest that tenure diversity is advantageous based on experience and perspective, but that groups may fail to realize these benefits.

FUNCTIONAL DIVERSITY

Diversity in background can refer to education, functional specialty, and job experience, indicating training in different expertise, abilities, and perspectives. Because of their access to diverse skill sets and unique information, often accessed through increased communication with those outside the team, cross-functional teams are assumed to be more effective than less diverse teams (Ancona & Caldwell, 1992b; Cummings, 2004; Jackson, 1992). As with tenure diversity, however, the advantages of cross-functional teams may be squandered through the increased conflict that often accompanies diversity, or by team members' unwillingness to share information held unevenly across the team (Wittenbaum & Stasser, 1996). As Gruenfeld and colleagues (1996) show, heterogeneous groups perform best when information is fully shared, whereas groups that are more familiar with each other perform better when information is unevenly distributed. In addition, because it leads to the surfacing of multiple points of view and task orientations, functional diversity also increases task conflict, which improves cognitive task performance (Jehn, Northcraft, & Neale, 1999; Pelled, 1993).

In fact, much OB research shows that teams composed of actors with diverse backgrounds are able to achieve superior performance (e.g., Barsade, Ward, Turner, & Sonnenfeld, 2000). Although functional diversity drives task conflict, because those with different specialized backgrounds are naturally more likely to disagree on process issues, this conflict leads them to think more deeply about task requirements, improving performance (Pelled, Eisenhardt, & Zin, 1999). The mere fact of recognizing that diverse actors have specialized knowledge allows these groups to explore divergent and innovative ideas (Janssens & Brett, 2003). Similarly, because they look to different external cues, functionally diverse teams respond better to environmental change (Keck & Tushman, 1993; Murmann & Tushman, 1997). Moreover, intrapersonal functional diversity improves information sharing and decision quality, as team members are more willing to accept others' functional expertise (Bunderson & Sutcliffe, 2002). Similarly, structurally

diverse work groups—whose members fill different roles and affiliations—achieve superior performance by exposing the group to unique knowledge and skills (Cummings, 2004). Thus, functional diversity improves performance by increasing the availability of task-relevant knowledge, leading to greater task conflict and information sharing.

Demographic Diversity

GENDER DIVERSITY

Gender is perhaps the most studied, yet least conclusive, aspect of work-group diversity. Gender is a particularly salient dimension of identification and categorization, with immediate consequences for workplace interaction. For example, Eagly's gender role theory (see Eagly et al., 1992) holds that actors develop expectations about their own and others' behavior based on their beliefs about the behavior that is appropriate for men and women, and they may evaluate women negatively when their behavior differs significantly from expectations. This is thought to be more salient and have a stronger effect for women than for men, because women are generally in the minority in the workplace—particularly in leadership roles—which reinforces negative stereotypes (Eagly et al., 1992).

There is evidence of increased conflict and process loss in mixed-gender groups (e.g., Alagna, Reddy, & Collins, 1982; Pelled, 1996b; Sackett, DuBois, & Noe, 1991), although these findings are not conclusive (Williams & O'Reilly, 1998). Kanter (1977) notes that the effects of gender diversity on group process are moderated by the proportion of men and women in a given group, an issue not taken into account by most gender studies. Although gender diversity was thought to increase conflict, there is no evidence to support this hypothesis (O'Reilly et al., 1997; Pelled, 1996a; Pelled et al., 1999). Moreover, the effect of being different varies between men and women (Bacharach & Bamberger, 2004; South, Bonjean, Markham, & Corder, 1982; Tsui, Egan, & O'Reilly, 1992), partially because groups dominated by females tend to isolate male minority members less than male-dominated groups do female minority members (Fairhurst & Snavely, 1983; Schreiber, 1979). Similarly, the effect of exclusion of women from male-dominated networks is also inconclusive (Brass, 1985; Ibarra, 1992, 1997; Mehra, Kilduff, & Brass, 1996).

The findings regarding gender diversity and organizational performance are also mixed, with some studies finding positive effects on at least some measures of performance (Fenwick & Neal, 2001; Jackson, Joshi, & Erhardt, 2003; Pazy & Oron, 2001; Rentsch & Klimoski, 2001), and others finding no significant effects (Richard, 2000; Watson, Johnson, & Merritt, 1998). Gender diversity may decrease perceived productivity in work groups, partially as a result of increased emotional conflict (Pelled, 1996b). Similarly, male-dominated work groups demonstrate less prosocial organizational behavior, which is also related to increased emotional conflict (Kizilos, Pelled, & Cummings, 1996). Proportionality and

gender of the focal actor are also consequential to the effects of diversity on individual outcomes such as satisfaction, commitment, and turnover (Tsui et al., 1992). Men in mixed work teams are less satisfied and have lower self-esteem than do men in male- or female-dominated teams, whereas women are most satisfied in male-dominated teams and least satisfied in female-dominated teams (Wharton & Baron, 1987, 1991). Women are more likely to leave homogeneous groups than are men, despite women's expression of greater commitment, positive affect, and perceived cooperation when working in all-female teams (Chatman & O'Reilly, 2004). Nevertheless, women are more supportive of their peers and view female superiors more positively when management is more diverse, perhaps due to higher perceived chances for advancement (Cohen, Broshak, & Haveman, 1996; Ely, 1994).

RACIAL AND ETHNIC DIVERSITY

Given that racial and ethnic diversity is significantly less studied than gender diversity, it is not surprising that its effects are somewhat murky. There is evidence that ethnic minorities behave more cooperatively than do Anglo-Americans in Prisoner's Dilemma Games, indicating collectivism (Cox et al., 1991; Earley, 1989). Contradictory evidence also exists, indicating that ethnic minorities behave more competitively when in the minority on a given task than do Anglo-Americans, whereas both groups are equally cooperative when in the majority (Espinoza & Garza, 1985). There is no more conclusive evidence, unfortunately, regarding racial diversity and conflict; racial diversity is found to cause emotional conflict (Pelled, 1993; Pelled et al., 1999), although not when the sample studied includes a large proportion of minorities (O'Reilly et al., 1997; Pelled, 1996b). This may be due to expectations of congruence for ingroup members, as disagreement is less disruptive to group processes when expressed by minorities or perceived outgroups (Phillips, 2003; Phillips, Mannix, et al., 2004). As with gender, proportionality seems to influence the effect of racial diversity.

The effects of racial and ethnic diversity on group performance are also mixed. Evidence from class-related group activity indicates that racially diverse groups perform similarly to racially homogeneous groups, but that they may consider more perspectives and generate more alternatives (McLeod & Lobel, 1992; Watson, Kumar, & Michaelsen, 1993). The results of field studies indicate a positive relationship between racial diversity and group creativity and implementation (O'Reilly et al., 1997). One possible explanation for these findings is "aversive racism" (Gaertner & Dovido, 1986), whereby individuals attempt to overtly demonstrate their lack of prejudice to compensate in situations in which perceived prejudices may be salient. Many studies, however, find no effect or weakly negative effects of racial diversity on performance (Kizilos et al., 1996; Pelled, 1996b; Pelled et al., 1999). Regarding individual-level outcomes, those in the minority are generally less satisfied and less committed to the organization, although these effects are stronger for whites

than for ethnic minorities (Riordan & Shore, 1997; Tsui et al., 1992), and such asymmetries have not been found consistently (see Bacharach & Bamberger, 2004). In summary, it seems that finer-grained studies are needed to fully understand the effects of racial and gender diversity on group process and performance.

Our review of groups and teams, negotiations, and demography and diversity is uniquely influenced by the organizational setting and the application of fundamental social psychological principles to organizational contexts. In the next section, we move more explicitly to the study of individuals embedded within the structure of organizations to examine how the reciprocal interaction of actors and their environments is affected by social psychological processes and how this in turn affects the environments in which actors operate.

THE ACTOR EMBEDDED WITHIN THE ORGANIZATION

The area of OB that is most different from traditional social psychology deals with the organizational actor as fully embedded within the organization. Here the focus is still on the individual, but the context within which he or she operates, that constrains and enables the individual's actions, is brought into much sharper focus. The organization as an identifiable and salient entity is highly developed. The focus is still on interaction of individuals, as in the previous section. However, the structure of the environment and social system plays a greater role in shaping the interaction itself. And often, the interaction has a feedback effect, influencing the social structure and environment, in turn. Because of the complexity of relationships and interactions represented by these phenomena, they are studied primarily in the field, distinguishing them from traditional social psychological research. In this section, we focus on the critical topics of social capital and networks, and power.

Social Capital and Networks

Of all programs of OB research, the study of social capital and networks, or the structure of interorganizational relationships, most explicitly views the actor's behavior as embedded in and, more important, constrained by complex social relationships and systems, as it sets all individual experiences in the context of the larger social structure, which is beyond the control of individuals. This research looks at different patterns of behavior that result from differences in structure among social systems, as well as the individual actor's relative position within those structures. The implications of network structure on macro-organizational outcomes have received a great deal of attention in sociology and strategy, whereas research in OB has focused primarily on the consequences of network structure on individual action and behavior. In this section, we first review the foundational work in this area, then review more recent research on the consequences of network composition for individual actors, paying particular attention to minority

group members, as well as consequences for organizational outcomes.

Social Networks and Embeddedness

The concept of social networks and the methodologies used to analyze them have developed through macro-organizational and sociological research over the past 30 years, moving from highly mathematical models in the natural sciences and information science to the social sciences. Granovetter (1973, 1985) provides the primary point of departure, arguing that because all interaction takes place in or is "embedded" within a social context (i.e., does not occur between atomistic actors without histories or futures), understanding that context itself is critical to understanding social interaction. Inasmuch as social networks structure small-scale, highly local interactions, they also impact the social structure in which all interaction occurs.

Granovetter (1973) also differentiates weak from strong social ties, which can be thought of as interpersonal relationships or connections within a network. Drawing on Homans (1950), Granovetter argues that the strength of a social tie is a function of the amount of time, intimacy, emotional intensity, and reciprocity that characterize the relationship it represents; that is, the more time actors spend together, the stronger their feelings of friendship and connectedness to each other. Based on homophily, assumed similarity, and cognitive balance theory (Heider, 1958; Newcomb, 1961), the stronger the tie between two actors, the larger the proportion of ties with third parties they will have in common. Strong ties are valuable because they breed trust, openness and exchange, even in the absence of formal contracts (Granovetter, 1985). Weak ties are also valuable, however, because they can form bridges that link otherwise unconnected actors, thereby facilitating communication and diffusion across the network (Granovetter, 1973).

Strong ties may be more interesting, however, inasmuch as they engender social capital, a property of social relationships and structures that facilitates action by the actors within those structures that could not be achieved without the relationship (Coleman, 1988). That is, strong ties give individual actors access to resources that they can use to in pursuit of their own interests, and so help explain differences among individual outcomes, as well as differences among macrosocial outcomes. Similar to cohesion, social capital inheres within the structure of relations between and among actors, rather than the actors themselves. Benefits accrue to actors with social capital because strong ties give them access to valuable information channels, engender obligations and expectations of reciprocity and trustworthiness, and promote the development of norms and sanctions that make trust less risky (Coleman, 1988). The advantages of social capital inherent in strong ties grant actors access to the unique resources of others within the network, while insulating them from opportunism and exploitation. The more social capital one has, the better connected one is, and the more advantages and rewards one captures.

In contrast to Coleman's focus on the cohesive nature of social networks, Burt (1992, 1997) focuses on the opportunistic side of social networks: weak ties. Burt (1992) argues that social capital can be measured not only in terms of access to people with specific resources but also in terms of the social structure in its own right. Structural hole theory poses social capital as a function of brokerage opportunities in a network, or the ability of one actor to bridge others on opposite sides of a hole in the social network, with positive economic effects for the network. Brokerage gives the focal actor several advantages: timing benefits resulting from unique information regarding new opportunities created by needs in one group that might be served by the skills of another; the ability to bring actors from opposite sides of the structural hole together when it would be profitable, or referral benefits; and control over whose interests are served and what information flows across the structural hole (Burt, 1997). Similarly, the presence of the broker gives the network access to more, nonredundant information.

Individual Consequences of Network Position

Building on Granovetter (1973, 1985), Coleman (1988), and Burt (1992, 1997), OB researchers argue that who we know is as consequential to individual outcomes as who we are. The process of elaborating contingencies and moderators associated with individual outcomes began with Burt (1997), who argued that bridging structural holes was more valuable to actors in senior positions and to managers working across significant boundaries within or across the organization. To do their jobs effectively, actors occupying such positions must capitalize on their social ties, whereas their access to and control of information and opportunities gives them more entrepreneurial prospects, making them seem more capable and more creative than others. Thus, structural hole brokers tend to be promoted earlier than their peers, although because they extract value from the uniqueness of their opportunities, the value of their social capital decreases as the number of actors occupying similar positions increases (Burt, 1997).

Not only does relative position within the network structure impact material outcomes, it also has consequences for effectiveness, performance, and satisfaction. Network centrality—the number of direct contacts and access of a given actor within a network—should, for example, increase individual performance, inasmuch as it bestows information and referral benefits to the focal actor. This relationship is contingent upon the type of network, such that centrality in friendship and communication networks is associated with satisfaction and performance, whereas centrality in adversarial networks lowers satisfaction and performance (Baldwin, Bedell, & Johnson 1997).

Although networks and social capital are largely structural theories, their impact on individual outcomes can be based on perception alone. For example, being perceived of as having high-reputation and high-status friends within an organization boosts the focal actor's reputation, although actually having such a friend has no

incremental effect on reputation (Kilduff & Krackhardt, 1994). Similarly, actors with more accurate mental representations of intra-organizational networks are seen as more powerful, independent of their informal and formal structural positions (Krackhardt, 1990). Being perceived as prominent within a given network is often a function of being visible, affiliated with central organizations, and connected to a social network through both strong and weak ties (Burt, 1982; Cole, 1979; Cole & Cole, 1973). These same characteristics also make actors poor self-estimators, making more internal attributions based on downward social comparison (Cerulo, 1990; Festinger, 1954). Thus, prominent scientists, for example, overestimate their own productivity when their prominence is attributed to internal effort or personal characteristics, whereas they underestimate their relative productivity when their prominence is attributed to external circumstances (Cerulo, 1990).

Social Capital and Minority Groups

The impact of who you know is particularly salient for minority group members. A great deal of research therefore focuses on the impact of the structure of network ties on outcomes consequently achieved by minorities. In general, minority group members benefit from having heterogeneous, nonoverlapping networks, whereas majority group members benefit from having homogeneous networks characterized by multiplex ties. Men generally have more multiplex, homophilous, and strong ties than do women and are more likely to hold central positions in organizational interaction networks; in contrast, women are more likely to differentiate their personal networks, gaining social support and friendship from other women, but instrumental access through network ties to men (Ibarra, 1992).

Like women, minority managers tend to have more racially heterogeneous and fewer intimate network relationships than do nonminorities (Ibarra, 1995). Nevertheless, minorities achieve the best outcomes when they use different groups as social resources. Minority group members with the highest potential for advancement balance the number of cross-race and same-race ties and high-status and low-status ties within their networks, ensuring themselves access to both information and psychosocial support (Ibarra, 1995). Because they maintain potential status distinctions, differentiated networks of this sort may also be beneficial to the interaction of racially heterogeneous work groups. Although actors in racially homogenous groups that segment work-related and nonwork relationships experience lower levels of behavioral and psychological integration with their work teams, similar segmentation in the context of racially diverse work teams actually increases in-team integration (Phillips, Rothbard, & Dumas, 2004).

These findings highlight the need for minority group members to proactively manage their social networks to achieve superior organizational outcomes, as heterogeneous and differentiated networks do not readily emerge for most minority group members. Distinctiveness theory (McGuire, 1984) suggests that actors identify with others with whom they share a relatively rare characteristic within a given social context, because relative rarity heightens the salience of such characteristics. Relative minority group members, therefore, tend to make identity and friendship choices within their own minority groups, rather than with the majority group (Mehra, Kilduff, & Brass, 1998), although Ibarra's (1992, 1995) research points to superior outcomes for those with more balanced networks. Integration into heterogeneous networks may be more difficult for women than for racial and other minorities, however, as racial minorities' relative network marginalization tends to result from individual preferences for same-race friends, whereas women's marginalization is attributable more to exclusionary pressures than to preferences for female friends (Mehra et al., 1998).

Organizational Consequences of Social Networks

At the intraorganizational level, just as network structure influences the process of microinteraction, microinteraction influences network structure, and hence the organization itself. Networks have a significant impact on employee turnover, which tends to occur in clusters, based on employee positions in advice networks. When actors see others in similar positions leaving an organization, they tend to reconsider their options and alternatives, and ultimately leave, as well (Krackhardt & Porter, 1985, 1986). Similarly, attitudes toward work are often subject to the social influence of those with whom an actor interacts regularly and are similar to those of structural equivalents, or actors in similar positions (Erickson, 1988; Krackhardt & Brass, 1994; Krackhardt & Kilduff, 1990; Rice & Aydin, 1991). Evaluations of job design are also affected by network position; actors' evaluations are influenced by those with whom they interact most frequently (Krackhardt & Brass, 1994; Salancik & Pfeffer, 1978). Power, leadership, and motivation are also partially determined through network membership and position (Krackhardt & Brass, 1994).

When OB researchers go beyond the individual level, the material consequences of network structure become more apparent. Field studies at the business-unit level, for example, demonstrate that network structure can help explain outcomes related to information transfer. Strong ties between business units within the same organization are more capable of transferring tacit, complex, uncodified, and interdependent knowledge from one to the other than are weak ties. Nevertheless, weak ties are capable of enabling the transfer of simple, codified, and independent knowledge (Hansen, 1999). Thus the ability of an organization to exploit its own knowledge internally, and hence to innovate and to compete, is contingent upon the structure of its own internal networks. Uzzi (1997, 1999) finds similar results at the interorganizational level in his field studies. The trust, information, communication, and coordination ability inherent in strong ties that are embedded in multiplex relationships—that is, relationships that are both social as well as transactional—lower the cost of transacting among members of such relationships, as they do among

members of networks marked by strong ties (Uzzi, 1997, 1999).

Although social capital and social networks can be built and used instrumentally, the study of social networks does not focus explicitly on their strategic use. Rather, such research generally falls into the domain of power and influence, to which we now turn our attention.

Power and Influence

Organizations are influenced and characterized by the search for and exercise of power. Whereas social psychology deals extensively with the behavioral antecedents and consequences of power and its phenomenological experience (e.g., Anderson & Berdahl, 2002; Dovidio & Ellyson, 1982; Keltner et al., 2003; Overbeck & Park, 2001; Reynolds, Oakes, Haslam, Nolan, & Dolnik, 2000; Tiedens & Fragale, 2003; etc.), and interpersonal influence and persuasion (e.g., Petty & Cacioppo, 1986a, 1986b, 1979a, 1979b; Petty & Krosnick, 1995), OB is more concerned with power as a social phenomenon, situated within the organizational context.

Most OB research on power posits completing views of dependence relationships within organizations or systems. Ocasio (2002) identifies three main schools of thought: the functional school, which sees power emerging in response to organizations' efforts to interact with and manage their environments; the structural school, which emphasizes the criticality of structural position in determining power relationships; and the institutional school, which highlights the role of culture and institutions in distributing power (Ocasio, 2002). Such explanations are not fully satisfactory, however, given the often mixed empirical support for resource dependence theories of power (Astley & Zajac, 1990; Lachman, 1989). A broader view of power has therefore been posited by Ocasio and Pozner (2004), who also take the social psychological mechanisms associated with status into account.

Functional Perspectives

Functional views of power take organizations as social systems adapting to changing environments. Power therefore accrues to the individuals and organizational subunits that contribute to adaptation, survival, and success given the problems facing an organization at a given time. March (1962) and Cyert and March (1963) develop the idea of the organization as resolving conflict with political coalitions, whose composition is contingent upon the contribution made by members given the organizational context. Perrow (1961) builds on Cyert and March by explaining that power accrues to subunits that resolve the tasks most important to the organization, which he defines as securing the resources needed to function and grow; legitimizing operations; assembling necessary skills; and coordinating member activities and relations with other organizations and consumers.

Hickson, Hinings, Less, Schneck, and Pennings (1971) find that subunits gain power to the extent that they cope with the critical uncertainties of other subunits in a way that cannot be achieved by third parties. Thus it is not the performance of Perrow's four basic tasks that generate power but, rather, the extent to which this performance makes others dependent on the focal subunit. Hickson and colleagues also point out that power decreases as a subunit's tasks become routinized and as the information and uncertainty absorption provided by that subunit become less critical. Salancik and Pfeffer (1974) argue that the most power accrues to the organizational subunits that contribute the most critical and scarce resources, and that this power is used to influence resource allocation, in turn.

Whereas these arguments are intuitively compelling, they are not always supported empirically. Functional arguments are supported when research focuses on the contemporaneous coincidence of power with control over contingencies and resources, yet in a longitudinal study, Lachman (1989) finds no correlation between control over contingencies and power over time. Similarly, Astley and Zajac (1990) find that nondirectional interdependence among organizational units is a better predictor of power than dyadic dependencies. This suggests that, in addition to resources and constraints that accrue to actors based on long-term commitments and relationships, power is a function of properties of the broader organizational system.

Structural Perspectives

Structural perspectives focus on the embeddedness of groups and individuals within the structure of social relationships embodied by the organization. They hold that it is not only the ability to perform certain functions or provide resources that generates power but also one's relative position within formal and informal organizational structures. This view is perhaps best expressed by Emerson's (1962) assertion that power is a function of the social relation, not the individual actor. Cook and Emerson (1978) demonstrate further not only that social exchange establishes power but also that the constraints and resources imposed on actors by long-term social commitments play a role. This concept has been successfully extended to multilateral relationships, such as exchange networks (Cook & Emerson, 1978; Cook, Emerson, Gilmore, & Yamaguchi, 1983; Willer, 2003), and different types of exchange (e.g., reciprocal or negotiated) (Molm, Peterson, & Takahashi, 1999). Brass (1984) reinforces the importance of structural position to power distribution in his study of individual power; he finds that certain actors, such as boundary spanners, are likely to accrue more power based not simply on their own abilities but because of their central and critical network positions.

Similarly, much theory and many studies show that power can accrue to actors through others' perceptions of the power and prestige associated with their positions and affiliations, rather than actual capacities and skills (Adler & Kwon, 2002; Bourdieu, 1977, 1985, 1989; Finkelstein, 1992; Krackhardt, 1990). Network position is also central to Burt's (1997) finding that social capital,

or the ability to broker network holes, is more valuable to certain organizational actors: those with relatively few peers, in senior positions, working across significant intra- or interorganizational boundaries, or who are more visible. Individual actors' personal affiliations also have implications for power attributions, as individuals in groups may use the perceived power of a new member to attribute power to the group, and outsiders may base their perceptions of individual group members on the group's reputation (Fiol, O'Connor, & Aguinis, 2001; Fombrun, 1983). Kilduff and Krackhardt (1994) show that friendship with prominent actors increases attributions of the focal actor's own power and skills.

Institutional Perspectives

Institutional perspectives on power agree that structural and functional arguments do not adequately capture the sources of organizational power, because they are embedded in institutions. Rather, they suggest that prevailing rules, norms, and culture shape both structure and function as well as power distribution. The neo-Weberian argument articulated by Jackall (1988) posits that it is both hierarchical position and the control over culture—which represents organizational values, relevant categories, and acceptable alternatives—that form the bases for power. Selznick (1957) argues that power relationships determined by the institutionalization of value-infused organizational commitments and self-definitions. This is echoed by Stinchcombe (1965) and Kimberly (1975), who pose that the structures created at an organization's founding delineate the power of individuals and subgroups, which is resistant to change. Finally, Brown (1978), Oakes, Townley, and Cooper (1998), and Thornton and Ocasio (1999) present a political–cultural approach to organizational power. Brown, supported by the empirical findings of Oakes and colleagues, describes paradigm control and control over agendas as sources of power, whereas Thornton and Ocasio find that certain determinants of power are more salient than others based on cultural framing of organizational attention.

Status and Power

In contrast to perspectives of power and organizational dependence, a more interactionist approach is taken by the sociological social psychologists who study status. This intellectual tradition is rooted in early social psychological studies of status determination in small groups (Sherif, White, & Harvey, 1955). Status can be defined as one's position of honor within a social field (Weber, 1946), and it is often accompanied by beliefs about social worth, such that an actor in a given status position is generally thought to be "better than" or "worse than" an actor in a different position (Sell, Lovaglia, Mannix, Samuelson, & Wilson, 2004; Sewell, 1992). Social fields are thus marked by status structures, or rank-ordered relationships among social actors. Such hierarchies are inherently relational and contingent upon shared values within the social system; that is, two systems with mem-

bers identical on relevant dimensions but different rules of the game would have differently ranked status structures. Although they often conflate the two concepts (e.g., Berger, Conner, & Fisek's [1974] power and prestige order), these theorists explain the complex social psychological links between status and power.

One way to think about the relationship between power and status is through the mechanism of status conferral. Social actors bestow status on each other by enacting voluntary compliance, deference, acceptance, and liking without threat or coercion (Kemper & Collins, 1990). When status-conferring microinteractions are repeated through interaction ritual chains, they contribute to the definition of the macrosocial status structure (Collins, 1981). Status conferral increases the likelihood that the high-status actor will be deferred to again, implying that high-status actors can exert power through deference rather than coercion.

Another interactionist argument is presented by expectation states theory, an outgrowth of social exchange theory. This theory holds that based on their relative status positions, actors form expectations about their own and each other's abilities, skills, and performance; these expectations ultimately determine the distribution of participation, influence, and further prestige (Berger, Cohen, & Zelditch, 1972; Humphreys & Berger, 1981). Based on intersubjective expectations, higher-status actors are given more opportunities to contribute, are more likely to offer contributions, to receive positive evaluations of their contributions, and to be influential in group decisions (Berger et al., 1974). Behavior interchange patterns develop over time into stable interactions that are consistent with the power and prestige order and are generalized to situations outside those in which the original status ordering was created (Fisek, Berger, & Norman, 1991). Status thus becomes an organizing structure for group interaction, in that it defines the terms under which power may be legitimately and acceptably used (Sell, Lovaglia, Mannix, Samuelson, & Wilson, 2004). Snyder and Stukas (1999) find that such status expectations create self-fulfilling prophecies, whereby the perceiver adopts behavior that causes the relatively high-status actor to appear to confirm the perceiver's expectations.

Social psychology has produced a number of findings that help OB scholars understand the microlevel mechanisms working on both the relatively high-status actor and the lower-status actor. High-status actors receive abundant resources, both physical and social, such as attention, flattery, and respect, giving them the phenomenological sense of power (Keltner et al., 2003). Actors experiencing a sense of power have been shown to be more likely to take action, regardless of its potential risks (Galinsky et al., 2003), to attend more to rewards and less to threat and punishment, and to be less inhibited in their behavior (Keltner et al., 2003). This engenders cognitive and behavioral effects on those with whom the relatively high-status actor interacts, as he is perceived by others as more powerful, engendering a submissive reaction on the part of the perceiver (Dovidio & Ellyson, 1982; Tiedens & Fragale, 2003). The perceiver then inter-

prets the actor's dominant behavior as an indicator of status, reinforcing the status-to-power link (Ellyson & Dovidio, 1985).

Status also has an effect on the course of that interaction. Status may increase access to resources that can be used to create dependence (Thye, 2000). Similarly, perceptions of status affect the most microprocesses of social interaction to such an extent that it can create and perpetuate feelings of power, which in turn increase perceptions of power. At the same time, one can have status without power, as well as power without status, and power use may lead to status-reducing conflict and resistance (Willer, Lovaglia, & Markovsky, 1997). Thus, although the link between power and status is sufficient to demonstrate that power is not simply a structural–functional phenomenon, it is still insufficient to explain power alone.

Organizational behavior takes a rather broad view of power, incorporating interactionist, structural, functional, cultural, and experiential perspectives. Because it approaches power from many angles, it has yet to produce a unified theory of power. Nevertheless, this thorough investigation of power, from the psychological to the structural, will ultimately provide a comprehensive view that can be applied not only to organizational contexts but also to any arena of social interaction.

CONCLUSION

As most reviews eventually admit, we have been openly selective in our review of OB research. We focused on research that has a timeless quality and that has already spawned new streams of research. In selecting this research, we hope to show that organizational behavior is not merely an application of social psychological research to organizational contexts. Moreover, we mean to demonstrate the benefits of field research in elaborating the complex mechanisms at work in many social phenomena, particularly those involving small groups and larger social units. Finally, we intend to show how situating social psychological research within a macrosocial context such as the organization provides insight into the dynamics of social interaction, that is, the way that actors' individual responses to social stimuli influence not only their own behavior but also the reactions of other actors as well as the context in which they interact.

We have relied on a levels-of-analysis approach to guide our review of organizational behavior. In doing so, we have revealed how OB scholars define themselves. In this regard, the tensions that define social psychology (individual vs. group research) are similar to those that occur within OB. If anything, the divisions run deeper in OB. A given problem, such as an underperforming team may be accounted for via an individual level of analysis, an interpersonal level of analysis, a team approach, and in many cases a more macroapproach. OB has challenged young researchers to heal the rift and engage in what is euphemistically called mesoresearch. The idea is that a mezzanine is the floor that is halfway between the lobby (micro) and the upper (macro) levels of the organization. Some have tried to navigate this crevasse, but many have failed.

As a field, organizational behavior could be likened to a teenager, desperately trying to gain independence from its mother and father disciplines: social psychology and sociology. Thus, far, mom and dad are not overly impressed by OB. Moreover, the ungrateful teenager enjoys all the benefits of having an influential and successful mom and father but is not reciprocating—at least judging by the frequency with which social psychology and sociology journals cite OB papers (as opposed to vice versa). And, like most teenagers, OB does not really desire to follow in mom and dad's footsteps. And, like many teenagers, OB is not bashful about wanting to take whatever new car (theory or paradigm) that social psychology might have developed out for its own spin. We suspect that as OB continues to mature, there will be a greater independence and perhaps a deepened appreciation between the two fields.

CHAPTER 41

Social Action

MARK SNYDER
ALLEN M. OMOTO

In many ways, working alone and working together, people take action that benefits society. Not all these efforts are necessarily motivated by an explicit desire to benefit society, certainly, but the combined effects of individual action can have a profound effect on society. For example, people may practice the habits of recycling and conserving energy, as well as use mass transit, in order to preserve and conserve natural resources or even to save a few dollars or to avoid the stress of driving at rush hour. They may serve as volunteers and provide services to other people who have difficulty caring for themselves. They may participate in programs in schools and in the workplace that provide opportunities for community service. Or, in an effort to spend more time with their children and be a positive influence in their lives, they may coach little league sports teams or serve as the leader or chaperone of youth groups. They may join neighborhood groups and organizations and, where none exist to meet the needs of their communities, take the initiative to found them and assume leadership roles in them. They may vote and work on political campaigns, and even run for office themselves, in order to elect political leaders who will work on behalf of causes they value. They may engage in lobbying and advocacy efforts to arouse the passions and efforts of other people or to work for the passage of legislation of concern to them. They may join and be active in social movements that are dedicated to causes of concern to them, such as improving the living conditions of disadvantaged groups in society, protecting and expanding human rights, and working for peace at home and abroad.

These activities are all instances of individuals seeking to address problems of society by engaging in what is often referred to as civic engagement, citizenship behaviors, or (more generically) *social action*. It has often been suggested that one way to solve many of the problems confronting society is to promote such forms of social action, that is, to encourage people to act in ways that will benefit not only themselves as individuals but also the larger communities and the society of which they are members (e.g., Omoto, 2005a; Omoto & Snyder, 2002; Snyder & Omoto, 2001; Van Vugt & Snyder, 2002). Social action by individuals and groups can and does take many forms. Some social action is explicitly political, such as involving oneself in the political process by voting or working for an election campaign, but many forms of participation are not necessarily politically motivated or guided, such as volunteering one's time to help others in need, looking out for one's neighbors to deter crime, conserving natural resources, and becoming active in community groups or organizations.

SOCIAL ACTION AND SOCIAL PROBLEMS

More generally, many social commentators have emphasized the importance of social action as a form of "citizenship" and "citizen participation" involving individuals taking action in response to societal problems (e.g., Boyte & Kari, 1996) and in generating "social capital"—bonds of trust among citizens that are built through participation in the affairs of their larger communities

(Coleman, 1990; Portes, 1998; Putnam, 1993, 1995, 2000). In fact, there is a substantial body of research that examines such citizenship behaviors and the ways in which the coordinated activities of individuals can serve the common good (e.g., Kymlicka & Norman, 1994; Putnam, 1993, 1995; Van Vugt, Snyder, Tyler, & Biel, 2000; Verba, Schlozman, & Brady, 1995).

The role of social action and citizen participation in solving societal problems is an enduring fixture of American society and is widely endorsed, regardless of political leaning (e.g., Chambré, 1989). Those on the political right (in the United States, and elsewhere) may promote civic participation as a means to save government money, to enhance local control over important issues, and to avoid what they see as potentially oppressive government-imposed solutions to local problems. And, those on the political left may advocate for grassroots organizing, and encourage individuals and groups to cooperate in order to effect positive community change, including community growth and empowerment driven by citizen participation. Although they may not agree on which problems are pressing or on the best solutions to adopt, there appears to be agreement in valuing and encouraging involvement of individuals in taking action to solve social problems. As one indication of how much a part of the shared ideology of the U.S. social action is, one need only note that every President from John F. Kennedy to George W. Bush, over a period of close to a half century, in accepting the nomination of his party or in his inaugural address to the nation, has stressed the importance of citizen involvement and doing good works. (See also the historical account of de Tocqueville, 1835/1969, who stressed how deep the roots run in North America for interest in and commitment to public and shared service as well as efforts to join together and work with others without regard to political differences.)

Our concern in this chapter is with understanding the nature of social action—to articulate principles that can aid in understanding how and why individuals take action on behalf of others and that benefit society. The phenomenon of social action is intriguing for a variety of reasons. From a practical standpoint, social action involves real people taking real actions in the service of real causes, often doing so over extended periods of time and at considerable personal cost and sacrifice. Moreover, the outcomes of social action have real consequences for the well-being of individuals and the effective functioning of society. From a theoretical standpoint, they represent compelling instances of motivated and goal-directed activities, ones that capture the bridging of individual and collective action in pursuit of ends that benefit not only those taking action but also society at large. In fact, as we discuss in greater depth later in this chapter, considerations of social action simultaneously span and link several levels of analysis, and, accordingly, research on these topics holds the promise of helping to develop broader and more comprehensive understandings of many phenomena of interest to all stripes of psychologists as well as sociologists, economists, historians, anthropologists, and political scientists.

In this chapter, we seek an understanding of the principles that account for and govern social action. Our analysis proceeds sequentially and on two fronts, seeking descriptive principles and explanatory principles. The quest for *descriptive principles* seeks answers to the general question of what social action is, including the tasks of discovering basic organizing principles that reveal the characteristic features of social action, that tell us what can profitably be included in the category of social action and what might be excluded from that category. The search for *explanatory principles* seeks answers to the general questions of what causes and what accounts for social action and involves a search for the causal determinants of social action and the purposes served by social action.

DESCRIPTIVE PRINCIPLES: WHAT SOCIAL ACTION IS

To pursue the goal of explicating descriptive principles of social action, let us articulate, by building on the examples with which we began this chapter, an organizing framework of characteristic features that cross-cut various forms of social action. In so doing, we seek to specify what is to be included in the category of social action and what is to be excluded from that category (as well as some phenomena that test the limits of what is and what is not social action). Moreover, understanding the nature of social action may inform the search for an understanding of the processes that generate and account for social action; that is, knowing what social action is may help explain what causes social action. We hasten to point out that ours is an initial attempt to provide organizing principles for this realm and not an exhaustive list of defining and mutually exclusive characteristics. In other words, we have a more modest goal of trying to offer a set of principles that can help to map the terrain of social action—a taxometric tool, so to speak, that can be used to link and distinguish different forms of social action.

An Individual Phenomenon, but Also a Social Phenomenon

To begin with, we propose as our first descriptive principle that social action is both an individual phenomenon and a social phenomenon. The phenomena of social action are *individual* phenomena in that they involve the actions of individuals, reflecting their individual concerns, their personal values, their own motives, and their particular goals. These phenomena are *social* as well, and they are social in several different ways. First, they are social in that they are engaged in not only by individuals but also by collections of people, and often by people who band together to perform these activities in groups, organizations, and communities (for a related discussion of the "levels" at which helping and prosocial behavior can occur, see Penner, Dovidio, Piliavin, & Schroeder, 2005). Second, they are also social in that they are done on behalf of other people, who are the beneficiaries of social action, and often for the betterment of society at large.

That is, they are actions that are generally intended to serve a social good. Thus, social action involves activities that have social and societal impact, impact that is arguably most evident when considered collectively, as the combined consequences of individual actions. Furthermore, and building on this idea that social action is, at one and the same time, both an individual and a collective phenomenon, social action represents a connection between the individual and the social, a way for individuals to join their interests with the interests of other people, to bond with their communities, and to become engaged with society at large. That is, and as we shall see, considerations of social action provide a template for understanding the linkages between and among individuals, the groups to which they belong, the communities of which they are members, and with the larger society—and for bridging individual, group, and societal perspectives on the human condition.

Socially Valued, but Not Socially Mandated

Next, we note that many forms of social action have in common that, at least in North America, they are socially valued but they are not socially mandated. Indeed, surveys of public opinion in the United States consistently reveal widespread support for the ideals of helping others and getting involved in the affairs of one's community to make society a better place for all. For example, in the case of volunteerism as a form of social action, national surveys reveal that, by margins of over 3 to 1, Americans agree that "people should volunteer some of their time to help other people and thereby make the world a better place" and that "nonprofit organizations generally play a major role in their communities" (Independent Sector, 1988, 1999). The history and value of social action, of course, varies by culture and by country (e.g., Curtis, Grabb, & Baer, 1992; Levine, Norenzayan, & Philbrick, 2001), but our general point here is that many social action activities are culturally and socially valued, and especially when they are seen to contribute to a common good.

However, as much as social action is valued, there are no laws that mandate participation in such activities, no rules or commandments that dictate that one must be a volunteer or that one must join a community organization or that one must participate in a social movement or even (in the United States, at least) that one must vote. Rather, when people become involved in social action—whether it is when they volunteer, when they join community organizations, when they join social movements, or when they vote—they do so as because they choose to do so and because they want to do so. That is, involvement in social action, when it occurs, is a volitional or chosen action, undertaken without the requirement or the obligation to become involved. To the list of defining characteristics of social action, then, we add "activity that is seen as socially valued," but to the list of characteristics that help us to exclude certain behaviors from the category of social action we add "activity in response to requirements or coercion."

Reactive Impetus, Proactive Action

As much as social action occurs without obligation and with volition, the fact of the matter is that the impetus for social action typically is "reactive," because it occurs in response to a perceived need to change something or solve a problem. Thus, individuals who are concerned about threats to the environment may respond to those threats by forming an environmental action group to work to protect and preserve the quality of the environment. Similarly, those who are concerned about the lack of child-care services in their neighborhood may be moved to organize a network of volunteers to provide the needed services. And, in response to low wages and bad working conditions, workers may form unions to change their situations. In each case, the impetus for action, and the formation of vehicles for taking action, is provided by the perception of problems that need to be solved. Furthermore, the veridicality of the perception and, even how widely held the perception is, are much less important than the simple fact that one or more individuals think that something needs to be done.

However, whereas the precipitating conditions for social action may be reactive, when individuals mobilize themselves to take action, the actions they take are "proactive" in the sense that individuals must take the initiative to get involved, make the time and invest the effort to work toward their goals, and overcome obstacles to participation (including, at times, the skeptical reactions of friends and family who doubt whether their actions will really make a difference). Thus, for example, a social movement may come about because of a need for change, but then people who wish to participate in this social movement must figure out when, where, and how to act. As such, their actions take on a proactive character.

Moreover, at times, social action can and does occur in the context of institutional structures or mandates. For example, voting occurs in the context of clearly defined social structures that dictate when, where, and how it will occur. Other times, social action occurs outside formal structural contexts. For instance, many forms of volunteering are informal, as when neighbors help each other out and devise structures for their involvement, including "town hall" meetings, phone trees, and neighborhood block watch associations. Nevertheless, whether it occurs in the context of formal structures or not, social action can be construed as simultaneously reactive and proactive. And, in fact, it can be speculated that there may be important consequences for encouraging social action participation as well as the effects of social action activities to the extent that these activities are construed as relatively reactive versus proactive in nature.

Individual Actions, Aggregated Consequences

Although people may engage in social action as individuals, the impact of social action becomes particularly evident in the aggregation of the actions of individuals and the aggregated consequences of individuals' actions.

Thus, another descriptive principle of social action is that, commonly, it involves individual actions and aggregated consequences. For example, in voting, it is the aggregated actions of individual voters that decide elections. Similarly, in human rights movements, it is the aggregated actions of individual participants that change society. And, in volunteerism, it is the aggregated actions of individual volunteers that help to solve societal problems, such as when tutors who teach children, one by one, to read contribute to solving the problem of illiteracy.

That social action involves individual actions and aggregated consequences serves to underscore, yet again, the principle that social action is, at one and the same time, both an individual phenomenon, involving the actions of individual social actors, and a collective phenomenon, involving the aggregated consequences of the actions of many individuals working alone or in coordinated fashion.

Multiple Pathways, Common Goals

In many forms of social action, the same outcome can come from different means. These multiple pathways to common goals can be illustrated in the case of participation in a social movement (e.g., Klandermans, 1997), say an environmental action movement. Here, someone participating in such a movement who wants to take action to protect the environment and conserve resources could engage in recycling, could turn down the thermostat, could join an environmental action group, and could recruit their friends and neighbors to engage in these activities. All these actions are different means toward the shared end of protecting the environment, conserving and preserving resources, and enhancing general sustainability (e.g., Oskamp, 2000). Stated another way, these actions reflect the descriptive principle of multiple pathways to a common goal.

Similarly, in many forms of social action, there is often a certain, if even implicit, "substitutability," both on the part of those who engage in social action and on the part of those who benefit from it. For example, in the case of volunteerism as a form of social action, a volunteer Big Brother/Big Sister could shift from working with one child to another without his or her status as a volunteer changing. Similarly, as the recipient of the services of a Big Brother/Big Sister program, a child could shift from one volunteer to another but still be a beneficiary of social action. To some extent, this substitutability is related to, and may even derive from, the fact that many forms of social action are focused on helping "categories" of people rather than specific individuals, and on meeting broad needs and serving general causes. That is, even though social action may be carried out in the context of specific individuals delivering services to specific recipients, it is generally conceptualized by those who engage in social action, and by society at large, in terms of helping categories of people (e.g., helping "the needy" rather than helping the specific recipients of help) or furthering broad social causes (e.g., the Green movement).

Consequences at Several Levels, Direct and Indirect Effects

Just as there are numerous routes to the goals of social action, so too are there diverse consequences and outcomes of social action. In keeping with the view of social action as both an individual and a collective phenomenon, these consequences and outcomes can be viewed as spanning a continuum that runs from the individual through the collective. Thus, when it comes to the outcomes of pursuing agendas for social action, many of these outcomes will be at the level of the individual (such as the increases to self-esteem, affirmation of values, and new skills that may accrue to those who engage in social action). Other outcomes will be of a more interpersonal nature (such as the new people one meets, the new friends one makes, and the new patterns of socializing that will develop). And, other outcomes will affect one's relationships (such as changes in patterns of social support, impact of participation on one's existing relationships). Still other outcomes will affect groups, organizations, and society (such as when organizations and movements meet their goals through the service of their members, or nations becoming "kinder and gentler" through the good works of their citizens).

As well, the consequences of social action range in terms of their directness and their concreteness. Some consequences are specific and concrete whereas others are diffuse and abstract. For example, in the case of volunteerism, there are the direct benefits to volunteers of becoming involved (e.g., increased self-esteem, meeting people, and making friends) and the direct benefits to the recipients of volunteer service (e.g., the companionship provided by volunteers to homebound elderly persons and the tutoring provided by volunteers to children who cannot yet read).

At the same time, there are growing indications of indirect benefits, not necessarily foreseen or sought by volunteers, but not necessarily unwelcome either. Thus, among the consequences of volunteerism (and other forms of social action) are better health and psychological functioning, and even a longer life (e.g., Berkman & Glass, 2000; Brown, House, Brown, & Smith, 2004; Brown, Nesse, Vinokur, & Smith, 2003; House, 2001; House, Robbins, & Metzner, 1982; Kawachi & Berkman, 2000; Musik, Herzog, & House, 1999; Piliavin, 2003, 2004a, 2004b; Schwartz, Meisenhelder, Ma, & Reed, 2003; Thoits & Hewitt, 2001). On the other hand, there may also be unforeseen and negative consequences of volunteer work, such as when volunteers feel embarrassed, stigmatized, or otherwise uncomfortable when their acts of volunteerism, and especially the causes and people that their efforts support, become known to their broader social networks (e.g., Ratner & Miller, 2001; Smith, Omoto, & Snyder, 2001b).

Dimensions of Variability across Forms of Social Action

In the context of the shared features of social action, there are some important dimensions of variability—ways

in which not all forms of social action are created alike. Thus, involvement in social action may vary in how extended over time it is. For example, voting takes but a few moments of one's time, but serving in political office extends for the length of one's run for office and, if elected, one's term of office. Nevertheless, even social actions that, individually, take little time, such as recycling, may become repeated actions, occurring with regularity and predictability and acquiring the status of habits that may even become integrated into one's identity (e.g., Callero, Howard, & Piliavin, 1987; Grube & Piliavin, 2000). Giving blood and helping to build houses for homeless or impoverished individuals are other examples of repeated actions that require relatively more time. Moreover, many forms of helping, such as participating in immediate disaster relief, may be limited in time, but other forms, such as volunteering on an ongoing basis, may extend over considerable periods of time, with many volunteers serving for periods of years and even decades. In short, an important distinction here is between *episodic* versus *sustained* activities (e.g., see Wilson, 2000).

Social action also varies in the degree of institutional support and structure surrounding it. For example, social action can occur in the context of *formal* organizations (such as the Red Cross or the Salvation Army) that recruit volunteers and clients, and that engage in selection, training, placement, and monitoring of service. Or, it can occur in relatively more *informal* settings, such as when neighbors take the initiative to help others on their blocks who need assistance (e.g., reciprocal baby-sitting arrangements, or helping elderly neighbors by mowing their lawns or cleaning their gutters). This dimension of "formalness" or degree of "institutionalization" has consequences for estimating the prevalence of social action activities, to be sure, but it also may have implications for why people might be attracted to certain social action activities as well as how, and how easily, they are carried out. Related to our substitutability point discussed earlier (the principle of "multiple pathways, common goals"), we offer the conjecture that social actions that occur within formal organizations may have a higher degree of substitutability associated with them than actions that take place in more informal contexts.

When formal organizational structures for social action exist, furthermore, they may vary in whether they are *local* in reach (e.g., a neighborhood block watch), *national* in focus (e.g., the Sierra Club), or even *international* in scope (e.g., Amnesty International). Thus, there is variability in the extent to which social action efforts are embedded in or organized around structures, with these structures themselves differing in degree of breadth. In many cases, formal structures for social action are linked in umbrella networks across multiple levels. For example, many local animal protection organizations are part of regional affiliations as well as tied to a national organization, the Humane Society of the United States. Moreover, the activities and efforts at the multiple levels are often coordinated (e.g., national campaigns that have local events), a fact that helps to underscore our point about the impact of social action being most acutely observed

with aggregation (the principle of "individual actions, aggregated consequences").

What Is Not Social Action?

Taken together, our set of characteristic features of social action and the dimensions of variability that we have presented also give some indication of what we believe should be *excluded* from the category of social action. First, actions that occur under obligation, whether legal or moral or contractual, such as helping members of one's own family or one's spouse, would not qualify as social action because they occur with obligations stemming from familial and marital bonds. Similarly, the payment of taxes, although of benefit to society and a benefit that is most apparent in the aggregation of the inputs of many taxpayers, would not qualify as social action because it occurs with the legal obligation to pay taxes and the threat of penalties and sanctions for evading payment. More generally, actions performed under institutional pressure and in response to obligations to comply, and those that have sanctions for noncompliance, would not qualify as social action.

In addition, we wish to make clear that social action is not simply synonymous with behavior that is good for everyone. Some activities that can be characterized by our descriptive principles, for example, may benefit some individuals while disadvantaging or harming others. This state of affairs is especially evident in intergroup contexts or in situations of direct competition between social groups. In fact, many social actions, including social movements and services, develop and flourish in settings that are characterized by competition between movements or groups. Individuals may engage in social action activities intended to support one group, but those activities may simultaneously have negative effects on other (often opposing) groups.

Returning to our principle of "socially valued, but not socially mandated," therefore, we add the *caveat* that "socially valued" is determined within a specific group, societal, or cultural context. For example, social action on behalf of gay rights or the right of women to terminate a pregnancy may not be universally accepted and admired. In fact, depending on one's political leanings and one's religious or moral values, such activities may be construed as actions that work to the detriment of another group or against one's sense of the greater good. As another example, consider Ku Klux Klan activities and rallies. These activities may not be generally endorsed by the majority of Americans, yet they can be characterized by many of the descriptive principles that we have discussed. What is good for one social movement or cause may not be good for everyone or for all social actors. Thus, the simple point is that social action cannot be characterized or defined simply by its effects—all social action is not necessarily good for all people.

Similarly, although many examples of social action are also prosocial behaviors (e.g., Batson, 1998; Dovidio, Piliavin, Schroeder, & Penner, 2006), we do not wish to imply that helping and prosocial behaviors are the same

things as social action. While it is true that many forms of helping behavior share characteristics of social action, our descriptive principles can be applied, as noted previously, to many "unhelpful" behaviors as well. In addition, many instances of helping occur in direct response to an appeal for help or out of an obligation to provide aid and cannot logically be aggregated across actions or actors. These helping behaviors may be *ad hoc*, informal, and personally directed, and they include examples such as providing a ride to an elderly neighbor, fixing a meal for a coworker who has just had a baby, or making a one-time donation to a charitable cause in memory of a deceased family member or friend. These are all prosocial actions, to be sure, and they are interesting and important phenomena. However, they do not possess many of the characteristics of social action that we have explicated, rendering a full treatment of them outside the scope of this chapter. Thus, we view prosocial behavior and social action as only partially overlapping sets, and for the sake of conceptual clarity, we use the descriptive principles we have outlined to determine when prosocial behavior can also be considered a form of social action.

Finally, there are cases that test the boundaries of what constitutes social action. For example, service learning and mandatory volunteer programs in schools and corporations (that require people to volunteer or do other forms of community service) and "incentived" volunteerism (such as elder volunteer programs that pay limited stipends to volunteers) build institutional structures around what would otherwise be voluntary actions and create curious mixtures of voluntary and nonvoluntary social action. In these programs, incentives (e.g., course credit and stipends) are generally small and may be just enough to get individuals to engage in social action. In addition, individuals may retain choice about the causes and organizations with which to volunteer and donate their time. Thus, the *act* of volunteering or providing assistance may be dictated by an external agent or barely sufficient justification (e.g., Festinger & Carlsmith, 1959), but the social actor him- or herself has a fair degree of choice about where, when, and how to engage. And, for many programs, social action (e.g., volunteering) is but one option that individuals have for meeting requirements. (For further discussion of service learning and mandatory volunteerism programs, see, for example, Bringle & Duffy, 1998; Stukas, Clary, & Snyder, 1999; Stukas, Snyder, & Clary, 1999; Tschirhart, Mesch, Perry, Miller, & Lee, 2001.)

Thus, in some cases it may be meaningful to talk about activities as forms of social action that are characterized by the principles that we have outlined earlier. In other instances, the "fit" to our descriptive principles of social action may be less good. We do not include further discussion of "hybrid" variants of social action in this chapter (such as service learning). However, we note that they share several of the characteristic features of social action that we have described. In addition, they are topics worthy of research, for both practical reasons revolving around program implementation and improvement, and also to more fully build the body of scientific information on social action and related phenomena. At this time, however, we are not yet ready to fully apply our principles of social action to these intriguing and important behaviors.

Summary

At the outset, we suggested that our first goal for this chapter was to offer a set of descriptive principles that could be used to characterize social action. Having reviewed several principles, we emphasize again that this is neither an exhaustive nor necessarily a prioritized list of principles. That is, we leave open the possibility that our list of principles may need to be modified, most likely, we believe, needing to be expanded rather than reduced, in order to better capture and characterize the many diverse forms of social action. And, in the absence of compelling evidence, we are currently reluctant to claim that any principle or characteristic is more important than any other in defining or understanding social action. We have offered our descriptive set of principles in hopes of providing a conceptual framework for approaching the study of social action, and to bring some (even tentative) order to a dizzying array of social behaviors that sometimes have been studied together and sometimes been considered apart. As we suggested, our goal has been a modest one—simply to provide some guideposts and roadmaps for traversing the topography of social action.

To summarize, then, we have articulated a set of descriptive principles of social action. These principles include characteristic features of social action as well as dimensions of variability across forms of social action. Together, these principles help to organize the wide range of behaviors that can be considered forms of social action, and they also offer guides for determining which phenomena are to be included and which are to be excluded from the category of social action. Moreover, these descriptive principles serve to define what various forms of social action have in common, as well as some of the ways in which they differ from each other. They also aid in determining the degree of "prototypicality" of the different forms of social action, with some forms (such as volunteerism) matching the prototype of social action better than others (such as service learning). And, as we shall see, these descriptive principles point the way toward a consideration of the explanatory principles of social action that help to account for why social action occurs and may determine the forms that it takes.

EXPLANATORY PRINCIPLES: WHY SOCIAL ACTION OCCURS

Clearly, social action occurs. It occurs at the level of individual behaviors such as recycling, energy conservation, blood donation, voting, charitable giving, and volunteering. And, it occurs at the level of collective actions such as participating in neighborhood groups, community organizations, self-help groups, political campaigns, and social movements. But, *why* does it occur? What leads peo-

ple to engage in social action, and what keeps them involved in social action? It is to these questions that we now turn, as we seek to articulate a set of explanatory principles of social action.

Many of the characteristic features of social action suggest that it involves individuals and groups actively setting and pursuing agendas for action. Specifically, that various forms of social action occur without obligation, that individuals seek out opportunities to engage in social action, that they persist in these activities over extended periods of time, often incurring personal costs at the same time as they do social good, and that social action may involve multiple routes to the same ends, all are suggestive that social action is a purposeful phenomenon in which individuals set and pursue agendas that take them along a behavioral course in which they do social good and contribute to society. And, of course, many of these efforts are coordinated, with the full impact of them felt only as a result of aggregation across individuals.

In this sense, then, the descriptive principles of social action provide a springboard for consideration of the causal or explanatory principles of social action, which help to account for why social action occurs and the forms that it takes. That is, the analysis of descriptive principles of social action suggests that attempts to understand the causes of social action should pay careful attention to considerations of motivation as individuals seek to find ways to take action on behalf of the social good of society. Accordingly, it is with the matter of motivation that we begin our consideration of the explanatory principles of social action.

The Role of Motivation

Across diverse literatures on numerous forms of social action, investigators have adopted a *motivational* perspective, focusing theoretically and empirically on the role of motivations in "disposing" people to take action, in channeling them into particular forms of action, in guiding them through the course of their involvement, and in sustaining their efforts over time. To some extent, this emphasis on motivation reflects the fact that many of the characteristic features of social action appear to be describing and defining *motivated* forms of action—chosen activities that are entered into freely and without obligation, continuing over extended periods of time and even in the face of substantial personal costs, and in which there are multiple routes to reaching the same end of contributing to the social good. In this spirit, researchers have searched for personally based motivations that move people to seek out forms of social action, that lead them to initiate involvement in social action, and that guide and sustain their actions over time.

Volunteerism

One form of social action in which the role of motivation is clearly evident is volunteerism. Every year, in countries around the world, millions upon millions of individuals volunteer their time and efforts to directly help others (Curtis et al., 1992). In the United States alone, it is estimated that 44% of adults volunteer (Independent Sector, 2002); they volunteer for such activities as providing one-to-one companionship to the lonely, tutoring to the illiterate, counseling to the troubled, and health care to the sick. Other volunteers invest their time and effort in political campaigns, advocacy efforts, and other causes, the goals of which are not so much the direct delivery of help and assistance to others but, rather, the improvement of the conditions of life of entire groups. Accordingly, volunteerism represents a noteworthy example of social action. Volunteers contribute their time and effort with the purposes of solving problems faced by their communities, of alleviating the suffering of others, and of generally bettering the human condition. And, indeed, volunteers play critical roles in ameliorating such problems as hunger and poverty, illiteracy, and alcohol and drug abuse, as well as in advancing the agendas of various social movements and political causes such as environmental action and human rights movements (see Wilson, 2000, for a review of research on volunteerism).

Research on volunteerism has examined the motivations that dispose and sustain involvement in this form of social action (e.g., Clary & Orenstein, 1991; Clary et al., 1998; Davis, Hall, & Meyer, 2003; Davis et al., 1999; Omoto & Snyder, 1995; Penner & Finkelstein, 1998; Piliavin, 2005; Simon, Stuermer, & Steffens, 2000). Much of this research has been guided by *functionalist* theorizing that emphasizes the purposes served by action and the role of such purposes in initiating, guiding, and sustaining action (e.g., Snyder, 1993; Snyder & Cantor, 1998). In the case of volunteerism, a functional analysis concerns the needs being met, the motives being fulfilled, and the functions being served by engaging in volunteer service (Clary & Snyder, 1991; Omoto & Snyder, 1990; Snyder, Clary, & Stukas, 2000; Snyder & Omoto, 2000).

A central tenet of functionalist theorizing is that different people can and do engage in the very same behaviors to serve quite different psychological functions. According to this logic, acts of volunteerism that are quite similar on the surface may reflect markedly different underlying motivations; that is, they may be serving distinctly different psychological functions. Thus, for example, several individuals may all engage in the same form of volunteerism, say working in a shelter for individuals who are homeless, but do so in the service of quite different motives, with one person doing so to make friends, another to boost a fragile sense of self-worth, and yet another to acquire skills relevant to a career in social services. In accord with this functional principle, research has revealed a diversity of motivations that bring people to volunteerism and that sustain their involvement in volunteerism, including affirming values, enhancing self-esteem, making friends, acquiring skills, and community concern.

Several inventories having been developed to assess motivations for volunteerism, some seeking to measure motivations of generic relevance to volunteerism and

some seeking to measure motivations for specific forms of volunteerism (e.g., Clary et al., 1998; Omoto & Snyder, 1995; Ouellette, Cassel, Maslanka, & Wong, 1995; Reeder, Davison, Gibson, & Hesson-McInnis, 2001; Schondel, Shields, & Orel, 1992). Nevertheless, strong family resemblances exist in the sets of motivations identified in these diverse programs of research, and across diverse ages of the volunteer populations studied (e.g., Okun, Barr, & Herzog, 1998; Omoto, Snyder, & Martino, 2000). As well, the inventories of motivations identified in studies of volunteers have been successfully "translated" to tap the motivations for other forms of social action, such as involvement in community leadership programs (e.g., Bono, Snyder, & Duehr, 2005) and involvement in the political process (e.g., Miller, 2004).

Although there is some variability in the precise numbers of motivations identified for volunteerism, there is a set of recurring motivations. Specifically, it is common for volunteers to express motivations related to personal *values*, including humanitarian concern about others or other personal guiding values, convictions, and beliefs. Another important type of motivation revolves around *community concern*, or the desire to support and assist a specific community of people, whether or not the volunteer considers him- or herself to be a member of that community. Some people volunteer for reasons that are relatively more self-focused. For example, motivations have been identified that include volunteering for *career* reasons, either to bolster career and networking opportunities or to obtain career relevant experiences, and volunteering to gain greater *understanding* or knowledge about a problem, cause, or set of people. Other motivations for volunteerism include *personal development* concerns (e.g., developing skills and testing oneself), ego or *esteem enhancement* (e.g., to feel better about oneself or bring stability to one's life), and *social* concerns (e.g., a desire to build one's social network and to meet new people and make new friends). People may seek out opportunities to volunteer for one or more of these motivations (e.g., Kiviniemi, Snyder, & Omoto, 2002), but the simple point is that they engage in their work in an effort to meet personal and specific needs. These personal needs or motivations differ across persons, but they can also differ within the same individual over time or life circumstances.

A second central tenet of functionalist theorizing in the context of volunteerism is that these motivations are related to more general agendas for action, and that these motivations guide and direct the unfolding course of people's pursuit of these agendas. In fact, in support of this functional principle, research has documented how the motivations that bring people to engage in volunteerism foreshadow and get played out over the entire life history of their service as volunteers, predicting their experiences as volunteers and the outcomes of their volunteer service, including their contributions to the well-being of others and the benefits, costs, and other personal outcomes that accrue to volunteers themselves (e.g., Omoto & Snyder, 1995; Penner & Finkelstein, 1998). When it comes to initiating involvement in

volunteerism, people are particularly likely to become involved when circumstances suggest that engaging in social action can and will serve their own motivations. Thus, in studies of persuasive messages to recruit volunteers, the messages that have been found to be particularly effective are those that target specific motivations of individual recipients—in other words, messages that are fine-tuned to individually based needs and motives (e.g., Clary et al., 1998; Omoto, Snyder, & Smith, 1999; Smith, Omoto, & Snyder, 2001a). Volunteers also gravitate toward tasks with benefits that match their personally relevant motives (e.g., Houle, Sagarin, & Kaplan, 2005).

Moreover, once in volunteer service, matching between motivations, expectations, and experiences is predictive of greater satisfaction and lesser burnout (e.g., Crain, Omoto, & Snyder, 1998; Omoto et al., 2000). Similarly, when it comes time to decide whether to continue to be involved in volunteering, volunteers are particularly likely to do so in circumstances in which their own motivations are being fulfilled (e.g., Clary et al., 1998; O'Brien, Crain, Omoto, & Snyder, 2000; Williamson, Snyder, & Omoto, 2000). This principle of the "matching" of motivations and experiences and the facilitating effects of such matches on events related to the initiation and sustaining of social action have been observed in other social action contexts as well, including studies of the determinants of voting behavior (e.g., Burgess, Haney, Snyder, Sullivan, & Transue, 2000; Lavine & Snyder, 1996). The functional theoretical perspective guiding research on volunteer motivations and the motivations identified in related research guided by it serve as reminders that volunteers act both on behalf of *others* (e.g., volunteering to alleviate the problems of homelessness, poverty, etc.) *and* on behalf of *themselves* (e.g., volunteering to make friends, acquire new skills, and affirm personal values). This joining of concern for others and self is, of course, highly congruent with the nature of social action as individual action taken on behalf of larger societal concerns (i.e., the descriptive principle of "an individual phenomenon, but also a social phenomenon") and the bridging of individual and collective concerns that is characteristic of social action.

Civic and Political Participation

An emphasis on the role of motivations for social action, and on the importance of recognizing a diversity of motives that may be differentially important across individuals who engage in social action, is also evident in research on the motivations for civic engagement and political participation. Thus, in their attempts to understand individuals who had become active in civic and political causes, Verba and colleagues (1995) identified four categories of benefits that people may seek from civic participation: selective *material benefits* (e.g., furthering one's own career), selective *social gratifications* (e.g., being with other people), selective *civic gratification* (e.g., making the community or nation a better place), and *collective outcomes* (e.g., influencing government policy). These benefits clearly span a continuum from outcomes of relatively

specific benefit to individual activists to outcomes that benefit larger collectives of individuals in communities, states, and nations.

Based on interviews with political activists, Teske (1997) has also identified a diversity of motives that may underlie political participation, including the affirmation of one's principles, the good feelings derived from doing the right thing, growth and development as a person, increased self-esteem, and gaining community. Finally, adopting an explicitly functional approach to motivation, Miller (2004) has examined the role of several motives (including value expressive, social, ego defensive, self-interest, and collective interest) in predicting political participation.

Social Movements

The role of motivation has also been central to understanding participation in social movements. It is well known and documented that members of certain social groups (ethnic minorities, women, gays and lesbians, etc.) are often targets of prejudice and discrimination, have limited economic and employment opportunities, and do not enjoy full access to education and health care. Sometimes, attempts to change these disadvantaged conditions take on a collective form, as when people decide that the only way to change these disadvantageous conditions is to join together with other members of their group to take collective action for the good of the group. The activities of social movements can include public discussions, lobbying, petition drives, boycotts, protests, and civil disobedience. The list of social movements is a long one, with movements dedicated to issues of race, class, gender, sexual orientation, peace, the environment, labor, nuclear power, to name but a few, attracting legions of participants around the globe.

Motivational issues have been a central concern in attempts to understand why people participate in social movements and engage in collective action (Klandermans, 1997; Klandermans & Oegema, 1987; Simon et al., 1998, 2000; Stryker, Owens, & White, 2000; Tropp & Brown, 2004). Thus, in his theory of social movements, Klandermans (1997) has proposed three classes of motivation for social movement participation, each originating from different types of expected costs and benefits of participation. The *collective motive* involves the shared benefits that the social movement seeks (e.g., equal rights and higher wages). The *normative motive* involves the expected reactions of significant others to one's participation in a social movement (e.g., approval or disapproval, praise or criticism). And, the *reward motive* involves the individual and personal costs and benefits of participation (e.g., time taken away from work or new friends made in the movement). The role of these three motives has been documented in a variety of social movements, including (among others) the labor and peace movements in the Netherlands (Klandermans, 1984, 1997; Klandermans & Oegema, 1987); for related studies of social movements, see also Simon and colleagues (1998); Stuermer (2000); Stuermer and Simon (2004b); Stuermer, Simon, Loewy, and Joerger (2003).

Organizational Citizenship

The role of motives for participation has also been examined in another domain of social action, namely, organizational citizenship behavior. It has been suggested that for firms and organizations to operate successfully and to encourage employee satisfaction and camaraderie, workers must do more than the formally specified technical aspects of their jobs; toward those ends, it has been suggested that workers engage in prosocial behaviors directed at helping others and the organization itself, phenomena referred to as organizational citizenship behaviors (Borman & Penner, 2001; Brief & Weiss, 2002; Cropanzano & Byrne, 2000; Katz, 1964; Organ, 1988). Most conceptualizations of organizational citizenship behaviors have drawn distinctions between prosocial behaviors that are directed at helping specific individuals or groups within the organization and prosocial behaviors directed at the organization itself (e.g., Organ & Ryan, 1995; Smith, Organ, & Near, 1983). And, a variety of personality, attitudinal, and motivational variables have been linked to organizational citizenship behaviors (for reviews, see Borman, Penner, Allen, & Motowidlo, 2001; Motowidlo, Borman, & Schmitt, 1997; Organ & Ryan, 1995).

Of particular relevance to our current concerns with motives and social action, Penner, Midili, and Kegelmeyer (1997) have conceptualized organizational citizenship as proactive behaviors, consciously chosen by individuals and engaged in to meet their needs and to satisfy their motives. Drawing from functionalist theorizing proposed and developed in the context of volunteerism, Penner and colleagues have suggested that the same acts of organizational citizenship could reflect different motives for different individuals. Guided by and in support of this theorizing, Rioux and Penner (2001) have identified and developed measures of a set of motives for organizational citizenship behaviors—specifically *prosocial values*, *organizational concern*, and *impression management*. Moreover, they have found that prosocial values motives were most strongly predictive of organizational citizenship directed at individuals, whereas organizational concern motives were most strongly associated with organizational citizenship behaviors directed at the organization (see also Finkelstein & Penner, 2004). For additional perspectives on the motivational bases of organizational citizenship behaviors, see Bolino (1999) and Folger (1993).

Summary

Thus, in four domains of social action—volunteerism, civic and political participation, social movements, and organizational citizenship—we have seen the important role that motives play in disposing people to become involved. In each domain, we have seen that there is a diversity of motives potentially in play. Moreover, it appears that the sets of motivations, although they may involve some degree of specificity for particular forms of social action, include some recurring themes and interrelated themes. Specifically, there is clear emphasis on the

importance of recognizing a diversity of potential motivations, as well as the necessity of identifying which motive or motives are particularly salient for which individuals at any given time in promoting and sustaining social action.

The importance of motivations is evident across many of the unfolding stages of participation in social action, as motivations set the stage for and foreshadow the expectations that people form in anticipation of getting involved in social action, their choices to get involved, the experiences that they have while participating, their satisfaction with their participation, and their ultimate decisions to continue their involvement over time or to terminate their participation. That is, motivations set the stage for the agendas for action that individuals pursue in the context of social action.

The Role of Identity

Not only are motivations implicated in social action, so too are there indications of an important role for identity and identification concerns in understanding social action. That is, for some people and under some circumstances, involvement in social action appears to derive from, as well as become a part of, one's identity, part of that which defines who one is, both as a matter of *individual identity* and as a matter of *social identity*. It is, so to speak, not just that one *"does"* social action but that one *"is"* a social actor. Identity concerns are thus another explanatory principle of social action.

Individual Identity

In the case of individual identity, roles and habits have been implicated in the initiation and persistence of social action. Consider the case of blood donation as a form of social action. In their attempts to explain why people become blood donors and especially why some people become regular and habitual blood donors, Piliavin and Callero (1991; Callero, 1985; Callero et al., 1987; Charng, Piliavin, & Callero, 1988; Piliavin, 1989) have noted that for some blood donors, there develops over time a "role person merger" in which what one does as a blood donor becomes a defining part of who one is as a person. This identity as a blood donor is thought to be important in sustaining blood donation over time (see Piliavin, Grube, & Callero, 2002, for further discussion of roles and social action).

Extending this perspective, the role of individual role identity in other forms of social action have also been examined, including the giving of time as a volunteer and the giving of money as a volunteer (e.g., Grube & Piliavin, 2000; Lee, Piliavin, & Call, 1999; Martino, Snyder, & Omoto, 1998), organizational citizenship behavior (e.g., Finkelstein & Penner, 2004; Krueger, 2004), and whistle blowing and other activities of "principled organizational dissent" (Piliavin et al., 2002). In each case, involvement in social action seems to be not just a behavior but also an identity. By extension, and more generally, taking on the identity as a participant in social action may be important for sustaining involvement in social action activities.

Social Identity

At the level of social identity, students of social movements have considered the role of collective identification in motivating and sustaining social movement participation. Across a variety of social movements, *collective identification* with a social movement and the groups that benefit from social movement activities have been found to constitute one pathway to social movement participation, including predicting who becomes involved, extensiveness of involvement, and persistence in social movement activities (e.g.. Simon et al., 1998, 2000; Stuermer & Kampmeier, 2003; Stuermer & Simon, 2004b; Stuermer et al., 2003). Moreover, collective identification predicts social movement participation independently of another pathway to involvement made up of considerations of the rewards and punishments, costs, and benefits associated with social movement participation. For a review of theory on the dual-pathway model of social movement participation and evidence in support of it coming from investigations of a variety of social movements (including those of gay people, old people, and fat people), see Stuermer, 2000, and Stuermer and Simon, 2004a.

In a related vein, there have been examinations of the role that social identity plays as the "social glue" that builds group loyalty and that holds groups together, such that group members develop extremely positive impressions of their groups and stay invested in them even when they could obtain better outcomes by leaving the group (e.g., Van Vugt & Hart, 2004). This state of affairs is one that would facilitate social action within groups, with individual group members translating their social identities as group members into working loyally on behalf of the group and the betterment of its members. In fact, research suggests that those who identify most strongly with their social groups are likely to invest more of their personal resources in the group, work harder for the group, and show greater self-restraint in consuming the group's resources (e.g., Barreto & Ellemers, 2000, 2002; De Cremer & Van Vugt, 1999; Kramer & Brewer, 1984).

Considerations of Self and Considerations of Others

A recurring theme across diverse domains of social action, and captured in another of our explanatory principles, is that considerations of *self* and considerations of *others* are invoked and implicated in the initiation and maintenance of social action.

Volunteerism

In research on the motivations that underlie volunteerism as a form of social action, for example, it has been suggested (e.g., Omoto & Snyder, 1995) that much of the variability in motivations for volunteering is captured in a two-category classification system in which motivations are grouped into those that focus on *others* who are the beneficiaries of volunteerism (e.g., values and community concern motivations) and those that focus on

the *self* and the benefits that accrue to the self from volunteering (e.g., career advancement and esteem enhancement). As well, the distribution of motives for volunteerism into relatively self-serving and relatively other-oriented has been discussed by Bierhoff (2002) and Chambré (1987), and the variation in the balancing of these motives across nations has been examined by Van de Vliert, Huang, and Levine (2004). In a related vein, Miller (1994) has proposed that the moral foundations of caring and helping may vary across cultures, especially with respect to the extent that caring and helping reflect personal and individual considerations versus the extent to which these prosocial actions reflect interpersonal and social obligations.

Social Movements

Similarly, in theory and research on social movement participation (e.g., Stuermer & Simon, 2004a), the multiple pathways to involvement that have been identified tend to group into those that focus on the individual actor (e.g., calculations of personal rewards and costs of joining and participating in a social movement) and those that focus on others (e.g., identification with a larger group that will benefit from the actions of the movement). In fact, research suggests that these different pathways, one focused on the self and one on others, have independent predictive value in accounting for participation in social movements (for a review, see Stuermer & Simon, 2004a).

Social Dilemmas

A similar distinction between a focus on the self and a focus on others is found in theory and research on social dilemmas and their resolution. Specifically, this work has attempted to understand in the context of social dilemmas when and why individuals focus more heavily on the collective concerns of all members of a community or a society and when and why they focus more on their own individual concerns. The focus on collective concerns is a prosocial orientation that tends to lead to greater involvement in collective actions for the common good, whereas the focus on individual concerns seems to be an orientation that tends to inhibit social action on behalf of the greater good, instead leading people to emphasize more selfish considerations of personal gain. In fact, research on social dilemmas, including studies of energy conservation and the use of public transportation (e.g., De Cremer & Van Vugt, 1999; Van Lange, Van Vugt, & De Cremer, 2000; Van Lange, Van Vugt, Meertens, & Rutter, 1998; Van Vugt, Meertens, & Van Lange, 1995), suggests that the resolution of social dilemmas in ways that involve acting on behalf of a collective good stems from prosocial orientations that involve beliefs, feelings, and motivations in which concern for others figures prominently. (For a review of this work on social dilemmas, see Van Lange, 2000.) At the same time, some of the theoretical and empirical literature on social dilemmas also argues that prosocial action is undertaken in the service of selfish concerns about personal gain, both at an individual level (as a manifestation of a form of "Machiavellian intelligence," e.g., Orbell, Morikawa, Hartwig, Hanley, & Allen, 2004) and as a result of evolutionary pressures and concerns (as a manifestation of a "selfish gene" [e.g., Dawkins, 1976], and the evolution of cooperation [e.g., Axelrod, 1984], and reciprocal altruism [e.g., Trivers, 1971]; see also Van Vugt & Van Lange, 2006).

Leadership

Finally, a related distinction between a focus on the self and a focus on others can be found in studies of leadership, specifically the sources of motivations that leaders can use to promote social action. For example, Tyler (2002) has proposed two sources of motivations that leaders can use to promote cooperation in groups: rewards/punishments and attitudes/values. In the case of the former, rewards/punishments can be interpreted as reflecting extrinsic considerations and focus on the other people who have the ability to dispense rewards and punishments. For attitudes/values, meanwhile, the focus is on relatively more intrinsic and self-considerations, including the influence of attributes of the self who holds the guiding attitudes and values. Furthermore, it is suggested that leaders who appeal to attitudes and values (as internal motivations coming from the self) rather than using promises of rewards and threats of punishments will ultimately be more effective in gaining voluntary followers and cooperation within groups (Tyler, 2002; see also Tyler & Blader, 2000). This work is relevant to social action in that leaders can encourage and influence group members to behave cooperatively, generally benefiting the group as a whole and aiding in finding effective solutions to social dilemma problems. In fact, Tyler and his colleagues have examined internal motivations for cooperative behavior and how authorities can gain support and deference from group members through the use of fair procedures (i.e., procedural justice). These procedures convey and foster respect and pride and also inspire identification with the community on the part of group members. Consequently, group members are more likely to accept the decisions of authorities and to show restraint when faced with social dilemmas involving conflicts between individual- and group-serving actions (e.g., Tyler, 2000; Tyler & Degoey, 1995).

Implications for Initiation and Maintenance of Social Action

The importance of recognizing that considerations of self and considerations of others are both involved in social action is underscored by the fact that these considerations may be differentially involved in the initiation and the maintenance of social action. Across diverse domains of social action, there are indications that the factors that are important in accounting for the initiation of social action are not necessarily the same as the factors that are important in accounting for the maintenance of social action. For example, consider the case of volunteerism. Although considerations of values and related other-oriented motivations figure prominently in the motiva-

tions reported by new volunteers, such motivations have relatively little predictive power in accounting for the ultimate duration of service as a volunteer. By contrast, although self-oriented motivations such as esteem enhancement are relatively rarer among the motivations that volunteers claim to have brought them to volunteer in the first place, such motivations have relatively greater predictive power in forecasting just how long volunteers will remain active in service to others (Omoto & Snyder, 1995; but see Penner & Finkelstein, 1998). More generally, it may be that when it comes to understanding the initiation of social action, other-oriented considerations may be important, but when it comes to understanding the maintenance of social action over sustained periods of time, the critically important factors are related to self-oriented considerations (see Snyder, Omoto, & Smith, in press, for further discussion of this point). This contention is speculative at this point; it remains for future research to more fully explore differences between the factors that are crucial to the initiation versus the maintenance of social action, and especially how these factors might be differentially focused on the self or on others.

Implications for the Locus of the Impetus for Social Action

It also should be noted that in drawing the distinction between a focus on the self and a focus on others, it is not a question of where the motivations are located. That is, it is not that the motivations for social action are thought to vary between those that reside within the self and those that reside within others. In all cases, the motivations that lead to social action are properties of the individual social actors and are thought to reside within them; however, what varies is the focus of attention to be on the actor or on others, who often are the targets of the action. Thus, the humanitarian concerns and sense of societal obligation that lead people to try to improve the welfare of others through social action and the desires for social recognition and career advancement that also can motivate social action both reside within the individual actor; however, what varies is whether the driving force behind social action is the quest for benefits to the self or benefits to others through social action.

Implications for the Selfish/Selfless Nature of Social Action

Finally, we point out that there is some conceptual overlap between this social action explanatory principle of considerations of self and considerations of others and distinctions that have been made between "egoism and altruism" or "selfish and selfless" motivations in the literature on helping and prosocial behavior (e.g., Batson, 1991, 1998). To be sure, there does seem to be something selfish and egoistic about social action that is prompted by the quest for benefits to the actor him- or herself; similarly, social action that is undertaken to generate benefits to others and to society at large does seem to have a rather selfless and altruistic quality to it. How-

ever, even social action that is motivated by desires for benefits to the self delivers benefits to others and to society at large and is, in that sense, prosocial and altruistic in its consequences. And, social action that is undertaken out of concern for others and for society at large does deliver benefits to the individual actor as a member of society.

Nevertheless, individual actors faced with decisions about whether or not to get involved in social action may face tensions and trade-offs between potential benefits to self and potential benefits to others. In fact, research on social movements suggests that individuals may calculate the rewards and punishments, costs, and benefits associated with joining a social movement (e.g., Klandermans, 1984, 1997); among the benefits and costs to be weighed are the benefits of the social movement to society should the movement succeed and the costs to the self of the time and energy taken away from other personal pursuits by involvement in the social movement. As well, research on volunteerism indicates that, at the same time as volunteers clearly deliver services of benefit to others, they often experience personal costs, including, at times, being made to feel embarrassed, uncomfortable, or otherwise stigmatized as a result of their volunteer service (e.g., Snyder, Omoto, & Crain, 1999). Furthermore, for a general cost–benefit approach to understanding involvement in volunteer organizations, see Chinman and Wandersman, 1999, and Chinman, Wandersman, and Goodman, 2005.

The Role of Personal Connections to Other People

Theory and research on diverse forms of social action, conducted from diverse conceptual orientations, point to an important role of connections to other people—whether direct and behavioral or indirect and symbolic—in understanding social action. For, connections to other people are involved in prompting people to become involved in social action and in sustaining their continued involvement in social action, and particularly social action that directly benefits others. Although connections to others can take many forms, we focus on research on empathy and common group memberships, two of the more extensively researched forms of connections to other people, as exemplars of this explanatory principle of social action.

Empathy

The connections between individuals that facilitate social action may be feelings of empathy and bonds of identification. That is, to the extent that individuals feel empathy and identify with other people, they become more likely to engage in various forms of social action that potentially benefit those with whom they empathize and those with whom they identify. The important role of empathy has been revealed in studies of prosocial action involving one-to-one helping and volunteerism.

Researchers in personality, social, and developmental psychology have provided evidence for the role of empathy—an emotional reaction including feelings of

compassion, concern, and tenderness—in spurring individuals to help people in need. For example, to the extent that an individual feels empathy for another person, he or she will be more likely to offer help (e.g., Batson, 1998; Dovidio, Allen, & Schroeder, 1990; Schroeder, Dovidio, Sibicky, Mathews, & Allen, 1988), even in situations in which helping is relatively demanding and may not bring direct benefits to the helper.

Moreover, people who have a general tendency to react to the plight of other people with feelings of empathy (i.e., people who are high in *dispositional* empathy) are particularly likely to help others (Davis, 1983, 1996; Davis et al., 1999; Penner, Fritzsche, Craiger, & Freifeld, 1995). More specifically, people who are generally disposed to feel empathy are also more likely to feel empathy for a specific person in need, which, in turn, fosters helping and related forms of social action (Carlo, Eisenberg, Troyer, Switzer, & Speer, 1991; Davis et al., 2003; Eisenberg et al., 1989).

The role of empathic connections with other people in promoting and sustaining involvement in social action has been examined in the specific context of volunteerism, where Davis has traced the role of empathy over the course of volunteering (for a review, see Davis, 2005). In his work, he has shown that individual differences in empathy are related to initial decisions to volunteer and to the subjective experiences of volunteers during their service (e.g., Davis et al., 1999), although less so to sustaining their involvement over time (e.g., Davis et al., 2003).

Common Group Membership

While empathic connections seem to facilitate the provision of help, and perhaps other forms of social action, it also seems to be the case that the effects of empathic connections with others may depend on whether those others are members of one's own ingroup or whether they are members of an outgroup. Thus, for example, in research on volunteerism, it has been demonstrated, in both field and laboratory studies, that *empathy* is a critical ingredient in accounting for volunteering to help ingroup members whereas another type of connection, *liking*, is a critical ingredient in accounting for volunteering to help outgroup members (e.g., Stuermer & Siem, 2005; Stuermer, Snyder, Kropp, & Siem, 2005; Stuermer, Snyder, & Omoto, 2005).

More generally, there are growing indications that quite different motivations are involved in helping ingroup and outgroup members. For example, although people typically help ingroup members because of their identification with the common ingroup and a concern for their collective welfare (e.g., Simon et al., 2000), outgroup helping often reflects self-serving considerations, including the desire to appear unprejudiced or to avoid feeling guilty (Dutton & Lake, 1973; Gaertner & Dovidio, 1977).

Although not necessarily conducted in social action contexts, other research similarly suggests that people may have different reasons for helping ingroup and outgroup members, and especially when group member-

ships are made salient by contextual cues, structural differences, or histories of asymmetrical intergroup relations. For example, changing group conceptualizations or boundaries so that former outgroup members are now viewed as members of one's ingroup leads to increases in helping those members (Dovidio et al., 1997). The provision of help to others might also be a means for asserting group dominance or an attempt to renegotiate the power structure between groups (e.g., Nadler, 2002). Additional research is needed to carefully examine both of these intriguing possibilities. For now, our point is that there is suggestive evidence that group memberships and conceptualizations of ingroups and outgroups may play important roles in determining when, why, and on whose behalf social action is enacted.

Other Personal Connections

Finally, there is considerable support from research derived from a social exchange perspective for the principle that connections to others facilitate social action. Illustrative of the findings in this domain, it has been frequently demonstrated that increases in the social action tendency to cooperate are promoted by stronger ties between the parties to the exchange (e.g., Granovetter, 1973; Macy & Skvoretz, 1998; Orbell, van de Kragt, & Dawes, 1988).

The Role of Community

In addition to the importance of personal connections with other people, there are growing indications, across diverse forms of social action, that a sense of *connection with a larger community*, including a psychological sense of community (e.g., McMillan, 1996; McMillan & Chavis, 1986; Sarason, 1974), can facilitate social action. This explanatory principle has been revealed in studies on the resolution of social dilemmas, volunteerism, and civic participation.

Social Dilemmas

For example, it has been demonstrated that fostering a community orientation can promote the resolution of social dilemmas associated with, among other things, the use of public transportation and energy conservation (e.g., De Cremer & Van Vugt, 1999; Ostrom, 1990; Schlager, 2002; Van Vugt, 2002; Van Vugt & Samuelson, 1999), thereby averting the "tragedy of the commons" first described by Hardin (1968). Similarly, Tyler (2000; Tyler & Blader, 2000) has observed that promoting identification with and commitment to community can promote collective solutions to social dilemmas and compliance with authorities in regulating social dilemmas.

Volunteerism

Similarly, research on the processes of volunteerism has yielded recurring indications that connection to community can draw people into volunteerism and sustain their involvement over time. In reciprocal fashion, moreover,

involvement in volunteerism seems to strengthen and build connections to community. Specifically, community concern and the influences of other community members figure prominently in the motivations of new volunteers (Omoto & Snyder, 1995; Stuermer & Kampmeier, 2003). Moreover, over the course of their service, volunteers become increasing connected with their surrounding communities, including the communities defined by the volunteers, staff, and clients associated with their volunteer service organizations (Omoto & Snyder, 2002). And, their effectiveness as volunteers is enhanced by a sense of connection to a relevant community (Omoto & Snyder, 2002).

Reversing the causal order, volunteering also appears to build and foster a sense of community. For example, as a consequence of their work, volunteers are increasingly surrounded by a community of people who are somehow connected to their volunteer service, including people they have recruited to be volunteers (Omoto & Snyder, 2002). In addition, volunteering can and does contribute to the creation of bonds of social capital (e.g., Stukas, Daly, & Cowling, 2005), and it even has been considered a central indicator or measure of social capital itself (Putnam, 2000). Research also suggests that as connections to a community of shared concerns increase, participation in the community, including in forms of social action other than volunteerism (such as giving to charitable causes, attending fund-raising events, and engaging in social activism), also increases (Malsch, 2005; Omoto & Malsch, 2005; Omoto & Snyder, 2002).

Civic Participation

Furthermore, beyond social dilemmas and volunteerism, cross-sectional research has demonstrated positive associations between sense of community and civic participation. Thus, for example, individuals who report a stronger psychological sense of community are more likely to be registered voters and to be active in their neighborhoods (Brodsky, O'Campo, & Aronson, 1999), to engage in neighboring behaviors such as lending their neighbors food or tools (Kingston, Mitchell, Forin, & Stevenson, 1999), and to participate in community organizations (Chavis & Wandersman, 1990; Perkins & Long, 2002; Wandersman, 1980; Wandersman, Florin, Friedmann, & Mier, 1987) and political activities (Davidson & Cotter, 1989). Moreover, bonds of connection within communities and the social capital associated with them have been implicated in the provision of public goods (Anderson, Mellor, & Milyo, 2004), the reduction of crime within communities (Saegert, Winkel, & Swartz, 2002), and the promotion of the health of community members (Kawachi, Kennedy, Lochner, & Prothrow-Stith, 1997). Finally, residential stability has been implicated in identification with one's community, which in turn manifests itself in diverse forms of helping behaviors, procommunity involvement, collective efficacy, and social action (Kang & Kwak, 2003; Kasarda & Janowitz, 1974; Oishi et al., 2005; Sampson, Raudenbush, & Earls, 1997).

Thus, there is substantial evidence that connections to a community promote social action, often for the benefit of the community, as well as broader involvement in society. However, we also note that there are hints of an association between individualism and broad indicators of social capital. Thus, in the United States, the states with higher levels of social capital, as indexed by greater amounts of civic engagement and political participation, are also the most individualistic; similarly, there is a positive association between individualism and social capital across different countries (Allik & Realo, 2004). These associations may suggest that as much as bonds of connection with community may promote social action, the apparent liberation from social bonds that may come with individualistic cultural views may also make people dependent on being or staying involved with society (as suggested over a century ago by Durkheim, 1893/1984; see also Sarason, 1974). For further discussion of, and evidence for, cross-cultural variation in social capital and bonds of trust and reciprocity, see Buchan, Croson, and Dawes (2002); Fukuyama (1995); and Yamagishi and Yamagishi (1994).

As reviewed in this section, then, connections to communities (and often psychological communities rather than geographically defined ones; Omoto & Malsch, 2005; Omoto & Snyder, 2002) are related to diverse forms of social action. In fact, it appears likely that there is a cyclical process at work here, one in which connections to community lead individuals to engage in social action that, in turn, further builds community connections and social capital. As a result of this self-perpetuating and accretionary process, social action becomes more likely and sense of community is increased. More generally, it may be that social action begets social action *via* a mechanism or principle of community such that one of the more significant consequences of social action is the creation and perpetuation of a culture of service, participation, and involvement.

Summary

To summarize, we have described a set of explanatory principles of social action that provide explanations for why social action occurs and that give some indications for why social action takes the forms it does. Specifically, we began by examining research from diverse domains that illustrates motivational approaches to social action, and while motivational concerns were central in each of these domains, there was not perfect agreement on the specific motivations most critical for understanding and predicting social action. Next, we discussed how individual and social identities seem to be related to the initiation, persistence, and some of the effects of social action activities. Another explanatory principle that we identified, and one for which there is precedent for and links to other literature, is the relative importance of considerations of the self relative to considerations of others. Finally, we described two types of connections that appear to be important for social action, namely, personal connections to specific others (including empathy and common group memberships) and connections to broader, more diffuse communities. To the extent that connections are salient or strong—whether they are cog-

nitive, emotional, or behavioral connections—social action, and especially helping, appears likely to result.

AN INTEGRATIVE MODEL OF SOCIAL ACTION

Thus, at this point, we have accomplished our goals of providing both descriptive and explanatory principles of social action. Our set of descriptive principles are useful for characterizing and comparing different forms of social action, as well for identifying their dimensions of variability and indicating what is to be included in and what is to be excluded from the category of social action. Meanwhile, our set of explanatory principles helps us to understand how and why social action occurs, including the factors that provide the impetus for social action, that guide the forms it takes, and that influence how it unfolds over time. To conclude this chapter, then, we now offer a heuristic model of social action, a model that we believe will be useful for organizing and perhaps guiding future work on these important and wide-ranging topics. As with our principles, we see this model as a starting point, as an initial attempt to bring order to a diverse set of topics and principles. The ultimate utility of this model can and will be determined in future theoretical and empirical work.

In reflecting on the principles we have identified for characterizing and understanding social action, it is noteworthy and impressive that these principles recur across research in diverse domains, conducted by researchers working in different countries, coming from a multiplicity of disciplines, and guided by a range of theoretical predilections and perspectives. But, perhaps these recurring themes are no accident. The principles may recur because they may reflect the operations of a common, integrative heuristic model for theory, research, and application on social action. In this model of social action, which builds on and extends earlier models of volunteerism as one form of social action (e.g., Omoto & Snyder, 1995, 2002; Snyder et al., in press), social action is conceptualized as a process that unfolds over time and that can be viewed from multiple levels of analysis. As such, there is both a "horizontal" and a "vertical" organization to this heuristic model of social action.

Horizontal and Vertical Organization of the Model

With respect to the *horizontal* organization or structure of the model, one of the key features of social action is that it unfolds over time. That is, there are the *antecedents* of social action, which specify those factors that bring people to social action, including the personal motivations that dispose people to get involved and the social circumstances that call for and prompt action. Then, there is the social action itself (which may itself involve sustained, ongoing, recurring action) and the *experiences* of those involved in social action, including the perceived and actual costs and benefits that accrue to social actors involved in social actions. Finally, there are the *consequences* of social action for those who take social action, for those who are affected by it, and for society at large.

This horizontal structure defines the unfolding history of social action, taking us through three successive stages in the processes of social action, allowing us to see what leads to social action, what happens during social action, and what results from social action.

With respect to the *vertical* organization or structure of the model of social action, there are various levels of analysis that run from the individual to the cultural, such that at each stage of the processes of social action, it is possible to articulate principles of social action from the perspective of the individuals involved in social action, the interpersonal relationships of which they are a part, the groups and organizations to which they belong, and the larger community, societal, and cultural contexts in which social action takes place.

In conceptualizing social action, therefore, we find it useful to view it from the vantage point of multiple levels of analysis. At an *individual* level, the model calls attention to the activities and psychological processes of individual actors and the recipients or targets of social action. At an *interpersonal* level, many forms of social action occur in the context of or because of people's interpersonal relationships. At a *group* level, many forms of social action are enacted by groups and collectives, take place in the context of community-based organizations and institutions, or are carried out for the purpose of addressing the conditions of members of groups and institutions. Finally, at a broader *societal* level, the model considers the linkages between individuals and their societies as well as cultural dynamics associated with the emergence and evolution of traditions of social action and community involvement.

Putting the horizontal and vertical structures of the model together results in a "matrix," depicted in Figure 41.1. The columns of this matrix represent stages of the process of social action and the rows reflect the different levels of analysis or perspectives that can be brought to bear on understanding social action.

Thus, with respect to the first (antecedents) stage of the process of social action, which addresses the question of what brings people to social action, diverse features of persons (e.g., their motivations and reasons for participation, their helping dispositions or personalities, and their identities as social actors) are the focus and the search is for relevant traits, motives, and characteristics that dispose people to take social action. In addition, interpersonal relationships and social networks, as well as groups and formal organizations, can and do play important roles in recruiting people to participate in social action. Moreover, differing cultural orientations may set the stage for determining how certain forms of social action will be construed, including whether causes will be judged "worthy" of action. In fact, these cultural orientations are likely to influence whether solving a particular societal problem is seen as a matter of personal choice and individual responsibility or whether it is construed as one of normative obligation and collective concern.

Similarly, with respect to the second (experiences) stage of the process of social action, which focuses on the question of what happens during social action, there is value in regarding social action in terms of the pursuit of

Level of Analysis	Stages of Social Action

agendas. Thus, not only do individuals have and pursue goals, but agendas for social action can also be seen at other and multiple levels of analysis, including those pursued by and affecting targets of social action, the separate and shared group memberships of social actors and targets, the organizations that support social action, and the larger community and society.

And, finally, at the third (consequences) stage of the process of social action, which is concerned with the question of what results from social action, social action can and does have outcomes and consequences for those who engage in it, as well as consequences for other people, including relationship partners, groups, organizations, communities, and the larger society. Consideration of these consequences, in fact, brings us back to where we started in our analysis, that is, to the realization that social action involves people working alone and working together, often in attempts to benefit themselves and society.

Generativity of the Model

This model, it should be emphasized, is not a theory of social action per se but a broad framework for identifying conceptual issues for empirical investigation. And, by virtue of its deliberate generality, it is applicable to many (if not most) forms of social action. Moreover, we view it as a generative model; that is, it provides a way of asking questions about *moderator*s and *qualifiers* of the principles of social action and it can point the way toward identifying unstudied and understudied questions that have the potential to generate *extensions* of scientific understanding of social action.

Many of the moderators, qualifiers, and extensions can be identified in the various "rows" of the model and may operate to change the unfolding processes of social action. Briefly, and to give a feel for how this model may help to organize and generate knowledge of social action, let us consider some representative examples of moderators at the different levels of analysis. First, at the level of individual social actors, differences in personality (e.g., Davis et al., 1999), interpersonal orientation (e.g.,

Lavine & Snyder, 1996), and age (e.g., Boling, 2005; Okun & Schultz, 2003; Omoto et al., 2000) appear to moderate the processes of social action. At the levels of interpersonal relationships and group memberships, there are indications that ingroup versus outgroup status importantly moderates the resolution of social dilemmas (e.g., Dawes & Messick, 2000), the giving of aid to a person in need (e.g., Levine, Prosser, Evans, & Reicher, 2005), and the processes of volunteerism (e.g., Stuermer, Snyder, & Omoto, 2005). Finally, at the broader level of societies and cultures, there are growing indications of important differences between societies and cultures in the construal of helping, social participation, and civic engagement; these differences, moreover, may moderate the forms that social action takes across cultures (e.g., Allik & Realo, 2004; Buchan et al., 2002; Miller, 1994; Van de Vliert et al., 2004).

Taken together, then, the moderators identified in the rows of the model may involve features of the persons who engage in social action (including individual differences in personality, attitudes, values, and motivations), features of the social circumstances and environments in which these persons function (including their memberships in relationships, groups, and organizations), and the features of their surrounding communities that either promote or impede social action (including their culturally based conceptions of the nature of involvement and participation in society).

In addition to the moderators that can be defined and situated in the "rows" of our heuristic model of social action, there are also moderators that can be identified across the model's "columns." These moderators can be thought of as specifying differences in the ways that constructs defined with respect to the rows of the matrix operate in social action. One such illustrative moderator is the distinction between the initiation and the maintenance of social action and the findings from research on various forms of social action that the factors that dispose people to become involved in social action in the first place may be quite different from the factors that sustain involvement in social action over time (e.g., Omoto & Snyder, 1995). Moving across the columns, ad-

ditional moderators or qualifiers emerge, including intriguing (and as yet untested) possibilities about the ways in which societal consequences of social action produce changed social and cultural environments for future social action—in short, the ways by which social actors and their coordinated social actions change society.

Finally, over and above the ways that the heuristic model of social action helps to organize the existing research on social action and to make clearer the operation of the different principles of social action that we have identified in this chapter, an additional benefit of our proposed model is its generativity in uncovering topics for future research. That is, the "cells" of the model (defined by the conjoint vertical and horizontal structures) that are relatively "underpopulated" in terms of theoretical statements and research findings would seem to be excellent candidates for future theoretical inquiry and empirical investigation. The body of work on social action, in all of its diverse forms, can only benefit and grow from such attention.

Challenges and Prospects

Our heuristic model of social action also serves to underscore some of the challenges posed by the study of social action (see also Omoto, 2005b). For example, to the extent that investigators seek to understand social action *in vivo*, they may find themselves chronically "behind the curve," only able to identify and study instances of social action (e.g., the emergence of social movements in response to problems in society and the formation of grassroots community organizations to deliver needed volunteer services) *after* they have already occurred. In such circumstances, investigators may find themselves shut out of the early stages of the processes of social action, unable, for example, to study the features of individual social actors *before* they become involved in social action.

Moreover, because involvement in social action may extend over long periods, practical constraints associated with following research participants over time may make it difficult to follow the unfolding dynamics of social action to their natural conclusions. Accordingly, the research literature on social action may be more likely to include studies of short-term rather than long-term social action. Nevertheless, studies of long-term social action may be well worth the effort, especially because they are likely critical in establishing a relatively complete and comprehensive understanding of these important phenomena.

In addition, a focus on studying instances of social action as they actually occur may lead to an overrepresentation of studies of successful instances of social action, as ones that fail to meet their goals may not stay in existence long enough to capture the attention of researchers. Yet, a full understanding of social action will surely need to come to grips with the differences between those instances of social action that succeed and those that fail, as challenging as it may be to identify and investigate instances of failed social action.

CONCLUSION

Reflecting on social action, we cannot help but be struck by the recurring themes and principles, both descriptive and explanatory, that emerge from investigations of diverse domains of social action and their ability to be encompassed in a broad and integrative model. The study of social action simultaneously brings into sharp relief, and also connects, research on a wide range of topics, from volunteerism to social movements to political participation to social dilemmas. In addition, and particularly striking, are the bridges that theoretical and empirical work on social action builds between the psychology of *individuals*, their concerns for the *interpersonal relationships* of which they are part and the *groups* to which they belong, and their participation in their larger *societies*.

As such, the study of social action provides new perspectives on the linkages between individuals and society, highlighting the mutual interplay and influence of individuals and the larger society and opening the door for theoretical, as well as practical, advances across a broad spectrum of social scientific domains. In the end, though, it is through their involvement in social action that individuals contribute to the functioning of society, and the changes wrought in society by social action affect the lives of its individual members.

Moreover, in the study of social action, researchers can engage in diverse forms of "action research" (e.g., Chein, Cook, & Harding, 1948; Lewin, 1946, 1947; Sanford, 1970). They can intertwine basic and applied research foci and methodologies in the interests both of theoretical advance and of solving pressing social problems. In addition, they can engage real people in real contexts who are seeking real solutions to the real challenges they face. Thus, just as social action connects individuals and society, the study of social action holds vast potential for connecting psychological science, social policy, and public good. This end is exciting, indeed, and, certainly worthy of vigorous pursuit.
