**object language.** When a second language is introduced to talk about a given language it is called the metalanguage; the given language is the object language. These are relational terms: one language is an object language, another a metalanguage only in relation to one another. Thus, the metalanguage can, in turn, be an object language in relation to another language. The necessity for the object language—metalanguage distinction in semantic theory is revealed by the semantic paradoxes. H.W.N.

John L. Pollock, *Technical Methods in Philosophy* (Boulder, Colo., 1990).

**obligation.** To be under an obligation signifies being tied, required, or constrained to do (or from doing) something by virtue of a moral rule, a duty, or some other binding demand. There are also familial or parental obligations deriving from a role or relationship. Obligations are nor-

mally understood to form a subset of the moral factors which impinge on a person; there are other moral concerns such as to be kindly or generous which are not usually thought of as obligations. Kant, however, called these latter 'broad' obligations, allowing some latitude in their execution, in contrast to, for example, the strict obligation (as he saw it) always to tell the truth. Kant thought all moral requirements were 'categorical' obligations. Obligations oblige one to do something in a way analogous to the way, for example, a closed road obliges one to find another route: they force or demand a course of action. Obligation is sometimes contrasted with \*value, as being what is peremptory and demanding rather than enticing and attractive. The topic of moral obligation is challengingly discussed by G. E. M. Anscombe in her 'Modern Moral Philosophy' (1958), reprinted in her collected philosophical papers, *Ethics, Religion and Politics*, iii (Oxford, 1981). N.J.H.D.

\*categorical imperative; ought; ethics and aesthetics.

**obligationes.** A late-medieval disputation-form involving two parties, the 'opponent' and the 'respondent'. After laying down some proposition as the initial case, the opponent proposes other propositions to the respondent, who must reply to each in turn by either conceding, denying, or doubting it. The respondent must do this according to rules describing the relation of the proposition at hand to the initial case and to what has gone before. Medieval philosophers argued about the proper rules to adopt for *obligationes*; one common set of rules has features of constructive \*counterfactual reasoning. The terminology and methods of *obligationes* appear in theological, metaphysical, and scientific investigations. P.K.

\*logic, history of.

Paul Vincent Spade, 'Three Theories of Obligationes: Burley, Kilvington, and Swyneshed on Counterfactual Reasoning', *History and Philosophy of Logic* (1982).

**observation and theory.** Provide different points of access to the world—observation from the bottom up, theory from the top down. Empiricists favour observations as a secure and objective basis for knowledge; we and the Babylonians would have seen eye to eye. Theory, in contrast, is prone to error and prejudice; too many theories have turned out to be false and require speculative conjectures. Advocates of theory find observationally based epistemologies too pinched in their scope; attempts by the logical empiricists and others to construct theory on the basis of observations failed dramatically. Yet there is great danger in speculative theory, especially in the social sciences where data is scarce, and a judicious balance between theory and data is the hallmark of good practice. What is observed is generally agreed to exist, but \*realists, in contrast to \*empiricists, allow that some non-observational terms in well-confirmed theories genuinely refer. P.H.

Robert Klee, *Introduction to the Philosophy of Science* (Oxford, 1997), ch. 3.

**obversion.** A proposition is obverted by negating its second term and changing its \*quality from affirmative to negative or vice versa. Thus 'All rabbits are herbivores' (All *S* are *P*) becomes 'No rabbit is a non-herbivore' (No *S* are non-*P*). All the four forms of proposition considered by traditional logic may be validly obverted. c.w.

\*logic, traditional.

J. N. Keynes, *Formal Logic*, 4th edn. (London, 1906), ch. 4.

**occasionalism.** A theory about the nature of much of what we take to be causation. It asserts that all relations between physical things, or between human minds and physical things, which we intuitively suppose to be causal, are in fact not causal. Instead, the relations are a consequence of God's will in the sense that particular events, the 'causes', are constantly conjoined with other events, their 'effects', because when a cause occurs God wills the effect to occur. One reason it was put forward was as the only conceivable explanation of causal necessity. P.J.P.N.

\*causality; parallelism, psychological; pre-established harmony.

N. Malebranche, *The Search after Truth* (1674–5), tr. T. M. Lennon and Paul J. Olscamp (Columbus, Oh., 1980), vi. ii. 3.

**Ockham, William** (1285–1347). An English Franciscan dubbed the 'More than Subtle Doctor', Ockham defended \*nominalism, condemning the doctrine that universals are real things other than names or concepts as 'the worst error of philosophy'. Rejecting \*atomism in favour of \*hylomorphism, he practised poverty in metaphysics by refusing to posit distinct kinds of entities for each of Aristotle's ten categories and restricting his philosophical diet to really distinct substances and qualities with certain relations thrown in for good theological measure. Yet, he defended the Franciscan school's recognition of a plurality of substantial forms in living things (in humans, really distinct forms of corporeity, of sensory and intellectual soul).

By contrast with Hume and Malebranche, Ockham maintains the Aristotelian distinction between efficient \*causality properly speaking and *sine qua non* causality, based on whether the correlation between *As* and *Bs* is produced by *A*'s power or by the will of another. Against Henry of Ghent, he denies that there is any *sine qua non* causality in nature, and finds it metaphysically impossible that regularities in nature be drastically rearranged, although natural functioning can be obstructed by God and creatures alike. Like other Aristotelians, Ockham deems physics and biology possible because the uniformity of nature principle is true. Even for a nominalist, natures are powers; co-specific individuals, maximally similar powers that operate in maximally similar ways.

An Aristotelian reliabilist in epistemology, Ockham takes for granted that human cognitive faculties work 'always or for the most part'—indeed, that we have *certain* knowledge of material things and of our own mental acts.

Ockham draws no sceptical conclusions from the logical, metaphysical, or natural *possibility* of their obstruction, because he defines certainty in terms of freedom from *actual* error.

Notoriously enthusiastic about logic, Ockham's distinctive treatment of the logic of terms ('supposition theory') reflects his metaphysical disagreements with other notables (e.g. William of Sherwood, Peter of Spain, and Walter Burleigh). His *Summa Logicae* rearranges the traditional syllabus somewhat by subsuming the 'topics' under the theory of inference; and contains his brilliant and extensive development of modal syllogistic.

In action theory, Ockham defends the liberty of indifference or contingency for divine and created rational beings. Not only is the will a self-determining power for opposites (as Scotus insisted), its options include willing evil under the aspect of evil and willing against good under the aspect of good! So far as non-positive morality or ethics is concerned, Ockham endorses a 'modified right reason theory', according to which virtuous action requires the agent's free co-ordination of choice with right reason (the primary norm). Because suitably informed right reason dictates that God, the infinite good, should be loved above all and for his own sake and hence obeyed, \*divine commands become a secondary norm. Priorities are reversed in the soteriological category of merit and demerit, where free and contingent divine statutes make following the dictates of right reason a necessary condition of merit and eternal blessedness.

Excommunicated for his defiant defence of Franciscan poverty against Pope John XXII, Ockham spent the rest of his career under the protection of Louis of Bavaria, energetically promoting a 'separation of Church and State' according to which the authority of neither is *regulariter* subordinate to that of the other, although each might interfere with the other *casualiter* in a grave crisis. M.M.A.

**Ockham's razor, or the principle of parsimony.** A methodological principle dictating a bias towards \*simplicity in theory construction, where the parameters of simplicity vary from kinds of entity to the number of pre-supposed axioms to characteristics of curves drawn between data points. Although found in Aristotle, it became associated with William Ockham because it captures the spirit of his philosophical conclusions. M.M.A.

Marilyn McCord Adams, *William Ockham* (Notre Dame, Ind., 1987), ch. 5, pp. 143–67.

**O'Neill, Onora** (1941– ). British moral and political philosopher. She has written on Kant's moral philosophy and employs a Kantian approach in considering ethical and political issues, including such traditionally neglected issues as the position of children and the role of parenting, gender, and questions of international justice. She criticizes much political and moral philosophy which is commonly called Kantian by both its proponents and detractors. Such work often emphasizes moral imperatives and duties; but is not really true to Kant's emphasis on principles that *can* be universally adopted. In recent (mainly US) liberal political philosophy \*'Kantianism' is understood to be rights-based and therefore to de-emphasize such categories as virtue, need, and obligation. O'Neill argues that a properly Kantian approach encompasses these categories.

**one-over-many problem.** How can many things, e.g. Frances, Sarah, and Geoffrey, all *be* one thing, e.g. left-handed? Age-old solutions postulate a 'universal', e.g. the idea of left-handedness, related to these particulars and standing 'over' them. Doubtless various kinds of such \*universals exist. But we can still ask: How can many things all *be* related-to-one-universal? Explanation of 'being so-and-so'—predication—seems inevitably to presuppose the very thing it seeks to explain.

D. F. Pears, 'Universals', in A. Flew (ed.), *Logic and Language*, 2nd series (Oxford, 1955).

**ontological argument for the existence of God.** A line of argument which appears to appeal to no contingent fact at all, but only to an analysis of the concept of God. The argument is that this concept (unlike many others) is *necessarily* instantiated. Sometimes an intermediate step is the argument that if it is possible for this concept to be instantiated then it is instantiated, and this concept is obviously possible.

Anselm gives the classical formulation, and the classical critique is Immanuel Kant's. The argument has recently been subtly reformulated and defended by (among others) Charles Hartshorne, Norman Malcolm, and Alvin Plantinga.

G.I.M.

Anselm, *Proslogion*, tr. S. N. Deane (La Salle, Ill., 1991).

**ontology.** Ontology, understood as a branch of metaphysics, is the science of \*being in general, embracing such issues as the nature of \*existence and the categorial structure of reality. That existing \*things belong to different categories is an idea traceable at least back to Aristotle. Different systems of ontology propose alternative categorial schemes. A categorial scheme typically exhibits a hierarchical structure, with 'being' or 'entity' as the topmost

category, embracing everything that exists. Some schemes take the division between \*universals and particulars as the next step in the hierarchy, others the division between abstract and concrete entities. These divisions do not necessarily coincide, since some philosophers believe in the existence of \*concrete universals and some in the existence of abstract particulars. Universals may be further subdivided into properties, kinds, and relations. While many metaphysicians hold universals to be abstract entities, they disagree over whether universals exist separately from the particulars which instantiate them (the 'Platonic' view) or only exist 'within' those particulars (the 'Aristotelian' view). There is also disagreement over what distinguishes abstract from concrete entities, the most common view being that abstract entities do not exist in physical space and \*time, and so lack physical extension and do not undergo change. As a corollary it is often held that abstract entities lack causal powers and so are incapable of entering into causal relations with other entities, though this threatens to make our knowledge of abstract entities problematic. Many philosophers, for this and related reasons, deny the existence of abstract entities, holding that only concrete particulars exist.

Concrete particulars are commonly further divided into \*substances and non-substances, the hallmark of the former being that they are logically capable of independent existence, whereas non-substances depend logically for their existence upon that of other things, and ultimately upon the existence of substances. Material bodies provide the most obvious example of particular substances, but Cartesian egos or souls, if they existed, would also belong to this category. The concrete non-substances traditionally include such entities as particular events, particular qualities, and particular places and times. However, some revisionist metaphysicians hold that some or all of these categories are in fact more basic than the category of material objects, attempting to construct the latter from 'bundles' of particular events or qualities located at particular places and times.

Traditional ontological concerns, such as those just described, are currently enjoying a modest revival after a period of neglect prompted by widespread opposition to metaphysics. It is now better appreciated that the natural sciences embody implicit ontological schemes which cannot be wholly justified on purely empirical grounds and which can on occasion engender theoretical perplexities, as in the quantum-mechanical disputes over wave-particle duality. Only metaphysical reflection can ultimately dispel such perplexities.

The term 'ontology' has some additional special uses in philosophy. In a derivative sense, it is used to refer to the set of things whose existence is acknowledged by a particular theory or system of thought: it is in this sense that one speaks of 'the' ontology of a theory, or of a metaphysical system as having such-and-such an ontology (for example, an ontology of events, or of material substances). In a separate, technical sense the term 'ontology' is the official name of a logistical system created by the Polish logician

Stanisław Leśniewski—a system similar in scope to modern predicate logic and developed by him in conjunction with \*mereology, the formal theory of part–whole relations. Leśniewski’s system differs in important respects from the now orthodox formal logic of Frege and Russell, especially in the more general role it assigns to names. E.J.L.

**opacity and transparency:** *see* referential opacity.

**opacity, opaque contexts:** *see* referential opacity.

**open and closed thought.** Modern theories of knowledge focus on change of \*belief. They ask what, given a background of beliefs and expectations, is the best way to change one’s beliefs in the face of new evidence. A fertile and flexible system of beliefs will be able to change in response to unexpected evidence. This gives it a chance of containing truths. Similar points hold for desires and for emotions. Some systems of belief, desire, and emotion are such that they can evolve. Others are traps from which it is hard to escape, as they have ways of reinterpreting or neutralizing the impact of contrary evidence, unwelcome example, or unorthodox art. One function of philosophical \*scepticism is to combat the tendency to closure in human ways of thinking. Yet total openness is probably impossible: a more reasonable ideal is that of a flexible cage, which can slowly change its shape. Indeed, the claim to have a completely open mind is usually a sign of some deep and inflexible self-deception. A.M.

Karl Popper, *The Open Society and its Enemies* (London, 1961).

**open question argument.** Argument used by G. E. Moore against ethical naturalists, especially J. S. Mill. Influenced by Hume on ‘is’ and ‘ought’, the argument runs thus: Naturalists claim that ethical words—e.g. ‘good’—can be defined in natural terms—e.g. ‘pleasure-maximizing’. But, since it is an open question whether what maximizes pleasure is good, the definition fails, committing the \*naturalistic fallacy. It is not an open question whether, say, bachelors are unmarried men, so a definition of ‘bachelor’ as ‘unmarried man’ would succeed. Since Mill was trying not to define ethical words, but to tell us what is good (something Moore himself does), the argument fails *ad hominem*. It was taken over by emotivist and prescriptivist anti-naturalists, though Moore himself used it to support non-naturalism. R.C.

\*fact–value distinction; non-natural properties.

G. E. Moore, *Principia Ethica* (Cambridge, 1903).

**open texture.** This term has been used for an apparently unavoidable feature of empirical \*concepts, namely that there is always the possibility of some unforeseen kind of case in which it is not clear whether, or how, the concept should be applied. Wittgenstein’s discussion of \*rules strongly supports this. Open texture is not \*vagueness, but more like the possibility of vagueness; not all concepts are actually vague. For example, until the advent of test-tube fertilization, biological motherhood was a precise concept, but now ‘mother’ is ambiguous between ‘she who was the source of genes’ and ‘she who gave birth’. The concept was always open-textured, because it could not provide in advance for all such possible new situations. L.F.S.

F. Waismann, ‘Verifiability’, in G. H. R. Parkinson (ed.), *The Theory of Meaning* (Oxford, 1968).

**operation.** An expression  $E_1$  operates on another expression (or expressions),  $E_2$ , when a further expression,  $E_3$ , results, and where  $E_2$  is (or are) said to fall within the scope of  $E_1$ .  $E_1$  might be ‘Tom thinks that’;  $E_2$ , ‘Mike is a vegetarian’;  $E_3$  will be ‘Tom thinks that Mike is a vegetarian’. The operators most commonly discussed by logicians are operators on sentences (like ‘Tom thinks that’), particularly \*truth-functional ones, where the truth-value of the sentence  $E_3$  would be a function of the truth-value of the sentence(s)  $E_2$ . Examples of truth-functional operators are ‘It’s not the case that’ (or ‘not’) and ‘or’. R.P.L.T.

W. Hodges, *Logic* (Harmondsworth, 1977), sects. 12–14.

**operationalism.** A grass-roots movement in philosophy of science, articulated and defended by P. W. Bridgman, which grew out of what was perceived to be the actual practice and views of physicists around the time that the theories of relativity and \*quantum mechanics were first developed. Like \*Logical Positivism, operationalism emphasizes close contact with experiment as necessary to objective discourse, but focuses on concepts rather than statements, seeking to safeguard them against meaninglessness by defining them solely with reference to precisely defined experimental operations. For example, ‘the length of a table’ may be said to be the number of times a measuring-rod needs to be laid end to end on the table, going from one end of it to the other. If there is more than one way to measure length, such as recording the time taken for light to travel out and back along the table, then there is more than one concept of ‘length’ involved. Furthermore, questions which cannot be decisively answered with reference to operations are banned from science, such as ‘Did everything in the universe double in size overnight?’ Given the radical departure of modern \*physics from previously sacrosanct ideas such as Euclidean geometry, it is not difficult to see why Bridgman sought to purify scientific concepts operationally so as to avoid any further impediments to progress. G. J. Massey, *Understanding Symbolic Logic* (New York, 1970), app. A.

**ordinary language and philosophy.** If proof were needed that philosophy cannot be reduced to or conducted wholly in ordinary language, some is provided by the fact that the two are in conflict. Ordinary language has largely succeeded in obscuring or obliterating vital linguistic differences, and thus in subverting distinctions that are essential to philosophical discourse. Consider the word 'valid', which has a clear meaning in logic but an unclear (though popular) use in ordinary language. Even more, consider the following pairs: begs the question—raises the question; reform—change; refute—reject; infer—imply; disinterested—uninterested. In everyday language the first term of each pair has largely replaced the second, thus making the distinction unintelligible in most contexts, and impoverishing conceptual and analytical resources. However, whereas close attention to language is essential in philosophy, the ideas that all philosophical problems are problems in language, or that they can be settled by grammatical analysis, or attention to everyday usage, are quite different and quite absurd. Philosophy can and should concern itself with genuine, substantive problems, and like any other problem-solving discourse is fully entitled to its own necessary technical terms.

\*analytic philosophy; philosophical inquiry: first premisses and principles; Wittgenstein; linguistic philosophy.

Oswald Hanfling, *Ordinary Language and Philosophy* (London, 1999).

**ordinary-language philosophy:** *see* linguistic philosophy; J. L. Austin.

**organic society.** A view of society as a unitary natural growth, as opposed to views which depict it as an aggregate of individuals pursuing self-interest or as a planned or constructed entity.

If society is seen in terms of the biological metaphor of a living organism, certain features are typically attributed to it. It is thought to persist through time, and consequently the importance of maintaining tradition is stressed. Since it has grown rather than been constructed,

it ought not to be subjected to sudden and drastic changes, for drastic change may weaken or destroy it. The parts of an organism are mutually dependent, and indeed their identity depends on there being members of one organism rather than another. This implication is characteristically extended not just to the institutions of society but to the individual persons who have their being in it. In some political philosophies, notably that of Hegel, the organic view passes from metaphor to metaphysics and society as the *Volkegeist* is thought literally to have a life of its own. In that direction lies totalitarianism and racism. But the metaphor need not be twisted in that direction and in the moderate position of Burke the organic view of society offers a persuasive rival to the metaphors of building, construction, and planning.

R.S.D.

\*conservatism.

E. Burke, *Reflections on the Revolution in France* (1790), ed. Conor Cruise O'Brien (Harmondsworth, 1968).

Ted Honderich, *Conservatism* (London, 1990).

**original position.** In Rawls's theory, the imaginary situation in which principles of \*justice are to be chosen. We are asked to agree in advance on principles for evaluating social institutions under a \*veil of ignorance—as if we didn't know what place we would occupy in the society. It is a hypothetical social contract designed to ensure that the principles chosen will be fair to all, because if you don't know who you are, you have to be equally concerned for the interests of everyone—though it may be just as difficult to decide what you should choose in this situation as it is to decide what is just.

T.N.

J. Rawls, *A Theory of Justice* (Cambridge, Mass., 1971).

**original sin.** According to this Christian doctrine, the \*sin of early humans, represented in the Hebrew Bible by Adam and Eve disobeying a divine command not to eat the fruit of the tree of knowledge, had disastrous consequences for their progeny. An influential tradition founded by Augustine claims that the descendants of Adam inherit by causal transmission from him both an innate propensity to sin and innate \*guilt. This view is problematic because it seems that guilt can be neither inherited nor innate.

P.L.Q.

\*shame.

N. P. Williams, *The Ideas of the Fall and of Original Sin* (London, 1927).

**origination.** The creation of new causal chains by free human choices. The traditional doctrine of free will or \*libertarianism asserts that there are such genuine creations. Not everything is a link in a deterministic causal chain. Random atomic variations are, of course, not sufficient for origination, which requires a kind of control by the \*will, a self, a soul, or a mind—this being required for \*responsibility. Determinists argue that origination does not exist, or that it is an essentially vacuous and unintelligible notion filling the space where a genuine cause should be.

R.C.W.

\*freedom and determinism; determinism.

**Ortega y Gasset, José** (1883–1955). Philosopher and essayist, born in Madrid. Among his most influential books are *El tema de nuestro tiempo* (1923) and *La rebelión de las masas* (1932). Ortega's two most distinctive contributions to philosophy are a metaphysics of vital reason and a perspectival epistemology. For Ortega, reality and truth are defined with respect to my life, a combination of myself and my circumstances ('yo soy yo y mi circunstancia'). Something is real only in so far as it is rooted and appears in my life. The \*self is not an entity separate from what surrounds it; there is a dynamic interaction and interdependence of self and things which together constitute reality. Because every life is the result of an interaction between self and circumstances, every self has a unique perspective and truth is perspectival.

Andrew Dobson, *An Introduction to the Politics and Philosophy of José Ortega y Gasset* (New York, 1989).

**ostensive definition.** Explaining the meaning of a word by ostension, by pointing to something to which the word applies, has been variously thought to constitute (i) a form of explanation which provides language with a foundation, (ii) an explanation which, in presupposing a general grasp of language, is only secondary, and (iii) a procedure which does not qualify as a \*definition or explanation at all. While ostension may serve to point the learner in the right general direction, there is certainly a question as to how much eventual understanding may owe to any such procedure, and how much it requires exposure to word usage over a period of time.

B.B.R.

B. Rundle, *Wittgenstein and Contemporary Philosophy of Language* (Oxford, 1990).

**Other.** Primarily understood as the other human being in his or her differences. The problem of \*other minds was first formulated clearly by John Stuart Mill in *An Examination of Sir William Hamilton's Philosophy*, although there are clear antecedents in Descartes. It was taken up by Husserl in the Fifth of his *Cartesian Meditations* where the other is constituted as an *alter ego*. However, it is only with Levinas that the philosophy of the Other was freed from the epistemological problematic. In *Totality and Infinity* Levinas charged previous philosophy, including that of Husserl, with reducing the Other to an object of consciousness and thereby failing to maintain its absolute alterity: the radically Other transcends me and the totality into whose network I seek to place it. According to Levinas, by challenging my self-assurance the Other opens the question of ethics. The priority of the Other becomes equivalent to the primacy of ethics over ontology.

Questions have been raised about this conception of the Other. Derrida asked whether the absolute alterity of

the Other is not inevitably compromised by the fact that the Other is *other than* what is given initially. The logical problem has especially devastating consequences in the political realm, particularly if the Other is not accorded the ethical priority Levinas gives it. In this way the now widespread use of the language of otherness in anthropological discourse to describe the West's encounter with non-Western cultures tends to keep the dominant discourse intact, just as the reference to the feminine as Other reasserts male privilege.

The notion of the Other is also used by other European thinkers in a broader sense. Death, madness, the unconscious are all said to be Other. In each case the challenge of the Other is the same: that in some way the Other cannot be encapsulated within the thought-forms of Western philosophy without reducing the alterity of the Other.

R.L.B.

J. Derrida, 'Violence and Metaphysics', in *Writing and Difference* (Chicago, 1978).

M. Theunissen, *The Other* (Cambridge, Mass., 1984).

**other minds.** A problem in the theory of knowledge about whether—and if so, how—one can know, or be justified in believing, that other individuals (humans and animals) have thoughts and feelings. Also sometimes taken to include a related question: How do we know that plants and rocks (not to mention machines) do not have minds? Also, more specifically, a problem about the character of another's thoughts and feelings: How do I know strawberries taste the same to you as they do to me?

Assuming that one has some kind of \*introspective access to one's own thoughts and feelings (so that there is no problem about one's own mind), the problem of other minds is usually taken to be a question about what our judgements about other people's minds are based on. Are they based solely on observable behaviour? If so, what reason do we have to think that such behaviour is a reliable symptom (expression) of mental activity? If people can act one way and feel another, if they can believe something without ever showing it, why not suppose a daffodil does the same—thinks and feels without ever showing it? If a machine can beat us at chess without (according to some) having a mental life, why suppose our neighbour is any different?

\*Behaviourism is a view that identifies mental activity with behavioural tendencies and dispositions. If someone acts jealous and is disposed, in a wide variety of circumstances, to behave jealously, then that person is jealous. There is no further fact about this mental state that is hidden from our view. Behaviourism provides a convenient solution to the problem of other minds since, according to it, 'other minds' are as accessible as 'other behaviour'. This solution to the problem does not, today, enjoy much support. Although some aspects of our mental life may consist of behavioural tendencies (vanity and shyness, for example), others do not. An itch isn't just a tendency to scratch.

For those who (unlike behaviourists) take the mental life of another person or animal to consist of inner,

unobservable (by others), events and states, the argument from analogy has always been an attractive answer to the problem of other minds. Just as I am entitled to infer that *X* will do *A* because it resembles in a variety of significant ways (is analogous to) *Y*, and *Y* generally does *A*, so we know (or at least are reasonable in believing) *X* feels pain because *X* resembles me—acts in many of the same ways I do—when I feel pain. Arguments from analogy have been criticized as a very feeble sort of argument for other minds—much too feeble to support the knowledge claims we typically advance about such matters. It is true that I tend to yell and suck my finger when I burn it. I do so because it hurts. But is this a reason to conclude, by analogy, that it must also hurt my neighbour because he behaves that way when he burns his finger? Perhaps it is, but the inference is from a single case (one's own case), and analogies from a single case are notoriously weak. Is the fact that *one* chocolate in the box, the one you ate first, was caramel-filled a reason to think that every (any?) other similar-looking chocolate will be filled with caramel? Is it a good enough reason to say you *know* it is?

The argument from analogy can be strengthened by looking not at a single piece of behaviour but at the full range of behaviour exhibited by other organisms. Many philosophers have thought that verbal behaviour is particularly relevant. People *say* it hurts. At least they make noises similar to those I make when I say it hurts. We can, of course, make machines that will produce the same noises when they are poked, but will they (can they?) exhibit the full range of dispositions—verbal and otherwise—that human beings do? There is also the fact that other human beings (and some animals) have nervous systems remarkably like one's own—something daffodils, rocks, and computers lack. In so far as there is reason to think mental activity *\*supervenes* on the neural substrate (something that many materialistic theories of the mind maintain), then this similarity of hardware is an even stronger analogical basis for inferring similarity of mental life in biologically and behaviourally similar organisms.

**other-regarding actions:** *see* self-regarding and other-regarding actions.

**ought.** 'Ought' can express purely personal counsel—'I ought to move my Queen, or I'll lose it next move'. It can also express an impersonal or 'transpersonal' moral imperative. I may be urging myself (or another similarly placed) towards morally desirable or necessary action, or away from the morally deplorable. The context of its use may be the small scale of an individual act, or the grandest

scale of a vision of what human life 'ought to be like'. Essential to the moral 'ought' is the sense of a strong constraint laid upon the will: it contrasts with the operating of a moral ideal which, rather, beckons and attracts the moral agent.

'Why ought I?' is a legitimate question, inviting answer in terms of intelligible moral rules or practices, until one reaches such an ultimate limit as, for example, respect for persons or right to life. It may be argued that 'ought implies can', in the strenuous sense that to recognize an unconditional moral 'ought' itself supplies the motivation to respond.

**'ought' and 'is':** *see* 'is' and 'ought'.

**overdetermination and underdetermination.** The *problem of overdetermination* is a problem for our understanding of *\*causality*. An effect is overdetermined when it has two independent causes, each sufficient on its own for its effect. The problem is that in such cases neither cause satisfies our ordinary criteria for causal efficacy: neither cause, for example, is necessary in the circumstance for the effect. So we either have to deny that causal overdetermination occurs, or show that our preferred account is not incompatible with it, or modify that account. The *problem of underdetermination* concerns the relationship between *\*theory* (scientific theory, or any generalization) and the *\*empirical data*. For any given theory, the evidence will never determine the choice between that theory and some rival theory. The problem then is to show how theory choice can ever be rational.

**Owen, G. E. L.** (1922–82). Gwili Owen greatly influenced the study of ancient philosophy world-wide. He was professor successively in Oxford, Harvard, and Cambridge. He published a few very influential articles, notably on the place of the *Timaeus* in Plato's philosophy and on the role of dialectic in Aristotle's philosophical method; and he was a protagonist in the group of European scholars which produced the series of *Symposia Aristotelica*. A recurring theme in his work was the importance of method and argument, as against thesis and doctrine, in the practice and history of philosophy. He applied this insight to challenge a number of orthodoxies in the interpretation of Plato and Aristotle. Owen was active in the recruitment and motivation of graduate students and junior faculty members. His medium was the cut-and-thrust of dialectic, through which he showed that the study of ancient philosophy demands philosophical acuity combined with philological rigour. A seminal article,

which illustrates many features of his thought and style, is 'The Platonism of Aristotle', reprinted in his *Logic, Science and Dialectic* (London, 1986).

J.D.G.E.

**owl of Minerva.** Minerva, the Roman goddess of \*wisdom, was the equivalent of the Greek goddess Athena. She was associated with the owl, traditionally regarded as wise, and hence a metaphor for philosophy. Hegel wrote, in the preface to his *Philosophy of Right*: 'The owl of Minerva spreads its wings only with the falling of the dusk.' He meant that philosophy understands reality only after the event. It cannot prescribe how the world ought to be.

**Oxford Calculators.** In the 1320s and 1330s, a group of natural philosophers based at Oxford—principally Thomas Bradwardine, William Heytesbury, Richard Swineshead—produced a series of path-breaking treatises on the analysis of motion. Distinguishing between the study of motion with regard to its causes and its study with regard to its effects, they developed a quasi-mathematical account of the latter in which motions are characterized in terms of 'intensive' magnitudes which cannot be measured directly, but must be assessed according to their spatio-temporal effects.

N. Kretzmann *et al.* (eds.), *The Cambridge History of Later Medieval Philosophy* (Cambridge, 1982).

**Oxford philosophy.** The study and teaching of philosophy in Oxford go back at least to the early thirteenth-century Augustinian, or Neoplatonist, Robert Grosseteste, one of the few medieval philosophers to know Greek. In the early fourteenth century Duns Scotus and William of Ockham were the most important of a large number of Franciscan scholars who opposed the rationalism of the Dominican St Thomas Aquinas. They held that reason is not competent to establish any but the most general elements of religious faith. In their epoch Oxford superseded Paris as the centre of philosophical study. After the Black Death of 1348 and, even more, after the heresies of Wyclif had led, later in that century, to the imposition of ecclesiastical control over religious speculation, Oxford remained, for the most part, philosophically infertile for some 500 years. Hobbes and Locke studied there, unprofitably in their opinion, and Locke taught in Oxford for some years, but neither became a philosopher until a considerable time after they had left it.

Two distinguished philosophers taught in Oxford around the middle of the nineteenth century in an isolated and, philosophically, uninfluential way: J. H. Newman, drawing on Aristotle, the British Empiricists, and Bishop Butler, and H. L. Mansel, chief disciple of the last

important Scottish philosopher, Sir William Hamilton. Newman's theory of belief and Mansel's theory of the limits of religious thought remotely echo the resistance of Scotus and Ockham to the pretensions of reason in the domain of religious belief.

In the last quarter of the nineteenth century a major new school emerged: the anglicized \*Hegelianism that was initiated by T. H. Green and had as its most distinguished exponent F. H. Bradley. They rejected the claim of the common view of the world, and of its scientific extension, to be genuine knowledge, seeing it as a practical makeshift, riddled with internal contradictions. True knowledge can be achieved, not by the analytic understanding, but only by that philosophic reason which recognizes that nature is a product of mind or, at any rate, is formed and articulated by it.

Russell and Moore in Cambridge drove this idealistic orthodoxy from the field, even if its adherents long continued to dominate the philosophical professoriate of the British Isles. Its last notable exponent was the brilliant but intellectually wayward R. G. Collingwood. \*Idealism was less impressively criticized on its home ground by J. Cook Wilson and H. A. Prichard, in and after the Edwardian decade. They set about it with something of the relentless literalism of G. E. Moore, but with a numbing rather than inspiring effect.

In the 1930s Oxford philosophy came to life again. The new Cambridge ideas had been imported with style, rigour, and authority by H. H. Price and were given a more radical turn by Gilbert Ryle. He took philosophy to be concerned not so much with genuine problems as with puzzles or muddles. 'The whole and sole task of philosophy', he wrote, 'is . . . the detection of the sources in linguistic idiom of recurrent misconstructions and absurd theories'. That conviction culminated in his chief work, *The Concept of Mind* (1949) in which mind-body \*dualism is attributed to a mistaken assimilation of statements about minds to statements about physical things. The former, he contends, do not report private inner episodes of thought and feeling but refer to the dispositions of human bodies to act, and talk, in certain ways in given circumstances.

The Oxford philosophy of ordinary language, as it came to be called, received its most exquisite expression in the highly entertaining work of J. L. Austin, who shared Moore's power to dominate a generation of philosophers by the force of his personality and exceeded Moore in the refinement of his linguistic discrimination. After Austin's death in 1960, the return of A. J. Ayer to Oxford after a twenty-year absence, and a focusing of interest on the work of W. V. Quine and other American analytic philosophers, the ordinary-language school disintegrated and nothing specifically Oxonian has replaced it.

A.Q.

PHILOSOPHY IN BRITAIN: LATE TWENTIETH CENTURY

A. J. AYER brought logical positivism from Vienna to Oxford, presenting it as continuous with the British empiricist tradition. For fifty years he was a figurehead of philosophy in Britain, addressing epistemological questions in a distinctively skilful and forceful style.

P. F. STRAWSON planted the seed of his Kantian metaphysics in the fertile Wittgensteinian soil of 1950s Oxford. He moved from an early critique of Russell's philosophical logic to foundational metaphysical questions; this shift in focus offered a model response to the decline of 'ordinary language' philosophy in Britain.

GILBERT RYLE, leading light of Oxford philosophy in the middle decades of the twentieth century, hunter of conceptual confusion and category-error.

KARL POPPER urged that the mark of a scientific theory is that it is open to falsification, and that the mark of a good society or government or social institution is that it is open to change by the people.

# P

**pain.** A feeling of pain can be either 'physical', a \*sensation (e.g. toothache), or 'mental', an emotion (e.g. the pain of a bereavement). There are two main kinds of philosophical theory of sensations of pain. According to one of them, a sensation is painful in virtue of having a special, intrinsic quality, a quality which happens to be universally disliked for its own sake. According to the other, there is no such intrinsic quality shared by all sensations of pain; what they have in common is simply that they are all disliked for their own sake. Which of these theories is true is of consequence for the status of a claim of \*hedonism, namely that pain and only pain is or should be shunned for its own sake.

I.S.P.

\*pleasure; happiness.

R. Trigg, *Pain and Emotion* (Oxford, 1970).

**Paine, Thomas** (1737–1809). Born in Thetford, Norfolk, the son of a Quaker farmer, he died in New York after an adventurous career on both sides of the Atlantic. Arriving on American shores in 1774, he put his talents as a pamphleteer at the service of the rebellious colonists, notably in his *Common Sense* (1776). Back in England when the French Revolution broke out, he immediately came to its defence in his most influential work, *The Rights of Man* (1791–2), penned as a reply to the conservative attack on the ideology of the Revolution by Edmund Burke. In part II of that book, Paine defended a then novel view: among the \*natural rights governments must respect are welfare rights of all citizens to education, old-age pensions, and the like. In *The Age of Reason* (1794–95), enormously popular in its day, he gave a spirited defence of deistic anticlericalism unmarked, however, by any novel philosophical arguments. His radical ideas for social, political, and economic reform were most fully developed in his last major work, *Agrarian Justice* (1797).

H.A.B.

\*deism; justice.

**panpsychism.** A doctrine about the nature of spatio-temporal reality. It asserts that each spatio-temporal thing has a mental or 'inner' aspect. Few panpsychists would be happy with a characterization of their view as that all things have minds, even sticks and stones. Instead, they

want to say that there may be varying degrees in which things have inner \*subjective or quasi-conscious aspects, some very unlike what we experience as consciousness. A full-blown mind would only be possessed by things approaching the complexity of human beings. On the other hand, it is difficult to characterize precisely to what extent all spatio-temporal things are supposed to have an inner 'mental' aspect. Most of those who espouse this doctrine feel impelled to do so because they do not see how the mental can be caused by, or composed from, non-mental things.

**pantheism.** First used by John Toland in 1705, the term 'pantheist' designates one who holds both that everything there is constitutes a unity and that this unity is divine. Pantheists thus deny the radical distinction between God and creatures drawn in monotheistic religions. A familiar philosophical example of pantheism is Spinoza's doctrine that there is only one \*substance and it is divine; he describes this substance as *Deus sive natura* (God or nature). Pantheism is distinguished from \*panpsychism by the fact that panpsychists, who maintain that everything is psychic in nature, need not also hold that everything is divine.

**Papineau, David** (1947– ). English philosopher, currently Professor of Philosophy of Science at King's College London. Papineau has worked in metaphysics, epistemology, and the philosophies of science, mind, and mathematics. His overall stance is vigorously realist and physicalist in metaphysics, and reliabilist in epistemology. He is one of the originators of the teleological theory of mental \*representation, a solution to the problem of \*intentionality which derives the intentional content of our beliefs from the conditions under which actions based on these beliefs and certain desires will succeed in satisfying those desires. Since 'satisfying' desires amounts to making their

contents true, the theory needs to explain how desires get their contents. Papineau explains the contents of basic desires in terms of the biological functions with which natural selection has endowed them.

**paradigm, scientific:** see Kuhn.

**paradigm case argument.** A type of argument common in the heyday of \*linguistic philosophy, with its emphasis on actual linguistic usage. Philosophers have long disputed over whether there are such things as, say, free will or a good inductive argument. The paradigm case argument claims that if the expressions 'free will' and 'good inductive argument' are standardly applied in some situations and rejected in others, then the former must represent genuine cases of free will etc., or the expressions could not have the meanings they do have. It can, however, be doubted whether this proves the existence of free will etc. in any but a trivial sense. The argument is akin to, but weaker than, \*transcendental arguments, which appeal not to how we actually do speak but to how we must if we are to speak at all, either in general or on some given subject-matter.

A.R.L.

R. J. Richman, 'On the Argument of the Paradigm Case', *Australasian Journal of Philosophy* (1961), discussed by C. J. F. Williams (ibid.) and Richman (ibid. 1962).

**paradox of analysis.** An ambition of much twentieth-century analytic philosophy was to give the correct analysis of certain terms, concepts, or propositions. Yet, as G. E. Moore pointed out, if an analysis is correct, the *analysans* must state no more or less than the *analysandum*. Hence analysis, if successful, is trivial, and if unsuccessful, is false. Moore's paradox recalls a question tackled by Plato (in *Meno*) and Aristotle (in the *Posterior Analytics*): whether—and by what means—we can ever know new things. Paul Feyerabend argued that the paradox of analysis showed that philosophy cannot be analytic and scientific at the same time.

A.BRE.

J. King, 'What is Philosophical Analysis?', *Philosophical Studies*, 90 (1998).

**paradoxes.** There are many separate entries in this work for this or that 'paradox'. Is there a common feature marked by this term? Part of any such feature would be the idea of conflict.

One interpretation of 'paradox' is 'statement conflicting with received opinion'. Thus one of the Socratic paradoxes is the remark that no one ever knowingly does wrong, which is inconsistent with the popular opinion that people often do things they know they shouldn't. Here the 'paradox' represents a philosophically serious challenge to the received opinion.

A different use of 'paradox' is also marked by \*'antinomy', which applies not to a statement which conflicts,

but to the conflict itself, when it is a conflict between what are (or have been) regarded as fundamental truths. For example, Kant maintains that an antinomy arises between basic principles involved in reasoning about space and time. From these principles, a good argument can be given for the conclusion that the world must be finite in space and time, but the principles also allow an equally good argument that the world cannot be finite, but must be infinite.

'Antinomy' marks a different feature of a case from the first use of 'paradox', but 'paradox' is often given this latter use as well. It is common to find one philosopher calling a case a paradox and another calling the same case an antinomy. In so far as it is a received opinion that given principles do not conflict, then the report that they do conflict will be contrary to that opinion and paradoxical in the first sense. But that does not reduce this second use to the first. They mark different features.

A third use of 'paradox' is to mark conflict in criteria for classification. A phenomenon may be called paradoxical when it resists classification not because there is insufficient information about it, but because the information brings out conflicts in the criteria for classification which may have been previously unnoticed. Thus 'paradoxical sleep' (REM sleep) has features once thought distinctive of a waking state and other features supposed distinctive of a sleeping state. The paradoxes of quantum physics involve light phenomena exhibiting both wave characteristics and particle characteristics. If criteria are regarded as fundamental principles, this interpretation might be reduced to the 'antinomy' reading. But the feature of involving a classification problem is worth keeping track of.

Use of the term 'paradox' may leave unclear just what is being called paradoxical and what is meant by so calling it. This is not merely because of unclarity about which of the three foregoing meanings of the term is intended. There may be disagreement about what is in conflict. For example, it is sometimes said that Kant's antinomy calls for a rejection of the law of excluded middle: the world is neither finite nor not-finite (infinite). Others will argue that it is quite unnecessary to answer in this way. Kant's idea was that there is no world as a completed whole. This could be expressed by saying that both the claim that the complete world is finite and the claim that the complete world is non-finite are false because there is no such world. That is perfectly compatible with the law that for every proposition whatever, either it or its negation must be true. The negation of 'The world as a complete whole is finite' is not 'The world as a complete whole is not finite', but rather, 'Either there is no such thing as the world as a complete whole or there is but it is not finite'. Another alternative would be to question the quality of either or both of Kant's arguments for the two sides of his antinomy, without questioning general logical principles.

Here we have a disagreement over just which fundamental laws are in conflict in the sense of constituting an inconsistent group. Of course, whenever any group of claims is in conflict, adding any additional claims will give

a larger group which is still in conflict. 'P and not-P' is a group in conflict, and adding any other claim, Q, gives us 'P and not-P and Q', which is also in conflict. But it may be that Q is not to blame for the conflict—not a genuine party to the conflict belonging under the heading of conflictant. A logical-revisionist side wants to put in the law of excluded middle as a conflictant in Kant's antinomy and thereby consider its rejection as a way out of the conflict. A logical-traditionist side will refuse to consider that a possibility and identify other conflictants which may have been unnoticed. They will hold that in any case of logical conflict, it is confused to blame logical laws, since they are essential to the idea of *logical* conflict. Without at least an intuitive grasp of logical laws it would be impossible to recognize the existence of any logical conflict. They are necessary truths indispensable in good reasoning which are above the conflicts they enable us to identify.

The logical revisionists may respond that it is possible to make some changes in logic while retaining the basis for classifying some groups of claims as logically consistent or inconsistent. They can point to many honourable candidates for 'alternative logics'. It is important to ask, however, whether these candidates are presented as universally applicable criteria of conflict which are themselves beyond conflict. This is not to suggest that it is acceptable to presume that there are such criteria and ignore the view that every claim whatever is revisable, that no claim is beyond conflict. But the significance of attributions of 'paradox' or 'antinomy' often depends on how the idea of 'conflict' implicit in these terms is itself understood.

This may be illustrated by considering one of the most famous philosophical paradoxes, the \*liar paradox. What might be called a 'version' involves the sentence A: The sentence A is not true. A good candidate for a fundamental principle about truth is the principle that a sentence is true if and only if what it says to be the case is in fact the case. (And that means 'all of what it says'. ' $2 + 2 = 4$  &  $2 + 2 = 5$ ' does not qualify as true just because it says correctly that  $2 + 2 = 4$ .) Suppose then, that we assume that what the sentence A says to be the case, all of what it says, is correctly reported as the claim that A is not true. This claim is true if A is not true, and not true if A is true. That entails that A is true if and only if A is not true, which is a contradiction.

Now, what is the paradox? What should be identified as conflictants in this case? The logical traditionist will treat classical logical principles as immune from blame for the trouble. So just what are the conflictants? One answer compatible with the traditionist approach is as follows: It is natural and common to assume that what the sentence A says can be correctly reported simply by quoting the sentence, either directly or indirectly. The claim that this assumption is false thus conflicts with a received opinion and is in that sense paradoxical—but it happens to be the truth of the matter none the less. The assumption to the contrary, that all of what A says is just that the sentence A is not true, leads to a contradiction by traditional logical rules.

This has not been the most popular response to the 'paradox'. It is far commoner to respond in a revisionist

way. But then it is appropriate to ask: What is to be identified as the paradox?

An early propounder of the liar paradox, Eubulides of Megara, did actually present his version as an assertion—'I am lying'. But was that a statement contrary to received opinion? His intention was to discredit rationalism by showing that its basic standards of reasoning themselves lead to what they reject—inconsistency. The derived contradiction may be contrary to reason, but it is also derived according to reason.

It is not Eubulides' assertion, or the sentence A, which conflicts with respectable opinion. Rather, it is attempts to determine the truth-value of these sentences which provoke conflicting claims. In so far as we can derive a contradiction from an 'unquestionable recognition' of what A says along with classical logical rules we have a conflict which is a candidate for 'antinomy'. The commonest contemporary responses to this problem take it in this way, as an antinomy calling for restrictions on classical logical principles.

The most popular restriction holds that there is no such thing as truth *simpliciter*—only truth at a level, where to say that a claim is not true-level-*n* is to make a claim of level *n* + 1 to which 'true-level-*n*' cannot be meaningfully applied. This cannot be formulated in unrestricted natural language without undoing its purpose. B: 'The sentence B is not true at any level' will raise trouble unless some restriction is placed on what we are allowed to say. So it is denied that we can talk meaningfully about 'truth-at-some-level-or-other'. These denials of meaning are quite implausible. If 'truth *simpliciter*' is meaningless then 'There is no such thing as truth *simpliciter*' should also be meaningless, just as 'There is no blah-blah-blah' is meaningless. The fact that the former is not meaningless suggests that it is not true. The 'levels' response requires denying that there even were general principles about truth that led to inconsistency. The 'universal laws' would not be false or conflicting but rather 'blah-blah'—and 'blah-blah' is not a candidate for logical conflict.

This criticism could be parried by taking a nominalistic approach and saying not that there is no truth *simpliciter* but rather that the traditional use of the word 'true' without implicit or explicit levels tended to lead its users into inconsistencies. The 'universal laws' would then be certain sentences of a sort found to be no longer useful, but still easily distinguishable from 'blah-blah'.

However, this does not satisfactorily explain why the alleged inconsistencies of plain 'true' ought to be avoided. The traditional answer would be that it is absolutely impossible, universally impossible, in all possible languages, for inconsistencies to be true. This can't be allowed on this 'nominalist' line any more than it could on the previous one. The universality of the logical criteria are given up on this approach, and that deprives the 'inconsistencies' of their problematic significance.

A more recent approach to the liar paradox treats criteria for truth or falsity as sequential. The ruling that the paradox is true satisfies a criterion for ruling it false; that

finding satisfies a criterion for finding it true; and so on, *ad infinitum*. Where other sentences get a permanent truth assignment, some self-referential sentences (the liar paradox is one) oscillate indefinitely. Various interpretations may be placed on such data, including assigning 'values' other than the true–false pair. The patterns of 'valuation' produced by various rules may make an interesting object of mathematical study. It is rather like a psychiatrist classifying 'paradoxical' personality types, love–hate relationships, double or multiple binding personal interactions, manic-depressives, etc., from a detached perspective.

Classical logical laws cannot be treated as applicable sequentially without ignoring the universality which is essential to their identity. If a claim is found true, then found false, then true, and so on indefinitely, then either half of these 'findings' are mistaken or else it was not the same claim from one 'finding' to the next.

However, the anti-traditionalist may not be concerned with how classical laws need to be applied. He may have been led by his exposure to paradoxes and antinomies to have given up the belief that there is in matters of theory any mandatory received opinion or any fundamental principles to get into conflict of a privileged logical kind which it is essential to proper thinking to resolve. He can agree with the classicist that without the absolutely universal and necessary logical principles there is no fixed basis for determining the correct response to a paradox or antinomy, but draw a very different moral. His response to those troubled by paradox may be like that of the psychiatrist easing a patient's distress not by answering his questions, but by changing his attitude towards them.

This conflict over the very identity and nature of the conflict illustrates how, in a paradox case, we may encounter considerable difficulty in achieving agreement about the correct description of the problem. Whether an opinion has a status that would make its rejection significant, or a 'law' is really fundamental, may be unclear. And even the significance of rejection or conflict may be a matter of disagreement. It is perfectly compatible with classical logic to regard difference of opinion as healthy or even desirable. But those who wish further not to be constrained by the idea that one side in a contradiction must be wrong will not settle for that. Paradox cases raise general questions about method and principle, which is one reason the topic has been of such interest in philosophy. J.C.

**paradoxes, logical.** F. P. Ramsey held that 'the well known contradictions of the theory of aggregates . . . fall into two fundamentally distinct groups'. The first group 'involve only logical and mathematical terms' and have come to be called (by many) 'logical paradoxes'. The second group 'cannot be stated in logical terms alone' and 'contain some reference to thought, language, or symbolism, which are not formal, but empirical terms'. Ramsey held that the \*paradoxes of the second group 'may be due not to faulty logic or mathematics, but to faulty ideas concerning thought and language', and in that case, 'they would not be relevant to mathematics or logic, if by "logic" we mean a symbolic system, though of course they would be relevant to logic in the sense of the analysis of thought'. Those who follow Ramsey's suggestion call the second group 'semantic paradoxes'.

All but one of Ramsey's examples come from *Principia Mathematica*, where they are listed under the common heading of 'Contradictions which have Beset Mathematical Logic'. The ones he calls 'logical' are Russell's paradox, Burali-Forti's paradox, and the paradox of the relation which holds 'between two relations when one does not have itself to the other'. The ones now called 'semantic' (by those who accept this distinction) are the liar paradox, Berry's paradox, König's paradox of the least undefinable ordinal, Richard's paradox, and Grelling's paradox. (The last is the one paradox not in the *Principia* list.)

Ramsey's distinction should be regarded as controversial. His two alternative meanings for 'logic'—'a symbolic system' and 'the analysis of thought' do not rule out non-logical symbolic systems or psychology, and are, anyway, not mutually exclusive. The notions of reference, definition, or truth have as much claim to belong to logic as does the notion of a class. This was clearly the intention of the authors of *Principia* since they attempted to allow these terms to occur in their ideal language while at the same time laying down rules which would prevent contradictions formulated in such terms from being derivable in their system.

A pragmatic motive for Ramsey's distinction arises from the fact that, in order to both allow the 'semantic' terms and avoid contradictions, *Principia* presents what is known as 'the ramified' (as opposed to 'the simple') theory of types. On the simple theory, both the propositional functions 'x is a general' and 'x has all the qualities of a great general' would be of type 1, one type above that of the things (individuals) to which they apply. But the latter function is built up by quantifying the function 'x is a quality of a great general', which, in the simple theory, would be of type 2. And this fact about its derivation is important to the *Principia* treatment of 'semantic' paradoxes. Functions are not ordered simply by the order of their arguments but by the order of the arguments to the 'matrices' from which the functions are derived. (Matrices, roughly, are what is left when quantifiers are deleted from a formula.) The ramified hierarchy of orders is the basis for a rule requiring that a proposition of the *n*th order can only be allowed apparent variables of order *n* – 1. This is much

more restrictive than the simple type rule that a propositional function of type  $n$  determines a class whose members are of type  $n-1$ . The simple rule would have 'a property of individual  $a$ ' represent a property of type 2 whose instances would be type 1 properties of  $a$ . But the ramified rule would make that phrase illegitimate and give us instead an infinite hierarchy of properties: 'a first-order property of  $a$ ', 'a second-order property of  $a$ ', etc. This was so restrictive as to rule out the definition of the least upper bound of a class of real numbers. The *Principia* response was 'the axiom of reducibility', which guarantees that for every such function of  $a$  in the infinite hierarchy, there is an extensionally equivalent first-order function.

Ramsey argued that the axiom of reducibility is implausible, and unnecessary if *Principia* is restricted to terms of set theory, which would be all that is required for its primary mission of being a foundation for mathematics. This has been a popular idea, and today it is the simple theory of types that would be most likely to be discussed by set theorists. There is nothing wrong in that, but it would be unfortunate if the success of a simplification of one theory of sets were mistaken for a conclusive basis for a distinction between 'logical' and 'semantic'.

**parallel distributed processing.** A form of computation in which items are represented not by symbols but by patterns of activity distributed over a network of simple processing units. Particular patterns result from massively parallel computations of the levels of activation in individual units. Connections between the units excite or inhibit the spread of activation. As a model of human \*cognition it is proposed as a rival to the \*language of thought hypothesis, one that offers a closer approximation to brain processing.

\*connectionism.

P. Smolensky, 'The Proper Treatment of Connectionism', in *Behavioural and Brain Sciences* (1988).

**parallelism, psychophysical.** The thesis that mind and body never influence one another, but nevertheless progress along parallel paths, as though they interacted. This response to the \*mind-body problem is partially motivated by the view that two distinct kinds of being or substance exist, immaterial and material, and by the difficulty of understanding how substances of either kind can act upon substances of the other. Leibniz held that God arranged things in advance so that our minds and bodies would be in harmony with one another and with what happens to all other substances: the doctrine of \*pre-established harmony. In the absence of some such explanation, parallelism would be a remarkable coincidence; but one suspects that a being capable of instituting pre-

established harmony could also find a way to allow mind and body to interact.

\*occasionalism.

G. W. Leibniz, *Philosophical Papers and Letters*, ed. L. E. Loemker (Chicago, 1956), chs. 35–6, 47, 52, 54–5, 58, 60–1, 63, 67, 71.

**paralogisms.** In Kant's critical philosophy, a fallacious argument. In the *Critique of Pure Reason* Kant identifies three paralogisms in the first edition and a fourth in the second edition. They are invalid inferences to conclusions expressing the simplicity of the soul, the personality of the soul, the immortality of the soul, and the existence of the external world. In each case, the mistake is to try to derive a tenet of transcendental realism from premisses expressing only transcendental idealism—that is, conclusions about a putative non-spatio-temporal reality from premisses only about possible appearances.

**paraphrasis:** see Bentham; contextual definition.

**Pareto optimality.** Pareto optimality, developed by Vilfredo Pareto, is the most widely accepted criterion of economic efficiency. A state of a given system (e.g. a distribution of a given quantity of goods) is Pareto optimal, and thus efficient, if and only if there is no feasible alternative state of that system (e.g. no feasible alternative distribution of those goods) in which at least one person is better off and no one is worse off. And, for purposes of this criterion, a person is 'better off' with some alternative  $A$  rather than  $B$  if and only if this person *prefers*  $A$  to  $B$ . An advantage of this criterion is that it provides a way of evaluating alternative social states that does not require interpersonal utility comparisons.

D.W.HAS.

Allen Buchanan, *Ethics, Efficiency, and the Market* (Totowa, NJ, 1985).

**Parfit, Derek** (1942– ). Best known for his innovative ideas about the nature of \*personal identity, where he contends that, in a significant sense, 'identity' is not what matters in the continuity and persistence of persons throughout their lives. This view was outlined in a number of articles in the 1970s but was fully expounded in his *Reasons and Persons* (Oxford, 1984). In that book, he draws out some of the consequences of his views for moral theory, arguing that certain traditional conceptions of prudence and self-interest must be questioned once the conception of the nature of the self on which they depend is criticized. His theories have excited considerable comment. Since 1967 a Fellow of All Souls, Oxford, he is also a keen architectural photographer.

N.J.H.D.

**Parmenides** (fl. c.480 bc). Citizen of Elea and leading figure of the \*Eleatics. His philosophical work was expounded in his poem, of which more than a hundred lines survive. The poem begins with a first-person narrative of an allegorical journey, at the end of which the

narrator meets a goddess. The goddess tells him: 'you are to find out everything: both the steadfast heart of well-rounded Reality, and the opinions of mortals, which contain no genuine proof'. In the rest of the poem, in a long speech, the goddess fulfils the double promise.

The section on 'Reality' (or 'Truth': the translation is controversial), of which much survives, expounded and claimed to prove the truths Parmenides took to be demonstrable.

An indubitable foundation for knowledge is found, as by Descartes, in the mind and its relation to its objects. (1) One cannot coherently doubt that thinking is possible and actually occurs. (2) Thinking must have an object which exists. On these two principles all positive knowledge rests. It follows that (3) something exists; and (4) 'what is not' is not a possible object of speech or thought, so that any attempted theory must be incoherent if it involves apparent reference to anything as non-existent.

The next step, since it must be that something exists, is to consider the aggregate of all that exists, 'that which is' or 'whatever is'. Arguments relying heavily on (4) above are deployed to show that this must have certain properties. (1) It cannot come to be nor cease to be. (2) It has no gaps but is a coherent whole. (3) It is 'not deficient', hence complete and bounded, hence cannot be changed or moved, 'but remaining the same in the same and on its own it lies, and so remains steadily there'. (4) It is 'perfect from every direction, like the mass of a well-rounded ball, in equipoise every way from the middle'. Another thesis, announced but not explicitly proved, states: 'nor was it ever nor will it be, since it all is now together, one, coherent'.

There is continuing controversy about the meaning of these conclusions and about the arguments by which they are supported. The arguments are presented as compelling demonstrations of necessary truths, but they indisputably contain gaps and ambiguities. They often seem to appeal to intuitions drawn from common experience of a spatially and temporally extended world; and the words used to express the conclusions are drawn from everyday vocabulary and have spatial and temporal connotations.

The problems in the theory of Reality therefore raise the central question of Parmenides' view of ordinary experience. This is perhaps to be found in the last part of the poem, the account of 'the opinions of mortals' (of which not much survives), and in occasional asides earlier. The 'opinions', as expounded by Parmenides, constitute a systematic cosmological theory (dualistic, showing interest in astronomy and biology, and traces of the ideas and interests of Pythagoras and his sect). This theory, however, is said to be undemonstrable, 'deceptive', and based on a mistake. Yet it is also described as 'likely' and 'reliable', and as the best of its kind. The 'mistake' or 'deception' therefore is not that of taking the false for the true but of taking the unprovable for the true; and it is a purely theoretical mistake, with no practical consequences.

On this reading, Parmenides does not deny the reality of the ordinary world, but denies only the possibility of knowledge about it. It must therefore be identified, not

with Reality, but with some non-essential aspect of it. The logical exploration of Reality reveals, then, its essential and ascertainable structure. This structure can hardly be spatio-temporal, if that implies some real connection with the spatial and temporal relationships of ordinary experience. For Parmenides denies the applicability of the past and future tenses to Reality, so that temporal succession must be an illusion. Likewise, ordinary spatial perspectives, and therefore all ordinary spatial intuitions, are presumably no certain guides. If Reality is 'bounded' and 'spherically symmetrical', the words must be understood in transferred senses, indicating that Reality is essentially complete, definite, and without differences of aspect.

If Reality is known by human thought, it would seem that that thought too cannot be purely superficial but must find a place within the essential structure of Reality. Cryptically, Parmenides says that 'you will not find thinking apart from what is, in which it [thinking] is made manifest'. This may indicate an idealist conclusion: that Reality is itself a thinking thing, and the object of its own thought.

**partiality and impartiality.** Moral philosophers with widely different outlooks, including Kantians and utilitarians, have argued that impartiality is an important, or even constitutive, element in moral thinking. Some dissidents, however, suggest that this ideal is defective, and that partiality, in some cases, is morally permissible, or even desirable. But disagreement about what impartiality requires threatens this debate with collapse.

Impartiality enjoins us, at the least, to give equal consideration to all persons in our moral thinking. Nepotism, which favours one's relatives, violates the requirement. But does impartiality demand that we *treat* everyone equally? Partialists often insist that relational facts can sometimes justify different treatment: we invite friends rather than strangers to parties, and we take our own children, excluding others, on holiday. In response, impartialists claim that their requirement comes into play at a more fundamental level. Relational facts may be granted relevance, so long as the principles we adopt can *themselves* be impartially endorsed (I must allow, in caring especially for my children, that others may care for theirs). P. F. Strawson, *Introduction to Logical Theory* (London, 1952), chs. 6, 7.

**particulars and non-particulars.** Particulars are normally contrasted with \*universals, the former being instances of the latter—as a particular apple is an instance of the universal, or kind, *apple*. Particulars (in this broad sense) may be concrete, existing in space and time—as does a particular apple—or they may be abstract, as in the case of mathematical particulars like sets. (Sometimes, however, the term 'abstract particular' is used to denote what is otherwise known as a particularized quality or individual property, such as the redness of this apple.)

Some philosophers, notably P. F. Strawson, draw a distinction between particulars and *individuals*. On this view, some but not all individuals are particulars, though all particulars are individuals—particulars being spatio-temporally existing individuals governed by determinate criteria of \*identity. Amongst 'non-particulars' Strawson lists such items as properties, numbers, propositions, and facts.

**Pascal, Blaise** (1623–62). A near contemporary of \*Descartes, Pascal played a considerable role in the scientific revolution of the early modern period, and his achievements included inventing the first mathematical calculator, and establishing the possibility of a vacuum. He is best known for his religious writings, which began after his *nuit de feu* ('night of fire') on 23 November 1654, when he had a powerful conversion experience. Pascal rejected conventional philosophical 'proofs' of God's existence, maintaining that the nature and existence of God were beyond the power of human reason to establish; instead, God was the 'God of Abraham, Isaac and Jacob, not the God of the philosophers', and had to be approached via a living tradition of faith.

Pascal is famous for his 'wager' argument, which is not a demonstration of God's existence, but a 'pragmatic argument'—an attempt to show it is rational to set about becoming a religious believer; for if there is a God, the believer can look forward to an 'infinity of happy life', while if there is no God, nothing of significant value will have been lost. In order to acquire belief, Pascal recommends that we embark on a course of praxis, such as regularly going to church, which 'in the natural course of events will make you believe'.

**Pascal's wager.** An argument for the rationality of believing in God, assuming that no satisfactory evidence is available. Pascal argues that the expected value of theistic belief is vastly greater than that of unbelief, since if one believes, and commits oneself to a life of faith in God etc., and it turns out to be true, then one wins an enormous good (Heaven etc.). But if one believes, and it turns out to be false, then one has lost little, if anything. Therefore (unless the probability of God's existence is infinitesimal), it is rational to adopt theistic belief and the corresponding mode of life.

**passion and emotion in the history of philosophy.** The term 'passion' has a long and convoluted history, both in and out of philosophy. Aristotle used the term *pathé* (plural) to refer to such things as 'anger, fear, pity, and the like' which lead to 'one's condition becoming so transformed that his judgment is affected, accompanied by pleasure and pain' (*Rhetoric*). Aristotle's analysis of anger included a distinctive cognitive component, a specified social context, a behavioural tendency, and physical arousal. (He had little to say of 'feeling'.) He insisted that having the right passions was essential to the virtuous life.

The Stoics, too, took an interest in emotion on the way to forming their ethics. But whereas Aristotle took emotion to be essential to the good life, the Stoics analysed emotions as conceptual errors, conducive only to misery. Passions are mistaken judgements about the world and one's place in it. In the Middle Ages, passions remained central to concerns in religion and ethics, especially matters of faith and sinfulness. Aquinas distinguished between the higher and the lower passions, faith and love among the former, greed, lust, anger, envy, and pride among the latter. So, too, in Buddhism, there were important distinctions between desirable aesthetic *rasas* (e.g. the erotic) and ordinary agitating *klesas* (e.g. lust).

Descartes summarized a good deal of his philosophy in his treatise *The Passions of the Soul*, where he insisted that the passions involve the interaction of mind and body in an undeniable way. A passion is both physiology (the agitation of the 'animal spirits'), a 'perception which we relate to our soul', and an attitude toward the world. Hatred, for example, 'arises from the perception of an object's potential harmfulness and involves a desire to avoid it'. But Descartes also uses the term 'emotion', as did Spinoza and Hume after him, to refer to the more unruly passions. That term, which has all but replaced 'passion' as the general term for the various phenomena grouped together by Aristotle, did not receive its current broad meaning until the mid-nineteenth century with the psychologizing of the field. Today, 'emotion' is the category term, and 'passion' is reserved for an overwhelming and all-absorbing emotion or desire.

The psychological maturity of the concept of emotion is marked Charles Darwin's 1872 treatise *On the Expression of Emotion in Animals and Men*, and William James' seminal

essay 'What is an Emotion?', of 1884. Darwin pointed out the continuity between humans and their near kin in the mammalian world, and James urged a somewhat reductive understanding of emotion as the sensations that accompany physiological disturbances caused by upsetting perceptions. The recent history of interest in emotion has been largely framed by reactions to James and a renewed defence of physiology-based (or neurology-based) theories of emotion. Jean-Paul Sartre is one of those who reacted to James. In a 'phenomenological' analysis of emotion, he argued that emotions are 'magical transformations of the world'—strategies for coping with a difficult world.

**paternalism.** The power and authority one person or institution exercises over another to confer benefits or prevent harm for the latter regardless of the latter's informed consent. Paternalism is thus a threat to autonomy as well as to liberty and privacy. On any normative theory, however, paternalism is desirable toward young children, the mentally ill, and others similarly situated. Liberals invariably seek to limit paternalism to the minimum; their criterion is whether a fully rational person informed of all the relevant facts would consent to the intervention—as might be presumed of an unconscious accident victim whose life is at risk—on the ground that the current paternalism would protect or augment freedom at later stages. Under such a criterion, legal paternalism in the form of legislation that creates 'crimes without victims' (e.g. gambling, homosexuality) would be unjustified state interference with consensual private conduct among adults.

Rolf Sartorius (ed.), *Paternalism* (Minneapolis, Minn., 1983).

**patriotism.** Patriotism, is, unlike nationalism, a sentiment, not a doctrine. It involves love of and support for one's country, which, while etymologically one's 'fatherland', i.e. native land, may be an adoptive homeland, though not, perhaps, as the Latin motto *ubi bene ibi patria* has it, simply the place where one is well off. Yet, in classical \*republicanism, by contrast with most sorts of nationalism, there is a connection between the fact that one's country benefits one and one's supposed special \*obligation to love and support it. Enemies of such special obligations, like \*cosmopolitans (e.g. Martha Nussbaum), thus tend to be suspicious of patriotism, while \*communitarians (e.g. Alasdair MacIntyre) are more favourably disposed to it. Its bad press—'the last refuge of a scoundrel'

(Samuel Johnson), 'no patriot yet but was a fool' (Dryden)—is referable to the fact either that it may, as a sentiment, be unreasonably immoderate, or that, as Hume argued, it involves pride in what relates to oneself, which, while natural, cannot be justified to those with other attachments.

**Peacocke, Christopher** (1950– ). Professor at New York University, formerly at Oxford, Peacocke has worked in the philosophy of mind, language, and logic, and more recently at the intersection of metaphysics and epistemology, where he has argued for a new \*rationalism. In *Sense and Content* (1983) he argued that experiences have 'sensational properties': properties which are not simply a matter of how the experience represents the world to be. Subsequently he developed an account in which experiences have *non-conceptual* contents: the representational content of the perceiver's experience is not wholly determined by the concepts the perceiver possesses. Whether this claim is defensible depends on what the concepts are—and this naturally became a focus of Peacocke's work. He argues that there is no more to a concept than what is specified by an account of what it takes for a thinker to possess that concept. The theory of any given concept, then, is the theory of the possession conditions for that concept.

**Peano, Giuseppe** (1858–1932). Italian mathematician, now mainly remembered for what are called 'Peano's postulates', characterizing the natural numbers. They state that 0 is a number which is not the successor of any number, that every number has just one successor which is a number, and that no two numbers have the same successor. In addition, there is the crucial postulate of mathematical induction, which ensures that the natural numbers are the *least* class containing 0 and closed under the successor function. In fact Peano took the postulates (with acknowledgement) from Dedekind, who should be counted as their author.

Peano was an important influence on Russell, and gave him the idea of deriving mathematics from logic. Much of the notation of *Principia Mathematica* is in fact based on that of Peano and his school.

\*logic, history of.

H. Wang, 'The Axiomatisation of Arithmetic', *Journal of Symbolic Logic* (1957).

**Pears, David** (1921– ). British philosopher who has written extensively on topics in the philosophy of language and the philosophy of mind, on Wittgenstein, on Russell, and on

Hume. He was a Student of Christ Church, Oxford and has taught at the University of California, Los Angeles.

Pears is the translator, with Brian McGuinness, of Wittgenstein's *Tractatus*, and his major interest is, perhaps, in the work of Wittgenstein, both early and late. The culmination, to date, of this work, is his two-volume study of the development of Wittgenstein's philosophy, *The False Prison*. In this study Pears stresses the continuity of Wittgenstein's philosophy and emphasizes the importance of his post-*Tractatus* discussions of \*solipsism and \*phenomenalism to the philosophy of the *Philosophical Investigations*. The second volume also contains a lengthy discussion of the rule-following considerations and the \*private language argument and an assessment of Kripke's interpretation of Wittgenstein's argument. H.W.N.

D. Pears, *The False Prison* (Oxford, 1988).

**Peirce, Charles Sanders** (1839–1914). American philosopher who is perhaps best known as the originator of \*pragmatism. He was educated at Harvard, where his father was a mathematics professor. His greatest philosophical influence was Kant, and he saw himself as constructing the philosophical system that Kant might have developed had he not been so ignorant of logic. But the influence of Thomas Reid and other common-sense philosophers became increasingly important: in late writings, the two influences were combined in his 'critical common-sensism'. Describing himself as a logician, Peirce made major contributions to formal logic (independently of Frege he and his students developed a logic of quantifiers and relations after 1880) and to the study of the logic of science. Indeed, he lectured on these topics at Harvard in the late 1860s and held a lectureship in logic at Johns Hopkins University from 1879 until 1884. But he also served as an experimental scientist, working at the Harvard laboratory after he had graduated in chemistry, and being employed for over twenty years by the United States Coastal Survey.

Peirce was a difficult man, widely perceived as an immoral libertine, prone to paranoia and wild mood swings, and possessing an assessment of his own intellectual powers which may have been accurate but which was sometimes accompanied by contempt for the capacities of those of lesser talents. In 1884, when confident of obtaining tenure at Johns Hopkins, information about his irregular life-style, together with suspicion of his unorthodox religious beliefs, led to his being removed from his post. From then until his death, it was understood that he could expect no orthodox academic employment: he lived precariously with his second wife in north-eastern Pennsylvania, writing extensively and giving a few important series of lectures arranged by his friend William James. He never completed the canonical statement of his philosophical position that he sought, but he published extensively and left hundreds of thousands of manuscripts; his work is gradually becoming more readily available.

*Theory of Inquiry and Pragmatism*. In a late paper, Peirce described himself as a 'laboratory philosopher', claiming

that years of laboratory experience encouraged him, like any experimentalist, to approach all issues in the distinctive manner which comprises his pragmatism. This is clearest in the approach to epistemological matters which emerges in his earliest published work, from the 1860s and 1870s—most clearly in a series of papers in the *Popular Science Monthly* (1877–8).

His epistemological work begins from a rejection of Cartesian strategies in philosophy. They do not, he pointed out, accord with our ordinary practice of carrying out investigations: the latter is a co-operative venture, while Descartes suggests that a responsible investigator should carry out a solitary investigation of his or her cognitive standing. Ordinary inquiry takes for granted all the propositions we find certain as we begin the inquiry, while Descartes's sceptical arguments prompt philosophical doubt about what occasions no real doubt. And ordinary inquiry is impressed by the number and variety of the arguments supporting a conclusion, while the Cartesian requires a single indubitable train of reasoning to ground any belief. Peirce proposes to begin from our everyday and scientific experience of inquiry, and to investigate the norms which govern cognition on that basis.

The first paper of the series suggests that inquiry begins only when one of our previously settled beliefs is disturbed, and it is ended as soon as we have a new answer to the question that concerns us: the aim of inquiry is to replace doubt by settled belief. What methods should we use if we are to carry out our inquiries well? He considers four, the first three being devised to bring to light the key features of the fourth. (1) The method of tenacity requires us to choose any answer, and to take all means necessary to maintain it; (2) the method of authority requires us to defer to an authority and accept whatever the authority requires (it may be no accident that Peirce wrote soon after the bull of papal infallibility had been promulgated); and (3) the a priori method requires us to go by what seems agreeable to reason. It will be no surprise that these methods fail: the second has the advantage over the first that our beliefs will escape the constant buffeting of disputes from those who have decided differently, but we are still likely to meet those who accept a different authority, and our own authority will not be able to settle matters about everything. So fixation of belief must be independent of will or human choice. The third method secures that, but it is likely to make belief a matter of fashion: selection of belief still has a subjective basis. Hence we should adopt (4) the 'method of science', which holds that 'there are Real things, whose characters are entirely independent of our opinions about them; those realities affect our senses according to regular laws, and, though our sensations are as different as our relations to the objects, yet, by taking advantage of the laws of perception, we can ascertain by reasoning how things really are'.

Peirce probably believed that this claim was a presupposition of inquiry and that we should adopt only such methods as were in accord with it. The remainder of the series of papers offers a more detailed account of what this

method involves: Peirce was one of the first philosophers to arrive at a satisfactory understanding of statistical reasoning, and this is central to his account of science. He is a 'contrite fallibilist': any of our current certainties might turn out to be mistaken, but relying upon them will not prevent our making cognitive progress; any errors will emerge with time.

The 'pragmatist principle' forms part of this theory of inquiry, and was elaborated in the second paper of the series, 'How to Make Our Ideas Clear'. When William James won notoriety for pragmatism, crediting it to Peirce, the latter renamed his principle \*'pragmatism'. It is a rule for clarifying the content of concepts and hypotheses, and is supposed to reveal all features of the meaning of concepts and hypotheses that are relevant to scientific investigations. Suppose I wish to test whether a sample before me is sodium. In the light of my knowledge of sodium, I can predict that if it is sodium then, if I were to drop it into hot water, it would ignite: I make predictions about the consequences of actions if the hypothesis is true. Peirce expresses his principle: 'Consider what effects, which might conceivably have practical bearings, we conceive the object of our conception to have. Then our conception of those effects is the whole of our conception of the object.' When I have listed *all* the predictions I would make about the consequences of my actions if the substance were sodium, I have a complete clarification of my understanding of the hypothesis: nothing which could be relevant to testing it scientifically has been omitted.

As well as showing its value in clarifying hypotheses, and arguing that it can be used to dismiss some metaphysical 'hypotheses' as empty, Peirce illustrates the value of his pragmatism by clarifying our conception of truth and reality. If a proposition is true, then anyone who investigated the matter long enough and well enough would eventually acknowledge its truth: truth is a matter of long-term convergence of opinion. 'The opinion which is fated to be ultimately agreed upon by all who investigate, is what we mean by the truth, and the object represented in this opinion is the real.' Although the principle bears a superficial resemblance to the \*verification principle of the later Logical Positivists, there are important differences. First, there is no suggestion that, in clarifying our conception, we list only those conditional expectations that are analytic or true by definition: Peirce expects the content of a conception or hypothesis to develop as our scientific knowledge advances. And, second, as he developed his philosophical position, he insisted that the principle could only be taken seriously by someone who shared his realism about natural necessity: the conceptual clarifications are expressed as subjunctive \*conditionals ('would-bes'); and such conditionals report real facts about the world.

*System.* Peirce's logic is a theory of cognitive norms: methods of inquiry, standards of inference, rules for identifying plausible hypotheses, principles for clarifying meanings, and so on. He was unsatisfied with the kind of grounding he provided for cognitive norms in the papers just

discussed, and his attempts to correct the Kantian framework were directed at remedying this. His sophisticated \*architectonic approach to philosophy rested upon a classification of the sciences. Logic was the least fundamental of three normative sciences, being a special application of a system of norms initially developed in ethics and aesthetics. All of these investigations made use of a system of \*categories, a correction of Kant's system, which was defended through a kind of phenomenological investigation. And these philosophical and phenomenological inquiries used mathematical methods to study experience and reality, mathematics being the only discipline which had, and needed, no foundations. So Peirce's later work developed a highly sophisticated account of how we can have knowledge of cognitive or logical norms.

His system of categories is most easily understood from the perspective of his logic of relations. Properties and relations can be classified according to the number of relata they have: '... is blue' is a *one-place* predicate, '... respects ...' is a *dyadic, two-place* relation, and '... gives ... to ...' is a *triadic, three-place* relation. Peirce argued that a language adequate for scientific or descriptive purposes must contain terms of all these three kinds, but that there are no phenomena which can only be described in a language which contains expressions for four-place relations. Thus he classified phenomena and elements of reality numerically: according to whether they are forms of *firstness*, *secondness*, or (like giving) *thirdness*. The irreducibility of thirdness is, he thinks, a distinctive part of his philosophical outlook, something which allies him with realist philosophers in opposition to nominalism. In early work, his defence of his categories was largely found in his work on formal logic, but later he turned to phenomenology: reflection on experience of all kinds was to convince us that triadicity was ineliminable but that no more complex phenomena were involved in experience.

Thus we are aware that our experiences have raw qualitative characters which do not directly involve relations with other things: they exhibit firstness. They also stand in relations to each other, interacting against one another and so on: this involves secondness, as when fire immediately follows our dropping the sodium in hot water. But we are aware that this interaction is intelligible, it is 'mediated': we can bring it down into a continuous spread of small changes which go together to make up the big one; and we are aware that it conforms to a law. Finding it intelligible introduces thirdness: we understand the two elements of the interaction by reference to a third mediating fact. The aim of inquiry, for Peirce, is to find the thirdness (law and pattern) in the manifold of sensory experiences that we undergo. The norms employed by the scientific method are to be vindicated by showing how they provide means for finding more and more pattern and mediation (more and more thirdness) in the world of our experience.

*Signs.* According to Peirce, the most important forms of thirdness involve \*meaning and representation, and all of his work is underpinned by a sophisticated theory of

meaning: his semiotics. He probably believed that everything was a sign, but the signs of most interest to him were thoughts and 'the assertions of a scientific intelligence'. This theory of meaning ('speculative grammar') was to provide foundations for his writings in logic.

The key to the thirdness involved in signs was Peirce's notion of *interpretation*. A \*sign denotes an object only by being understood or interpreted as standing for an object: and this interpretation will always be another sign with the same object. Semiotics is thus primarily a theory of understanding, an account of how we are guided and constrained in arriving at interpretations of signs. Interpretation often involves inference, developing our understanding of the object in question. Thus my understanding of your assertion that you are tired may be manifested in my thinking that you want me to believe you are tired, in my believing you are tired, in my expecting you to fall asleep, in my offering you a cup of coffee, and so on. The interpreting thought mediates between the sign and its object.

Peirce was famous for his classifications of signs, and some of his terminology has acquired wide currency. For example, signs can be distinguished according to the features of them exploited in arriving at an interpretation. A symbol denotes a particular object because there exists a practice of interpreting it as denoting that object; an index denotes an object to which it stands in a direct existential relation; the conventions governing the use of ordinary indexical expressions such as 'this' do not fix the reference unaided but rather guide us in interpreting it as an index. And iconic signs share some feature with their object which each could possess if the other did not exist: maps are straightforward examples, the conventions governing their use fixing how we are to interpret them as icons. Mathematical and logical symbolisms are iconic representations, and it was important for Peirce that sentences of natural languages have iconic elements too: formal inference exploits the fact that sentences exhibit a form which is shared with their subject-matter. Much of Peirce's later work attempted to use this systematic theory of meaning to provide a proof of the pragmatist principle.

Science itself is a process of sign interpretation. And Peirce's account of scientific reasoning has some important elements. As mentioned above, Peirce models all inductive reasoning on statistical sampling: quantitative induction involves attempting to estimate the chance of a member of a population having a particular property; and qualitative induction tests hypotheses by sampling their consequences. He denies that induction ever establishes that a conclusion is true or even probable. Rather, the practice of inductive testing is justified because continued use of it will eventually lead us to converge on the correct value for the chance of a member of the population having the property in question. The pragmatist principle teaches that \*probability is a \*propensity: if the chance of a coin coming up heads is 0.43, then, if we were to continue to toss it fairly, the proportion of times on which it comes up heads *would* converge on 0.43.

The logic of \*abduction is a logic of discovery: it studies how we are guided in constructing new hypotheses from the ruins of defeated ones; and it examines the norms guiding us in deciding which hypotheses are worth testing. All scientific activity is grounded in the hope that the universe is intelligible, and intelligible to us. And we are to take seriously no hypothesis that 'blocks the road of inquiry', forcing us to accept regularities as brute or inexplicable. It is connected to this that Peirce espouses 'synechism', the doctrine that we are to expect the universe to display continuities rather than discontinuities. Peirce contributed to the mathematical analysis of continuity, exploiting his ideas about the logic of relations and trying to use it as the basis of his realism about natural necessity: continuity is 'ultimate mediation'. The logic of abduction advises us to favour theories that posit continuities over those that allow for brute unmediated discontinuities.

*Metaphysics.* Although Peirce envisaged that pragmatism would eliminate 'ontological metaphysics', he claimed that scientific progress demanded that we construct a 'scientific metaphysics'. Supposedly this was an empirical discipline, differing from the special sciences in using no sophisticated techniques of experiment and observation: it was 'coenoscopic', relying only on familiar everyday observations which are surprising only because their familiarity prevents our noticing them. In part, it was an attempt to describe how the world must be if science was to be possible—if there were to be no inexplicable phenomena, if 'realism' was to be true, if the three categories were to be as Peirce suggested. And in part it was an exercise in 'descriptive metaphysics': drawing out features of our everyday conception of mind or matter (for example) can be a valuable corrective to unthinking theoretical prejudices, especially in psychology.

Two elements of this metaphysics are especially interesting. Peirce defended an evolutionary \*cosmology, explaining how the world of existing things and law-governed behaviour evolved from pure possibility. Offering an evolutionary explanation of law, he argued, was the only alternative to asserting that fundamental laws are simply true, with no explanation of why they obtain being available. If every regularity must have an explanation, we avoid a regress of ever more general and abstract laws by invoking a historical explanation. And Peirce's account of how this evolutionary process works leads to a form of objective idealism according to which matter is 'effete mind', and physical phenomena are modelled on thought and sign interpretation rather than the mental being reduced to the physical. This is because a 'realist' account of law involves finding 'mediation' in the natural world, and sign interpretation is our best model of mediation.

Secondly, it may accord with the importance he attached to statistical reasoning in science that he accepted *tychism*, the thesis that there is absolute chance, that the universe is not wholly governed by determinist laws. This partly reflects his understanding of the importance of statistical laws in science, and his understanding that

observation could never establish that laws were so exact as never to permit slight deviations. He also supposed it was required to explain the evolutionary process discussed in his cosmology: without appeal to such 'chance spontaneity', he doubted that we could make sense of growth and increasing complexity. **Pelagius** (fl. 400). British theologian. Settled at Rome, he enjoyed a following of high-born Christian rigorists, to whom he taught that perfection is possible. When he fled to Palestine via Africa before the impending sack of Rome by the Visigoths in 410, Augustine, apprised of his teachings, accused him of denying \*original sin and the need for grace. Pelagianism is the doctrine that without God's aid men are 'able to fulfil the divine commands', or at least (semi-Pelagianism) to 'believe, will, desire, try'. Both versions are ambiguous between denying that the powers of good acting or willing must be granted by God and denying that the exercise of those powers must be helped or caused by God. The doctrines were anathematized in the fifth and sixth centuries, and again by the Council of Trent (1545–63), agreeing in this with Luther and Calvin. C.A.K.

B. R. Rees, *Pelagius: A Reluctant Heretic* (Woodbridge, 1988).

### Penelope's wooers.

Aristippus said that those that studied particular sciences, and neglected philosophy, were like Penelope's wooers, that made love to the waiting women.

Francis Bacon, *Apophtegmes New and Old* (London, 1625).

This aphorism could mean either that any study other than philosophy is only indulged in because of inability to succeed at philosophy, or that those frustrated in reaching satisfactory philosophical conclusions scientize the subject. The tendency of Logical Positivists to do the latter led Wittgenstein to accuse them of not really doing philosophy, and he would probably say the same of today's \*cognitive-science philosophers. Despite his dogmatic-sounding strictures, however, he himself produced a new way of philosophizing. J.O.G.

\*Logical Positivism.

**people.** The whole body of enfranchised or qualified citizens, generally linked by a common language and history,

considered in democratic theory as the ultimate source of political \*authority. The general slogan that political authority derives from the people is compatible with a large number of modes in which the will or consent of the people is made known to the political authority, and it is compatible with despotic as well as liberal forms of government. For example, according to Hobbes, individuals covenant with each other to submit their wills to the will of one who is thereby authorized to act on their behalf. The authority of this Leviathan therefore derives from the people, but it is an absolute and potentially despotic authority. Locke, on the other hand, grants the people power to alter the legislature when it acts contrary to the trust they have placed in it. Burke recommends yet another form of representation of the people—one in which there is a communion of interests and a sympathy in feelings and desires. This 'virtual representation' of a \*natural aristocracy does not attach importance to a universal franchise. In the nineteenth century the idea of 'the people' became identified in philosophers such as Hegel with 'the nation'. The spirit of the people became a mystical entity, or *Volkgeist*, which identified and unified a nation. R.S.D.

\*democracy.

G. H. Sabine, *A History of Political Theory* (London, 1937).

**perception.** The extraction and use of information about one's environment (exteroception) and one's own body (proprioception). The external senses—sight, hearing, touch, smell, and taste—though overlapping to some extent, are distinguished primarily by the kind of information they convey (e.g. about light, pressure, sound, and temperature). Proprioception concerns stimuli arising within, and carrying information about, one's own body: acceleration, position and orientation of limbs, and so on.

Perception is of either things or facts. Seeing an object or an event (both count as things for this classification), a cat on the sofa, a man on the street, an eclipse, or a robbery, does not require that the object or event be identified or recognized in any particular way (perhaps, though this is controversial, in any way whatsoever). One can see a cat on the sofa and mistake it for a rumpled sweater; see a man (in camouflage or at a distance, for instance) and take him for a tree. People have believed all manner of superstitious things about the eclipses they observed. Seeing objects and events is, in this sense, non-epistemic: one can see *O* without knowing or believing that it is *O*. Perceiving facts, on the other hand, is epistemic: one cannot see that there is a cat on the sofa without, thereby, coming to know that there is a cat on the sofa. Seeing a fact is coming to know (that this is a fact) in some visual way. Smelling a fact (e.g. that the toast is burning) is coming to know this fact in an olfactory way. In this way, then, thing-perception is cognitively less demanding than fact-perception. Both the dog and the cook can smell the burning toast (a thing), but unless it is a very smart dog (or a very dumb cook), only the cook will be able to smell, thereby coming to know (the fact), that the toast is burning.

Other ways of describing what we perceive are variations on these two themes. In seeing *where* he went, *when* he left, *who* went with him, and *how* he was dressed we are describing the perception of some fact without revealing exactly what fact it is. One cannot see where he went unless one sees some fact about where he went—that (for instance) he went to the attic. We often describe what facts we have observed (e.g. that Judy was at the ball-game) by mentioning only the thing we observed (Judy) and where we observed it (at the ball-game). What we end up explicitly saying (that we saw Judy at the game) is non-epistemic (we could see Judy at the game without ever recognizing her, without ever knowing that she was at the game) although what we normally succeed in communicating by this form of words (this is called a conversational implication) is something epistemic: that we saw (i.e. came to know by seeing) *that* Judy was at the game.

A great deal of perception (of both things and facts) is indirect. We perceive things on television, in the movies, and on records. One sees that the gas tank is empty by seeing not the gas tank, but the gas gauge and the fact that it reads 'empty'. This gives rise to questions about whether there are objects, and facts about those objects, that are seen directly. Direct realists believe that physical objects (some of them anyway) and certain facts (though not all facts) about these objects are seen in some direct, unmediated fashion. One does not see the cup (nor the fact that it is a cup) by perceiving, in some more direct manner, an internal object (a cup-ish \*sense-datum) and certain facts about this datum (e.g. that it resembles a coffee-cup). A \*representative theory of perception denies this—taking sense-data as the primary objects, and facts about sense-data as the basic facts, of perception. F.D.

**perception, representative theory of:** *see* representative theory of perception.

**perception, veil of:** *see* veil of perception.

**percepts.** The subjective \*experience accompanying \*perception of objects and events. Percepts are ordinarily distinguished from \*sensations or \*sense-data in being cognitively enriched by past experience and memory and by the constancy mechanisms (for shape, size, colour, etc.) that make our experience correspond more closely to the objective state of affairs (the distal stimulus) than to conditions at the sensory surfaces (proximal stimulus). Sense-data of round pennies (seen at an oblique angle) may be elliptical, but in normal viewing conditions the percept is supposed to correspond to the known shape (round) of the penny. F.D.

R. Firth, 'Sense-Data and the Percept Theory', *Mind* (1949–50).

**perfectionism.** The view that promotion of human excellence is one of the factors that should be weighed in judging the political and social worth of a society. Much recent discussion is keyed to the treatment in John Rawls's *A Theory of Justice*. Rawls lumped together thinkers as different as Aristotle and Nietzsche as perfectionists. The rejection of perfectionism follows from Rawls's stipulation that in the \*'original position' designers of the political and social order do not have a 'conception of the good'. Any case for perfectionism must contain two elements. One is an argument that some forms of human activity or experience have special value. The other is that a policy of furthering this special value should play a part in some aspects of our conduct toward others, including some social and political decisions. An extreme perfectionism could be used to justify élitist social attitudes, but a moderate perfectionism might merely argue that governments should spend modest amounts of tax money on support for the arts and for the kinds of scientific research that are most unlikely to have practical applications.

J.J.K.

A representative modern perfectionism is to be found in Hastings Rashdall, *The Theory of Good and Evil* (Oxford, 1907).

**performative utterances:** *see* linguistic acts.

**performing arts.** The performing arts include music, theatre, opera, dance, mime, and so on. What distinguishes them as a group is the fact of human performance being involved in the end-stage products of the art. In such art-forms, what we appreciate directly and what we importantly critically attend to are concrete performances; and in so far as there are works in such art-forms, they are conceived as works *for* performance. Performing arts thus contrast with arts such as painting, sculpture, etching, and the novel, where the primary product is an object that does not stand in need of performance in order to be experienced directly by a public. Performing arts are all temporal arts, in the sense that performances and experiences of them are necessarily extended in time, but not all temporal arts are performing arts. The art of film provides an obvious exception: films are screened, over a period of time, but they are not performed. The genres of tape music, computer music, and electro-acoustic music are additional examples of temporal yet non-performing arts, since their presentation does not involve human performance.

Within the performing arts an important distinction is between art-forms that involve the creation of repeatable *works*, defined by scripts, scores, or other notational artefacts, and ones not involving works, but instead performances devised on the spot, or improvised, on every occasion. In the former case it is common to think of the work defined by a notation as a kind of abstract object—a *type*—whose performances are thus instances—or *tokens*—of that type. Again, though most performing arts involve instantiable types, it is not true that all arts involving instantiable types are performing arts; witness the arts of poetry, photography, and cinema.

One important issue about the performing arts concerns the matter of the *authenticity* of performances, usually construed as something more than mere correctness, and covering matters such as conformity to the intentions of artists, to antecedent performing traditions, or to the historical contexts of creation of works. A second important issue concerns the role of *interpretation* in performance, and what the relationship is between such performative interpretation and the more straightforward sort of interpretation—critical interpretation—involved in criticism.

**Peripatetics.** This is the name given, first, to philosophers who worked in the school founded by Aristotle (the Lyceum or Peripatos), and, secondly, to later philosophers who commented on and interpreted his writings. Notable members of the first group are Theophrastus (371–287) and Strato (c.335–270), as well as Eudemus and Aristoxenus; of the second, Aristocles of Messene, Aspasius (second century AD), and above all Alexander of Aphrodisias (early third century AD). Peripatetics were characteristically scientists or scholars, rather than philosophers. That stance reflects Aristotle's division of inquiry into autonomous specialisms for which he claims to have completed, in main outline, the philosophical foundations. But it ignores the tentative and dialectical character of the philosophical originator of the Peripatos.

J.D.G.E.

There is no satisfactory study of the Peripatetics in English; but for Theophrastus, see W. W. Fortenbaugh *et al.*, *Theophrastus of Eresus*, 2 vols. (Leiden, 1992).

**perlocutions:** *see* linguistic acts.

**Perry, Ralph Barton** (1876–1957), a leading figure in the movement of American \*New Realism and the editor of its manifesto (1912). Perry occupied the most extreme position among his fellow realists—he was purest of the pure. He agreed with James's neutral monism and negative answer to the question 'Does consciousness exist?', and tried to explain perception without duplicating objects, some of whose configurations were 'physical' and others were what we ordinarily take to be 'psychical'. In *General Theory of Value* (1926), written after the steam had gone out of New Realism, he gave a naturalistic account of values, defining value as 'any object of any interest'. By virtue of his long tenure at Harvard, along with his colleague C. I. Lewis, he did much to professionalize philosophical teaching and research. His biography of William James won the Pulitzer Prize in 1936.

**persecution of philosophers.** Even the most unworldly of intellectual disciplines has never been able to divorce itself entirely from the worldly conflict which determines the course of human history. Philosophy was born into a society dominated by revolution and counter-revolution, and the earliest of its great exponents, Socrates, was executed because his teachings, it was said, corrupted the young. Modern philosophy originated in an era no less revolutionary, and some of its leading exponents were exposed to similar dangers.

Unused to having their own ideas taken seriously, philosophers today may be surprised to learn that the Parliament of the time regarded the doctrines of Thomas Hobbes (1588–1679) as a probable cause of the Great Fire of 1666. Safely dead, Hobbes is the greatest of British philosophers; alive and kicking, he was dangerous to know, and those in charge of the universities were not distracted by the notion of academic freedom from persecuting anyone who sympathized with his 'lewd, scandalous and immoral doctrine'. In 1668 Daniel Scargill was deprived of a fellowship at Corpus Christi College and expelled from Cambridge for being 'an Hobbist and an Atheist'. Scargill was promised in 1669 that he could return if he delivered a public recantation: two drafts of this were rejected; in the third, the unfortunate Scargill confessed to having been an agent of the Devil, but he was never restored to his fellowship and was obliged to live in extreme poverty.

The hostility of more orthodox thinkers was aroused above all by the intellectual ruthlessness with which Hobbes insisted that all divine authority must reflect earthly power. Nothing is more binding than the word of God: this Hobbes would be the first to allow. But, he argued, the word of God, like all words, may be interpreted in rival ways. What counts as an authoritative interpretation must therefore depend on the power of those capable of enforcing it.

Benedict de Spinoza (1634–77) shared with Hobbes the honour of being regarded by all respectable persons with the horror of 'atheism' which is matched by the horror of 'communism' in the twentieth century. Educated in the rabbinical tradition, Spinoza broke with Judaism: he was formally anathematized in 1656, and it is reliably reported that an attempt was made on his life. Like Socrates, he took no payment from his pupils: 'mischief', said one of his biographers, 'could be had from him for nothing'. Like Hobbes, he repudiated the conventional conception of God and subjected the authority of Scripture to critical scrutiny. His *Tractatus Theologico-Politicus* (1670) was prohibited by the authorities and placed on the Index of the Catholic Church.

Bertrand Russell (1872–1970) challenged conventional wisdom throughout his long life. His opposition to the First World War led to imprisonment and his being deprived of his lectureship at Trinity College, Cambridge. A decisive influence on the campaign against nuclear weapons in the 1960s, and an advocate of civil disobedience, he was also—with Jean-Paul Sartre (1905–80)—a

leading light in the International War Crimes Tribunal investigating American atrocities in Vietnam. His book *Marriage and Morals* (1929) was cited as evidence of his depravity when he was deprived of the professorship he had been offered at the City College of New York in 1940. La Guardia, the Mayor of New York, described Russell as 'an ape of genius, the devil's minister of men'. An application was made to the State Supreme Court to compel the Board of Education to rescind the appointment. Russell, the Court was told, should be regarded 'not a philosopher in the accepted meaning of the word' but as someone who 'by cunning contrivances, tricks and devices and by mere quibbling . . . puts forth fallacious arguments and arguments that are not supported by sound reasoning', an advocate of everything 'lecherous, libidinous, lustful, venereal, erotomaniac, aphrodisiac, irreverent, narrow-minded, untruthful, and bereft of moral fibre'. Russell, it was added, also 'winks at homosexuality'.

It would honour the profession if it could be said only that philosophers have been persecuted; but the truth is that, if philosophers have been among the hunted, they have also been among the hunters. Hobbes's contemporary Ralph Cudworth was a philosopher too, but he was also Master of Corpus Christi: when Scargill was expelled, Cudworth's name was on the expulsion order. Spinoza's contemporary Leibniz, a great philosopher in his own right, must surely have recognized Spinoza's greatness; but he pretended otherwise. Russell's contemporary J. M. E. McTaggart thought that 'academic freedom is very precious and fragile', but he also argued for Russell's removal from Trinity: 'it is quite different', McTaggart said, 'when he had done something the law pronounced to be a crime'.

**persistence through time.** That something continues to exist from one moment to the next has been seen by some philosophers as requiring explanation. Each point in \*time, they say, is 'logically independent': from the fact that anything exists at a particular time, it does not follow that it must exist at some later time. Hence, if an object persists through time, this must have some cause. Descartes and Spinoza both hold, though in significantly different ways, that God is the cause, the former presenting this as a proof of God's existence. Leibniz relies on the same considerations to argue that all true propositions are analytic: if you are the same individual you used to be, he says, this can only be because your existence then and now are both essential to your nature. Hume, by contrast, argues that the very notion of an object persisting through time is a 'fiction' derived from our propensity to run into one a sequence of experiences that are essentially distinct.

**person-affecting principles.** Some moral principles evaluate choices in what Parfit calls 'person-affecting terms', which appeal to a choice's effects upon the interests of particular individuals. One choice is morally worse than another in these terms only if it is *worse for* at least some specific individual, who would have fared better given the other choice. According to Parfit, person-affecting principles at best are only part of a plausible moral theory since they fail to explain why certain choices which affect the membership, as well as interests, of \*future generations are wrong. For example, if a choice between risky and safe energy policies determines both whether a catastrophe occurs and which distinct set of individuals (all with lives worth living) exists, in the distant future, then the former cannot be criticized in person-affecting terms, since there is no affected individual who would have fared better had the latter been chosen.

A.D.W.

\*population.

D. Parfit, *Reasons and Persons* (Oxford, 1984), pt. 4.

**personal identity.** The way philosophers refer to facts about \*persons which are expressed in identity judgements such as 'The person over there now is identical to the person who was there yesterday', the truth of which is a consequence of the fact that persons remain in existence over time. The problem is to say in an informative way what the necessary and sufficient conditions are for this kind of fact. These conditions are called criteria of identity for persons. A second related problem, raised by Parfit, is what importance facts about such identities should have in our evaluative thought.

No consensus on the first problem has emerged. What has proved difficult is finding a balance between the intuitions that are generated by imaginary cases, for example, brain transplants, which indicate that psychological continuities are crucial, and, by contrast, our actual practices of tracing people plus a sense of our identity as concrete substances, which seem to link us to something substantial.

Theories can be classified in various ways; one division is between those which state the criteria in psychological terms and those which do not; another, regarded as important by Parfit, is between theories which view personal identity as reducible to other continuities and those which do not; a third division is between theories which tie the person to a continuing substance, say the body, brain, or soul, and those which do not.

Locke's influential theory is of the latter sort. He proposed that persons are essentially capable of self-consciousness. Their identity should be analysed in terms of \*consciousness, which is standardly interpreted as the proposal that a person is identical with whoever's exploits they remember as their own—the memory criterion. His negative thesis is that this consciousness is not necessarily tied to a body or soul.

The neo-Lockean research strategy defends a modified Lockean view. To avoid possible circularities in the use of the concept of memory they have constructed

psychological concepts, which are explicitly defined without using the concept of personal identity. The psychological continuities required are weakened. The structure of the theory is more complex to deal with problems of fission.

The major alternative approach to this tradition requires the persistence of some substantial item for the person to survive. A Cartesian view is that we have non-material souls and survive so long as the particular soul does. More popular, though, are accounts according to which the continuant required must be physical. One suggestion, defended by Williams, is that the person is tied to the body. This fits our treatment of actual cases, but generates a counter-intuitive verdict when we consider imaginary ones. A related theory, developed by Wiggins, is that it is a mistake to allow, as Lockeans do, any distinction between the person and the animal. Personal identity is, on this view, a case of animal identity.

An alternative physicalist account claims that a person is tied to that (physical) item which sustains the person's basic psychological capacities, supposedly the brain. This fits certain intuitions better than bodily theories, but has difficulty explaining exactly why psychological continuities grounded in more radically non-standard ways are not also enough for the person to survive.

The difficulty of constructing a defensible theory has led to a reconsideration of the methods philosophers have employed, which has been encouraged as well by Parfit's discussion of whether personal identity matters. He argues, in various ways, that it does not, one being that brain-splitting plus transplants would give what matters to us but, because it generates two candidates, does not preserve the original person. So, he concludes, identity does not matter. Many are unhappy with Parfit's conclusion, and also wish to reconsider the method employed to reach it.

These methodological inquiries have led to no agreement, and all of the described theories are under active development.

**personalism.** As a label applied primarily to the philosophy of the French thinker Emmanuel Mounier (1905–50), a Christian version of existentialism stressing communion on the basis of shared values, with the person, as distinct from the political individual, as the locus of a 'unique vocation' directed towards fellowship. Other philosophers who have made personhood a fundamental concept include the German philosopher Rudolf Hermann Lotze (1817–81), the American idealists Josiah Royce (1855–1916) and Edgar Sheffield Brightman (1884–1953),

and the Scottish humanist, John Macmurray (1891–1976). Common to these thinkers is the view that the finite individual is somehow grounded in and seeks its fulfilment in an infinite spirit, or God, understood as personal, though Macmurray opposed idealism and considered 'God' mainly a negative concept given positive content only in actual relations among persons. Personalism in these wider senses has affinities with the process theism of Alfred North Whitehead (1861–1947) and Charles Hartshorne (1897–2000). An early exponent was the Norwegian philosopher Niels Treschow (1751–1833).

**persons.** On a purely functional view, possession of a range of specific psychological capacities is both necessary and sufficient for being a person. The characteristics in question are determinable 'a priori' by reference to our concept of a person. Locke's definition of a person as 'a thinking intelligent Being, that has reason and reflection, and can consider it self as it self, the same thinking thing in different times and places' is an example of a functional definition. Given this approach, there is no reason in principle why an artefact or immaterial soul should not count as a person, as long as the functional conditions are met. On the other hand, a brain-damaged human being who lacks the relevant capacities will fail to count as a person.

Descartes claimed that a person is a compound of body and soul. It has been objected that talk of immaterial souls is illegitimate because of difficulties in specifying singularity and identity conditions for them. Instead, P. F. Strawson proposes that the concept of a person is 'primitive', that is to say, it is of a type of entity such that both predicates ascribing states of consciousness and those ascribing corporeal characteristics are equally applicable to a single individual of that single type.

The most familiar examples of persons in the Strawsonian sense are human beings. Some have claimed that only human beings can be persons, or, more modestly, that persons must at least be animals of some sort. According to what David Wiggins calls the animal attribute view of persons, a person is any animal that is such by its kind as to have the biological capacity to enjoy fully an open-ended list of psychological attributes. The list of attributes is to be filled in by reference to the class of actual persons.

The animal attribute theory is, in some respects, more restrictive than a purely functional approach. It rules out non-animal persons, and does not even allow that possession of the enumerated psychological attributes is sufficient for an individual animal to count as a person; the animal must also be a *typical* member of its kind. On the other hand, the animal attribute theory is more permissive than the purely functional approach to the extent that it does not exclude from the class of persons a brain-damaged human being who has lost the psychological capacities included in the functional definition.

The most serious challenge facing the animal attribute view results from reflection about what the identity of a person consists in. If, as Locke argued, the persistence of the animal with which a person shares her matter is neither necessary nor sufficient for the persistence of the person, the person and the animal cannot be identical. For writers influenced by Locke, \*personal identity is to be understood as consisting in the obtaining of various forms of psychological continuity or connectedness. This approach may be motivated both by ethical considerations and by reflection on puzzle cases. From the fact that the continuities in question are not all or nothing, some have drawn the conclusion that persons have an ontological status akin to that of clubs or nations. Another view would be that a person is what underlies her psychological capacities, namely, her brain.

In defence of his position, the 'animalist' may argue that thought experiment and conceptual analysis are not the best way of theorizing about persons and personal identity. The most reliable point of reference for an understanding of the nature of persons is what is known about the nature of \*human beings, even if such an approach lays itself open to accusations of parochialism. If some of our intuitions about puzzle cases conflict with our best overall theory of persons then we may be entitled to reject those intuitions as deviant. Q.C.

**perspectivism:** see Nietzsche.

**persuasive definition:** see definition.

**pessimism and optimism.** The metaphysical theories that this world is, respectively, the worst and the best of all that are possible. Taken in this literal, cosmic sense—worstism and best-ism—the theories are of relatively recent date, at least in Western thought, optimism going back to the eighteenth, pessimism to the nineteenth century. The history of the terms themselves reflect the recent growth of the theories. 'Optimisme' came into currency in France towards the middle of the eighteenth century, with the English word 'optimism' following somewhat later in the century. From the outset, the term was used to describe Leibniz's position, particularly as developed in his *Théodicée* (1710). The first recorded use of the antithetical term 'pessimism' is in a 1794 letter of Coleridge. By the 1880s it had also generally established itself as the name of a metaphysical system—that in Schopenhauer's *Die Welt als Wille und Vorstellung* (1819).

Hence there are good historical and etymological grounds for regarding—as I shall here—the metaphysical theories as embodying the primary meanings of the two terms, even though current usage is much vaguer, largely indicating a negative or positive attitude towards things. The two terms are also used more precisely and narrowly to refer to the value of human existence. In this anthropological sense, the Platonic and Aristotelian ideas of human perfectibility are taken to be optimistic; whereas statements of pessimism are to be found in the books of Ecclesiastes and Job as well as in *Oedipus at Colonus*, where Sophocles writes that 'Not to be born is the most to be desired; but having seen the light, the next best is to die as soon as possible'.

Leibniz's metaphysical optimism is based on his rationalistic theology. From the ontological argument, he knows that God, the most perfect being, exists; and such a being must have created the best of all possible worlds; hence this must be that world. Imperfections are explained as necessary for this richest compossible whole—just as shadows are required by a picture to give form to the light and colour.

For Schopenhauer, on the other hand, this world is so bad that if it were to become even slightly worse it would collapse into chaos. Any goods and pleasures are required for this compossibly worst whole. Schopenhauer's position is based on his metaphysics, although this is often overlooked by those more familiar with his popular essays than his main philosophical work. Whereas Leibniz's metaphysics is rationalistic, Schopenhauer's is empirical, based on an inner, immediate experience of our living bodies as will or desire. Hence the real, underlying nature of the world is not a most perfect being; rather it is will, feeding and preying upon itself. Desire is positive, satisfaction is the negation or suspension of desire. Hence the world is wrong, both morally and in the preponderance of pain over pleasure. Nor is there any hope that it can be rectified, since the fault lies in the substance rather than any accident or form of the world. Schopenhauer develops this thesis by drawing on Kant: the apparent orderliness, goodness, satisfaction in the world derive not from what the world is in itself, but from the structuring required to make it into a perceivable, livable world at all. Schopenhauer also draws inspiration from Buddhism and Hinduism, which he regards as essentially pessimistic religions—as opposed to Judaism and Islam, which he takes to be optimistic. Yet at times he seems to recognize that, like Christianity, most major religions contain both optimistic and pessimistic elements: they are more or less pessimistic about this world and more or less optimistic about the next or real world.

While pessimism and optimism have never been central issues in philosophy, pessimism did have some vogue in Germany towards the end of the nineteenth century, chiefly from Eduard von Hartmann's elaborate *Philosophy of the Unconscious* (Eng. tr. 1884), which develops Schopenhauer's pessimism, while trying to combine it with Hegelian elements. Anglo-American philosophers have

shown little interest in the debate, apart from Sully's work (see below) and occasional witty criticism—as, for example, in William James's 'German Pessimism' (1875).

What is probably most memorable about Leibnizian optimism is its satirical rebuttal in Voltaire's *Candide* (1759). While Schopenhauer's pessimism has produced no similar satire—which is itself, perhaps, notable—it has inspired the influential reactions of Nietzsche, beginning with his *Birth of Tragedy* (1872), which largely accepts Schopenhauer's pessimism, although sublimating it through the ideal of tragic life. Yet in his later writings, Nietzsche is hostile; for while he agrees in general with Schopenhauer's description of the will, he forcefully opposes his negative, ascetic attitude towards it with a joyous affirmation.

Nietzsche's provocative views on truth can also be seen as a reaction to Schopenhauer. For while Schopenhauer was a pessimist about the world, he was an optimist about knowledge and truth; for it is through knowledge, he holds, that any good is achieved—either in transitory, will-less aesthetic contemplation, or in the insight leading to ascetic renunciation and nirvana, the highest and most lasting good. Nietzsche, in short, reverses this: he is a metaphysical optimist, but an epistemological pessimist, warning of the dangers for life of knowledge or truthfulness.

**Peter of Spain** (c.1205–77). Born in Lisbon he studied at Paris (c.1220–9), taught medicine for several years at Siena, and was later Court physician of Gregory X at Viterbo. He was appointed Archbishop of Braga (1273), Cardinal-Archbishop of Frascati (1273), and was elected Pope John XXI in 1276. His writings cover a wide range of subjects, but he is most famous for the treatise *Summule Logicales*. It covers practically all the topics then taught under the heading of logic and became one of the great logic textbooks of the Middle Ages. During the two and a half centuries after its publication it was the subject of numerous commentaries.

**petitio principii**: see begging the question.

**Petrarch** (Francesco Petrarca) (1304–74). Italian medieval poet and moral philosopher who revived practical ethics with its emphasis on introspection and experience for the Renaissance, taking as his models the classical Latin essayists and letter-writers Cicero and Seneca, as well as the early Christian Augustine. In *On his Own Ignorance*, Petrarch elaborated a mature critique of contemporary \*scholasticism, such as was found especially at the University of Padua with its concentration on logical sophisms

and philosophy of nature, and its scorn for moral issues. Petrarch preferred a rhetorical approach to ethics, realizing the importance of appealing to the imagination and the emotions in discourse aimed at moving the will. His major moral philosophical work, *On Remedies for Fortune, Fair and Foul*, a manual of Stoic psychotherapy, aims at tempering and healing disturbed passions. Reason dialogues with Elation and Hope in one book, and with Pain and Dread (linked to *melancholia*) in another in order that an inner equilibrium can be attained, the Stoic 'peace of soul'.

**phenomena and noumena**. These terms mean literally 'things that appear' and 'things that are thought'. Platonic Ideas and Forms are noumena, and phenomena are things displaying themselves to the senses. In Plato's metaphor of the divided line (*Republic*, bk. 6), whatever lies above the dividing-line is noumenal, that which is below it is phenomenal. In *Republic* 517b the distinction is between that which is revealed to sight and that which is intelligible; at 524c the contrast is between terms cognate with noumena and phenomena. This dichotomy is the most characteristic feature of Plato's dualism; that noumena and the noumenal world are objects of the highest knowledge, truths, and values is Plato's principal legacy to philosophy.

Kant deals with this duality in his Inaugural Dissertation (1770), *On the Form and Principles of the Sensible and the Intelligible World*. The intelligible world of noumena is known by pure reason, which gives us knowledge of things as they are. Things in the sensible world (phenomena) are known through our senses and known only as they appear. To know noumena we must abstract from and exclude sensible concepts such as space and time.

Kant called the determination of noumena and phenomena the 'noblest enterprise of antiquity', but in the *Critique of Pure Reason* he denied that noumena as objects of pure reason are objects of knowledge, since reason gives knowledge only of objects of sensible intuition (phenomena). Noumena 'in the negative sense' are objects of which we have no sensible intuition and hence no knowledge at all; these are things-in-themselves. Noumena 'in the positive sense' (e.g. the soul and God) are conceived of as objects of intellectual intuition, a mode of knowledge which man does not possess. In neither sense, therefore, can noumena be known. For both Plato and Kant, nevertheless, conceptions of noumena and the intelligible world are foundational for ethical theory.

**phenomenalism.** The doctrine that physical objects are reducible to sensory experiences, or that physical object statements can be analysed in terms of phenomenal statements describing sensory experience. The main twentieth-century defenders of the view, A. J. Ayer and C. I. Lewis, tried, each in his own way, to show how the content of a physical-object statement involves appeal to nothing more than sense-\*contents or \*sense-data, or anyhow sensory \*experience. Consider: (1) This snowball is white. (2) There is a white sense-content. Does 1 have an analysis in terms of 2? If so, 1 must entail 2, but it does not. Nor does it help to assume that one is looking at the snowball and only at the snowball, or to ignore the experience of everyone else, etc. This last is especially problematic if we wish to construct selves from sense-contents. Let us waive that, however, and consider further the following: (3) The light shining on this is red. The conjunction of 1 and 3 together with assumptions of the sort indicated will actually entail not-2, and hence cannot entail 2. And it is then hard to conceive of any sense-contents whose existence would be *entailed* by a particular physical fact, even one as simple and observational as that reported by 1, even when combined with assumptions like those above (exclusive of 3). (See R. M. Chisholm, 'The Problem of Empiricism'.)

Moreover, phenomenologists must invoke not only actual but also merely possible phenomena, possible experiences. For a particular grain of sand may never be associated with any *actual* phenomena, since no one may ever perceive it. There is of course no hope of isolating the single fact of *there being a snowball before me* by means of the one \*conditional that if I were to open my eyes I would have a visual experience of whiteness and roundness. There are ever so many different conditions that in the absence of snow still give rise to the truth of that conditional. But perhaps the idea is rather this: if we consider the possible courses of action open to me at the moment and the experiential outcomes conditional upon those courses of action, some such infinite set of conditionals would capture the single fact of there being a snowball before me. If so, we could perhaps say that there being a snowball before me was necessarily equivalent to the joint truth of that set of conditionals.

However, the introduction of such possible phenomena imports a complication, for the possibilities in question must be in some sense 'real' and not just logical. But real possibility is grounded in actual conditions. And what could function as the 'base' or 'ground' for the phenomenologist's actual conditions relative to which his possible phenomena are to be defined? What can ground such conditionals as: I would experience a sense-content of something white if I acted in a certain way? Presumably it would be just me and my properties (whether or not I myself am also to be reduced, as in \*neutral monism, or to be left standing as in Berkeley's subjective \*idealism). If so, then the fact that there is a white piece of paper before me has a status relative to me similar to the status of the elasticity of a rubber band relative to the rubber band.

A major problem for such phenomenalism stems from perceptual relativity: white paper looks white under white light, red under red, etc. Any possible course of experience resulting from a possible course of action will apparently underdetermine our surroundings: it will determine, for example, that there is *either* white paper under red light or red paper under white light, or the like. For this reason among others, phenomenalism now has few defenders.

E.S.

\*perception; representative theory of perception.

**phenomenology.** One of the most important philosophical movements of the twentieth century. It was founded by Edmund Husserl at the beginning of this century and has had many followers, for example, Moritz Geiger, Alexander Pfander, Max Scheler, Oscar Becker, up to the present. Quite naturally, it has undergone many changes, refinements, shifts of emphasis, etc. Originally, it was primarily a theory of \*knowledge. Later on, in the years after 1913, phenomenology developed into a form of \*idealism.

Phenomenology distinguishes sharply between perceptual properties on the one hand, and abstract properties on the other. Consider two white billiard balls, called A and B. The white colour of A, which one can see with one's eyes, is said to be located in space where A is. The white colour of B, similarly, is taken to be located where B is. Furthermore, it is maintained that the colour of A is not identical with the colour of B, since they are located at two different places. The same shade of colour, according to this analysis, divides into as many 'colour instances' of that shade as there are individual things with this colour shade.

However, all of these instances are instances of the same colour shade. There exists, therefore, according to phenomenology, also the abstract colour shade of which the instances are instances. Let us call this abstract colour the 'universal whiteness'. Phenomenology asserts that there is not only a direct perception of instances of whiteness, but also a sort of direct perception of the universal whiteness. This perception is called 'eidetic intuition'. By means of eidetic intuition we have knowledge of the essential features of the world. Phenomenologists call such universals \*essences.

An essence can be presented to the mind in its totality in one mental act of intuition. Perceptual objects, however, can never be so presented. According to phenomenologists, we can only perceive aspects of them. This is one of the fundamental differences between essences and certain individual things. What does it mean to perceive merely aspects of, say, one of our billiard-balls? There seem to be

two notions of an aspect at work. Firstly, we must distinguish between the colour instance of billiard-ball *A*, which is a part of *A*, and the differently coloured sensations which we experience when we look at *A*. Assume, for example, that *A* is illuminated from one side, so that half of it lies in the shadow. Even though that billiard-ball is uniformly coloured, our colour sensation of it is not uniformly white: one part of it is much darker than the other. And if we were to put on coloured glasses, our colour sensation would not be white at all. Now, what phenomenologists sometimes seem to have in mind when they speak of perception through aspects is that the property instances of a perceptual object, its colour, its shape, appear to us only through the perspective variations of our colour sensation and the variations of our shape sensations.

Secondly, and much more obviously, spatial perceptual objects can only be perceived from a point of view. For example, when we look at billiard-ball *A*, only one side is turned towards us and we cannot see its back. In this sense, therefore, we can only perceive, from a given point of view, a spatial 'aspect' of it. It is clear that this notion of an aspect is quite different from the one mentioned in the last paragraph.

According to phenomenology, therefore, our knowledge of things divides into direct and indirect knowledge, that is, into direct knowledge and knowledge through aspects. Essences (universal properties) are known directly, but perceptual objects are only known through their aspects. However, in addition to perceptual things, there are also mental things and selves. How are they known? \*Consciousness, according to phenomenology, is known, like essences, directly. The mental act of seeing a billiard-ball, a desire to be once again in Venice, a remembrance of strolling down the beach in Manly, all of these so-called mental acts are presented to us without aspects. There is thus a fundamental difference between the objects of the outside perceptual world and the objects of the world of consciousness: the former are never given to us wholly and completely in single mental acts of perception, the latter are fully given to us when we attend to them. But the self, the mental individual from which all mental acts issue, is only presented to us indirectly, like a perceptual object. The realm of individual things thus divides into an 'immanent' part, consciousness, and two 'transcendent' parts, perceptual objects and the self. This makes consciousness special, because what we truly and directly know is only consciousness. But some phenomenologists go even further and claim that consciousness has a kind of being quite different from all other things. This claim plays an essential role in \*existentialism.

So far we have appraised phenomenology as a theory of knowledge. But it is often viewed not as a new philosophical view about old epistemological problems, but as a new method of doing philosophy, and one speaks then of the phenomenological method. Sometimes, one even talks of the science of phenomenology, which is claimed to have its own method and subject-matter.

So-called eidetic reflection, reflection on essences and their connections, is of course the heart of phenomenology. This reflection requires eidetic reduction. By means of eidetic reduction, we shift our attention from a particular instance of a property to the abstract property (essence) itself. After the shift has taken place, one will 'see' the essence directly and in its totality. Furthermore, after eidetic reduction, one also intuits connections among essences. One may intuit, for example, that the essences of ego and of spatial being reveal that the former can perceive the latter only in spatial perspective. Phenomenology, from this point of view, inquires into the structures formed by essences.

The knowledge gained by a study of the relationships among essences, according to most phenomenologists, is non-empirical. For example, the insight just mentioned that an ego can perceive a spatial being only in perspective is gleaned from a connection between the essence of an ego and the essence of something spatial; it is not inferred by induction from individual cases. Such an inference, for example, would be involved if one concluded from repeated observations of particular whales that all whales are mammals. But phenomenological truths are thought to be not only non-empirical in this sense, but also necessary. The inductive law about whales may be proven false, for example, by the discovery of a whale that is not a mammal but a fish. No such possibility exists, however, for the phenomenological truth about the connection between the essence of being an ego and the essence of observing spatial things. Since phenomenological truths are thought to be both non-empirical and necessary, they are said to be true a priori.

But this is not all there is to the phenomenological method. There is also phenomenological reduction. It seems that there are two sides to phenomenological reduction. Firstly, there is a general prescription to look at things without prejudice, to go to the things themselves, to leave theoretical speculation behind, etc. Secondly, however, there is also a more specific side to phenomenological reduction. It consists, as a first step, in the \*'bracketing of the objective world'. Phenomenologists rely at this point on a thesis which was defended by the Polish philosopher Twardowski, who, like Husserl, was a student of Brentano's. Twardowski distinguished between an individual act of presentation, the content of this act, and the object of the act. Assume that one is presented with the billiard-ball *A*. Then there occurs a particular mental act of presentation. This act has a unique content which is a property of the mental act, and it has, as its object, the billiard-ball *A*. Twardowski's thesis is that every act has an object, even those acts which intend things which do not exist. If one hallucinates a big polka-dotted bat, one's act of seeing has an object, even though this object does not exist. In general, Twardowski insisted (for example, against Bolzano) that we must distinguish between the question whether a mental act has an object and the question whether its object exists. Some mental acts have objects which do not exist. Phenomenological reduction is then a method of revealing

the essences of the objects of our mental acts, irrespective of whether these objects exist in reality, even irrespective of whether there really is a non-mental reality.

Phenomenological reduction enjoins us to study the objects of our mental acts precisely as they are, and irrespective of their existence. But for some phenomenologists this is only the first step. They adhere to the much more radical prescription that we must eventually turn away from the 'outside world' and concentrate exclusively on consciousness. In one of Husserl's later versions of the nature of phenomenology, this exclusive concentration on consciousness sets phenomenology apart from the natural sciences. Phenomenology thus has its own method, reflection on the essences of mental acts, and it has its own subject-matter, consciousness. Phenomenology, according to this conception, is the study of the essence of consciousness. The idealistic tenor of this position is obvious.

R.G.

For Husserl's development of phenomenology see his *Ideas: General Introduction to Pure Phenomenology*, tr. W. R. Boyce Gibson (London, 1931); also his 'Phenomenology', tr. C. V. Solomon, in *Encyclopaedia Britannica*, 14th edn. (Chicago, 1927), and *Cartesian Meditations*, tr. Dorian Cairns (The Hague, 1960). For a description of the phenomenological movement see Herbert Spiegelberg, *The Phenomenological Movement: A Historical Introduction*, 2 vols. (The Hague, 1960). For a general introduction, see D. Moran, *Introduction to Phenomenology* (London, 2000), and accompanying anthology: D. Moran and T. Mooney (eds.), *The Phenomenology Reader* (London, 2002).

**Philo** (c.20 BC–c.AD 50). Called Philo Judaeus or Philo of Alexandria. Foremost Jewish philosopher of the Hellenistic age, a leader of Alexandrian Jewry, who defended his co-religionists in an embassy to Caligula and in sophisticated apologetics. Philo's thoughtful, cosmopolitan, often allegorical Greek commentaries on the Septuagint Bible synthesize Platonic, Stoic, and Jewish values and ideas, laying a foundation for Christian, and later Muslim and Jewish, rational theologians—although the impact on Jews and Muslims was largely indirect. Philo's idea that the *Logos*, the word or wisdom of God, mediates God's absoluteness to creation by articulating divine wisdom in nature and in human intelligence, and his conception of philosophy as the handmaid (*ancilla*) of theology, were vital to the medieval synthesis. Cast, seemingly, in a subordinate role, philosophy would shape all three monotheistic cultures.

L.E.G.

Philo, *Works*, ed. and tr. F. H. Colson, 10 vols., Loeb Classical Library (Cambridge, Mass., 1929–53), with 2 suppl. vols. of Ralph Marcus's Eng. renderings of works preserved in Armenian translation.

H. A. Wolfson, *Philo: Foundations of Religious Philosophy in Judaism, Christianity and Islam* (Cambridge, Mass., 1962).

**Philo (the Dialectician)** (Greek, 4th–3rd century BC). By contrast to the \*Master Argument, Philo maintained that a predicate's 'bare suitability to a subject' was enough to make something capable of happening. This, he pointed out, would mean that things were capable of happening,

even though they were 'necessarily prevented by external circumstances'; thus a log, he held, would still be capable of burning, even though it was in mid-Atlantic. Philo also invented \*material implication: one proposition implies another, he held, when and only when either the first proposition is false or the second proposition is true; in particular, he held that the \*conditional 'If it is day, it is night' is true, and that the argument 'It is day; so it is night' is valid, throughout the night but never in daytime.

N.C.D.

Gabriele Giannantoni (ed.), *Socratis et Socraticorum Reliquiae* (Naples, 1990), i. 414–37 (= *Elenchos*, vol. xviii\*).

**Philoponus, John** (c.490–570s). From Alexandria, Philoponus opposed Aristotle's science, defending the Christian doctrine that the universe had a beginning. He argued thus: without a beginning, the universe must already have endured an infinite number of years; but then how could it be true that, by the end of next year, the universe would have endured a greater number of years? For how could infinity be added to? Philoponus also attacked Aristotle's dynamics, denying (as later did Galileo) that velocity in a vacuum need be infinite. He also denied that a thrown javelin continued to move because propelled onwards by the air behind it—if so why not propel javelins by bellows?—suggesting instead that a force or impetus was imparted to the javelin by its thrower.

T.P.

R. Sorabji (ed.), *Philoponus and the Rejection of Aristotelian Science* (London, 1987).

**philosophe**. A French word now domesticated into English, denoting any member of a very diverse though loosely associated group of scientists, writers, statesmen, and practical 'men of affairs' whose works and activities constituted the eighteenth-century \*Enlightenment movement in Europe and America (e.g. Voltaire, Hume, Franklin, Buffon, and Diderot). The philosophes were bound together as a group by their vigorous support of the developing natural sciences, by their insistent (and frequently courageous) challenges to the pervasive influence of outdated traditions, superstition, and prejudice, and by their common desire to facilitate the growth and spread of more liberal and humane political institutions. All of these concerns, in the philosophes' view, were only different sides of a single intellectual mission: to advance the cause of human reason, to perfect its methods, and extend their application across an ever widening range of pursuits.

P.F.J.

Peter Gay, *The Enlightenment: An Interpretation, i: The Rise of Modern Paganism* (New York, 1977).

**philosopher-king**. One of the rulers of the ideal state in Plato's *Republic*. (Plato himself does not use the term, referring to the rulers as 'Guards' (*phulakes*)). The basic principle of the organization of the ideal state is that government should be in the hands of those who, in virtue of their knowledge of the Good, are uniquely able to order the state for the good of its citizens. The central books of the *Republic* are devoted to an account of the educational

system (largely mathematical, but culminating in metaphysics) which is to lead to knowledge of the Good.

C. D. C. Reeve, *Philosopher-Kings* (Princeton, NJ, 1988).

### philosopher may preach.

The satirist may laugh, the philosopher may preach, but Reason herself will respect the prejudices and habits which have been consecrated by the experience of mankind.

(Edward Gibbon, *Memoirs of My Life*, ch.1)

The historian Gibbon was perhaps influenced by Hume, who professed himself unable, despite his scepticism, to avoid the 'current of nature' ineluctably sweeping him into belief in the very things he professed to doubt, such as the \*external world. But Hume gave this thought an additional twist. It is not just that habit and experience 'conspire' to make us see everything in certain ways, but that reason itself is 'nothing but a wonderful and unintelligible instinct' arising from them.

### philosophical inquiry: premisses and first principles.

There is an aspect of philosophy that is pervasive enough to be sometimes used to define it: the criticism of assumptions. Considering various ways of arriving at or approximating to knowledge, Plato places at the top 'dialectic'. It seems to be what \*philosophy essentially consists of, and its nature is explained by contrasting it with mathematics, in which unargued and unexamined assumptions are taken for granted. Rational thinking without assumptions is, however, an inconsistent notion. \*Reasoning is movement from an accepted or assumed belief to some other belief. Even if the premiss is merely assumed and not accepted, supposed, as the saying is, for the sake of argument, some rules of inference (and very often some suppressed premisses as well) are required to provide the conclusion drawn.

A certain amount of philosophy has been presented in an explicitly deductive form, with axiomatic premisses set out at the start as in the fascinating model of Euclid's geometry. Spinoza gave his great work *Ethics* the subtitle *Demonstrated in a Geometrical Manner*. His axioms turn out to be quite numerous; there are seven for the first book, five for the second, and comparable handfuls for the other three, supported in each case by definitions. Spinoza did not think that any philosophy set out in this way, even if all the inferences in it were valid, was on that account correct. He produced a version of Descartes's system in this rigorous form but thought it in many respects mistaken. The axioms had to be true, and that meant, since they could not be inferred, that they had to be self-evident.

It is a general characteristic of rationalist philosophers to argue in this way, for example of Descartes and Leibniz and, in our century, of McTaggart. Descartes presents 'I think, therefore I exist' as a kind of ultimate premiss, but does argue for it, assuming that 'I think' entails 'I exist' and asserting that the denial of 'I think' is self-refuting. He then goes on to conclude that, since his premiss has the self-certifying property of being 'clear and distinct', any other belief with that certifying property is also known for certain to be true, a principle used to authorize a number of substantial propositions. McTaggart claims to deduce his entire philosophy from the axioms that something exists and an obscure 'principle of determining correspondence'.

Rationalist philosophers commonly proceed, at least in the first stages of their work, by way of indirect proof or *reductio ad absurdum*, in which a proposition is established by inferring a contradiction from its negation. If that is to work it must be assumed that the inference involved is validated by a true logical law and that a contradiction is necessarily false. The thesis about contradictions is not and the relevant logical laws need not be things anyone would be likely to question.

But full-blooded deductive metaphysicians of this kind are rare; a rationalist need not be a rationalist through and through. On the other hand, the minimization of assumptions is also to be found among empiricists, particularly if they are mathematically trained and inspired. Russell proposed, and sketched, the achievement of a 'minimum vocabulary' for the description of the world by definitional reduction, and that project was realized in Carnap's *Logical Structure of the World*, in which the main elements of the whole apparatus of description are defined in terms of items of sense-experience and the relation of recollected similarity. But most empiricists follow a less arduous path.

The absolute first principle of \*rationalism would seem to be: whatever it would be a contradiction to deny is necessarily true. Empiricists would not deny that, but would maintain that while it determines the form of our representation of the world, it implies nothing about what the world is in fact like. Yet they too have, and give prominence to, large basic principles.

Locke, Hume, and Mill hold that all, or most, substantial items of knowledge (or justified belief) derive their title to acceptance from sense-experience (or introspection). That

seems broadly correct, but is it really self-evident? The claims of alleged moral, aesthetic, and religious experience have to be dealt with as do those of such substantial, but apparently unempirical, generalities as that every quality inheres in a substance, every event is part of the history of an object, and every event has a cause.

The classical empiricists were, in fact, committed by their conception of the nature of philosophy as an empirical study of the cognitive aspects of human nature to the view that the empiricist principle was itself empirical. The problem came to the surface in connection with the principle of verifiability, the twentieth-century version of the empiricist principle. Critics asked what sort of truth it itself was: empirical or, the only alternative its proponents acknowledged, analytic, true in virtue of the meaning of the words expressing it? Neither option was very attractive. To admit it was empirical left it weak and refutable. To claim it was analytic seemed to conflict with the facts of our use of the word 'meaning'. Popper frankly admitted that his roughly similar criterion of falsifiability, as a means of demarcating not sense from nonsense, but science from metaphysics, was a proposal or convention, recommended on the grounds of its intellectual advantages.

That undogmatic, persuasive conclusion is supported by the widespread recognition that the theory of knowledge is a normative discipline, an 'ethics of belief', setting out rules for the right acceptance of beliefs. That would make it nonsense on the strict letter of the verifiability principle, but, one might say, so much the worse for the verifiability principle. Many present-day philosophers, however, following Quine, have gone back to the position of the classical empiricists by taking the theory of knowledge to be the cognitive part of empirical psychology.

Many unexamined assumptions are more embedded in philosophical writing than those mentioned so far. One, which had a long and significant career, is that the greater cannot emerge from or be produced by the less. It is stated, as something too obvious to require discussion, by Descartes, and drawn on by Locke to prove the existence of God. It was mobilized again in the nineteenth century to dismiss Darwin's doctrine of evolution, but Darwin's view emerged victorious from the collision. Another is that sturdy support of mind-body dualism which denies the identity of a mental event with any corresponding brain event on the ground that it is conceivable or logically possible for either to occur without the other occurring. J. J. C. Smart pointed out that there is such a thing as contingent identity as of a lightning-flash and an electrical discharge, or, one might add, of a billiard-ball that is seen and one that is touched.

A philosophical treatise may be presented in a systematic order which does not correspond at all to the way in which the ideas it contains were arrived at. Premises and first principles are, therefore, more part of the expository rhetoric of philosophy than of its real substance. But orderly exposition nevertheless contributes valuably to making philosophy accessible to the kind of rational criticism on which it thrives.

**philosophical logic.** Despite its name, philosophical logic is neither a kind of logic nor simply to be identified with the philosophy of logic(s)—the latter being the philosophical examination of systems of logic and their applications. Though the subject of philosophical logic is hard to define precisely, it may loosely be described as the philosophical elucidation of those notions that are indispensable for the proper characterization of rational thought and its contents—notions like those of reference, predication, truth, negation, necessity, definition, and entailment. These and related notions are needed in order to give adequate accounts of the structure of thoughts—particularly as expressed in language—and of the relationships in which thoughts stand both to one another and to objects and states of affairs in the world. But it must be emphasized that philosophical logic is not concerned with thought inasmuch as the latter is a psychological process, but only in so far as thoughts have contents which are assessable as true or false. To conflate these concerns is to fall into the error of \*psychologism, much decried by Frege.

No single way of dividing up the subject-matter of philosophical logic would be agreed upon by all of its practitioners, but one convenient division would be this: theories of reference, theories of truth, the analysis of complex propositions, theories of modality (that is, of necessity, possibility, and related notions), and theories of argument or rational inference. These topics inevitably overlap, but it is roughly true to say that later topics in the list presuppose earlier ones to a greater degree than earlier ones presuppose later ones. The order of topics in the list reflects a general progression from the study of parts of \*propositions, through the study of whole and compound propositions, to the study of relations between propositions. (Here we use the term 'proposition' to denote a thought content assessable as true or false—something expressible by a complete sentence.)

Theories of \*reference are concerned with the relationships between subpropositional or subsentential parts of thought or speech and their extra-mental or extra-linguistic objects—for instance, with the relationship between \*names and things named, and with the relationship between predicates and the items to which they apply. According to some theories, a name refers to a particular thing by virtue of its being associated with some description which applies uniquely to that thing. Other theories hold that the link between name and thing named is causal in nature. (Theories of either sort are intimately bound up with questions concerning \*identity and \*individuation.) As for predicates—where a predicate may be thought of as

what remains when one or more names are deleted from a sentence—these are variously held to carry reference to \*universals, \*concepts, or \*classes. Thus the predicate ‘... is red’, formed by deleting the name from a sentence like ‘Mars is red’, is held by some philosophical logicians to stand for the property of redness, by others to express our concept of redness, and by yet others to denote the class of red things. Monolithic theories of reference are unpromising, however. Even if some names refer by way of description, other names and namelike parts of speech—such as demonstratives and personal pronouns—plausibly do not. And even if some predicates stand for universals, others—such as negative and disjunctive predicates—can scarcely be held to do so.

\*Truth and falsehood—if indeed they are properties at all—are properties of whole sentences or propositions, rather than of their subsentential or subpropositional components. Theories of truth are many and various, ranging from the robust and intuitively appealing \*correspondence theory—which holds that the truth of a sentence or proposition consists in its correspondence to extra-linguistic or extra-mental \*fact—to the \*redundancy theory at the other extreme, according to which all talk of truth and falsehood is, at least in principle, eliminable without loss of expressive power. These two theories are examples, respectively, of substantive and \*deflationary accounts of truth, other substantive theories being the \*coherence theory, the \*pragmatic theory, and the \*semantic theory, while other deflationary theories include the prosentential theory and the performative theory (which sees the truth-predicate ‘... is true’ as a device for the expression of agreement between speakers). As with the theory of reference, a monolithic approach to truth, despite its attractive simplicity, may not be capable of doing justice to all applications of the notion. Thus the correspondence theory, though plausible as regards a posteriori or empirical truths, is apparently not equipped to deal with \*a priori or \*analytic truths, since there is no very obvious ‘fact’ to which a truth like ‘Everything is either red or not red’ can be seen to ‘correspond’. Again, the performative theory, while attractive as an account of the use of a sentence like ‘That’s true!’ uttered in response to another’s assertion, has trouble in accounting for the use of the truth-predicate in the antecedent of a conditional, where no assertion is made or implied.

Whichever theory or theories of truth a philosophical logician favours, he or she will need at some stage to address questions concerning the *value* of truth—for instance, why should we aim at truth rather than falsehood?—and the \*paradoxes to which the notion of truth can give rise (such as the paradox of the \*liar). In the course of those inquiries, fundamental principles thought to govern the notion of truth will inevitably come under scrutiny—such as the principle of \*bivalence (the principle that every assertoric sentence is either true or false). A rejection of that principle in some area of discourse is widely supposed to signify an \*anti-realist conception of its subject-matter.

\*Propositions and \*sentences can be either simple or complex (atomic or compound). A simple sentence typically concatenates a single name with unitary predicate, as, for example, in ‘Mars is red’. (Relational sentences involve more names, as in ‘Mars is smaller than Venus’, but a sentence like this is still regarded as simple.) One way in which complex sentences can be formed is by modifying or connecting simple ones; for instance, by negating ‘Mars is red’ to form the \*negation ‘Mars is not red’, or by conjoining it with ‘Venus is white’ to form ‘Mars is red and Venus is white’. Sentential operators and \*connectives, like ‘not’, ‘and’, ‘or’, and ‘if’, are extensively studied by philosophical logicians. In many cases, these operators and connectives can plausibly be held to be \*truth-functional—meaning that the truth-value of complex sentences formed with their aid is determined entirely by the truth-values of the component sentences involved (as, for example, ‘Mars is not red’ is true just in case ‘Mars is red’ is not true). But in other cases—and notably with the conditional connective ‘if’—a claim of truth-functionality is less compelling. The analysis of \*conditional sentences has accordingly become a major topic in philosophical logic, with some theorists seeing them as involving modal notions while others favour probabilistic analyses.

There are other ways of forming complex sentences than by connecting simpler ones, the most important being through the use of \*quantifiers—expressions like ‘something’, ‘nobody’, ‘every planet’, and ‘most dogs’. The analysis and interpretation of such expressions forms another major area of philosophical logic. An example of an important issue which arises under this heading is the question how \*existential propositions should be understood—propositions like ‘Mars exists’ or ‘Planets exist’. According to one approach, the latter may be analysed as meaning ‘Something is a planet’ and the former as ‘Something is identical with Mars’ (both of which involve a quantifier), but this is not universally accepted as correct. Another issue connected with the role of quantifiers is the question how definite \*descriptions—expressions of the form ‘the so-and-so’—should be interpreted, whether as referential (or namelike) or alternatively as implicitly quantificational in force, as Russell held.

The fourth topic in our list is theories of \*modality, that is, accounts of such notions as \*necessity, possibility, and contingency, along with associated concepts such as that of analyticity. One broad distinction that is commonly drawn is that between \**de re* and *de dicto* necessity and possibility, the former concerning objects and their properties and the latter concerning propositions or sentences. Thus, a supposedly \*analytic truth such as ‘All bachelors are unmarried’ is widely regarded as constituting a *de dicto* necessity, in that, given its meaning, what it says could not be false. But notice that this does not imply that any man who happens to be a bachelor is incapable of being married—though should he become so, it will, of course, no longer be correct to describe him as a ‘bachelor’. Thus there is no *de re* necessity for any man to be unmarried, even if he should happen to be a bachelor. By contrast,

there arguably is a *de re* necessity for any man to have a body consisting of flesh and bones, since the property of having such a body is apparently essential to being human.

As for the question how, if at all, we can analyse modal propositions, opinions vary between those who regard modal notions as fundamental and irreducible and those who regard them as being explicable in other terms—for instance, in terms of \*possible worlds, conceived as ‘ways the world might have been’. (Although this appears circular, in that ‘possible’ and ‘might’ are themselves modal expressions, with care the appearance is arguably removable.) For instance, the claim that every man necessarily has a body made of flesh and bones might be construed as equivalent to saying, of each man, that he has a body made of flesh and bones in every possible world in which he exists. However, we should always be on guard against ambiguity when talking of necessity, because it comes in many different varieties—\*logical necessity, \*metaphysical necessity, \*epistemic necessity, and \*nomic necessity being just four.

Modal expressions give rise to special problems in so far as they often appear to create contexts which are non-extensional or ‘opaque’ (\*extensionality)—such a context being one in which one term cannot always be substituted for another having the same reference without affecting the truth-value of the modal sentence as a whole in which the term appears. For example, substituting ‘the number of the planets’ for ‘nine’ in the sentence ‘Necessarily, nine is greater than seven’, appears to change its truth-value from truth to falsehood, even though those terms have the same reference. (No such change occurs if the modal expression ‘necessarily’ is dropped from the sentence.) How to handle such phenomena—which also arise in connection with the so-called \*propositional attitudes, such as belief—is another widely studied area of philosophical logic.

Finally, we come to questions concerning relations between propositions or sentences—relations such as those of \*entailment, presupposition, and \*confirmation (or probabilistic support). Such relations are the subject-matter of the general theory of rational \*argument or \*inference, whether \*deductive or \*inductive. Some theorists regard entailment as analysable in terms of the modal notion of logical necessity—holding that a proposition *p* entails a proposition *q* just in case the conjunction of *p* and the negation of *q* is logically impossible. This view, however, has the queer consequence that a contradiction entails any proposition whatever, whence it is rejected by philosophers who insist that there must be a ‘relevant connection’ between a proposition and any proposition which it can be said to entail. (\*Relevance logic.) The notion of presupposition, though widely appealed to by philosophers, is difficult to distinguish precisely from that of entailment, but according to one line of thought a statement *S* presupposes a statement *T* just in case *S* fails to be either true or false unless *T* is true. For instance, the statement that the present King of France is bald might be said to presuppose, in this sense, that France currently has

a male monarch. (Such an approach obviously requires some restriction to be placed on the principle of bivalence.) As for the notion of confirmation, understood as a relation between propositions licensing some form of non-demonstrative inference (such as an inference to the truth of an empirical \*generalization from the truth of observation statements in agreement with it), this is widely supposed to be explicable in terms of the theory of \*probability—though precisely how the notion of probability should itself be interpreted is still a matter of widespread controversy.

No general theory of argument or inference would be complete without an account of the various \*fallacies and \*paradoxes which beset our attempts to reason from premiss to conclusion. A ‘good’ argument should at least be truth-preserving, that is, should not carry us from true premisses to a false conclusion. A fallacy is an argument, or form of argument, which is capable of failing in this respect, such as the argument from ‘If Jones is poor, he is honest’ and ‘Jones is honest’ to ‘Jones is poor’ (the fallacy of \*affirming the consequent), since these premisses could be true and yet the conclusion false. (Strictly, this only serves to characterize a fallacy of deductive reasoning.) A paradox arises when apparently true premisses appear to lead, by what seems to be a good argument, to a conclusion which is manifestly false—a situation which requires us either to reject some of the premisses or to find fault with the method of inference employed. An example would be the paradox of the \*heap (the Sorites paradox): one stone does not make a heap, nor does adding one stone to a number of stones which do not make a heap turn them into a heap—from which it appears to follow that no number of stones, however large, can make a heap. This paradox is typical of many which are connected with the \*vagueness of many of our concepts and expressions, a topic which has received much attention from philosophical logicians in recent years. This is again an area in which the principle of bivalence has come under some pressure.

Although philosophical logic should not be confused with the philosophy of logic(s), the latter must ultimately be responsive to considerations addressed by the former. In assessing the adequacy and applicability of any system of formal logic, one must ask whether the \*axioms or \*rules it employs can, when suitably interpreted, properly serve to articulate the structure of rational thought concerning some chosen domain—and this implies that what constitutes \*‘rationality’ cannot be laid down by logicians, but is rather something which the formulators of logical systems must endeavour to reflect in the principles of inference which they enunciate.

**philosophical novel, the:** *see* novel, the philosophical.

**philosophical practice, the ethics of.** Philosophical practice makes strenuous moral demands: honesty and fairness to opponents in argument; an ability to tolerate prolonged uncertainty over serious issues; the strength of character to change one's mind on basic beliefs, and to follow the argument rather than one's emotional leanings; independence of mind rather than readiness to follow philosophical fashion.

Moral respect for readers and hearers requires that a philosopher avoid non-rational persuasion, cajoling, deriding, or otherwise manipulating them into agreement. Philosophy should demonstrate that we can disagree profoundly over fundamentals without lapsing from a common reasonableness. That same respect requires a philosopher to expose the structure of his argument as perspicuously as possible, so as to encourage, not impede, its criticism.

Clarity and simplicity of style, the minimizing of technical expressions, abstaining from formal apparatus when ordinary language can be adequate, also express concern to be understood and to let argument and evidence alone carry the persuasive weight. A turgid and obscure style may veil real gaps in argument. A pretentious style may covertly work to disarm critical appraisal, replacing the authority of good argument with the would-be personal authority of the philosopher as sage.

Philosophy has a serious responsibility for language. It is one of its most important custodians—obliged to oppose terminologies that arrest or confuse thinking. Slipshod and imprecise language loses sensitivity to distinctions between reasonable and unreasonable, between good and bad argument—in any field, including the fields of personal and political morality. To impoverish the resources of language risks also impoverishing human experience, denying us the words we need to articulate its varieties.

Does a stress on style and the stewardship of language imply that philosophy is a branch of literature? In some important ways it is literature. But the *rapprochement* is carried too far when a philosopher lets the imaginatively vivid presentation of a slant on the world give it an appearance of self-evidence, and deflects critical alertness from the fact that categories have not been deduced and reasoned justification has been subordinated to expressing the quasi-poetic 'vision'.

Philosophers, then, need a wholesome sense of their fallibility. It is unwise for a philosopher to aspire to the role of expert or authority; for that works towards weakening the critical attentiveness constantly needed from readers and hearers.

R. W. H.

\*pseudo-philosophy.

Max Black (ed.), *The Morality of Scholarship* (Ithaca, NY, 1967).

**philosophy.** Most definitions of philosophy are fairly controversial, particularly if they aim to be at all interesting or

profound. That is partly because what has been called philosophy has changed radically in scope in the course of history, with many inquiries that were originally part of it having detached themselves from it. The shortest definition, and it is quite a good one, is that philosophy is thinking about thinking. That brings out the generally second-order character of the subject, as reflective thought about particular kinds of thinking—formation of beliefs, claims to knowledge—about the world or large parts of it.

A more detailed, but still uncontroversially comprehensive, definition is that philosophy is rationally critical thinking, of a more or less systematic kind about the general nature of the world (metaphysics or theory of existence), the justification of belief (epistemology or theory of knowledge), and the conduct of life (ethics or theory of value). Each of the three elements in this list has a non-philosophical counterpart, from which it is distinguished by its explicitly rational and critical way of proceeding and by its systematic nature. Everyone has some general conception of the nature of the world in which they live and of their place in it. \*Metaphysics replaces the unargued assumptions embodied in such a conception with a rational and organized body of beliefs about the world as a whole. Everyone has occasion to doubt and question beliefs, their own or those of others, with more or less success and without any theory of what they are doing. \*Epistemology seeks by argument to make explicit the rules of correct belief-formation. Everyone governs their conduct by directing it to desired or valued ends. Ethics, or \*moral philosophy, in its most inclusive sense, seeks to articulate, in rationally systematic form, the rules or principles involved. (In practice ethics has generally been confined to conduct in its moral aspect and has largely ignored the large part of our actions that we guide by considerations of prudence or efficiency, as if these were too base to deserve rational examination.)

The three main parts of philosophy are related in various ways. For us to guide our conduct rationally we need a general conception of the world in which it is carried out and of ourselves as acting in it. Metaphysics presupposes epistemology, both to authenticate the special forms of reasoning on which it relies and to assure the correctness of the large assumptions which, in some of its varieties, it makes about the nature of things, such as that nothing comes out of nothing, that there are recurrences in the world and our experience of it, that the mental is not in space.

The earliest recognized philosophers, the Pre-Socratics, were primarily metaphysicians, concerned to establish the essential character of nature as a whole, from the first cryptic utterance of Thales: 'All is water.' Parmenides is the first metaphysician whose arguments have come down to us. For the reasons given by the famous paradoxes of Zeno, he concluded that the world did not move and occupied all space. The Sophists, by sceptically challenging conventional moral assumptions, brought ethics into existence, notably in Socrates. Plato and Aristotle wrote comprehensively on metaphysics and ethics; Plato

on knowledge; Aristotle on (deductive) logic, the most rigorous technique for the justification of belief, setting out its rules in a systematic form which retained their intellectual authority for over 2,000 years.

In the Middle Ages philosophy, in service to Christianity, drew first on the metaphysics of Plato, then on Aristotle's, to defend religious beliefs. In the Renaissance free metaphysical speculation revived and, in its later phase, with Bacon and, more influentially, Descartes and Locke, turned to epistemology to ratify and, as far as possible to accommodate to religion, the new developments in natural science. Hume argued that such an accommodation is impossible, as indeed is metaphysics generally. In continental Europe Spinoza and Leibniz practised deductive metaphysics in the style of Parmenides and with comparably astonishing results. Kant, brought up in that tradition, was shaken out of it by reading Hume, rejected metaphysics in its traditional varieties, and ascribed the order of the public world to the formative work of the mind on its experiences. His German successors, taking advantage of some inconsistencies in Kant, revived metaphysics in the grand manner. In Britain the empiricism of Locke and Hume prevailed, and epistemology remained the central philosophical discipline up to the middle of the present century.

Metaphysics has various ways of setting about its none too clearly formulated topic: the general nature of the world. The first is that of purely rational demonstration. In this, large and striking conclusions are arrived at by showing that their denials involve self-contradiction. A prime example is the ontological proof of the existence of God. God is defined as perfect. A God that exists is more perfect than something, otherwise identical, that does not. Therefore God necessarily exists. In the same style Leibniz proves that reality is, in its ultimate constitution, mental, and Bradley finds contradictions lurking in the whole repertoire of fundamental notions of common belief and science (relation, plurality, time, space, the self, and so on) to arrive at the conclusion that reality is a single, indissectable tissue of experience, a spiritual unity in which nature and personal individuality are absorbed.

A second metaphysical procedure is to derive conclusions about what lies behind 'appearance', the perceptible surface of the world, about the true or ultimate reality that transcends appearance. Prime examples here are the arguments for God's existence from the world's need of a first cause and from the marks of intelligent design in the order of the perceived world. Even more important for the history of philosophy is Plato's theory of Forms or objective universals, not in space and time but in a world of their own, invoked to explain our recognition of recurrent properties in the flux of appearance and to serve as the objects of eternally true items of mathematical knowledge.

Hume attacked demonstrative metaphysics on epistemological grounds. Purely rational argument can establish only the formal truths of logic and mathematics. The denial of a self-contradictory statement is not a substantial

truth of fact, it is merely verbal, reflecting conventions for the use of words. Kant attacked transcendent metaphysics, arguing that the notions of substance and cause which it applies beyond the bounds of experience can yield knowledge only when applied to the raw material supplied by the senses. The Logical Positivists attacked transcendent metaphysics more vehemently with their verifiability principle, contending that its affirmations are devoid of meaning since uncheckable by experience.

Kant also opposed a kind of metaphysics which does not so much go behind the scenes of appearance as sideways from them by extrapolating indefinitely from them, as in the theses that the world is infinitely large, has existed from eternity, is composed of infinitesimal parts, and so on. He paired off assertions of these kinds with their denials and argued, in apparent defiance of logic, that both members of each pair were self-contradictory. This kind of metaphysics, dealing with the quantitatively (rather than, as transcendent metaphysics does, with the qualitatively) inaccessible, would seem open to the same objections, if they are correct.

Survivors of the long conflict between metaphysics and its detractors are theories of what has been called 'categories of being'. Dualism of the mental and physical, most sharply focused in Descartes, but pervasive long before and after him, is the most familiar of these. It has epistemological roots. One is the distinction between two kinds of experience: sensation and introspection. Another is the alleged infallibility of beliefs about one's own mind as contrasted with the fallibility of all beliefs about the objective material world. Materialists such as Hobbes argue that mental activity is bodily, if on a very small scale. Idealists such as Berkeley (and, in a way, phenomenologists such as Mill) argue that material bodies are complexes of sensations, both actual and either in the mind of God or hypothetical.

The Platonic realm of ideas houses a third alleged category, that of abstractions, such as properties, relations, classes, numbers, propositions. Values have been installed as a category so as to provide something for judgements of value to be true of.

Monism may be neither materialistic nor idealistic, but neutral. Russell, William James, Mach, even Hume up to a point, regarded both bodies and minds as composed of the same kinds of sensation, actual and possible, and the images that copy them. The two kinds of sensation combine to constitute bodies; sensations and images constitute minds.

Beside the kind of large-scale metaphysics considered hitherto, which aims at a conception of the world as a whole, there is a kind of small-scale metaphysics which examines the detailed structure of the world: individuals, their properties, and their relations to one another; the events in their history, and thus change, and also the states which are the dull, and the processes which are the more eventful, parts of that history; the facts which are the having of properties by individuals; and so on. Aristotle's doctrine of categories set this going as an organized inquiry

(his categories being quite different from the categories of being mentioned earlier). It has now been to some extent absorbed into philosophical logic, since its pervasive features of the structure of the world correspond to the formal characteristics of discourse (of thought and speech) which are assumed as the basic distinctions of formal logic.

The fundamental, but not most interesting, question of epistemology is that of the definition of knowledge. Plato addressed it in his *Theaetetus* and came up with the crucial result that it is something more than true belief, although it includes it. The idea that justification is the missing element runs into difficulties unless, as many hold, the infinite regress it seems to generate is stopped by maintaining that some beliefs are not justified by others, but by experience. For many philosophers, however, the problem is in itself of little interest since knowledge is of little interest. What matters is rational or justified true belief. However, it has been persuasively suggested that the missing third element in the definition is that the true belief should be non-accidental or that it should be caused by the fact that makes it true.

Nearly all epistemology involves two large distinctions: the first between what Leibniz called truths of reason and truths of fact, the second between what is acquired directly or immediately and what is acquired by inference. Truths of reason are necessarily true and discoverable a priori, that is to say without reliance on the senses and purely by thinking. Truths of fact are contingent and rest on experience for their justification. The two distinctions overlap. Some truths of reason must be immediate if any are to be inferred. These, primarily, are taken to be the axioms or first principles of logic and mathematics. The conventional view about non-immediate truths of fact is that they are indeed inferred, but not by deductive logic. For them, it is held, induction, the derivation of unrestricted generalizations from a limited number of their singular instances, is required. Whewell, Peirce, and, most vehemently, Popper have denied, or, at any rate, marginalized, induction. As they see it, general statements are first proposed as hypotheses worthy of examination, then their singular deductive consequences are examined; they are rejected if these turn out to be false, but preserved, with increasing confidence, the larger the number of tests they survive. This corresponds more closely to scientific practice than does the conventional theory of induction, but has the appearance of letting induction in by the back door.

Leibniz thought that all truths of reason rested on the law of contradiction but did not go on to conclude, as Hume and most subsequent empiricists have, that they are therefore analytic, in the sense that they are verbal, simply reiterating in what they assert something they have already assumed. Kant took the central problem of philosophy to be that of whether and how any beliefs are both synthetic, really substantial in content, and also a priori, discoverable by reason alone. He concluded that there were such beliefs: those of arithmetic and geometry and such 'presuppositions of natural science' as that there is fixed, permanent quantity of matter in nature and that

every event has a cause. He went on to ascribe the necessary truth of these substantial beliefs to the mind's imposition of order on the chaos of experience to which it is subjected. Few have followed him this far. Mill held that mathematical truths are really empirical; Herbert Spencer that what seem to be necessary truths are the well-confirmed empirical beliefs we inherit from our ancestors. More recently Quine has argued that there is no difference in kind between truths of reason and truths of fact at all, only in the degree of our determination to hold on to them in the face of discouraging evidence.

The distinction between the direct and the inferred has also been challenged at various times, the present included, by philosophers who cannot see a way out of the maze of beliefs. Current coherence theorists of knowledge follow in the steps of Hegelian idealists and the Viennese positivists (until Tarski led them out of the maze). Part of the hold of the distinction comes from the ancient principle that our perception of objective, material things is not direct, since it is always fallible, as shown by our liability to illusion, and so must be inferred from the supposedly infallible knowledge we do have of our private, subjective sense-impressions. Is this inference valid, or, at least, defensible? If not, must we sceptically suspend belief in the material world? If it is, what sort of inference is it: to more things of the same kind, actual and possible impressions, or to something of a different, experience-transcending kind, namely unexperienceable matter? The pattern of this problem, and the form of its possible solutions, has been seen to be repeated in a number of other cases. The evidence for our beliefs about the past is all present, our recollections and traces; how do we cross the gap, if we can? Our beliefs about other minds are based on what we observe their bodies to do and say. A solution not mentioned so far is that of denying the assumption that we are confined to the evidence specified. That seems more attractive in the case of perception, where it would imply that we perceive material objects directly, although not infallibly, and in the case of our beliefs about the past, where our recollections simply *are* our straightforward beliefs about the past, not evidence for them, than in the case of other minds, where some sort of telepathy would seem needed. The importance and centrality of these three kinds of belief hardly need to be stressed, not just for science, history, and psychology, but for our entire cognitive life.

A curious feature about epistemology is the very slight attention it has given to the source of by far the greater part of our beliefs, namely the testimony of others: parents, teachers, textbooks, encyclopaedias. There is an interesting problem here. If we depend on them for the principles by which we check the reliability of what we are told, how do we ever achieve cognitive autonomy?

\*Logic, which, as was said earlier, is the most powerful or coercive instrument for the justification of belief, is never taken to be part of epistemology. It was systematically organized before epistemology had established itself as an identifiable discipline. It began as, and still partly

remains, as orderly arrangement of rules of inference which apply to all kinds of thought and speech. From Aristotle to the mid-nineteenth century it largely slumbered. Since then it has been greatly enlarged, with Aristotle's logic included in a mildly modified way, and has become from one point of view a branch of mathematics. Its elements have always been seen as an essential preamble to the study of philosophy, and still are today. It is not exactly a part of philosophy, although critical reflection on its assumptions, philosophical logic, unquestionably is.

There are a large, and indeed indeterminate, number of specialized philosophical disciplines, philosophies of this and that—mind, language, mathematics, science (natural and social), history, religion, law, education, even sport and sex. Where the special field is, as in the cases of science and history, a form of the pursuit of knowledge, the corresponding philosophy is primarily epistemological. The metaphysics of nature is an idea calculated to put scientists off, although the problem of the reality of theoretical entities such as fundamental particles could well be remitted to it. Speculative or metaphysical philosophy of history, the elaboration of general schemes or patterns (cyclical or progressive) of the totality of historical events, is also regarded with suspicion. The rational basis for that suspicion is a topic for the critical, epistemological philosophy of history.

The \*philosophy of mind, as currently pursued, began from the epistemological problem of how we can know what is going on in another's mind. But it has come to be metaphysical. The old problem of personal identity can be posed either as 'How do we know that someone existing now is the same person as someone who existed at some previous time?' or as 'What is it for a person existing now to be identical with a person who existed before?' If personal identity, our own as well as that of others, is not to be inaccessible and unknowable, the two questions should receive much the same answer.

The \*philosophy of science is often taken to embrace topics which are important for pre-scientific thinking. One of these is that of the nature of causation and the associated issue of how a lawful connection is to be distinguished from a merely accidental concomitance. Another is that of the justification of induction and of the interpretation of the probability, or kinds of probability, it confers on its conclusions. Causal relations, general beliefs, and beliefs held to be no more than probable are all indispensable features of ordinary common-sense thinking.

The third and final main division of philosophy is ethics, or theory of value, the rationally critical examination of our thinking about the conduct of life. Action, as contrasted with mere behaviour, is the result of choice, the comparison of alternatives, undertaken in the light of the desirability or otherwise of their consequences and of the possibility or easiness of doing them. Two kinds of belief, then, are involved in action: ordinary, straightforward factual beliefs about what is involved in doing something and what its results will be, and beliefs about the value of those results and, perhaps, the disvalue of what we must do to secure them.

In fact, in post-Greek ethics, the kind of action that has monopolized attention is *moral* action, fairly narrowly conceived. That is probably the result of religious enthusiasm. Christianity began as a millennialist religion, indifferent to worldly concerns and preoccupied with salvation, partly out of conviction of the worthlessness of the world and the flesh, even more from a belief that the world was about to end anyway. Whatever the cause of this narrow vision it has had a distorting effect. In principle ethics should consider all kinds of deliberate, thoughtful conduct: prudent conduct and self-interested conduct, which aim, respectively, at minimum loss and maximum gain for the agent, technically efficient conduct, economical conduct, healthy conduct, and so on. Moral goodness and rightness are only one kind of rightness. Logic and epistemology, indeed, since they are concerned to distinguish right from wrong in reasoning and belief, can be described as the ethics of inference and belief without metaphorical licence.

Religious influence on morality caused it to be seen as God's commands to mankind. Since this led to problems of authentication and interpretation, God's voice was internalized, either as a kind of moral sense, perceiving the moral quality of actions and the characters of agents, or as a kind of moral reason, apprehending the self-evident necessity of moral principles. Two questionable assumptions are involved in these two kinds of moral intuitionism. The first is that moral characteristics are *sui generis*, quite unrelated logically to any natural, perceivable characteristics of agents and their actions. The second is that actions, or kinds of action, are intrinsically right or wrong, whatever consequences they may have or be expected to have. Both features, if really distinctive of morality, would make it wholly different from other modes of action.

Utilitarians reject both the distinguishing assumptions. They derive the rightness or wrongness of actions from the goodness or badness of their consequences, most plausibly from the consequences it would have been reasonable for the agent to have expected rather than from the actual consequences. Secondly, they take goodness to be pleasure or happiness, more exactly the general happiness, the greatest happiness of the greatest number. The doctrine would have been in closer accord with unreflective moral sentiment if it had been formulated negatively: an action is wrong if it causes harm to another, is permissible if it does not, and is morally creditable if it prevents or alleviates the suffering of another.

For all their differences intuitionists and utilitarians agree that there are objective moral truths and falsehoods. The bulk and intensity of moral disagreement lend colour to the claims of moral sceptics, who claim that moral judgements are no more than expressions of our likes and dislikes and that disagreements about moral issues are collisions of feeling that cannot be settled by rational means. The fundamental question for ethics, conceived simply as moral philosophy, is whether our moral convictions have any objective validity and, if so, of what kind. Are they, as intuitionists suppose, convictions of a unique and special

kind, or can they be brought into logical connection with the rest of our beliefs? Are the moral properties of actions intrinsic to them or are they dependent on the consequences of action? In what does virtue or moral goodness consist? Is it the disposition to do right actions or, more narrowly, the disposition to do right actions just because they are right? Under what conditions do agents deserve blame (or praise) for their actions? Does moral responsibility presuppose freedom of the will in the sense of freedom from any causal influence on choice?

Two other established forms of the theory of value are \*political philosophy and \*aesthetics. Political philosophy is an extension of ethics into the domain of organized social institutions and, like ethics generally, is perhaps over-moralized. Its fundamental problem is the basis of the moral obligation of the citizen to obey the state and its laws, which, viewed from the other end, is that of the state to compel the citizen to obey it. (It might be more interesting to inquire what it is that makes it generally reasonable for citizens to obey.) Does the obligation to obey depend on the content of the laws or on the way the state was set up and is maintained? Do men have rights that limit the morally legitimate sphere of action of the state?

Aesthetic value is recognized as distinct from moral value despite the appearance of moral elements in criticism—sometimes relevantly, sometimes intrusively. It is not very satisfactorily indicated by the word 'beauty'. Other languages do better. 'Beau' and 'schön' mean *fine*, the property of objects of art or nature deserving attentive contemplation for their own sake, independently of any further use we may put them to or any information we may get from studying them.

The more established parts of philosophy have all been mentioned here, but there is no evident limit to its field of application. Wherever there is a large idea whose meaning is in some way indeterminate or controversial, so that large statements in which it occurs are hard to support or undermine and stand in unclear logical relations to other beliefs we are comparatively clear about, there is opportunity and point for philosophical reflection. A.Q.

\*Philosophy is a collaborative pursuit, unlike the meditative activity of sages which is commonly conceived to flourish best in isolated or even hermetic conditions. The form of collaboration involved, however, is not

co-operative, like that of a surgical team, but competitive, a business of critical argument. Argument is meant to persuade, and to succeed must overcome counter-argument. Sages merely issue pronouncements to those who visit their retreats. Philosophers, therefore, are to a large extent found in groups, as is suggested by the large number of philosophical works composed in dialogue form: most of Plato's, for example, Scotus Eriugena's *De Divisione Naturae*, some of Berkeley's and Hume's *Dialogues on Natural Religion*.

The first three universally recognized philosophers—Thales, Anaximander, and Anaximenes—all came from Miletus, a prosperous Greek city in Ionia, on the western coast of what is now Turkey. It was overwhelmed by the Persians in 494 bc. Pythagoras was born in the neighbouring island of Samos, but removed himself—perhaps from dislike of the tyrant Polycrates, perhaps from fear of the Persians—to Croton in southern Italy, where he set up a tightly knit and disciplined school. Parmenides and his followers came from Elea on the lower shin, rather than, as with Croton, the fall of the foot of Italy. Anaxagoras, another Ionian, first brought philosophy to Athens, where he lived for some thirty years around the middle of the fifth century bc. From that date until the emperor Justinian closed the Athenian philosophical schools in ad 529, Athens remained the centre of philosophy, drawing people from other parts of the Greek, and later Roman, world to it, such as the Macedonian Aristotle, as well as producing philosophers of its own, of whom the greatest was Plato. The Sceptics Arcesilaus and Carneades were, at different times, heads of Plato's \*Academy. Zeno, from Citium in Cyprus, and Epicurus, from Samos, the founders of Stoicism and Epicureanism, both settled in Athens.

After the political collapse of Athens at the end of the fifth century bc two other great culturally significant cities developed, and philosophy was pursued there. In Alexandria, more notable for science and mathematics than for philosophy, there were Aenesidemus, Philo Judaeus, and the great systematizers of Christian doctrine Clement and Origen. Plotinus was educated there, but settled in Rome. The native Roman philosophers were of a popular, literary character: Lucretius, Cicero, Seneca, Epictetus, and the emperor Marcus Aurelius. Tertullian lived in, and St Augustine near to, Carthage but 200 years apart, which hardly makes Carthage a philosophical centre. But since Augustine did not leave it until he was 28 it must have had some philosophical culture. Boethius, the last ancient philosopher, or the first medieval one, was of an ancient Roman family and lived in Italy until his execution by the Ostrogoth king Theodric.

Between Boethius' death in 525 and the active career of St Anselm in the latter half of the eleventh century, philosophy outside the Arab world is almost a blank, probably as much in fact as in our knowledge of it. The solitary figure of substance in these 500 years is the Irish Neoplatonist John Scotus Eriugena. He was called to the Frankish Court of Charles the Bald in the late ninth century because of a reputation the Christian civilization of Ireland had been

able to retain until the Vikings destroyed it. The complexity and professional sophistication of his work and his knowledge of Greek throw a favourable, if not very informative, light on the state of Irish culture in his time.

Learning gradually revived, first in monastic schools such as those of York, Fulda, and St Gall. Of particular philosophical interest is that of Bec, in Normandy, where Lanfranc taught Anselm. Both were Italians and both became Archbishop of Canterbury. By the beginning of the twelfth century, around the time of Anselm's death, Paris emerged as the major philosophical centre. William of Champeaux, of the cathedral school there, is the first notable figure. More important was the brilliant and charismatic Abelard, who drew great numbers of students to the city. He was followed by Peter Lombard, compiler of the *Sentences* on which many medieval philosophers felt bound to produce a commentary, and by the Victorines. By 1215 the cathedral schools of Paris were sufficiently unified to be recognized as a university. There had been universities before, most notably at Salerno and Bologna, but they specialized in medicine and law respectively and were governed by their students.

Rashdall described signs of a university in Paris around 1170. By the thirteenth century it was fully fledged and philosophically dominant. The Englishman Alexander of Hales, his pupil St Bonaventure, the German Albertus Magnus, St Thomas Aquinas, Roger Bacon, Duns Scotus, and William of Ockham, even the fourteenth-century German mystic Meister Eckhart, all studied or taught there, often both. Oxford, where Franciscans secured a dominance like that of the Dominicans in Paris, started soon after Paris, but did not displace it until the fourteenth century. The Augustinian Robert Grosseteste, the first important Oxford philosopher and first Chancellor of the university, had Roger Bacon for a pupil, and from his time until the Black Death in 1348 Oxford was the home of a host of productive philosophers. The first of these to be of major significance was Duns Scotus, who shared with the largely very different William of Ockham a conviction of the impotence of reason in the supernatural domain. That marked Oxford off from the Paris of Aquinas, who held and copiously expressed the opposite view.

Oxford declined as a philosophical centre after the middle of the fourteenth century. The persistent heresies of Wyclif, its ablest late fourteenth-century philosopher, bringing down ecclesiastical repression, completed the work done by the Black Death. The Ockhamist tradition survived in Paris with John Buridan, Albert of Saxony, Nicole d'Oresme, and the combatively sceptical Nicholas of Autrecourt. With Gerson, who died in 1429, who used Ockham's nominalism to support mystical conclusions, the first great age of Parisian philosophy came to an end.

The first centre of the new Platonic humanism of the Renaissance was the Academy in Florence, founded in the mid-fifteenth century by Cosimo dei Medici, under the inspiration of the Byzantine Gemistus Pletho and his pupil Cardinal Bessarion and with Ficino and Pico della Mirandola as its most gifted members. The Florentine Academy

had more influence on literature and culture generally than on philosophy proper. Much more philosophically important was the University of Padua, site of a protracted controversy between two schools of interpreters of Aristotle: the Alexandrists (Pomponazzi, Zabarella, Cremonini) and the Averroists. Padua had been taken over by Venice in 1403; its thinkers benefited from the firm resistance of the parent city to papal interference. Galileo was Professor of Mathematics at Padua from 1592 to 1610.

There was some philosophical vitality in Spain in the sixteenth century, notably at Salamanca, the chief figures being Vittoria and the great, last-ditch systematizer of scholasticism: Suarez. But in France and England there was little going on in the religious turmoil of the sixteenth century as Protestantism was suppressed in the former and Catholicism in the latter. There was an active group of young English humanists at Oxford early in the sixteenth century, assembled around the visiting Erasmus, Colet, Thomas More, and Grocyn. Its interests were largely theological and after ten years its members went off in different directions. For most of the sixteenth century there was no philosophical centre of note.

From this time until the mid-eighteenth century in Germany and Scotland and the mid-nineteenth century in France and England the universities were largely torpid. Interesting philosophers were all independent men of letters. But there were some significant informal groupings. The most eminent of these was the circle of the abbé Mersenne, who served as a link between Descartes, Pascal, Gassendi, Arnauld, and Hobbes, recruiting the last three to write critical comments on Descartes's *Meditations*. Locke's *Essay Concerning Human Understanding* was the outcome of a discussion group considering questions of morality and revealed religion, which proved to need a philosophical foundation. But, for the most part, Locke worked alone, as did Spinoza and Leibniz, Berkeley and Hume. In Cambridge, a little earlier, there had been the circle of Platonists led by Cudworth and Henry More.

Holland was not exactly a philosophical centre in the seventeenth century, but major philosophers flourished there, despite a measure of persecution: Spinoza above all and Hugo Grotius. Equally important, Holland, because of its comparative tolerance of unorthodox religious opinions, was much favoured as a place of refuge for philosophers from France and England who were, or reasonably thought they would become, objects of oppression: Descartes early in the century, Locke and Bayle later.

Hume at least had the beneficent social setting of eighteenth-century Edinburgh and the friendship of Adam Smith. During his lifetime the Scottish universities came to life intellectually, keeping him out but taking in to the professoriate Hutcheson, Ferguson, Adam Smith, Reid and Dugald Stewart. So did the universities of Germany. There were a great many of them, none, after the brief initial glory of Halle, particularly predominating. That may be the cause, if it is not the effect, of the characteristically dogmatic and authoritarian character of German

professorial behaviour, which does not invite, or even allow for, critical exchange.

The most attractive philosophical centre of the eighteenth century was the world of the \*philosophes in Paris, agreeably anchored to the material world by the salons of Mme d'Holbach and Mme Helvétius. D'Holbach and Diderot were the philosophically most substantial of the group; Voltaire and Rousseau were, in different degrees, spiritually and, for the most part, physically remote. The contemporary drinking-clubs of Edinburgh performed a similar service in an even more philosophically marginal way. In England the circle around Bentham, animated by James Mill and culminating in J. S. Mill, was a more austere kind of salon.

Kant, notoriously, spent his entire life in the spiritual Siberia of Königsberg. Fichte and Hegel were at Jena and Berlin (Schelling was also briefly at Berlin, as Schopenhauer had been even more briefly). Schleiermacher was active in Berlin through the whole Hegelian period. After the middle of the nineteenth century German philosophers seemed to be spread broadly over the universities of the whole country. Lotze was at Göttingen, where Herbart had finished his career. Cohen and Natorp were at Marburg, Windelband and Rickert at Heidelberg, leading the two neo-Kantian schools. Dilthey and Cassirer both wound up in Berlin after various wanderings. Wundt was at Leipzig, Brentano at Vienna. This monadic organization of philosophy continued into the present century, with Husserl at Göttingen and then Freiburg im Breisgau, where his pupil Heidegger supplanted him.

By the middle of the nineteenth century, when German philosophy was fully professionalized, it was just taking the first steps in that direction in Britain and France. The concentration of the French university system on Paris has persisted to the present day, with nearly every philosopher of note winding up there sooner or later. In Britain, as Scottish philosophy petered out with the death of Hamilton in 1856, its doctrines were kept going with style and professionalism in Oxford by H. L. Mansel. Soon after his death in 1871 the idealist school of T. H. Green, Bradley, and Bosanquet quickly expanded and penetrated the rest of the country with the partial exception of Cambridge (for there were idealists there too, McTaggart, Ward, and Sorley, for example). But the latter soon gave way to the realists Russell and Moore after 1903, and they, in turn, in the 1930s, to Wittgenstein. (\*Oxford philosophy; \*Cambridge philosophy.)

Cambridge had made little contribution to philosophy in the Middle Ages, although it had come into existence very soon after Oxford. However, under the Tudor monarchs its former Protestantism had secured royal favour and, while Oxford slept, it produced Bacon and, later in the sixteenth century, the Cambridge Platonists with their massively learned reaction to Hobbes. In more recent times Cambridge, where philosophy has been studied as a full-time specialized subject, has always had many fewer students of philosophy than Oxford, where it has always been studied in conjunction with other subjects. Never-

theless the two universities achieved philosophical professionalism at much the same time, in Cambridge with Whewell, John Grote, and finally Sidgwick. Then, from about 1900, there was an extraordinary efflorescence. Four philosophers of outstanding gifts—Russell, Moore, Wittgenstein, and Ramsey—enabled Cambridge to dominate English philosophy until after the Second World War, despite the overwhelming numbers of their less inspiring Oxford colleagues. When Oxford philosophy revived, it was through the work of Cambridge-influenced Oxford philosophers: Price, Ryle, and Ayer. With these three, together with Austin and Strawson, Oxford took the lead and attracted visiting American philosophers in the first few post-war decades to such an extent that one of them reasonably described it as 'a philosophical boom town'. But since about 1970 the direction of movement has been reversed.

The universities of America were not much more than high schools or seminaries until well into the nineteenth century. Before that the only centre had been the Boston area, where Emerson and the Transcendentalists were to be found. (\*Transcendentalism.) There was a great period or golden age at Harvard from about 1890 up to the First World War, in the epoch of James, Santayana, and Royce, and with Peirce in the background. Another, still in progress, began at the end of the Second World War. (\*Harvard philosophy.) Dewey presided over an active department at Columbia, in the inter-war years the official headquarters of pragmatism. Berkeley, Princeton, and Michigan have been important departments since the 1940s. This period has been one in which a Germanic system of scattered local heroes has been largely overcome by the dominance of a few major centres, above all Harvard. Recently, after a period in which it either produced or drew to itself a very large proportion of the most highly regarded American philosophers, Harvard has suffered by the departure from the scene, either by death or retirement, of most of these leading figures: Quine, Goodman, Putnam, Nozick, and Rawls, who have not been replaced by quite such magnetic people. A new centre appears to be developing in the New York metropolitan area, embracing Columbia and New York University in the city itself and Princeton and Rutgers in neighbouring New Jersey.

**philosophy, literary genres of.** Philosophers have often been reluctant to admit that what they write is, in a sense, literature. Plato, a great poet, had the poets expelled from his Republic. Nevertheless, philosophy has been written through the centuries with regard to literary form and in accordance with various literary genres.

The dialogue was more or less invented by Plato and was used by him with unsurpassed mastery. But it has been used by other philosophers as well. Cicero in his philosophical dialogues imitated Plato. Berkeley, Hume, and Schelling (among others) used the form in more recent times. The dialogue serves to make clear that philosophy essentially is debate, controversy, dialectical argument.

The commentary is also a venerable genre. It was used in antiquity by e.g. Proclus in his influential commentaries on Plato. Among Arabic philosophers it was a favourite genre. Al-Farabi and Averroës became famous for their commentaries on Plato and Aristotle, and through them influenced later Latin medieval philosophy. But the commentary did not lose its importance with the waning of scholasticism. Even in modern times commentaries on Kant (Cohen, Cassirer, Bennett), on Hegel (McTaggart, Kojève, Hippolyte) or on Marx (Lukács, Althusser) have had an important impact. Philosophy feeds on philosophy. New interpretations of major thinkers open up new vistas.

The intellectual autobiography is useful for showing why a certain line of argument has seemed plausible or even necessary to the author and for bringing out the interplay between ideas and personalities. Plato's *Seventh Letter*, Augustine's *Confessions*, Descartes's *Discourse on the Method*, Mill's *Autobiography*, and Popper's *Unended Quest* could be mentioned here.

The short article is a genre adapted to the specialized philosophical journal of modern times. Within analytical philosophy the short article has suited the idea that the aim of philosophy is piecemeal problem-solving rather than building of systems. s.n.

Berel Lang, *The Anatomy of Philosophical Style* (Oxford, 1990).

**philosophy, the influence of.** The most direct influence of philosophy has been the speculative initiation, and incubation within itself, of other intellectual disciplines: physics and mathematics from the early Greeks, Christian theology from Plato, Plotinus, and Aristotle, law from Hobbes and Bentham, economics and psychology from Locke, Hume, and the Utilitarians, criticism from Aristotle and Kant. This is really too intimate a relation to be described as influence and is, accordingly, a little more fully discussed in this Companion under the heading *philosophy, the value and use of*.

The main influence, properly speaking, of philosophy has been to underlie and, to a considerable extent, to inspire a great number of significant movements of thought embodying attitudes to man and society and, as bearing on them, nature and the universe at large. The first of these is \*Stoicism, whose ideals of fortitude, cosmopolitanism, and public service suited the traditional outlook of the Romans and served them well as the working ideology of their world empire.

More profound and lasting was the influence of the philosophies of Plato, and, even more, Plotinus, on the elaborate and sophisticated system of Christian theology

with which the Fathers of the Church transformed an intellectually rudimentary kind of dissident Judaism into the operative faith of the Western world for a millennium and a half. With the recovery of Aristotle for the West in the twelfth century, Augustine's Neoplatonic theology was greatly modified by Thomist \*scholasticism, but was revived by the Protestant Reformation, which was to a large extent anti-philosophical, despite the part played in its emergence by men trained in philosophy: Wyclif, Luther, Calvin, and Melancthon.

The rejection of Thomist rationalism by Ockham, and his confinement of rational knowledge to the empirically intuitable natural world, led his followers, notably Buridan and Oresme, to anticipate the great scientific flowering of the seventeenth century with theories of inertia and a mechanical conception of nature. A renewed study of Plato was at the centre of the preoccupation of the leading figures of the Renaissance with the human soul. Descartes, although finally overwhelmed by Newton, for some time took a dominant place in the seventeenth-century scientific revolution, in which, like Leibniz, he directly participated.

The application of 'the experimental method of reasoning to moral subjects' practised by Hobbes and Hume (and so described by the latter) was too scandalous in its first appearance to have much immediate influence. Locke, in whom empiricism and Gassendi's materialism were mitigated by borrowings from Descartes, in effect invented \*liberalism. He exerted a major influence on the \*philosophes of eighteenth-century France by way of Voltaire. They cleared the ground for the French Revolution by their criticisms of absolute monarchy and its ideological instrument, the Church. But it was Rousseau who was to inspire the extreme, Jacobin phase of the Revolution. In the United States Locke was taken over wholesale and was honourably plagiarized in the Declaration of Independence. As the ideologist of the Glorious Revolution of 1688, he was not without honour at home. His principles were invoked by the Whig governments which were dominant through most of the eighteenth-century in Britain; wholly until the accession of George III in 1760 and from time to time until the start of a long period of Tory rule in 1784.

\*Romanticism was heavily dependent on philosophy. Its emphasis on emotion and liberation (especially of creative spirits) derived from Rousseau. Its notion of a higher, non-analytic kind of reason was taken from the post-Kantians, Fichte, and Schelling, most directly by Coleridge. Of romantic affiliation was Herder's notion of the unique individuality of particular peoples. The nationalism this implied was more aggressively affirmed by Fichte and bureaucratized by Hegel, with some marginal borrowings from Rousseau and Burke. The way was prepared for the rampant nationalism of the nineteenth century and the erosion of dynastic absolutism.

In Britain, where national identity had been assured, with some help from geography, for 400 years, the emphasis was on reform, intensified by the effects of

urbanization and the growth of industry. The \*utilitarianism of Bentham and the Mills discarded the natural-rights liberalism of Locke and reached back to the starker doctrines of Hobbes and Hume. Marx depended on Hegel, even if he turned him upside-down, basing history on man's material and economic life rather than on the progress of Spirit. Schopenhauer and Nietzsche rejected the rational optimism of the Enlightenment, respectively accepting and glorifying the will and preparing the way for all kinds of anti-rational excess in belief and practice.

In the wasteland of modernity a host of belief systems largely untouched by philosophy sprang up, like the oriental religions of imperial Rome: \*fascism, nudism, \*vegetarianism, parapsychology, environmentalism. \*Feminism broke away from its demure nineteenth-century liberal form, along with parallel movements for the emancipation of homosexuals and animals. Psychiatry turned from Freud's sombre recognition of the dependence of civilization on the control of instinct to ecstatic doctrines of the total liberation of impulse. If not inspired, all this was at least abetted by philosophies such as \*existentialism and \*post-structuralism which proclaimed the inescapable arbitrariness of choice, the death of man, and the inherent self-deceivingness of any kind of rationalism. English-speaking analytic philosophers, notably Russell and Popper, both widely read by non-philosophers, sustained the battered programme of the Enlightenment, arguing for the continuing liberalization of constraining institutions: education, marriage, property, and the state. A.Q.

\*philosopher may preach; pseudo-philosophy; Marxist philosophy; Platonism; Thomism.

**philosophy, teaching:** *see* teaching philosophy.

**philosophy, the value and use of.** The direct value and use of philosophy is either intrinsic or educational. Intrinsically it satisfies, or seeks to satisfy, the intellectual desire for comprehensive knowledge or understanding. We approach the world and the management of our lives within it with a miscellany of more or less unconnected beliefs, preferences, and habits of action, largely acquired from or imposed by others. There is a natural, if by no means universal, desire to order this material systematically, to find out how all the bits and pieces fit together, and to achieve theoretical and practical autonomy by a critical sifting and purification of the beliefs and preferences with which we find ourselves equipped. To be philosophically inclined is to want to make one's convictions systematic and authorized by ourselves by way of critical reflection on what we might otherwise take for

granted. It is to pursue a rationally founded conception of the world and system of values and, as a pre-condition of that, an understanding of what we really know or have good reason to believe. That is an idealized picture, no doubt, but it defines the intrinsic value and use of philosophy in terms of its aims, if not altogether in terms of what is achieved.

Educationally the direct value and use of philosophy is its emphasis on \*argument or \*reasoning. These are to be found, of course, in the study of any intellectual discipline, pretty much by definition. But the proportion of argument to data argued from is much higher than in any other study, apart from mathematics. And the data of philosophy are much more concrete and various in kind than those of mathematics. Philosophy starts from the commonest and most elemental items of common knowledge: that there are material things, past events, and other people, and that we have, or seem to have, knowledge of them. It goes on to ask whether that is so and what is required if our supposed knowledge is to be possible. Philosophy can claim, on this account, to be a good training in self-critical rationality and a valuable accompaniment to any study in which reasoning plays an important part, but is not explicitly reflected on. In so far as the study of philosophy includes the study of its history it can provide some acquaintance with the overall shape of the large movements of the mind in history. It often does this badly by disconnecting past philosophers from each other and from their intellectual environment.

Philosophy also has indirect uses. The most important of these has been that of first nurturing and then setting free other disciplines (often with a familiar kind of parental reluctance and retentiveness). Physics and mathematics proper (as distinct from mere reckoning in trade or surveying) derived from early Greek cosmology. Christian theology, in successive phases, was the child of the philosophies of Plato and Aristotle. Scientific psychology and economics developed from associationist and utilitarian philosophies of mind and action. Jurisprudence emerged from various kinds of political philosophy (from the Stoics, Bacon, and Hobbes), as did political science. Philosophy at least played some part in the transformation of history from mere chronicle into explanatory narrative and has tempted it at times into metahistorical systematization of history as a whole. In the present epoch linguistics has largely extricated itself from the maternal embrace of philosophy.

Finally, philosophy, in a popular sense of the word, has aimed to satisfy a widespread popular need, typically by way of guidance in the conduct of life (from Socrates, the Stoics, and the Epicureans onward) or, where there is no scope for guidance, as with the inevitability of death and other blows of misfortune, by way of consolation, for the most part more austere than religion does. (\*Popular philosophy.) A.Q.

\*Lumber of the Schools; bladders of philosophy; divine philosophy; fingering slave; clip an angel's wings.

**philosophy, women in:** *see* women in philosophy.

**philosophy and literature:** *see* literature and philosophy.

**philosophy and ordinary language:** *see* ordinary language and philosophy.

**philosophy and psychology:** *see* psychology and philosophy.

**philosophy and real life.** Claims by one philosophical tradition to capture real life better than another presuppose further claims concerning what it is about reality that philosophy should aim to capture. Traditional metaphysics bears the mark of \*Parmenides' conclusion that there is no real change in the world. In the light of the One, the life that does change is lost to view or dismissed as illusory. The complaint that philosophy has treated its questions at too abstract a level is often laid at the door of \*Plato's appropriation of \*Socrates, for whom philosophy was an activity designed educatively to recast questions rather than provide any answers. When \*Kierkegaard asked his philosophy teacher what relation philosophy had to actual life, it was with the thought that this long-standing trend should be reversed. That philosophical questioning begins with the 'existing' individual is the view of existentialists, whose reaction to the tradition culminating in \*Hegel was led by Kierkegaard himself. Whereas he focused on philosophers' attempts to capture within a closed system something that is essentially open-ended, later critics were concerned to replace the traditional vocabulary with one that better maps the contours of life as it is lived. \*Existentialism thus re-situated philosophy by replacing its impersonal viewpoint with a subjective one, and the methods of philosophical reasoning with a descriptive approach claiming to do better justice to life itself. Some \*linguistic philosophy may be said to be informed by a similar aim. This shift of viewpoint contrasts with \*Marxist philosophy's quasi-scientific socio-economic focus and with the generalizing tendencies of philosophical \*anthropology, but also with the approach of 'applied' philosophy which focuses on the ethical dilemmas of professional and political life. Employing traditional methods of reasoning, this draws on an armoury established by philosophy's recent analytic past and on standard versions of the more enduring moral theories. Apart from generating large and specialized literatures, \*bioethics and \*business ethics have contributed to a public image of the philosopher as a professional among others, and of philosophy itself as a service industry of use in formulating guide-lines for ethically acceptable behaviour. In this endeavour what counts is less any special philosophical insight than an ability inherited from analytic philosophy to give debates a manageable and surveyable form.

**philosophy and science.** How are \*philosophy and science related to one another?

*I.* It has often been claimed that the method of reasoning adopted by modern science is the method of reasoning that philosophy should also adopt in dealing with at least some of its problems. Thus Hume subtitled his *Treatise of Human Nature* 'An Attempt to Introduce the Experimental Method of Reasoning into Moral Subjects'. It was as if he took his sceptical philosophy to be a pioneering contribution to what we should now call experimental psychology. Similarly on Quine's view, in *Ontological Relativity and Other Essays* (New York, 1969), 82–3, epistemology should be regarded 'as a chapter of psychology and hence of natural science' because it studies 'a natural phenomenon'. Specifically, according to Quine, it studies a physical human subject that receives as input a sequence of patterns of irradiation in assorted frequencies and delivers as output a description of the three-dimensional external world and its history.

We need to ask the following question, however: how much of the procedures adopted by physicists, chemists, biologists, etc., since AD 1600 or thereabouts is to count here as a part of the method of natural science? Kant described himself, in the preface to the second edition of his *Kritik der reinen Vernunft* (tr. N. Kemp Smith (London, 1929)), 21–3, as seeking to put metaphysics 'on the sure path of a science'. He thought that via his critical method metaphysics could achieve the same level of consensual certainty as that which was supposed to belong to the mathematics and physics of his time. In the reformed metaphysics it would no longer be possible to construct pairs of arguments that were both apparently sound yet had mutually opposed conclusions. But this would not make metaphysics a branch of mathematics or physics. Similarly Russell held, in his *History of Western Philosophy* (London, 1946), 862–4, that in the practice of philosophical analysis (as, for example, in his own philosophy of mathematics) a method of procedure is used that resembles scientific reasoning in respect of its ability to achieve definite, consensually acceptable answers for certain problems and therewith successive approximations to the understanding of a whole field of inquiry. But Russell's claim was not as bold as that of Hume and Quine. In particular he did not share their view that the extent of the resemblance between philosophical and scientific method included a shared use of controlled experiment and observation. Popper too has theorized, in his *Conjectures and Refutations* (London, 1963), 198–200, that like any science philosophy must first proceed by the isolation of a problem and then by the proposal and criticism of a hypothesis for the problem's solution. But he does not expect an epistemological theory of this nature to be empirically refutable. How *could* he expect it to be empirically refutable if the subject-matter that might refute it does not belong either to the mental or to the physical world but to

what, in *Objective Knowledge: An Evolutionary Approach* (Oxford, 1972), 107–9, he calls ‘the third world . . . of problems, theories and arguments’? Again Comte, in his *Cours de philosophie positive* (Paris, 1830), i. 2–56, held it to be a fundamental law of mental development that both communities and individuals pass from a ‘theological or fictitious state’ into a ‘metaphysical or abstract state’ and from the latter into a ‘scientific or positive’ one. And it is from Comte’s use of the term ‘positive’ in this connection that \*‘positivism’ has come to be the name given to any philosophical theory that assigns a dominant intellectual role to empirical science. But Comte’s view was that metaphysical thinking should be replaced by scientific thinking, not that metaphysical thinking should consist in a kind of scientific thinking.

Many philosophers have implicitly or explicitly rejected any such scientific paradigm. Certainly the sceptical tradition cannot easily be reconciled with this conception of philosophy. If you deny that knowledge is possible, then *a fortiori* you deny that any paradigm of knowledge exists. If genuine science is beyond human capacity, it is pointless to urge philosophers to imitate it. Indeed, when Socrates claimed to know nothing but his own ignorance, he was scorning those of his contemporaries who claimed to know more than this. Nor can philosophy stand in unbiased judgement over the principles and assumptions of the sciences if it is itself one of them: for example, in Plato’s *Republic*, book 7, the author’s conception of philosophy—under the name of \*‘dialectic’—as an architectonic discipline left no room for it to take geometry, arithmetic, or one of the other sciences as its paradigm. Moreover, against Russell’s thesis that philosophy should proceed like a science, there stands the emphasis placed by some other analytical philosophers, like Ayer in his *Language, Truth and Logic* (London, 1946), 33–70, on the importance of the difference between \*analytic and synthetic propositions, with the conclusions of philosophical inquiry being said to be characteristically analytic while the conclusions of physical, chemical, or biological inquiry are said to be characteristically synthetic. The former articulate the implications of a word’s or phrase’s meaning; the latter describe features of objects. And, whereas scientific conclusions need always to be based on valid reasoning from appropriate premisses, there are philosophers, like Samuel Alexander and Derrida, who purport to spurn all attempts at philosophical reasoning. Alexander claimed, in his ‘Some Explanations’, *Mind* (1931), 423, to ‘dislike argument’. And Derrida has said, in ‘Limited Inc abc’, *Glyph* (1977), supplement, 56, that he detests discussion, subtleties, and ratiocinations.

II. In the face of so much disagreement the best way forward is to seek out those features in which philosophy does seem to resemble a natural or social science and those in which it does not.

For example, it is scarcely to be denied, even if it verges on platitude to assert, that both types of inquiry involve the solution of intellectual problems. In particular cases

they may involve the solution of practical problems also, but this is not a necessary feature. On the one side, for a scientist, to know what causes a given process is very often also to know how to produce it. But practical knowledge does not accompany theoretical if the process caused is the explosion of a supernova. On the other side, if as a philosopher one accepts an appropriate type of analysis of \*personal identity, one may have acquired thereby the ability to reconcile oneself to a loved one’s apparent death. Perhaps people are really immortal, so that reflection on the relevant philosophical analysis provides a technology of consolation. But others who accept the same analysis may nevertheless be inconsolable. A well-constructed analysis of logical entailment may assist the task of persuading someone to acknowledge the validity of a long and subtle argument. But others may still be unable to grasp it.

Again, the results of scientific inquiry are always expected to be consistent with one another overall, and so too are the results of philosophical inquiry. In either case any inconsistency is regarded as a fault or inadequacy, and functions as a sign of where more work needs to be done.

More interestingly, perhaps, it is worth noting that, as in science, so too in philosophy both deductive and inductive patterns of argument are to be found. Thus on the one hand Descartes, in his *Discours de la methode* (Leiden, 1637), part v, sought to *deduce* the existence of God from certain self-evident first principles, and Ryle, in *The Concept of Mind* (London, 1949), 8, claimed to be mainly using \**reductio ad absurdum* arguments. On the other hand the movement of philosophical thought is often inductive rather than deductive. This occurs when the validity of some general principle is supported by an appeal to involuntary intuition in a particular kind of case. For example, Bernard Williams, in his ‘Moral Luck’, *Proceedings of the Aristotelian Society* (1976), 117 ff., declares that his ‘procedure in general will be to invite reflection about how to think and feel about some rather less usual situation, in the light of an appeal to how we—many people—tend to think about other more usual situations’. Again Quine, for example in his *Word and Object* (Cambridge, Mass., 1960), 157–61, defends his hostility to logical modalities, intentional objects, and subjunctive conditionals by appeals to the logical intuitions that this or that utterance may provoke. And Putnam, in his ‘Mind, Language and Reality’, in *Philosophical Papers* (Cambridge, 1975), ii. 224, tells a science-fiction story to evoke an intuition about the use of the term ‘water’ on a look-alike planet earth in order to support the thesis that the meaning of a scientific term is never just a function of the speaker’s psychological state.

Important features of dissimilarity, however, are also to be found.

In science the data that support inductive conclusions are data that emerge, albeit involuntarily, from experiment or observation, not from intuition or intellectual conscience. Correspondingly, whatever the field of their research, scientists are expected to achieve consensus, and the history of modern science is full of such achievement.

Moreover, this expectation is embodied in accepted patterns of institutional endorsement, i.e. in the publication of universally respected textbooks, in elections to official academies, and so on. Nor could science progress through teamwork, as it often does, unless consensus were the norm.

But, where two philosophical theories oppose one another, that opposition is not necessarily seen as showing that one or both of the theories must be faulty. In this way philosophy is perhaps more like art than like science. An art gallery is the richer for the fact that it possesses paintings in the realist style as well as in the impressionist one. Our culture also profits analogously from the opposition between philosophical realism and philosophical idealism, albeit philosophical theories are constructed with the help of language and argument, not of canvas and paint, and convey an outlook on intellectual or social issues, not on visual ones.

Moreover, philosophy often has a normative aspect, which science lacks. Thus scientists set out to describe some aspect of how the world is, or of why it is so, or of what can be done to change it. But philosophers often set up ideals of how intellectual inquiry should proceed, or of what rationality requires, or of which socio-economic objectives should animate legislation. Roughly, while science can often supply knowledge of means, it is for philosophy to discuss the choice of fundamental ends.

III. Despite the important differences that exist between science and philosophy, each has had an important influence on the other. For example, the readiness of philosophers to question any customary assumption, or to explore any interesting speculation, has sometimes helped to open up new avenues of scientific inquiry or to provoke major revolutions in scientific theory. Empiricist theories of meaning, like Hume's, when mediated through the work of Mach, had a part in creating the climate of ideas in which it was possible for Einstein to regard the concept of absolute simultaneity as meaningless. Truth-functional analyses of implication, like the Stoics', are ancestors, via Boole's mathematical logic, of the systems of logic-gates that are essential to digital computers. But there is also the possibility that interest in methodological or epistemological problems may sometimes divert a scientist—especially a young and inexperienced one—from working on substantive scientific issues.

Conversely, major new developments in science tend to pose new problems for philosophers. Thus the triumph of quantum theory in physics sets new puzzles for those who investigate the structure of scientific explanation, since familiar deterministic assumptions seem no longer tenable. And new medical technology has generated many new problems in medical ethics with regard to the use of life-support mechanisms, organ transplants, experimentation on patients, choice of an infant's sex, etc.

Moreover, in addition to such interconnections between particular scientific developments and particular philosophical ones, the general notion of scientific

progress has also been linked—sometimes positively and sometimes negatively—with philosophical attitudes.

Thus Utilitarians like John Stuart Mill have looked to science for a technology of happiness and have therefore been especially keen that the social sciences should emulate, wherever possible, the style and method of the natural sciences and attain a comparable level of success at prediction and explanation. And even though a \*deontological ethics does not normally require assistance from science in order to achieve the realization of what it values, it does not repudiate such assistance either.

Some philosophers, on the other hand, have actually adopted a negative attitude to science, or part of science, as normally conceived. Sometimes this attitude rests on the claim that a superior science is relevant, such as a philosophically argued metaphysics or a creationist alternative to Darwinian \*biology. Sometimes it rests instead on the claim that modern science is itself to be blamed for all the environmental pollution that its users have generated. But neither claim is well founded. Not a single consequence of an alternative epistemology has ever been generally accepted by all those who repudiate or despise modern experimental science. And the sources of environmental pollution are all to be traced to the activities of those who misuse scientific knowledge, not to the activities of those who discover it.

IV. Even if philosophy is not a kind of science, nor a rival of science, and even if it has had differences from science that are crucial to its nature, it may nevertheless be conveniently thought of, like science, as a species of knowledge—the self-knowledge of reason. At least three kinds of knowledge are then recognized. Science gives us systematic, institutionally warranted, and technologically exploitable knowledge of the uniformities and probabilities in our natural and social environments. Everyday knowledge informs us about the immediately obvious features of the facts that confront us. And philosophy provides knowledge of the fundamental principles and assumptions in accordance with which we reason. It is that kind of knowledge which is provided when a paradox is discovered, discussed, and resolved; when some form of \*scepticism is proposed or refuted; when the body–mind interconnection is investigated; when the nature of mathematical proof is clarified; when foundations of moral or aesthetic value are established; when the possibility of the world's being subject to the control of an omniscient, omnipotent, and benevolent deity is examined; and so on.

Against this view of the relationship between science and philosophy a number of objections may be urged.

One possible objection is that belief is about matters of fact, as in science or everyday awareness, whereas philosophy is often concerned with rules, norms, values, or ideals. But again the premiss is false. Beliefs are not always about matters of fact. For example, one can claim to believe that a \**modus ponens* type of argument is necessarily valid or that children should be taught to read and write by the age of 7.

A second possible objection is that if philosophy does not, like science, aim at consensus it cannot be a species of knowledge. But there is a confusion here. Certainly it would be self-contradictory to say of one person that he knows that  $p$  and of another that he knows that not- $p$ . But it is quite admissible to say of one person (whether in science, in everyday experience, or in philosophy) that he thinks that he knows that  $p$  and of another that he thinks that he knows that not- $p$ —just as one painter or art critic may think that he knows the superiority of realism and another may think that he knows the superiority of impressionism. In other words to seek philosophical knowledge is to seek consensus, in that philosophers use argument in order to persuade one another of the correctness of their view. But a wise philosopher does not expect that philosophical consensus will ever be achieved, except locally and in the short run. So he does not expect that his arguments on a philosophical issue will be as cogent as those of a competent scientist on a scientific issue.

Thirdly, it might be said that philosophy cannot be a species of knowledge that ought to be classified co-ordinately with scientific knowledge since a sufficiently advanced neuroscience, matching software to hardware, could itself provide consensual knowledge about the fundamental principles and assumptions in accordance with which we reason. In other words, it will be said, a sufficiently detailed knowledge of the human brain's genetically controlled architecture will reveal the structure of our thinking ability. So philosophy is just a variety of scientific knowledge.

But that is to suppose the existence of a fully determinate, genetically programmed system of principles and assumptions, with no room for major variation in accordance with cultural inheritance or individual choice. \*Evolution would instead have given the human species a survivally more valuable endowment if the genetically programmed system constituted only a loose framework within which a variety of alternative patterns of reasoning were possible, with the choice or construction of a particular pattern being settled in accordance with the perceived needs of the situation. Thus it may be tempting to suppose, for example, that people have an innate ability, which a well-developed neurology could explain, to learn to calculate arithmetically in the scale of 10. But in fact the ancient Greeks and Romans, and early medieval Europeans, had no such ability because their arithmetic lacked the number 0.

How are these vast areas of conceptual space, left neurologically indeterminate by genetic programmes, to be filled and used? Much of this great task is achieved by the unreflective endeavour of scientists or of intelligent people building on the inherited achievements of their forebears. But there is also room for philosophers to contribute through the critical and reflective exploration of alternative options. And neuroscience cannot take on this task because, even if a neuroscientist were able to detect the patterns of reasoning preferred by particular philosophers, he would still be left with the task of criticizing and

evaluating those patterns. That is, he would still need, in important respects, to operate as a philosopher. L.J.C.

**philosophy and theology:** see theology and philosophy.

**philosophy and the public.** In an old Monty Python sketch on television, two teams of philosophers play a football match. The German idealists are competing against a squad of ancient Greeks for an undisclosed honour. But the game is a disaster because all the players waddle around scratching their beards rather than engaging with the ball. Such is philosophy's public image in Britain—philosophers are comic, their concerns inscrutable, and their capacity for recommending courses of action even to themselves terribly limited. To some members of the public, at least, philosophers remain as socially useless as Cratylus, the Hericlitean who found the world so perplexing that he was reduced to silently wagging a finger.

Behind the satire, though, there is a real disappointment that broadly empiricist philosophers seem temperamentally unable to answer purportedly profound and profoundly romantic philosophical questions that press themselves on the public—about the meaning of life, the nature of time, how to lead the good life. Even Stephen Hawking has rebuked philosophers for allegedly abandoning the great tradition of philosophy from Aristotle to Kant in favour of the mere analysis of meaning.

Julian Baggini suggests that the public's disappointment in philosophers now stems from a misconception. 'Carrying around some weird image of philosophers as New Age gurus or spiritual leaders, they don't seem to realise that the vast majority of modern philosophy is technical, specialised and about as relevant to the concerns of everyday life as theoretical physics.'

No wonder, then, that anxious members of the public, seeking happiness or the meaning of life, take succour in glib answers to questions that some professional philosophers might regard as strictly senseless. The extent to which the public buys books by non-philosophers purporting to be philosophy, such as *Sophie's World* by Jostein Gaarder or *Consolations of Philosophy* by Alain de Botton, is perhaps a good measure of the need for such succour. Worse yet, traditionally philosophical problems have been appropriated in considerable measure by charismatic academics from other disciplines who have achieved much public success with popular books. Thus the nature of time has been tackled by physicists, and

consciousness by evolutionary biologists and quantum theorists. Often such appropriations have been regarded as disastrous over-simplifications by professional philosophers. But when pitted against the showmanship of the evolutionary biologist Steven Pinker or the gusto of the zoologist Richard Dawkins, the compunctions of philosophers, and their concern that scientists' answers sometimes elide what makes a particular problem fascinating or at least difficult, are likely to be about as compelling to the public as an all-philosophers' football match.

In part, philosophy's public-relations problem is to do with the current dearth of philosophers who are good public performers. This is hardly a purely British problem, if it is a problem at all: the late John Rawls, for instance, was an impeccably reticent American academic, but in the age of the mass media this dignified reticence may well be taken as intolerable. Perhaps one thing that philosophy needs to improve its public image is a few charismatic monsters of egotism—a latter-day Russell, for instance—but monsters who are good on telly.

This PR problem applies primarily to anglophone philosophy. In France, to take one example, deference to philosophers is such that Pythonesque satire is all but inconceivable. One might well ask why. An answer might well take in the following points. In France, there is a tradition of the *philosophe engagé*, one who gets rather noisily involved in public affairs and who can perform his or her thoughts compellingly in newspapers or on TV. One need only think of Sartre or Bernard-Henri Lévy to get the idea. Across the Channel, too, philosophical work, such as it is, often has a romantic tenor that is publicly compelling. It may well be seductive to the public that Heidegger dealt with the question of being, a matter of great pomp and mystique; rather less sexy is an anglophone analytical philosophy that deals with questions of meaning. And yet, even when a continental philosopher such as Jacques Derrida engages with what are primarily linguistic matters, his tilting at the windmills of meaning has a romantic flourish that makes what he does publicly appealing and superficially comprehensible. Everyone thinks they know what he means by 'deconstruction', and many suppose it to be a grand philosophical project of the kind that anglophone empiricists seem incapable of pursuing.

What future for anglophone philosophers seeking a public role? One suggestion is that they can serve as intellectual firefighters, called in to quell blazing rows that are the result of muddled thinking or sloppy arguments over such issues as abortion, euthanasia, cloning, and war. Whether there is a public demand for them to perform this role is questionable.

**philosophy: world and underworld.** Ideas which either violate important canons of reasoning or which are simply far out and unfamiliar are frowned upon by some philosophers and are assigned by them to a philosophical underworld. Examples are concerns about black and white magic, revivals of alchemical and occult systems, offshoots of psychoanalysis and of C. G. Jung's psychology, large parts of New Age thinking, certain versions of feminism, general views surrounding astrology, unclear ideas proposed by scientists (Bohr's idea of complementarity or Kuhn's idea of incommensurability), and so on.

However, speaking of an *underworld* of \*philosophy assumes that there is a *world* of philosophy, i.e. a well-defined and more or less uniform domain of discourse and/or activity. Such *worlds* do indeed exist. Every school of philosophy that has not yet started falling apart has the unity required by the assumption. But it seems doubtful that the collection of all schools, at all times and in all places, or even the sum total of today's philosophy departments at Western universities shares ideas and standards that are sufficiently substantial to define a world and a corresponding underworld.

We have no comprehensive studies of the matter; however, there exists strong anecdotal evidence undermining any sort of uniformity. No self-respecting British philosopher would try to revive the idea, found in Augustine, that the harmonious musical intervals represent truth in a way

inaccessible to human reason. The Herder of the *Ideen* was beyond the pale for Kant, Kant for the Nietzsche of the *Antichrist*, Hegel for Schopenhauer, the Wittgenstein of the *Investigations* for Russell, Tarski for the Wittgenstein of the *Investigations*, and all of traditional philosophy for the founders of the Vienna Circle and the practitioners of deconstruction. All these ideas are now held (by Anglo-American philosophers) to belong to philosophy proper and are deposited in its history. Making them measures of philosophical excellence we obtain an 'underworld' devoid of content.

And this is exactly as it ought to be. Both in the West and elsewhere philosophy started out as a universal criticism of earlier views (in Greece the earlier views were those of the Homeric epics). The gradual subdivision of research and its professionalization left philosophers with two options: to become specialists themselves or to continue dealing with and being nourished by *all* human ideas, efforts, procedures. In the first case we do get underworlds—but there will be different underworlds for different schools (in the sciences the situation is the same; molecular biologists have an underworld that differs from that of, say, cosmologists and certainly from the underworld of some sociological schools). An honest professional philosopher would therefore say: 'Being a positivist [for example] I reject Jung's idea of a collective unconscious' and not: 'Jung is *philosophically* absurd'. In the second case we move beyond the domain of academic philosophy into a form of life that excludes nothing though it does not hesitate to make definite suggestions for definite occasions.

P.K.F.

\*pseudo-philosophy.

**phrastic:** *see* neustic and phrastic.

**phronēsis.** Practical \*wisdom. In ancient Greek the term (frequently interchangeable with *sophia*) has connotations of intelligence and soundness of judgement, especially in practical contexts. In Aristotle's ethics it is the complete excellence of the practical intellect, the counterpart of *sophia* in the theoretical sphere, comprising a true conception of the good life and the deliberative excellence necessary to realize that conception in practice via choice (*prohairesis*).

**physicalism.** The doctrine that everything is physical. Also called \*materialism, the view is associated with Democritus, Epicurus, Lucretius, Hobbes, Holbach, T. H. Huxley, J. B. Watson, Carnap, Quine, and Smart. Physicalists hold that the real world contains nothing but matter and energy, and that objects have only physical properties, such as spatio-temporal position, mass, size, shape, motion, hardness, electrical charge, magnetism, and gravity. Exceptions are sometimes made for \*abstract entities such as numbers, sets, and propositions.

The principal argument for physicalism is the success of physics. Physicists have been able to explain a large and diverse range of phenomena in terms of a few fundamental physical laws. The principle that the properties of larger objects are determined by those of their physical parts is confirmed daily. The physical basis of celestial phenomena was recognized in the seventeenth century, that of chemistry in the eighteenth, and of biology in the nineteenth. The neurophysiological basis of psychology has become increasingly apparent in the twentieth century.

The principal objections to physicalism have come from theology, epistemology, and psychology. Theological objections stem from the widespread belief in supernatural, immaterial gods, and in special creation and life after death. Epistemological objections come from idealist or phenomenalist philosophers such as Berkeley, Hume, Kant, Hegel, and Mill, who hold that our ideas or sense-data are the only objects of direct perception, from which they conclude that everything must reduce to the mental. Psychological objections have been especially acute since Descartes, whose \*dualism still has many vigorous adherents. The basic objection is that thinking, emotions, and sensations seem utterly unlike length, mass, and gravity. And physiologists are far from specifying neural states perfectly correlated with even one mental state. Physicalists respond either by denying the existence of the allegedly non-physical phenomena (\*eliminative materialism), or by arguing that it must really be physical (reductive materialism; also \*identity theory; \*behaviourism; \*central-state materialism).

D. M. Rosenthal (ed.), *The Nature of Mind* (Oxford, 1991).

**physicalism in the philosophy of mind.** Physicalism in the philosophy of mind is an application of the general metaphysical thesis of physicalism, namely the claim that everything in the space-time world is physical. Concerning the sphere of the mental, then, physicalism claims that all the facts about minds and mentality are physical facts. This claim is usefully divided into two parts: *ontological physicalism*, which holds that there are no mental particulars, all the individuals of this world being physical particulars and their aggregates, and *property physicalism*, which holds that all properties of these individuals are physical properties.

Ontological physicalism excludes such putative entities as immaterial souls, Cartesian mental substances, 'entelechies', and 'vital forces'. If all physical entities (e.g. all physical particles) were taken away from this world, nothing would remain—not even an empty space-time framework. This contrasts with Cartesian substance dualism according to which minds are substances of a special kind and could in principle exist even if nothing material existed. Many ontological physicalists, however, reject the reductionist view that all properties had by physical

systems are exclusively physical properties; they hold the dualist thesis that complex physical structures, like biological organisms, can have irreducibly non-physical properties, such as \*consciousness and \*intentionality, two properties often taken to be constitutive of mentality. This is what is known as non-reductive physicalism, a position that combines physical monism with property dualism. In contrast, property physicalism, or reductive physicalism, holds that all properties of physical systems are either physical properties or reducible to them; that is, in so far as mental properties are genuine properties of physical systems, they must be reducible to physical properties.

A general characterization of 'physical property' is a difficult, and controversial, matter; for the present purposes, we may skirt this general issue by taking as our paradigmatic physical properties the fundamental properties and magnitudes of theoretical physics (e.g. mass, energy, charge) and properties definable or reducible in terms of them.

\*Emergentism is a form of non-reductive physicalism. On this view, when a physical structure reaches a certain level of structural complexity, it comes to exhibit novel, \*emergent properties, most notably life and consciousness, whose occurrences are unpredictable and inexplicable on the basis of its physical constituents and the laws that govern them. A majority of those who hold a functionalist view about mentality, too, think of themselves as non-reductive physicalists; for, according to them, mental properties and kinds are functional—perhaps computational—properties and kinds defined in terms of input and output, not physico-chemical ones or biological ones. Non-reductive physicalism has been the most influential position on the \*mind-body problem since the 1970s. However, it has recently come under attack by reductive physicalists on the ground that it is not able to account for mental causation, and that it supports an incorrect view of the interlevel relationships of the sciences.

Most non-reductive physicalists acknowledge the priority of physical properties and physical laws, at least in the following sense ('the \*supervenience thesis'): the physical character of a thing determines its whole character, including its mental character. That is, there could not be two objects, or events, exactly alike in all physical respects and yet differing in some mental respect.

The principal argument against reductive physicalism has been the \*variable (or multiple) realizability of mental, and other higher-level, properties. Pain, for example, may be 'realized' in humans by the activation of C-fibres (let us say), but in different animal species (perhaps also in electro-mechanical systems) we must expect different physical mechanisms to subserve pain. In fact, there may be no upper bound to the possible realizers of pain in all actual and possible systems. If this is true, pain cannot be identified with any single physical kind. This point holds generally, it has been argued, for all higher-level properties, including biological properties in relation to physico-chemical properties. (See \*functionalism; reductionism.)

However, those who reject reductive physicalism for this reason, hold the thesis that mental and other higher-

level properties can be realized only by physical properties. This view can be called 'realization physicalism', and it can explain why mind-body supervenience obtains; it entails that physically identical systems realize the same higher-level properties, including mental properties. Realization physicalism, even if it may fall short of full reductive physicalism, is a strong physicalism position.

Another objection to reductive physicalism is based on the frankly dualist claim that, given their distinctively mental character, mental properties simply could not *be* physical properties. Even if, say, pain should turn out to have a single neural-physical correlate across all organisms and other possible pain-capable systems, how could the *painfulness* of pain *be* a neurobiological property? In moving from the mental to the physical, we lose, it has been argued, what is mental about mental properties, such as their qualitative character and their subjectivity. In this vein, it has been argued that for physicalism to be true, conscious events and processes must be shown not to be 'over and above' physical-biological processes, and that showing this requires showing that physical-biological facts of this world must logically entail facts about consciousness. But this cannot be shown, it has been argued in a manner reminiscent of the dualist arguments of Descartes, since we can perfectly well conceive of a world just like the actual world but one in which no consciousness exists and human-like creatures in it are mindless \*'zombies', and hence such a world is a logically possible world. This argument remains highly controversial, however. J.K.

**physics, philosophical problems of.** Most of these are distinctly *metaphysical*, and arise from attempting to take seriously the picture of the world provided by modern physics. Typically what philosophers of physics do is to employ recent thinking in metaphysics, about the \*identity of indiscernibles, \*dispositions, \*causality, \*time, etc., to inform our understanding of modern physics—though they frequently argue for revising current metaphysical thought as well. However, philosophers of physics are also concerned with the more general *epistemological* problems of philosophy of science, like the underdetermination of theory by empirical data or the status of unobservable entities. For such problems come into sharp focus when posed in the context of particular physical theories (e.g. string theory) or particular theoretical entities (e.g. quarks), bringing the hope that these problems may be better understood—perhaps even resolved.

The involvement of philosophy in physics is not new. Newton, Leibniz, Descartes, Mach, and Poincaré, to

name but a few classical physicists, all couched their ideas about the physical world in philosophical, as well as quantitative, terms. But the intermingling of philosophy with physics has become even more apparent with the emergence of the kind of abstract theories that have come to dominate physics in this century.

For example, as a prelude to establishing in his special theory of relativity that simultaneity is not an objective concept independent of an observer's state of motion, Einstein needed to 'clear the way' by giving an epistemological critique of the methods observers can use to establish whether spatially separated events are simultaneous. And Einstein cleared the way for his general theory of relativity by arguing (from the way that gravity affects objects independently of their size or make-up) that an object's motion under gravity is indistinguishable from the motion it would be seen to have, in the absence of gravity, from the perspective of an observer accelerating past it (Einstein's celebrated 'principle of equivalence'). Similar epistemological critiques, for example of the procedures by which we can determine both the position and momentum of a particle (the \*uncertainty principle), were formative in the early development of \*quantum mechanics.

In light of this, it is unfortunate that many physicists today regard philosophers as having little to contribute to the advance of physics; either because the problems that capture their attention are too mundane or idiosyncratic to be relevant, or because philosophers are perceived to lack the necessary mathematical training for settling fundamental issues.

Nevertheless, the twentieth century has given rise to a 'new breed' of physically trained philosophers in close contact with the technical side of physics and how it affects philosophical issues: like how to reconcile the tendency of macroscopic systems to approach equilibrium over time with the underlying time-reversal invariance of physical laws; how to make sense of removing the infinities predicted by quantum field theory by 'renormalizing'; and whether a plausible formulation of the 'cosmic censorship' hypothesis holds true in general relativity so that \*determinism can be safeguarded against naked singularities. Reichenbach was probably the first of this new breed, though since then the philosophers that immediately spring to mind are Earman, Fine, Grünbaum, Malament, Redhead, Shimony, Torretti, and van Fraassen.

Two examples will serve to indicate the capacity modern physics has to impinge on both metaphysics and epistemology. Both examples will again be drawn from the special and general theories of \*relativity (but \*quantum mechanics is also relevant).

The relativity of simultaneity in special relativity affects traditional metaphysical views about the nature of time; in particular, the view that only events occurring in the present (or past) are real, while events in the future are not yet 'fixed', or have yet to come into being. At the moment two observers in relative motion pass, their differing standards of simultaneity will force them to disagree on what

events are in the 'future' and what are in the 'past'. So, on the traditional view, they would have to disagree on which events are real, even when they (momentarily) occupy the same point in space! The obvious way to reinstate agreement is for the observers to say that only those events which can causally influence the event of the observers' coincidence are real, since relativity predicts that both observers will necessarily agree on events those are. (\*Space-time.) But this will now make what events are real dependent upon the particular spatial location of the observers' coincidence! Hence some (e.g. Putnam) have argued that any objective, ontological distinction between 'present' (or 'past') and 'future' events must be abandoned.

General relativity's prediction that space can fail to obey the axioms of Euclidean geometry naturally leads to the epistemological question how we can know which geometry is applicable to our universe. Imagine a world of two-dimensional creatures confined to a flat disk of finite radius who are using measuring-rods to try and determine the geometry of their world. Suppose there is a temperature gradient on the disk which makes all measuring-rods expand or contract equally, with the gradient suitably arranged so that rods shrink to zero length as they approach the disk's periphery. Then from their measurements the creatures will get the distinct impression that they live on a plane of infinite extent with a 'Lobachevskian' geometry. Of course, if they knew how the temperature of the disk was affecting their rods, the creatures could redescribe their situation as Euclidean. But since they are forever confined to the disk, there is no way of checking. So apparently they can either *assume* their instruments behave in a straight-forward way and adopt a more complicated geometry, or *assume* that the geometry is simply Euclidean and adopt a more complicated physical story about their expanding-contracting rods. Hence some (e.g. Poincaré and Reichenbach) have argued, using this disk parable, that which geometry is appropriate to *our* universe can only be a matter of convenience. R.CLI.

**Pico della Mirandola, Giovanni** (1463–94). Italian philosopher who developed a form of syncretism according to which all systems of thought and belief could be reconciled on the basis of their shared truths. Although no philosophy or religion was entirely bereft of such truths, Christianity held a privileged position, acting as the standard by which all other truths were judged. At the age of 23 he challenged all comers to debate 900 *Conclusiones* embodying his attempts to reconcile such apparently incompatible trends of thought as Scotism and \*Thomism, \*Kabbalah and Christianity. The alleged

heterodoxy of some theses led to a papal condemnation and a brief period of imprisonment. His project to produce a full-scale harmonization of \*Platonism and \*Aristotelianism was cut short by his early death, with only *De Ente et Uno* (1491), dealing with metaphysics, reaching completion.

**picture theory of meaning.** An account of the nature of \*meaning central to Wittgenstein's early philosophy, but which he later largely or entirely rejected. In attempting to understand the relation between language and world, Wittgenstein was struck by the analogy with picturing or modelling. Different coloured counters, variously arranged, might be used in a courtroom to model a motor-accident, for instance. Superficially, the counters may not resemble the physical objects they model, any more than propositions resemble the world; but propositions may still depict states of affairs, provided there are as many distinguishable elements within the proposition as within the situation it represents, so that the proposition possesses the appropriate pictorial form to be isomorphic to the state of affairs. Pictorial form may not be evident on the surface, but will always be revealable by deep analysis.

**pictures.** In aesthetics, following classical writers, a picture has been taken to be a mimesis, a \*representation of reality. But the word 'representation' here at once suggests the question which has absorbed recent writers. Do pictures denote as sentences or words denote? If they do, they must do so through conventions. Or do pictures resemble their objects? Either view faces problems. Why do artists accept with alacrity a new way of painting a wheel in motion if the new device is merely conventional? If pictures represent because they resemble their objects, how can a picture represent a mythological being? Flint Schier proposed a theory which he describes as 'generative'. Once you grasp that a picture represents the President then you can recognize the objects of any other pictures which use the same style of depiction. Thus we can then acquire a grasp of the method of representation from a single example; in this way learning to understand pictorial representation is quite unlike language-learning.

**piecemeal engineering.** Popper thought that politics should proceed by piecemeal social engineering rather than by large-scale reform or revolution. Because any policy will have unforeseen and often unintended consequences, we should only change institutions bit by bit and monitor carefully the effects of so doing. This is doubtless sensible advice, but regarding political activity

purely in terms of piecemeal engineering presupposes a consensus on aims and goals not characteristic of pluralist societies.

A.O'H.

\*conservatism; pluralism.

K. R. Popper, *The Open Society and its Enemies* (London, 1945).

**pietism.** Pietism, the religion of Immanuel Kant, springing from Lutheranism, influencing Wesley, and itself influenced by \*Calvinism and the Mennonites, emphasized conversion, salvation, and personal morality. In *Pia Desiderata* (1675) Philipp Jakob Spener (1635–1705) castigated corrupt conditions in the Church, and proposed various reforms. He and his followers were mocked as 'pietists', Spener said, by 'those who feared through such holiness to have their own deeds put to shame'.

**pineal gland.** This small protrusion in the centre of the brain is, in Descartes's notorious theory of mind–body interaction, singled out as the 'principal seat of the soul'. When the gland is stimulated by the \*animal spirits flowing through the nerves and brain, the soul residing in the gland will have a certain kind of sensation; conversely, when the soul wills a movement, it is able to transmit instructions to the body via the gland (*Treatise on Man* (1633)). Critics have standardly objected that positing a location for these supposed psychophysical transactions hardly removes the difficulty in seeing how an entirely immaterial substance can initiate, and respond to, physical thrusts.

**placebo.** A pharmacologically inert substance administered blind to a control group as a way of testing the active substance as a treatment for illness. Allegedly, the patient's belief in the effectiveness of a drug or treatment often brings about a cure or improvement in itself—the 'placebo effect'. This creates a bind which calls out for philosophical therapy. There may be certain conditions (warts, say) where no treatments are effective unless the patient has faith in them. How can someone who recognizes this fact be cured? Suppose I am a warty sceptic who is realist enough to realize that if I firmly believe the warts will go, then they will. How can I cultivate that belief without selling my critical soul? So far my consultants assure me I cannot avail myself of what may be the only known cure unless I surrender to irrationality. Know yourself and die! Whoever said rationality had survival value?

J.E.R.S.

**plagiarism** is not just a problem for university professors. It is the conceptual brother of \*forgery: both are defined in terms of an artefact (e.g. a poem) not being genuine, but being represented as genuine, and so represented with the intention to deceive. Genuineness has to do with authorship, or source of issue, and, roughly speaking, the

difference between plagiarism and forgery is that a person plagiarizes when he tries to pass off another's work as his own, but he forges when he tries to pass off his own work as another's. Both are prima facie morally wrong, but the more difficult question is the aesthetic one: Is there anything prima facie aesthetically wrong with either (or both)? Some have argued for a Yes answer on the basis of the role that knowledge of authorship plays in aesthetic perception and discrimination, while others have argued for a No answer on the basis of the irrelevance of plagiarism and forgery to aesthetic judgements respecting such things as cheques and articles in reference works, such as this one. Now I wonder who the author of this article really is? M.W.

There is very little philosophical literature on plagiarism, but Denis Dutton (ed.), *The Forger's Art: Forgery and the Philosophy of Art* (Berkeley, Calif., 1983) contains a number of good papers on forgery.

**Planck, Max** (1858–1947). German physicist who discovered the formula for black-body radiation. Taking his cue from Boltzmann's statistical reformulation of the second law of thermodynamics, he found that radiant energy may be treated statistically as if it exchanged only in discrete amounts involving a new constant  $h$ , subsequently known as Planck's constant. This prepared the way for Einstein's discovery that light could be treated as both wave and particle, the two aspects being related through Planck's constant. This constant took on a universal significance when physicists later extended the theory from light to matter generally, proposing that energy possessed by matter can be changed into radiant energy only in integral multiples of quanta. This set the foundation for \*quantum mechanics, which inaugurated a revolutionary break with classical physics. Planck was awarded a Nobel Prize for his contribution to physics in 1918.

The arrival of quantum mechanics gave rise to a variety of philosophical problems; it presented difficulties for \*traditional logic, constituted a challenge to scientific \*realism, and undermined deterministic views of the universe, with further repercussions in epistemology. O.R.J.

**Plato** (c.428–347 BC). The best known and most widely studied of all the ancient Greek philosophers. He was an Athenian, born into a noble family, and might have been expected to play a part in the politics of that city. But in fact he came under the influence of Socrates, who fired him with an enthusiasm for philosophy. When Socrates was condemned to death and executed in 399, Plato gave up all thought of a political career, and left Athens in disgust. It is said that he then travelled to various places, including Egypt, but we have no trustworthy information on this part of his life, until we come to his first visit to Italy and Sicily in 387. From that visit he returned to Athens, and soon after founded his \*Academy, just outside the city. This may be regarded as the first 'university'. Apart from two further visits to Sicily, in 367 and 361, he remained at the Academy until his death in 347.

It is often assumed that his first philosophical work was the *Apology*; this purports to be a record of the speeches that Socrates delivered at his trial. Apart from this one example, all Plato's philosophical works are dialogues. They are standardly divided into three periods: early, middle, and late. On the usual chronology, the early period includes *Crito*, *Ion*, *Hippias minor*, *Euthyphro*, *Lysis*, *Laches*, *Charmides*, *Hippias major*, *Meno*, *Euthydemus*, *Protagoras*, *Gorgias*. Many of these dialogues are short. They are listed here in order of length, from the *Crito* at 9 pages, to the *Euthydemus* at 36, the *Protagoras* at 53, and the *Gorgias* at 80. No one is confident of their order of composition. The usual chronology for the middle period includes *Phaedo*, *Symposium*, *Republic*, *Phaedrus*, in that order. The *Republic* is very long, and is divided into ten books. Some count the *Cratylus* as belonging to this period (placed after the *Republic*); some count it as an early dialogue. Finally, on the usual chronology for the late period, it begins with *Parmenides* and *Theaetetus*, and then (after a break) it contains *Sophist*, *Statesman*, *Timaeus* (and *Critias*), *Philebus*, *Laws*. Again there is one work which is very long, namely the *Laws*, which is divided into twelve books. The orthodox view is that this may be counted as Plato's last work, though in fact the evidence for this claim is very insecure. Another important dispute concerns the date of the *Timaeus*, which some would classify as a middle dialogue (after the *Republic*). A great deal of work has been done, and is still being done, towards establishing the order of the dialogues, but one cannot say that a consensus has been reached. (The above list simply omits all works whose authenticity may be considered doubtful.)

I. The early dialogues are our only worthwhile source for the philosophy of Socrates. They illustrate his preoccupation with ethics, and his insistence that it is vitally important to find correct definitions for ethically significant concepts, since otherwise we will not know how to live. No doubt Plato himself shared these views at the time. But he shows a more independent attitude to the Socratic claim that virtue (*\*aretē*) is knowledge, and to its associated paradoxes, e.g. that all wrongdoing must be due to ignorance (so that no one does wrong on purpose), and that all *\*virtues* must somehow be the same (so that one cannot have one but lack another). The dialogues show Plato to be very *interested* in these claims, but he is not clearly *endorsing* them. On the contrary, he seems rather to be exploring them, and recognizing the problems they involve. He can achieve this neutral stance partly because he is writing dialogues, between Socrates and other speakers, and we need not suppose that Plato believes whatever he makes his character Socrates say; and partly because most of the dialogues are anyway inconclusive. They will begin by propounding some problem for discussion, and during the discussion several answers will be proposed, but all will be rejected, so that officially no conclusion is reached. (Often one is tempted to read between the lines, to find an answer that Plato is recommending, despite its official rejection; but even so one should suppose that he is recommending it for further consideration, not for acceptance.) In these early dialogues, then, Plato is mainly concerned with Socrates' philosophy, but he is trying out lines of thought, and objections to them, and he is not confident that he has found answers. In a few cases (notably the *Meno* and the *Gorgias*) one can see that his confidence is growing, and that he has something to say which he very much wants his audience to believe. But that is because the middle period is dawning.

II. In the middle period Plato's interests broaden very considerably, and we find the metaphysical and epistemological doctrines for which he is best known. They now form the background against which he works out his new thoughts on how one ought to live, and on a number of other topics, ranging from the true role of *\*love* (*Symposium*, *Phaedrus*) to the structure of the physical world (*Timaeus*—assuming that to be a middle dialogue). There is space here only for a brief account of some of the better-known doctrines. Although Socrates remains the chief speaker of these dialogues (except for the *Timaeus*), still one can now be quite confident that the views put into his mouth are Plato's own views, and often they owe very little to the historical Socrates.

*Knowledge and the Forms.* Socrates had insisted that we must be able to answer the question 'What is X?' before we can say anything else about X. He understood this question as asking for the one thing common to all the many instances or examples of X, and he continued to stress its importance for ethical inquiry, even though he never found any answers that satisfied him. One may conjecture that this led Plato to ask *why* the search was yielding no

results, and that he came to the conclusion that it was because even the supposed instances and examples of X were unreliable. At any rate, he certainly did come to hold that, in interesting cases such as *\*justice* and *goodness* and *\*beauty*, every instance of X will *also* be an instance of the opposite to X. But this provokes a problem, for instances and examples seem to be crucial for language-learning. That is, one could not come to understand the word 'red' if there were no examples of red things, nor if every example of something red were at the same time an example of something non-red. How, then, do we manage to attach any meaning at all to words such as 'just', 'good', and 'beautiful'? This problem led Plato to suppose that there must *be* an unambiguous example of justice, not in this world but in some other, and that we must once have been acquainted with it. This is what he calls the 'Form' of justice. So his theory is that we are born into this world with a dim recollection of this Form, and that is why we do have *some* conception of what justice is, though it is only an imperfect conception, which explains why we cannot now answer the Socratic question 'What is justice?'

This is the theory of *Phaedo* 73–7. It significantly extends a line of thought introduced earlier in the *Meno*, which had noted that there is such a thing as *\*a priori* knowledge (since mathematics is an example), and had offered to explain this as really recollection of what we had once known in an earlier existence. The *Meno* had *hoped* that philosophical inquiry could yield similar knowledge of justice and the like, obtained by examination of what was already latent within us, but had offered no ground for such a hope. The *Phaedo* provides a ground, at the same time adding a new conception of what it is that must be known (or recalled), namely a paradigm example of X, a reliable and unambiguous guide to what X is, which the perceptible things of this world 'imitate', but always 'fall short of'. These are the Forms. Yet at the same time, and inconsistently, the Forms are thought of as themselves *being* the answers to the question 'What is X?', i.e. as being the one thing common to all the many instances of X, that in which they all 'participate'. In other words, the Forms are *both* perfect paradigms *and* universals. This ambivalent conception is found in all the middle dialogues (including the *Timaeus*). The associated theory of recollection (*\*anamnēsis*) is not so constantly mentioned; in fact it is restated only once after the *Phaedo*, i.e. at *Phaedrus* 249.

*The Soul (psukhē or psyche) and Morality.* In the *Apology* Socrates had been portrayed as agnostic on the immortality of the soul. In the *Phaedo* he is convinced of it, and the dialogue is as a whole a sustained argument for that claim. We find further arguments for the immortality of the soul in *Republic* x and in the *Phaedrus*, but in those dialogues there is also a more complex view of what the soul is. Whereas the *Phaedo*, like the early dialogues, had been content with a simple opposition between soul and body, in *Republic* iv the soul itself is divided into three 'parts', which roughly correspond to reason, emotion,

and desire. (But in *Republic* VIII–IX the ‘reasoning’ part is associated with the desire for knowledge, the so-called ‘spirited’ part with the desire for honour and prestige, and the ‘desiring’ part—itself recognized to be ‘many-headed’—is clearly confined to bodily desires.) An explicit motive for this division is to allow for conflict within the soul, and one consequence of this is that Plato is no longer tempted by the Socratic claim that all virtue is knowledge, and its associated paradoxes. He does retain the early view that virtue is a condition of the soul, but wisdom is now viewed as a virtue of the reasoning part, whereas courage is a virtue of the spirited part, and justice is explained as a suitable ‘harmony’ between all three parts. Another consequence of the threefold division of the soul is that Plato seems to have become uncertain how much of the soul is immortal. (*Republic* x. 611–12 is deliberately evasive; *Phaedrus* 245–9 clearly claims that the team of all three parts is immortal; *Timaeus* 69–72 is equally clear in its claim that only the reasoning part is immortal.) Plato thinks of the immortal soul as subject to reincarnation from one life to another. Those who live virtuous lives will be somehow rewarded, but the detail differs from one treatment to another.

*Political Theory.* In the *Republic* Plato sets out his ‘ideal state’. It is very decidedly authoritarian. He begins from the premiss that only those who know what the good is are fit to rule, and he prescribes a long and rigorous period of intellectual training, which he thinks will yield this knowledge. In a famous analogy, it will loose the bonds that keep most men confined in a \*cave underground, and allow us to ascend to the ‘real’ world outside, which is a world of Forms, available to the intellect but not to the senses. This is to be accomplished by a full study of mathematics, which will turn one’s attention towards the Forms, since it is an a priori study and does not concern itself with what is perceptible; and after that a study in \*‘dialectic’, i.e. in philosophical debate. Those who complete this training successfully, and so know what the good is, will form the ruling élite. From time to time they will be required to give up their intellectual delights and go back into the cave to govern it. They will govern with a view to maximizing the happiness of the state as a whole, but Plato thinks that the way to achieve this is to impose a strict censorship to prevent wrong ideas being expressed, to ensure that each person sticks to his own allotted job, so that he does not meddle with affairs that are not his concern, and so on. Plato was firmly against democracy, and seems to have seen no connection between happiness and individual liberty.

III. The late dialogues open with two criticisms of the theories of the middle period, in the *Parmenides* and the *Theaetetus*. The *Parmenides* is concerned with metaphysics, and its first part raises a series of objections to the middle period’s theory of Forms. The most famous of these is the so-called \*third man argument, which evidently exploits the fact that Forms are supposed to be both universals and perfect paradigms. Scholars differ in their

view of how Plato himself reacted to these objections. Provided that the *Timaeus* is regarded as a middle dialogue, one can hold that Plato saw that the objections depend upon Forms being both universals and paradigms, and thereupon ceased to think of them as paradigms. But if the *Timaeus* is later than the *Parmenides*, as stylometric studies appear to indicate, then one is forced to conclude that Plato made no such modification to his theory. The second part of the *Parmenides* is a riddle. It draws a bewildering array of contradictory conclusions, first from the hypothesis ‘The One is’ and then from its negation ‘The One is not’, and then it just ends without further comment. There have been many attempts to extract a serious moral that Plato may have intended, but none have won general approval.

As the *Parmenides* attacks the metaphysics of the middle dialogues, so the *Theaetetus* attacks their epistemology, but again the attack has its puzzling features. The middle dialogues (and in particular the *Timaeus*) claim that perceptible things are not stable, and for that reason there can be no knowledge of them; rather, only Forms can be known. The first part of the *Theaetetus*, however, argues that it is self-refuting to ascribe such radical instability to perceptible things, and it proceeds to assume that we do know about them. But it nevertheless insists upon distinguishing this knowledge from perception, on the ground that knowledge requires belief (or judgement) while mere perception does not. The second part of the dialogue then professes to be exploring the claims that knowledge is to be identified with true belief, or with true belief plus an ‘account’. But what is puzzling about this discussion is that it appears to focus not upon knowledge of facts (*savoir*) but upon knowledge of objects (*connaître*), and on the face of it the latter does not involve belief or judgement at all. Again, the solution to this puzzle is a matter of controversy.

Although the late dialogues begin with two enigmatic and self-critical pieces, in which Plato’s own position is once more unclear, in subsequent writings he has evidently recovered the confidence of his middle period. In the *Sophist* he gives us a new metaphysics and a more sophisticated investigation of language, in the course of a long investigation of ‘not being’. This includes the important point that even in the simplest sentences one may distinguish two expressions, \*subject and predicate, that have different roles to play. In the *Statesman* he reaffirms his view that ruling is a task for experts, and argues that the expert should not be bound either by law or by the wishes of the people. But it is admitted that law is a second best, where no expert is available. Of constitutions bound by law he considers that monarchy is best, oligarchy in the middle, and democracy worst. But in the absence of law this order is reversed. In the *Philebus* he once more weighs the claims of knowledge and of pleasure to be the good, and at the same time undertakes a full examination of what pleasure is. He does not award victory to either contestant, arguing instead for the mixed life, but knowledge is ranked higher.

In all three of these dialogues Plato pays much attention to what he calls the method of 'collection and division'. At an earlier stage he had recommended the different method of 'hypothesis'. This is introduced in the *Meno*, apparently as a device which allows us to make progress with philosophical problems without first having to answer the awkward question 'What is X?' Then in the *Phaedo* and the *Republic* it receives a much fuller exposition, and becomes Plato's account of how a priori knowledge is possible. This method makes its final appearance in the *Parmenides*, and one way of reading the second part of that dialogue is as a prolonged demonstration of its inadequacy. Meanwhile, the new method of 'collection and division' has been introduced in the *Phaedrus*, and it is then both preached and practised at some length in the *Sophist* and the *Statesman*. It is presented as a method of finding definitions, though it is clear from what those dialogues say about it that it must be handled very carefully if it is not to lead us astray. The version in the *Philebus* introduces some new, and very puzzling, considerations concerning 'the indefinite'. This appears to connect with what Aristotle tells us about Plato's so-called 'unwritten doctrines', but that topic is too obscure to be pursued here.

Finally, in the *Laws* we find Plato again building an ideal state, but now in a very different mood from that of the *Republic* and the *Statesman*. He is now much more ready to compromise with principle in order to find something that will work in practice, and he puts a very high value on the law. In fact the work is remarkable for proposing a great deal of extremely detailed legislation. But Plato's general attitude remains very authoritarian, and he still pays no attention to individual \*liberty. It is justly said that the 'Nocturnal Council', which turns out to be the supreme authority in this state, would certainly not have tolerated the subversive ideas of Socrates, from which Plato began.

**Platonism.** 'Platonism' refers to (1) the doctrines held by Plato; (2) some central doctrine of Plato, especially the theory of Forms, or Ideas, or a doctrine relevantly similar to it, such as the view (contrasting with 'constructivism') that

logical and/or mathematical entities subsist independently both of the empirical world and of human thought (Frege); (3) the tradition of thinkers claiming allegiance to Plato, whether or not their doctrines were in fact held by him.

Plato's literary career spanned fifty years, and, apart from some letters of doubtful authenticity, he wrote only dialogues in which he himself never appears, but is, at best, represented by a leading participant, usually, but not invariably, Socrates. The dialogues are commonly placed in three groups: (1) The early dialogues consider a question such as how we are to define virtue or whether it is teachable, and examine various answers to it, but do not usually endorse a positive conclusion; these dialogues and their characteristic procedures are commonly known as 'Socratic' rather than 'Platonic'. (2) The middle dialogues, such as the *Republic*, expound metaphysical, political, and psychological doctrines. It is these doctrines which are most usually associated with Plato and known as 'Platonic'. (3) The late dialogues, such as the *Sophist*, reassess and modify the doctrines of the middle period.

Even within each of the two latter periods, dialogues differ significantly in method and doctrine. Thus it is not easy to extract from Plato's works a single consistent set of doctrines. (The Neoplatonist Olympiodorus reports that Plato dreamt that he had become a swan which flew from tree to tree, eluding the arrows of its hunters. This means that Plato eludes his interpreters, and his works must be 'understood in many senses, both physically, and ethically, and theologically, and literally'.) But it is tempting to suppose that Plato had a coherent view on the questions asked and the doctrines expounded by his characters, or at least more tempting than it is to suppose that Shakespeare had a coherent doctrine that can be extracted from the utterances of *his* characters. Many interpreters have attempted to elicit a system from Plato, among them Hegel, who, regarding (unlike Schleiermacher) the dialogue form as inessential, attributed to him a tripartite system consisting of \*dialectics, philosophy of nature, and philosophy of spirit. Most 'Platonists' have seen themselves as such by reason of their adherence to supposedly Platonic doctrines rather than to Plato's methods or his dialogue form. But different thinkers stress different aspects of his legacy.

Platonism as a tradition falls into six broad periods: (1) the Old Academy; (2) the Hellenistic ('Middle' and 'New') Academy; (3) ancient \*Neo-platonism; (4) medieval Platonism; (5) the Renaissance; (6) the modern period.

1. After Plato's death, his nephew Speusippus (405–335 BC) became head of the \*Academy, and he was succeeded in 339 by Xenocrates (396–314 BC). (The reason why Plato's most distinguished pupil, Aristotle, did not succeed him is probably that, as a non-citizen, he was unable to own property in Athens, rather than, as Anscombe suggests, his heterosexuality.) They continued to work, in the manner of Plato's later work, on metaphysics, logic, and mathematics.

2. Under its sixth head, Arcesilaus, the Academy espoused \*scepticism and deployed it especially against

Stoicism. Carneades continued and extended this approach. Academic scepticism stressed its continuity with the early aporetic dialogues, and persisted for two centuries. Augustine's *Contra Academicos* (AD 386) is directed against the scepticism that he knew from Cicero's *Academica*, but he attempted to reconcile this with the Neoplatonism he had learned from Plotinus by arguing that the Academy had a secret doctrine which they did not reveal to outsiders. Under Antiochus of Ascalon (c.130–68 BC) the Academy abandoned scepticism and adopted a synthesis of Platonism, \*Stoicism, and \*Aristotelianism.

3. Antiochus prepared the ground for so-called 'Middle Platonism', represented by, among others, the anti-Christian Celsus (late second century AD). In the second century Numenius of Apamea attempted to purge Platonism of later accretions and regarded the result as identical to \*Pythagoreanism. But the greatest Middle Platonists were in Alexandria: Philo (c.25 BC–AD 50), who combined Platonism with Judaism, Clement (c.AD 150–215) and, later, Origen (185–254), who, like Plotinus, was a pupil of Ammonius Saccas (c.175–242), generally regarded as the founder of Neoplatonism. (The distinction between Middle Platonism and Neoplatonism is not, however, sharp: from the first century BC Platonism was transformed into a metaphysical or theological system, involving, for example, ideas as thoughts in God's mind, the ideal of assimilation to God, and demonic intermediaries between men and God; the aporetic element in Plato was ignored.) The Alexandrians became Christian, and were less inclined to theurgy than the pagan Athenians. Plotinus, the greatest of the Neoplatonists, was not a member of the Academy, nor was his follower Porphyry (c.232–304), the author of an introduction (*Isagoge*) to Aristotle's *Categories*, which in Boethius' Latin translation, became a standard medieval work, nor Iamblichus (d. c.330). Iamblichus was responsible for many of the concepts, especially the triads, that appear in Proclus. The Academy was closed by Justinian in AD 529 (whereas the Alexandrian school survived the Arab conquest of 641), but through the works of Augustine (Plotinus) and pseudo-Dionysius the Areopagite (Proclus) Neoplatonism entered medieval Christianity.

4. Platonism persisted in the three main spheres of the medieval world: Islam, Byzantium, and the Latin West. Its impact on the Arabs, with their predominantly scientific interests, was less than that of Aristotle. But al-Fārābī was influenced not only by the ideal state of Plato's *Republic*, but also by the entirely apolitical Plotinus. His follower Avicenna developed Neoplatonism further. In Byzantium, Plato's dialogues continued to be read, and the revival of Platonism by Michael Psellos (1018–78/96) prepared the way for the later champions of Plato against Aristotle, Basilios Bessarion (1403–72) and Georgios Gemistos Pletho (c.1355–1450). They propagated Platonism in Italy, and Pletho inspired Cosimo dei Medici to found a new Platonic Academy in Florence in 1459. It was headed by Marsilio Ficino (1433–99) and attracted Greek refugees from Constantinople, who brought with them hitherto unknown Platonic texts. It lasted until 1521. In

the West, the philosophical works originally available were Platonic: Plato's *Timaeus*, Boethius, Apuleius (the author of works on Socrates and Plato, as well as of *The Golden Ass*), and Augustine. Later John Scotus Eriugena (c.810–77) translated Dionysius. (That *The Divine Names* etc. were not the work of the Athenian converted by St Paul was suspected by Lorenzo Valla (1405–57) and finally established by Erasmus. Earlier it was widely believed that Platonists such as Proclus had stolen his ideas.) But by the thirteenth century, despite more translations of Plato and Proclus, Aristotle eclipsed Platonism.

5. In the Renaissance, Plato became a focus of rebellion against scholasticism, and the need was felt for direct acquaintance with his texts. Eventually, though not immediately, this tended to undermine the so-far-unquestioned Neoplatonic interpretation of Plato. Petrarch (1304–74), though he had 'no Greek', championed Plato, 'the prince of philosophy', against Aristotle. Ficino translated Plato, Plotinus, and Hermes Trismegistus (the supposed author of a body of early post-Christian writings, which Ficino believed to be the work of an ancient Egyptian priest and one of the sources of Platonism). He produced a sustained defence of Plato's doctrine of the immortality of the soul, and regarded him as a forerunner of Christianity, in a tradition of 'pious philosophy' extending from Zoroaster to Nicholas of Cusa. Pico della Mirandola was also influenced by, among others, Plato, and was associated with Ficino's Academy. Platonism migrated to England through Erasmus, Thomas More (1478–1535), and others, giving rise to the \*Cambridge Platonists, who, as Coleridge observed, could as well be called the 'Cambridge Plotinists', since they revered Plotinus and did not doubt his interpretation of Plato.

6. In Ficino's day the only rival to the Neoplatonist interpretation of Plato was the persistent, if sometimes muted, tradition that Plato was a New Academic sceptic. This view, backed by the authority of Cicero, revived in the late fifteenth century: among its adherents were the Lutheran reformer Philip Melancthon (1497–1560) and the French sceptic Michel de Montaigne (1533–92). But a third view now began to form, namely that Plato had a positive doctrine, distinct from Neoplatonism, and that this could be discerned from his original texts. This view appealed to Protestants, who deplored the Neoplatonic influence on Christianity but often found Plato himself more tolerable. One of its pioneers was Jean de Serres (Ioannes Serranus) (1540–98), a Calvinist Huguenot, who contributed a Latin translation and an introduction to Henricus Stephanus' famous 1578 edition of Plato. Its most distinguished adherent was Leibniz, who on several occasions bemoaned the tendency to read not Plato but his commentators: we can recover such valuable doctrines as the theory of Ideas and recollection only if we remove the Neoplatonic covering. This view was confirmed by the history of philosophy, which emerged, especially in Germany, as a distinct discipline, alongside theology and philosophy itself: Jakob Brucker (1696–1770), Dietrich Tiedemann (1748–1803), Wilhelm

Tennemann (1761–1819), and Hegel, whatever the faults of their own attempts to reconstruct Plato's doctrines, finally demolished the Neoplatonic interpretation. (Like Friedrich Schleiermacher (1768–1834), Hegel dismisses Tennemann's view—which still finds supporters—that Plato had an 'esoteric' system which he did not commit to writing.) The discovery of the 'real' Plato also put an end to Platonism as a distinct and credible large-scale doctrine, partly because the dialogues cannot be plausibly read as advocating a definitive creed, and partly because they are usually interpreted as presenting a primitive version of some more developed modern philosophy, such as Kantianism (Tennemann) or Hegelianism (Hegel), which the interpreter believes in preference to Plato himself.

However, Plato provides an ingredient, often an essential ingredient, in much of subsequent Western philosophy. Galileo, for example, was a Platonist, not in the sense that he endorsed the mathematical theories of the *Timaeus*, but because he distinguished between the appearances of nature and its true mathematical structure, the latter being the object of true knowledge. Quasi-Platonic ideas play an important role in Kant and Schelling. In Schopenhauer ideas are what art, apart from music, portrays, and (contrary to Plato's own intentions) Plato has often been of service both to artists and to philosophers of art. Moreover, even in modern times Plato is often seen as containing in embryo the whole of Western philosophy; thus any serious philosopher must come to terms with him, whether as an ally or as an opponent. J. F. Ferrier (1808–64) claimed that 'all philosophic truth is Plato rightly divined; all philosophic error is Plato misunderstood', and Whitehead saw later philosophy as a series of \*footnotes to Plato. Nietzsche regarded Plato in this light (e.g. 'Christianity is Platonism for the people'), but since he rejected Plato's claim to a non-perspectival insight into true being, he saw his own thought as 'inverted Platonism'. For Heidegger, Plato initiated the decline of truth from 'unhiddenness' to 'correctness', and thus gave rise to the metaphysics and humanism that afflicted all later philosophy, including Nietzsche's. He also lectured, in 1924–5, on Plato's *Sophist*, in preparation for his revival of the 'question of \*being'. Jaspers interpreted Plato in terms of his own thought, and saw him as the 'representative of philosophy in general', an open-ended thinker more concerned with philosophizing as a way of life than with the advocacy of specific doctrines. (Sartre's *Being and Nothingness*, by contrast, refers only fleetingly to Plato's *Sophist*; but his early story *Er the Armenian* was inspired by the Myth of Er in the *Republic*.) While Platonism as a full-scale doctrine is no longer a live option, modern philosophers, including analytical philosophers such as Ryle, have often developed their own ideas, and their powers of argumentation and interpretation, in interaction with Plato. **Platonism, Neo-**: see Neoplatonism.

**plausibility.** A weaker counterpart to \*truth. It turns on a claim's credibility via the acceptance-justifying backing that a duly weighty source (human, instrumental, or methodological) can provide. Thus if we think of informative sources as being graded by reliability, then the plausibility of a contention is determined by the best authority that speaks for it. A proposition's plausibility accordingly depends on its probative status rather than on its specific content in relation to alternatives. In this regard it differs crucially from \*probability. The plausibility status of a group of conjoined propositions (unlike its probability status) is that of the least plausible of its members: plausibility is a chain that is as exactly strong as its weakest link. **pleasure.** Philosophers have discussed the nature of pleasure from an interest either in \*hedonism, or in \*philosophy of mind. The former was the main interest up to the mid-twentieth century.

*Ancient Greece.* A popular early view was to see pleasure as the replenishment of a natural lack; for instance, quenching thirst. This was modified by adding that the replenishment must be noticed. It was then realized that some pleasures involved no replenishment, as those of anticipation, or enjoying the exercise of abilities. Aristotle came to see pleasure as the perfect actualization of a sentient being's natural capacities, operating on their proper objects. This, however, is the account of 'real' pleasure, and other pleasures are approximations to this on the part of beings not in perfect condition. With humans, Aristotle holds that those who enjoy something are aware of that fact. This makes it natural to suppose that those who experience pleasure believe that they are actualizing in good condition—correctly in the case of those who are, falsely in other cases. The Stoics, taking familiar pleasures as their model, thought of pleasure as such a belief, and as false.

*Later.* These views set the parameters for later discussions up to the time of Descartes. The latter's sceptical arguments led the Empiricists in particular to concentrate on the inner data of the mind as what we really know. Since it seems that subjects know what they enjoy, it seemed natural to class pleasure as one of the inner givens of the mind. To English-speakers this seemed the more natural because pleasure would be classified as a feeling. Pleasure now becomes the experience of a feeling from some source or other. Then either all these feelings feel alike, or

they share some hedonic tone, or they have the characteristic of being wanted for their own sake, or preferred.

*Early to Modern.* In the early period there is no sharp distinction made between an interest in the concept of pleasure and in what it is that occurs when pleasure occurs. The latter, however, seems to predominate. By the time of Hume matters are muddier. In the twentieth century, interest shifted to philosophy of mind, to whether attributions of pleasure are attributions of publicly accessible facts or of inner events. Given that the attributions are in a public language, philosophers have turned to consider the meanings of various pleasure-expressions, with the assumption that criteria for their application will be publicly accessible. Attributing pleasure has been variously thought to be attributing a manner of indulging or a relation of the indulgence to a subject's desire or preference.

The discussion has been complicated by distinctions between enjoyment and pleasure, and the variety of pleasure-expressions. There are methodological problems: how do we determine that the expressions cover the same concept? or that different uses of the same expressions are genuine examples of the concept?

None of the above questions have won agreed answers, but the answers clearly affect one's attitude to hedonism. Different answers on the nature of pleasure give hedonism a different air; different selections of pleasure-expression give arguments for different forms of hedonism. None of them work.

**plenitude, principle of.** 'If a proposition *P* is possible then at some time *P* is true.' The principle, accepted by Aristotle, clashes with a common intuition that the non-realization of a \*possibility does not imply that the possibility did not exist. The question how to interpret Aristotle's principle

in such a way that it squares with the common intuition has proved a fertile debating-ground.

A.BRO.

Arthur O. Lovejoy, *The Great Chain of Being* (Cambridge, Mass., 1936).

**Plotinus** (204/5–270). Platonist philosopher, initiator of what we call \*Neoplatonism. We do not know his origins. He studied for over eleven years at Alexandria. Then he joined a Roman military expedition to the East, in order to learn from Persian and Indian philosophers (so says his editor and biographer Porphyry). But the expedition was aborted, and he came to Rome, aged 40. There he earned court patronage and spent the rest of his life teaching. From the age of 50 he wrote in Greek a series of essays and shorter articles, chatty in style but at the same time difficult and earnest, and enriched with superb similes. After his death Porphyry chopped them up and gathered them into six groups of nine, the *Enneads*.

Plotinus was a contemplative, who sought contact with a supreme principle, the Good, or One. He tells us that he often achieved momentary success. Religious rites were useless for the purpose; what was needed was an ascent of the soul, away from bodily things. It demanded personal goodness—and Plotinus appears to have been conscientious and competent in his help and advice to friends, though he deprecated involvement in public affairs. It also demanded hard philosophical inquiry.

His teaching defended the metaphysics that made this ascent desirable, and to the defence he brought a good scholar's knowledge of the state of his subject and also a good teacher's willingness to share and examine his pupils' difficulties on a footing of equality. Even his deference to Plato, whom he used only selectively but revered as faultless, does not really imprison Plotinus' thought, though it sometimes strains the ingenuity of his interpretations. He takes no notice of Christianity.

The essence of his metaphysics is: It is only possible to make things by thinking them, and to think things as a maker by being them. (It is backwards to regard thinking as *imagining*; it is *realizing* what the manufacturer then makes an image of.) Bodies are phantoms (\*'idols'), present in matter as an image is in a mirror, and the realities behind them are Forms. But even a thinker will produce only an idol unless the Forms he thinks are in him, and thus collectively are him. Original thought, which does not reason from previous thoughts, Plotinus calls Intellect. So Intellect is a maker. But there is no process in its making, only the timeless activity of thinking the intelligible Forms that it is.

Everything that has power must exercise it, by what he calls emanating (or 'beaming') something less powerful. Such 'procession' (as it is also called) accounts for the existence of the perceptible 'here' (our world), beamed from the intelligible 'there'. 'Here' contains \*souls as well as bodies, because many bodies—including the perceptible universe itself—are alive (i.e. ensouled), and their souls have spontaneously descended from, and can return to, 'there'. Human souls have parts, and the highest part is

still linked with Intellect 'there'. We humans choose which part our souls shall 'incline' to, and thereby we gain different future lives as plants or animals or demons (in no bad sense) or gods. These future lives will reward and punish us, so keeping the moral balance in our necessarily imperfect but providentially ordered 'here'.

Soul is the lowest of Plotinus' three universal principles, or 'hypostases'. It depends on Intellect, which in turn depends on the One, or Good. The One himself is 'beyond being', because attribution of being or any other predicate would make him more than One. The other hypostases are multiple (for example, the thoughts that Intellect is a composite), and therefore could not exist independently of this Unity. Desire to touch him is the pang of being smitten by 'beauty above beauty'.

**pluralism:** see monism and pluralism.

**pluralism, political.** A condition marked by the multiplicity of religions, ethnic groups, auto-nomous regions, or functional units within a single state; or a doctrine that holds such a multiplicity to be a good thing. The alternative is a unitary state where one religion or ethnicity is dominant and the central government rules everywhere. Pluralism can be an adaptation to an existing and unavoidable multiplicity for the sake of peace (\*toleration) or it can be a programme aimed at sustaining cultural difference, conceived as a good in itself or as the legitimate product of communal \*self-determination. A considerable variety of institutional arrangements are consistent with pluralism in either of these senses, including decentralized government (federalism), functional autonomy (particularly with regard to education and family law), and voluntary association.

The hard questions posed by political pluralism mostly have to do with its limits. It isn't only a multiplication of groups but also of loyalties that pluralism legitimizes. And in the case of individual men and women, multiplication is also division. Attachment and obligation are both divided: what then is the individual to do when their various versions come into conflict? At what point is division incompatible with a common citizenship? States committed to pluralism will set this point fairly far along the continuum that extends from unity to disintegration. None the less, they are likely to defend some significant commonalities: a single public language or a civic education for all children or a 'civil religion' with its own holidays and ceremonies.

Political pluralism also refers to the existence of legal opposition parties or competing interest groups in a unitary state, where what is pluralized is not culture or religion but political opinions and conceptions of material

interest. The ruling group, whatever its character, concedes that its ideas about how to govern are not the only legitimate ideas and that its understanding of the common good must incorporate some subset of more particular understandings.

**plurality of causes.** A term sometimes used where more than one cause is required for a particular effect, e.g. ignition plus oxygen for an explosion, or (more frequently) where alternative causes can produce the same (type of) effect, e.g. poisoning or decapitation cause death. Arguably, such cases are only apparent, and further analysis would indicate the 'true' causal relationship, which is claimed to be always one-one. The latter view—not required by counterfactual analyses of \*causality—encourages, for example, monetarism in economics.

J. L. Mackie, *The Cement of the Universe* (Oxford, 1974).

**pneuma.** Breath, sometimes equated by the Greeks with air, the breath of the cosmos. Aristotle thought that heat in the *pneuma* enables the transmission of sensitive soul to the embryo, and that it is located near the heart in the mature organism, serving to mediate movement and perception. The Stoics thought of it as a fine, subtle body forming the \*soul of the cosmos, and explaining growth, behaviour, and rationality. Descartes used the Latin equivalent, *spiritus*, from which come 'spirit' and 'sprite' in English.

**poetry.** No satisfactory single-concept theory of poetry has been produced: a poem is not essentially a representation, or essentially expression, or essentially a formal or 'organic' unity. Not because none of these functions is relevant to poetry, but because no one of them does justice to its complexity and many-levelled nature.

Poetry can indeed represent or describe: but it may also celebrate, praise, mourn, present alternative worlds. It certainly expresses, but it can also transform, the emotions of ordinary life, and display emotions with more than usual precision, not least because of the discipline and constraints of poetic *form*.

Distinctive of poetry at its best is an 'all-in', maximally dense, simultaneous deployment of linguistic resources—sound and rhythm as well as sense, the bringing-together of numerous strands of meaning, through metaphor and other figures, through ambiguities (often unresolved),

controlled associations and resonances, allusions: all of these contributing to a well-integrated, unified effect.

The reference a poem makes to the world is often given a heightened, pregnant character through symbolical or allegorical or mythical language—in some cases the personal mythology of the poet. (William Blake and W. B. Yeats are notable examples.)

Given the total dependence of the poem's meaning and effect on the precise words in their order, any attempt at paraphrase must become 'heresy'. A poem is not a disposable wrapping for a detachable and re-expressible message.

Now, this emphasis on the thinglike integrity of a poem makes for suggestive analogies between poems and non-linguistic artefacts (a vase, sculpture, or melody): hence a claim like 'A poem should not mean but be' (MacLeish). But this exaggerates: meaning is indispensable—as is reference to the world beyond the poem—if poetry is not to be impoverished: and, in any case, the sound of words can hardly work in sustained disregard of their sense.

The subject-matter of poetry is limitlessly varied. Often enough a poem presents some vividly imagined concrete particular, a momentary, fugitive sensory impression or a recollected emotion, but also—and no less legitimately—its concern may be with abstract ideas and relationships, or with a wide-ranging religious or metaphysical perspective. Crucial here is the absence of any hierarchy of poetic subject-matter: 'ontological parity', in Justus Buchler's phrase: 'All appearances are realities for the poet.'

The relevance to philosophy of the study of the language of poetry is already obvious enough. But there is more to note. Poetry is forever fighting against the pressures and seductive power of ordinary language to falsify experience in easy, slack cliché. Poetry feels itself often up against the 'limits of language', and forced to modify, maybe do violence to, normal syntax. Theory of knowledge and philosophy of religion cannot ignore poets' claims to 'timeless (visionary) moments'—'epiphanies'.

That is easy to say: but to distinguish veridical from illusory in this area is notoriously hard.

**Poincaré, Jules Henri** (1854–1912). A leading contributor to the brilliant French tradition of applied mathematics and physics, Poincaré also wrote extensively on \*methodology and the philosophy of science, in which he is usually classified as a conventionalist. He regarded scientific structures as containing conventional elements which either are principles held to be true by definition or are selected from competing alternatives on pragmatic grounds of \*simplicity and convenience. But science must also be empirically adequate, and so Poincaré could also be called a metaphysical realist, since science is based on a belief in the unity and simplicity of nature, and it is the (endless) task of science to discover the most general order. But like Duhem, Poincaré distinguished sharply between scientific and metaphysical claims. Although never fully

developed, Poincaré's ideas were influential on scientists like Einstein and on later positivist and pragmatist philosophers of science.

**polar concepts.** When a pair of \*concepts opposite in meaning is such that neither of the pair can be understood unless the other is understood also, as with 'genuine-counterfeit', 'straight-crooked', 'up-down', they are said to form a 'conceptual polarity'. Ryle used the notion in an attempt to refute scepticism by arguing that if, as the sceptic's argument requires, we understand the concept of error, we must also understand that of being right; which Ryle thought proved that we must sometimes be so.

Ryle misses the sceptical point, however. The sceptic can grant that we might have to understand the conceptual polarity 'error-correctness' in order to understand the concept of error, but simply demands how we know on any given occasion that we are not in error. And the sceptic need not even grant so much: he can point to apparent polarities which are such that one of the poles has no clear application, as in 'mortal-immortal', 'perfect-imperfect', 'finite-infinite', where we can only be said properly to understand one of the poles, the other being merely its indefinite negation, possessed of no unequivocal sense or use.

\*scepticism.

Gilbert Ryle, *Dilemmas* (Cambridge, 1954), 94 ff.

**Polish notation.** Logical symbolism devised by Łukasiewicz. Propositional constants represented by capital letters:  $Kpq$  is 'p and q',  $Apq$  is 'p or q',  $Cpq$  is 'if p, q', and so on. Similar devices are used for quantifiers and modalities. Because \*constants are written before their \*arguments, the ambiguity of expressions like 'p and q or r' is removed without using brackets: '(p and q) or r' is  $AKpqr$ , while 'p and (q or r)' is  $KpAqr$ .

A. N. Prior, *Formal Logic*, 2nd edn. (Oxford, 1962).

**Polish philosophy.** Political philosophy, especially concerning nationhood, and formal logic—these have been two areas of distinction for Polish philosophy. Although philosophy in Poland goes back to the thirteenth century and Witelo, famous for his works on optics and the metaphysics of light, its real academic life began at the University of Cracow (established in 1364) in the fifteenth century. Subsequently all the controversies of medieval philosophy were addressed in Poland. Jan of Głogów, Michał of Wrocław, Jan of Stobnica, and Benedykt Hesse were among the most important Polish schoolmen. Conciliarism became a dominant position among writers working on political matters. Paweł Włodkowic (Paulus Wladimirus) was perhaps the most famous Polish thinker of that time. He developed the concept of just war, which

influenced the development of international law. According to Paweł, it is prohibited by natural law to convert pagans to Christianity by war.

During the \*Renaissance (the golden period of Polish culture), Copernicus was the nation's most remarkable thinker. Although he was not particularly interested in typical philosophical questions, his astronomical work had obvious philosophical sources. His mathematical approach to astronomy had its roots in Padua in Italy, where he studied and became influenced by Platonism. He combined this view with the Aristotelian empiricism of his Cracow teachers. A famous controversy as to whether he was an instrumentalist or realist in his approach to heliocentric astronomy influenced many subsequent scientific discussions. The Polish Renaissance was also a period of intensive development in political and social philosophy. Andrzej Frycz-Modrzewski wrote a treatise *De republica emendanda* (1551) in which he proposed a deep programme of reforms of the state, church, and society. Similarly, as in Western European countries, the Renaissance brought a revival of \*Stoicism in Poland (*Dialectica Ciceronis* by Adam Burski is a particularly valuable work in this tradition).

The Reformation brought into being another important stream of philosophical thought, namely Socinianism, a movement established by Faustus Socinus, who came to Poland (then the most tolerant country in Europe) from Italy, and developed by the Polish Brethren. Joachim Stegmann, Samuel Przykowski, and Andrzej Wiszowaty contributed to Socinian philosophy: they focused on ethics and social philosophy, basing their doctrines on the ideals of non-violence, justice, and tolerance. The Counter-Reformation policy forced the Socinians to emigrate from Poland. They moved to the Netherlands and England, and influenced several great European philosophers, including Grotius and Locke. The early post-Renaissance period in Poland was marked by the return of \*Aristotelianism with Sebastian Petrycy of Pilzno, the first translator of Aristotle into Polish.

The period of 1650–1750 witnessed a deep political and cultural crisis in Poland. The \*Enlightenment brought a major change. It happened in close connection with attempts to save Polish independence, which was imperilled by Russia, Prussia, and Austria. Stanisław Staszic and Hugo Kołłątaj were the most important political thinkers in Poland in the eighteenth century. Their ideas considerably influenced the content of the 3 May Constitution (1791), the second constitution in nation's history. A type of \*positivism (Jan Śniadecki) was the most popular philosophy of the Polish Enlightenment, but \*Kantianism and \*Scottish philosophy were also fairly influential.

Poland finally lost its independence in 1795. Subsequent philosophy was largely a response to the national tragedy, deepened by the defeat of the national uprising in 1830–1. The philosophy of this period (approximately until 1863) is called the Polish national philosophy. This philosophy was related to \*Romanticism and to German \*idealism. Polish Messianism, which originated with Józef

Hoene-Wroński (also a famous mathematician) and was represented by great Polish national poets (notably Adam Mickiewicz and Juliusz Słowacki), attributed to Poland a special historical role as the Christ of nations and promised a new era. Józef Gołuchowski, Józef Kremer, Karol Libelt, Bronisław Trentowski, and August Cieszkowski (he invented the term 'Historiosophie') developed other kinds of the Polish national thought, more akin to academic philosophy. The defeat of the national uprising (1863–4) led to a strong criticism of the national philosophy in Poland. It was accused of unrealistic and irresponsible political claims, harmful to nation and individuals. The group of Warsaw positivists, influenced by the ideas of \*Comte, \*Mill, and \*Spencer, demanded that Polish thought be sober and strongly rooted in reality. Polish positivism recommended a programme of foundational work in all domains important for society.

Philosophical life in Poland intensified at the turn of nineteenth century, and this continued in independent Poland after 1918. Kazimierz Twardowski, a student of Brentano, established an analytic movement at the University of Lvov, and between 1918 and 1939 the Lvov group grew into the Lvov–Warsaw School, in which the main figures were Jan Łukasiewicz, Stanisław Leśniewski, and \*Alfred Tarski. Polish mathematical logic developed partly as a result of Twardowski's programme of \*analytic philosophy, partly out of the interests of Polish mathematicians in set theory and topology. Its innovations included many-valued logic, general metamathematics, the \*semantic definition of truth, Leśniewski's systems, and Chwistek's systems. The Lvov–Warsaw School had affinities with the \*Vienna Circle, but eschewed its anti-metaphysical radicalism and was more sympathetic toward the philosophical tradition. \*Kazimierz Ajdukiewicz and \*Tadeusz Kotarbiński were other distinguished exponents of Polish analytic philosophy. \*Phenomenology flourished in Poland—it was \*Roman Ingarden who introduced Husserl's ideas and developed a realistic version of phenomenology. Neo-Thomism was also influential.

After 1945 Poland became part of the Communist bloc. While Marxism was dominant, other currents persisted in Polish philosophical life, and this phenomenon, unique in Eastern Europe, contributed to the anti-Communist revolt in 1989. At present, analytic philosophy, phenomenology, and Catholic philosophy are the main features of the philosophical map. But pluralism, respect for logic, and sensitivity to the essential problems of national life remain characteristic of Polish philosophy. In spite of honouring idealistic Messianism as the glorious past, most Polish philosophers are inclined to realistic and anti-speculative thinking. J.WOL.

**political obligation.** The sense or fact of being bound to obey the laws of a political community and the commands of its legally constituted officers and/or to act consistently in ways that serve the common good. Principled refusals of obligation can take the form of treason, rebellion, passive resistance or disobedience, and conscientious objection (the last of these is sometimes legally recognized in specific cases; military service is the most common example). How an individual, originally free of all bonds, comes to be obligated is perhaps the central question of liberal political theory. It is usually answered by pointing to some intentional act or presumed show of intention, taken as the political equivalent of a promise. (\*Consent.) Just as unreasonable promises (to live as a slave or to commit suicide) or promises made under duress or without full understanding are not binding, so with acts of consent: free individuals cannot obligate themselves to obey a dictator or a totalitarian regime (the political equivalent of accepting slavery); even more obviously, unfree individuals cannot do so: their declarations of commitment have no moral effect at all.

Political theorists from other traditions (conservatives, communitarians, rationalists of various sorts) who doubt the liberal starting-point, the reality of original freedom, commonly regard individuals as bound whether they consent or not—born bound or objectively constrained. But they too must address the limits of this obligation, arguing either that only regimes of a certain sort (which maintain just social arrangements or support the good life or are, at least, very old) can bind their subjects or that individuals are released from pre-existing obligations by specific acts of tyranny or oppression.

It is entirely possible, however, to deny the existence of anything like political obligation. On this view, there are only moral duties, which sometimes require individuals to obey, sometimes to disobey, the laws of the state, sometimes to serve, sometimes to refuse to serve, the interests of the community. Since political communities are always morally imperfect, no general obligation is possible; judgement is necessary at every moment. If this is right, then citizenship loses much of its specific moral character. For a citizen, as the term is usually understood, is a person with a particular set of political obligations—to these other people (fellow citizens) and to the community they constitute. Some of the actions that follow from such obligations would still be morally required, but they would now be required of all capable persons. The particularist reference, however, might well be immoral, since it deprives non-citizens of equal attention and regard, and hence is required of no one at all.

Assuming that there is such a thing as political obligation, it is an interesting question whether it is singular in character: are all obligated persons bound in the same way or to the same degree? Other particularist obligations (to

friends or relatives, say) vary in their intensity and reach depending on the nature of the relationship and of the commitments actually made. The test case here is perhaps the resident alien, who is commonly conceived to have some, though not all, of the obligations of a citizen. But what about citizens variously disadvantaged or disengaged or committed elsewhere? Can all citizens be equally bound to vote, pay taxes, serve on juries, and so on, even though they are not equally benefited by these activities and by the acts of state they make possible, and even though they are not equally committed to or equally approving of this political regime and its characteristic works? **political philosophy, history of.** Political philosophy evaluates social organization, especially government, from an ethical viewpoint, but also studies the facts about social organization. There are thus two not sharply distinguishable aspects of political philosophy, and how they ought to be related is a good question: the ethically normative aspect ('ethics'), and the descriptive-explanatory. Arguably, some close connection between these aspects is necessary for political philosophy to flourish, and the history of political philosophy can be interpreted in this light. Among ethical concepts, \*autonomy, or \*freedom as rational self-determination, is central, but other concepts, including \*justice, \*democracy, \*rights, and \*political obligation, are also fundamental. The important concepts of a political philosophy must be combined coherently into an account of a properly structured and functioning community. In the history of political philosophy, the term 'community', or its synonyms or translations, is sometimes prominent, sometimes not, and when used it may have very varying meaning. Political philosophy as such, however, arguably tends to aspire to an account of a appropriately structured and functioning community, with its main constitutive institutions and values. Which institutions are emphasized is one of the interesting variables in the history of political philosophy. Institutional detail, for example, provides an essential framework for interpreting what is meant by autonomy, if that notion plays a role in a political philosophy.

Plato's *Republic* is the beginning. This colossal work, whose main subject is justice in the individual and the state, contains conceptual analysis crucial for both ethics and descriptive-explanatory inquiry. Plato attempts to define what justice is, first as a matter of individual just action, and eventually as a characteristic of the just individual and the just society. Plato wishes to show how, for the individual, being just can be a good in itself. In the just individual, the three parts of the psyche are so ordered that reason rules, the 'spirited' part of the psyche responds to

reason, and the appetites obey. In the just state, there is a supposedly corresponding clear division of classes among the rulers (qualified as such chiefly by personal capacity, eugenics, careful and lengthy education, life conditions including absence of personal property and of family, and ultimately a knowledge of the Form of the Good), the soldier auxiliaries, and the bulk of the population. We should value justice not only for its extrinsic advantages, but also for its own sake, because only when just are we really happy or flourishing. Arguably Plato has a concept of autonomy (and may well be an important contributor to the theory of autonomy) but thinks it is a realistic goal only for the few who are fit to rule, in contrast to some later authors who expand the group whose autonomy ought to be expressed or promoted through politics. Arguably, also, Plato's approach to political philosophy is weakened by his utopianism and his anti-empirical theory of knowledge, dominated by a certain picture of mathematical knowledge. Plato's attack on the arts is another notable feature of his views. It suggests to some modern readers that Plato's notion of reason ruling in the individual and community downgrades much emotion, especially sympathetic identification across class lines. The arts as institutions in Plato's community are to be subject to strict state controls. Plato's political philosophy, although anxious about arts institutions, thus at least pays them the tribute of close attention.

Aristotle, Plato's student, like him insists that the city state (*polis*) is higher than the individual. In this sense, community matters more than the individual for Aristotle, as it did for Plato. Aristotle is often said to be more empirically minded than Plato. His aversion to \*utopianism, his classification of different sorts of constitutions and states, and other points are often adduced to show that Aristotle emphasizes more than his teacher the descriptive-explanatory component of political philosophy. Although this is true, Aristotle's work in ethics and his politics cannot be understood apart from one another. The point of ethical theory is the improvement of moral education, carried on especially though not exclusively by the *polis*. The statesman should apply ethical theory to promote happiness (*eudaimonia*), an activity of the soul in accordance with virtue. The promotion of happiness requires morally educating persons into the appropriate virtues. Arguably Aristotle is a 'perfectionist' in politics (who thinks a social system is justified by producing some persons of excellence, rather than by taking account of the flourishing of all). He has been criticized for toleration of slavery and the subordinate status of women, cultural chauvinism (including his low estimation of non-Greek 'barbarians'), and his acceptance of class divisions. As to autonomy, some think Aristotle lacks the notion. It might be argued, however, that Aristotle's virtue of practical wisdom (*phronēsis*) comes close to doing some of the work that autonomy does in some later philosophers. The person educated into *phronēsis* has a capacity to recognize the relevant principles or reasons in deciding what to do, in relation to happiness or flourishing. Like any virtue or

vice, *phronēsis* is in some sense allegedly voluntary, and one deserves praise for it, although this is in some ways puzzling. The virtues and vices in general require a good *polis* for their development, which suggests that it is not entirely up to the individual whether to become virtuous or vicious. Aristotle never resolves this apparent conflict between ethical assessment and his explanation of how virtue develops.

Little will be said about the period between Aristotle and the rise of modernity. This is not for lack of important political philosophy, such as Augustine's *City of God* or Aquinas's extension of Aristotelianism. Perhaps the major issue bequeathed to Western modernity by Augustine and by Aquinas and others from the medieval part of that period is the question of the proper relation between religious authority and political authority. (One way to express this question is to ask for an account of human community that appropriately combines religious and political institutions.) Aquinas in particular expounds views which give human government the role of providing the conditions for attainment of ultimately religious goals. His views allow human government some authority, which may, however, be resisted under certain circumstances, when it deviates from its proper function. The question of the proper role of religious and political institutions in a community is still very much alive.

Thomas Hobbes's political philosophy might be viewed as an attempt to lay the foundation for what was developing as the modern secular nation state. Hobbes none the less and very logically also discusses various non-governmental institutions supportive of government and fitting into a larger picture of community. The Hobbesian community, however, with its tendency towards individualist egoism, is very far from what some have meant by the notion of community. In his *Leviathan* Hobbes insists on the importance of avoiding by means of a strong sovereign the war of all against all of the \*state of nature. Given men's desires, it is rational for them to agree to abide by the laws of a sovereign who provides them with security. Despite Hobbes's authoritarianism, his work also leads to the thought that if the sovereign does not provide appropriate protections, the point of abiding by the law is lost. Hobbes is much influenced by materialism and geometric method, as well as by hostility to Catholicism and to individualistic Puritanism.

Some scholars argue that John Locke must not be read as replying directly to Hobbes's political philosophy, though a more complex Lockean reaction to Hobbes can be acknowledged. In the *First Treatise of Government* Locke's target is the patriarchal religious traditionalism of Sir Robert Filmer. Here, and to a lesser extent in the more widely read *Second Treatise*, religion plays a significant role in Locke's politics, along with rationality and empiricism. In the *Second Treatise* Locke holds that '*Civil Government is the proper Remedy for the Inconveniences of the State of Nature.*' Above all, government is necessary for the protection of a right to property. Locke founds legitimate government on the \*consent of the governed, and affirms

constitutionalism and the right of revolution. Locke might plausibly be read as an expositor of a form of positive freedom, a freedom requiring government and law in order to be realized. A comparison with Rousseau on this point will be instructive.

Jean-Jacques Rousseau's *Social Contract* has been plausibly interpreted as an attempt to define a form of political organization in which autonomy and political \*authority can be reconciled, a state in which there is a moral obligation to obey the law. Rousseau's work is very much an attempt to picture an appropriately arranged community, with an emphasis on the authoritative state but also with some attention to subordinate institutions such as religion and the family. Rousseau seems to recognize two stages of the social \*contract. Presumably in the first stage there is unanimity about the binding authority of majority votes. For this unanimity to be more than a mere contingency, presumably Rousseau thinks that reasons could be given appealing to our capacity for rational self-determination to show why majoritarianism is a decision-making rule to be embraced. On one way of reading Rousseau, he may think a theorem by Condorcet supplies an argument why (under the circumstances Rousseau assumes) we should subsequently prefer majority judgements over individual judgements about the common good. This arguably makes it seem autonomous for an individual to accept the majority's judgement who subsequently votes on what the law should be (under the circumstances Rousseau describes) and finds himself in a minority. All citizens (males: a very regrettable expression of Rousseau's sexism) vote on whether a law should be passed, sincerely aiming at the common good, with approximate equality of influence on the outcome (presumably one reason for absence of discussion). The effort is to determine the \*general will, which aims at the common good. The general will itself 'cannot err'. It aims at a law of general form which also furthers the general interest, not mere particular interests. If anyone shows partiality, if factions develop, if economic inequality allows some to buy others or requires some to sell themselves, or other failures occur, the social contract is nullified. Otherwise, the law passed by the majority is morally binding on the citizen who has participated in making it. Direct participation is vital; representation will not do. Many interpreters have doubted, on numerous grounds, whether Rousseau's scheme really preserves autonomy. Rousseau is actually pessimistic himself about the prospects for real-world instances of reconciliation of autonomy and authority. In general, Rousseau (although a great psychologist) is not very helpful on the descriptive and explanatory side of political theory, and not very helpful about telling us what to do to promote the main goals of his politics under the refractory circumstances of actual history. He tends toward scorn of corrupt realities and a sometimes wistful utopianism. For all that, in Rousseau a version of autonomy is at work which has been enormously influential. One sign of this, ironically, is in the seriousness with which influential political leaders (e.g. Robespierre, Bolivar) have taken Rousseau, even

when they should have found it difficult to justify their acts on the basis of Rousseau's ideas. Rousseau's community has seemed to some so all-encompassing as not to allow adequately for individual conscience, private life, freedom of religion, and political dissidence. Some liberals, in particular, have found the Rousseauian community stifling of individual freedom.

A classical expression of \*liberalism attempting to find space for individual freedom in a broader community context is to be found in John Stuart Mill. Mill combines normative ethics and factual inquiry in his political philosophy and related work. His most frequently read work of explicit political philosophy is probably *On Liberty*, in which he attempts to distinguish when society has legitimate authority over the individual and when not. Mill argues that a necessary condition of society's controlling the individual (through either governmental penalties or the coercive influence of public opinion, which has its own penalties) should be that such control is needed to prevent one individual from harming another or others. This is often called 'the harm principle'. Mill acknowledges some exceptions in applying this doctrine, which only applies to those in 'the maturity of their faculties' (a notion which seems to exclude not only the young, but also, alarmingly, those societies in which 'the race itself may be considered as in its nonage'). One justification for social control which is mostly ruled out by Mill under normal circumstances is what others often call '\*paternalism', control of a person for that person's own good. For society to proceed with the exercise of control, prevention of harm is not sufficient but there must also be violation by one individual of another's right, or violation of an obligation of the first to the second. *On Liberty* also includes a defence of liberty of thought and discussion, a plea for individuality, a rejection of religious authority in political matters, and discussion of many specific applications of Mill's views, in which Mill's anti-statism emerges. The ultimate moral basis here, as in all of Mill, is the \*greatest happiness principle or principle of utility, most clearly defined and defended in *Utilitarianism*. On Mill's version of the principle, quality as well as quantity of pleasure counts morally, a doctrine that has interesting and probably élitist political implications. Mill's *Considerations on Representative Government* deserves close study in conjunction with his other major works. In it, Mill defends the importance of some popular participation in government, but also argues that society needs to choose exceptional political representatives of superior intelligence and morality, and then allow them to choose what is best, voting them out if necessary. Mill's fears about the tyranny of the majority, so evident in *On Liberty*, also show up in *Considerations* in other ways, for example in his argument for special voting procedures to allow for the representation of minorities, and in his argument that extra votes ought to be given to those of superior intelligence. It should be added that Mill appears in other works to have become more sympathetic to socialism in his later years, although the exact nature of his commitments is somewhat controversial. Whether compatible with

\*socialism or not, Mill's emphasis on individual \*liberty is only possible in the context of a broader community structure and set of traditions, however open to change Mill wants these to be. Some critics claim that liberal \*individualism (with its commitments to such institutions as the \*market) tends to subvert community, but there is also a sense of community in which the liberal individualist (such as Mill) is simply offering still another sort of account (to be evaluated on its merits) of the properly functioning community.

Marx and Engels give a very different, historically dynamic account of society, critical of liberal individualism among other rival visions of community. An adequate understanding of Marx requires some acquaintance with Hegel, but we shall not comment on Hegel here except to note that Marx thought of his own work as standing Hegel upon his head. By this, Marx seems to have meant that the Hegelian interpretation of history as primarily a study of leading ideas and their dialectical changes, which explain other institutional changes, needed to be radically revised. For Marx, \*historical materialism distinguishes between economic base or infrastructure and superstructure, including non-economic institutions and ideological aspects of the society. Historical materialism depicts changes in the former as, for the most part, the causes of changes in superstructure, including ideological \*superstructure. Marx and Engels argue that after the ancient world and feudalism, the economic structures of capitalism, including its two main antagonistic classes, the bourgeoisie and the proletariat, have come to the fore in world history. Class conflict is a main characteristic of all history, but conflicts between owners of the means of production and wage-earners within the capitalist system are seen as central in this period. Sharpening class conflict and accompanying contradictions will eventually force a coming to consciousness of class analysis, and eventually (first, they predict, in the more advanced countries) a revolution in which \*capitalism is overthrown. They argue that capitalism is a global system which will exhaust all possibilities by its own logic before falling, a view later elaborated by Lenin. During the transitional 'dictatorship of the proletariat', it is to be expected that there will be greater centralization of economic and political power in the state, but eventually a 'withering away of the state' is to be expected (Engels's phrase). These changes are meant to occur in some sense in accordance with historical-economic laws, though the exact nature and status of such laws is a matter of dispute. Marx and Engels want to combine description and prediction in various ways that generate interpretative puzzles, but that are a consequence of the desire both to avoid utopianism and to stay consistent with leading historical trends, but also to contribute actively to historical change that the authors consider desirable. Marx and Engels do not necessarily rule out normative ethical and political theory, but given their historical materialism, the study of history and economics generally seems to them more important. It has been left to some subsequent Marxists (including some of the Praxis

group from what was formerly Yugoslavia) to stress the importance of what Marx and Engels did not entirely overlook, but de-emphasized. Arguably Marx and Engels have a concept of collective autonomy or self-determination which requires for its realization as freedom growth in understanding of historical laws and an ending of the exploitation and domination of some classes by others.

In the twentieth century a plethora of political and intellectual developments shaped political philosophy. For a long time, after the Russian Revolution and before recent changes, including the dissolution of the Soviet Union, the main political positions thought by many to be in contention were one or another variety of liberalism (including under this broad category the sort of \*'conservatism' which argues for a limited state, 'free markets', private property, and certain other traditional values) and Marxism. This sort of opposition was always over-simplified. Two counter-examples can be mentioned. In the USA John Dewey's avowedly democratic pragmatism was indebted both to Hegelianism and at times even to aspects of Marxism, but also preserved many features of the legacy of liberalism. Dewey's respect for scientific method, although tempered in later years, was combined with an interest in normative 'democratically' orientated thought of a non-utopian variety. Dewey asserted the importance of a critique of capitalist economic relations even as he tended to remain critical of Marxism. The concept of democratic community, used in a eulogistic way, is very prominent in Dewey. Within the quite distinct, broad and diverse tradition of anarchism, there had developed (over a long period, but especially from William Godwin and Pierre-Joseph Proudhon on) a critique of centralized state power along with a critique of capitalism. Anarcho-syndicalism is a notable example. In more recent academic philosophy in the English-speaking world, these bodies of work have had some but rather limited influence. Recent academic political philosophy in English has been mostly a quarrel among liberalisms (well exemplified by the contrast between John Rawls's *Theory of Justice*, with its two principles of justice constructed by an autonomous choice by rational beings in the 'original position' behind a 'veil of ignorance', and Robert Nozick's 'conservative' (old-liberal), rights-centred (though selectively so), pro-capitalist, minimal-state *Anarchy, State, and Utopia*) the practical relevance of which may have been diminished by recent economic and political changes. Since the widely proclaimed 'end of the Cold War' between capitalism and \*communism, with the collapse of Soviet communism and a decline in living-standards in parts of the capitalist world, including some dependent regions, both Marxism and militant free-market capitalism have come to seem to some observers (rightly or wrongly) no longer as straightforwardly relevant as was once the case. Also, in recent political philosophy, \*'communitarianism' has come to be a label applied to a variety of views stressing ideas about community and critical of individualist liberalism. Communitarians (including Charles Taylor, Michael Sandel, Alasdair MacIntyre, and perhaps Michael Walzer) are

sometimes critical of liberalism, but sometimes are themselves types of liberals.

There may perhaps at other times have been a more assured consensus on which great authors should be included in the canon of 'Western' political philosophy, and less suspicion of the very idea of a canon. Feminists, certain minorities in the 'developed world', and persons from the 'underdeveloped world', among others, have made a compelling case for reassessment of the traditional canon. Then, too, the growth of descriptive and explanatory studies relevant to political philosophy (not a sudden development, but a tendency with a long history of its own) as well as normative work in other disciplines has complicated study of the history of political philosophy. Subjects such as political science, anthropology, sociology, history, jurisprudence, literary studies, and the like sometimes generate work which deserves inclusion in the category of political philosophy. Some of the most interesting discussions in political philosophy over the last few decades in the English-speaking world, for example, have involved philosophers who are also legal scholars (say, H. L. A. Hart, Ronald Dworkin, Joseph Raz, and proponents of critical legal studies such as Roberto Unger).

The idea of autonomy (requiring for its intelligibility some value-laden picture of a community with its main constitutive institutions) has been central in much important Western political philosophy, especially for modernity. Autonomy has been considered a crucial part of human welfare, a focus for describing favoured political institutions such as democratic government, and a notion useful in supporting other notions such as political obligation, rights, justice, and the like. Whether the idea of autonomy should survive critique (especially critique from the descriptive-explanatory side of the subject) remains to be seen, but the idea's defeat would require a radical shift in political perspective. Isaiah Berlin distinguishes negative and positive freedom in politics and opts to support the former as a primary value. (For Benjamin Constant in the nineteenth century, similarly, the liberties of the ancients and the moderns are fundamentally different, and the ancient emphasis on political participation and public life is no longer appropriate in the modern world.) For Berlin, positive freedom (often denominated autonomy) is recognizable in many great philosophers, including Plato, Rousseau, and Marx, but allegedly easily leads to totalitarian excesses. Arguably, Berlin's view is exaggerated, and has been effectively criticized by Charles Taylor in his paper 'What's Wrong with Negative Liberty'. This family of concepts of freedom as autonomy, combined with an institutionally detailed account of community, still has an important potential use for any political philosophy critical of arbitrary political and economic power. **political philosophy, problems of.** Political philosophy in Western civilization began as the philosophy of the ancient Greek *polis* (the Greek word from which 'political' is derived). Accordingly, political philosophy in its inception took as its subject how best to govern and to live in a city-state of that day. Its goal was the creation and preservation of an ideal society. Although Plato devoted several dialogues to issues of political philosophy, it is his *Republic* (c.380 BC) that is arguably the most memorable, widely read, and pioneering contribution to the subject. Apart from the question of its actual influence on statecraft, it provided both theorists and practitioners with a model of a political philosophy in which the author undertook to identify a range of problems concerning governance and social order, and then tried to ground their solution on appropriate metaphysical, epistemological, and anthropological principles. These solutions in their turn raised questions of educational philosophy, both moral and cognitive, because in the absence of the right sort of educational regimen there is (or so Plato argued) no hope of at least creating (let alone preserving) the ideal society that was the intended purpose or aim of political philosophy.

In the centuries after Plato, the problems of political philosophy ceased to focus on the governance of face-to-face societies on the scale of the ancient city-state. Today, especially, it is much larger political units, typically nation-states (with their increasingly global scope) that are the political entities whose structure is under discussion. What might be called the apparent Platonic prejudice in favour of identifying the ideal, possibly even an ideal beyond reach, has been generally subordinated by political philosophers to what might be called the Kantian prejudice in favour of exploring the presuppositions of the actual as well as the ideal political possibilities.

From this perspective, and despite the importance of the *Republic*, it is Aristotle rather than Plato who provided philosophy with its first genuine political treatise. In his *Politics* (c.330 BC) Aristotle made no attempt to imitate his teacher's style of presentation, which was to use imaginary dialogues between Socrates and his companions to sketch a portrait of the ideal society, its origin, and the obstacles to its preservation. Instead, Aristotle's treatise concentrates on stating, defending, and applying the principles that governments actually as well as ideally rely on. Yet it was not only in style that Aristotle deviated from Plato. On the most fundamental question—what is the nature and structure of the ideal society—they differed radically. Plato argued in the *Republic* that there is exactly one form of ideal state, its class structure is based on the

fixed differential capacities of its citizenry, rigidly orchestrated so that each class of persons performs the tasks for which the natural talents of its members best fits them. Aristotle in his *Politics* is far more tolerant of diverse forms of government and social structure. He saw advantages under the right conditions for allocating governing authority in any of three main ways: monarchy, aristocracy, and 'polity'. (The latter is roughly what we would call constitutional democracy. Plato in the *Republic* insisted on rule by philosopher-kings.)

The problems of political philosophy (in the material mode) that have preoccupied thinkers for the past several centuries are essentially the questions (in the formal mode) concerning political life and institutions. These are what the authors of the great treatises in political philosophy since the Reformation and Renaissance have endeavoured to answer, plus an array of issues and questions to which those answers in their turn have given rise. Thus to identify these problems and some of the major proposed solutions to them, one must quarry in works as diverse as Thomas Hobbes's *Leviathan* (1651), John Locke's *Second Treatise* (1690), Jean-Jacques Rousseau's *Social Contract* (1762), William Godwin's *Enquiry Concerning Political Justice* (1793), G. F. W. Hegel's *Philosophy of Right* (1830), J. S. Mill's *On Liberty* (1859), T. H. Green's *Lectures on the Principles of Political Obligation* (1895), Friedrich Hayek's *Constitution of Liberty* (1960), John Rawls's *Theory of Justice* (1972), and Jürgen Habermas's *Theory of Communicative Action* (1984, 1987). This is to name but a representative few of the best-known. The problems of political philosophy that these philosophers undertake to solve would appear to be divisible, at least provisionally, into three distinct sets differentiated from each other in various ways and subject to solution by different methods. Given the range and complexity of matters that can legitimately be considered relevant to the goals of political philosophy, it is hardly surprising that a vast library exists of attempts to deal with those problems in both abstract theoretical and relatively practical terms.

First and foremost, there are problems of political philosophy that are essentially *conceptual*. Thus, Plato opens book 1 of the *Republic* by asking, What is justice?, and Aristotle opens book 3 of the *Politics* by asking, What is a state? Political philosophies will differ from one another as they vary in their starting places, as they provide different conceptions of certain central ideas, and as they allot greater or lesser centrality to the values represented by a given concept in their theory. These concepts play a double role: first, they are proper topics of philosophical inquiry in their own right; second, they serve as the building-blocks of any possible political theory. Although there is no canonical set of such concepts, virtually every comprehensive political philosophy will find it necessary to explain, in order to use effectively, many if not all of the following three dozen concepts: \*authority, \*autonomy, \*citizenship, \*coercion, \*collective responsibility, \*community, \*consent, \*desert, devolution, \*duty, \*equality, \*fairness, \*justice, \*law, \*liberty, \*loyalty, majority rule,

\*obligation, order, ownership, \*power, \*property, public interest, \*punishment, representation, \*rights, slavery, social class, \*society, sovereignty, \*State, \*terrorism, \*toleration, \*violence, welfare, \*well-being. The variety and complexity of these concepts, and the interconnections among them, show that the problems of political philosophy overlap, intersect, and merge with the problems of legal, social, economic, ethical, and educational philosophy. In so far as the task of political philosophy is thought to be one primarily of analysis and clarification, conceptual questions will be regarded as fundamental.

Some philosophers have gone so far as virtually to identify the problems of political philosophy with all and only the problems that can be settled by conceptual analysis. Notable examples can be found in T. D. Weldon's *Vocabulary of Politics* (1953), Anthony Quinton's *Political Philosophy* (1967), and Felix E. Oppenheim's *Political Concepts: A Reconstruction* (1981). The self-denying approach manifest in these volumes was mainly a product of the positivistic and linguistic phases of general philosophy in the mid-twentieth century, when all philosophical problems were held to be 'conceptual', and the only method of philosophical discussion was 'analytic'. By the end of the century this approach had few if any adherents. There is no doubt that conceptual questions are central to any possible political philosophy, as they are (or at least have been) to the nature of philosophical problems generally. But as politics itself is a matter of eminently practical importance, its philosophical problems must reflect this fact. The discussion of nothing but conceptual questions—even questions about political concepts—cannot suffice for the task.

This brings us to the second category of problems, the *normative*, in which a philosopher undertakes to state and defend substantive principles that can serve to answer normative questions. Among them are these: What principles ought to be adopted and enforced such that compliance with them will achieve social justice? What principles are used and presupposed in defending a given political practice or institution? Just as there is no established canon of the conceptual issues in political philosophy, so there is no fixed set of normative principles in the workshop of political philosophy. Yet some questions are so central and typical that they arise again and again across the centuries for anyone who reflects on social order and disorder and the lessons they teach about human frailty and aspirations. A partial list looks like this: What is the proper scope and role of law in providing conditions for social stability? What forms of coercion to secure compliance with just laws are permissible? Under what conditions, if any, may the citizen violate the law and even forcibly resist its enforcement? What conditions must be satisfied if non-violent resistance to lawful orders are to be justified? Is there any legitimate role for violence against persons or property in a constitutional democracy? Can political terrorism be justified, at least as a last resort? What rights, if any, apart from those provided by the laws of the land, do individuals or groups have? What obligations do individuals have to

obey the laws and governments set over them, and what is the source of these obligations? How can political authority best be reconciled with individual autonomy? To what extent ought individuals to be left free to bargain with others in acquiring and transferring property, including even property in their own bodies and lives? How should conflicts between social utility (efficiency) and distributive justice (equity) be resolved? Under what conditions, if any, should claims based on the equal worth of all persons prevail over considerations of efficiency? Is a strict meritocracy a threat to equality? How free are persons when the options among which they must choose are not all of their own making? What normative principles in general ought to be seen as presupposed by preferred political practices and policies, and how are these principles to be justified? Again, in this more practical arena there are many questions that political philosophy needs to deal with.

Standard political philosophies or ideologies, such as anarchism, fascism, totalitarianism, socialism, communism, liberalism (whether in its contractarian, utilitarian, or libertarian versions), and communitarianism are constituted by their different answers to these and related questions. In so far as the task of political philosophy is thought to involve justifying a set of political institutions of one sort rather than of another—or, at a minimum, evaluating them—it is the answers to these normative questions that form the core of political philosophy. But how philosophers ought to answer the normative questions of political philosophy admits of no simple answer. This question is itself one of the perennial higher-order problems of political philosophy.

In addition to conceptual and normative problems, systematic and comprehensive political thinking also involves various *empirical* problems. By way of illustration, consider these questions: Which institutions and practices are appropriate to implement the principles of distributive justice? How can the self-interest of governors and other officials be harnessed to serve the interest of the general public? What constitutional mechanisms will provide effective checks on executive power without causing governmental paralysis? Does equality of opportunity require inequality of liberty? Which forms of punishment—corporal, incarcerative, pecuniary, etc.—provide the most effective deterrence to crime? What constraints do the best political principles impose on the recourse to punishment? Is a capitalist economy causally related to liberal-democratic political institutions? How plastic is human nature?

In raising questions such as these—questions that are at least in part answerable only by empirical inquiry and data from history and the social sciences—we not only approach but actually cross the boundary that divides political philosophy from political science. (We might think of political *theory* as a third point, along with political *science* and political *philosophy*, the three of which triangulate a space subdivided by somewhat vague and elastic boundaries.) Although every classic political

philosophy contains views on some empirical questions (they are prominent in Aristotle, rarer in Plato), most philosophers today would argue that to the extent that such questions can be answered only by experiential data, systematic observation, the investigation of practices, statistical methods, and the answers then devoted to describing, predicting, or explaining individual or group behaviour, to precisely that extent the questions are not philosophical at all. For practical political purposes it is constantly necessary to ask and answer such questions, but philosophy has little or nothing to contribute to the answers.

Such a convenient and familiar sorting of the problems of political philosophy into conceptual, normative, and empirical categories, however, eventually runs afoul of two difficulties. The lesser is that as the boundaries between concepts, norms, and empirical generalizations are themselves somewhat blurred and uncertain, particular cases will arise—often these are among the most interesting cases—where the attempt to keep the problems and their methods of solution precise and distinct from each other will fail. Consider a question such as this, brought to prominence in John Rawls's *Theory of Justice*: Would a rational and self-interested person situated behind a veil of ignorance choose some version of the principle of utility as the fundamental principle for the society in which he expects to live? Is this question primarily conceptual or normative? or is it partly empirical? or perhaps a mixture of two or even all three of these?

The graver difficulty arises from (in the phrase of W. B. Gallie) the 'essentially contested' nature of political concepts. Their analysis and interpretation typically is shaped by implicit practical concerns. Or, to put the point another way, the central political concepts are not—and so cannot be used as if they were—merely descriptive and unblemished by the ideological concerns of the philosopher who employs them. As a result, what may begin by seeming to be the wholly neutral task of defining or analysing a political concept will probably end by merging subtly (and perhaps tacitly) with normative considerations. Thus, the image—and for some, the ideal—of unbiased, ideologically neutral answers to the problems of political philosophy is likely to be elusive at best. It is considerations of this sort that are the first step toward a post-modernist perspective on political theory.

Cutting orthogonally across the distinctions among the conceptual, the normative, and the empirical problems of political philosophy is the contrast between pure and applied philosophy and the issues properly belonging to each. For every great treatise in political philosophy, from Hobbes to Rawls, in which conceptual and normative problems in their pure form are addressed to the relative exclusion of empirical and applied issues, there are as many and more essays and books by thinkers hardly less eminent that focus on making first-order political judgements, evaluating the prevailing political order, and proposing revisionary (even revolutionary) practices and policies—as evidenced by such classic tracts as Thoman

Paine's *Rights of Man* (1791–2), Karl Marx and Friedrich Engels' *Communist Manifesto* (1848), J. S. Mill's *The Subjection of Women* (1862), Georges Sorel's *Reflections on Violence* (1906), and R. H. Tawney's *Equality* (1931). More recent works written in this vein include F. A. Hayek's *Road to Serfdom* (1944), Karl Popper's *Open Society and its Enemies* (1945), Jean-Paul Sartre's *On Genocide* (1968), Peter Singer's *Animal Liberation* (1975), Michel Foucault's *Discipline and Punish* (1975), Michael Walzer's *Just and Unjust Wars* (1975), Onora O'Neill's *Faces of Hunger* (1986), Amartya Sen's *Inequality Reexamined* (1992), and Ted Honderich's *After the Terror* (2002). In books such as these, philosophers have displayed their interest in evaluating and criticizing substantive political, social, and economic practices and institutions, and they have done so by relying on and invoking principles and ideals not themselves the primary focus of the author's argumentative or analytic attention. The problems thus addressed are more plausibly viewed, many would argue, as mainly or wholly political rather than philosophical. Yet it would be a mistake to press this distinction too hard; to do so would be to ignore some of the most interesting and influential contributions philosophers have made to some of the problems that fall on the boundary between political advocacy and applied political philosophy.

As the history of political philosophy shows, what interests philosophers is shaped in part by the great issues of the day. These typically provide the fuel not only for political organization and agitation but for political reflection as well. And as these issues change over time, with the changing material circumstances of life, so do the paramount problems of political philosophy.

Thus, ancient writers were concerned to explain how the state emerged from family and tribal units, a problem that political philosophers today are happy to leave to cultural and historical anthropology. Late medieval and early modern philosophers focused on the proper division of authority between church and state, the sacred and the secular, another set of issues largely ignored by philosophers in recent decades (though there is some possibility that they may return to the agenda because of the increased number of sectarian fundamentalist religious movements world-wide). The explorations, conquests, and colonizations by Europeans of African, Indian, American, and Asian peoples four centuries ago provoked philosophers to reflect on the nature of property, freedom, and rights as these issues became focused in the twin practices of enslaving native peoples and colonizing their territories. With the struggle to promote liberal democratic ideas in Western Europe since the Protestant Reformation, problems of political equality versus inequality, of tradition and stability versus liberation and progressive change, or collective versus centralized political decision-making, and of individual autonomy versus communal solidarity came to dominate the concerns of political philosophy just as they dominated political debate and political struggle during the same period. The Industrial Revolution, factory labour, and imperialism of the nine-

teenth century forced new sets of problems and new ways of conceptualizing human relations on to the agenda of political philosophy. Such vexed matters as racism, sexism, ageism, human population growth, maldistribution of the world's material resources, and the unremitting assault on the natural environment, are all issues that bedevil governments and provoke partisan disagreement and, accordingly, have begun to find a place on the agenda of political philosophy as well.

**political scepticism.** V. S. Naipaul observed that in the late twentieth century the opium of the people was not religion but politics. Naipaul is certainly expressing a widespread and justifiable suspicion after high hopes had been raised about just what politicians and politics can achieve, but this need not amount to political scepticism in any systematic sense. Such scepticism derives from two sources. First, there is the sociological observation, enshrined in public choice theory, that bureaucrats and politicians tend to serve themselves and the interest of their bureaucracies before those of their clients. This would explain recent phenomenal increases of state power, even where governments are ostensibly committed to reducing it. Then, secondly, there are doubts, particularly associated with Hayek and Oakeshott, about whether centrally planned political attempts to achieve results are ever well directed or based on enough information to make them truly rational. The moral of both these points would seem to be to reduce government as much and as quickly as possible, but with the paradoxical proviso that in most countries it would need a massive political initiative to do so.

A.O'H.

\*conservatism.

John Gray, *Limited Government* (London, 1989).

**political violence:** see violence, political.

**politics and determinism.** Setting aside the special cases of economic and historical determinism, the clearest consequences of \*determinism in politics are for a cluster of ideas about punishment and reward, in which the concept

of \*desert is central. Conservative advocates of tougher sentencing are apt to stress the mischievousness and evil of criminals, just as they discount the circumstances and aetiology of criminal behaviour. Tougher punishment, they argue, is what evil men and women *deserve*. Philosophers disagree about the implications of determinism for responsibility and punishment (\*compatibilism and incompatibilism), but there is at least one understanding of desert that takes it to follow from actions that are wholly within the power of the agent, and which is therefore incompatible with determinism. Indeterminism is thus a natural accompaniment to beliefs that some criminals are evil out of their own choosing and deserve to be punished for it.

The argument about the compatibility of determinism with responsibility and punishment can be viewed, therefore, as a theoretical counterpart to the political debate about how much weight should be given to social deprivation in combating crime.

The idea that unequal possession of wealth is more or less deserved is also a recognizable (though not universal) feature of conservative thought. It is argued that since left-wing thought about distribution can be said to be founded on a principle of equality rather than desert, \*conservatism, by contrast, is especially vulnerable to determinism. Desert is less fundamental to conservative thinking about distribution, however, than it is to conservative ideas about crime and punishment: conservatives will more readily acknowledge the role of circumstance and luck in the distribution of property than in the causes of crime.

**politics and the philosophers.** Before the professionalization of the universities in the eighteenth and nineteenth centuries, political service of one kind or another was the main alternative to the Church as a source of steady income for a good many philosophers. As a result, many have had cause to dabble in politics. From ancient times onwards, however, philosophers have debated whether they should seek to guide their political masters according to their philosophical ideals or whether instead they should adapt their skills to the political requirements of the moment. Plato offered the model for the first view, and attempted unsuccessfully to persuade Dionysius I and his successor Dionysius II of Syracuse in Sicily to adopt a code of laws modelled on his political ideas. \*Enlightenment thinkers also followed this approach, hoping to turn the monarchs of their time into philosopher-kings. Voltaire briefly sought to serve Frederick the Great in this capacity, for example, and Diderot was taken up by Catherine the Great. Bentham's numerous attempts to get governments to take up his various constitutional schemes and reforms, such as his proposal for an ideal

prison based on his Panopticon design, also fits into this line of thinking. In the twentieth century Gentile believed he had persuaded Mussolini that Fascism was the embodiment of his actualist philosophy, whilst Heidegger tried with rather less success to make similar claims about Nazism, and Lukács and Sartre even more disastrously about Stalinism. However, all these philosophers generally discovered that even when politicians invite their advice they rarely take it, or only do so for as long as it proves convenient, leaving the philosopher looking politically naïve.

Machiavelli offers the model for the second view. Superficially this tack seems less honourable, requiring the philosopher to adapt his or her ideals to the prevailing political wind. However, as we have seen, it has generally been the first view that has involved philosophers in being the dupes of tyrants, whereas the second has proved both more democratic and more successful. Locke, for example, acted as medical adviser and ideologist in residence for the Earl of Shaftesbury, and although the initial failure of his patron's political activities briefly forced him into exile, his services to the Whig cause were ultimately rewarded with a number of government offices. Tom Paine was perhaps the democratic philosopher *par excellence*, contributing theoretical support to both the American and the French Revolutions, and causing the British government to prosecute and outlaw him for seditious libel in the process. Modern examples include the Italian Marxist Antonio Gramsci, whose philosophy was intimately connected to his activity as one of the founders of the Italian Communist Party, and Bertrand Russell, who played a major role in the pacifist movement during the First World War and was one of the leading lights of the Campaign for Nuclear Disarmament during the 1950s.

In general, however, philosophers have found themselves wavering between these two positions. They have been deeply ambivalent about politics and rarely successful at it, perhaps because whilst compromise is a political virtue it is rarely regarded as a philosophical one. Burke's end-of-poll address to the voters of Bristol, in which he stressed that the duty of the MP was representation rather than delegation, epitomizes the resulting ambivalence of philosophers towards politics. Unsurprisingly, the electorate rejected him at the next election, and he sat for the rest of his parliamentary career for a rotten borough in the gift of his patron, Lord Rockingham. J. S. Mill's parliamentary career was not dissimilar. MP for Westminster from 1865 to 1868, he confined his electioneering to telling his electorate that it was unnecessary for him to consult them directly since he undoubtedly knew their own interests better than they themselves. In recent times John Hospers is one of the few philosophers to enter the electoral lists, standing in 1972 as the first Presidential candidate for the Libertarian Party in the United States—he polled 5,000 votes.

J. Hamburger, *Intellectuals in Politics* (New Haven, Conn., 1965).

M. Walzer, *The Company of Critics* (London, 1989).

**Pomponazzi, Pietro** (1462–1525). Italian Aristotelian philosopher who provoked a controversy in 1516 with his treatise *De Immortalitate Animae*. Defying a decree of the Fifth Lateran Council (1513) which enjoined philosophers to teach that the personal immortality of the soul was demonstrable on rational grounds, he maintained that neither Aristotelian philosophy nor reason provided support for Christian dogma. He claimed to accept the authority of the Church as a matter of faith, but refused to allow such considerations to influence his judgement in the realm of philosophy, whose autonomy he staunchly defended. Despite attempts to convict him of heresy, he was able to hold on to his chair at the University of Bologna. Fearing another uproar, he forbore to publish a treatise in which he explained miracles in terms of astrological influences and other forms of occult causation. J.A.K.

M. Pine, *Pietro Pomponazzi: Radical Philosopher of the Italian Renaissance* (Padua, 1986).

**pons asinorum** (Latin: asses' bridge). Proof given of theorem 5 in book 1 of Euclid's *Elements* (concerning the angles of isosceles triangles): inability to follow the proof is supposed to demonstrate stupidity. In medieval times the theorem was described as *elefuga*, the flight of the miserable (from geometry). The term is sometimes applied to Pythagoras' theorem, sometimes to a medieval logic teaching aid, and sometimes to any argument supposed to separate intellectual sheep from goats. M.C.

**Popper, Karl** (1902–94). British (originally Austrian) philosopher, whose considerable reputation rests on his philosophy of science and his political philosophy. In his early work he was associated with the positivists of the \*Vienna Circle, and shared their interest in distinguishing between science and other activities. However, Popper did not think that it was possible to approach that (or any other philosophical problem) by an analysis of language or meaning, nor did he see the success of science in terms of its being more verifiable than, say, ethics or metaphysics. For Popper always took a sceptical Humean stand on \*induction, as a result of which he claimed it is impossible to verify or even to confirm a universal scientific theory with any positive degree of probability. What we can do, though, is to disprove a universal theory. While no number of observations in conformity with the hypothesis that, say, all planets have elliptical orbits can show that the hypothesis is true or even that tomorrow's planet will have an elliptical orbit, only one observation of a non-elliptical planetary orbit will refute the hypothesis. Falsification can get a grip where positive proof is ever beyond us; the demarcation between science and non-science lies in the manner in which scientific theories make testable predictions and are given up when they fail their tests.

Popper, in contrast to the Logical Positivists, never held that non-scientific activities were meaningless or even intellectually disreputable. What is disreputable is \*pseudo-science, which arises when holders of an

empirical theory refuse to be deflected by observational disproof or where a supposedly scientific theory never makes any empirical predictions. Popper convicts Marxists of the first sin and psychoanalysts of the second, contrasting them with a true scientist like Einstein.

Questions, though, remain. Is it true that scientists always reject their theories when faced with counter-evidence, as Popper says they should? And if the most we can ever do in science is to disprove theories, how do we know which theories to believe and act on? Popper says that we ought to act on those theories which have survived severe testing. His critics, though, find this hard to distinguish from the induction he officially rejects.

The themes of human ignorance and the need for critical scrutiny of ideas are also prominent in Popper's political philosophy. This is an advocacy of so-called open societies against the pretensions of planners and politicians who claim the right to impose their blueprints on the rest of us by virtue of supposed knowledge of the course of history. There can be no such knowledge. History is affected by discoveries we will make in the future, and do not know now. Moreover, any policy, however well-intentioned, has unforeseeable and unintended consequences. The only way to overcome our ignorance is to allow those affected by policies to voice their criticisms and for people in a society to be able peacefully and regularly to change their rulers. This last right, rather than formal democracy, is the mark of the open society, a concept taken for granted in the western Europe, but of increasing interest currently in eastern Europe and South America.

In his later years, Popper placed his theory of scientific and political error-seeking within a generalized theory of evolution. He also defended versions of scientific realism, \*indeterminism, and \*dualism with commendable valour, if not always with great subtlety of argument. A.O'H.

**popular philosophy.** There are three main kinds of popular philosophy: first, general guidance about the conduct of life; secondly, amateur consideration of the standard, technical problems of philosophy; thirdly, philosophical popularization.

At the start some recognition should be given to a movement explicitly called 'popular philosophy' in mid- and late eighteenth-century Germany. Its leader was Moses Mendelssohn, and it set itself against obscure technicalities and systematic elaboration, in the interests of closeness to experience and usefulness for life. The acquisition of imperial authority by Kant soon put an end to this project, and installed a style of German philosophy from which even Christian Wolff would have shrunk.

General guidance about the conduct of life is what is colloquially meant by the word 'philosophy' and is what most people expect from philosophers and are, for the most part, disappointed not to receive from them. Dispensing such guidance soon became an important aspect of Greek philosophy. It began with Socrates' attacks, through the mouth of Plato, on the calculating amorality of his Sophist contemporaries, permeated Aristotle's *Ethics*, and became the main substance of philosophy in the long epoch from the reign of Alexander the Great to the fall of the Roman Empire. The Stoics and Epicureans did not wholly ignore logic and 'physics', which Aristotle saw as making up philosophy, together with ethics. But, especially in the Roman period, in Epictetus, Seneca, and others, the ethical element was overwhelming.

In the Middle Ages, only the clergy were literate and educated, and guidance for the conduct of life became professionalized and legalistic. The moral life, directed as it was towards the eternal, disdained man's earthly existence and took little account of personal individuality. Philosophy, in so far as it touched non-philosophers, was official and authoritative. The humanism of the Renaissance reversed all that. The diversity of human beings was celebrated, as in the *Colloquies* of Erasmus. The rational, if unsystematic, exposition of *Lebensweisheit* emerged in the form of the essay, in Montaigne and, then, by imitation, in Bacon (whose essays were, in fact, congelations of aphorisms). In the seventeenth and eighteenth centuries the *moralistes* of France, such as the rather laboriously cynical La Rochefoucauld, had an earnest British associate in Samuel Johnson, a lively American one in Benjamin Franklin, and a brilliant German one in Lichtenberg. Chamfort, who died in 1794, is a latter-day *moraliste*; the rough and hearty William Cobbett of *Advice to Young Men* is a more likeable Franklin. Addison's *Spectator* essays are a bland English version of the same sort of thing. By the end of the eighteenth century, prudence, and the idea of rational management of life, had been obscured by the clouds of romanticism.

One major philosopher of the nineteenth century applied himself with supreme wit and penetration to *Lebensweisheit*: Schopenhauer, mainly in the non-technical parts of his *Parerga und Paralipomena*. Nietzsche may be seen as carrying on the same task, for which he was marvellously equipped as a writer but hopelessly unfitted as a human being. Earlier in the century Emerson had addressed himself to the subject; towards its end Shaw, particularly in his prefaces, dispensed a great deal of advice, in the style of Samuel Butler, whom he much admired. Together they dismantled Victorian respectability for the English-speaking world.

Perhaps the most distinguished popular philosopher of the present century was Alain (Émile Chartier), who published his thoughts in several thousand 600-word pieces in a daily paper. Havelock Ellis, John Cowper Powys, and Aldous Huxley were less copious but comparably influential. On a more modest level is the American Sydney Harris, a syndicated columnist, raised above such writers as

Ann Landers and Abby by the generality of his concerns. G. K. Chesterton contributed marginally to the tradition, as did such aphorists as Logan Pearsall Smith and Gerald Brenan. In the last three decades professional philosophers, after a long period of abstention from anything but the most abstract and uncommitted attention to problems of conduct and practice, have resumed a measure of direct involvement, mainly at the political or collective level, but to some extent more personally, as in Richard Robinson's *An Atheist's Values* and Robert Nozick's unkindly treated *The Examined Life*.

The second kind of popular philosophy, namely amateur philosophy, presupposes the existence of professional philosophy to define itself against. That, in effect, is much the same thing as institutionalized philosophy, which was to be found in ancient Greece with Plato's Academy, Aristotle's Lyceum, and the other Athenian schools; emerged again, by way of cathedral schools, in the medieval efflorescence of universities from the twelfth century onwards; but subsided, with the Renaissance, until the slow revival of universities in the eighteenth and nineteenth centuries. In that last gap all notable philosophers, from Descartes to Hume, were, formally, amateurs. Amateur philosophy as a genre is really a creation of the nineteenth century with its mass literacy and self-education.

Coleridge, for all his plagiarism and incoherence, is too substantial to count as an amateur. Carlyle was a prophet rather than any sort of philosopher, as was Ruskin. Herbert Spencer achieved a sort of professionalism by the sheer bulk of his output. The historian of philosophy J. D. Morrel was a school inspector like Arnold. J. H. Stirling, the enraptured expositor of Hegel, was a doctor. Shadworth Hodgson was a gentleman-philosopher with private means. More perfect cases are the eighth duke of Argyll, Secretary of State for India among other things, and James Hinton, author of *The Mystery of Pain*. A. J. Balfour was about as grand as, and a better philosopher than, the duke of Argyll.

In the twentieth century amateur systems increasingly failed to find their way into print; most of them languished in typescript and photocopy. One arresting exception is *The Social Contract of the Universe* by C. G. Stone, a most ambitious piece of deduction. There are also the works of L. L. Whyte and George Melhuish, and, in the United States, Ayn Rand, strenuous exponent of objectivism and self-interest.

Philosophical popularization, the third of the kinds mentioned earlier, was made necessary by the conjunction of ever greater professional obscurity and difficulty with a public demand for enlightenment. G. H. Lewes's *Biographical History of Philosophy* is the first important book in English to respond to this opportunity. The introductions to philosophy by Paulsen and by Windelband were fairly soon translated from German after their late nineteenth-century publication. A. W. Benn wrote excellent little histories of ancient and modern philosophy. But the best piece of philosophical popularization remains Russell's *Problems of Philosophy*. In the years between the wars there were Olaf Stapledon, the stylish John MacMurray,

pioneer of philosophy on the radio, and the irrepressible and in every sense fluent C. E. M. Joad. Since 1945 what was a modest cottage industry has become a large productive field as university populations have increased. Hospers's *Introduction to Philosophical Analysis* and *Human Conduct* may be singled out for their scope, reliability, and well-deserved circulation, although the former, at any rate, first published in 1956, is, understandably, showing signs of age. The most convincing successor to Hospers's *Introduction* (which has been badly watered down in later editions) is Roger Scruton's *Modern Philosophy* (London, 1994), which covers a great deal of ground, is replete with historical references, and mitigates its passages of comparative toughness with plenty of wit. Only the most austere of professionals nowadays seem able to resist enticements to explain themselves to a wider public. There are two recent new developments in the field of popularization by professionals. The first is the appearance of very short books covering most, or at any rate a large part, of the subject, such as Thomas Nagel's *What Does It All Mean?* (Oxford, 1987) and Simon Blackburn's *Think* (Oxford, 1999) and *Being Good* (Oxford, 2000). The second is the publication of books by professional philosophers on subjects of direct general human interest that are the topics of current public controversy: for instance, Mary Midgley's *Beast and Man* (Hassocks, Sussex, 1978), Jonathan Glover's *Causing Death and Saving Lives* (London, 1977) and *What Sort of People Should There Be?* (London, 1984), and Peter Singer's *Practical Ethics* (Cambridge, 1979). There was a period after the deprivations of war had driven people back to almost Victorian levels of reading and thinking in which there was much philosophical popularization on the British radio and television, and even in the colour magazines of Sunday papers. The profit motive and dumbing-down egalitarianism have since turned television into a mirror in which Caliban can contemplate himself and the Sunday magazines into vehicles for fashion advertising.

**population.** How many people ought there to be? According to traditional \*consequentialism, which holds that we ought to do what maximizes value, it is good to increase the population provided that the increase in value derived from causing people to exist with lives worth living is greater than any decrease that this might also cause in the value of pre-existing lives; and we ought to increase the population provided that there is no alternative that offers a greater increase in overall value. Most moral theorists reject this view, since it seems to make procreation often obligatory and, in particular, implies that it can be obligatory to cause more and more people to exist, even if this continually lowers the overall quality of life, provided that the total amount of good in the world continues to increase. Some consequentialists contend, alternatively,

that we ought to maximize average value per life lived. On this view, it is obligatory to increase the population only if each new life would contain more value than the average life. But this view also implies, implausibly, that it is wrong to cause a person to exist if his life would contain less than the average value, even if his life would be well worth living.

Faced with these problems, many moral theorists embrace the commonsensical view that the optimum population size must be determined solely by reference to the interests of existing people. There is no reason to increase the population for the sake of those who would thereby be brought into existence. This view, however, ignores what is surely relevant—namely, that our present action can affect the welfare of people who will later exist. (For complications, see the entry on future generations.) Thus many theorists have revised their view to hold that the interests of only present and future people count. The possible interests of possible people do not count.

While initially this view seems compelling, it has proved untenable. If future people are those who definitely will exist, while possible people are those who might or might not exist, then the two categories overlap, since some of those who might or might not exist will in fact exist. But, if some people are both future people and possible people, then we cannot discriminate in the way suggested between future and possible people. Alternatively, we might define a future person as someone who will exist independently of one's present choice and a possible person as someone who might or might not exist depending on the outcome of one's choice. Given this distinction, the claim that the interests of possible people do not count supports the desired conclusion that the expectation that a person would have a life worth living does not itself provide a moral reason to cause him to exist. The problem is that it also implies that the expectation that a person would have a life that would be worse than no life at all provides no reason not to cause him to exist, since the person's existence depends on the outcome of one's choice.

What most of us believe is that, while there is no moral reason to cause people to exist just because they would have lives worth living, there is a reason not to cause people to exist if their lives would not be worth living. Moral theorists have tried to defend this view in many ways; for example, by appealing to the claim that wrongs require victims, to the asymmetry between harming and failing to benefit, or to the distinction between doing and not doing. The current consensus is that an adequate defence has yet to be found.

**pornography.** In everyday use, 'pornography' refers to an array of images and texts, now including ones on the Internet, that are meant to produce sexual arousal in those who

see or read them and that are, standardly, sexually explicit—offering direct representations of sexual acts or sexualized body parts. Etymologically, ‘pornography’ derives from the Greek roots ‘porne’, which means ‘sexual slave’ or ‘harlot’, and ‘graphos’, which means ‘depiction of’, thus connoting a depiction of sexual slavery or prostitution. And indeed, much actual pornography, even when it takes children, men, or animals as its objects, is modelled on a male–female, master–slave paradigm. Pornography comes in many genres, including heterosexual, homosexual, transsexual, and sado-masochistic; it can be more or less explicit and is sometimes frankly violent. Some distinguish ‘pornography’ from ‘erotica’, reserving the latter label for sexualized depictions conveying mutuality, love, and respect or for those that, at a minimum, do not sexualize coercion and violence. Others challenge the viability of the distinction or criticize its role in privileging culturally favoured over more marginalized and idiosyncratic sexual tropes and tastes.

Traditionally, objections to pornography have condemned it as obscenity. Recent feminist critics eschew this tactic as hostile to sexuality. Their objections to pornography, instead, are based on claims of its harms—harms taken to be located in its effects, but for some, found also in the very speech acts that constitute pornography. The harms claimed include the coercion and abuse of those used as subjects in pornography’s production, an increase in acts of sexual violence throughout society, and a diffuse but powerful tendency to eroticize the degradation of women. ‘Pornography makes sexism sexy’ (MacKinnon). In contrast, ‘pro-sex’ feminists defend and at times celebrate the practice of pornography. Praising free sexual experimentation, they argue that pornographic speech, if it is to be countered at all, should be countered with more speech, including more sexual speech. Civil libertarians defend the legal protection of pornographers, claiming that there are fundamental liberty rights at stake in sexual expression. Navigating the challenges that pornography presents is difficult. In terms of social policy, toleration of pornography is in many ways perilous to women’s safety and freedom, yet constraints on free expression often have serious costs. In personal morality, subtle questions arise in determining when graphic sexual depictions are expansive, and when degrading, of the erotic life. The sophistication of the current debate about pornography’s moral and legal status evinces an acknowledgement of the peculiar power of sexual speech and the complex connections between viewing and doing, fantasy and reality.

**Port-Royalists.** Port-Royal was a monastery near Paris committed to the teachings of Bishop Cornelius Jansen (\*Jansenism). Antoine Arnauld, Blaise Pascal, and Pierre Nicole wrote influential Jansenist theological treatises at Port-Royal, and Arnauld and Nicole co-authored *La Logique; ou, L’Art de penser* (Logic; or, The Art of Thinking (1662)), generally known as the Port-Royal Logic. This work was a manual on method in logic and semantics, with overtones of epistemology. It built on the foundations of the Cartesian doctrine of clear and distinct ideas and attacked \*Pyrrhonism and medieval theories of logic. It heavily influenced subsequent manuals in logic for over two centuries. This work was also a key source for reflections on controversies about miracles, including how to weigh apparently reliable human testimony in favour of miracles against the improbability of the miracle’s occurrence.

**positive and negative freedom:** *see* liberty.

**positivism.** A movement akin to \*empiricism and \*naturalism introduced towards the middle of the nineteenth century by Comte, the French sociologist (to use a term he himself invented), with the social reformer Saint-Simon as a forerunner, whom he served as secretary in his youth. What is distinctive about positivism in its original form is its attempt to describe the history of human thought as evolving through certain definite stages, which

Comte called the religious, the metaphysical, and the scientific. Of these the last was the most productive and valuable, though the earlier ones had their value too and were not to be simply dismissed as primitive and useless; indeed Comte himself, towards the end of his life, thought it necessary to introduce a sort of 'religion of humanity'. Positivism fitted in well with the evolutionary tendencies of the age. It was both descriptive and normative, describing how human thought had in fact evolved and prescribing norms for how our thinking, including thinking about human thought itself, should proceed. In this respect it could be said to link the eighteenth-century doctrines of inevitable progress to the evolutionary ethics of later in the nineteenth century, which saw our duty as that of furthering a process that was going on anyway, though positivism was more concerned with prescribing methods of thought than ethical norms. This emphasis on furthering the inevitable, if perhaps little else, it shared with Marxism, though a later version of positivism (that of Mach) was to be the subject of a vigorous attack in Lenin's *Materialism and Empirio-Criticism* (Moscow, 1908).

In the form Comte gave it, positivism was rather fond of categories and hierarchies, though these were seen not as static and cut off from each other, but as dynamic and developing along a certain path, so that positivism emphasized the unity of the sciences. Not only did human thought itself develop through the three stages mentioned above, but the sciences form a natural hierarchy in terms of method and subject-matter, ranging from astronomy through physics and the biological sciences to the human science of sociology. They also developed historically in this order, though of course without the earlier ones being superseded by the later ones so that they disappeared. (Mathematics stood rather outside this scheme, being presupposed by it.) It is not surprising then that the emphasis fell on the newest stage, the science of humanity, with the growing realization that human beings, at least in the mass, were suitable objects for scientific study, a realization which led to the study of them as institutionalized in societies which were themselves developing, i.e. to sociology. Psychology, however, which at that time was amenable only to study through the subjective method of introspection, Comte ignored, presumably because introspection did not seem subject to proper scientific control.

Many philosophers have been labelled 'positivist', especially those of an evolutionist persuasion, but after Comte there was less emphasis on categorizing and on the historical development of thought, and also perhaps less on the social-reformist and somewhat authoritarian zeal that had a lot to do with the personality of Comte himself. The emphasis on the value and all-embracing capability of science remained, and indeed was intensified in so far as theology and metaphysics tended to get short shrift. But there was a more critical approach to science itself, to what it was and what it could do; the point was not to limit its scope, which became ever wider, but to examine its pre-suppositions and proper procedures. Science became more self-conscious, and more concerned to extrude

metaphysical elements from science itself. It is based on observation, and so should not, it was thought, appeal to what cannot be observed, on pain of reintroducing metaphysics. This means that things like atoms and electrons should not be treated as real but unobservable entities, but as devices which help the scientist to give the simplest unifying description of phenomena and make accurate predictions, rather as the square root of minus one is usually treated by mathematicians and physicists as a convenient device which does not correspond to anything real, even in the sense in which numbers might be real, but is distinguished from the 'real' numbers by being called 'imaginary'. This approach (\*instrumentalism) was especially pursued by Mach, who used it also in denying a place in proper scientific descriptions to physical objects, which cannot strictly be observed, he thought. Positivism here has obvious affinities with the empiricism of earlier philosophers, especially, so far as philosophy of science goes, with Berkeley, who also anticipated Mach in rejecting Newton's attempt to prove the existence of absolute space by observing the behaviour of the surface of the water in a bucket as it started and stopped rotating. Berkeley (in his *De Motu*, or *Of Motion*) and Mach argued that the deformation of the surface might occur because the rotation was relative to the framework provided by the fixed stars rather than to that provided by an absolute space; Mach in fact thought that it was not just relative to, but caused by, this relation to the fixed stars.

Mach, with other philosophers of science of an anti-metaphysical bent, notably Duhem and, a little later, Poincaré, was writing towards the end of the nineteenth century. The trend continued, but in the twentieth century the emphasis shifted very much towards logic and language, resulting in \*Logical Positivism, the form usually referred to when the word 'positivism' is used by itself in a twentieth-century context, at any rate when that context is philosophical rather than scientific. Concerning science, the emphasis was then on the unity of the sciences, especially their reducibility to physics. (\*Reductionism.) In science today 'positivism' refers especially to the unity of the natural and social sciences, but in philosophy is less used. Logical Positivism has been sublimated into anti-realism, and reductionism in the sense of the attempt to reduce all sciences to physics has been largely abandoned. (\*Realism and anti-realism.) But the appeal to science in matters concerning the mind remains vigorous, and both here and in anti-realism the spirit of positivism still flourishes in philosophy, though it is far from being unchallenged, and it is open to dispute how far it can be called dominant.

\*Legal positivism shares something of the spirit and motivation of positivism in the general sense, and originated at about the same time, but in fact has developed rather independently.

**Positivism, Logical:** see Logical Positivism.

**possibility.** Possibility, \*actuality, \*necessity are interdependent modalities. On most accounts, and in some sense of 'entail', necessity entails actuality and actuality entails possibility, but the converses are not valid.

To characterize  $\phi$  as a possibility is generally to claim for some appropriate  $\phi$ ,  $\phi$  is possible.

Where  $\phi$  is a proposition, it can be understood as:

- (1)  $\phi$  is logically possible; its negation entails a contradiction.
- (2)  $\phi$  is metaphysically possible; consistent with metaphysical necessities. Kant's necessary synthetic truths are examples of the latter.
- (3)  $\phi$  is nomologically possible; consistent with scientific laws.
- (4)  $\phi$  is epistemologically possible; consistent with what is known.
- (5)  $\phi$  is temporally possible; consistent with truths about the past.
- (6)  $\phi$  is conceivable to a rational agent.

A distinction has been drawn between \**de re* and *de dicto* modalities, as, for example, where there is a mix of quantifiers and modal operators. Consider the propositions (i) It is possible that something has the property  $P$  and (ii) There is something that possibly has the property  $P$ . (i) is characterized as a *de dicto* use, attributing possibility to a proposition. (ii) is characterized as *de re*, attributing to a particular object the property of possibly having the property  $P$ . On such a *de re* use what follows the modal operator is not a complete sentence. (ii) can be represented as 'There is a particular  $x$  such that it is possible that  $x$  has  $P$ '.

The clarity or usefulness of the distinction has sometimes been questioned. For example, the \*Barcan formula endorses equating (i) and (ii). Also, a determination of *de re* versus *de dicto* use is often unclear, as, for example, where sentences with proper names follow the modal operator, as in 'It is possible that Napoleon was assassinated'.

M. Loux (ed.), *The Possible and the Actual* (Ithaca, NY, 1979).

A. Prior, *Time and Modality* (London, 1957).

**possible worlds.** We often talk about what might have been the case, about what is possible. I might have been a vicar—that is, although I am not actually a vicar, my being a vicar is possible. Philosophers have become accustomed to talking of such possibilities in terms of the idea of a

possible world: to say that I might have been a vicar is to say that there is a possible world in which I am a vicar. A possible world is a world which differs in some possible way from our 'actual' world: e.g. a world in which tigers have no stripes, or in which no people existed.

The idea of a possible world in something like the contemporary sense is normally credited to Leibniz, who thought that God chose this world, from an infinity of possible worlds, to be the actual world. Since God must choose the best, this world is therefore the best of all possible worlds—the doctrine famously satirized by Voltaire in *Candide*.

Possible worlds became a focus for philosophical interest in this century with the development, by Saul Kripke and others, of a semantic interpretation for \*modal logic. Modal logic adds two symbols to the basic vocabulary of logic:  $\diamond$ , read as 'possibly' or 'it is possible that', and  $\Box$ , read as 'necessarily' or 'it is necessary that'. (There are different systems of modal logic, which differ in which modal formulae are taken as \*axioms.) Thus we can construct formulae such as  $\Box(p \ \& \ q)$ ,  $\diamond p$ ,  $\diamond \Box p$ , and so on. Intuitively, these formulae should be interpretable as saying something about what is necessarily or possibly true. But how should we understand their \*truth-conditions? Possible worlds provide the answer. The modal sentence ' $\Box(p \ \& \ q)$ ' is true if and only if ' $(p \ \& \ q)$ ' is true at all possible worlds. (\*Formal semantics.) The essential idea is fairly intuitive. A necessary truth, such as ' $2 + 2 = 4$ ', is one that is true in all possible worlds: there is no possible situation in which it is false. Something that is merely possibly true, such as 'I am a vicar', is true in some possible situation. There is no impossibility in the idea of a situation in which I am a vicar.

This suggests a way of *reducing* problematic modal claims into claims that do not contain any modal notions. If we take the idea of a *world* as primitive, we can understand the modal operators 'possibly' and 'necessarily' as quantifiers over worlds: 'Possibly  $p$ ' is thus rendered 'There is a world in which  $p$ ', and 'Necessarily  $p$ ' becomes 'At all worlds,  $p$ '. Modality is explained away!

However, it could be objected that we cannot really take the idea of a world as basic, since hidden within it is the idea of possibility: a 'world' here is being tacitly understood as a *possible* world. If we are to reduce modality, we must have an independent account of what these possible worlds are. So what are these possible worlds? The most striking answer is David Lewis's idea that other possible worlds are real: they exist in just the same sense as the actual world exists. What makes worlds distinct is the fact that they are spatio-temporally separated from one another. And what makes the actual world actual is simply the fact that we inhabit it—other speakers in other worlds who utter the words 'the actual world' will be referring to their world. 'Actual' therefore becomes an indexical.

The idea of a possible world can be put to use in other areas of philosophy. Two examples: first, Lewis and Robert Stalnaker have explicated the idea of a proposition as a *set of possible worlds*. The proposition expressed by the

sentence 'Pigs fly' is that set of worlds in which 'Pigs fly' is true. Second, Lewis has argued that we understand the idea of a property, such as redness, not as a universal, but as a *set of possible individuals*: all those individuals, in this world and others, to which the predicate 'is red' truly applies. Lewis argues forcefully that we cannot make adequate sense of the applications of the notion of a possible world unless we accept worlds as real. This idea has met with much resistance. Others think that we should rather explain possible worlds in terms of sets of sentences, or as constructions out of the inhabitants of the actual world, or think with Kripke that possible worlds are stipulated rather than 'discovered'. **possible-worlds semantics:** see formal semantics, the philosophical relevance of.

**post hoc, ergo propter hoc.** 'After this, therefore because of this.' Strictly, the \*fallacy of inferring that one event is caused by another merely because it comes after it. More loosely, the fallacy (characteristic of superstitious beliefs) of assuming too readily that an event that follows another is caused by it without considering factors such as counter-evidence or the possibility of a common cause. (\*Causality.) The name appears to derive from Aristotle's *Rhetoric* (1401<sup>b</sup>29–34). P.J.M.

H. W. B. Joseph, *An Introduction to Logic*, 2nd edn. (Oxford, 1916), ch. 27.

**post-analytic philosophy.** A somewhat amorphous tendency (hardly 'school') of thought which defines itself mainly in opposition to the mainstream 'analytic' line of descent. This reactive movement may be dated back to Quine's essay 'Two Dogmas of Empiricism' (1953) which launched a root-and-branch attack on the logical empiricist programme and thereby did much to promote the turn toward a radically holistic conception of meaning, knowledge, and truth. Other sources include late Wittgenstein on 'language-games' and cultural 'forms of life' as the furthest we can get by way of epistemic justification, and Richard Rorty's neo-pragmatist view of truth as what's currently and contingently 'good in the way of belief'. These ideas have found additional support in Thomas Kuhn's paradigm-relativist conception of scientific theory change—itsself much influenced by Quine—and in the 'strong' sociology of knowledge where priority is accorded to the socio-cultural determinants of whatever passes for 'truth' at any given time.

Feminist philosophers have likewise argued for a more holistic and context-sensitive approach, one that would emphasize those factors in the process of knowledge acquisition that are standardly treated—by 'malestream'

analytic philosophers—as belonging to the background 'context of discovery' rather than the scientific 'context of justification'. Ideas have also come from farther afield, e.g. from hermeneutic approaches (Dilthey, Heidegger, Gadamer); from Michel Foucault's Nietzsche-inspired sceptical genealogies of knowledge; and from post-structuralist ideas about 'reality' as a linguistic or discursive construct. Meanwhile, some thinkers in the broadly post-analytic camp would reject these more extreme versions of the case against 'old-style' analytic philosophy. Very often this involves an attempt to reformulate its scope and limits in response to such sceptical relativist arguments. Thus the prefix 'post-' sometimes betokens 'farewell to all that', while sometimes it announces 'business continued under different management'. C.N.

J. Rajchman and Cornel West (eds.), *Post-Analytic Philosophy* (New York, 1985).

**post-modernism.** In its broad usage, this is a 'family resemblance' term deployed in a variety of contexts (architecture, painting, music, poetry, fiction, etc.) for things which seem to be related—if at all—by a laid-back pluralism of styles and a vague desire to have done with the pretensions of high-modernist culture. In philosophical terms post-modernism shares something with the critique of Enlightenment values and truth-claims mounted by thinkers of a liberal-communitarian persuasion; also with neo-pragmatists like Richard Rorty who welcome the end of philosophy's presumptive role as a privileged, truth-telling discourse. There is another point of contact with post-modern fiction and art in the current preoccupation, among some philosophers, with themes of 'self-reflexivity', or the puzzles induced by allowing language to become the object of its own scrutiny in a kind of dizzying rhetorical regress. To this extent post-modernism might be seen as a ludic development of the so-called \*'linguistic turn' that has characterized much philosophical thinking of late. C.N.

\*modernism; German philosophy today.

Thomas Docherty (ed.), *Postmodernism: A Reader* (Hemel Hempstead, 1993).

**post-structuralism.** School of thought which emerged in the late 1970s, claiming to supersede—or at any rate to 'problematize'—the earlier \*structuralism. Best understood as a French-inspired variant of the so-called \*'linguistic turn', it is the idea that all perceptions, concepts, and truth-claims are constructed in language, along with the corresponding 'subject-positions' which are likewise (so it is argued) nothing more than transient epiphenomena of this or that cultural \*discourse. From Saussure post-structuralism takes the notion of language as a system of immanent relationships and differences 'without positive terms'; from Nietzsche, its outlook of extreme epistemological and ethico-evaluative relativism; and from Foucault, its counter-Enlightenment rhetoric of 'power/knowledge' as the motivating force behind talk of reason

or truth. Such thinking is vulnerable to all the familiar criticisms—including forms of transcendental refutation—rehearsed against thoroughgoing sceptics and relativists down through the ages.

C.N.

J. Sturrock (ed.), *Structuralism and Since* (Oxford, 1979).

**potentiality.** A potentiality, or latent ability, is a second-order \*capacity of an object or person, a capacity to acquire, develop, or regain another (first-order) capacity. Thus a normal new-born human infant has a potentiality to speak English, meaning that it has the capacity (absent, for instance, in infant chimpanzees) to acquire the ability to speak English. The realization of such a potentiality—that is, the acquisition of the relevant first-order capacity—may involve both natural processes of maturation and the presence of suitable environmental conditions.

In a more general sense, potentiality is traditionally contrasted with actuality, a distinction intimately related in Aristotelian metaphysics to the distinction between matter and form, and one which more or less coincides with the modern distinction between the dispositional and the occurrent.

E.J.L.

\*disposition; propensity.

R. Tuomela (ed.), *Dispositions* (Dordrecht, 1978).

**pour soi:** see for-itself and in-itself.

**power.** A central concept in political philosophy and, often metaphorically, in other inquiries as well. Discussions of power in politics typically refer to one of two sources of power, or to an amalgam of both. These are the physical and organizational resources produced by an economy, and the simpler but less tangible resource of co-ordinated individuals. We may call these exchange power and co-ordination power. They enable different things. For example, the power of a charismatic leader backed by large numbers may readily bring down a regime but may not have much value in creating a new one in its place or in maintaining one. Exchange-power may be especially valuable in maintaining a regime.

Power is typically a causal notion: its application produces results. A presumption of much power talk is that it is somehow additive: put enough little bits together and you have a big chunk of power. There may often be truth in this view, as in a military engagement. But it is also often conspicuously wrong and misleading. It is wrong directly in that bits of power need not add any better than other things do. Addition can fail when power is all of one type or when the two types are mixed. For a transparent example of the former, note that the charismatic leaders of two groups with different goals or values could dissipate all their power by attempting to add it together. For an example of the latter, note that a regime might amass greater and greater exchange power only to find itself now destitute of co-ordination power, as did the military junta in Argentina in the 1980s. That regime destroyed almost all of the opposition to its general policies and its dictator-

ship only to create opposition to its destruction of those people.

Among the greatest political power theorists have been Thomas Hobbes and Karl Marx. Hobbes supposed that an all-powerful sovereign would produce such order as to make life better for all. In his fiction of the contractual creation of a sovereign out of the conditions of the state of nature, Hobbes recognized but largely ignored the difficulty of creating power merely by willing it. But without power, the sovereign would be of no value to those who want order. For Marx the power of a ruling class is to be explained by relations of production. There are subjective elements at play because a class must come to have class consciousness before its members are likely to co-ordinate properly for their class interests. Marx grasped the role of the co-ordination of large numbers of individuals in his schematic accounts of failed and potential revolutions. But he may finally have underestimated the potential role of power from exchange as the technology of weapons and of policing benefited from the evolving capitalist mode of production. That mode, while it created a proletariat, also created a state apparatus that, while it has remained intact, has been impervious to threats from Marx's revolutionary class.

Historically, power has been invoked most by conflict theorists. In the view of these theorists, there is usually someone or some group who are thought to have power and to use it for some purpose. In contemporary debates, especially those centring on the work of Michel Foucault, this assumption is sometimes not made. There is somehow power in the system or in the culture we have inherited, and that power controls us, sometimes in deleterious ways. Hence, despite the language of power and exploitation, there is relatively little connection to the long tradition from Thrasymachus into the present. In Western academic life, the older tradition seems to fit the increasingly bitter conflict between these two power schools.

**power, will to:** see will to power.

**practical reason.** Argument, intelligence, insight, directed to a practical and especially a moral outcome. Historically, a contrast has often been made between theoretical and practical employments of \*reason. Aristotle's 'practical syllogism' concludes in an *action* rather than in a proposition or a new belief: and *phronēsis* (see book vi of *Nicomachean Ethics*) is the ability to use intellect practically. In discussions of motivation, furthermore, appeals to practical reason may seek to counter claims that only desire or inclination can ultimately prompt to action. A measure of disengagement from personal wish and want,

a readiness to appraise one's acts by criteria which (rising above individual contingent desire) can be every rational moral agent's criteria, marks a crucial point of insertion of reason into practice. To Kant, the bare notion of being subject to a moral law suffices to indicate how practical reason can operate. Considering any moral policy, ask: Could it consistently function as universal law? The scope of practical reason, however, is much wider than this: practical reasoning must (for example) include the critical comparison and sifting of alleged human goods and ends, and the reflective establishing of their ranking and place in a life plan.

O. O'Neill, *Constructions of Reason* (Cambridge, 1989).

**practical syllogism.** A kind of inference whose function is to produce action. Aristotle says that the premisses of practical syllogisms move agents to act (*De Anima* 434<sup>a</sup>16–21). On one interpretation, these premisses express desires and beliefs (e.g. a desire for warmth and a belief that making a fire would do) that, via inference, issue in actions. It is debated whether the conclusion of an Aristotelian practical syllogism is a mental item (e.g. a desire to make a fire now) or an overt action. Whether the action-producing function claimed for practical syllogisms is instead performed by non-inferential causal processes is an open question.

D. Charles, *Aristotle's Philosophy of Action* (Ithaca, NY, 1984).

**pragmaticism.** A rule for clarifying the meaning of concepts and hypotheses defended by Charles S. Peirce: we should list the experiential consequences our actions would have were the hypotheses true. The name was introduced in 1905 to distinguish Peirce's \*pragmatism from rival versions: he hoped it was 'ugly enough to be safe from kidnappers'. Pragmaticism differed from other versions in its commitment to realism and in the claim that a strict proof of it could be given.

C.J.H.

C. S. Peirce, 'What Pragmatism Is', in *Collected Papers*, v (Cambridge, Mass., 1934).

**pragmatics.** The study of language which focuses attention on the users and the context of language use rather than on \*reference, \*truth, or \*grammar. Thus, pragmatic analysis of a command notes that the speaker must be a superior and that the hearer has the ability to carry out the command. On the discourse level, pragmatic analysis tells us how participants in a conversation interact with one another as when a speaker signals the hearer that he or she is telling a story or is engaged in prayer. Also on the discourse level, pragmatic analysis shows us how conversational settings disambiguate what is being said. At a party attended by Bill Adams, we understand that the speaker is referring to that Bill and not Bill Baker when he says 'Bill is stupid'. In like fashion, this sort of analysis shows us how the conversational setting implicates. Bill Adams is applying for a job, and you are asked about his application. If all

you say is that he is a nice fellow, you imply conversationally that there is not much more to be said on his behalf.

**pragmatic theory of truth.** For pragmatists, \*truth, like other concepts, is to be understood in terms of practice. The notion of truth as a relation of correspondence between belief and reality is not rejected but clarified by reference to actions, future experiences, etc. Each of the pragmatists has a distinctive way of carrying out this practical clarification.

Peirce defines truth as the ultimate outcome of inquiry by a 'community of investigators', an outcome of 'settled' 'habits of action'. James clarifies truth in terms of 'leading'. True beliefs, he says, 'lead to consistency, stability and flowing human intercourse'. Dewey identifies truth ('warranted assertibility') with the solution of a problem. Inquiry, he holds, starts from a 'problematic situation' and, if successful, ends with a situation that is so 'determinate' and 'unified' that hesitancy to act has been eliminated.

Although classical pragmatists repeatedly affirm their allegiance to \*realism, today the debate still rages over whether the relativity to practice in this theory of truth entails a type of \*idealism or \*scepticism.

P.H.H.

C. J. Misak, *Truth and the End of Inquiry: A Peircean Account of Truth* (Oxford, 1991).

**pragmatism.** The characteristic idea of philosophical pragmatism is that efficacy in practical application—'What works out most effectively in practice'—somehow provides a standard for the determination of truth in the case of statements, rightness in the case of actions, and value in the case of appraisals. However, it is the first of these contexts, the epistemic concern for meaning and truth, that has historically been the most prominent. With Immanuel Kant, pragmatism insists that since our limitedly human efforts at inquiry can never achieve *totality*, we must settle for *sufficiency*, which is ultimately a practical rather than a theoretical matter, so that prioritizing practical over theoretical reason is an inescapable part of the human condition.

In matters of cognition and inquiry, pragmatism calls for a steadfast refusal to allow us to view the very best that we can possibly do as not being good enough. Its operative injunctions are: Approach the issue of the cognitive accessibility of truth by asking the classical pragmatic question: If that is indeed how realities stand, then what would be the best sort of evidence for it that we could expect to achieve? The operative injunctions are: 'Realize that we have no access to matters of fact save through the mediation of evidence that is often incomplete and imperfect. And realize too that to say that the best evidence is not good enough is to violate Peirce's cardinal pragmatic imperative never to bar the path of inquiry.'

In line with this perspective, a realistic cognitive pragmatism insists upon pressing the question: 'If A were indeed the answer to a question Q of ours, what sort of evidence could we possibly obtain for this?' And when we obtain such evidence—as much as we can reasonably be expected to achieve—then pragmatism sees this as good enough. ('Be prepared to regard the best that can be done as good enough' is one of pragmatism's fundamental axioms.) If it looks like a duck, waddles like a duck, quacks like a duck (and so on), then—so pragmatism insists, we are perfectly entitled to stably the personal claim that it is a duck—at any rate until such time as clear indications to the contrary come to light. Once the question 'Well, what more could you reasonably will ask for?' meets with no more than hesitant mumbling, pragmatism says: 'Feel free to go ahead and make the claim.'

It is not that true *means* warranted assertibility, or that warranted assertibility entails truth. What is the case, rather, is that evidence here means 'evidence for truth', and (methodologically) warranted assertibility means 'warrantedly assertible as true'. After all, evidentiality is here a matter of truth estimation, and where the conditions for rational estimation are satisfied—*ipso facto*—there is rational warrant for letting those estimates stand surrogate for the truth. The very idea that the best we can do is not good enough for all relevant reasonable purposes is—so pragmatism and common sense alike insist—something that is simply absurd, a thing of unreasonable hyperbole.

Although pragmatism is largely epistemic in orientation, it has a metaphysical component as well. This pivots on the idea that human concepts and distinctions are generally dichotomous and on-off, while nature herself is not hard-edged. In consequence, we think in black and white about a reality that admits various shades of grey, or—to put it into more contemporary terms—we think by digital concepts about an analogue reality. The subtlety and complexity of nature are such that what we see as differences in kind are in fact differences in degree, with thought imposing discontinuities upon a continuously standard reality. It is the purposes at hand that determine the *modus operandi* of our conceptualizations even as the line between childhood and maturity may be set at 18 for consent in marriage, at 16 for purchasing alcoholic beverages, and at 21 for voting. But pragmatism also holds that our distinctions—though partly conventional—are never totally so but will inevitably hinge on purposive efficiencies inherent in the inexorable rulings of a non-negotiable reality.

Pragmatism as a philosophical doctrine traces back to the Academic \*Sceptics in classical antiquity. Denying the possibility of achieving authentic knowledge (*epistēmē*) regarding the real truth, they taught that we must make do with plausible information (*to pithanon*) adequate to the needs of practice. Kant's stipulation 'contingent belief, which yet forms the ground for the effective employment of means to certain actions, I entitle *pragmatic belief*' (*Critique of Pure Reason*, A 824/B 852) was also influential for the development of the doctrine. Another formative step was Schopenhauer's insistence that the intellect is

universally subordinate to the will, a line of thought that was elaborated by several German neo-Kantian thinkers, including Hans Vaihinger and Georg Simmel, who stressed the controlling dominance of practical over theoretical reason. Moral \*utilitarianism, with its tests of the rightness of modes of action in terms of their capacity to provide the greatest good of the greatest number was yet another step in the development of pragmatic thought. For it too invokes much the same utility-maximization model, and there is a deep structural analogy between the (act-utilitarian) contention that an action is right if its consequences redound to 'the greatest good of the greatest number', and the thesis-orientated version of a pragmatic theory of truth, holding that an empirical claim is correct if its acceptance is maximally benefit-producing.

However, pragmatism as a determinate philosophical doctrine descends from the work of Charles Sanders Peirce. For him, pragmatism was primarily a theory of meaning, with the meaning of any concept that has application in the real world inhering in the relations that link experiential conditions of application with observable results. But by the 'practical consequences' of the acceptance of an idea or a contention, Peirce meant the consequences for *experimental* practice—'experimental effects' or 'observational results'—so that for him the meaning of a proposition is determined by the essentially positivist criterion of its observable consequences. And, moving beyond this, Peirce also taught that pragmatic effectiveness constitutes a quality-control monitor of human cognition—though here again the issue is that of *scientific* praxis and the standard of efficacy pivoting on the issue of specifically *predictive* success. Peirce developed his pragmatism in opposition to idealism, seeing that the test of applicative success can lead mere theorizing to stub its toe on the hard rock of reality. But his successors softened up the doctrine, until with present-day 'pragmatists' the efficacy of ideas consists in their mere *adoption* by the community rather than in the success that the community may (or may not!) encounter as it puts those ideas into practice.

Although Peirce developed pragmatism into a substantial philosophical theory, it was William James who put it on the intellectual map in his enormously influential *Pragmatism: A New Name for Some Old Ways of Thinking* (New York, 1907). However, James changed (and—as Peirce himself saw it—ruined) Peircean pragmatism. For where Peirce saw in pragmatism a road to impersonal and objective standards, James gave it a personalized and subjectivized twist. With James, it was the personal (and potentially idiosyncratic) idea of efficacy and success held by particular people that provided the pragmatic crux, and not an abstracted community of ideally rational agents. For him, pragmatic efficacy and applicative success did not relate to an impersonalized community of scientists but to a diversified plurality of flesh-and-blood individuals. Truth for James is accordingly what reality impels and compels human individuals to believe; it is a matter of 'what pays by way of belief' in the course of human activity within the surrounding environment; and its acquisition is an

PHILOSOPHY IN AMERICA: THE FOUNDERS

JONATHAN EDWARDS's Puritan faith runs throughout his philosophy, where all explanation ends in God.

C. S. PEIRCE, perhaps the greatest American philosopher, inventor of pragmatism, published no books and found little recognition in his lifetime.

WILLIAM JAMES, in philosophy as in psychology, sought to understand any thing by asking what difference it makes in practice or in experience—by seeking to discover its function.

GEORGE SANTAYANA's writings proclaim him a truly American philosopher in their rejection of European idealism in favour of a naturalistic view of the world and the place of humankind in it.

invention rather than a revelation. With James, the tenability of a thesis is determined in terms of its experiential consequences in a far wider than merely *observational* sense—a sense that embraces the affective sector as well.

John Dewey, like Peirce before him, saw inquiry as a self-corrective process whose procedures and norms must be evaluated and revised in the light of subsequent experience. But Dewey regarded this reworking as a social and communal process proceeding in the light of values that are not (as with Peirce) connected specifically to science (viz. prediction and experimental control), but rather values that are more broadly rooted in the psychic disposition of ordinary people at large—the moral and aesthetic dimension now being specifically included. Peirce's pragmatism is scientifically élitist, James's is psychologically personalistic, Dewey's is democratically populist.

Pragmatism had a mixed reception in Europe. In Italy Giovanni Papini and Giovanni Vailati espoused the doctrine and turned it into a party platform for Italian philosophers of science. In Britain, F. C. S. Schiller was an enthusiastic follower of William James, while F. P. Ramsey and A. J. Ayer endorsed pivotal aspects of Peirce's thought. Among continental participants, Rudolf Carnap also put pragmatic ideas to work on issues of logic and philosophy of language, and Hans Reichenbach reinforced Peirce's statistical and probabilistic approach to the methodology of induction. However, the reception of pragmatism by other philosophers was by no means universally favourable. F. H. Bradley objected to the subordination of cognition to practice because of the inherent incompleteness of all merely practical interests. G. E. Moore criticized William James's identification of true beliefs with useful ones—among other reasons because utility is changeable over time. Bertrand Russell objected that beliefs can be useful but yet plainly false. And various continental philosophers have disapprovingly seen in pragmatism's concern for practical efficacy—for 'success' and 'paying off'—the expression of characteristically American social attitudes: crass materialism and naïve democratism. Pragmatism was thus looked down upon as a quintessentially American philosophy—a philosophical expression of the American go-getter spirit with its success-orientated ideology.

However, Americans have had no monopoly on practice-orientated philosophizing. Karl Marx's ideas regarding the role of practice and its relation to theory have had a vast subsequent influence (some of it upon otherwise emphatically non-Marxist thinkers such as Max Scheler). Important recent developments of praxis-orientated philosophy within a neo-Marxist frame of reference are represented by Tadeusz Kotarbiński in Poland and Jürgen Habermas in Germany. Kotarbiński has endeavoured to put the theory of \*praxis on a systematic basis within a special discipline he designates as praxiology. Habermas has pursued the concept of praxis deeply into the domain of the sociological implications of technology.

Be this as it may, pragmatism has found its most favourable reception in the USA, and has never since

Peirce's day lacked dedicated advocates there. At Harvard in the next generation after James, C. I. Lewis was concerned to apply pragmatism to the validation of logical systems. He focused upon (and in his own work sought to develop) the idea of alternative systems of logic among which one must draw on guides of pragmatic utility. And for all his differences with Lewis, W. V. Quine continued this thinker's emphasis on the pragmatic dimension of choice among alternative theoretical systems. Richard Rorty has endeavoured to renovate John Dewey's rejection of abstract logical and conceptual rigidities for the flexibilities of expediency in practice. In a cognate spirit, Joseph Margolis has re-emphasized pragmatism's anti-absolutism based on the transiencies of historical change. And Nicholas Rescher's 'meth-odological pragmatism' sought to return pragmatism to its Peircian roots by giving the doctrine a specifically methodological turn, seeing that anything methodological—a tool, procedure, instrumentality, programme, or policy of action, etc.—is best validated in terms of its ability to achieve the purposes at issue, its success at accomplishing its appropriate task. It follows that even the factual domain can be viewed in such a light that practical reason becomes basic to the theoretical.

One overarching and ironic fact pervades the development of pragmatism, namely that the doctrine can be seen either as a validation of objectively cogent standards or as a subverter of them. There is a Peircian or objective pragmatism of 'What works *impersonally*'—though proving efficient and effective for the realization of some appropriate purpose in an altogether person-indifferent way ('successful prediction', 'control over nature', 'efficacy in need fulfillment'). And there is a Jamesian or subjective pragmatism of 'What works for X' in proving efficient and effective for the realization of a particular person's (or group's) wishes and desires. The objective pragmatists stand in the tradition of Peirce and include F. P. Ramsey, C. I. Lewis, Rudolf Carnap; the subjective pragmatists stand in the tradition of William James and include F. C. S. Schiller and Richard Rorty. (John Dewey straddles the fence by going to an social interpersonalism that stops short of impersonalism.) Looking at James, Peirce saw subjective pragmatism as a corruption and degradation of the pragmatic enterprise, since its approach is a venture not in validating objective standards but in *deconstructing* them to dissolve standards as such into the variegated vagaries of idiosyncratic positions and individual inclinations. And this is how objective pragmatists view the matter down to the present day—this writer included. N.R.

**pragmatism, neo-**: see neo-pragmatism.

**praxis.** The Greek word for 'action'. It enters the philosophical literature as a quasi-technical term with Aristotle (meaning 'doing' rather than 'making [something]'), is developed by some of the Left Hegelians, and is now primarily associated with Marx and Marxism. In the 1960s and 1970s the term characterized the approach of east European (especially Yugoslav) Marxists (known as the Praxis Group), whose central concern was to study and influence the role of free creative activity in changing and shaping ethical, social, political, and economic life along humanistic socialist lines.

R.DE G.

Nicholas Lobkowitz, *Theory and Practice: History of a Concept from Aristotle to Marx* (Notre Dame, Ind., 1967).

**predicate:** see subject and predicate.

**predicate calculus.** A device (also called the functional calculus, or calculus of relations) for formalizing and systematizing the logical relations between propositions when these are considered not (as for the \*propositional calculus) as unanalysed, but as analysed to bring out their structures, so that two different propositions, instead of being identical or totally different, may be partially different, having something in common, like 'All cats are black' and 'Some cats are black'. This \*calculus, like the propositional calculus, can be presented either as an axiom system or as a natural deduction system for the relevant area. Unlike the old Aristotelian logic it takes account of relational predicates (which can be dyadic like 'greater than', triadic like 'between', or in general *n*-adic), as well as of non-relational predicates like 'black' (which yield the monadic predicate calculus, to which certain special theorems apply). The predicate calculus is called *extended* or *second-order* if its variables range over what its predicates, as well as what its subjects, stand for; otherwise it is called *restricted* or *first-order*. (\*Higher-order logic.)

A.R.L.

D. Hilbert and W. Ackerman, *Principles of Mathematical Logic* (first pub. in German, 1928–38; New York, 1950).

**predicative theories.** Theories which aim to obey the principle that an abstract object exists only if it has a predicative definition. (\*Vicious-circle principle.) Russell's \*type theory is not one, since it contains an axiom of reducibility which nullifies that principle. The axiom was needed to obtain the classical theory of real numbers, which a predicative theory cannot do. For on the classical theory there are uncountably many real numbers, whereas the predicative universe must be countable, since it cannot outrun the available definitions.

H. Weyl produced the first predicative theory of real numbers in *Das Kontinuum* (1918). His results have since been extended, and it turns out that a surprisingly large amount of the classical theory can be reconstructed. Accordingly, some philosophers have claimed that predicative mathematics includes all the mathematics that is actually needed in the sciences, and therefore all that is empirically justified.

The intuitionist theory of real numbers is also a predicative theory, but further constrained by being restricted to \*intuitionist logic.

D.B.

\*impredicative definition.

- C. S. Chihara, *Ontology and the Vicious Circle Principle* (Ithaca, NY, 1973).  
 S. Feferman, 'Systems of Predicative Analysis', *Journal of Symbolic Logic* (1964).  
 H. Wang, *A Survey of Mathematical Logic* (Amsterdam, 1962), esp. chs. 23–5.

**prediction.** The key role of prediction in human affairs inheres in our stake in the future. After all, we are all going to have to spend the rest of our lives there. And from the outset, the existence of *Homo sapiens* has hinged on predictive knowledge: 'What will happen when I enter that cave? Will I find shelter or fierce animals?' 'What will happen when I eat those mushrooms? Will they nourish or poison me?' Without some degree of cognitive control over the future, we humans could not exist as the intelligent creatures we are.

Prediction is literally *foretelling*, specifying occurrences in advance of the fact. A correct forecast can, of course, be the result of pure accident, of lucky guesswork and pure chance. But only *rational* prediction that is based on grounds whose merits are discernible prior to the event is of epistemological interest: predictions whose merits are discernible only after the fact are useless. It can be questioned as a matter of principle whether such cogent predictions can be made at all. Every rational prediction is an \*induction—a projection of some sort from past experience, though it need not, of course, be a simple linear projection that is at issue. Thus only in the setting of lawful regularity—where occurrences fall into discernible patterns—will rational prediction be possible at all. The extent to which *this* world is such an orderly cosmos is a discussable question. But the course of wisdom is clearly to hope for the best. Two extremes can be contemplated: (1) that of \*determinism, of a 'Laplacian' cosmos in which literally everything that happens can in principle be pre-calculated, and (2) that of a chaotic world where nothing can be securely predicted because all apparent patterns are at best transitory stabilities. Since classical antiquity, most philosophers have taken an intermediate position, holding that the real world admits of rational prediction in many cases, but with many important exceptions, pre-eminently relating to chance ('stochastic') events in physical nature—such as quantum phenomena or the 'swerve' of Epicurus—and to the spontaneous decisions that manifest the \*free will of human beings.

Some cogent predictions can be equipped with an explicit explanatory rationale. Others may have no further backing than the unarticulated judgement of an informed expert. But even here rational control is possible through establishing a 'track record'.

The ability to underwrite successful predictions is our best quality-control test of the adequacy of scientific theorizing. To be truly satisfactory, our scientific explanations must have a rationale that also engenders adequate predictions. (In this regard the linkage of cosmology to quantum theory becomes crucial.)

The most important feature of a good prediction, rational cogency apart, is its specificity or detail. It is safe (and uninteresting) to predict that Henry will die some time, but far more risky (and interesting) to predict that he will die exactly 756 days hence. It is a consequence of \*Bayes's theorem that the more daring a prediction—the lower its a priori likelihood—the more informative it is, other things being equal. To be sure, other things are not in general equal. For example, a great deal more turns on predicting the outcome of a war or the course of a nation's economy than on the result of a boxing-match. This factor of inherent significance of the matter at issue is the third principal consideration in assessing the merit of a prediction.

There are many obstacles to predictability. In nature we have volatility and \*chance (stochastic phenomena); in human affairs innovation and chance (free will). \*Chaos is a phenomenon that straddles both domains. Processes are chaotic whenever minute differences in conditions (so small as to fall beneath the threshold of detectability) can produce large-scale differences in result. (Lightning bolts and smoke swirls are an example in nature, political assassinations and battlefield fatalities in human affairs.) Chaos is to all appearances a more important source of unpredictability than any putative indeterminism in physics.

Would we want the predictive project to be perfectible? Our psychological and emotional condition is clearly such that we would not want to live in a pre-programmed world where the rest of our fate and future is fully discernible in the realities of the present. The human yearning for novelty—for new experiences and prospects and possibilities—is surely a characteristic aspect of what makes us into the sorts of creatures we are. The feeling of open horizons—of new developments that make for suspense and surprises—is integral to our human nature. Without some exposure to chance and uncertainty we cannot function as the creatures we are—the sort of creatures we have become under the pressure of evolutionary development. We thrive in the interstices of chance that pervade a world of predominantly lawful order. N.R.

**prediction paradox.** A variety of distinct puzzles have come to be associated with this name. (1) involves the sentence *A*: 'Event *E* will happen tomorrow and it cannot be proven by a sound argument using *A* as a premiss that *E* will happen tomorrow'. *A* begins with a prediction but goes on to deny that *A* could be a true premiss leading to the prediction. This could only happen if *A* were not true. So *A* involves a denial of its own truth, making it a relative of the \*liar paradox. (2) A notoriously unreliable speaker can say *B*: '*E* will happen but you don't know it will' and tease his audience by making a prediction which can turn out true even though his audience, being unable to trust him, will not *know E* is going to happen.

In both these cases, the 'prediction' can be replaced by a non-prediction *P* and still leave the same essential problem. So the title 'prediction paradox' is not well-deserved. A somewhat better candidate for the title is (3): *X* needs to stage event *E* on just one of the next *n* days without *Y* (who knows that *X* is committed to staging *Y* on these terms) being able to predict in advance which day it will be. The last day looks like a bad choice for *X*. This tends to make the next-to-last day also look bad, and then the next-to-next, leading to a paradoxical argument ruling out the whole series of days. The contest between *X* and *Y* raises interesting problems in game theory. Unlike (1) and (2), which crucially involve statements (*A* and *B*), no statements need be made for the contest to arise between *X* and *Y*. J.C.

\*exam paradox.

James Cargile, 'The Surprise Test Paradox', *Journal of Philosophy* (1967).

**pre-established harmony:** *see* harmony, pre-established.

**preface paradox.** Paradox about belief and rationality. Recognizing his own fallibility, the author writes in the preface, with all sincerity, 'Though I believe everything I've written, no doubt this book contains mistakes (for which I apologize)'. He believes each of the statements in the book, yet also believes that at least one of them is false, which is close to believing a contradiction; yet his position seems both modest and rational. The paradox stems from the fact that it cannot be rational to believe a contradiction. R.M.S.

A. N. Prior, *Objects of Thought*, ed. P. T. Geach and A. Kenny (Oxford, 1971), 84ff.

**prejudice, Burkian:** *see* Burke.

**prescriptivism.** A theory about the meaning of moral terms such as \*'good', \*'right', and \*'ought'. Its principal advocate has been R. M. Hare. The theory draws a contrast between descriptive meaning, whereby language is used for stating facts, and the 'prescriptive' meaning which is characteristic of moral language. Moral terms are used primarily for *guiding action*, for telling people what to do. As such they are similar to imperatives, which also have prescriptive meaning. Moral discourse is not, as the

\*emotive theory of ethics had seemed to suggest, a manipulative process of playing on people's feelings. It is a rational activity, addressed to others as rational agents. It is, however, logically distinct from the activity of descriptive discourse, and hence no statements of fact can entail any conclusion about what one 'ought' to do. R.J.N.

R. M. Hare, *The Language of Morals* (Oxford, 1952).

**present:** see time.

**presentism.** The presentist maintains that only presently existing objects and presently occurring events are real, thereby excluding from reality past and future objects and events. Indeed, for the presentist, only the present \*time is real, so that our talk about past and future times must be interpreted very differently from our talk about the present. He will be perfectly happy to allow that certain objects *did* exist or *will* exist, which do not presently exist and so are not real. What he wants to avoid saying is that *there really are* past and future times, ontologically on a par with the present time, at which these presently non-existent objects exist. His position may be likened to that of the opponent of \*modal realism, who contends that non-actual \*possible worlds are not ontologically on a par with the actual world, but are merely maximal consistent sets of propositions representing ways the world could have been. E.J.L.

M. J. Loux, *Metaphysics: A Contemporary Introduction*, 2nd edn. (London, 2001).

**Pre-Socratic philosophy.** The term includes all early Greek theorists, with cosmological or philosophical interests, active before the end of the fifth century BC, except for the \*Sophists. This convenient though arbitrary usage recognizes that philosophy began in Greece from, or in conjunction with, abstract cosmological theorizing, and was not generally recognized as a separate discipline in this period.

Abstract cosmology was founded by the sixth-century Milesians: Thales, Anaximander, and Anaximenes. They aimed to construct probable theories about the universe as a whole. They sought economical explanations in well-defined terms, and used the principle of \*sufficient reason as a guide to these. Lacking the means of experimental verification, they tied their theories to the observable world by the concept of *phusis* (nature), which implied a basic uniformity of behaviour in the natural world. There was an overall teleology (guidance by a supreme intelligence identified with the fundamental component of the physical world). This style of 'natural philosophy' (*phusologia*) was continued in the fifth century by Anaxagoras and Democritus among others.

Like every ambitious scientific programme, natural philosophy generated philosophical problems. The most pressing was the epistemological one, particularly since the project required the rejection of all traditional authorities. It is likely that the Milesians were not explicit about their epistemology; but Xenophanes rejected all human claims to knowledge outside the area of immediate experi-

ence. Instead he envisaged the construction (and cumulative refinement) of 'better opinion', the criterion for which was 'resemblance to truths', i.e. the truths of immediate experience. His own cosmology systematically makes parsimonious extrapolations from ordinary experience. This strain of empiricism, revived in the later fifth century, can be traced in Anaxagoras, some of the medical writings attributed to Hippocrates, and perhaps Socrates.

A different type of approach appears in the theology of Xenophanes, which deduced the properties of God from a priori principles of what is 'fitting' for a divinity. The outstanding theorists of the late sixth and early fifth centuries claimed to discover truths of which the denial would be in some way unreasonable or unthinkable. Pythagoras possibly appealed to occult or mystical experience. But Heraclitus and Parmenides (leader of the Eleatics) in their different ways focused on the workings of human reason itself, thereby founding logic and metaphysics. Heraclitus' *logos*, to which he appealed for confirmation, reflects or embodies reason. Parmenides, in the first surviving attempt at consciously rigorous argument, claimed to start from a premiss which cannot coherently be denied, and to deduce step by step the properties of any possible object of knowledge.

Both Heraclitus and Parmenides were concerned with another systematic legacy of the 'natural philosophers': the problem of unity and diversity in the universe, and (arising from that) the problem of appearance and reality. Heraclitus detected a general pattern of 'unity-in-opposites', exemplified in the identity of the river which survives the change of its waters. He did not (as some have thought) deny the principle of \*non-contradiction, but rather saw ambiguities in the very essence of things. Parmenides, by contrast, argued that anything knowable must be fully determinate and absolutely unified. This led him to a strong form of monism about underlying reality.

Parmenides' ideas, particularly his arguments against 'coming-to-be' and 'ceasing-to-be', and his insistence on absolutely definite objects of knowledge, were widely influential. His immediate follower Zeno of Elea turned his style of argumentation to destructive ends, exposing the logical inadequacy of certain natural assumptions about the physical world. Another near-contemporary, Empedocles, idiosyncratically blended Parmenidean metaphysics and Pythagorean doctrines of the soul with a cosmology, which, in parallel to the medical theory of Alcmaeon of Croton (*fl.* c.450?), explained the diversity of appearances by a finite but plural number of basic 'roots' (the first appearance as such of the 'four elements') with clearly defined properties.

The later part of the fifth century was dominated, in the western Greek world (southern Italy and Sicily), by (real or self-styled) Pythagoreans. Pure mathematics was taken as the paradigm, perhaps the only possible kind, of knowledge. (A reduction of all sciences to arithmetic seems to have been seriously attempted.) Philolaus (*fl.* c.450?) argued for finite units and quantities as the only possible objects of knowledge.

## EARLY GREEK PHILOSOPHY

**PYTHAGORAS**, one of the earliest known Greek thinkers: the mythology that attached itself to him in antiquity has made it difficult to affirm much more than that he was a charismatic founder of a religious sect with strong ethical ordinances.

**HERACLITUS**, was to be a model for various modern European philosophers in point of the oracular obscurity of his style, his supposed disregard for his fellow humans, the ambition of his philosophy, and the importance in it of opposition and flux.

**SOCRATES**: Plato paid homage to his mentor by his literary representation and continuation of the Socratic enterprise in a series of philosophical dialogues, in which Socrates seldom meets his match.

**DEMOCRITUS**, perhaps a younger contemporary of Socrates, was one of the earliest proponents of an atomic theory of the universe, and seems to have been a forerunner of Epicurus in ethics.

In mainland Greece and the Aegean islands, the later fifth century was the age of the Sophists (of whom one, Protagoras, was an original philosopher); and of Socrates. Of those others denominated 'Pre-Socratics', most revived the original programme of natural philosophy, taking account of the new situation created above all by the Eleatics and by the new attention to biological theory and psychology. (An isolated figure, Melissus, belongs with the \*Eleatics, and is most notable for his radical critique of sense-perception.) The leading figures were Anaxagoras and the early proponent of \*atomism, Democritus. Anaxagoras and Democritus represent opposite, repeatedly recurring tendencies in physics: Anaxagoras is a 'field theorist', assuming the continuity and ubiquity of physical forces, while Democritus is a 'particle theorist', claiming that they are localized and particulate. Anaxagoras was closer in spirit and style to the original Milesian enterprise, identifying the cosmic intelligence as 'Mind' (\**nous*) and attributing to it an overall teleological control. The Atomists made a fundamental break in creating reductive \*materialism: there are only (lifeless and mindless) atoms and void with their essential properties. They aimed to derive, from these foundations, not only living and sentient beings of familiar kinds, but 'gods' (large, long-lived beings inhabiting intercosmic void) and moral values.

Pre-Socratic philosophy never entirely broke free, except with the Eleatics, from its origins in the problems of a scientific programme. Democritus is the first and only Pre-Socratic known to have elaborated an ethical theory, though in Heraclitus and Empedocles ethical values are given a place in the natural world. The scepticism about moral and religious systems associated with the antithesis between *nomos* ('custom') and *physis* ('nature' or 'reality'), which figured in the discussions of the Sophists, has its roots in Xenophanes' attacks on traditional religion and values. Even in the limited sources, an increasing philosophical sophistication in ontology and epistemology, and an increasing command of the techniques of argument, can be traced.

The interpretation of the Pre-Socratics has been controversial at least since the late fifth century BC. (\*Cratylus.) Many of their works were already lost or scarce in late antiquity, and the rest perished thereafter, apart from quotations in surviving writers. In the scarcity of primary sources Aristotle's remarks on them were generally taken as authoritative from medieval times until recently. Only in the nineteenth century did a new climate of thought, and advances in scholarship, allow some Pre-Socratics to emerge as important philosophers in their own right. Understanding has been both furthered and impeded by the imperialism of those modern philosophers who, like Aristotle, have sought to force the history of philosophy into a preconceived mould. In default of substantial new primary materials, scholarship can advance only by gradually reaching a better (philosophically informed, but not prejudiced) understanding of (a) the nature and aims of the sources; (b) the language and concepts used by the

Pre-Socratics and their contemporaries; (c) their philosophical intentions, as shown by the totality of the evidence.

**presumption.** A concept borrowed by epistemology from law that represents a way of filling in—at least *pro tem*—certain gaps in our otherwise available information. The 'presumption of innocence' is a paradigm case here; a presumption is a matter not of secured facts, of *given* information, but rather of answers that are *taken* in the absence of counter-indications. Presumptions are accordingly defeasible, vulnerable to being overturned—but only by some duly established conflicting considerations. A presumption accordingly has a favourable burden of proof on its side: counter-evidence is needed to effect its undoing.

A specific presumption is always grounded in a principle of presumption. Such principles operate in various domains. For example, a cognitive presumption operates in favour of the data of sight ('Accept what you see to be so'). In communicative contexts we have a presumption to the effect that people are truthful ('Accept what your interlocutors maintain'); in everyday enquiry we have the presumption that our sources are reliable ('Accept what encyclopedias and authorities maintain'); in science we have the presumption of evidential sufficiency ('Accept what the most strongly established theory or explanation maintains'). However, the result of applying such principles of presumption is always tentative and provisional: the rider 'until such time as indications to the contrary come to view' is attached to all presumptive principles.

The validations of the principle of presumption can be of two sorts. Some are justified a priori and proceed by showing that they are *sine qua non* prerequisites of a certain cognitive practice. Others are a posteriori and experiential, grounded in the *ex post facto* consideration of a track record showing that operating on this basis yields better results for the enterprise at issue than would otherwise be available. Practical efficacy is the crux for presumption.

Presumptions play a key role in the cyclic justifications at issue in an epistemological coherentism that dispenses with the self-evident certainties of an epistemic foundationalism.

**Price, Henry Habberley** (1899–1984). Wykeham Professor of Logic and Fellow of New College, Oxford, 1935–59; a shy, reclusive figure, belonging to no school or group and

seeking no disciples. His major work is *Perception*, in which, adopting from Russell and Moore the term ‘sense-datum’ for the basic object of perception, he seeks to clarify the sense in which sense-data ‘belong to’ material objects, rejecting, on the one hand, the causal theories of Locke and Russell and, on the other hand, the ‘phenomenalism of, for example, J. S. Mill. He pursues these issues further in *Hume’s Theory of the External World* (Oxford, 1940). In *Thinking and Experience* (London, 1953) he explores the nature of thinking, playing down the then fashionable emphasis on the use of ‘symbols’, and arguing that concepts should be seen as ‘recognition capacities’. G.J.W. H. H. Price, *Perception* (London, 1932).

**Price, Richard** (1723–91). Welsh dissenting minister noted for his defence of a non-naturalist moral philosophy. His argument for the non-definability of goodness anticipates G. E. Moore, and elements of his intuitionism have reappeared in the work of H. A. Prichard and W. D. Ross. Price’s defence of individual freedom and national independence figured prominently in his criticism of the British declaration of war against the American colonies, and his advice to the Americans after the war helped to shape their new Constitution. He edited Bayes’s essay on the doctrine of chances, pioneered actuarial theory, and became a Fellow of the Royal Society. His enthusiasm for the cause of the French Revolution provoked Edmund Burke to write his famous and severely critical *Reflections on the Revolution in France*. O.R.J.

\*Bayesian confirmation theory.

D. O. Thomas, *The Honest Mind: The Thought and Work of Richard Price* (Oxford, 1977).

**Prichard, Harold Arthur** (1871–1947). Oxford philosopher who emphasized the unanalysability of certain epistemological and ethical concepts, notably knowledge and moral obligation (see his *Knowledge and Perception* (London, 1950) and *Moral Obligation* (London, 1949)). Knowledge, or being certain, was an infallible state of mind, which its possessor could *know* that he possessed, though it had to be distinguished from merely feeling certain, or thinking without question. Moral philosophy, he suggested, rested on a mistake in that it tried to justify moral obligation by reducing it to something else, such as interest, but any such analysis could only succeed by destroying what was supposed to be analysed; like knowledge, moral obligation presented itself directly to our intuitions. Prichard’s moral philosophy therefore contains obvious analogues both to Moore’s view of good as unanalysable and to Kant’s view of duty as entirely independent of interest. A.R.L.

H. A. Prichard, *Moral Writings*, ed. J. MacAdam (Oxford, 2002).

**Priestley, Joseph** (1733–1804). English Utilitarian philosopher, scientist, and unorthodox theologian. Priestley’s main political work is his *Essay on the First Principles of Government* (1768). This work is of interest because it is

here that Bentham may have discovered the formula of the ‘greatest happiness of the greatest number. Priestley, again before Bentham, attempts to bring about the fusion of the principle of utility with democratic ideas. The problem of government is therefore that of finding a way to identify the interest of the governors with the interests of the governed. Priestley’s solution is that identity of interests can be achieved by making it necessary for the rulers to court the favour of the people. ‘It is nothing but the continued fear of a revolt in favour of some rival, that could keep such princes within bounds.’ Priestley is important for many discoveries in chemistry and physics. R.S.D.

Elie Halevy, *The Growth of Philosophical Radicalism*, tr. Mary Morris (London, 1928).

**prima-facie duties:** see duty.

**primary and secondary qualities.** Deriving from the Greek Atomists and common in the seventeenth century (Galileo, Descartes, Boyle) the distinction between these is famously found in Locke’s *Essay Concerning Human Understanding*, where primary qualities (e.g. shape) are ‘utterly inseparable from . . . [a] body’, however small (ii. viii. 9) and secondary qualities (e.g. colour) ‘in truth are nothing in . . . objects themselves, but powers to produce various sensations in us’ (ii. viii. 10). It is often supposed to be an epistemological doctrine concerning perceptual error and illusion, and so to depend on some idea that while we often err about the colours of objects we do not do so about their shapes, or that our perception of colour can vary with our position or with our mental and physical states. In fact, however, it is really a corollary of the corpuscular theory of matter, or, more generally, of the ‘mechanical philosophy’.

Primary qualities belong not only to observable things such as an almond, but also to the insensible minute corpuscles which were supposed to make it up. An almond has solidity, extension, shape, mobility, and number, and according to the corpuscular theory the almond’s corpuscles have these qualities too. Secondary qualities, such as colour and taste, belong to the almond but not to its corpuscles. They arise from the arrangement of the solid, shaped, and mobile corpuscles themselves. Of course, like its colour, the almond’s primary qualities of solidity and extension also result from its consisting of solid, extended corpuscles. What distinguishes them from secondary qualities is that these are those features which corpuscles need to have in order to account for *all* the qualities (primary and secondary) of the things they make up.

Because material things consist of arrangements of insensible corpuscles, they act on our sense-organs in certain ways. Interaction between an almond’s corpuscles and those of our taste-buds results in the production, in our minds, of a certain idea, that of sweetness; though quite how such causation between the physical and the mental takes place is, Locke says, a mystery. Similarly, via the intermediary of reflected light, interaction between an almond’s corpuscles and those of our eyes produces in

us the idea of its colour. Secondary qualities of objects are those arrangements of its corpuscles which cause certain ideas *in us*.

Fire causes pain in us, and snow causes ideas of coldness and whiteness. However, while we think of pain simply as something caused in us by the interaction between fire and our bodies, we think of snow as being, in itself, white and cold. Locke suggests that the corpuscular account of objects, and our perception of them, gives us no reason to think of snow's coldness and whiteness like this. We do perceive snow as being cold and white in itself; but since our doing so is a result of the arrangement of primary-qualified corpuscles, there is no need to suppose snow really is as we perceive it. Snow does have a certain corpuscular arrangement, which fits it to produce ideas of coldness and of whiteness in us; but just as there is nothing in fire resembling pain, so there need be nothing in snow resembling the whiteness and coldness it appears to have. The case is otherwise with primary qualities. In order to explain how we perceive objects as having shape, and being solid, we need to suppose that objects have those properties in the way they appear to have. R.S.W.

\*representative theory of perception.

R. S. Woolhouse, *John Locke* (Brighton, 1983), ch. 4.

**prime matter.** (Latin *materia prima*; Greek *prōtē hulē*; 'first' or 'primary' matter.) Traditionally, \*matter which 'in itself' has no determinate positive qualities, but the potential to have such qualities. Prime matter is posited as what persists through a \*change in which one Aristotelian element (e.g. water) turns into another (e.g. air). This conception of prime matter is traditionally ascribed to Aristotle, although the attribution has been challenged (as has the notion's intelligibility). P.J.M.

\*substratum; *apeiron*.

Aristotle, *De generatione et corruptione*, tr. and ed. C. J. F. Williams (Oxford, 1982), app.

**prime mover.** This is a label given to an ultimate cause of motion or change in the universe; it is an idea of fundamental importance in rational \*cosmology. In ancient philosophy the topic is most fully developed by Plato and Aristotle. Both maintain that the original cause of motion must possess mind. But Aristotle argues against Plato that the prime mover must be itself unmoved. Although criticized by Kant, it re-emerges in current big bang theory. The idea has never been more succinctly expressed than in its earliest presentation in Plato's *Phaedrus* 245c–e. J.D.G.E.

**principle.** The history of philosophy abounds in principles: the principle of \*sufficient reason, Hume's principle ('No ought from an is'), the principle of \*double

effect . . . A principle will often be put forward as an allegedly obvious truth from which to derive further truths. The principle or principles may be thought so basic and general that all or most of knowledge, or anyway of philosophical knowledge, can be derived: we then have philosophical \*foundationalism, as typified in the work of Spinoza. But Descartes's 'I think therefore I am' is not of the general form required of a principle. Using it, or something like it, as a starting-point would amount to a different, epistemological, form of foundationalism.

A moral principle is less a starting-point for reasoning than a guide for deliberation and action. In moral philosophy, you may find a hybrid of the two—for example, the 'utility principle'. R.P.L.T.

\**arkhē*; utilitarianism; regulative principles; rules.

**principle of sufficient reason:** *see* sufficient reason, principle of.

**principles, regulative:** *see* regulative principles.

**Prior, Arthur Norman** (1914–69). New Zealand-born philosopher who taught at the University of Canterbury in New Zealand and the University of Manchester before becoming a Fellow of Balliol College, Oxford. He first gained his reputation in ethics, and then went on to do fundamental work in logic and metaphysics. Prior was a leading figure in the movement to apply modal logic to the formalization of a wide variety of linguistic phenomena. In 1953 he invented tense logic, introducing two new modal operators 'It will be the case that' and 'It has been the case that'. Prior used his tense logic to articulate theories about the structure and metaphysics of time, and to mount a robust defence of free will and indeterminism. Tense logic is also employed for the manipulation of time-dependent data and has numerous applications in computing. In 1956 Prior and Carew Meredith were the first to give a possible-worlds semantics employing the 'accessibility' relation between worlds. Their idea, now standard in modal semantics, was that 'Necessarily *p*' is true in a world *w* iff *p* is true in every possible world accessible from *w*. An iconoclast and a resourceful innovator, Prior inspired many to undertake work in tense and modal logic. B.J.C.

B. J. Copeland (ed.), *Logic and Reality: Essays on the Legacy of Arthur Prior* (Oxford, 1996).

A. N. Prior, *Papers on Time and Tense*, new edn. ed. T. Bräuner, B. J. Copeland, P. Hasle, and P. Ohrstrom (Oxford, 2003).

**prioritarianism** is the view that gains in the well-being of the worse-off are morally more important than the same size gains for the better-off. This view contrasts with \*utilitarianism, which counts a gain in the well-being of one individual the same as it counts the same size gain for anyone else. Pure \*equality in the distribution of well-being is often accused of favouring reducing the well-being of the

better-off even when this will not benefit the worse off. Prioritarianism rejects such 'levelling down'. B.H.

M. Clayton and A. Williams (eds.), *The Ideal of Equality* (London, 2002).

**prisoner's dilemma.** The prisoner's dilemma describes a possible situation in which prisoners are offered various deals and prospects of punishment. The options and outcomes are so constructed that it is rational for each person, when deciding in isolation, to pursue a course which each finds to be against his interest and therefore irrational. For example, if I am an employer and you a worker, it may be to my advantage not to pay you (rather than pay you) whether or not you do the work, and for you not to do the work (rather than do it) whether or not I pay you; but it is to the advantage of neither of us that I should not pay and you should not work. Such a scenario postulates a lack of enforced co-operation; and to avoid the undesirable outcome, the actors in the drama need to be forced into co-operation by a system of rules. So it has been argued that we can find in this dilemma a basis for the generation of the institutions of morality—or, at least, of prudent co-operation. But that conclusion is challenged by others who point out that the same choice-theoretic problems also arise with ends that are immoral or prudentially harmful. J.D.G.E.

From an immense literature on this topic, I select the collection of essays, classic and modern, edited by David P. Gauthier, *Morality and Rational Self-Interest* (Englewood Cliffs, NJ, 1970).

**privacy.** In US legal philosophy the area of individual rights. In philosophy of mind the characteristic of each person's experiences and thoughts that they are known immediately only to that person. Epistemological \*foundationalists took such supposedly infallible and self-intimating knowledge to be the firm basis they sought. The alleged privacy of each person's thoughts and experiences gives rise to the \*'other minds' problem as well as to general \*scepticism regarding knowledge. Attempts to avert such consequences include appeals to the public nature of language, the medium in which thoughts have in any case to be formed. More general attacks on the notion of the mind as an inner realm uniquely accessible to each individual are found in \*Heidegger's \**Dasein* from the 1920s and \*Ryle's behavioural analysis of mind from the 1940s. Latterly, \*Dennett and \*Churchland, respectively, see in the flow of subjective experience but a scrambled version of, and a poor way of accessing, what really happens at more basic 'sub-personal' levels. A.H.

A. J. Ayer, 'Basic Propositions', in *Philosophical Essays* (London, 1954).

G. Ryle, *The Concept of Mind* (London, 1949).

**private language problem.** Sections 243–315 of Wittgenstein's *Philosophical Investigations* criticize the idea, presupposed by Cartesianism and empiricism, of a language whose primitive terms signify the speaker's 'private' sensations and perceptions, allegedly inalienably owned and truly known only by their bearer. 'Ownership' of experi-

ence is misconstrued, since different people can have the very same sensation. Private knowledge of experience is misconceived, since neither knowing nor being ignorant of one's current experience make sense. That the mutual intelligibility of a putative 'private' language is problematic is obvious. The originality of Wittgenstein's argument is to show that it must be unintelligible even to its speaker. For it presupposes the possibility of private ostensive definition, of a private (mental) \*sample functioning as a standard for the correct application of a word, and of a rule which cannot logically be followed by another person, all of which are shown to be incoherent. The consequences of the argument, if it is correct, ramify throughout metaphysics, epistemology, and philosophy of mind. Unsurprisingly, it was heatedly debated in the following decades and controverted both by traditional empiricists and by contemporary materialists and functionalists. P.M.S.H.

P. M. S. Hacker, *An Analytical Commentary on the Philosophical Investigations*, iii: *Wittgenstein: Meaning and Mind* (Oxford, 1990), 1–287.

**privatization** is the granting of individual property rights over previously communally owned or unowned resources. Efficiency-based arguments and justice-based arguments are given in its favour. The least plausible justice-based argument is from the right to property, since many theorists today agree that distribution of property rights should be derived from principles of justice, rather than vice versa. Justice-based arguments for privatizing communal resources, such as service-providing institutions, focus on personal responsibility and increases in freedom of choice which come with competition by providers on a market. It is not clear, however, that all goods allocation should be responsive to individual preferences. Informed choices about education and health care are limited by lack of expertise of precisely the kind sought. Furthermore, even if markets hold individuals responsible for their market choices, those choices are themselves limited by the market advantages and disadvantages that individuals start with. It is also not clear that individuals should be held accountable for all their choices. A moral duty of assistance requires helping those not in a position to help themselves, even if they once were.

Arguments from efficiency highlight the state's moral duty not to waste communal resources. Market competition reduces waste, whilst publicly run services are notoriously wasteful. So, it is argued, why not improve efficiency through privatizing, whilst giving credits to less advantaged citizens to purchase services? This, however, reduces benefits to market preferences, and efficiency to market efficiency. Market efficiency modifies the goods supplied. For efficient exchange on a market, benefits need clear boundaries, which, for example, are lacked by a 'good state of public health'. Consequently, privatization encourages 'commodification': changes to goods making them more market-friendly, such as turning them into distinctly priced units or solely developing their revenue-

yielding properties. This has negative side-effects. Elephant populations in Zimbabwe increased after elephants were privatized. Yet, the value inherent in having 'free-roaming creatures in their natural habitat' is lost when individuals have control-conferring property rights over these creatures. In the social sphere, it can be argued, all aspects of the provision of goods representing a society's assistance to its disadvantaged members should be subject to democratic, communal control. **privileged access.** The supposed special authority possessed by a subject's beliefs about his or her current mental states, as compared with others' beliefs about those states. Attacked as a myth by Ryle, the idea is still debated. Accounts of first-personal authority vary, ranging from, at one extreme, \*in corrigibility, that the subject cannot be wrong, to the subject's merely being better placed in some respects than others. Recent debate has focused on reconciling it with \*externalism. P.F.S.

\*introspection; inner sense.

W. Alston, 'Varieties of Privileged Access', *American Philosophical Quarterly* (1971).

B. Gertler (ed.), *Privileged Access: Philosophical Theories of Self-Knowledge* (Aldershot, 2003).

**probabilistic causality.** If classical \*determinism is true, every event has a sufficient cause which necessitates its occurrence. However, since the advent of quantum physics, we may have to acknowledge that some events, such as the spontaneous decay of a radium atom, lack any such determining cause. Even setting aside such considerations, we are frequently confronted with situations—most obviously in games of chance—in which the outcome of a process cannot be predicted with certainty, but in which some possible outcomes appear to be more probable than others. For these reasons, some philosophers of causation have argued that we need to generalize any account of \*causality to accommodate the possibility of probabilistic causation. According to one widely adopted approach, to say that an event *c* was a probabilistic cause of another event *e* is to say that, in the circumstances in which *c* occurred, the occurrence of *c* raised the chance of *e* occurring—although spelling out what precisely may be meant by this and dealing with various apparent counter-examples is no easy matter, quite apart from the fact that it is difficult to dissociate the notion of causation from that of some kind of necessitation. E.J.L.  
D. H. Mellor, *The Facts of Causation* (London, 1995).

**probability.** Although there is a well-established mathematical calculus of probability, the nature of its subject-matter is still in dispute. Someone who asserts that it will probably rain is not asserting outright that it will: the question is how such guarded assertions relate to the facts.

The modern mathematical treatment of probability owes its origins to Pascal's treatment of games of chance, and the classical equipossibility theory arises most naturally in this context. To say that the probability of a fair die landing six uppermost is one-sixth is to say that among the six equally likely outcomes, the ratio of favourable to unfavourable cases is one to five. But paradoxes arise where there are different, equally possible candidates for the set of equally possible outcomes. And in defining probability in terms of equal possibility the theory runs into circularity.

The possibility of deriving probabilities from statistical data has often been thought to require a 'relative frequency' interpretation. The probability of a 50-year-old man who smokes forty cigarettes a day dying within ten years is, on this view, simply the number of deaths in that period among such men. The attraction of this interpretation is that it appears to make the probability of an event as objectively ascertainable as the height of a house. But a given individual will generally belong to various classes with differing life expectancies. In such cases we can no longer speak of *the* probability of a given individual's dying: but this may be just what concerns us.

Much discussion of the frequency theory has concentrated on games of chance, where prior assumptions about frequencies rather than actual frequencies take the lead. What happens in the 'long run' in 'roughly' a given proportion of cases is introduced to bring these into line with each other. But this account owes explanations of what 'roughly' means, and of how long a long run is, and these seem to depend on the notion of probability. (It is improbable, not impossible, that a fair coin never shows heads in however long a run.) More sophisticated versions involve the idea of a limit to which actual frequencies tend as the number of events increases; but no data guarantee the existence of this limit.

The frequency interpretation has no obvious application to a statement like that made by John Dalton in 1803 that 'the most probable opinion' about the nature of heat was that it was 'an elastic fluid of great subtilty'. This has led some philosophers to attempt to analyse probability in terms of so-called 'degrees of belief'. This account has often been thought of not as an alternative to the frequency interpretation, but as the analysis of a different concept, the word 'probability' being ambiguous. Personalist theories take probability judgements to be expressions of the willingness to make certain bets: to believe that the probability of the coin showing heads is one-tenth is to be willing to stake a pound to win nine if heads show. To avoid this arbitrariness by substituting 'degree of reasonable belief' is to invite an explanation of reasonable belief. It is difficult to see how this might be given without reference to probability, hence without circularity.

'Logical relation' theories attempt to avoid arbitrariness by building evidence into the probability judgement. On this view a probability judgement concerns a logical relation between a statement and the evidence: 'It will probably rain tomorrow' is really in shorthand, the

statements of supporting evidence being suppressed. On this view we have no dispute with Dalton, since he was speaking (presumably correctly) about the relation of a theory to the evidence available to him. M.C.

**probability, conditional:** see conditional probability.

**problematic.** (1) Perplexing, questionable. (2) In traditional logic, problematic propositions are those that are marked with a sign of \*possibility, especially in connection with Aristotle's modal syllogistic; e.g. 'It is possible for all eggs not to be speckled', 'Some people can touch their toes'. The possibility might be logical, physical, epistemic, etc. Its \*scope is often ambiguous. (3) The word is sometimes used in the German manner as a noun, for a set of problems or a way of seeing problems. C.A.K.

H. W. B. Joseph, *An Introduction to Logic*, 2nd edn. (Oxford, 1916).

**process.** A process is a series of \*changes with some sort of unity, or unifying principle, to it. Hence 'process' is to 'change', or 'event', rather as 'syndrome' is to 'symptom'. What sort of unity might a given process have? Perhaps just this: that the process is found to recur sufficiently often in nature—it seems to belong to a 'natural kind'. In this case, lumping the constituent changes together is as natural as lumping the different features of a cow together as a unity. But with both cows and processes, some philosophers have thought there must be some underlying principle of unity that binds the constituent features, or changes, together.

Whitehead made much use of the notion of a process, and 'process theology' grew out of his work. On the whole, however, modern metaphysics has rather dropped the notion of a process in favour of the notion of an event, the influence of Einstein perhaps supplanting that of Whitehead, Bergson, et al. R.P.L.T.

\*event; process philosophy.

A. N. Whitehead, *Process and Reality* (New York, 1929).

**process philosophy.** The doctrine that either what is becoming, or that what is ultimately consists in \*change, or both. A \*process is a sequence of changes.

Strong and weak process philosophy may be usefully distinguished. On the weak version,  $x$  changes if and only if either  $x$  is  $F$  at a time,  $t_1$ , and  $x$  is not  $F$  at a later time,  $t_2$ , or  $x$  is not  $F$  at  $t_1$  and  $x$  is  $F$  at  $t_2$ ; so something's changing consists in its gaining or losing at least one property. It is sometimes maintained (with dubious coherence) that each thing is always changing in every respect.

On the strong version, there are only changes or, at least, the existence of enduring items logically depends upon changes such that it is ontologically misleading to speak of what is or things that are. One locus classicus of strong process philosophy is Plato's *Theaetetus*, where the thesis is ascribed by Socrates to Protagoras, Heraclitus, and Empedocles; another is Heraclitus' *Cosmic Fragments*.

More recently, 'process philosophy' has been used as a name for the \*event ontologies of James, Bergson, and Whitehead (notably, in his *Process and Reality*). It should also be extended to Russell's neutral monist doctrine that minds and physical objects are logical constructions out of events.

The existence of change, which is logically entailed by the existence of process, has been denied by Parmenides in his poem, by F. H. Bradley in *Appearance and Reality*, and by J. M. E. McTaggart in *The Nature of Existence*. If some of the arguments of these philosophers are sound then there really is no change and a *fortiori* no true process philosophy. However, at least prima facie, change is a pervasive feature of what is, and many things that are may be described without contradiction as processes. S.P.

**process theology:** see theology and philosophy.

**Proclus** (c. AD 410–485). Pagan philosopher of \*Neoplatonism who became head of the Academy at Athens and was the last great systematizer of Greek philosophy. His works, which survive in bulk, include: *The Elements of Theology* (tr. E. R. Dodds, 2nd edn. (Oxford, 1963)), *Platonic Theology*, and commentaries on several Platonic dialogues and on Euclid. His thought abounds in triads: Plotinus' procession (emanation) and return is replaced by abiding–procession–return. He is theurgical, magical, and often fanciful, as when he derives the Greek *khronos*, 'time', from *khoros* and *nous*, arguing that time is the (circular) 'dance' of the 'mind'. By way of Dionysius the Areopagite (c. AD 500) he influenced medieval thought and especially the Renaissance revival of Platonism. Hegel admired him: he was compared to Proclus and Schelling to Plotinus. M.J.I.

A. H. Armstrong (ed.), *The Cambridge History of Later Greek and Early Medieval Philosophy* (Cambridge, 1967).

**professional ethics.** The codes and guide-lines which govern the conduct of professions. Such codes can be seen as the application of general morality to the specific contexts of professional relationships. The oldest and most familiar of these is the Hippocratic oath, which in a modified form still applies to the doctor–patient relationship. In the contemporary world many occupations consider

themselves professions, and the governing bodies of these occupations issue codes of professional ethics. They have a status in between that of morality and that of law, in the sense that while their content is like that of morality, any breach of their prohibitions can result in serious disciplinary sanctions by the relevant governing body. The content of professional codes always contains provisions that the professional will work for the best interests of the patient/client. For this reason professional ethics can be in conflict with \*consumerist ethics, which approaches the professional relationship from the point of view of client demand and rights rather than professional perceptions of need and duty.

**programs of computers.** A formally specified set of instructions which guide the operations of a symbol-manipulating device. A program written in a particular programming language is executed in a given computer when a processor carries out the sequence of instructions in the program, or converts them into instructions corresponding more closely to the basic operations of the machine. The resulting process, which consists in the manipulation of symbols, or data structures, determines the subsequent behaviour of the machine. By programming computers we enable them to produce certain behaviours in response to certain inputs. Psychologists use programs to model the structure of human psychological processes; e.g. reasoning (\*cognition); and philosophers dispute whether mind is a program implemented in neural hardware (\*computers) or whether a correctly programmed computer can replicate as well as simulate mentality (\*artificial intelligence). Constructivist logic offers another application of programming where a proof can be treated as a class of programs for verifying a formula.

**progress.** Improvement over time, especially the gradual perfection of humanity. A robust sense of confidence in human progress is characteristic of the philosophers of the eighteenth-century \*Enlightenment. The French philosopher Condorcet enthusiastically expressed this view of 'the human race, emancipated from its shackles, released from the empire of fate and from that of the enemies of its progress, advancing with a firm and sure step along the path of truth, virtue and happiness'. But philosophers have not always been so sanguine about the future. Some historians (e.g. J. B. Bury) have argued that the idea of progress is a peculiarly modern concept, although a few (e.g. Robert Nisbet) have argued that it is an idea which

has its origins in the medieval Christian conception of providence, if not even earlier. In its most straightforward version, the belief in progress acknowledges a single, temporal progression of all peoples from the most 'primitive' to the most advanced, usually one's own society. The epitome of this sort of teleological thinking is to be found in G. W. F. Hegel, who argued that not only in philosophy and the arts, but in human history and religion too, rational progress is demonstrable, if only we turn a 'rational eye' to look for it.

It is important to distinguish between progress in the realm of science and technology, where improvements in medical cures, modes of transport, and various scientific theories are easily established, and moral or spiritual progress, which raises profound philosophical problems about the nature of happiness and morals. It is by no means obvious that we are happier, more moral or compassionate, less dogmatic or belligerent, than our more 'primitive' peers and ancestors. Jean-Jacques Rousseau, for example, argued (during the Enlightenment) that advances in the arts and sciences had corrupted rather than improved humanity.

At the end of the twentieth century, after two world wars and fifty years of potential nuclear conflict, the concept of progress had come into ill repute. The conservative philosopher Friedrich von Hayek bemoaned the fact that confidence in progress had become a mark of 'a shallow mind'. But even those who see history as 'just one damn thing after another' (in the eloquent phrase of poet John Masefield) tend to insist that we can nevertheless learn from history, improve ourselves, and progress beyond it.

\*pessimism and optimism.

J. B. Bury, *The Idea of Progress* (London, 1920).

R. Nisbet, *History of the Idea of Progress* (New York, 1980).

**projectivism.** The thesis that some apparent properties of the external world really belong to the mind that perceives it. For example, the world appears coloured, auditory, olfactory, gustatory. Actions seem good or evil, and objects ugly or beautiful, events necessary or contingent, but, according to projectivist views, these characteristics are at least partly due to our mental constitution and are not, or are not wholly or really, in the object. If \*Hume is right about causation, we do not perceive objective causal necessities but mistake our own psychological expectation that one event will follow another for such mind-independent inevitability. This is projectivism about causation. Projectivism is \*idealism about a restricted class of properties.

**proletariat:** see bourgeoisie and proletariat.

**proletariat, dictatorship of the:** *see* dictatorship of the proletariat.

**proof theory.** The study of formal proofs in logic. As a discipline in its own right, proof theory is usually reckoned to begin in 1934, when Gerhard Gentzen introduced \*natural deduction and the sequent calculus for classical first-order logic. He showed that any proof in either of these systems can be converted to a proof in the other. His cut elimination theorem—still undoubtedly the best theorem in proof theory—showed that any sequent calculus proof can be converted into a tableau (or truth-tree) in which formulae are steadily broken down, not built up. He adapted this theorem to give a \*consistency proof for arithmetic. Gentzen's intuitionist versions of the natural deduction and sequent calculuses are an essential tool for studying intuitionist logic.

S. R. Buss (ed.), *Handbook of Proof Theory* (Amsterdam, 1998).

**propensity.** A propensity is a probabilistic \*disposition of an object or person to behave in a certain way—for example, the disposition of a radium atom to undergo radioactive decay in a given time-period with a certain degree of chance. Propensities are more firmly linked to behaviour than mere tendencies are, because the mere tendencies of an object may be counteracted by the contrary tendencies of other objects.

E.J.L.

\*capacity; power; potential.

R. Tuomela (ed.), *Dispositions* (Dordrecht, 1978).

**proper names:** *see* names.

**properties.** Things may be said to own in some sense the attributes that they are acknowledged to have; hence the term 'property'. In traditional logic, deriving from Aristotle, however, the term has a more restricted use. According to the so-called doctrine of the predicables, which is concerned with the different things that can be predicated of a species (i.e. whether or not they are essential to the species and whether or not all and only members of the species can have these things predicated of them), a property or *proprium* is something that is not essential to the species but is such that all and only members of the species have it. Thus, arguably, the ability to laugh might be a *proprium* of man.

However that may be, a property has come to be regarded as the same as an attribute, and anything that is picked out by a predicate which can be applied to a thing in such a way as to characterize it is thus a property of that thing. Likewise, 'property' and 'quality' are sometimes used synonymously, although according to Aristotle's doctrine of the categories a \*quality is simply one category of things that can be predicated of a subject, and thus just one kind of property.

There has been much discussion among philosophers about the exact ontological relation which holds between

a thing (and more specifically a \*substance) and its properties. Leibniz, for example, argued that substances were nothing but collections, though infinite collections, of properties. Other philosophers have argued, in a similar spirit, that statements about substances can be analysed into statements about the location of properties at given places and times. But the notion of a predicate, of which that of a property is a counterpart, depends on the idea that there is a subject for predicates to be *of*, and there seems to be no good reason for supposing that properties have any ontological priority among the kinds of entity that exist.

Like predicates, properties are general and can in principle belong to many things, whether or not they do so in fact. There is nothing in the generality of a property that prevents its belonging in fact to one thing only; but it must be logically possible for it to be attributed to more than one thing. Whether there are, despite this, such things as individual properties is a disputed matter.

D.W.H.

\*essentialism; properties, individual.

P. F. Strawson, *Individuals* (London, 1959).

**properties, individual.** Consider a red tomato. Some philosophers (e.g. Stout) argue that there exists a particular redness of the tomato. This redness is an individual property, or 'abstract particular'. Other objects may be the same shade of red; those *rednesses* resemble, but are not identical to, the redness of the tomato. It is sometimes claimed, further, that individual properties are constitutive of events and physical objects and they play a key role in causal relations. In contrast, others (e.g. Armstrong) argue that ontological economy speaks to eliminating individual properties in favour of ordinary particulars, which exist in any case, and universal properties, which can be exemplified in indefinitely many ordinary particulars.

\*haecceity; properties; tropes.

D. M. Armstrong, *Universals and Scientific Realism*, i (Cambridge, 1978).

G. F. Stout, *Studies in Philosophy and Psychology* (New York, 1930).

**properties, non-natural:** *see* non-natural properties.

**property.** What is owned. Property in general is defined by a system of rules that assigns to persons rights over things, where the things capable of being owned can range from a person and his or her labour to land, natural resources, and what is produced by labour from land and natural resources. The rules of property defining rights of owners and duties owed to owners may be moral, legal, or both. Specific forms of property differ from each other depending on the rights and duties which the rules confer, how the rights or duties are acquired, and the kinds of things which are capable of being owned. Thus, all specific

forms of property rules must perform two essential functions: to assign rights to persons (natural or artificial), and to prescribe mechanisms for the acquisition, transfer, and alienation of those rights.

One specific form of property is private property. This form, associated with John Locke's political philosophy and with \*capitalism, assigns to owners the rights to use what they own in any way they choose so long as they respect the moral or natural rights of others. In private property persons acquire rights over things that are not owned by being the first to appropriate them or labour upon them, and they acquire rights to own things from others by gift, bequest, or exchange. First appropriation and labour, according to private property, justifies persons owning and profiting from land, natural resources, and material goods they produce from what they own. Not everyone will be able to have private property in land if all land is already owned; however, land may be purchased or leased from owners by those who have sufficient money or goods to exchange. In private ownership each person owns himself or herself; that is, each person has the right to decide how he or she is to labour, and has the right to exchange his or her labour for goods or money with whoever will pay.

Communal property, a specific form associated with Karl Marx and with \*socialism, assigns rights over land and the means of production to the workers or the community as a whole, rather than to individual persons. As communal property, land and the means of production may not be privately appropriated. Rather, decisions concerning the use of land or the means of production are made collectively by the workers involved or, depending on the specific form of communal ownership, by all the members of the community or their elected representatives. Any surplus or profits realized from land and resources may be distributed to the workers or community members equally, in proportion to their labour and contribution, or according to their needs.

Corporate property, public property, and joint property are forms which combine elements of the private and communal forms. Corporate ownership resembles private ownership in the rights of owners to use what they own as they, alone, choose; but it resembles communal ownership in that there may be many persons who share the ownership rights.

Great interest lies in discovering which specific form of property is morally or politically justifiable. While private ownership has often been considered superior because it supposedly stimulates efficient production of great wealth and preserves the freedom of owners, it is also criticized because it perpetuates unjust distributions of income, creates unnatural desires for material goods, and lacks respect for the quality of the environment. Communal ownership is supposed to create insufficient incentives for economic growth, be wasteful of labour and energy, and inadequately satisfy consumer demand. But communal ownership is believed to create more just distributions of wealth, less \*exploitation and \*alienation among workers,

and greater control by the community as a whole over its environment and economy. J.O.G.

Jeremy Waldron, *The Right to Private Property* (Oxford, 1988).

**proposition.** The precise formulation varies, but a proposition, or propositional content, is customarily defined in modern logic as 'what is asserted' when a sentence (an indicative, or declarative, sentence) is used to say something true or false, or as 'what is expressed by' such a sentence. The term is also applied to what is expressed by the subordinate clauses of complex sentences, to forms of words which, if separated from the complex sentences of which they are part, can stand alone as indicative sentences in their own right. Accordingly, such sentences and clauses are often called 'propositional signs'.

In medieval logic, by contrast, a *propositio* was what would now be called a propositional sign. It was with this sense in mind that some of the 'traditional logicians' of the nineteenth century held that we should not be concerned with the proposition, a mere linguistic entity, but with the *judgement*, the (possibly mental) act of affirming or denying a predicate of a subject. Some modern logicians have argued what would appear, were it not for this shift in meaning, to be the opposite view: that we should not be concerned with the *sentence*, a mere linguistic entity, but with the proposition, an abstract entity designated by declarative sentences in particular languages. It is, though, an obvious mistake to suppose that, because different sentences say the same thing, there must be a same thing they say. Probably the most sensible view is that a proposition is neither a sentence 'in itself' nor some entity other than a sentence, but merely a certain sort of sentence used in a certain sort of way. C.W.

\*statements and sentences.

A. N. Prior, 'Propositions and Sentences', in *The Doctrine of Propositions and Terms* (London, 1976).

C. Williamson, 'Propositions and Abstract Propositions', in N. Rescher (ed.), *Studies in Logical Theory* (Oxford, 1968).

**propositional attitude.** A kind of state of mind, the term for which was introduced by Russell and has gained currency in recent philosophy of language and mind.

Predications of some mental states (e.g. of belief in 'Ted believes that *p*') appear to express a relation between a person (here Ted) and a proposition (here the proposition that *p*); these states are the propositional attitudes. Want and desire, though not usually ordinarily attributed using 'that' clauses, are often included.

The class is singled out by philosophers for two reasons: (i) a set of questions pertains to the sentences used in ascribing attitudes; (ii) the attitudes feature in a distinctive mode of explanation—of rational beings; one species of such explanation is of action, considered usually to require ascriptions of the attitudes belief and desire. J.HORN.

\*content; intentionality; referential opacity.

Jerry A. Fodor, 'Propositional Attitudes', *Monist* (1978).

**propositional calculus.** A systematization of that part of logic concerned with operators corresponding to some uses of 'not', 'or', 'and', 'If . . . then', and 'If and only if', some of which are interdefinable. They are represented in the \*propositional calculus (PC) in one standard notation as ' $\sim$ ', ' $\vee$ ', ' $\wedge$ ', ' $\supset$ ', and ' $\equiv$ ', respectively. A class of \*well-formed formulae is defined for PC and a definition of \*proof which generates the set of \*theorems of PC. A desideratum is a system where the set of well-formed formulae of PC which are logical truths are derivable as theorems. This can be shown for PC quasi-syntactically by a method of normal forms. Alternatively, on the semantics of the connectives given by \*truth-tables, it can be shown that a formula is a theorem if and only if it is a \*tautology. (\*Completeness; \*consistency; \*decision procedure; \*decidability.)

There are alternative axiomatizations of PC which generate the same set of theorems. In an axiomatization a theorem is defined as an axiom or derivable from axioms in accordance with the specified rules.

An alternative to axiomatization of PC is to dispense with axioms and to use only rules of inference. (\*Natural deduction.) Here a theorem will be a formula derivable from the empty set of premisses.

R.B.M.

B. Mates, *Elementary Logic* (Oxford, 1972).

**propositional function.** A function from individuals to propositions with a common structure about those individuals, or a formula representing such a function. Thus  $C(x)$  might assign *Bach was a composer* to Bach, *Chopin was a composer* to Chopin, and so on. When a \*quantifier is prefixed, propositional functions are used to represent general propositions. Thus  $\forall x C(x)$  asserts that all  $C(x)$  is true for all  $x$ , and so represents the false proposition *Everything was a composer*.

**proprioception:** see perception.

**Protagoras** (c.490–420 BC). The most celebrated of the \*Sophists of the fifth century BC, he came from Abdera on the north coast of the Aegean, also the birthplace of Democritus. He travelled widely throughout the Greek world, including several visits to Athens, where he was associated with Pericles, who invited him to write the constitution for the Athenian colony of Thurii. The ancient tradition of his condemnation for impiety and flight from Athens is refuted by Plato's evidence (*Meno* 91e) that he enjoyed a universally high reputation till his death and afterwards. He was famous in antiquity for agnosticism concerning the existence and nature of the gods, and for the doctrine that 'Man is the measure of all things', i.e. the thesis that all

sensory appearances and all beliefs are true for the person whose appearance or belief they are; on the most plausible construal that doctrine attempts to eliminate objectivity and truth altogether. It was attacked by Democritus and Plato (in the *Theaetetus*) on the ground that it is self-refuting: if all beliefs are true, then the belief that it is not the case that all beliefs are true is itself true. While that charge of self-refutation fails because it ignores the relativization of truth in the theory, it may be reinstated as follows: either the theory undermines itself by asserting as an objective truth that there is no objective truth or it merely asserts as a subjective truth that there is no objective truth. But to assert a subjective truth is to make no assertion. So either the theory refutes itself, or it asserts nothing. In the *Protagoras* Plato represents him as maintaining a fairly conservative form of social morality, based on a version of social contract theory; humans need to develop social institutions to survive in a hostile world, and the basic social virtues, justice and self-control, must be generally observed if those institutions are to flourish.

G. B. Kerferd, *The Sophistic Movement* (Cambridge, 1981).

**protasis.** In a conditional proposition, the 'if' clause, i.e. ' $P$ ' in such forms as 'If  $P$ ,  $Q$ ', ' $Q$ , if  $P$ ', ' $(P \rightarrow Q)$ ' or ' $(P \supset Q)$ ', is called the protasis, or antecedent, and the main clause ' $Q$ ' is called the apodosis, or consequent.

C.A.K.

**protocol sentences.** According to \*Logical Positivism, 'protocol sentences' provide a record of scientific experience which is to be used in assessing theories and hypotheses. In accordance with his \*empiricism, Carnap insisted that they should record experience directly, contain nothing which resulted from induction. Whether protocol sentences described \*sense-data or were like ordinary observation reports was a matter of controversy which, Carnap eventually held, was to be settled by a decision.

C.J.H.

O. Neurath, 'Protocol Sentences', in A. J. Ayer (ed.), *Logical Positivism* (London, 1959).

**Proudhon, Pierre-Joseph** (1809–1865). French philosopher and social critic whose book *What is Property?* influenced many nineteenth-century socialists, anarchists, and communists. His famous answer to the question posed by the title of his book is that '\*property is theft'. Man, Proudhon believed, is born a social being who seeks justice and equality in all his relations, but large landed estates that create rent for the owner of private property make these impossible. He did not oppose all forms of property. Rather, he believed that small producers and farmers bound together by free contracts were the best safeguards of liberty, justice, and equality. Many of his ideas were adopted by the syndicalist trade union movement. Both Bakunin and Sorel recognized their debt to Proudhon, while Marx attacked many of his ideas as too utopian.

**pseudonyms, philosophical.** Søren Kierkegaard's elaborate use of pseudonyms inspires scholarly attention. His motives apparently included the desire to attack under one name his own writings under another. Posterity thereby knows his disdain for the construction of unified systems. Research on the motives of other philosophers who use pseudonyms awaits further identifications of these writers. Here are a few examples. Several anthologies include 'Free Will as Involving Determinism and Inconceivable without It', by 'R. E. Hobart', without mentioning that the author's real name is Dickinson S. Miller. In collections she edits herself, Amélie Oksenberg Rorty sometimes includes essays of her own signed by 'Leila Tov-Ruach'. The author of this entry does not know the real name of the entrant to the *Analysis* Competition 'Problem' No. 10, *Analysis* 17/3 (January 1957), who uses the pseudonym 'Al. Tajtelbaum'. The name is interesting because it belonged originally to the philosopher-logician-mathematician better known as Alfred Tarski. D.H.S.

**pseudo-philosophy** consists in deliberations that masquerade as philosophical but are inept, incompetent, deficient in intellectual seriousness, and reflective of an insufficient commitment to the pursuit of truth. In particular, this encompasses discussions that deploy the rational instrumentalities of philosophical reflection in the interests of aims other than serious inquiry—the fostering of power interests or ideological influence or literary éclat or some such. (To be sure, philosophers in general incline to pin this charge of insufficient intellectual seriousness and cogency on those who adhere to rival schools of thought that differ from their own position in matters of fundamental principle.)

Such ineptitude is seldom professed by exponents on their own account but emerges in the objections of opponents. Some key examples are the no-truth theory attributed by the Platonic Socrates to the Sophists of classical antiquity, the conflicting-truth theory attributed to the so-called Averroists by the medieval schoolmen, the radical nihilism sometimes attributed to Renaissance sceptics, and the irrationalism and relativism imputed to existentialists and post-modernists by the more orthodox philosophers of our own day. The more extreme enthusiasts of Derrida-inspired deconstruction afford a graphic case in point. For there is little point in spinning elaborate textual webs to demonstrate that texts never bear any stable interpretative construction. If texts are unable to convey any fixed message, there is clearly no point to any endeavour to convey this lesson by textual means.

The 'pseudo-' label is particularly apt in application to those who use the resources of reason to substantiate the claim that rationality is unachievable in matters of inquiry. For their practice patently belies their teaching. About that which cannot be treated with philosophical cogency, philosophers must needs remain silent. N.R.

\*ideology; pseudo-science; philosophy: world and underworld.

**pseudo-science.** A term of epistemic abuse of variable and disputed content. The most general feature of the situation is one in which one segment of the epistemic community attempts to alert another that certain theses have had conferred on them an epistemic status they do not deserve. Important features of these discussions are at variance with the common philosophical assumption of the centrality of testability. But testability appears not to exonerate, nor its lack to inculpate. If we consult the grounds implicit in adverse appraisals we find that objections are commonly to spurious claims as to the warrantability of a thesis rather than its untestability. Someone who maintains that Cassius was wrong, and that the fault was in our stars but that he could not say which stars, is advancing an untestable thesis, but ought not to be conflated on that account with someone who casts horoscopes.

Another ostensibly pertinent ground is failure to capitulate to repeated falsification reports. But it is conceded both that there are no rules for determining when a thesis should be abandoned and that there have been occasions when those who clung to their theories did well to do so. Moreover, non-capitulation is often a misleading description of a more pernicious practice—that of implying that a thesis has been repeatedly confirmed when the most that has been shown is that it can be reconciled with its apparent falsifiers. Popper's Adler anecdote, in which Adler explains away an apparent refutation on the score of his 'thousandfold experience' and is met with the sarcastic rejoinder, 'And now I suppose your experience is a thousand-and-one fold', illustrates a distinct and more pertinent malpractice than wanton tenacity—that Adler will henceforth illicitly treat his ability to turn the force of a falsifier as further confirmation of the theory.

Neither can capitulation to falsification reports serve as a rebuttal of the charge, for it is not uncommon for exceptions to a general thesis to be generously conceded while the putatively verified instances on which the prestige of the theory depends are without rational justification. Freud's concession that not all dreams are wish-fulfilments in the light of the recurring traumatic dreams of war neurotics does not absolve his dream theory of suspicion if there is reason to think that his reports of confirming instances were the outcome of Procrustean methods of interpretation.

Popper introduced the relevance of the investigator's sincerity. Once it is recognized that the charge of pseudo-science involves not just methodological inadequacy but imponderable judgements about its tendentious motivation, the intractability and longevity of the disputes is less surprising. Those who characterize an epistemic doctrine or practice as pseudo-scientific are normally responding to a *Gestalt* which they may then confusedly rationalize

according to whatever view of the nature of science prevails. In the end we may be compelled to say of pseudo-science what Duke Ellington said about jazz—that it is impossible to define because it is a matter of how it sounds.

\*pseudo-philosophy.

Ernest Gellner, *The Psychoanalytic Movement* (London, 1985).

Terence Hines, *Pseudo-Science and the Paranormal* (Buffalo, NY, 1988).

**psyche** ('soul'). In ancient philosophy the psyche is the animator of each animated (living) or 'ensouled' thing (*empsychon*). Plato uses the idea that the psyche is the principle of \*life in a famous argument for the immortality of the psyche (*Phaedo* 105c–e). Aristotle, in his *De anima*, counts self-nutrition, reproduction, movement, and perception as 'psychical' powers, as well as thinking, and then speculates that the rational part of the psyche may be separable from the body.

**psychic research:** see ESP phenomena, philosophical implications of.

**psychoanalysis, philosophical problems of.** Philosophers have long debated whether psychoanalysis is a \*science, a \*pseudo-science, or something *sui generis*. There are many reasons for the longevity of the controversy which are of little philosophical interest. These include a lack of consensus on whether what is in question is a therapeutic or an explanatory enterprise and, if explanatory, which theses are to be considered definitive of it. There is also a general ambiguity. Is substantive or methodological psychoanalysis under discussion? Is the subject such statements as 'the main sources of human character are, for example, the incestuous and sexual conflicts of infancy', or such statements as 'the main formative influences and pathogenic occasions in a person's life can be discovered by the use of a method devised by Freud deploying \*dream interpretation, free association, and analysis of the behaviour of the subject in the analytic situation'?

A great deal of discussion has been devoted to testability and kindred notions such as the willingness to capitulate to falsification reports. The lack of consensus on the testability of psychoanalytic theory is due not merely to differing conceptions of psychoanalytic theory but to differing conceptions of testability. Those who hold the theory untestable are often said to have confused the obstinacy of its adherents with the formal properties of 'the theory in itself'. This meets the objection that it is inappropriate to speak of the 'in-itself' of a theory much of which is so neologistic that we can only discover what falsifies it by taking note of what is permitted to count against it, and is so equivocal that almost a century later radically divergent accounts are still given of its commitments. The testability

of psychoanalytic theses is sometimes confused with the testability of statements about the consequences of crediting them. Catholic theology does not become testable because the consequences of pilgrimages to Lourdes are.

The testability of the therapeutic claims themselves is also in dispute because it has been argued that, although a thesis may seem to be indisputably testable where its advocates have in fact modified it in the light of falsifying reports, this does not show the theory to be testable unless the advocates had no discretion in the matter.

In view of these considerations it is understandable that even when precautions are taken to restrict discussion to the same substantive theses, or at least the same verbal formulas, disagreement persists. Some analysts think that Freud's claims about infantile life could be validated by a movie camera (Robert Waelder); others have denied this (Joan Riviere). Some think that Freud's aetiological claims are as epidemiologically testable as those linking smoking to lung cancer (Grunbaum); others do not. The relevance of the outcome of controlled inquiry is in any case bypassed by those who hold that psychoanalytic discourse ought not to be subjected to the same modes of assessment as are conventionally held to characterize sciences such as medical epidemiology. An alternative criterion often invoked, and to which Freud himself frequently appealed, is that of narrative comprehensiveness. Freud holds his infantile sexual aetiology up like the missing piece of a jigsaw puzzle and defies his critics to give an adequate account of the neuroses without it. A disabling assumption of much discussion is that it is the legitimacy of this narrative rationale which divides critics from supporters of psychoanalytic theses; but just as divisive is the conviction that psychoanalytic narratives tend to be unpersuasive or tendentious.

Another mode of validation whose merits have been debated is that of therapeutic efficacy. Therapeutic efficacy is incapable by its nature of warranting the historicity of a reconstruction or the veridicality of an interpretation; these may be false and the therapy based on them nevertheless efficacious, just as they may be true but therapeutically unhelpful. A further, though philosophically redundant, difficulty is that the appeal to therapeutic results played a nugatory role in the controversies. Freud himself seemed to have little confidence in it since he normally met the suggestibility objection by denying that he had any prior conviction which might have influenced his patients' responses, and by invoking data such as the fantasies of psychotics, or the anonymous productions of culture in which contamination was presumed not to operate. Where it was the generality of his conclusions about infantile life that were disputed, it was maintained that these had been confirmed (and the method thus vindicated) by the direct observation of children.

Another much discussed issue is whether unconscious wishes are \*reasons or causes. The substantive question 'Are unconscious wishes like reasons?' must be distinguished from 'Are even rationalizing wishes deterministically related to the behaviour they rationalize?' Put

otherwise, the first question is whether the hysteric, say, stands in relation to his symptoms as a malingerer to his deceptive performances, except that he is not consciously monitoring them, or whether repressed wishes act, rather, like psychic splinters and the symptoms they produce are thus conceptually analogous to inflammations. Whether the assimilation of causes to reasons is justifiable has no bearing on this question, which can only be resolved by an inspection of the grounds proffered for believing an unconscious wish operative, and these vary.

The pertinent question is thus: What makes an explanatory narrative credible? This in turn resolves into two distinct problems: the degree of circumstantiality required to support a causal narrative, or to warrant a choice between narratives, and the degree to which the subject's epistemic authority (belated in the case of analytic accounts) allows us to dispense with both laws and circumstantiality.

The first problem is one of devising rules of thumb for judging the goodness of a case for a causal connection when all we have to go on is the circumstantial density of a narrative (and perhaps its analogy to better-attested, less questionable ones).

The second problem is that of deciding, in cases where narrative coherence is insufficiently probative, whether its probative value can be enhanced, or even replaced, by the endorsement of the subject. Is not Shylock the arbiter of the sources of his resentment of Antonio? Why then can we not allow that someone who is initially ignorant of the sources of his attitudes, propensities, vulnerabilities, etc. might not ultimately come to stand in relation to them as Shylock continuously did to his murderous resentment? The assessment of this argument requires delicate taxonomizing not often in evidence. Apologists have often claimed for Freud's narratives virtues which he did not consistently claim for them himself, appealing rather to unreproducible nuances of the psychoanalytic interaction. This raises a distinct issue: What makes a narrator credible? This absolves those who insist on discussing the credibility of psychoanalytic narrators of gratuitously personalizing the issue.

Beyond the dispute over whether the knowledge psychoanalysis aims to provide is to be judged by natural science or humanistic standards looms another: whether epistemic criteria of either kind are in order. It is held that, however matters may stand with respect to vulgar notions of correspondence truth, psychoanalysis has provided vistas whose poetic truth is beyond reproach. F.C.

**psychologism.** Acceptance of some or all of the following commitments jointly define a psychologistic outlook: a

belief that logical laws are 'laws of thought', i.e. psychological laws; a conflation of truth with verification; a belief that the private data of consciousness provide the correct starting-point for epistemology; and belief that the meanings of words are ideas. Gottlob Frege rejected all these theses, and therefore much of prevailing nineteenth-century germanophone philosophy. His criticisms converted Edmund Husserl to anti-psychologism. They have been profoundly influential in anglophone \*analytic philosophy.

**psychology and philosophy.** Psychology, for most of its history, coincided with the philosophy of mind. Everyday reflections on one's own thoughts and deeds and on the behaviour—bodily motions, verbal and otherwise—of others lead naturally to speculations concerning the springs of action. Such speculations, refined and systematized, are prominent in the writings of Plato and Aristotle, and in the philosophical tradition that runs from them through Descartes, Hobbes, Hume, Kant, and James, to our own day. Along the way, psychology as a self-standing discipline gradually condensed from the philosophical fog. Recent years have seen a partial reversal of this process as philosophers, anxious to attain scientific respectability, have sought to psychologize philosophy under the banner of '\*cognitive science'.

While it is convenient to date the onset of psychology's emancipation from philosophy from 1879, the year Wilhelm Wundt established the first psychological laboratory at the University of Leipzig, it was well into the twentieth century before psychology became generally recognized as a distinguishable academic speciality. Even today, however, it is easy to find parallels in empirical psychology to virtually any philosophical view of the mind. This is scarcely surprising. Our conception of the mental as comprising a distinctive subject-matter, one that includes perceiving, knowing, imagining, planning, and the initiating of action, is a philosophical staple. Psychology emerged as a science once questions about such things began to be formulated in a way that demanded empirical investigation. Thus Hume, impressed by Newton, advanced associative principles designed to account for familiar mental operations and to set the study of '\*human nature' on an appropriately scientific footing. Hume holds that ideas—mentalistic counterparts of material particles—attract one another in accordance with three simple associative principles: resemblance, contiguity, cause and effect.

Hume was not the first associationist, nor was he the last. Clark Hull's conception of stimulus-response bonds and B. F. Skinner's notion of reinforcement put a behaviourist spin on \*associationism. More recently, advocates of 'connectionist' or 'neural network' accounts of the mind, abjuring \*behaviourism, have advanced mathematically sophisticated associationist models of cognitive and perceptual processes. These compete with computational approaches traceable to Hobbes.

Early psychologists wore their philosophical commitments on their sleeves. William James's *Principles of Psychology* (1890) mingles chapters on the brain, instinct, and hypnotism with chapters advancing views on the \*mind-body problem, and E. B. Titchener's debt to the atomistic, sensationalistic doctrines of the British Empiricists in *Lectures on the Experimental Psychology of the Thought Processes* (1904) is explicit. Nowadays psychologists are less aware of, or at any rate less willing to acknowledge, their philosophical roots.

The ongoing influence of philosophical theses might be thought to provide a partial explanation of the fitful, two-steps-forward, one-step-back quality of theoretical advance in psychology, but it would be naïve to imagine that the discipline might be streamlined simply by writing out the philosophers. The exclusion of philosophers does not amount to the exclusion of philosophical presuppositions, and wholesale elimination of these presuppositions, in eliminating as well everything that depends on them, would amount to changing the subject. Still, it is widely believed that philosophy, *qua* philosophy, has little to offer physics, biology, or medicine. Why, then, should anyone imagine that philosophers *are* in a position to offer advice about the nature of \*mind? Perhaps minds are distinctive, different from hearts, or livers, or the amino acids. But why should anyone presume this to be so?

The question is not whether imaginary disciplinary boundaries between philosophy and the empirical sciences are to be enforced, but whether the relation between philosophy and psychology is, or has been, or must be, special. According to one influential view, emanating from the work of Wittgenstein and aggressively promoted by D. C. Dennett, psychology presupposes a discredited Cartesian conception of mind according to which mental states and processes occur in private. Our access to mental items is asymmetrical: you observe the contents of your own mind directly, I can only infer those contents from what you say and do. Such a picture frustrates both philosophers, bent on resolving epistemological and metaphysical puzzles, and psychologists, who seek scientific legitimacy for their inquiries.

Skinner, following John B. Watson in turning \*empiricism on its head, declared that, because we observe only behaviour, reference to inferred mental causes of behaviour must be eliminated. Psychological explanation, then, amounts to the correlation of environmental contingencies and subsequent behavioural responses. On the philosophical front, Gilbert Ryle in *The Concept of Mind* (1949) attacked the 'Cartesian Myth' on very different grounds. Ryle held that descriptions of mental goings-on are descriptions of what agents say and do (or are apt to say and do), not descriptions of hidden occurrences causally responsible for sayings and doings. Although Ryle is often called a behaviourist, the arguments he deploys have little in common with those used in support of the psychological doctrine of the same name.

The 'functionalist' conception of mind, traceable to Aristotle, fine-tuned by Hilary Putnam, D. M. Armstrong,

and Jerry Fodor, and now beloved of philosophers and psychologists alike, can be seen as a direct descendant of Ryle's anti-Cartesianism. \*Functionalism, as a replacement for psychological \*behaviourism, however, has proved attractive in part owing to the increasing prominence of the digital computing machine. Perhaps the brain resembles such a device. Were that so, we could assume that minds are 'realized' in brains just as programs are 'realized' in computing machines. To engage in psychology, on such a view, is to seek to discover by empirical means the brain's program. A view of this sort promises simultaneously to liberate psychology from traditional metaphysical worries about the mind and its relation to the body, and to provide it with a subject-matter distinct from neurophysiology and biology.

Although psychologists have been on the whole happy with these results, functionalism is under fire in philosophy. In characterizing mental items exclusively by reference to actual and possible inputs and outputs, functionalism evidently ignores their qualitative dimension. In the earliest accounts of the doctrine, this was touted as a virtue, a way of factoring out spooky mental \*qualia and allowing for the 'multiple realizability' of mental characteristics. (A characteristic is multiply realizable if it is capable of being embodied in very different sorts of physical system: human brains, computing machines, possible alien silicon-based 'brains'.) Recently, however, Thomas Nagel, Frank Jackson, David Chalmers and others have argued that any account of the mind must accommodate non-material mental qualities, exhibited in \*consciousness. Some of these arguments are intended to encourage us to return to a fundamentally Cartesian conception of mind, a conception not unlike that embraced by Wundt and Titchener in the earliest days of experimental psychology. Does this portend the reintroduction into psychology of non-physical entities? Perhaps not. Perhaps it is simply a reflection of a powerful conviction that, as C. B. Martin puts it, 'every quantity stands in need of a quality'. The subjectivity of consciousness poses additional problems. Conscious awareness incorporates a point of view inaccessible to objective scientific investigation. Some, like Colin McGinn, have despaired at finding a home for points of view in the natural world; others—Ted Honderich, for instance—locate subjectivity in perfectly natural relations which perceivers bear to their environments.

Such considerations make it clear that the historical break between philosophy and psychology was never a clean one. Psychologists continue to look over their shoulders at philosophers, and philosophers continue to offer advice to psychologists. There is no reason to think that it should always be this way, but there is no reason to suppose that things are destined to change much in the foreseeable future.

**psychoneural intimacy.** The term is used to describe what is generally recognized to be the close tie between neural events and mental events. It is held that there is a necessary co-occurrence of some sort between types of mental events and types of neural events. The thesis of psychoneural intimacy is compatible with most of the doctrines put forward in the literature concerning the relationship between mental events and physical events—but not some that radically separate mind and brain, perhaps to safeguard free will. Most doctrines of the psychoneural relation can be read as different proposals about the nature of the necessity involved. P.J.P.N.

\*mind-body problem.

T. Honderich, *A Theory of Determinism: The Mind, Neuroscience and Life-Hopes* (Oxford, 1988), ch. 2.

**psychophysical laws.** Putative natural \*laws reporting regular or necessary relationships between mental events and physical events. For example, if, as Honderich maintains, the occurrence of some neurological event is a sufficient condition for the occurrence of some psychological event (and, as is entailed by this, the occurrence of that psychological event is a necessary condition for the occurrence of that neurological event), then arguably some psychophysical law could be discovered which would facilitate the prediction of psychological events from knowledge of neurological events, because true neurological sentences would logically entail the occurrence of psychological events.

Not only Honderich's physicalistic \*determinism but certain versions of the mind-brain \*identity theory logically imply the existence of psychophysical laws. Some philosophers have maintained that types of mental event may be identified with types of physical process in the brain (or central nervous system) and that there is no a priori reason why predictive inferences about mental event-types should not be drawn from premisses about physical event-types. Unfortunately such type identifications have proved most difficult to establish empirically.

On a token version of the mind-brain identity theory it is less plausible that there should exist psychophysical laws. Although, on this theory, any token mental event is numerically identical with some token neurological event, it does not follow that qualitatively similar mental

events are numerically identical with qualitatively similar neurological events. From the fact, then, that an event of some specifiable neurological type had occurred it would not follow that an event of some specifiable psychological type had occurred (even though it would still follow that a psychological event of some psychological type had occurred). Donald Davidson, for example, argues that, although every mental event is numerically identical with some physical event and although every event (including every mental event) may be subsumed under some natural law, nevertheless there are no psychophysical laws. This is because it is *qua* physical events, not *qua* mental events, that mental events are law-governed, and even a complete knowledge of physical events would not facilitate predictions of (specifiable) types of mental event.

All the philosophical problems accruing to natural laws accrue *a fortiori* to psychophysical laws. For example, whether natural laws are causal laws, Humean regularities, relations between \*universals, essentially predictive, or descriptive of necessities are all also questions about psychophysical laws. Deciding whether there are psychophysical laws and if so what they are like requires specifying correctly the ontology of the psychophysical relation. However, their existence is consistent with most traditional solutions to the \*mind-body problem. s.p.

\*anomalous monism.

**public morality.** As traditionally understood, the 'police powers' of government extend to the protection of public health, safety, and morals. Legislation to protect public morals prohibits or restricts acts and practices judged to be damaging to the character and moral well-being of persons who engage in them or who may be induced to engage in them by the bad example of others. Typical forms of 'morals legislation' prohibit or restrict prostitution, pornography, and other forms of sexual vice, as well as gambling, cruelty to animals, and the recreational use of drugs.

In recent times, the legitimacy of such legislation has come under severe attack from certain forms of liberal political thought. Under pressure from 'law reform' movements inspired by the philosophy of J. S. Mill and others, many jurisdictions have decriminalized a variety of putatively 'victimless' offences.

In the early 1960s the legitimacy of morals laws, particularly the legal prohibition of consensual homosexual sodomy, was the subject of a celebrated debate between two eminent British jurists: Patrick Devlin defended 'legal moralism' on the ground that a society is constituted in significant measure by the sharing of moral beliefs by its members and that the legal toleration of acts condemned by a society's constitutive morality puts that society at risk of disintegration. Therefore, Devlin argued, a society has

the right to enforce the morality prevailing within it, irrespective of the critical soundness of that morality, for the sake of preserving social cohesion. H. L. A. Hart countered that Devlin's 'social disintegration thesis' was either an empty 'conceptual' thesis which trivially identifies society with whatever moral views happen at the moment to be dominant in a community, or else it was an 'empirical' thesis which historical evidence fails to vindicate.

Contemporary defenders of morals legislation typically eschew Devlin's approach in favour of the traditional justification of morals legislation under which its primary purpose is not social cohesion *per se*, but, rather, the protection of morally good character against the corrupting influences of vice. Thus, they reject Devlin's 'relativism and understand the critical soundness of a moral judgement to be a necessary condition of its justified legal enforcement.

R.P.G.

\*liberalism; liberty; toleration; public-private distinction; enforcement of morals.

**public-private distinction.** Privacy is an important, though a recent and by no means a universal, value. Analyses of it are dominated by liberal conceptions of a 'private sphere' which sets normative and empirical limits to state and social power over the individual. In his private life the individual is not and should not be regulated by laws or subject to social pressure; in public life he shares, assents to, or anyway obeys, norms and laws governing his relations with others, and accepts social and political authority.

Conceptions of the boundary between public and private have altered. Economic relations have been understood to be private, and their legal regulation resisted. Now 'the family' epitomizes the private sphere. However, the implication that family relations are not and should not be regulated by the state or subject to shared, publicly accepted standards of morality is contested.

**publishing philosophy.** The Greek word for bookseller dates from the time of Plato, who foreshadowed the alliance between philosophers and publishers when he prescribed his own work the *Laws* as the set text for study in the ideal city it describes. Cicero's friend Atticus was one of those who made a business of the copying and distribution of books in the ancient world. In the early Roman Empire some books were priced as low as six sesterces; Cicero had claimed that a feeble slave could earn

three sesterces a day at Rome. Nor did mass production await the age of printing: the emperor Constantine ordered multiple copies of works by Christian writers for dissemination through his empire.

At some medieval universities students were required to own copies of their teacher's lectures, and they might pay someone to supply them with a copy. In 1304, thirty years after Aquinas's death, his *Quaestiones disputatae de veritate* could be rented from a Paris bookseller for four shillings. But, since the work runs to more than a thousand pages, a substantial burden of labour remained. Aquinas's output of eight million words in thirty years is equivalent, in today's terms, to two substantial monographs per annum and a few journal articles too.

Descartes moved to Leiden in 1636 specifically to be at the centre of publishing. The liberal Dutch laws had allowed the Elseviers to become the leading publishers of the time; they numbered Galileo among their authors, and had expressed interest in Descartes's work. But they 'made difficulties' for him, and so it was their neighbour Jan Maire who became known to posterity as the publisher of the *Discours*. The print run was 3,000, out of which Descartes received 200 free copies.

The late seventeenth century saw the flourishing of learned journals. Until 1710, that was where one had to look to find Leibniz's work: he first published his 'New System' in 1695 in the *Journal des savants* (the official organ of the French Academy of Sciences, founded in 1666); he also wrote in Latin for such journals as the Leipzig-based *Acta eruditorum*.

Spinoza dared not let his greatest work, the *Ethics*, be published while he was alive, and sought refuge in pseudonymy for his *Tractatus Theologico-Politicus* of 1670; just as well, since it was generally considered blasphemous. More surprising, perhaps, that Kant too was the author of a banned book: in 1794 King Frederick William II's Spiritual Affairs Commission issued an order forbidding professors to lecture on his *Religion within the Bounds of Mere Reason*. Kant had published it under the imprint of the Königsberg philosophy faculty in order to avoid censorship.

The three greatest works of English-language philosophy were published in London. Thomas Hobbes entrusted his *Leviathan* to Andrew Crooke, who was to be found at the sign of the Green Dragon in the precinct of St Paul's cathedral. The controversy over the book both aroused demand and made the publisher nervous about satisfying it, with the result that the price rose from eight and a half shillings in 1651 to thirty in 1668, before settling at seventeen in 1692. The notoriety of *Leviathan* made publishing difficult for Hobbes: after 1662 he was obliged to seek a licence from the Archbishop of Canterbury for the publication of any work on politics or society; and in the case of *Behemoth* this was refused, even though the work was a favourite of the king.

Thirty-eight years after *Leviathan*, Locke's *Essay* was first printed by Elizabeth Holt in 1689 for the publisher Thomas Bassett, at the George in Fleet Street, just down the road

from St Paul's. Locke had signed a contract with Bassett in May 1689; printing began immediately, and copies were on sale by the end of the year. By 1700 the book was in its fifth edition, with another publisher, the rights having been sold on twice before the second edition.

The first two books of Hume's *Treatise* were published by John Noon in 1739, at the White Hart in Cheapside, on the other side of the cathedral. Noon specialized in philosophy and religion, and paid Hume £50 for the right to print an edition of no more than 1,000 copies. By the time the third book appeared in the following year, Thomas Longman had already supplanted Noon as publisher. Some were more loyal: the Paris publisher Rey was one of the few people whom Rousseau did not suspect of scheming against him, and voluntarily settled an annuity of 300 francs on Rousseau's 'womenfolk' in grateful acknowledgement that the publisher owed his prosperity to the philosopher.

Up to the middle of the twentieth century, much philosophy publishing in English was undertaken by general commercial presses, British and American. But as philosophy books have become more specialist, they have mainly been handled by specialist publishers. Large commercial presses like Penguin and Harper Collins occasionally show interest in the subject, but most philosophy books are published either by specialists in academic publishing or by specialists in textbook publishing. One or two of the European giants of science publishing, such as Kluwer of Dordrecht, dabble in philosophy, usually at the technical end of the subject where it is most like a science.

At the start of the twenty-first century there are two large commercial presses with a strength in philosophy. Blackwell built on its prestige as publisher of Wittgenstein and disciples to head the field for a period in the 1980s, but in the 1990s decided to concentrate mainly on textbook, reference, and journal publishing. Routledge now publishes a broader range of philosophy than any other press, having inherited a legacy of works by such as Russell, Popper, and Wittgenstein from companies that it swallowed. In 1922 Kegan Paul had offered Wittgenstein no fee and no royalties for the English publication of his *Tractatus*; when the author tried to negotiate some money at the time of a reprint in 1933, he received no reply, and so that was the end of his dealings with the company. In 1998 Routledge was itself taken over by an ancient publishing company, long moribund, now growing fast: Taylor and Francis, then still auspiciously located just off Fleet Street. One of the parent company's founders, Richard Taylor, had established a pioneering independent academic journal, the *Philosophical Magazine*, in 1798.

Most publishers of academic philosophy today are university presses, helped or hindered in their business by their relationships with their parent institutions. The university presses of Oxford and Cambridge are the largest and most international of academic philosophy publishers. CUP claims to be the oldest university press in the world, having published its first book in 1584, just in time for the birth of modern philosophy. Their leading American counterparts are Harvard and Princeton; others have

strengths in specific areas—for instance, MIT in cognitive science, Chicago in social and political theory, Cornell in aesthetics and philosophy of religion. In 2002 the University of California Press withdrew from philosophy publishing, despite the university's continuing prominence in the subject: increasing difficulties in the academic book market were cited.

Charges frequently made against academic publishers are that they encourage the proliferation of books beyond what the readership can cope with, and that they sell back to universities books that the universities have paid their members to write. But it was the universities that built publication into the career structure for academics. And any profiteer would be scared off by the margins in philosophy publishing.

The electronic revolution in publishing is proceeding more slowly than predicted by zealots and Jeremiahs. Paper will continue to be the principal commercial medium for philosophy publishing for a while yet, even though informal electronic dissemination has become a staple of philosophical intercourse.

Most philosophers who publish several books do not stick with one publisher for all of them; they optimistically hope that the next one will be free of the shortcomings of the last. But monogamy is less meaningful when it can only be one-way. And a good publishing relationship may even be refreshed by the author's straying into an unsuitable dalliance. To complicate matters, philosophy editors often turn out to be consorts of philosophers; which of those blessed estates leads to the other varies from case to case.

P.N.M.

**Pufendorf, Samuel von** (1632–94). German legal and political philosopher. A follower, at some distance, of Grotius and Hobbes, he carried on their project of secularizing natural law. Other, less direct, influences were Descartes and Spinoza, from whom he derived a mathematical ideal of philosophical exposition. A Protestant, in his first book he attacked the (Catholic) Holy Roman Empire. He served as court librarian to the king of Sweden, during twenty years in that country, and then to the elector of Brandenburg. Nevertheless he entertained the idea of a European federation. While in Sweden he wrote a history of the country which was exemplary in its reliance on archival materials. His chief work, *The Law of Nature and Nations* (1672), firmly distinguishes natural law from divine law. He consistently concluded that in terrestrial matters the church should be subordinate to the state. Like Althusius, he argues for two contracts: one to form a community out of mere individuals, the other between the community so formed and a ruler. Where Hobbes derived the law of nature from our fear of violent death at each others' hands, Pufendorf more cheerfully deduced it from man's sociable instinct.

Leonard Krieger, *The Politics of Discretion* (Chicago, 1965).

**punishment.** Since punishment involves intentionally inflicting deprivations on persons by someone with

authority to do so, and since the deprivations themselves are typically not unlike the harms that crimes cause (fines are like theft, imprisonment like kidnapping, etc.), punishment has generally been thought to need justification, especially in a constitutional democracy committed in theory to the protection of human rights and the values of individual liberty, privacy, and autonomy. Justification may be undertaken either by reference to extrinsic (consequentialist) considerations, or by reference to intrinsic (retributive) factors.

In an effort to accommodate both retributive and consequentialist norms, some recent theories justify punishment by dividing the issue in a manner reflecting the different competencies of an ideal legislature and judge. Thus, the primary concern amounts to answering a legislative question: Why is *anyone* punished, or made liable to punishment, in the first place? The secondary issue is in effect the judicial question: Why is *this* person being punished, and in why in *this* manner?

The former can be answered best by citing the benefits conferred on a society (family, organization, civil polity) by the institution of punishment as a permanent, public threat-system that provides an indispensable incentive to obey the law. In so far as the justification of punishment is conceived in this manner, it is inescapably forward-looking, purposive, and consequentialist in nature (though not necessarily utilitarian).

Assuming such a system to be in place, with its various offices (judges, prosecutors) and rules (crimes and punishments defined by statute, due process of law), then the punishment of a given individual is justified to the extent that the rules of the system incorporate appropriate constraints on trials and sentencing and are correctly applied to the individual case. Central to such rules is the procedure by which the accused is found guilty of a crime on the basis of suitable evidence weighed in an unbiased manner. If the actual infliction of punishment is understood in this fashion, it is always backward-looking (resting on the conviction and sentencing of a guilty offender) and thus plausibly viewed as retributive.

Retribution accommodated in this narrow manner falls far short of its role in a full-blown retributive theory of punishment, such as Kant's or Hegel's. They appeal to retributive notions not only to determine who ought to be punished, but also to determine what punishment the guilty person deserves and the very rationale for a system of punishment in the first place. Deserved punishment for the retributivist is equivalent (as in *lex talionis*) or at least proportional in its severity to the harm done in the crime and the culpability of the offender. The retributive rationale of a system of punishment is that justice requires inflicting harm on wrongdoers. Whether such an a priori principle as this can be defended against alternative (typically consequentialist) principles continues to be debated.

The goals or purposes of any system of punishment are likely to be several and diverse, including vindicating the law, crime prevention, and offender rehabilitation. Philosophical disputes over punishment typically focus on

which goal is to take priority over others and why. As Friedrich Nietzsche shrewdly observed, 'punishment is overdetermined by utilities of every kind' (*Genealogy of Morals*, II. 14). He failed to note that the penalty schedule—the actual ordering of crimes ranked in their gravity with punishments ranked in their severity—is underdetermined by every theory of punishment. The two-tiered theory described above can reasonably claim to offer the most hospitable accommodation to the diverse relevant principles, but it provides no solution to this problem.

**pushpin and poetry** is a critical slogan popularized by J. S. Mill in criticism of the work of Bentham. (Pushpin was a primitive game which involved shoving pins.) Mill cites Bentham as holding that \*poetry is no more valuable than pushpin, if they give the same amount of \*pleasure. This is in accord with the principle of \*utility. However, Bentham's point when he made the remark was not about private value but that the two activities should be equally worthy of governmental subsidy if they give the same amount of pleasure.

J. S. Mill, 'Bentham', in *Works*, x. 113.

**Putnam, Hilary** (1926–). Harvard philosopher, trained originally in the tradition of \*Logical Positivism, especially by Rudolph Carnap. Putnam later came under the influence of such philosophers as W. V. Quine, Ludwig Wittgenstein, and Nelson Goodman. In the process, he strayed from the fold, and eventually became a severe critic of that movement. Against positivism, he argues that there is no privileged foundation (e.g. \*sense-data) to our knowledge, no fixed principle of verifiability, no \*fact–value distinction as the positivists characterized it, and that sentences (our beliefs) cannot be assessed as true or false individually (i.e. \*holism rather than atomism is correct).

Putnam is also a critic of another foundationalist position, which he calls metaphysical realism. All God's eye points of view that claim to give us the account of the Furniture of the World are wrong-headed whether they come from a relativist–positivist or a realist–materialist perspective. His own 'middle' position he characterizes as 'internal realism'. It is a kind of latter-day \*Kantianism that talks about the (real) world, but does so always within the framework of our mind (concepts, sets of beliefs, commitments). His position, Putnam claims, characterizes the objectivity of both science and ethics better than do the

extreme positions he opposes. If anything, these extreme views undermine rather than support objectivity.

Of late, Putnam has rejected \*functionalism, the theory that mental states are computational states—a theory he himself founded earlier in his career. Of late he has also written about matters of ethics and politics. Like his views in metaphysics and epistemology, he tends to want to hold a middle, yet somewhat liberal, position between two extremes—although he confesses there were times (e.g. during the Vietnam War) when he flirted with Marxism, a position he now finds extreme.

**Pyrrho** (4th–3rd century BC). A citizen, and priest, of Elis, identified (through the writings of Timon of Phlius) as the first representative of 'Pyrrhonian \*scepticism', the refusal to commit oneself to any positive belief. Anecdotes were told of his indifference to disaster (and his friends' saving him from accidental falls). He was said to have accompanied Alexander to the borders of India and learned this detachment from the 'gymnosophists', or naked philosophers. Like Diogenes the \*Cynic he pointed to animals as living undisturbed, and enviable, lives: a pig on board ship during a severe storm continued to eat while people (except Pyrrho) panicked. Mocked for being alarmed by a fierce dog, he conceded that it was hard to strip off human nature, but attempted to maintain tranquility by balancing any plausible-sounding thesis with its plausible opposite, and binding himself to nature, custom, impulse, and craft-discipline without affirming any thesis to be true.

Diogenes Laertius, *Lives of the Philosophers*, tr. R. D. Hicks (London, 1925).

**Pyrrhonism.** A sceptical tradition whose leading figure was Pyrrho of Elis (c.365–270 BC), but handed down to us in the works of Sextus Empiricus. Pyrrho argued that the reasons in favour of a belief are never better than those against (*isostheneia*—a situation of equal strength), and that the only possible response to this is to stop worrying (*ataraxia*) and to live by the appearances. He suggested that this life would have a lot to recommend it; critics maintained that it would be very uncomfortable, at best. The question who was right depends on what is meant by 'live by the appearances'.

Sextus' work was rediscovered in the mid-sixteenth century; the sceptical concerns of Montaigne and Descartes are a direct response, though Cartesian scepticism seems to be directed more against the possibility of knowledge than against the possibility of having better reasons in favour of some belief than against it.

J.D.

\*scepticism, history of; scepticism.

J. Annas and J. Barnes (eds.), *The Modes of Scepticism: Ancient Texts and Modern Interpretations* (Cambridge, 1985).

**Pythagoras** (c.550–c.500 BC). An elusive figure who may have been an intellectual catalyst. Little is known of his life; authentic detail has been drowned in the many legends and tendentious later 'reconstructions' of his activities. A polymath and a charismatic figure, he emigrated from his native Samos to southern Italy, where he founded a sect characterized by common beliefs and observances. These included prescriptive rules (such as a ban on the eating of beans and certain meats), the preservation and pursuit of esoteric knowledge, and reverence for the founder himself.

Modern scepticism about the alleged political, philosophical, mathematical, and scientific achievements of Pythagoras is mostly justifiable. The earliest sources present him primarily as a magician claiming 'occult' or mystical experiences like those of a Siberian shaman. On this basis he asserted 'metempsychosis', a doctrine of repeated incarnations of souls, with punishments and rewards for behaviour in previous lives.

Apart from this, no definite meaning attaches to the term '(early) Pythagorean'. The original society did not last long, but throughout the fifth century BC (and even after) various theorists in the western Greek world were called 'Pythagoreans'. Many of these were interested in mathematics and astronomy, and their cosmic or occult significance; the interest may go back to Pythagoras himself. Some apparently attempted to reduce all knowledge to mathematics (using such identifications as 'Justice is the number 4'). Systematic dualism of associated polarities (right = male = good, left = female = bad, etc.) is also attested. Pythagorean influence, in this wider sense, appears in Parmenides and Empedocles, and later in Plato and the Neoplatonists.

E.L.H.

\*Pythagoreanism.

W. Burkert, *Lore and Science in Early Pythagoreanism*, tr. E. L. Minar (Cambridge, Mass., 1972).

**Pythagoreanism.** Way of life and doctrines attributed to Pythagoras. There were proponents of Pythagoreanism for at least eight centuries from Pythagoras' day, but there was no persisting core of Pythagorean doctrines. From the fourth century BC onwards, teachings from other schools were borrowed and regularly attributed to Pythagoras himself. This, together with our lack of early writings, makes it hard to discover the original nature of the school.

There was, reportedly, an early split between those for whom Pythagoreanism was a way of life, something like a religion, and those for whom it was a body of scientific, mathematical, and philosophical teaching. The ethical and religious teachings were broadly puritanical, often bizarre, and of little philosophical interest. Pythagorean contributions to geometry were reputedly great, but their extent is uncertain. Aristotle records some of the philosophical doctrines, notably that numbers are 'the first things in the

whole of nature', and that 'the elements of numbers are the elements of all things'. Pythagoreans knew that concordant musical intervals (octave, fourth, and fifth) could be expressed by arithmetical ratios. This may have led them to believe that the universe as a whole could be explained and understood in mathematical terms—an idea that has since proved remarkably fruitful. But Aristotle understood their theory as confused: they represented things as *composed* of numbers, and failed to 'separate' the numbers from the things numbered. Aristotle may be right about the crudeness of early Pythagorean thought. But there is earlier evidence of some subtlety of argument.

Philolaus (born c.470 BC) was the first to write down Pythagorean doctrines, and a few fragments of his work survive. Among his conclusions are that the 'being' of things is eternal, and 'admits of divine, but not human, knowledge'; and that 'all the things that are known have number'. Evidently he held that *human* knowledge was possible only of things that can be numbered. His reasoning seems to be this. Anything that can be known must have limits (spatial or temporal) to distinguish it from everything else. But things thus distinguishable from one another may be counted. The universe *as we know it*, then, must consist of things that can be counted. He also argued that the universe must contain 'limiting things' and 'unlimited things', united by 'harmony'. Perhaps he thought that only if things of one sort had imposed limits on things of the other could there be 'things with limits' (and hence knowable things). But his words are obscure and their interpretation disputed.

Some early Pythagoreans believed that the soul was an 'attunement', like that of a lyre. This suggests that to have a soul is to have one's bodily components related to one another in a certain (mathematically expressible) way. This, however, seems inconsistent with the well-attested Pythagorean belief in reincarnation.

Plato's successors attributed much of his thought to Pythagoras. No doubt Plato *was* influenced by Pythagoreans, for example, in his views on immortality in the *Phaedo* and his exercise in mathematical cosmology in *Timaeus*, but his philosophical debt was probably small. After Plato, 'Pythagoreanism' became in effect a brand of Platonism, with emphasis on number theory and the more mystical aspects of his thought.

In the first century BC there was a revival of the school (often called neo-Pythagoreanism), from which many writings survive. These contain a medley of teachings from various schools. What marks them as Pythagorean is their religious rather than their philosophical content: miracle stories, a reverence for numbers and concern with an ascetic way of living.

Pythagoreanism influenced the development of \*Neoplatonism, and in writers such as Iamblichus (c. AD 300) the two schools became indistinguishable.

**qualia.** The subjective qualities of conscious experience (plural of the Latin singular *quale*, ‘of what kind’). Examples are the way sugar tastes, the way vermilion looks, the way coffee smells, the way a cat’s purr sounds, the way it feels to stub your toe. Accounting for these features of mental states has been one of the biggest obstacles to materialist solutions to the mind–body problem, because it seems impossible to analyse the subjective character of these phenomena, which are comprehensible only from the point of view of certain types of conscious being, in objective physical terms which are comprehensible to any rational individual independently of his particular sensory faculties. T.N.

\*subjectivity; consciousness, its irreducibility.

T. Nagel, ‘What Is It Like to Be a Bat?’, *Philosophical Review* (1974).

**qualities.** In ‘Napoleon had all the qualities of a great general’ we could, in everyday usage, substitute ‘features’, ‘properties’, ‘traits’, ‘characteristics’, ‘attributes’, and some other terms, for ‘qualities’. Aristotle included ‘quality’ in his list of ‘categories’ of the various possible kinds of objects of thought. He said ‘By “quality” I mean that in virtue of which people are said to be such and such.’ However, he goes on to discuss qualities of things other than people, such as the sweetness of honey.

A quality is something which can be possessed, as, for example, Napoleon possessed the quality of courage. Qualities can also be attributed, as the quality of courage was just attributed to Napoleon. Furthermore, the same quality may be possessed by more than one thing, as, for example, Alexander possessed courage just as Napoleon did, and in a very different way from the common possession of a yacht by joint owners or of a spouse by polygamists. And a quality can be attributed to a number of things, truly or falsely.

These qualities of qualities, their possessability by, and attributability to, numbers of things, have made them puzzling to many philosophers, who find it peculiar that there should be things with those qualities. One source of puzzlement seems to arise from finding it incredible that one and the same thing could be understood and attributed by several different minds and also possessed by or ‘in’ several different things. Locke says ‘a snowball having the power to produce in us the ideas of white cold and

round,—the power to produce those ideas in us, as they are in the snowball, I call qualities; and as they are sensations or perceptions in our understandings, I call them ideas’. Jonathan Bennett points out that the interpretation of the pronoun ‘they’ in this passage, as referring back either (ungrammatically) to ‘power’ or to ‘ideas’ raises problems. The quality, say round, is both identified with the idea round, and distinguished from it.

Locke then goes on to speak of a subclass of ‘qualities which . . . are nothing in the objects themselves, but powers to produce sensations in us’ as ‘secondary qualities’. Secondary qualities, then, are qualities which are ‘nothing but’ qualities. ‘Primary’ qualities of a body, by contrast, have further qualities such as being ‘utterly inseparable from the body’. It was held further that the idea of a \*primary quality *resembles* the quality, while the idea of a secondary quality does not.

These distinctions, or attempts at them, make verificationism about qualities hard to resist, since the notion of an undetectable quality is hard to square with the quality of being a power to produce an idea. If we say that the idea produced needn’t convey any idea of the quality, then Locke’s project of explaining how we understand qualities in order to attribute them is undermined. This problem as to how the idea points to the quality also arises in connection with what Locke calls a ‘third sort’ of qualities, which are powers in one object to produce powers in another which then reach us. For example, a quality in the sun causes the mercury to rise in a thermometer. A primitive man may get from the thermometer the idea of a red column rising, but with no idea at all of the sun’s role.

The view that it is an essential quality of a quality that it produce some distinctive sort of idea in us ought to be given up. It may be true of *sensory* qualities, such as red, or cold have been held to be, though even that is interestingly controversial. J.C.

\*properties; properties, individual; universal.

Aristotle, *Categories*.

John Locke, *An Essay Concerning Human Understanding*, II. viii.

**quality of life (QOL)** in a population is often defined in terms of social indicators such as nutrition, air quality,

incidence of disease, crime rates, health care, educational services, divorce rates, etc. The difficulty is in knowing how to weigh these factors. Is clean drinking-water more or less important than good schools? Should a high divorce rate be counted negatively? One way of achieving a unified index would be to define QOL as a subjective measure of perceived satisfaction or dissatisfaction, summed over a members of the population. But it is possible to conceive of circumstances in which perceived satisfaction could vary quite independently of what we regard as QOL. Even Ivan Denisovitch, in his Siberian labour camp, went to bed a 'satisfied' man. A third alternative is to define QOL in terms not of perceived happiness but of the availability of happiness requirements: what human beings need in order to be happy. If requirements such as Maslow's need hierarchy can be found which are universal rather than idiosyncratic, an objective definition of QOL is possible. S.McC.

\*well-being.

M. Nussbaum and A. Sen (eds.), *The Quality of Life* (Oxford, 1993).

**quantification.** The application of quantifiers (for example: 'all', 'some', 'a few', 'more than half'). In predicate logic, the prefacing of a sentence by either the universal quantifier ( $\forall x$ ), 'For any  $x$ ', or the existential quantifier ( $\exists x$ ), 'There exists at least one  $x$  such that'. Quantification turns a sentence with free variables into a sentence with bound variables, for example:  $Fx$ , 'Something is  $F$ ', into  $(\exists x) Fx$ , 'There exists at least one  $x$  that is  $F$ '. The propriety of the universal and existential quantifiers is not beyond philosophical question. The use of the universal quantifier assimilates 'all', 'any', and 'every', which are arguably distinct concepts. The use of the existential quantifier enshrines formally the doctrine that 'exists' is not a first-order predicate, but 'exists' might be some kind of first-order predicate. S.P.

Martin Davies, *Meaning, Quantification, Necessity: Themes in Philosophical Logic* (London, 1981).

Mark Sainsbury, *Logical Forms* (Oxford, 1991), ch. 4.

**quantifier.** A logical symbol used to do roughly the same work as 'every' or 'some'. The word 'quantifier', which stems from the logicians' sense of \*\*'quantity', was first used by Peirce in 1883, but the idea is present in Frege's *Begriffsschrift* (1879). Combined with \*variables, quantifiers provide an adequate symbolism for representing relational propositions involving both the universal ( $\forall$ , read 'for every'), and the existential ( $\exists$ , read 'for some'), quantifier: 'Someone is loved by everybody', can mean either ' $\forall x \exists y (y \text{ is loved by } x)$ ' or ' $\exists x \forall y (x \text{ is loved by } y)$ '. \*Ambiguity is thus avoided by quantifier notation. Quine christened two interpretations of the quantifiers 'objectual' and 'substitutional', respectively. The first gives the \*truth-condition for, for example, ' $\exists x (x \text{ is heavy})$ ' as ' $x$  is heavy' is satisfied by some object', the second as 'Some sentence of the form " $x$  is heavy" is true'. C.J.F.W.

C. J. F. Williams, *What is Existence?* (Oxford, 1981), chs. 6–8.

**quantity and quality.** From at least the thirteenth century onwards, that a proposition is \*universal ('All  $S$  are  $P$ ' and 'No  $S$  are  $P$ ') or \*particular ('Some  $S$  are  $P$ ' and 'Some  $S$  are not  $P$ ') was called its quantity; and that it is affirmative ('All  $S$  are  $P$ ' and 'Some  $S$  are  $P$ ') or negative ('No  $S$  are  $P$ ' and 'Some  $S$  are not  $P$ ') was traditionally called its quality. C.W.

\*logic, traditional.

I. M. Bochenski, *A History of Formal Logic*, tr. and ed. I. Thomas (Indiana, 1961), 210–11.

**quantum logic.** Originating with von Neumann and Birkhoff in the mid-1930s, the name 'quantum logic' denotes an interpretation of quantum experimental results by means of a non-Boolean lattice. According to some critics, the name is misleading. They see von Neumann and Birkhoff as having shown that the mathematics, not the logic, of the quantum realm has this non-classical character. More generally, the idea of a quantum logic has both a negative and a positive part. Negatively, it is the thesis that classical, e.g. first-order, formalization of quantum physics is one in which certain principles of logic cease to be valid. More particularly, classical laws of logic, such as distributivity, fail under any formalization in which atomic formulae of quantum physics are formalized as truth-functionally atomic formulae of classical logic and, likewise, if the quantum 'connectives' of *meet* and *join* are construed truth-functionally. Further factors that impede classical formalization include the apparent failure of quantum objects to be well individuated and the inherently probabilistic character of quantum claims. The positive part of the quantum logic thesis requires the specification of a suitably non-classical logic to fit the quantum realm. There is as yet no settled consensus among those who favour the idea. For those who don't, a purpose-built logic for quantum physics has no more rationale than a purpose-built logic for household economics. This scepticism may be influenced by the thought that, from the fact that quantum mechanics lacks an adequate formalization in classical logic, it hardly follows that there must be some other non-classical logic in which the formalization succeeds. J.WOO.

M. Dalla Chiaro and Roberto Giuntini, 'Quantum Logics' in D. M. Gabbay and F. Guenther (eds.), vol. 6 of *Handbook of Philosophical Logic*, 2nd edn. (Dordrecht, 2000).

**quantum mechanics, philosophical problems of.** These concern how best to interpret the theory, and are still being pursued, as in the famous Bohr–Einstein debates in the 1930s, through the use of various 'thought' experiments designed to play off one interpretation against another. The problems still receiving most attention, first raised in classic 1935 papers by Einstein and Schrödinger, are the question whether quantum mechanics is a complete theory—does it 'say all there is to say' about physical reality?—and the measurement problem, or the paradox of Schrödinger's \*cat.

Both problems arise in response to the superposition principle in quantum mechanics, which is what distinguishes the theory most from Newtonian mechanics. This principle says that if a physical magnitude  $M$  is assigned a definite value  $m_1$  when a quantum system is in state  $\psi_1$ , and similarly if the (distinct) value  $m_2$  is assigned by the state  $\psi_2$  to the system, then there are also states of the system achieved by combining  $\psi_1$  and  $\psi_2$  in which  $M$  has no definite value whatsoever! To see the peculiarity of the situation, just let  $M$  be position and  $m_1$  be 'the particle is *here*' while  $m_2$  is 'the particle is *over there*'. The way in which  $\psi_1$  and  $\psi_2$  are combined, or superposed, determines the respective probabilities that a \*measurement of  $M$  will be found to yield  $m_1$  or  $m_2$ . And this superposition of states extends to composite systems: two particles can be in limbo between, say, both having value  $m_1$  and both  $m_2$ , with equal probabilities of finding them with either combination.

The completeness problem starts from the worry that superpositions might not really indicate that magnitudes fail to have definite values, but just that quantum mechanics is not able to tell us what the true values are and so resorts to predicting only what values we would probably find if we looked. In fact Einstein (with his collaborators Podolsky and Rosen) argued that quantum predictions themselves give reasons for thinking this. Consider a pair of widely separated particles emitted from a source in opposite directions in a superposed state like the one mentioned at the end of the last paragraph. Since there are only two possibilities—that both particles will be found to have value  $m_1$  or both  $m_2$ —and they have equal probability, once we have measured the  $M$ -value of one of the particles, say particle  $A$ , we can predict with certainty the  $M$ -value of particle  $B$  (since it must be the same). Now surely such a prediction gives us good reason to attribute a definite  $M$ -value to  $B$  (whether it turns out to be  $m_1$  or  $m_2$ ). And surely the  $A$  measurement could not bring that value into existence, since it would be performed at great distance from particle  $B$ , and so could not affect it without influences travelling faster than light. Thus  $B$  must actually have had a definite  $M$ -value all along, despite the fact that it started out locked in a superposition with  $A$ !

Tantalizing though this argument is, it is not sound. For in 1964 Bell cleverly showed that, even if we accept its conclusion of incompleteness, we must *still* invoke some sort of faster-than-light influence to reproduce the quantum predictions—so, in this context, the completeness issue turns out to be a red herring! But this pushes us to still other problems, such as whether the required faster-than-light influences are truly *causal* influences, and whether they can be tolerated by relativity theory (even given that we know they cannot be exploited to transmit a signal faster than light). The debate continues to rage.

The other main problem raised by superpositions pertains to measurement. We may be happy with indefiniteness of values as long as it is consigned to the micro-realm; but there is as yet no principled way in quantum mechanics to prevent it from infecting the everyday world of macroscopic objects, like tables and chairs. Suppose we set

up a device whereby if a radioactive atom decays it sets off a chain reaction terminating in the death of a cat, whereas if it does not decay the cat lives—so the cat's state of being functions as our device for measuring the state of the atom. The law governing the time evolution of quantum states then requires that when the atom evolves into a superposition of 'decayed' and 'not decayed' it drags the cat's state with it, and together they end up in limbo between 'decayed-dead' and 'not decayed-alive'. Not only do we not get an answer from our (now admittedly perverse) measurement of whether the atom has in fact decayed, but we are left saying that much-cherished properties of everyday macroscopic beings do not exist!

There is of course no problem here if quantum mechanics is incomplete. But those who think otherwise have been hard pressed to resolve the problem. Some say quantum evolution somehow gets temporarily suspended so that any unwanted superposition between macroscopically distinguishable states 'collapses' into one or the other of its components  $\psi_1$  and  $\psi_2$ ; others search for a precise mechanism for this collapse, which only operates when systems are sufficiently macroscopic; and still others refuse to acknowledge the problem by arguing that the difference between the collapsed and uncollapsed state of a macroscopic object is so difficult to detect experimentally that 'for all practical purposes' we can live with the superpositions the theory predicts. This list in no way exhausts the avenues that have been pursued, and none has yet come out on top.

The two problems outlined above are far from being the only ones; perhaps they are not even the most interesting. But others peculiar to relativistic quantum mechanics and quantum field theory (like problems to do with particle localization and identity), though increasingly being addressed by philosophers, would involve too much mathematics to elaborate here.

R.CLI.

\*determinism, scientific.

D. Z. Albert, *Quantum Mechanics and Experience* (Cambridge, Mass., 1992).

J. S. Bell, *Speakable and Unspeakable in Quantum Mechanics* (Cambridge, 1987).

J. T. Cushing and E. McMullin (eds.), *Philosophical Consequences of Quantum Theory* (Notre Dame, Ind., 1989).

**quantum theory and philosophy.** The philosophical issues raised by quantum theory are largely dependent upon how \*quantum mechanics is interpreted in order to minimize the philosophical problems that arise within the theory, which is a matter of ongoing controversy.

1. The fact that there are mutually incompatible quantum theories, each with a claim to being empirically adequate, presents difficulties for realist interpretations of quantum mechanics which maintain that theoretical terms refer to objectively existing features of the world. Which theory is the correct one? Since empirical adequacy rules out an experimental basis for this choice, it has been suggested that \*anti-realism or \*instrumentalism about

quantum entities or laws should be adopted, a view which may find application in other areas of science.

2. Quantum theory is often presumed to provide a strong counter-example to the truth of \*determinism. The location of an electron (say) can best be described in terms of the probability of its being found at a particular location, the shape and evolution of such probabilities, known as wave-functions, being governed by the Schrödinger equation. However, if a measurement of location is made, we do not observe the electron to be in a superposition of possible states: the electron will be found at a particular location, and it is no longer possible for it to be anywhere else. Thus, von Neumann postulated that Schrödinger evolution is interrupted and the wave-function 'collapses', it is discontinuously and indeterministically reduced to a particle-like state.

The postulated collapse of the wave-function is more problematic for determinism than Schrödinger evolution, since according to the latter, the state of a system is uniquely determined by any earlier state. But, even if indeterministic collapse can be avoided, this provides little comfort to a strong determinist, since construing Schrödinger evolution realistically involves accepting that the fundamental \*ontology of the world is irreducibly probabilistic. The determinist has two main options: to regard the statistical element of quantum mechanics as epistemic, a sign that the theory is incomplete, in the hope that probability will be eliminated on discovery of a hitherto hidden variable; or to adopt an instrumentalist or anti-realist stance towards the entities and processes the theory describes. According to one such approach, the 'Copenhagen interpretation', which is perhaps the current orthodoxy in physics, we need not understand the superposition of probable states that the Schrödinger equation describes as assigning mutually incompatible properties to the same entity, if observables, such as location or momentum, exist *only when a measurement is being taken*. Thus, the determinist might argue, the wave-function and its collapse are not objective features of causal reality, and so are not genuine instances of 'effects' which lack deterministic causal antecedents.

3. Quantum theory conflicts with intuitions about \*causality. The \*Einstein, Podolsky, and Rosen paradox presents a dilemma for quantum theory: either it is incomplete, or the presumption of the spatio-temporal *locality* of physical interactions—the impossibility of \*action at a distance—fails. However \*Bell's theorem, in so far as his inequalities have been empirically shown to be false, shows that any hidden variable theory would *also* violate locality (or another of Bell's assumptions).

4. Supporters of 'many-worlds' interpretations of quantum mechanics avoid both the indeterministic collapse of the wave-function and action at a distance by maintaining that each time a quantum experiment is performed with different outcomes of non-zero probability, *all* outcomes obtain, each in a *different* world. Hence the universe (everything that exists) incorporates many worlds, where

a world is understood as a totality of classically defined macroscopic objects which are perceived by a conscious observer as being in a definite state—a \*cat is never both alive *and* dead—and excludes microscopic entities which might be in superposition, which explains why we do not experience superpositions. The postulation of the existence of many worlds has been compared to \*Lewis's modal realism—the metaphysical claim that \*possible worlds exist in the same sense as the actual one—and has sometimes been taken to offer empirical support for it. However, the many-worlds hypothesis currently lacks empirical confirmation, and there is doubt whether such confirmation is possible in principle. It also postulates far fewer worlds than Lewis, who maintains that every logically possible world exists.

5. The peculiarities of quantum theory, or some extension of it, are also invoked to provide accounts of \*mind, specifically to explain \*consciousness, because quantum events are causally relevant to the working of the brain, or cognitive processes can be modelled in terms of quantum computation. Such approaches are hindered, however, both by the lack of consensus about the interpretation of quantum theory and by the absence of empirical evidence that quantum-theoretic phenomena are relevant to the explanation of the mind. S.R.A.

\*Bell's theorem; field theory; quantum logic.

Henry P. Stapp, *Mind, Matter and Quantum Mechanics* (New York, 1993).

**quasi-memory.** An artificial \*memory concept, so defined that the quasi-rememberer need not have been the person involved in the original event. *X* quasi-remembers *E* if and only if *E* occurred, *X* apparently recalls something *E*-like, and the apparent recalling causally depends on the occurrence *E* in an appropriate way. This does *not* require that *X* witnessed *E*. The point is to avoid circularity objections to psychological analyses of \*personal identity. P.F.S.

S. Shoemaker, 'Persons and their Pasts', *American Philosophical Quarterly* (1970).

**quasi-realism** is a modern label for a position similar to Hume's in which, although judgements have in fact no independent object, they nevertheless behave from the perspective of the judge as if they did. More specifically, it is the name of a research programme in which, without supposing an independent reality for a set of judgements to be about, an attempt is made to explain and capture the same inferential relations between these judgements as they would have if they did have such independent truth-values. R.H.

\*moral realism.

Simon Blackburn, *Essays in Quasi-Realism* (Oxford, 1993).

**quasi-virtue:** *see* shame.

**quiddity.** Historically meaning 'essence', 'quiddity' has come to denote the unique nature, or 'whatness', of a property. According to 'quidditism' each property has its own quiddity that distinguishes it from every other property. So two properties may be indiscernible (have the same individuals falling under them and the same higher-order properties holding over them) but nevertheless distinct (fail to be identical) because their quiddities differ. The rejection of quidditism is therefore equivalent to the acceptance of the \*identity of indiscernibles applied to the case of properties.

F.MACB.

\*identity of indiscernibles; haecceity.

Robert Black, 'Against Quidditism', *Australasian Journal of Philosophy*, 78 (2000).

**quietism, philosophical.** The view, associated with the later Wittgenstein, that philosophy should not aspire to produce substantive theories (e.g. of the nature of meaning, the foundations of knowledge, or of the mind's place in the world), adjudicate disputes in science or mathematics, make discoveries, or dictate how language should be used. Philosophy's proper role is therapeutic rather than constructive: the philosopher diagnoses conceptual confusions. Although the results of such therapy can be profoundly liberating, philosophy does not itself advance human knowledge, but 'leaves everything as it is'.

P. M. S. Hacker, 'Philosophy', in Hans-Johann Glock (ed.), *Wittgenstein: A Critical Reader* (Oxford, 2001).

**Quine, Willard Van Orman** (1908–2000). Probably the most important American philosopher since the war, Quine spent his career at Harvard University. His extensive writings have shaped the development of recent philosophy, particularly in logic, the philosophy of language, epistemology, and metaphysics. After completing his doctorate, he visited the Vienna Circle, coming under the influence of Rudolf Carnap. Although critical of its fundamental doctrines, Quine remained true to the underlying spirit of \*Logical Positivism. He shared its commitment to \*empiricism and to the belief that philosophy should be pursued as part of science.

The papers published in *From a Logical Point of View* (1953) defended views about language and ontology, challenging the assumptions of the prevailing orthodoxy. After 1960, with the publication of *Word and Object*, Quine emphasized his \*naturalism, the doctrine that philosophy should be pursued as part of natural science. *Pursuit of Truth* (1990) is a clear, concise formulation of his philosophical position.

Most modern empiricists had held that the meanings of everyday and scientific propositions determine which experiences count as evidence for or against them:

there are \*analytic truths (truths which hold by virtue of meanings) which record these links with experience and guide us in forming our opinions. 'Two Dogmas of Empiricism' (1953) rejected this picture: experience counts for or against our entire body of beliefs in a holistic manner, and little that is systematic can be said about the meanings of particular sentences. The analytic-synthetic distinction is to be abandoned, and with it the idea that mathematics and logic have a status radically distinct from that of empirical science: 'Any statement can be held true come what may, if we make drastic enough adjustments elsewhere in the system.' We can even retain an ordinary belief about our surroundings in the face of contrary experience 'by pleading hallucination or by amending certain statements of the kind called logical laws' (p. 43).

In *Word and Object*, this denial that anything systematic can be said about the meanings of particular sentences leads to Quine's most famous doctrine, the \*indeterminacy of translation. We undertake 'radical translation' when we attempt to translate a previously unknown language, relying only on information about the evidence that native speakers take to be relevant to the truth or falsity of their utterances. Quine argued that many alternative translation manuals will always fit the evidence, there being no fact of the matter which is correct. There are no objective facts about which words and sentences have the same \*meanings.

Among the consequences of these views about meaning is a deep scepticism about the possibility of \*modal logic, and the doctrine of ontological relativity. The ontology of a theory is the range of objects that must exist if the theory is true; Quine holds that we can state the ontology of a theory only relative to a translation manual and a background language. There is no non-relative fact of the matter what the ontology of a theory is; or indeed what the ontology of any theorist is.

Quine's own ontological taste is for \*physicalism: the physical facts are all the facts, all changes in the world involving physical changes. And this helps to support his philosophical naturalism. The philosophical study of knowledge, for example, is a branch of natural science, drawing on psychology to explain how sensory stimulation gives rise to scientific beliefs. Controversy has surrounded the claim of naturalized epistemology that our philosophical needs are met by such a study: some have objected that it changes the subject by failing to address \*scepticism directly, or by focusing on how we *do* form our opinions rather than on normative questions of how we *ought* to assess them.

**Quinton, Anthony** (1925– ). British philosopher, based in Oxford and member of the House of Lords, who has written on political philosophy, ethics and metaphysics, the philosophy of mind, and a variety of historical figures. His lengthiest work is his treatise on *The Nature of Things*, which takes as its central notion the concept of \*substance. By exploring the questions associated with this concept Quinton develops, in three parts, his views on a wide-ranging set of traditional philosophical problems. In part I, problems of identity and individualism, the relation between matter and

extension, and personal identity and the soul are discussed; in part II knowledge, scepticism, and the concept of perception are the topics; in part III the notion of essence, the distinction between theory and observation, mind–body dualism, and fact and value are discussed. The general position defended is a form of materialism. H.W.N.

**race.** Higher-level organisms form species, that is groups of organisms that breed among themselves but that are reproductively isolated from all other organisms. We humans belong to the species *Homo sapiens*. Although species are the fundamental units of biological classification, they can often be subdivided into groups that are distinguishable by special features. Early biologists of the modern era, notably the French naturalist Buffon, assumed that this is true of humans, and they spent much time and effort trying to decide what constitute the true divisions, generally known as races. In his *Descent of Man* (1871), Charles Darwin argued that many human differences are due to sexual selection, where differing standards of beauty are the chief causal factors tearing human populations apart.

Notoriously, the German Nazis were keen race theorists, believing that distinctions can be drawn between Aryans and others, especially Jews. Naturally, in the post-Second World War years, the very idea of race fell from favour, and it was argued that not only is it a socially pernicious notion but that it has little or no scientific validity. The major defining mark of the human species is how little difference there is between peoples, not how much.

In recent years, the pendulum has swung back a little. Anthropologists now recognize that there are several distinctive human forms, and medical geneticists are keenly aware that there are distinctive diseases much more commonly associated with certain groups than with others. For instance, Ashkenazi Jews (those from Eastern Europe) are more prone to carry a gene for Tay-Sachs diseases than are other peoples. M.R.

\*anti-Semitism.

T. Dobzhansky, *Mankind Evolving* (New Haven, Conn., 1962).  
C. P. Groves, *The Biology of Race* (Berkeley, Calif., 1989).

**racism.** Although the roots of theoretical racism can be traced back at least to the fifteenth century, the term did not come to prominence until the 1930s when it was used to describe the pseudo-scientific theory that 'race', as a decisive biological determinant, established a hierarchy among different ethnic groups. Racist theories were largely developed after the fact to justify practical racism, which can exist independently of them. Polygenesis, the

attempt to explain the differences among kinds by positing diverse origins, provided a basis for maintaining permanent inequalities between peoples; by contrast, the philosophies of history that imposed a single goal on history could be used to justify colonialism, as well as the destruction of indigenous cultures and peoples. Most potently, the two tendencies are combined to demand an assimilation that is still withheld on the basis of blood purity or skin colour. R.L.B.

\*fascism.

B. Boxhill (ed.) *Race and Racism* (Oxford, 2001).  
R. H. Popkin, 'The Philosophical Bases of Modern Racism', in *The High Road to Pyrrhonism* (San Diego, 1980).

**Radcliffe Richards, Janet** (1944– ). English philosopher whose book *The Sceptical Feminist* was published in 1980 and provides a vigorous defence of liberal feminism against both anti-feminists and radical feminists. According to Radcliffe Richards, \*feminism should not be concerned with benefiting a particular group of people (women), but with removing a particular kind of injustice. The central task of the book is to expose the faulty thinking which grounds that injustice. Although influential, it has been said to be too unworldly in its understanding of women's oppression, and insufficiently radical in the remedies it proposes. There is not much discussion of the inequalities of power which perpetuate injustice, and an acceptance that 'women's work' is less fulfilling and valuable than work outside the home. Richards's feminism is logical rather than ideological, cerebral rather than celebratory. S.M.

\*justice.

**Radhakrishnan, Sarvepalli** (1888–1975). Idealist philosopher who taught at Oxford and was the President of India during 1962–7. Best known for his elegant exegesis of \*Indian philosophy and Hinduism in English, this prolific statesman broadly adhered to monistic \*Vedānta, trying to reinterpret it as a kind of universal religion. Rejecting both Berkeleyan and Hegelian idealisms, he upheld a teleological and openly religious view of matter, life, and mind as all evolving with a divine purpose or *idea* which gives meaning to existence. Interpreting classical Indian and

modern Western philosophies in a syncretic manner, Radhakrishnan argued that ultimate reality is a changing but 'ordered' whole which science can only understand incompletely. It is directly accessible to a blissful intuitive experience that mystics of all religions describe in strikingly similar ways as ineffable.

A.C.

\*science, art, and religion.

S. Radhakrishnan, *The Idealist View of Life* (London, 1988).

**radical feminism:** see feminism, radical.

**radical interpretation and translation:** see translation, indeterminacy of.

**radical philosophy.** Movement formed in 1971, in opposition to narrowness and insularity of professional philosophy in Britain, particularly Oxford. The Radical Philosophy Group has organized various national conferences, but its main influence has been through the magazine *Radical Philosophy*. This has persistently forsworn allegiance to any particular doctrine, but describes itself as a journal of socialist and feminist philosophy. Additionally, although it is not a Marxist journal, many of those involved with it have seen themselves as continuing a Marxist philosophical tradition. Other preoccupations include a commitment to interdisciplinary work, widening interest in continental philosophy, and reforming bad practices in academic philosophy.

Since some of its defining concerns are now shared by many distinguished philosophers, it is to be wondered whether its self-image of opposition to the narrowness of the professional discipline is any longer appropriate (although the attempt by Cambridge philosophers to deny an honorary degree to Derrida might suggest that this is premature).

\*Oxford philosophy.

R. Edgley and R. Osborne, *A Radical Philosophy Reader* (London, 1985).

**Rāmānuja** (1017–1137). South Indian consolidator of devotional theistic interpretation of Vedic philosophy called qualified non-dualism. Unlike the unqualified monists, Rāmānuja postulates three realities—God, matter, and individual souls—the last two being parasitic on the first. God, a person with infinite excellent attributes, is the self of selves, and the universe is his inseparable body. Highest liberation consists not in identification with God (as in non-dualism), but in enjoying a God-like state of joy at knowing one's eternal dependence upon the Lord. With a distinctively realistic epistemology of error, Rāmānuja opposes the idealism of \*Śaṅkara, who deemed the world an illusion that is 'neither real nor unreal'. Rāmānuja bombards this illusionism with charges of inconsistency, asking tough questions: 'Whose illusion is it? It could not be *God's* because he never errs, and could not be *ours* because we are its effects according to non-dualism!'

\*Indian philosophy; Vedānta.

Julius Lipner, *The Face of Truth: A Study of Meaning and Metaphysics in Rāmānuja* (Albany, NY, 1986).

**Ramsey, Frank P.** (1903–30). Cambridge mathematician, logician, and philosopher whose short career included important, though brief, contributions to a wide range of subjects, including probability theory, economics, and the foundations of mathematics. He was amongst the first to understand and recognize the importance of Wittgenstein's *Tractatus*, and one of the few contemporary philosophers whose opinion Wittgenstein respected. But he was not uncritical of Wittgenstein's ideas at the time.

Ramsey did pioneering work in the theory of subjective \*probability, arguing that degrees of rational belief should conform to the axioms of the probability calculus. He developed a method for eliminating reference to theoretical entities in science by framing what are now called 'Ramsey sentences'. His analysis of generalizations was to treat them as expressing rules for the anticipation of experience rather than propositions to which truth-values could be assigned. He was also a proponent of the \*redundancy theory of truth.

E.J.L.

F. P. Ramsey, *The Foundations of Mathematics and Other Logical Essays* (London, 1931).

—*Philosophical Papers*, ed. D. H. Mellor (Cambridge, 1990).

**Rashdall, Hastings** (1858–1924). English philosopher who expounded a theory known as 'ideal utilitarianism'. Rashdall was a Fellow of New College, Oxford, and dedicated his main work, *The Theory of Good and Evil*, to the memory of his teachers T. H. Green and Henry Sidgwick. The dedication is appropriate, for the particular version of \*utilitarianism put forward by Rashdall owes elements to both Green and Sidgwick. Whereas he holds that the concepts of \*good and \*value are logically prior to that of \*right, he gives right a more than instrumental significance. His idea of good owes more to T. H. Green than to the hedonistic utilitarians. 'The ideal of human life is not the mere juxtaposition of distinct goods, but a whole in which each good is made different by the presence of others.' Rashdall has been unfairly eclipsed as a moral philosopher by G. E. Moore.

R.S.D.

H. Sidgwick (with additional ch. by A. G. Widgey), *Outlines of the History of Ethics* (London, 1946).

**ratiocination.** Reasoning. St Thomas Aquinas distinguished ratiocination (*ratiocinatio*) from the direct, non-inferential apprehension of truth possessed by God and angels. Human beings, he claimed, arrive at 'the knowledge of intelligible truth by advancing from one thing to another'—i.e. by an inferential process, ratiocination. Ratiocination, understood simply as \*reasoning, some times misses its mark; and, plausibly, some human knowledge is acquired non-inferentially.

A.R.M.

\*inference; argument.

St Thomas Aquinas, *Summa Theologiae*, pt. 1, Q. 79, Art. 8.

**rational choice theory** explores the extent to which complex social and economic phenomena can be regarded as the outcome of calculative, self-interested individual action. The advent of game theory (during the Second World War) showed that the outcomes of action can often be understood as the joint result of individual choice in combination with the choices of other actors ('players'), all of whom aim at maximizing (or at least satisficing) individual preference-satisfaction. Where two or more actors have regular interactions on the same matter, a strategy that reliably provides utility to all of them may emerge, and become enshrined in a convention. Rational choice theory has been claimed to explain many social institutions, from marriage to morality, though sceptics doubt its usefulness in the face of limits to obtainable information and to the time available for weighing indefinitely many alternative possible outcomes.

A.BRE.

K. S. Cook and M. Levi (eds.), *The Limits of Rationality* (Chicago, 1990).

**rationalism.** Any of a variety of views emphasizing the role or importance of reason, usually including \*intuition, in contrast to sensory experience (including introspection), the feelings, or authority. Just as an extreme empiricist tries to base all our knowledge on experience, so an extreme rationalist tries to base it on reason. But whereas \*empiricism appears in the eighteenth century and again in the first half of the twentieth century, extreme rationalism has been considerably less popular. In fact it reached its peak in the brash days when philosophy itself was beginning, back in the ancient Greek world. Parmenides maintained that, whatever the senses might say, the very notion of change involved a contradiction, and so reason demanded that reality be entirely devoid of change. As usually interpreted he said the same about plurality too. His fellow citizen and near-contemporary Zeno of Elea supported him with a set of paradoxes, including the famous Achilles and the tortoise. (\*Zeno's paradoxes.) These two, together with a handful of followers (including to a certain extent, but only to a certain extent, Plato), represent the acme of extreme rationalism, and later rationalists have seldom been willing to dismiss the senses quite so single-mindedly. They perhaps have in mind the words the slightly later philosopher Democritus, by no means an extreme empiricist, gives to the senses to defend themselves against pure reason (fragment 125): 'Wretched mind, do you take your evidence from us and then overthrow us? Our overthrow is your own downfall!'

It is indeed hard to see how a being entirely devoid of any contact with the world through the senses could ever amass the materials needed to exercise its reason at all. How, for instance, could it acquire a language to express its thoughts in, and what sort of thoughts could it have if it had no language at all?

Rationalism, however, does not have to take an extreme form. It can content itself with claiming simply that some of our knowledge, though not all of it, can come

to us otherwise than through the senses. This is quite compatible with saying that without some use of the senses we would not have any knowledge at all. Rationalism in fact can take two main forms, according as it claims that some of our propositional knowledge, i.e. knowledge of the truth of certain propositions, comes to us without coming through the senses, or claims that some of the materials from which our knowledge is constructed are present in the mind without coming through the senses. This latter will be the case if some of our concepts are \*a priori, where this just means 'prior to experience'. It might be, for instance, that concepts such as those of substance or causation are present with us from the beginning in the sense that, as Kant thought, we do not *find out* that the world contains substances and causes, but cannot help but see the world as composed of substances which have attributes and of events which are caused by other events. Having the concepts in this way, however, must be distinguished from having them explicitly, in the sense of having words for them or consciously thinking about them, as we are doing now. On the theory in question, small children and possibly even animals can do the former without its following that they can do the latter.

It is not surprising that, contrary to the claims of the extreme empiricist, we must bring some equipment with us if we want to know something about the world. If we could really start as blank tablets, then why don't ordinary blackboards, or at any rate photoreceptive camera plates, know things about the world? On the other hand, it is only in a backhanded sense that we can be said to 'know' that the world contains substances and causes if the truth of the matter is that we can only know the world at all by treating it as though it did. A more substantive rationalism is that which says that we can know certain propositions to be true without deriving this knowledge from our senses, even if in some or all cases we must use our senses to get the concepts that are involved in the propositions: I may know without looking that whatever has a size has a shape, but only if I already have the concepts of size and shape, i.e. if I know what size and shape are.

Kant made, or at least brought into clear and explicit focus, a distinction between \*analytic and synthetic statements (or judgements in his case, as he was more concerned with the workings of the mind than with linguistic analysis). Even empiricists usually allow that we know analytic statements a priori, but they defuse this concession by adding that such knowledge hardly counts as knowledge in any meaty sense, since such statements do not say anything substantive about the world. Synthetic statements, however, do, and rationalism in its stronger versions is concerned to claim that some of them can be known a priori. The one about everything with size having shape would be a standard example, and others would be mathematical propositions, which empiricists usually try to treat as analytic, though without much success in the opinion of rationalists. In fact around the start of the twentieth century a sustained attempt was made by Frege and Russell to reduce mathematics to pure logic in their

## FOUNDERS OF MODERN PHILOSOPHY (EUROPEAN)

RENÉ DESCARTES: 'had he kept himself to geometry,' said Hobbes in tribute, 'he had been the best geometer in the world'. But Descartes's vision of the unity of mathematics and the natural sciences inspired his philosophical project.

GOTTFRIED WILHELM LEIBNIZ left such voluminous writings on philosophy, mathematics, and physics that a complete edition is still not in sight; one scholar estimated it would be twenty years' full-time work just to read his manuscripts.

IMMANUEL KANT was the fountainhead from which the main stream of continental European philosophy flowed in the nineteenth and twentieth centuries; his influence has steadily spread through English language philosophy too, especially in metaphysics and ethics.

BARUCH SPINOZA's greatest work, his *Ethics*, is in fact a systematic metaphysical treatise which builds theorems upon axioms upon definitions. His intellectual adventurousness led to his ejection from the orthodox Jewish community in Amsterdam.

theory known as logicism; but it is now generally agreed, especially since Gödel's first incompleteness theorem in 1931, that this cannot be done.

However, even what I have called this 'more substantive' rationalism, which claims that we can know certain interesting truths a priori, does not escape a certain tension in its relations with the weaker rationalism which says that we have to treat the world in certain ways if we are to make sense of it. For when it comes to justifying these claims to know the world without looking at it, the rationalist is in danger of being driven to say simply that we cannot think coherently without accepting these propositions—which is rather weaker than claiming some special insight which definitely tells us that they are true. Would not such an insight be a sort of magic?

Be that as it may, the main form that rationalism has taken in the last few decades has been of the weaker kind, and connected, like so much of philosophy during that period, with language. It stems from Chomsky, who holds that certain grammatical structures are innate in our minds, so that all human languages share certain common features which make it possible for children to learn them. Other sorts of language may be spoken by, say, Martians, but our children could not learn them, nor their children ours.

An interesting recent development concerning the a priori is the claim by Kripke and Putnam that the a priori–empirical distinction does not coincide, as it has usually been thought to do, with the necessary–contingent distinction. Kripke claims that some propositions that are true only contingently can be known a priori (an example might be that the knower himself exists), while some propositions that are necessarily true can only be known empirically (an example here might be the chemical composition of some substance). This latter might sound rather strange: might not water, say, have turned out to have some structure different from  $H_2O$ ? Kripke and Putnam would agree that we might have found ourselves faced with a liquid that was wet and colourless, filled the oceans, and was good for making coffee with, i.e. had all the ordinary and easily observable properties of water, but which had a structure quite different from  $H_2O$ . But such a liquid would not be water, because the word 'water' gets its meaning from its use to name the liquid we actually have around us, which is  $H_2O$ . Of course we might have called the other stuff water had we come across it, but then the word 'water' would have had a different meaning from the one it actually has, because it would have acquired its meaning in a different way, i.e. by its relations to a different stuff. This doctrine, incidentally, that water is essentially  $H_2O$ , i.e. would not be what it is unless it had the structure  $H_2O$ , illustrates the essentialism whose recent revival has been pioneered by Kripke and Putnam among others, and which is itself in the spirit of rationalism rather than empiricism, even though our finding out that water is  $H_2O$  relies on observation: the fact that things have essences at all is not something that observation can tell us.

Finally, rationalism, like empiricism, can refer either to the psychological genesis or to the philosophical justification of our knowledge; i.e. it can say either that we do in fact get some or all of our knowledge, or all of our knowledge in a certain sphere, from reason, or else that only to the extent that we do so can we properly claim to have knowledge. Again, as in the case of empiricism, we are bordering on \*naturalism, but rationalism has perhaps more usually been concerned with the genetic questions. When justification is at issue rationalism is usually concerned (as with Plato and to a lesser extent Aristotle) with distinguishing real or proper knowledge from lesser grades of cognition like true opinion, which are unstable and cannot be relied upon.

When contrasted with feeling or sentiment, especially in the eighteenth-century opponents of the '\*moral sense' school, rationalism, often then called intuitionism, takes the form of an ethical doctrine claiming that we have a priori intuitions of moral truths. Ethical intuitionists vary in whether they treat such intuitions as isolated or as linked together in a rational system.

In the latter case logical reasoning is involved, and though no one would deny that ethical conclusions can be logically derived from premisses which include ethical premisses, the rationalist, defying one form of the '\*naturalistic fallacy, will claim that they can be so derived sometimes from purely non-ethical premisses. It is in this sort of case that the ethical intuitions involved have the air of arising from reason, in parallel with logical intuitions, and so are thought to belong most appropriately under rationalism.

Rationalism can also oppose reason to authority, in particular to religious revelation, and the name has been used in this sense, especially since the end of the nineteenth century, though not usually in philosophy. A.R.L.

**rationality.** This is a feature of cognitive agents that they exhibit when they adopt beliefs on the basis of appropriate reasons. Aristotle maintained that rationality is the key feature that distinguishes human beings from other animals. The adjective 'rational' is used to characterize both agents and specific beliefs. In both cases rationality can be contrasted with either non-rationality or irrationality. A stone or tree is non-rational because it is not capable of carrying out rational assessments. A being who is capable of being rational but who regularly violates the principles of rational assessment is irrational. Among rational beings

some beliefs are non-rational since they are matters of taste and no reasons are required. Beliefs that are contrary to the dictates of reason are irrational. Rational beliefs have also been contrasted with beliefs arrived at through \*emotion, faith, authority, or by an arbitrary choice. The point of each contrast is to capture a sense in which we believe a proposition either without carrying out an appropriate assessment or in spite of the results of such an assessment. For example, we determine the balance in a cheque-book rationally when we enter the correct credits and debits and do the arithmetic. Irrational ways of determining a balance include picking a number at random or choosing a number because we find it pleasant. When dealing with empirical matters, rational beliefs are arrived at by accumulating relevant evidence; a rational individual will suspend belief until an adequate body of evidence has been accumulated and evaluated. Rational belief is established in mathematics by providing a formal proof. There has been an intense debate throughout the history of philosophy on the question whether matters of value are subject to rational assessment.

It has long been held that rational assessment requires rigorous rules for deciding whether a proposition should be believed. Formal logic and mathematics provide the clearest examples of such rules. Science has also been considered a model of rationality because it was held to proceed in accordance with the \*scientific method which provides the rules for gathering evidence and evaluating hypotheses on the basis of this evidence. In this view, rational assessment yields results that are universal and necessary; if two individuals who have access to the same evidence arrive at incompatible conclusions, at least one of them must be behaving irrationally.

More recent discussions have proposed accounts of bounded rationality that pay closer attention to human cognitive limitations and recognize considerable scope for rational disagreement. The central role attributed to rules in rational evaluations has also been challenged. Following rules is not always required, since one task of rational assessment is to determine which rules should be followed in a particular situation. To insist that this decision must be made by following other rules can create an \*infinite regress that would make it impossible to arrive at rational results in many situations that serve as paradigms of reason, such as constructing mathematical proofs or evaluating scientific hypotheses. Nor is following rules—even correct rules of logic—automatically rational. Consider again an individual who is constructing a logical proof: this individual must decide which rules to apply at each stage of the proof. Mindlessly applying rules just because they are logically correct is foolish. In addition, Kuhn and others have argued that there are no fixed rules of scientific method. Rather, we must learn what the correct rules of method are as science develops. These considerations suggest that our ability to be rational depends on a basic ability to exercise intelligent judgement that cannot be completely captured in systems of rules.

**ravens, paradox of the.** A problem in \*confirmation theory to which attention was first drawn by Hempel. Prima facie, a generalization such as 'All ravens are black' is confirmed by—gains strength from—each new observed instance of a black raven. But this generalization is logically equivalent to 'Anything which is not black is not a raven'. And this latter generalization is confirmed by each new instance of a non-black non-raven, such as white handkerchiefs and pale pine writing-desks. So, if we accept the seemingly innocent principle that whatever confirms a hypothesis *h* also confirms any hypothesis logically equivalent to *h*, we must conclude that observations of white handkerchiefs will confirm that all ravens are black—which would render ornithology paradoxically easy. Yet it is not obvious which of the premisses of this argument could be rejected.

**Rawls, John** (1921–2002). Major social and political philosopher. Educated at Princeton, he taught at Cornell and Harvard, and in 1971 published *A Theory of Justice*, whose leading idea is that of \*justice as fairness—the hope for social institutions that do not confer morally arbitrary lifelong advantages on some persons at the expense of others. This condemns as unjust not only racial, sexual, and religious discrimination, but also many forms of social and economic inequality; the view is a strongly egalitarian form of \*liberalism. It is based on a new form of social \*contract theory—not an actual social contract but a hypothetical one.

We are to imagine ourselves in an \*original position of equality, in which we do not know most of the socially significant facts about ourselves—race, sex, religion, economic class, social standing, natural abilities, even our conception of the good life. Under this \*veil of ignorance, we are to decide what principles we could agree to on the basis of a desire to further our own aims and interests, whatever they may be. Not knowing our position in society or our conception of the good, we are driven by this fiction to an equal concern for the fate of everyone, and Rawls maintains that we would give priority in choice of principles to avoiding the worst possible life prospects, with emphasis first on the preservation of personal and political liberty and second on the amelioration of socio-economic inequality.

The principles he defends are: (1) each individual is to have a right to the greatest equal liberty compatible with a like liberty for all; (2) (a) social and economic inequalities are to be attached to offices and positions open to all under

conditions of fair equality of opportunity; and (b) such inequalities are justified only if they benefit the worst-off (the \*difference principle). The first principle has priority over the second, and both principles are to govern not detailed political choices but the basic structures—political, economic, and social—which determine people's chances in life. Equal \*liberty rules out persecution, discrimination, and political oppression. Equal \*opportunity ensures that those with equal ability and motivation have equal chances of success, whatever class they are born into. The difference principle allows unequal abilities to produce differential rewards only to the extent that this is instrumentally necessary for the good of all, especially the least fortunate (for example, by providing the incentives which fuel productivity).

Rawls opposes \*utilitarianism, holding that the maximum total good may not be pursued by means which impose unfair disadvantages on minorities, including the unskilled. More generally, he claims that the right is prior to and independent of the good, and cannot be defined as that which will promote or maximize the good. Certain conditions on the social relations between people and the way they may be treated take precedence over the production of desirable results. This is opposed to the idea that rights are just human conventions justified instrumentally by their usefulness in promoting the general welfare.

In numerous essays after the book, some collected in *Political Liberalism* (New York, 1993), Rawls further develops the theory of \*justice and its relation to general moral theory and moral epistemology. He employs what he calls the method of 'reflective equilibrium', by which coherence in our moral views is achieved through mutual adjustment between particular moral judgements, general principles, and theoretical constructions like the social contract which model the ideas of morality. **Raz, Joseph** (1941– ). Legal, moral, and political philosopher, based in Oxford since 1970. Principally known for three theories. First, a conception of \*authority invoking second-order practical reasons, reasons in favour of or against acting on an existing reason one might have to act (or not to act). Authority requires second-order reasons not to consider the independent merits of performing actions commanded, and these reasons must not themselves be based on those merits. The theory is used to develop a qualified form of \*legal positivism. Secondly, his interest theory of \*rights sees rights as successful

justifications for imposing duties on others, based on the recognition of the fundamental interests of creatures capable of possessing rights (persons). Thirdly, he is the best-known contemporary proponent of the political theory of \*perfectionism, which holds that liberal states should not be neutral across the values and practices of their citizens, but should in fact promote individual life-styles which most advance personal \*autonomy.

**real.** 'Real' is often used with some opposite term in mind, such as 'ideal', or 'fake'. In these cases, one can infer from 'A is not a real F' that A is not an F at all (one of the things that tempts philosophers to equate 'real' with 'existent'). Hence to contrast 'real' with a term like 'relational' may mislead: from 'A was a relational change' one *can* infer that A was a change.

If 'reality' is taken to be the sum total of all that is real, then for 'real' we do have to read something like 'existent'. Talk of such a sum total may itself be problematic, of course: it can smack of treating 'everything' as a name for an enormous entity. R.P.L.T.

**Realism, New:** *see* New Realism.

**realism, quasi-:** *see* quasi-realism.

**realism and anti-realism.** Primarily directions, not positions. To assert that something is somehow mind-independent is to move in the realist direction; to deny it is to move in the opposite direction. No sane position is reached at either extreme. Not everything is in every way independent of minds; if there were no minds, there would be no pain. Not everything depends in every way on minds; if I forget that Halley's comet exists, it does not cease to exist. Many philosophical questions have the

general form: Is such-and-such mind-independent in so-and-so way? Given specifications of such-and-such and so-and-so, one may call someone who answers 'Yes' a realist. Since different philosophers take different specifications for granted, the word 'realism' is used in a bewildering variety of senses.

In medieval scholastic philosophy, realism was a theory of predication opposed to *\*nominalism* and *conceptualism*. On a realist analysis, the sentence 'Snow is white' is true if and only if the substance snow has the property of whiteness; whiteness exists independently of our thought and talk, just as snow does. Unlike substances, properties are predicative: their nature is to be properties of something. In contrast, conceptualists deny that anything predicative exists independently of thought; the truth of 'Snow is white' requires only our concept of white to apply to snow. Nominalists go further, holding the only predicative item required for the truth of 'Snow is white' to be the word 'white' itself, whose existence depends on a particular language, not just on a kind of thought.

Kant opposed realism to *\*idealism*, distinguishing transcendental and empirical versions of each. The empirical realist holds (like Kant) that we can have knowledge of the existence and nature of material objects in space and time. The transcendental realist holds (unlike Kant) that the existence and nature of the objects so known is wholly independent of our knowledge of them. Kant argued that the two kinds of realism make an untenable combination, because perception yields knowledge only of appearances. Thus the empirical realist should be a transcendental idealist, for whom material objects are nothing beyond their appearances to us; the transcendental realist should be an empirical idealist, a sceptic. However, the argument relies on the dubious premiss that *\*perception* yields knowledge only of appearances. Realists may deny that the nature and existence of what we perceive (e.g. a tree) depends on our perception of it. Perhaps the dependence is the other way round: my perception of the tree depends essentially on the tree, because I could not have had *that* perception without perceiving *that* tree. If so, the combination of transcendental and empirical realism may be defensible.

After Kant, 'realism' meant above all the view that we perceive objects whose existence and nature are independent of our perceptions. The issue has subsequently been generalized. For any linguistic or psychological act (e.g. a judgement, a perception), one can ask whether it involves a relation to something independent of it. That something (e.g. a property, a material object) would constitute an independent standard of correctness for the act. The standard makes the act correct only if they are related. Realists see anti-realists as sacrificing the independence to the relation; anti-realists see realists as sacrificing the relation to the independence.

An independent standard of correctness need not be a particular *thing*. To discuss whether the judgement 'Rape is wrong' is correct independently of being judged is to discuss the objectivity of moral truth, not the existence of

moral objects (to adapt Kreisel's remark that what matters is the objectivity of mathematical truth, not the existence of mathematical objects). The existence of objects is relevant only when it is required for a judgement to be true. The truth of a perceptual judgement may depend on the existence of trees, that of a scientific theory on the existence of electrons.

Realism is still accused of leading to *\*scepticism* by disconnecting our beliefs from their standard of correctness. To know something is to believe it because it is true, but to assume that a belief is true in the realist sense is not to explain why it is believed. The problem is particularly acute where the realist cannot postulate a causal connection between the facts and our beliefs. How, for example, could our belief that  $5 + 7 = 12$  be caused by a fact about abstract objects? Even where a causal connection is postulated, e.g. between the existence of electrons and our belief that electrons exist, the question is whether it is of a kind to help the realist. If the observational evidence can be explained by many mutually inconsistent theories, how except by luck can we choose the true one?

Many anti-realists take the argument further, giving it a linguistic turn. They infer that we cannot even understand what realist *\*truth* is; the epistemologically inaccessible is also semantically inaccessible. If we could never know the realist *\*facts*, how could we even think about them? Realism is held to make nonsense of our thought and talk by attributing to it an unintelligible standard of correctness.

Anti-realist alternatives take many forms. It may be global or restricted to a local practice (anti-realist accounts of morality and realist accounts of natural science often reflect the same confidence in a scientific world-picture). The anti-realist may hold (1) the practice does not involve judgements at all, or (2) the judgements it involves are incorrect, or (3) they are correct only in some mind-dependent sense.

1. *\*Emotivists* treat moral principles as expressions of approval or disapproval. *Formalists* treat mathematical proofs as series of moves in a formal game like chess. *Instrumentalists* treat scientific theories as calculating-instruments used to predict future experience. In each case, apparent judgements are treated as not really candidates for truth. Emotivists say 'Rape is wrong' while denying that 'Rape is wrong' is genuinely true. This risks inconsistency: given the usual practice in speaking of truth, if rape is wrong then 'Rape is wrong' is true.

2. *Error theorists* treat morality as a vast illusion; moral judgements are untrue because no values exist to make them true. *\*Eliminativists* believe that neuroscience has refuted everyday psychology by showing that beliefs and desires do not exist. Even the truth of arithmetic has been denied on the grounds that numbers do not exist. On such views, we are mistaken in judging 'Rape is wrong', 'I want a drink', or ' $5 + 7 = 12$ '; although what we say may be useful, it is not literally true.

3. The truth of ordinary judgements may be admitted, but treated as mind-dependent, in order to allow us access

to it. Mind-dependence comes in many varieties. Stipulation provides an extreme case. By stipulating that my fish is named 'Mary', I make it true that my fish is named 'Mary'; my knowledge of that truth is correspondingly unproblematic. Both fictional and mathematical truth have been assimilated to the stipulative model. A story is created by being told; anti-realists have called mathematics the free creation of the human mind. The model is more complex than it appears. Stipulating something does not automatically make it true. Some stipulations are inconsistent, others made without due authority.

In most practices, no single act of stipulation is authoritative. A river is named 'Thames' by long-standing agreement. Anyone can mistake the name, but the mistake lies only in deviation from social consensus (the people cannot all be fooled). However, this is still an extreme model of mind-dependence. Many practices would be radically changed if their participants came to regard the truth of their judgements as constituted by present consensus. As we now think of morality, we allow that everyone in our society may share a false moral belief, all being blind to some morally relevant consideration.

A more subtly mind-dependent standard of truth is consensus in the long run. By refining our current morality we might eventually overcome our present blindness. Such a standard has been suggested for science as well as morality. Of course, we must not achieve the long-run consensus by lapsing into barbarism. What counts is an imaginary long run in which rational inquiry is pursued, unhindered by the contingent limitations of finite humans in constricting environments. Mind-dependent truth becomes something like idealized rational acceptability, in Putnam's phrase. The mind on which truth depends is not the human mind, as described by empirical psychology, or groups of human minds, as described by empirical sociology; it is an ideal mind, as prescribed by normative rules embodied in our thought and talk. Hegel's *objective idealism* prefigured this view.

Rational inquiry is not guaranteed to stabilize in consensus. We cannot assume that each moral disagreement will be resolved, or that historians will discover who killed the Princes in the Tower, or that mathematicians will either prove or refute Goldbach's conjecture ('Every even number greater than 2 is the sum of two primes'). If truth implies consensus, we cannot assume that either a proposition is true or its negation is. This jeopardizes *\*bivalence*, the principle that every proposition is either true or false. Anti-realism may, as Dummett has argued, require revisions of logic.

For realists, a proposition is true or false even if we can never know which. Anti-realists ask how we can grasp such a standard of truth, if not by magic. How can we refer to conditions whose obtaining we cannot recognize? Many reject the challenge, arguing that such notions cannot be reduced to more basic terms. Others accept it. Some argue that reference is a causal relation; our use of, for example, the word 'rain' is causally related to a

condition that also obtained in the inaccessible past. The idea that the world contains mind-independent conditions, properties, and relations is central to such an account; scholastic realism supports modern realism.

When we have a thought, its truth or falsity is not a fact about us, unless we are thinking about ourselves. But it is a fact about us that we are having that thought. In having it, we refer to what it is about. *\*Reference* to something requires at least indirect acquaintance with it, and therefore with states of affairs involving it. Such acquaintance constitutes knowledge. Thus a pre-condition of thinking about something is possession of at least some knowledge about it. Realists and anti-realists may agree that such a pre-condition exists. For anti-realists, it is substantial. Reflection on it uncovers surprising incoherences in our thought of things as independent of us. For realists, the pre-condition is minimal. It permits us no end of ignorance and error.

**realism in metaphysics.** A problem of metaphysics much discussed in recent decades is that of realism. But the first problem here is *how to formulate* the problem. Here is one way:

*Realism:* Tokens of most common-sense, and scientific, physical types exist objectively, independently of the mental.

This, however, can be variously interpreted; here is just one possibility:

*Realism 1:* Most physical types commonly postulated by humanity have tokens that exist as such independently of the mental: i.e. these tokens might have existed and might have been of their respective types even had there been nothing mental.

One problem with this is that the truth of realism would require that there be humanity, and that it postulate types, indeed physical types. Surely the philosophical doctrine or realism is not specifically about humanity and what humanity does or does not postulate. So we try again.

*Realism 2:* Consider the physical types commonly postulated by humanity, and the statements, about each of these, that its tokens exist independently of the mental. Realism is the doctrine that most of these statements are true.

This is a realist doctrine all right. But so is the doctrine about the first physical type mentioned in the Bible and the statement that its tokens exist independently of the mental. And there are indefinitely many 'realist' doctrines of a similar cast, all of which seem inappropriately tied to the vagaries of human postulation. Why should realism be restricted to *these* statements, or, worse, to *most* of them?

For a doctrine less tied thus to humanity, consider this:

*Realism 3:* There are tokens independent of the mental in that they might have existed and have been of their respective types even had there been nothing mental.

This is indeed a kind of realism, but it is compatible with a Kantian doctrine of a noumenal reality beyond our ability to know or even to comprehend, and with the view that ordinary common-sense reality is dependent on human construction through conceptualization. So realism 3 is a rather weak doctrine. According to a stronger version:

*Realism 4:* The world of common-sense reality exists as it is thought to exist by at least the main lines of common sense, and this it does largely independently of the mental, in that it might have existed propertied and interrelated much as it is in fact propertied and inter-related even in the absence of anything mental.

Here 'common-sense reality' is the world as we commonsensically believe it to be, composed of things large and small, along with the medium-sized dry goods of daily commerce. For Kant such common-sense reality has only 'phenomenal' reality, constituted by human construction. Beyond this there is the 'noumenal' in-itself reality independent of human construction. But this is inaccessible to human cognition. Unlike Kant, more recent constructivists appeal to conceptual schemes distinctive of a particular culture. (Here Wittgenstein may be an exception, but his views are elusive: Is there a human form of life, unlike that of the lion, or is there more than one human form of life?)

Note how brief reflection has led us back to the aspect of realism 1 that we found initially off-putting. The problem is that if we abstract from humanity and its postulations, then we are left with too thin a notion of realism, one compatible with a Kantian view: an inaccessible noumenal reality along with a constructivist account of our ordinary world. A more interesting realism does after all apparently require reference to ourselves and our common-sense postulations.

Many and varied are the constructivist heirs of Kant in more recent times. For Nelson Goodman we make stars through our 'versions'. According to Hilary Putnam's 'internal realism', the world is somehow internal to our conceptual scheme. As Benjamin Whorf would have it, language is itself our main world-making tool. For Thomas Kuhn different thinkers live in different worlds, each defined by its own theoretical ontology. And many other varieties of anti-realism and relativism are now on the market.

**reality, levels of.** The old conception of reality as hierarchical, embodied in the Great Chain of Being, re-emerged, secularized and purged of supernatural elements, in the late twentieth century. The world comprises not merely

levels of complexity and levels of description, but levels of *being*: higher-level items depend on, but remain distinct from, items at lower levels. At the most basic level (if there is a most basic level) is the world described by physics. Arrangements of entities at this level 'realize' higher-level entities, and arrangements of these realize entities at still higher levels. The economy of Saskatchewan—a very high-level entity—is realized by the inhabitants of Saskatchewan, relations they bear to one another and to persons and institutions elsewhere. Persons and institutions are themselves realized by complex arrangements of psychological, biological, and inorganic entities. These in turn have still lower-level realizers.

Proponents of levels point to the 'irreducibility' of descriptions of and laws governing higher-level items. This encourages a picture of these higher-level items as 'floating above' their lower-level supports. Higher-level goings-on are thought to be governed by higher-level laws discoverable by the special sciences.

The nature of the realizing relation remains something of a mystery. *Supervenience* is occasionally invoked, but this is to re-label the relation, not to explain it. Some have doubted the coherence of levels: if higher-level entities depend on, but are distinct from, entities at lower levels, how could something at a higher level have a higher-level effect except by bringing about a lower-level change? Such 'downward' causation threatens the idea that the fundamental physical level constitutes a closed system governed by inviolable laws.

One possibility is that philosophers have conflated the innocuous idea that ways of describing and explaining the world exhibit a hierarchical structure with the much less innocuous idea that corresponding to each of these ways is a level of being. Moves of this kind have a chequered philosophical pedigree. They express the remarkable idea that we can 'read off' the structure of reality from the structure of the language we use to describe reality. Perhaps we can get by with one complex world capable of being described in endless ways depending on our interests and the level of detail we hope to comprehend.

J. Heil, *From an Ontological Point of View* (Oxford, 2003).

J. Kim, 'The Layered Model: Metaphysical Considerations', *Philosophical Explorations*, 5 (2001).

**realization.** This is a term commonly used in contemporary metaphysics and philosophy of mind to denote a relationship between properties at different levels which is supposedly at once weaker than identity and stronger than mere causal connection. Thus, it is often held that mental properties are 'realized' by physical properties of the brain and nervous system, but that one and the same mental property—such as a certain quality of pain—may be realized by different neural properties in different sentient creatures. This is known as the 'multiple realization thesis'.

E.J.L.

\*variable realization.

J. Heil, *The Nature of True Minds* (Cambridge, 1992).

**reason.** The general human ‘faculty’ or capacity for truth-seeking and problem-solving, differentiated from instinct, imagination, or faith in that its results are intellectually trustworthy—even to the extent, according to \*rationalism, that reason is both necessary and sufficient for arriving at \*knowledge. Although the reason–emotion and reason–experience distinctions are overworked, the claim that reason is the defining characteristic of human beings (the human essence) remains powerful.

A. BEL.

\*reasoning; rationality; ratiocination; bladders of philosophy.

Nicholas Rescher, *Rationality: A Philosophical Inquiry into the Nature and the Rationale of Reason* (Oxford, 1988).

**reason, practical:** *see* practical reason.

**reason as slave of the passions.** A fundamental claim of Hume’s moral psychology, used in his rebuttal of the rationalist pretence that reason can oppose the passions and teach us moral truths. ‘Reason is, and ought only to be the slave of the passions, and can never pretend to any other office than to serve and obey them’ (*Treatise*, II. iii. 3). In an employment of \*Hume’s fork, Hume insists that *demonstrative* reasoning (for example, in mathematics) plainly has no effect in itself on the passions; and *probable* reasoning is of significance to the passions only by ‘directing’ our aversion to pain, or our propensity to pleasure, to those things that we take to be causally related to them.

Hume may have inherited the expression from the article on Ovid in Bayle’s *Dictionnaire*, one of the favourite works of Hume’s early adulthood: ‘Reason has become the slave of the passions’.

J. BRO.

J. L. Mackie, *Hume’s Moral Theory* (London, 1980), ch. 3.

**reasoning.** Suppose you have (in mind) \*reasons for believing you have been lied to, or reasons against visiting the dentist, or reasons to be proud of your children. These are mental states, states of holding reasons for, or against, believing something or doing (or choosing or aiming at) something or feeling somehow. The word ‘reasoning’ describes two associated *processes*: searching for such reasons (often co-operatively), and giving them when you or somebody else has found them. A third process, gaining understanding of reasons that somebody else has given, is similar.

Searching for reasons involves cogitation (thinking things through) and commonly also—though this is not reasoning—research. If you are confronted by a practical problem (‘What should I do on this matter?’) or a theoretical problem (‘What is the truth on this matter?’) or a response problem (‘How should I feel on this matter?’), solving it is bound to involve some cogitation, however perfunctory: you must bring to mind further questions that seem relevant to solving the problem, you must ponder (‘weigh’) their relevance, and, if you have answers to them, you must finally derive (work out, calculate) a solution ‘in the light of’ the answers. Any answers you lack

may be worth trying to discover, either by further cogitation (e.g. proving a lemma in mathematics) or by gathering information. The latter is where research comes in: ask someone, go and look, devise an experiment, etc. Since both parts of this composite activity contribute to finding reasons, both parts might with justice have been counted as reasoning, but in fact the research part is not—which is why philosophers who play down the role of research in theoretical inquiry can be called rationalists (Latin *ratio*, reason) and philosophers who emphasize it empiricists (Greek *empeiria*, experience).

Giving reasons is setting them out, to oneself or someone else. This too is a process, though a quite different one from searching for reasons. Since it can be rehearsed and repeated, it is likely to be more orderly than the search was. And since it is useful for persuading people, and necessary for transmitting knowledge (at the least, for displaying your *authority* as a purveyor of correct solutions), there is a motive for making it as orderly and lucid as possible. Even if you are not going public, reason-giving is a way of checking for yourself that a search has been conducted properly—that you have reasoned well.

You reason well when the reasons that you find, or give, *favour* (and not just seem to you to favour) the belief or action or response they are presented as reasons for; that is, they make it more likely that the belief is true or the action right or the response appropriate. So standards are required for judging whether, and preferably also for measuring how strongly, such-and-such reasons favour (or, as we often say, support) such-and-such a solution. Logic has sometimes been seen as the science of determining these standards, although nowadays its pretensions are narrower. The full-blown science would do two things: first represent each process of reasoning as the statement or production of an abstract entity called an argument, and then propose rules and principles that good arguments must observe (the rules license progressions through an argument, the principles are unspoken premisses we are allowed to add to any argument). Deductive logic achieves a bit of this brilliantly, but attempts to go beyond it have had little success. For example: what would be the *inductive* rule that specifies rightly when and to what degree observations (e.g. ‘All your known ancestors were male’) support generalizations (e.g. ‘All your ancestors were male’)? and what would be the *moral* principle that specifies rightly when and to what degree somebody’s wanting a service from you is a good reason for your providing it? If such questions cannot be answered, good reasoning is an art that has no science.

C. A. K.

\*ratiocination; rationality.

**reasoning, psychology of.** Logicians are concerned to formulate normative principles of deductive and inductive

reasoning, which instruct us how to reason correctly. Psychologists, on the other hand, seek to discover by empirical means what sorts of inferences human beings typically do make when confronted by reasoning tasks and what kinds of psychological processes underlie our reasoning activity. Some of their empirical evidence suggests that we are subject to deep-seated reasoning biases which often lead us to draw incorrect conclusions from the premisses or data presented to us. For example, performance on the Wason selection task suggests that people make systematic errors of deductive reasoning with conditional sentences, sometimes failing to see that 'If  $p$ , then  $q$ ' can be falsified by finding  $p$  to be true when  $q$  is false. Other studies indicate that people are subject to fundamental biases in their probabilistic reasoning, such as so-called base rate neglect. However, how do we know what constitutes *correct* reasoning if we really are so subject to reasoning bias? A paradox looms here. E.J.L.

J. St B. T. Evans and D. E. Over, *Rationality and Reasoning* (Hove, 1996).

**reasons, internal and external.** This distinction between two sorts of practical reasons is owed to Bernard Williams. An agent  $S$  has an internal reason  $R$  to act only if  $R$  would motivate him to act if he were fully informed and deliberated correctly, starting from what he is presently motivated to do. Any reason that does not satisfy this condition is called 'external', but Williams claims that there are no external reasons. The thrust of Williams's *internalism* is, then, that each agent's reasons are constrained by what he is actually motivated to do, i.e. by his actual desires. One can have a reason to do something that one does not want to do, but only if one's actual desires would be changed by the provision of full information or by correct deliberation in such a way that one ends up wanting to do what one initially did not want to do. One's actual desires constitute the starting-point for this process, and so are bound to affect the result. Since people differ in their actual desires, the internalist claims that there can be no considerations that are reasons for everyone, irrespective of their own aims and purposes. Universal moral reasons thus become potentially suspect. J.D.

**reasons and causes.** Phenomena the relation between which bears on the status of rational, or free, beings in the natural world.

Much common-sense psychological and historical explanation of people's beliefs and actions proceeds by saying what their *reasons* were. There are questions whether such explanations (i) are *causal*, (ii) mention items which are *causes* of what is explained. A negative answer to (i) is given by philosophers who place the study of human beings outside the causal sphere (often assumed to be coextensive with the objective sphere of science). An affirmative answer to (ii) ensures that accounts given from an internal human perspective and from a more external, causal perspective are concerned with the same items. Intermediate positions are possible.

When \*action explanation is in question, the central question is often put, perhaps misleadingly, by asking 'Are reasons causes?' J.HORN.

\*mental causation.

Donald Davidson, 'Actions, Reasons and Causes', in *Essays on Actions and Events* (Oxford, 1980).

**recurrence:** see eternal recurrence.

**recursion, definition by.** A recursive \*definition of an expression proceeds by first specifying a special subclass of the items it applies to and then specifying the remaining items it applies to in terms of a relation which any such item bears to an item to which the expression already applies. Thus the term 'ancestor' may be defined recursively as follows: (1) both of a person's parents are ancestors of that person; (2) any parent of an ancestor of a person is also an ancestor of that person; (3) nothing else is an ancestor of a person. E.J.L.

B. C. van Fraassen, *Formal Semantics and Logic* (New York, 1971).

**reducibility, axiom of.** An axiom scheme of Russell's ramified theory of \*types. This theory was constructed to avoid vicious-circle fallacies, which at one time Russell held to be the root error behind a wide variety of paradoxes including the \*liar paradox and his own \*Russell's paradox.

The ramified theory imposes a twofold classification on propositional (sentential) functions. First, such functions are arranged in a hierarchy according to the type of argument they take. So, for example, there are functions of individuals, functions of functions of individuals, etc. Second, the theory stratifies the functions which take a particular type of argument into orders according to the kind of expression that picks out the function (this is the ramification).

Russell prohibited unrestricted quantification over *all* the functions taking a particular type of argument. But this prohibition restricts the expressive power of the theory. So, to achieve the effect of the unrestricted quantification, Russell proposed the axiom of reducibility. Included in the lowest order of propositional functions are the predicative functions, which are picked out by expressions free from bound variables. The axiom of reducibility guarantees that the legitimate quantification over all predicative functions achieves the effect of the prohibited quantification over all functions regardless of order. The axiom applying to functions of individuals says that for any such function there is a predicative function that is formally equivalent (i.e. agrees in its mapping of arguments onto values).

A.D.O.

B. Russell and A. N. Whitehead, *Principia Mathematica* (Cambridge, 1910), i, ch. 2 of the Introduction and \*12.

**reducibility of consciousness:** see consciousness, its irreducibility.

**reductio ad absurdum.** One of the following proof strategies:

1. A proposition  $P$  is proved by taking as a premiss the negation of  $P$  and demonstrating that, in conjunction with previously established premisses or axioms, a contradiction follows. Also known as indirect proof.

2. The negation of a proposition  $P$  is proved by taking  $P$  as a premiss and demonstrating that, in conjunction with previously established premisses or axioms, a contradiction follows.

In the notation of the \*propositional calculus, if  $((\sim P \cdot Q) \supset R)$  and  $((\sim P \cdot Q) \supset \sim R)$  are provable and  $Q$  is a conjunction of established premisses, then a contradiction  $(R \cdot \sim R)$  follows, which suffices for a *reductio* proof of  $P$ .

R. B. M.

\**reductio ad impossibile.*

B. Mates, *Elementary Logic* (Oxford, 1972).

**reductio ad impossibile.** Proof of a proposition which involves demonstrating that its negation entails a contradiction; since a contradiction cannot be true, whatever entails it cannot be true. Proofs that  $\sqrt{2}$  is irrational and that there are infinitely many primes are classic examples. Sometimes called indirect proof, and commonly called \**reductio ad absurdum*, though this term is sometimes applied to arguments where what is entailed is merely an obvious falsehood rather than a contradiction. M. C.

**reductionism.** One of the most used and abused terms in the philosophical lexicon, it is convenient to make a (three-part) division.

*Ontological* reductionism refers to the belief that the whole of reality consists of a minimal number of entities or \*substances. One could be referring simply to entities of a particular kind (as in 'All organisms are reducible ultimately to molecules'), but often the claim is meant in the more metaphysical sense that there is but one substance or 'world stuff' and that this is material. Hence, ontological reductionism is equivalent to some kind of \*monism, denying the existence of unseen life forces and such things, claiming that organisms are no more (nor less) than complex functioning machines. However, one might well be trying to reduce material things to some other substance, like \*consciousness. Alternatively, one might even think that there are two or more irreducible substances. The aim would then be to reduce all other substances to these fundamental few.

*Methodological* reductionism claims that, in science, 'small is beautiful'. Thus the best scientific strategy is always to attempt explanation in terms of ever more minute entities. It has undoubtedly been the mark of some of science's greatest successes, and not just in physics. The major methodological reductive triumph of recent years has been the demonstration that the unit of classical heredity, the gene, is a macro-molecule, deoxyribonucleic acid (DNA). One should, however, keep in mind that

'small' in this context is a relative term, and one should be wary of making a straight identification between methodological reductionism and the commonly used 'micro-reductionism', especially if the latter implies that explanation is to be done in terms of micro-entities. The psychologist may try to reduce major sociological movements to the feelings and behaviours of individual humans; but may yet (with reason) think it would be silly to attempt a further reduction to molecules or below.

Despite its successes, methodological reductionism has been highly controversial, for it denies the claims of those (especially Marxists) who argue that the world is ordered hierarchically, and that entities at upper levels can never be analysed entirely in terms of entities at lower levels. Especially contentious has been so-called 'biological reductionism', generally associated with the socio-biological movement, where human nature is supposedly fully understandable in terms of genetics. It may be doubted whether anybody has ever truly argued that we humans are mere marionettes manipulated by the double helix; but it cannot be denied that some senior biologists have been much given to silly (and socially dangerous) flights of fancy about the control exerted on our lives by our biology.

\**Theory* reductionism raises the question of the relation between successive theories in a field, as between Newton's theory and that of Einstein. Is it always one of replacement, where the new entirely expels the old, or is it sometimes one of absorption, or 'theoretical reduction', where the older is shown to be a deductive consequence of the new? Many have argued that, as in the Newton-Einstein case and also the classical-molecular genetics episode, one gets reduction rather than replacement. In the 1930s this kind of thinking was taken to the extreme, with the 'Unity of Science' movement committed to the belief that eventually all the sciences will (and should) be reduced to one super-theory (inevitably taken to be something in physics).

This kind of thinking has been strongly challenged by such thinkers as the philosopher-historian Thomas Kuhn, who believes that because the terms between theories are always 'incommensurable', theory reduction is never possible. Since this view of reduction is tied strongly to the picture of scientific theories as hypothetico-deductive systems, and since this latter picture has now fallen very much out of favour, many philosophers today would agree with their scientist colleagues that what matters is less the relationship between old and new than the relative merits of successive theories through time. This meshes also with the conviction of those who have turned their philosophical gaze from the physical sciences to other fields such as biology and psychology. Although few would deny the ontological claim that organisms, including humans, are made from the same materials as the rest of the physical world, it does not necessarily follow that the modes of explanation are the same throughout the scientific world or that a theoretical reduction is always possible or indeed fruitful. M. R.

\*reductionism, mental; methodology; scientific method; simplicity.

E. Nagel, *The Structure of Science* (New York, 1961).

M. Ruse, *Philosophy of Biology Today* (Albany, NY, 1988).

**reductionism, mental.** Reductionism about a given subject-matter *X* is the claim that facts about *X* can be 'reduced' to—that is, can be construed to be—facts about an apparently different subject-matter *Y* ('the reduction base'). Reductionism in philosophy of mind is the claim that facts about mentality are reducible to physical facts, i.e. facts about matter and material processes.

What is required to implement mind–body reduction? According to the \*dualism of Descartes, minds exist as 'mental substances', objects wholly outside the physical domain. On this view, facts about mentality would be physically irreducible since they would be facts about these immaterial entities. The first requirement for mind–body reduction, therefore, is the renoucement of minds as non-physical objects. This can be done either by identifying minds with brains or other appropriate physical structures, or by attributing mental properties to organisms and possibly other types of physical systems, rather than to immaterial minds. In either case, it is physical systems that have psychological properties.

The remaining step in mind–body reduction concerns mental properties (e.g. being in pain, sensing a green patch, believing that snow is cold) and their analogues in systematic psychology. Let *M* be a mental property: the physical reduction of *M* is usually thought to require a 'physical correlate' of *M*, i.e. a physical property with which *M* is necessarily coextensive. When a pervasive system of physical correlates is found for mental properties, mental properties could, it is thought, be identified with their physical correlates.

Logical \*behaviourism sought to reduce mental properties by defining them in terms of behaviours and behavioural dispositions. Although mentality seems intimately tied to behaviour, it is now widely agreed that psychological concepts in principle resist behavioural definitions. The demise of behaviouristic reductionism has led to the hope that the mental might be physically reduced through empirical laws connecting mental and physical properties. Nomological reduction of mental properties would proceed by providing for each mental property *M* a nomologically coextensive physical correlate *P*; that is, where '*M* occurs at time *t* if and only if *P* occurs at *t*' holds as a matter of law. According to the \*identity theory of mind, every mental property has a neural correlate with which it is to be identified; if pain is uniformly correlated as a matter of law with, say, the activation of c-fibres, pain may be reductively identified with c-fibre activation, and similarly for other mental properties and kinds.

The significance of mind–body reduction is claimed to be twofold: ontological economy and unity of theory. By dispensing with minds as substances of a special sort and their irreducible psychic features, we simplify our ontology. By construing mental properties as complex neural

properties and taking physical organisms as their bearers, psychology can be integrated with the underlying biological and physical sciences.

Two lines of consideration have been responsible for the decline of reductionism. One is psychophysical anomalism, the claim that there are no laws connecting mental and physical phenomena, and hence no laws of the sort required for the nomological reduction of the former to the latter. The other is the variable (or multiple) realizability of mental properties. If a mental property is multiply realized by a variety of physical properties in diverse species and structures, it could not, the argument goes, be identified with any single physical property. These considerations have led many philosophers to favour non-reductive physicalism, the doctrine that although all the individuals of this world are physical, certain properties of these individuals, in particular their psychological properties, are not reducible to the physical properties. (\*Mind–body problem; \*physicalism; \*functionalism.) However, it remains a controversial question whether the variable realizability of the mental should be considered an obstacle to mental reductionism; it might be argued that the variable realizability in fact entails reducibility, that is, the possibility of *variable reductions* (or 'local reductions') relative to the species of organism or type of physical system involved.

**reductionism, psychological, in personal identity.** The thesis, advocated by \*Parfit, that our identity over time should be understood as psychological connectedness or psychological continuity with its normal cause, or with any other cause so long as there exists no other person psychologically connected with or continuous with us as we were. Parfit calls such connectedness or continuity 'Relation R'. Psychological connectedness is realized by, for example, direct memories, the relation between an intention and its later implementation in action, the persistence of beliefs or desires. Psychological continuity is the holding of overlapping chains of strong connectedness. For example, a person remembers some of their experiences the previous day, and on that day they remembered some of their experiences on the day before that, and so on.

The thesis is reductionist in avoiding the postulation of a Cartesian soul or substantial ego. Parfit argues that personal identity is not necessarily determinate. It need not be true or false that a later person is numerically identical with an earlier person, so answers to the questions 'Will it be me who suffers?' or 'Will it be me who dies?' need not be true or false.

As Parfit recognizes, there are interesting affinities between his view and some Buddhist views. The Buddha taught that it in a sense is and in a sense is not the same person who is reborn. Locke is also a psychological reductionist about personal identity, because he thinks sameness of person over time extends as far and only as far as may be established by memory, because being the same person presupposes the possibility of considering oneself the same person. Although Locke insists that the soul is redundant to the explanation of personal identity, he nevertheless claims it likely that the soul is that which is consciousness.

s.p.

John Locke, *An Essay Concerning Human Understanding*, book II, ch. 27: 'Of Identity and Diversity'.

Walpola Rahula, *What the Buddha Taught* (Bedford, 1967), esp. ch. 6: 'The Doctrine of No-Soul: *Anatta*'.

**redundancy theory of truth.** This theory of \*truth, pioneered by F. P. Ramsey, draws on the apparent equivalence between asserting a proposition *p* and asserting that *p* is true to claim that the truth-predicate 'is true' is redundant, in the sense that it is, in principle, always eliminable without loss of expressive power.

Difficulties appear to arise for the theory from cases in which propositions are said to be true even though the speaker may not know which propositions they are, and so cannot assert them himself, or when there are too many such propositions for each to be asserted individually, for example when someone claims 'Something that John said yesterday is true' or 'Everything asserted by a Cretan is true'. If the latter sentence is paraphrased as 'For any proposition *p*, if a Cretan asserts that *p*, then *p* is true', it is arguable that deleting the concluding words 'is true' renders the sentence ungrammatical and so senseless.

E.J.L.

\*deflationary theories of truth; disquotation.

S. Haack, *Philosophy of Logics* (Cambridge, 1978).

**Rée, Paul** (1849–1901). German philosopher, noted for his radical \*empiricism and uncompromising rejection of metaphysics and religion. The son of a wealthy Prussian landowner, Rée fought in the Franco-Prussian war of 1870. On his return he devoted himself to the study of philosophy, receiving a doctorate from the University of Halle.

In 1875 he published *Psychologische Beobachtungen* (Psychological Observations), a slim volume of aphorisms. In 1877 he published the much more substantial *Ursprung der moralischen Empfindungen* (The Origin of the Moral Sentiments). Strongly influenced by the British Empiricists and the work of Darwin, Rée argued that there are no universal moral principles whose truth is given a priori. What is regarded as right or wrong in any given society reflects the needs and cultural conditions of that society. Nietzsche, with whom Rée was on terms of close friendship from 1875 until 1882, commended this work as a 'decisive turn-

ing-point in the history of moral philosophy'. Rée was Jewish, and his influence on Nietzsche was resented by several of Nietzsche's anti-Semitic friends. Rée had no contact with Nietzsche after 1882 and in his last years he expressed a low opinion of Nietzsche's achievements. Granting that Nietzsche was often very clever and that he could write superbly, Rée dismissed Nietzsche's \*transvaluation of values as a 'mixture of insanity and nonsense'.

In 1885 Rée published *Die Illusion der Willensfreiheit* (The Illusion of Free Will) in which he maintained that it was entirely possible to abandon the belief in freedom and moral responsibility *in practice* and not only in one's philosophical theorizing.

Rée fell to his death from a Swiss mountain, and *Philosophie*, which was intended as a summation of his most basic convictions, was published posthumously in 1903. Here he offers a forthright defence of \*atheism. Metaphysical systems Rée dismisses as 'fairy-tales' and 'lies'. Religions, he concludes, 'are true neither in the literal nor in an allegorical sense—they are untrue in every sense. Religion issues from a marriage of error and fear.'

p.e.

Paul Rée, *Die Illusion der Willensfreiheit* (Berlin, 1885). Eng. tr. of key passages of this book contained in P. Edwards and A. Pap (eds.), *A Modern Introduction to Philosophy*, 3rd edn. (New York, 1973).

—Basic Writings, tr. and ed. R. Small (Champaign, Ill., 2003).

**reference:** see sense and reference.

**referential opacity.** Truth about a given object is not usually affected by the manner of referring to it, so that you could switch between, say, 'James', 'he', 'the fat one', 'Angela's ex'. But some (linguistic) contexts—i.e. verbal surroundings—do limit this freedom. For example, 'She knows who . . . is' may be true with 'that novelist' in its blank, but false when the novelist is referred to as 'the owner of the footprint' (this is the ancient \*masked man fallacy). Such contexts are called referentially opaque, as opposed to referentially transparent. Possible explanations are: the expression does not really refer (Russell), or refers to something else (Frege, perhaps Aristotle), or does more than refer (Quine).

C.A.K.

W. V. Quine, 'Reference and Modality', in *From a Logical Point of View*, 2nd edn. (Cambridge, Mass., 1964).

**referring.** Both expressions and their users can refer, and it is a matter of controversy which kind of referring is more fundamental. Intuitively, for an expression to refer is for it to stand for or pick out something, but what this involves has been long debated. According to Frege the reference of an expression is determined by its \*sense, but lately Kaplan and Kripke have argued that some terms, such as demonstratives, proper names, and natural-kind terms, refer directly. A speaker refers if, in the course of expressing a \*propositional attitude (e.g. the belief expressed in uttering 'Magritte was a philosophical painter'), he uses an expression ('Magritte') with the

communicative intention of indicating to his audience the individual this attitude is about (Magritte). K.B.

\*communication.

Kent Bach, *Thought and Reference* (Oxford, 1987).

**reflective equilibrium.** Philosophers often attempt to justify general \*principles on the grounds that they accord with our intuitive judgements concerning particular cases. It must be conceded that our unreflective intuitions may be confused or inconsistent. However, by successively advancing principles which seem to accord with most of our intuitions and re-examining any conflicting intuitions in the light of those principles, we may hope to move step by step towards a position of 'reflective equilibrium', in which our considered intuitions are fully in harmony with our considered principles. Whether the principles thus emerging would thereby be justified is a disputed issue. E.J.L.

\*Rawls.

**reflexivity.** A reflexive \*relation is a binary, i.e. two-term, relation which everything has to itself (in symbols,  $R$  is reflexive if and only if  $\forall xRxx$ ). 'Reflexive' may be understood relatively to what one is talking about (the domain of discourse); for example, *being the same age as* and *being no older than* are both reflexive relative to the domain of animals. Or one can distinguish 'strongly reflexive' (everything has it to itself) from 'weakly reflexive' (everything has it to itself that has it to anything). 'Irreflexive' means: nothing has it to itself. 'Non-reflexive' may mean either 'not reflexive' or 'neither reflexive nor irreflexive'. C.A.K.

W. Hodges, *Logic* (Harmondsworth, 1977).

**reform.** The attempt to improve social, political, or legal institutions or policies without altering what is fundamental to them. The distinction between reform, as described above, and change (which does attempt to alter what is fundamental) was introduced by Burke and made by him central to \*conservatism. The distinction can be used to defend the politics of modifying tradition against those of revolution. Yet the distinction between reform and change can be hard to defend in many political contexts, partly because it is not always clear what is of the essence and what is simply an accident, and partly because of uncertainty about how long a change has to be in existence before it ceases to be a change and becomes a new tradition. Moreover, even if the distinction can be clarified, it cannot be used to characterize all forms of conservatism because some are in favour of certain kinds of revolutionary change. R.S.D.

E. Burke, *Letter to a Noble Lord* (1796).

A. Quinton, *The Politics of Imperfection: The Religious and Secular Traditions of Conservative Thought in England from Hooker to Oakeshott* (London, 1978).

**regress, infinite:** see infinite regress.

**regulative principles** guide our conduct although we have no assurance that they are actually true. Thus Kant claimed that it was rational to look for (and hope for) a system of knowledge which was complete and coherent in certain ways although we had no a priori guarantee that it could be found. A later Kantian philosopher, Peirce, held that all logical principles were hopes or regulative \*principles. C.J.H.

\*rules.

I. Kant, *Critique of Pure Reason*, tr. N. Kemp Smith (London, 1968), app. to the Transcendental Dialectic.

**Reich, Wilhelm** (1897–1957). Austrian psychiatrist and social theorist whose notoriety for the orgone theory (an energy that is supposed to permeate the cosmos and possess healing powers) has obscured his earlier ideas, some of which are of philosophical interest.

Undoubtedly Reich's philosophically most interesting idea is that of the 'muscular armour' which grew out of his earlier notion of the 'character armour', Reich's term for the set of chronic defensive attitudes a person adopts to protect himself against external injury (such as being hurt or rejected by other human beings) and against his own repressed emotions, especially rage and anxiety. Even in his earlier psychological studies, which were brought together in *Character Analysis* (1933), Reich repeatedly pointed to the chronic tensions he noted in the faces and movements of many of his patients. While teaching at Oslo University in the 1930s he undertook a systematic study of the anchoring of neurotic attitudes in the body, e.g. anxiety in the hunching of the shoulders and in veiled eyes, rage in a tight chin, disgust in a certain expression of the mouth, etc. Reich from then on rejected the purely verbal approach of Freudian and other analytic techniques. In retrospect he observed that, prior to the discovery of the muscular armour and methods of dissolving it, analytic treatment could not achieve more than a very limited measure of success. He now abandoned the dualistic theories about body and mind tacitly or explicitly accepted by many psychologists and most psychoanalysts. In the place of \*dualism he advocated an \*identity theory: the muscular armour and the character armour are 'functionally' identical in the sense of serving the same function, namely that of blinding emotions such as anger and anxiety. It is a mistake to regard the muscular rigidity as a mere accompaniment or an effect of the corresponding character attitude: it is 'its somatic side and the basis for its continued existence'.

Reich developed social theories during the 1930s when he was attempting to fashion a synthesis of \*Marxism and \*psychoanalysis. Opposing what he described as the 'feudal individualistic psychology' of Freud, Reich denied that a given society is the result of a certain psychic structure. The reverse is true: 'character structure is the result of a certain society'. The ideology of a society can anchor itself

only in a certain character structure, and the institutions of that society serve the function of producing this character structure. These ideas were presented in 'Character and Society' (1936) and in two books, *The Mass Psychology of Fascism* (1933) and *The Sexual Revolution* (1936). P.E.

Paul Edwards, 'Wilhelm Reich', in Paul Edwards (ed.), *Encyclopedia of Philosophy* (New York, 1967), contains biographical information and discussions of all of Reich's major theories.

**Reichenbach, Hans** (1891–1953). Although closely identified with the Logical Positivist movement, Reichenbach was critical of the narrow scope of its verificationism, and preferred to speak of himself as a '\*logical empiricist'. Most significant and influential was his thinking on probability and \*induction. He was one of the most powerful advocates of a frequency interpretation of induction, believing the assignment of probabilities to be an empirical matter rather than something for a priori determination. Thus the estimation of the probability of throwing a six on a die is to be understood as the converging limit of a long series of throws rather than the simple result of an evenly distributed apportioning of the total possible number of outcomes. Probability thus understood, induction in turn is to be analysed empirically. This means that there can be no ultimate proof of induction; but, through discovered frequencies one can calculate which strategies or options are most reliable, given that induction does work.

Reichenbach was also much interested in problems of \*space and \*time, feeling that the physics of his day pointed him towards conventionalism. Notions like equality and simultaneity depend as much upon convention and definition as they do on empirical necessity. To talk, for instance, of the *equality* of successive time sequences requires a definition rather than empirical determination, for the result can only be understood relative to some particular system. Likewise, in dealing with \*quantum mechanics, Reichenbach felt that he must break from the strict traditions of earlier thinkers, for issues such as the supposed wave and particle nature of electrons demand more than classical logic. Therefore, although the answers of physics may be meaningful, with respect to the real world they must be considered as in some sense indeterminate in truth-status. M.R.

**Reid, Thomas** (1710–96). Deservedly remembered as Hume's most famous critic, Reid, a clergyman's son, attended Aberdeen Grammar School and Marischal College. His first job was as a presbytery clerk. During his next, as Librarian to Marischal, he was active in philosophical circles. His subsequent appointment as a parish minister was achieved through the patronage of King's College, Aberdeen, causing the congregation to protest and some even to assault him. At this time he was a keen astronomer. He presented a paper on quantity to the

Royal Society of London. He then became Regent in Philosophy at King's College. There he published *An Inquiry into the Human Mind, on the Principles of Common Sense* (1764), his most remarkable work, which combines philosophy and science. In the same year, as recognition of his talent grew, he replaced Adam Smith as Professor of Moral Philosophy in Glasgow. His *Essays on the Intellectual Powers of Man* (1785) and *Essays on the Active Powers of the Human Mind* (1788) appeared after his retirement at the age of 70. They were widely used as textbooks, especially in America. He then helped to found Glasgow Infirmary. Having himself always relied on patronage, he supported the French Revolution, but was disappointed by its excesses. His work became an official part of the French university curriculum.

He writes plainly but with authority. His aim is to expose the faults of 'the ideal system' and to replace it with 'the principles of \*common sense', a form of \*realism. The mind works according to innate principles of conception and belief which are challenged by the ideal system, whose proponents include Descartes, Locke, Berkeley, and Hume. Concerning belief in the external world, according to Reid the mind is so constituted that \*sensation automatically causes belief in external objects. A sensation of smell, for example, causes the belief that there is an external cause of the sensation. The belief is neither inferred nor rational but is caused by the occurrence of the sensation. Reid thus analysed \*perception into sensation and belief in what causes sensation. To Descartes and Locke, who say that there is an external physical world which we perceive by means of sensory representations, Reid replies that sensations cannot represent physical objects, since they do not resemble them in any way. To Berkeley and Hume, who argue that we take our perceptions for external objects, he replies that sensations cannot be taken for objects, since their difference from external objects is intuitively obvious to common-sense. In short the ideal system does not acknowledge the obvious qualitative differences between sensations and objects. The role of sensation is not representational but signification. How sensation can signify its external cause is inexplicable and certainly non-rational. Because sensations are unlike objects they give no content to belief in external objects, except in the case of secondary qualities like smell, taste, and colour, which are conceived as external causes of the corresponding sensations, but causes of indeterminate character. Sensations of primary qualities, unlike sensations of secondary, occasion clear conceptions of the external qualities causing them. This is an interesting departure from Locke's primary–secondary distinction.

Reid was an ethical intuitionist who argued that we naturally develop a power to judge what is due to a person as a right. Hume failed to see that approval is a power of judgement rather than feeling. What we judge, unlike what we feel, is true or false and can be contradicted. Reid stressed the importance of \*free will as a condition of deserving praise or blame, when the agent has the power to determine what he wills by conceptions of good and ill.

Free will is inconsistent with necessity but not with foreknowledge, any more than with memory.

Reid's criticism is frequently sound, and his positive theory occasionally inspired, as when, in discussing visible figure, he tries to marry optical fact with philosophical fancy. Here he departs from his original theory of perception when he says that we directly perceive what he calls 'visible figure', which is a real figure projected on to the retina, a figure representing the spatial relations of the parts of an external object. We have no sensation of visible figure. Reid thus preserves his fundamental principle that sensation is unlike anything external, while asserting that we are directly aware of something—visible figure—which does represent something external. Reid hoped that Hume would reply to his criticisms, but Hume's disdainful response was to recommend him to avoid Scotticisms and improve his English. v.H.

**reincarnation.** A distinct new bodily life, generally with a new identity and usually as a rebirth, of someone who has died. Beliefs in reincarnation can be found both in ancient Greece and in ancient India, and the Greek idea that the soul about to be reincarnated drinks from the river Lethe (forgetfulness) is typical of the assumption that those who are reincarnated remember little or nothing. The interesting philosophical question is: In what sense does the reincarnation count as the same person as the deceased? The Buddhist critique of Hindu metaphysics centred on this, and *The Questions of King Milinda* argues that any determination of sameness is essentially arbitrary. Even if psychic drives of the deceased in some way led to the new life, the relation between the two lives could be compared to that of a new flame to the pre-existing flame from which it is lit. 'Are these two different flames or the same flame?', the Buddhist philosopher asks; and the implication is that there is no basis for an answer. J.J.K.

**relations.** Ways in which things can stand with regard to one another (for example, some things are *older* than others), or to themselves (for example, each thing is *identical* to itself).

If one thing,  $x$ , stands in some relation,  $R$ , to any thing,  $y$ , then only if  $y$  stands in the same relation to  $x$  is  $R$  a *symmetrical* relation. Thus 'as old as' is symmetrical; if  $x$  is as old as  $y$ ,  $y$  is as old as  $x$ . Other relations are *asymmetrical*; Bud can't be heavier than Thelonus if Thelonus is

heavier than Bud. If  $x$  is larger than  $y$ , and  $y$  is larger than  $z$ , then  $x$  is larger than  $z$ . Such relations are *transitive*. By contrast fatherhood is *intransitive*: your father's father is no father of yours. Relations which hold only between numerically distinct objects are *irreflexive*. But not all relations are irreflexive; each thing is as old as itself.

Logicians treat both relations and non-relational properties as sets. Non-relational properties are identified with sets of single objects; for example, 'red' is the set which includes such things as ripe tomatoes, drops of fresh blood, etc. Two-term relations (e.g. 'double') are sets of ordered pairs (e.g.  $\langle 2,1 \rangle$ ,  $\langle 4,2 \rangle$ , etc.) Three-term relations, like 'between', are sets of ordered triples. And so on. The identity of a relation, so conceived, depends upon the membership of the set with which it is identified. The truth of a relational claim will depend upon whether the objects it says are related belong to ordered pairs (triples etc.) in the relevant set.

Relations might seem to be special sorts of object which can connect other things, but which are numerically distinct and ontologically independent from items they connect. But then, by an argument best known from F. H. Bradley, 3 is not the successor of 2 unless in addition to 'successor', there is a second relation—'connector', say—which links the numbers to 'successor', a third relation to connect 'connector' to 'successor', and so on. Frege avoids this sort of regress by treating relations as structurally incomplete partial objects which cannot occur without relate to complete them. So conceived, relations no more require additional relations to connect them to their relate than bricks require additional bricks to connect them to their shapes. Relations are not objects which can occur all by themselves until something connects them to relate.

An alternative solution from Wittgenstein's *Tractatus* banishes relations from the ranks of ontologically basic items: basic objects hang together without connectors like links in a chain, and facts which seem to involve relations between non-basic objects reduce to chainlike concatenations of basic objects. **relations, internal and external.** A distinction important to arguments between turn-of-the-century idealists and their opponents. If one item,  $x$ , stands in some relation,  $R$ , to another item,  $y$ , but neither its identity nor its nature depends upon this being the case,  $x$  is *externally* related to  $y$ . If  $x$  could not be the same item, or an item of the same kind, without standing in relation  $R$  to  $y$ , the relation is *internal*. You would think relations come in both flavours. Since no number can be identical to 2 unless it is greater than 1, 2 is *internally* related to 1. But presumably

your copy of the *Oxford Companion* would be exactly the same individual of exactly the same kind even if you did not own it, and even if it were lying on your floor instead of your table. If so, it is *externally* related to you and your table.

But F. H. Bradley and other idealists tried to show that either there are no relations at all, or else all relations must be internal. Like Parmenides and Zeno before them, they held that without relations nothing could be larger or smaller, nearer or farther, older or younger, or in any other way different from anything else, and the universe would be a completely undifferentiated whole. But since everything is related (e.g. temporally or spatially) to everything else, if all relations are internal, the nature and identity of each thing depends upon its relation to everything else. This dilemma was invoked to support extravagantly holist claims. The attempts of Bertrand Russell, G. E. Moore, and their followers to understand relations in such a way as to avoid holisms thus generated were decisive to the development of British \*analytic philosophy. J.B.B.

**relations, the nature of.** The nature of \*relations first became an important metaphysical issue in modern philosophy with Leibniz. He regarded it as a problem where the relation *R* which links individuals *a* and *b* is located. It cannot just be in one of them, for it would not then link them, nor can it be in some kind of void between them. Such reflections on relations were one main source for his monadistic metaphysics of windowless \*monads. For he had to interpret '*a* is *R* to *b*' as ascribing a separate predicate to each of *a* and *b*. 'Adam is the father of Cain' thus means that Adam has a certain property (being father of such-and-such a person) and Cain has a certain property (being child of such-and-such a father). These two individuals thus have properties which in a manner reflect each other but which do not bring them really together except in an 'ideal' or 'conceptual' way. A rather similar puzzle about the location of relations figures in the rationale of some forms of metaphysical monism (or absolute \*idealism) for which there is only one ultimate subject of predication. For since relations cannot be in either (or any) of the related terms separately it seems that they must really be a property of the whole the terms make up together, so that, if every item in the world is related to every other, then, according to a fairly obvious line of argument, the relations between them collapse into *gestalt* properties of that all inclusive whole to which they all belong, i.e. the Universe, the One, or the Absolute.

This account of the metaphysical significance of theories of relations is that of Bertrand Russell (especially in *The Principles of Mathematics*), and it certainly throws some light on Leibnizian monadism and Bradleian monism, though Russell is less than just to them in detail. For Rus-

sell a pluralistic metaphysics, stopping short of the extreme pluralism of monadism, becomes defensible once we realize that propositions of a relational form ('*Rab*') cannot and need not be reduced to ones of (single) subject-predicate form ('*Fa*' or '*Fa · Gb*'). William James also developed a (phenomenologically rather richer) account of relations than Russell's, similarly designed to resist the lure of monism; Husserl, Whitehead, and Hartshorne are all important in this context too.

Closely connected with such debates is the issue of the externality or internality of relations. A relation between two (or more) terms is said to be 'internal' if its holding is either necessitated by or necessitates the so-called 'natures' of these terms; otherwise it is external. (Their natures are best understood as what they are within their own bounds.) Russell claimed that all relations are external; absolute idealists, so far as they countenance relations at all, incline to think them all internal. Other philosophers affirm relations of both types, and some (e.g. Hartshorne) hold that the most important two-term relations are internal to one term, external to the other.

Discussion is often complicated by confusion between two different types of putative internal relation. Sometimes internal relations are those which Hume described as depending entirely on a comparison between ideas and external relations are those which may vary though the ideas remain the same (*Treatise*, i. iii. 1 and 2). A similar more modern classification (by Meinong and others) of relations is into *ideal* relations whose holding follows from what each term is 'like' (what one-place universals it exemplifies) within its own bounds (a colour contrast, for example) and *real* relations not thus settled by facts about what each term is 'like' considered on its own (juxtaposition in space or time and causality are typically thus conceived). (This classification concerns relations between particulars; relations between \*universals in abstraction from any exemplification may be called ideal in an obviously related sense.) It is a mistake, however, to take monists who claim that all relations are internal as claiming that they are all simply ideal in this sense; that way lies monadism rather than monism. They mean rather that their holding is a matter of their terms belonging together within a whole the character of which modifies that of each of them (rather than that they hold in virtue of the character of each term as that can be discovered separately). In short, for them it is as much the relation which determines the characters of the terms as the converse.

The fact that modern formal logic takes relational propositions easily on board, as Aristotelian and scholastic logic did not, tends to blind people to the fact that there are real metaphysical problems about relations essential to dealing with what William James described as 'the most central of all philosophical problems', the problem of the one and the many.

**relativism, epistemological.** Relativist theories of \*knowledge are as old as Methuselah, or at least Protagoras, and as fashionable as Foucault or Rorty, but their exact import remains elusive. Protagoras put it pithily, and provoked Socrates to question what he meant, and how it could possibly be true, by saying: 'Man is the measure of all things; of what is that it is, and of what is not that it is not.'

This *bon mot* is striking but susceptible of many interpretations. Protagoras was principally concerned with perceptual knowledge and individual human variations. He seems to have thought that whatever any given individual believed was true (for him or her). Socrates has little trouble showing the absurdities of this, since the individual has to understand what it is to make perceptual mistakes, whether detected by himself or others. Indeed, global \*relativism at the level of 'true for me' has so little to recommend it that its popularity with ordinary people is truly astonishing. We need only ask whether the claim that 'X is true for me' is itself merely true for me (and so on) to realize that what merit there may have been in the original relativization attached not to the truth-predicate, but to something in the content of the belief. One can indeed make a case for certain local relativisms, such as the relativities supposed to be involved in judgements of taste. But if such judgements do amount to no more than affirmations of personal or group likings, then these affirmations themselves seem to stand beyond relativization.

Sometimes the rhetoric of relativism merely draws our attention to the need for a conceptual framework to interpret reality without denying that there is a reality to be thus understood, but full-blooded relativism eschews the very idea of an uninterpreted reality that is as it is independently of us or of some scheme of understanding. Here the issues merge with those of metaphysics and semantics and the relativism debate moves confusingly between such issues as \*idealism and \*realism, \*coherence versus \*correspondence theories of truth, \*pragmatism and (again) realism. One persistent argument for radical relativism is that which points to the impossibility of saying, understanding, or communicating any truth without employing a language or conceptual scheme. It is then urged that the truth so conveyed is radically dependent upon the scheme in which it is set. If the relativist denies that truths expressed in one language or culture are capable of expression in others, there is room for argument about this thesis. But in fact the argument itself must be couched in a scheme or a language, and that would apparently pre-judge the issue. The idea of a \*conceptual scheme here staggers under the weight that relativism puts upon it, since, understood in an everyday fashion, the topic is

perfectly discussable (e.g. the question 'Can the concept of ennuï be expressed in English?' can be discussed in English), whereas the relativist will always insist that there is a philosophical sense in which no vantage-point is available from which to gain a purchase upon the conceptual scheme itself. The scheme seems to be at once in the world and beyond it. This is simply one aspect of the problem posed by the status of relativism itself as a truth. Is it true relative only to some culture or language or individual, or does its truth transcend such restrictions? If the former, then there are perhaps contexts in which it counts (relatively) as false; if the latter, then the thesis seems to be abandoned.

The range of the relativist relation is important. Perhaps we should take Protagoras seriously when he offers mankind as the relativization, and see this as an alternative to individual, cultural, or linguistic relativization. But what then of Martians? C.A.J.C.

**relativism, ethical.** The view that moral appraisals are essentially dependent upon the standards that define a particular moral code, the practices and norms accepted by a social group at a specific place and time. Given that there is in fact a plurality of social groups, with differing mores, the relativist argues that there exists no point of view from which these codes can themselves be appraised, no 'absolute' criteria by which they can be criticized.

In support of his claims, the relativist refers to anthropological evidence of cultural diversity, historical and geographical, now known to be enormously greater than could have been suspected by moralists like Hume or Kant. The relativist theory also draws on notions extensively deployed elsewhere in recent philosophy, such as 'alternative \*conceptual schemes' and \*'language-games'. On some accounts cultural divergence can amount to 'incommensurability', the complete absence of common concepts and perspectives.

Accepting the prima-facie divergences of moral outlook, a critic can none the less argue that the relativist tends to exaggerate their implications. Some common basic human values *can* be discerned over a great range of cultures, communities, social groups: e.g. moral condemnation of the leader who uses his power to exploit and oppress his people; and the agreement, among radically different groups, about the need for impartial determination of disputes by an authorized individual or body. Some writers, John Finnis for one, propose several 'basic forms of good' including knowledge, life, sociability, 'practical reasonableness', that underlie and give a rationale to moral rule-making, and provide significant common ground between groups and their codes. That suffices to give access to reasonable dialogue and makes

possible criticism both of one's own moral outlook and of the outlooks of others.

It has sometimes been thought that moral relativism gives a special support to toleration as a moral attitude to codes which diverge from one's own. Paradoxically, however, if that were accepted as a universal (and universally morally approvable) attitude, it would contradict the relativism which disallows any universally authoritative principles!

**relativism, linguistic:** *see* metaphysics, problems of.

**relativity theory, the philosophical relevance of.** In Einstein's special relativity temporal relations are not absolute; events happening simultaneously at different places in one frame of reference will not be simultaneous in all frames of reference. Minkowski's geometrical interpretation of the theory, which treats time as a fourth dimension, has been widely regarded as profoundly affecting our conceptions of \*space and \*time: but his often quoted remark that space and time will 'sink into mere shadows, and only a kind of union of them shall survive' is the sort of purple pronouncement which should be treated with scepticism.

General relativity raises questions about the relation between physics and geometry, denying the latter its traditional role as an \*a priori discipline; and it bears on the traditionally metaphysical dispute whether all motion is relative and whether space and time are relations among things or exist independently.

M.C.

J. R. Lucas and P. E. Hodgson, *Spacetime and Electromagnetism* (Oxford, 1990).

**relevance logic.** A system of logic in which premisses and conclusion are relevant to one another. It was born out of a paper by Wilhelm Ackermann, 'Begründung einer strengen Implikation', in the *Journal of Symbolic Logic* for 1956. In that paper Ackermann developed a formal theory of implication which was free of both the paradoxes of \*material implication (which C. I. Lewis had avoided in his calculus of \*strict implication) and those of strict implication (to which Lewis had succumbed). Ackermann's idea was of an implication in which the antecedent 'has a logical connection' with the consequent. Anderson and Belnap transmuted this, and gave two explications of 'logical connection' or 'relevance': one was 'variable-sharing', meaning at the propositional level sharing of content (in a valid entailment, premisses and conclusion must share a variable); the other was of dependency, that when an entailment is valid there is a way of deducing the conclusion from the premisses with no funny business, that is, in which the premisses really are used to obtain the conclusion. In satisfying these criteria, relevance logic distances

itself from classical logic, in which a contradiction entails any proposition whatever (so premisses and conclusion need share no variable) and any logically true proposition is derivable from any other propositions whatever (so the latter are not 'used' in deriving the former).

Several decades after its conception, relevance logic is now an accepted logic. What is not accepted, however, is—as was intended—that it is the one true logic to displace classical logic. It is part of a panoply of logics—classical, modal, intuitionist, linear, substructural, and so on—each one of which benefits from being elaborated in the context of others. Relevance logics are essentially those which reject weakening or dilution in its full classical form, as being a source of irrelevance. (Weakening says that if one proposition follows from another, it also follows from it in conjunction with any other proposition.) Linear logics do so too, and reject contraction as well (that repeated uses of an assumption can be replaced by a single use), emphasizing for constructive purposes the need to track uses of assumptions; they reintroduce irrelevance through the so-called 'exponentials', or modal connectives.

Relevance logics have axiomatic, natural deduction, and sequent (or 'consecution') proof theories; algebraic and possible-worlds semantics; and have been used as the basis for arithmetic and set theory. They should be distinguished from dialethic or paraconsistent logics, in which true contradictions are admitted. The idea of relevance simply has the consequence that contradictory assumptions do not spread or permeate to force triviality—as in classical theories—because of the rejection of the idea that a contradiction entails everything. As a consequence of this rejection, these logics also reject detachment for material implication (or disjunctive syllogism), basing valid detachment instead on the relevant conditional (or entailment).

**reliabilism.** In traditional epistemology what makes a belief justified, being a matter of the believer's rationality and responsibility, must lie within his 'cognitive grasp'. That is, for a belief to be justified the believer must be aware of what makes it justified. This restrictive, internalist conception of justification has the sceptical effect of disqualifying far too many beliefs that intuitively seem justified. Reliabilism, a form of externalism, holds that a belief can be justified if formed as the result of a reliable process, even if the believer is unaware of what makes it justified. Different versions of reliabilism impose various constraints designed to meet certain internalist objections, such as that reliabilism cannot disallow irrational and irresponsible epistemic behaviour without lapsing into internalism, and they spell out in different ways the operative standard of reliability, which may involve explanatory as well as statistical factors.

**religion, history of the philosophy of.** Since the terms English-speakers translate as ‘philosophy’ and ‘religion’ have taken dozens of meanings in the European languages from antiquity on, it is impossible to speak of ‘philosophy of religion’ as if it were one subject-matter stretched across Western intellectual history. The term is ambiguous even in contemporary usage, and its historical application provokes any number of problems. But the term has taken on a fairly specific technical sense in recent English-language philosophy. ‘Philosophy of religion’ comprises philosophical analyses of certain concepts or tenets central to the monotheistic Western religions and especially to Christianity. These concepts or tenets typically include the rationality of belief in \*God, the demonstrability of God’s existence, the logical character of religious language, and apparent contradictions between divine attributes and features of the world—say, between omnipotence and evil, miraculous interventions and natural law, omniscience and free will. The field has also reached out to include topics concerning the incarnation of God, the inspiration of Scripture, religious rituals or sacraments, the forgiveness of sin, mystical experience, and personal immortality.

‘Philosophy of religion’ and its equivalents in other European languages are fairly new, as philosophical terms go. They were coined towards the end of the eighteenth century as replacements or specifications of the earlier term ‘natural theology’. Hence in texts of the 1780s and 1790s the content of ‘philosophy of religion’ is a set of rationally discoverable truths helpful to religion and accessible to philosophy. This Enlightened philosophy of religion is the means of accommodating a newly critical philosophy with a somewhat sanitized Christianity. But the term had already changed its meaning by the early decades of the nineteenth century. For readers of Schleiermacher on religion, ‘philosophy of religion’ comes to refer to a moralized and aesthetic teaching about cosmic purposes. For Hegel, it is at least a study of the ways in which God is represented in religious consciousness. Hence it is one of the last stepping-stones on the way towards a properly philosophic understanding of the divine. ‘Philosophy of religion’ has something very much like the Hegelian sense in John Caird’s *An Introduction to the Philosophy of Religion* (1880), which is one of the texts by which the term was popularized in English. Indeed the Hegelian sense of the phrase remained so strong for English-speakers into the 1950s that some analytic philosophers preferred to speak of ‘philosophical theology’ rather than ‘philosophy of religion’. These terms are now used for the most part as if they were interchangeable.

Whatever the terms used, it is important to see that contemporary English-speaking ‘philosophy of religion’ treats topics and arguments that were earlier conceived as belonging to very different studies. The topics and argu-

ments fell under what certain Greek philosophers called simply ‘philosophy’ or ‘metaphysics’, what patristic and medieval Christians called ‘wisdom’ or ‘holy teaching’ or ‘theology’, and what philosophic writers in the modern period called ‘natural theology’ or ‘preambles of faith’ or ‘natural religion’. These different titles indicate very different views on the principles and procedures to be used in addressing such topics and arguments. The remainder of this entry will point to a few of the more interesting or influential of those views.

Greek philosophers before Socrates took up what we call religious matters in at least three ways. First, some of them criticized and even mocked implausible or contradictory features of ordinary religious conceptions. So Xenophanes attacks both the immorality and the anthropomorphism of the poets’ depictions of the gods. Second, some Pre-Socratics proposed mechanical or physical causes for events earlier attributed more directly to divine intention or design. Third, many of them wanted to understand the divine itself in ways at odds with conceptions drawn from ordinary experience. Their efforts in both directions were caricatured by the public imagination as a badly concealed impiety. So Aristophanes could in *Clouds* depict all philosophizers as irreligious, and Socrates could plausibly be accused in court of inventing new gods.

With Plato and Aristotle, these three relations to religion are transformed in ways that fix much of the later philosophical discussion. Plato’s Socrates defends traditional mythology and participates in civic rituals. He recounts to Phaedrus details of the myth about Boreas and Orithyia, for example, and he dismisses those who would explain it more naturalistically (*Phaedrus* 229b–230a). He makes a point of going to religious festivals (*Republic* 327a) and frequently alludes to the Mysteries. His last words are a command to carry out a ritual sacrifice on his behalf (*Phaedo* 118a). More formally, Plato’s dialogues often turn on a rejection of doubts about the divine. The Eleatic Stranger extracts from Theaetetus a heartfelt rejection of \*scepticism and a profession that all of nature issues from the divine (*Sophist* 265c–e). The Athenian in the *Laws* provides numerous sample arguments against those who would deny the existence, nature, or providence of the gods (book 10). At the same time, Plato advocates and performs extensive revaluations of the poetic accounts of the Olympian gods, and he composes his own myths to teach how different the divine is from ordinary conceptions of it. His constant teaching is that human beings in the present life know little enough of their own souls and less of the divine. The work of philosophy is thus to lead souls out the snares of sensory and especially political illusion so that they may begin to participate in the divine. The Platonic representations of this journey include references to various kinds of divine agency, including revelation and judgement. But Plato’s most enduring representation of divine action comes in the *Timaeus*, which tells the story, however ironically or allegorically, of a divine artisan who makes the cosmos.

It is impossible to say how much of the language and images of civic religion and of initiation into the mystery cults there may have been in Aristotle's public works. Only the private or school writings survive intact. In them there are certainly both criticisms of popular misconceptions and moments of piety. More important for the later traditions are Aristotle's arguments for the existence of a divine first mover of the cosmos and his characterization of that entity. At the end of *Physics* (book 8) and then summarily at the high point of *Metaphysics* (book 12), Aristotle argues that the impossibility of infinite regress in motion requires that there be a fully actualized being who causes all other motions by being the universal object of desire. In the same passage of *Metaphysics*, Aristotle describes the life of this being as an endless thinking on itself, a thinking that produces uninterrupted blessedness. Beyond this passage, and a few tantalizing allusions elsewhere, the Aristotelian writings give no sense of a divine agent and certainly none of a cosmic artificer.

The Platonic and Aristotelian doctrines were elaborated in many different directions during antiquity. Both entered into complex relations with the teachings of Stoicism, which was at some times and in some places the philosophy preferred by the Roman ruling classes. The Stoic reinterpretation of pain and misfortune was made possible by an absolute doctrine of divine providence. The Stoics were quite interested in physical doctrine, and they concocted a number of theories about cosmic origin. But the physical processes were held to be under the control of a divine mind, a mind that could perfectly well be associated with the traditional civic gods. These three schools—the Platonists, the Aristotelians, and the Stoics—contended at length with the gentle irreligion of the Epicureans, for whom the gods' interventions in human affairs were hurtful fictions. What 'gods' the Epicureans allowed were fully physical and natural, subject to the same laws of pleasure and tranquillity that bound human life. A very fine illustration of the contest among these views, and of the general disdain for the Epicurean doctrines, is given by Cicero in *On the Nature of the Gods*.

The course of philosophical speculation about the divine was altered from as early as the first century AD by contact with Judaism and then Christianity. So too were the courses of those religions. In pagan philosophy, the contact produces renewed interest in describing and pursuing the divine. In Judaism and Christianity, there is a energetic and perhaps surprising effort to present the claims of revelation in philosophically articulate ways. The renewal among pagans is most evident in the extraordinary flowering of Neoplatonism, which includes such figures as Plotinus, Porphyry, and Iamblichus. It led not only to mystagogical rereadings of Plato, but also to philosophical defences of the documents and practices of paganism. The new effort of philosophical expression can be seen among Jewish thinkers in Philo, among Christians in Clement of Alexandria and Origen. It led not only to philosophical explorations of Scripture, but also to a claim that the best philosophy is found in

Scripture—indeed, that philosophy had passed to the Greeks from Israel.

Beginning with the fourth or fifth century AD, it becomes increasingly difficult to speak in any sense of 'philosophy of religion', because it becomes difficult to talk of philosophy apart from religion. After about 500 AD, philosophy is subsumed within the three monotheistic religions—Judaism, Christianity, Islam. It is subsumed, not abolished. The most important thinkers of the three religions carried on teaching and wrote works that engaged the legacy of ancient philosophy powerfully and creatively. But they understood their teaching and their writing not as philosophy, but as the study of divine law, as interpretation of divine revelation, as the codification and clarification of religious traditions. It is irresponsible to call this simply 'philosophy' or even 'philosophy of religion'. Medieval religious thinkers knew what 'philosophy' meant to the ancients, who had invented the word and the thing. They admired and appropriated the ancient legacy, but they also held that the aims of ancient philosophy had been met and decisively superseded in divine revelation. To apply the name 'philosophy' to the writings of those medieval thinkers is thus to ignore or undo what they made clear with such emphasis. Most medieval writing about God, nature, human knowledge, and human living is both philosophical and deeply religious, but it is self-consciously not a philosophy of religion.

During the thousand years from the fifth to the fifteenth century, the largest part of speculative talent in the West was devoted to considering questions about God. The body of writings is correspondingly enormous. A first survey of philosophically articulated doctrines in those writings is best found in a history of Jewish, Byzantine, Islamic, or 'medieval' philosophy. What can be said here is that hardly one of these writings neglects the issues raised by the confrontation of ancient philosophy with the monotheistic religions. In many of them the conversion or ascent from philosophy to faith is the central theme—as in Augustine's *Confessions* and Bonaventure's *The Mind's Way to God*. For other medieval texts, philosophy serves as a propaedeutic to faith grasped and expressed as theology. In Boethius' *Consolation of Philosophy*, the figure of Philosophy reminds him of truths without which his faith cannot be restored. Though Christ never appears, Christ is the end of the whole teaching. Again, in Martianus Capella and Bernard Silvestris and Alan of Lille, philosophical doctrines are presented allegorically as exterior symbols of the Christian doctrine represented within. Other authors insist that philosophy must be studied thoroughly before proceeding to higher reaches of theology. Maimonides begins the *Guide of the Perplexed* by rebuking his student for wanting to jump over philosophical physics in order to reach higher. Roger Bacon argues that nothing can be known of God without the prior study of languages, mathematics, optics, experiential science, and moral philosophy. In other authors, and certainly the 'scholastic' authors writing in Latin after 1200, the terms, topics, and arguments of Aristotelian philosophy are so

fully appropriated that academic theology could not proceed well without them.

Any list of the most influential 'scholastics' would include Thomas Aquinas, John Duns Scotus, and William of Ockham. These three can illustrate both the range and the diversity of engagements between Christian theology and the Aristotelian inheritance. For Aquinas, theology uses, corrects, and completes the best of ancient philosophy. Aquinas pays respectful attention to pagan philosophers and chiefly to Aristotle, whose works he expounds in detail. But whenever he writes in his own voice, as an ordained teacher of theology, Aquinas systematically transforms every Aristotelian doctrine he touches, often in a direction quite opposed to Aristotle's own intention. Duns Scotus begins by refusing frankly to accommodate Aristotle, but what is called his 'Augustinianism' is in fact a dialectical juxtaposition of doctrinal inspirations from Augustine, Islamic Neoplatonism, his immediate predecessors, and Aristotle read through Averroës. Scotus typically deploys these sources to address questions that are explicitly theological and to analyse examples at the boundary between the present dispensation and the dispensation of heaven, between the mundane and the miraculous. Finally, in Ockham, one has an immensely learned critique of Aristotle fuelling an assault on the linguistic and epistemic presuppositions of any theology that employs Aristotelian models or demonstrations. But Ockham hardly intends to undo Christianity. His whole hope is to keep in view the unbounded and yet saving power of God.

Many of the medieval dispositions of faith towards philosophy carry forward into what we call the Renaissance and the early modern period, but they are complicated in at least three ways. First, the Christian reform movements that culminated in the Reformation were often sharply critical of the use of philosophy in theology or, indeed, of philosophical approaches to the divine. This criticism varied in intensity from one reforming group to another, and often coexisted with much philosophical erudition. Petrarch mocks Aristotle in favour of experience, then subordinates both to the Gospel. Erasmus criticizes the scholastic uses of ancient philosophy as bad theology and bad philology. But more commonly the criticisms of philosophy arose from claims about the opposition of philosophy and the Gospel, or from a vivid conviction of the impotence of sinful human reason, or from a confidence that God would teach what was needed by inspiration—and would do so often to the least lettered.

The second complication in the relations of philosophy to theological topics arose from fierce disputes over the conclusions of the new sciences. The condemnation of Galileo is the most famous example in these quarrels, though also the most misunderstood. Religious opposition to the philosophical implications of new science made philosophic authors cautious in expressing their views. It thus becomes difficult to know how to construe their writings. On the surface of Descartes's texts, for example, there is a scrupulous Catholic orthodoxy and

protestations of obedience. But Descartes is also coy about some of his cosmological views and he conceals them in various ways before publishing. Spinoza builds into his *Theologico-Political Treatise* a series of miscues and misdirections in order to make it unlikely that a casual or dull reader will discover his views on the truthfulness of Scripture. A similar caution in writing about religious matters can be felt well into the nineteenth century.

The third complication comes from a hardening and indeed impoverishment of the conceptions of philosophical reason and of religious knowing. One can see this in the Catholic writers in and after the Counter-Reformation. The threat of the Reformation was met within the Catholic Church by legislating on innumerable points of doctrine. This not only shrank the scope for religious speculation, but also reduced much of theology to law. Religious argument was consequently reduced to the forms of forensic argument—to aggressive demonstrations, to the collection of proof-texts, to extended attacks upon opposing positions.

These complications could by no means undo the ancient engagement of philosophy with religious topics or the ancient dependence of religious thought on philosophical lessons. While the rediscovery of certain ancient texts led to a flourishing of scepticism in some sixteenth-century authors, the overwhelming majority of modern philosophers up to the first half of the nineteenth century affirmed the existence and activity of God, and most of them counted themselves Christians or Jews of one sort or another. In retrospect it is possible to suggest that some of their notions about God or religion and some of their ways of dividing religion from science hastened the demise of the intellectual engagement with questions of religion. But one cannot hold that most philosophers in modernity were uninterested in religion or that they considered questions about God defectively rational. If many of the propagandists of Enlightenment were trenchant critics of religion, they often enough professed views about a divine origin or governance of nature. The only major philosophical figure who is often cited as obviously anti-theistic is David Hume. His *Dialogues Concerning Natural Religion* are typically regarded as the charter for modern philosophy of religion. But it is exceptionally difficult to argue that atheism is the conclusion of the *Dialogues*, and such evidence as there is for Hume's own atheism is biographical rather than philosophical.

The relations of religion and philosophy at the end of the eighteenth century and beginning of the nineteenth were mentioned above in narrating something of the origin of the term 'philosophy of religion'. What needs to be added is that the two main philosophers of these decades, Kant and Hegel, by no means exclude religious topics or even religious sentiments. If neither seems quite an orthodox Christian, both labour to save religious conclusions and to open a space for religious experience. Now it may be that their notions are so opposed to those of ordinary religion as to encourage anti-theistic scepticism. If Kant wants his reader to pass through a 'critique of all theology

based on speculative principles' in order to reach what seems a positive moral theology (*Critique of Pure Reason*, 2. 3. 7), many of his readers took only the negative lesson. If Hegel accredits Christian theology as a necessary misapprehension of higher truths, he condemns it as a misapprehension. So, after Kant and Hegel, one encounters resolutely anti-religious and anti-theistic philosophers. The best known are Marx, Schopenhauer, and Nietzsche. For Nietzsche in particular the falsity and, indeed, the iniquity of Christian doctrine need no demonstration and little reflection. What does interest him is the 'natural history' of religions and religious persons, that is, the cultural and individual pathologies produced by religious practice. 'God is dead' not because a divine entity has perished, but because human beings, who once confected God, have now murdered God by acting out their as yet unuttered disbelief (*Gay Science*, sect. 125). Yet Nietzsche's thought, as he well knew, remains so thoroughly conditioned by his quarrel with religion that he still stands within the theocentric traditions of Western philosophy.

Indeed it was only in the twentieth century that it became common for Western philosophers to write philosophy without so much as raising questions about God. The very existence of 'philosophy of religion' as a subfield within philosophy is good evidence for this. The subfield was created in the twentieth century as an academic speciality because philosophy as a whole was no longer engaged with questions about God or about religious beliefs about God. Of course, the relegation of these questions to a speciality has hardly meant their demise. English-speaking philosophers have returned to questions about God, sometimes along unexpected paths, and have addressed them convincingly with philosophic methods or presuppositions that might have seemed little suited to religion. In recent decades, indeed, there has been a remarkable if still specialized resurgence of philosophic concern with a whole range of religious issues, including some of the most technical aspects of Christian theology.

M. D. J.

\*God and the philosophers; God, arguments against; God, arguments for; Bonhoeffer.

For reasons already made clear, it is not sensible to write a unitary history of 'philosophy of religion'. No such history has in fact been written, nor has anyone attempted to compile the corresponding bibliography. There are historical anthologies of texts selected according to one or another notion of 'philosophy of religion', but these anthologies are necessarily both partial and anachronistic in their selections. One representative recent anthology in English is Louis P. Pojman, *Philosophy of Religion: An Anthology* (New York, 1987); a somewhat older and well-established one is Max J. Charlesworth, *Philosophy of Religion: The Historic Approaches* (London, 1972). To pursue these topics before the 20th cent., one would better begin with some of the individual works mentioned above or with the bibliographies in the entries for pertinent periods in the history of philosophy.

For a more extended narrative, see now the first two volumes of Anthony Kenny's *New History of Western Philosophy: Ancient Philosophy* (Oxford, 2004) and *Medieval Philosophy* (Oxford, 2005).

**religion, problems of the philosophy of.** The philosophy of religion is an examination of the meaning and justification of religious claims. Claims about how the world is, often embodied in creeds, are more typical of Western religions—Christianity, Judaism, and Islam—than of Eastern religions such as Buddhism, Hinduism, and Confucianism. These latter tend to concentrate much more on the practice of a way of life than on a theoretical system by means of which (among other things) to justify that practice. Hence Western religions have proved a more natural target for the philosophy of religion. The central claim of Western religions is the existence of \*God; and the two major problems here are: Can a coherent account be given of what it means to say that there is a God; and, if it can, are there good reasons to show that there is or that there is not such a God?

In order to explain what it means to say that there is a God and to make other religious claims, theists use ordinary words such as 'personal', 'creator', 'free', 'good', etc., which we first learn to use from seeing them applied to mundane objects and states; or technical terms such as 'omnipotent', defined ultimately in terms of ordinary words. The question then arises: Do these ordinary words have different senses when used for talking about God from the senses they have when used for talking about mundane things, or the same senses? To use the technical terms: Are they used equivocally or univocally with their mundane senses? If the former, how could we understand what the new, religious senses are? If the latter, how could God be the inexpressible mysterious other which he is supposed to be, when he can be described by the same words having the same senses as can mundane things? The answer given by \*Aquinas was that religion often uses words in somewhat the same and somewhat different senses from their mundane senses, i.e. in analogical senses. We learn the meanings of the relevant words from their application to mundane things—e.g. learn the meaning of 'wise' from seeing it applied to wise men, such as Socrates—and then, when they are applied to God, suppose them to be attributing to him the nearest thing to the mundane property which could belong to the cause of all things. This answer presupposes that at least some words—e.g. 'cause'—are used univocally in religious and mundane discourse; and it has the consequence that the other words are not used in senses very different from their mundane senses.

God is said to be 'personal', 'bodiless', 'omnipresent', 'creator and sustainer of any universe there may be', 'perfectly free', 'omnipotent', 'omniscient', 'perfectly good', and 'a source of moral obligation', and to have these properties 'eternally' and 'necessarily'. It has been a major concern of the philosophy of religion to investigate whether a coherent account can be given of the meaning of these expressions (bearing in mind the possibility that some of them have senses analogical with their normal senses), and whether they can be combined in a logically consistent way, so that the claim that there is a God can be expressed in an intelligible and coherent way. For

example, is God's being eternal to be understood as his being everlasting (existing at each moment of unending time), or as his being timeless (outside time). (\*Eternity.) There are serious difficulties in making sense of the idea of a personal being existing timelessly—that is, at no moment of time. How could he cause events, except by acting as or before they happen; or know about events, except by those events causing his knowledge as or after they occur? Yet if we think of him as everlasting, does his omniscience mean that he knows what we will do before we do it; and in that case how can our actions be free? Does God's being a source of moral obligation mean that he could command us to torture children, and that it would become our duty to do so if he commanded it?

Given that a coherent account can be offered of what it is for there to be a God in more or less the traditional sense, we come to the question of whether there is any good reason to believe that such a God exists. Some have claimed that if one finds oneself believing that there is a God, then it is rational to believe this without looking for arguments in support of the claim—just as it is rational for me to believe that I ate toast for breakfast or am now listening to a car passing the window, if I find myself believing these things. I do not need further evidence in order rationally to believe such a thing—unless, that is, I acquire evidence to suppose that the belief is false, and in that case I may need evidence confirming the belief in order to outweigh the former evidence and so to continue rationally to hold the belief. The view that the belief that there is a God needs no prior support from other evidence in order to be held rationally is the view of 'reformed epistemology', advocated by Alvin Plantinga and developed in a 1984 collection on *Faith and Rationality* which he co-edited. Basic beliefs are ones which the subject believes, but not for the reason that they are supported by any other beliefs which he holds. Beliefs are 'properly basic' if the subject is justified in holding them even if not supported by other beliefs'. What Plantinga calls 'classical foundationalism' is the view that the only properly basic beliefs are self-evident beliefs (beliefs in obvious \*logical truths, such as that  $2 + 2 = 4$ ), incorrigible beliefs (beliefs about our current mental states), and beliefs evident to the senses (beliefs about what we are now perceiving via the five senses). It would seem to follow from classical foundationalism that belief that there is a God cannot be properly basic, and so requires to be based on other beliefs, i.e. to be justified by argument from other beliefs. Plantinga argues (for reasons quite apart from those concerned with religious beliefs) that classical foundationalism has too narrow a class of properly basic beliefs (it should, for example, include memory beliefs). And further, he argues, it is self-defeating, because belief in classical foundationalism itself is neither (by its own standards) a properly basic belief nor, apparently, supportable by properly basic beliefs. Yet once we abandon classical foundationalism, he claims, we have no good reason for denying that belief that there is a God may be properly basic.

There is much to be said for the principle that it is rational to hold any belief with which one finds oneself, in the absence of counter-evidence—a principle sometimes called 'the principle of credulity'. But Plantinga is not advocating this as a general principle; rather, he holds that 'there is a God' may be held without further justification, even if 'I am now aware of the Great Pumpkin' may not; and he has recently developed a theory of epistemology which has this consequence. (See his *Warranted Christian Belief*.) This theory concerns what makes a belief 'warranted'. Warrant is the characteristic which turns true belief into knowledge. If my belief that the Second World War ended in 1945 is warranted, then if it is also true, I know that the Second World War ended in 1945. (A belief being 'warranted' is very similar to its being justified or rational—that is, the believer being justified or rational in holding the belief.) Plantinga's account of warrant is a complicated one, but its central component is that to be warranted a belief must be produced in the right way—that is, by a 'properly functioning process'. Thus perception, memory, and induction are all processes which lead us to acquire beliefs; and plausibly we are functioning properly when we acquire beliefs by means of them (in the absence of counter-evidence). So, any belief of mine acquired by perception will be warranted (in the absence of counter-evidence—for example, my memory that I have just ingested a hallucinatory drug). So too will any belief acquired by induction from my perceptual beliefs. Plantinga suggests that we all have a sense additional to the normal five, a 'sense of divinity' which produces in many of us the belief that there is a God; and that, since there is a God (Plantinga claims), our cognitive faculties are functioning properly when the 'sense of divinity' does produce that belief. If he is right about this, then (unless—improbably—the belief is acquired by some other process) whenever we find ourselves with the belief that there is a God, we are warranted in continuing to hold it (so long as we do not find evidence or arguments tending to show that there is no God). But if we do not find ourselves with the belief that there is a God to start with, or our belief is only a weak one outweighed by counter-evidence (for example, the evidence of suffering suggesting that there cannot be a perfectly good being in charge of the universe), Plantinga does not give any positive reason to hold that belief or hold it in a stronger form so that it is not outweighed. He is concerned only to show that a simple religious believer who can give no arguments for his belief *may* still be warranted in holding it.

If atheists and weak believers are to be given a strong belief that there is a God, they need to be shown that other things which are more evident to them make it probable that there is a God by public standards of what is evidence for what. There has been a long history in Western philosophy of positive \*arguments for the existence of God. Anselm, Aquinas, Duns Scotus, Descartes, and Leibniz and innumerable other philosophers have given such arguments. Most of these arguments are arguments from observable phenomena to a God who, it is claimed,

provides the explanation of their occurrence. (One exception is the \*ontological argument, which has as its premisses pure conceptual truths.) The \*cosmological argument argues from the universe to a God who creates it; the \*teleological argument argues from the orderliness of the universe (either in respect of conforming to laws of nature, or in containing animals and humans in an appropriate environment) to a God who makes it thus. The argument from consciousness argues from the existence of conscious embodied agents (humans and animals) to a God who endows them with consciousness. The argument from religious experience argues from the occurrence of religious experiences, in the sense of experiences in which it seems to the subject that he is aware of God, to millions of people of different centuries and cultures, to a God of whom they really are aware.

It is crucial for assessing the worth of such arguments whether they are to be regarded as deductive or inductive (or probabilistic) arguments, and whether they are to be taken separately or together. A deductively valid argument is one in which if you assert the premiss or premisses from which it starts, but deny the conclusion, you contradict yourself. So, for example, the cosmological argument will be a valid deductive argument if and only if 'there is a universe, but no God' involves a contradiction—if it is like 'he is less than 5 feet tall and more than 6 feet tall at the same time'. It does not at first sight look as if 'there is a universe, but no God' is self-contradictory. If, however, the arguments are taken as inductive arguments, then they will be like the scientist's arguments from observable data to his hypothesis of unobservable entities which cause the observable data—like the physicist's observations of lines on photographic plates to his conclusion that they are caused by electrons or positrons; the arguments do not guarantee the truth of the scientist's hypothesis, but they can make it very probable. Arguments for the existence of God have to be weighed against \*arguments against the existence of God. The most important of these is provided by the \*problem of evil: that an omnipotent and perfectly good God would not allow the occurrence of pain and suffering.

The arguments for the existence of God are more plausible if regarded as inductive, and taken together. Arguments from observable data to an explanatory hypothesis in science, history, or any other area, in the opinion of this writer, make the hypothesis probable in so far as (1) the hypothesis makes probable the occurrence of the data, (2) the occurrence of the data is not otherwise probable, and (3) the hypothesis is simple. (\*Simplicity.) Thus the hypothesis that Jones committed some crime is probable in so far as the clues are (1) such as you would expect to find if Jones committed the crime, and (2) not otherwise to be expected, and (3) the hypothesis is simple. The simplicity of this hypothesis consists in it being a hypothesis that one person did some act, which caused each of the many clues. A hypothesis that many different individuals, not in collusion with each other, did quite separate acts which caused the clues, would be much more complicated, and

so would satisfy criterion (3) far less well. If arguments for the existence of God are regarded as arguments to an explanatory hypothesis, they must be judged by these criteria. Consider the teleological argument from the almost total conformity of all material objects to laws of nature, i.e. from the fact that all material objects throughout endless space and time have exactly the same powers and liabilities to act as each other (e.g. attracting each other in accordance with Newton's laws, or with whatever are the fundamental laws of nature; and the regularities of chemistry and biology which follow from the fundamental laws). Since God, by hypothesis, is omnipotent, he will be able to bring about this order; and if it is a good thing that such order should exist, then in virtue of his perfect goodness he will have reason for bringing it about. So the argument tries to show that (1) this order is a good state, which in consequence a God would probably bring about, but which (2) otherwise would be a vast improbable coincidence, and (3) that a God is a simple being. It argues for (1) by pointing out that the existence of finite beings (such as humans) with the ability to make differences to themselves, each other, and the world is a good thing. In order for humans to be able to make these differences, there have to be simple regularities in the world which humans can discover and utilize—for example, if there is a regularity that watered seeds grow into plants, humans can develop an agriculture; but otherwise they cannot do this. It argues for (3) that the hypothesis postulates one being who is the simplest kind of person that there can be, having infinite degrees of (i.e. zero limits to) the characteristics of knowledge, power, and freedom which are involved in being a person.

The main argument against the existence of God has always been the 'argument from evil'—that is, from pain and malevolence. Theists sometimes claim that since by hypothesis God is so much greater than us, we cannot expect to understand why he allows all the things that happen to happen; there are bound to be puzzling phenomena such that we cannot understand why God allows them to occur, and so we should not count evil as evidence against the existence of God. However, almost all atheists and many theists have felt that the claim that God is perfectly good would be empty of meaning unless some explanation could be given of why, being perfectly good, he allows the enormous amount of pain and malevolence that there is in the world. An explanation of this is called a 'theodicy'. Evils are traditionally divided into moral evils (ones knowingly caused or allowed to occur by humans) and natural evils (the ones for which humans are not responsible, such as the effects of disease and earthquake). A central plank of most theodicies is the 'free will defence' to moral evil: the claim that if God is to give humans the great good of a free choice between good and evil, it is inevitable that there will be some moral evil. (There would be, it is claimed, a contradiction in supposing that God could cause us freely to choose the good—for to choose 'freely' is to choose without being caused how to choose.) Theodicy needs more complicated arguments

to attempt to deal with the problem of natural evil. (\*Evil, the problem of.)

All religions have set a high value on faith. But how is 'faith' to be understood? (\*Faith and reason.) If it is understood as forcing yourself to believe what seems probably false, there would seem to be little merit in it. But if it is seen as giving oneself totally to attain a great good (e.g. the vision of God for oneself and others), when it is no more than probable that this goal is attainable, it would seem more plausibly a virtue.

Other claims, common to all Western religions, include the claims that God hears prayers and answers them, sometimes by miracles; that God has revealed certain truths; and that there is a life after death in which the good will enjoy the vision of God and the bad will be deprived of it for ever. A miracle has often been understood as a violation of a law of nature, by God intervening in the world. But then, how can something be a law of nature if it can be violated, and so there can be exceptions to its operation; is not a purported law of nature which does not always predict accurately not really a law of nature? One answer to this is to regard exceptions to the operation of a purported law of nature as showing it to be no true law of nature only if they are repeatable exceptions; you only show 'all metals expand when heated' not to be a law of nature if you show that regularly when a certain metal is heated under certain conditions, it expands. The occasional non-repeatable exception is a violation; and, if brought about by God, a \*miracle. Hume (*Enquiry Concerning Human Understanding*, sect. 10) has a famous argument purporting to show that there could never be a balance of evidence in favour of the occurrence of a miracle thus understood. To show a miraculous event *E* to have occurred at time *t*, we need to show first that there is some law of nature which its occurrence would violate. We need a lot of evidence from what has happened on many other occasions to show some purported law *L* to be a law of nature (e.g. evidence of observers to show that on many other occasions, objects have behaved in the way predicted by *L*). But then that evidence will tend to show that *L* will be obeyed at other times also, including at *t*. The evidence in favour of the occurrence of *E* will consist only of the testimony of a small number of observers; and so the force of their evidence will always be outweighed by the force of the testimony of many observers who testify to the operation of *L* on many other occasions. An obvious response is that the sums are not quite so simple—evidence of observers as to what happened on other occasions is only indirect evidence about what happened at *t*, whereas the evidence of the observers at *t* is direct evidence, and so has much more force.

Why does God not make nature perfect to begin with? Why does he need to intervene in the natural order? One reason that he might have is—in order to answer prayer. He wishes to bring about good in response to human request; and, to make that possible, he leaves nature capable of improvement. Another reason for performing a miracle would be to give his authority to some prophet

who had publicly prayed for the miracle to occur or whose teaching was forwarded by the miracle, and so thereby publicly to authenticate the prophet's teaching as a revelation from God. Philosophy of religion has a concern with whether God would be expected to provide a revelation, and what are the tests that he has done so (e.g. whether the Koran, or the Christian Bible and Creeds record such a revelation). Joseph Butler's *The Analogy of Religion* is a famous discussion of these issues.

Whether it is coherent to suppose that human beings can survive their death depends on the correct account of \*personal identity (see also \*immortality). If there can be such life, the issue arises whether what Christianity, Islam, and some other religions have claimed as the character of the afterlife is compatible with the goodness of God. Such religions claim that the good (judged so to be in virtue of their faith or works—Protestants have emphasized one, Catholics the other) will enjoy the vision of God for ever, whereas the bad will be permanently deprived of it, possibly in a \*Hell of endless sensory pain. Could a good God act thus? One answer is that in their life on Earth human beings freely form their character; and only a person with a good character would want to have, and so be capable of enjoying, a vision of God—it is humans who make the ultimate choice of their fate.

In recent years the philosophical techniques and results of the Anglo-American tradition of philosophy have been applied not merely to the most general claims of Western religions, but also to specifically Christian doctrines (as well as occasionally to the specific doctrines of other religions). The Christian doctrines include the three central Christian doctrines of the Trinity (that God is three persons of one substance), the Incarnation (that God became incarnate as a human being, Jesus Christ), and the Atonement (that Christ's life and death atoned for the sins of humans). The initial philosophical task is to see how far a clear meaning can be given to these doctrines; and the next task is to consider if there are any grounds for believing them true. It is normally supposed that revelation will provide the main grounds, but there may also be a priori arguments for or against their truth. This interest in specifically Christian doctrines has gone along with investigation of how far it is possible to compare religions in respect of their truth-claims and their ability to provide 'salvation', and to whether one can say with justification that one religion is 'the true religion' or at least better than other religions.

**religion, scepticism about.** There has been an undeniably powerful current of anti-religious thought in the history of modern philosophy. Among its several quite distinct sources, the following are noteworthy.

In his *Dialogues Concerning Natural Religion*, Hume's 'Philo' showed how, in cosmological speculation, imagination outruns our ability to confirm or rebut. We might (with 'Cleanthes') argue to a finite, anthropomorphic cause of the world; or (with 'Demea') do more justice to divine transcendence and mystery—but at the cost of virtual (if religiously toned) agnosticism. Neither route would lead to the \*God of Christian theism.

For Kant, the traditional arguments to God were all dependent on the \*ontological argument, which in turn treated existence, invalidly, as a predicate and a perfection. To argue from the world to God involved, also, illicit extension of categorial concepts ('cause', notably), which functioned reliably and necessarily within the phenomenal world, and there alone.

Both Schopenhauer and Nietzsche saw the case for theistic belief as quite destroyed: theism was no longer a live option—God could be pronounced 'dead'. The task was now to accept and develop the implications of a non-theistic view of the world.

Critics of teleological arguments deemed them too weak to reach beyond the world's orderer to its creator; they also were seen as decisively damaged by naturalistic, evolutionary explanations of the development of living forms. It was no longer necessary to claim that the cause must manifest a higher level of being than its effect, e.g. that the causal origin of mind and intelligence must itself be intelligent; and an increasingly detailed and desentimentalized understanding of the life-world, e.g. the mutual predatoriness of species, made it correspondingly harder to superimpose a benign teleology upon nature or to see the working there of a 'divine hand'.

Some theologians welcome the demise of natural religion, arguing that it is wholly in revelation that Christian belief is founded. An appeal to revealed doctrine, however, referring back essentially to scriptural documents, was, for many, less readily seen as a path to renewed belief than to anxieties of another kind—over the radical historical uncertainties uncovered by scholarly biblical criticism. Besides, the 'revealed' component could not furnish the *entire* grounding of Christian belief. Philosophical sense still needs to be made of the connecting of revealed content with the alleged divine Source: a rational-theological component is indispensable.

A further set of difficulties for Christian belief has centred upon issues in the philosophy of mind. Science and philosophy again converge in the setting of the problem. The more detailed understanding is available of the embodiedness of conscious and personal life, the stronger the pressures towards forms of materialism and physicalism, and the less plausible become religious beliefs that involve bodiless mental or 'spiritual' life—whether God's life or that of the human 'soul'. If the believer responds with a doctrine of resurrection rather than survival of dis-

embodied spirits, there remains a serious philosophical problem over personal identity: is the resurrected individual the 'same' person who died, or a new, though qualitatively identical, person?

Problems in that area continue into the field of \*religious experience. All direct encounters of person with person involve bodily presence and behaviour, visible and audible. An already well-founded religious belief is not daunted by, for example, the idea of prayer to an invisible and inaudible deity; and a believer may experience a powerful, vivid sense of the reality of God. It has become much less convincing, however, to use such religious experience as an argument to God's reality. Naturalistic forms of explanation, Freudian and other, have been proposed for religious experience; and analogies are often drawn between religious or mystical experiences and drug-induced or pathologically abnormal states of consciousness. These cannot displace the theist's explanation, but they certainly challenge the use of such experiences in theistic apologetic.

Some religious philosophers have looked to moral experience for an alternative to the traditional theoretical arguments for God. To mount a plausible moral argument to God, however, would seem to require as a starting-point a cognitivist, 'realist' or rationalist type of moral theory. No account of moral judgement in emotivist, expressivist terms could ground an inference to a divine source of the world's being. Even today's advocates of \*moral realism most often insist that they are dealing with human insights into a human reality, not with disclosures of a transcendent realm of values.

Perhaps the area in which the difficulties facing theism are most formidable—even intractable—is the \*'problem of evil'. Once it is claimed that the being upon whom the universe depends is personal, that theistic explanation is personal explanation, then, given also that the deity is the unique, unrivalled, omnipotent ground of the world, what are we to make of the vast extent of suffering in that created world? If in nature's fundamental laws of operation we find intelligibility, simplicity, elegance, beauty, how to explain the absence of any analogous beauty in the pattern (or absence of pattern) in the distribution of satisfaction, fulfilment, and suffering in the lives of sentient individuals? Stories about the world as a 'vale of soul-making' are of very limited applicability: unhelpful *vis-à-vis* the suffering of non-human animals, or with the congenitally mentally handicapped. Nor has sense been made of the 'allowing' of human suffering of such undeserved intensity that no promised beatitude hereafter seems a morally tolerable compensation.

It would be, however, absurdly one-sided to leave the matter there. It can be claimed that significant philosophical work goes on in all of these problem areas, work of relevance to the religious questions, and that in some at least of these the sceptical case is seriously challenged. Hume and Kant failed in fact to demolish the theistic 'proofs'. Debate has rekindled on every one of these arguments. Impressive reworkings of the \*cosmological argument

have recently appeared (Grisez, Miller); \*teleological arguments are defended in new forms (Swinburne); and the 'fine tuning' witnessed to by recent cosmology has initiated a new phase in the dialogue between science and religion.

Finally, the theories of \*meaning on which philosophical scepticism in the mid-twentieth century heavily relied have been displaced by more complex accounts. If a philosophy of language and meaningfulness is complex enough to cope with contemporary scientific theorizing (e.g. with the thought models and paradoxes of quantum theory), it will not also be able to be sharply dismissive of all religious and theological language. The thought models, the metaphors, the paradoxes that arise in that context, will continue to deserve patient and attentive analysis.

**religion and epistemology.** The epistemology of religion is the attempt to solve philosophical problems about \*knowledge which arise from religion. For example: Is there mystical knowledge? Is there knowledge by \*revelation or \*natural theology? Can \*God be known to exist, for example, if there is a sound proof of God's existence? Is it possible to have knowledge of the properties of God: omnipotence, omniscience, benevolence, simplicity, and eternity? (Omniscience is arguably a part of omnipotence, if omnipotence is the ability to do anything, and knowing is something that can be done.)

Arguably, religion yields ways of experiencing and understanding that exceed the secular powers of the senses and the intellect. Augustine's claim *creo ut scio*, 'I believe in order to know', rather than a dogmatic reversal of ordinary intellectual priorities, is a principle conducive to non-reductivist explanation. Aquinas maintains that reason needs to be supplemented by faith in order to obtain a fuller understanding of reality, even if this falls far short of adequate knowledge of God, because we are finite and imperfect beings. Pascal famously said there are two mistakes: to deny reason and to allow only reason.

Hume and Kant have argued that in a sense there is no epistemology of religion if this implies knowledge of God. Hume criticizes arguments from design in *Dialogues Concerning Natural Religion* and the likelihood of miracles in the *First Enquiry*. In the *Critique of Pure Reason* Kant argues that there is no persuasive a priori or a posteriori argument for the existence of God. Nevertheless, in his moral philosophy he allows God, freedom, and immortality as postulates of pure practical reason.

All the problems of epistemology are problems for the epistemology of religion. For example, knowing what belief is, is necessary for knowing what belief in God is. Knowing whether there is knowledge is necessary for knowing whether there is mystical knowledge.

It could be that once metaphysical problems about ultimate reality and one's own existence are grasped with clarity, it is seen that their answers have to be theological. For example, 'Why is a particular person you?', 'Why is it now, now?', 'Why is there a universe?', 'Where is there metaphysical room for what ought to be as well as what is?' only admit of answers if theism is true. Nevertheless, a God whose existence and nature could be established by human beings with logical certainty would arguably not be the God of Judaism, Christianity, or Islam, the God of faith.

**religion and morality.** Ethical requirements can readily be thought of as commands—with authority behind them. Whose authority? Could it be that the sole ground for moral judgements is their being willed or forbidden by \*God? Could his will, alone, constitute moral rightness? That would imply that we can understand moral requirements *only* if we believe in God and can know his command.

On such a view, to speak of morality is no more than to speak of what, as a matter of fact, God wills or commands: a disquieting view, because it follows that if God were to will a set of imperatives totally at variance with those of morality as we know it, that set would at once have unconditional moral authority, whatever its content.

A religious person wants to say (meaningfully, seriously) that *what God commands is right and good*. But if all we mean by 'morally right and good' is 'what God commands', then the statement 'What God commands is right and good', means no more than 'What God commands is ... what God commands': no longer news, but only a trivially true statement. We must, then, see moral obligatoriness and goodness not as constituted by divine command, but as having a distinct and irreducible character of their own, a character that we ourselves have the moral competence to recognize, and which requires no further authentication.

Perhaps, however, we have not acknowledged with full seriousness what a \*divine command is: the command of a being with total power over his universe. How can we speak of appraising the command of such a being? Natural though this response is, it would reduce morality to mere passivity under divine power. The worship of God (in the Judaeo-Christian tradition) has been very different indeed from the worship of sheer power.

Supposing, however, that there is no God, no life after the death of the body, and no final vindication of good and defeat of evil, can the moral life still be lived seriously, and altruistic concern sustained?

A secular moralist will argue that far from morality losing its viability and seriousness in the absence of a God and a future life, the opposite is at least as reasonable: individual moral agents are more thoroughly responsible for one another. Why should people matter less, on a secular, agnostic view? With their limited life-span, it becomes more urgent and important that they have just and fair treatment in their one life here and now. Removal of promised reward or compensation does not undermine the genuinely moral, though it does undermine the merely prudential; and the prudential often masquerades (even within 'moral education') as the moral.

But it must be acknowledged, nevertheless, that the religions have played an important role in moral learning. To have (some) moral competence or capability does not mean we are morally omniscient, with nothing to learn. Any number of central moral notions, attitudes, qualities of character, have in fact come to general awareness only or chiefly through religious teachers. R.W.H.

**religious experience, argument for the existence of God from.** This can be considered a special version of the teleological argument, claiming that the widespread occurrence of religious experience, with a common phenomenological core and giving rise to a common core of interpretation, requires explanation. And it is argued (e.g. by C. D. Broad and Richard Swinburne) that the most plausible explanation involves the existence and activity of \*God.

Alternatively, religious experience can be construed as a *non-inferential* mode of cognition, analogous to sense, which grounds a knowledge of God in a more direct way than argumentation. It is especially important not to treat this sort of appeal to religious experience as if it were an appeal to argument, since that would invite inappropriate sorts of criticism and defence. G.I.M.

**religious language.** What is religious language? It is cosmogony, historical narrative, myth, moral discourse, as

well as blessing and cursing, confessing, adoring. It crucially involves metaphor, symbol, analogy, parable, paradox. It is, typically, language avowing the inexpressible, unconceptualizable nature of its object, or the indescribability of mystical experiences which nevertheless it strives to express! Given the diversity of religious language, there can be no single way of confirming or rebutting its many and complex claims.

It should not surprise one that the language we use to describe temporal events, material objects, and our dealings with them will not suffice also to describe the \*God of Judaeo-Christian theism and our supposed encounters with him. Unlike finite objects, God is thought of as without limits: not a constituent of the universe, not the effect of any cause.

Obliqueness is uneliminable from discourse about deity. The language of revelation is oblique through and through: likewise the metalanguage in which revelation is affirmed to have occurred. (But then so too is some of our discourse about the life of the mind.) Even attempts to ground all the 'revealed' talk and all accounts of religious experience in a cosmologically argued 'uncaused cause' requires an analogical extension of that basic category of cause, beyond its home in everyday and scientific explanation.

A decision about accepting or rejecting the claims of theistic language to have a real object must be based on a holistic judgement. Do we do more damage to our overall experience of the world if we reject the theistic paradoxes and the perilously stretched analogies than if we retain them? And this is a test we can carry out only roughly, since what we think of as our 'experience' cannot be more than partially extricated from the 'interpreted'—religious or agnostic or atheistic—views of the world, between which we are attempting to make a reasoned decision.

**Religiousness A and B.** Kierkegaard's distinction between two 'stages' or 'spheres' of existence, the former said to be a necessary preliminary to the latter. As in Kierkegaard's ethical stage, Religiousness A retains the idealist assumption that the eternal truth is humanly accessible, except that, where in the case of ethics self-revelatory social and familial duties provide the access, in this case the relation to truth is established by self-abnegation and is expressed in categories of \*inwardness (resignation, suffering, and guilt). Religiousness A conceives the truth as something to be recollected. By confining human knowledge to history Religiousness B makes truth practical, future-orientated, and dependent on the eternal having entered time in human form as an ethical example. This is Christianity,

and, by having to face the paradox of the Incarnation, Christian faith achieves the highest pitch of inwardness.

**remembering:** see memory.

**Renaissance philosophy.** That of the West during the fifteenth and sixteenth centuries. The principal concerns of Renaissance writers were philosophy of nature (embracing science, occultism, and metaphysics), psychology (including theory of knowledge), and moral and political philosophy—one of the main contributions to which was the employment of fables of golden ages, past and future, in order to retrieve and refashion personal and social virtues associated with antiquity.

Arguably the first major Renaissance philosopher was Nicholas of Cusa (1401–64) and the last was Francisco Suarez (1548–1617). Other important figures include Marsilio Ficino (1433–99), Pietro Pomponazzi (1462–1525), Giovanni Pico della Mirandola (1463–94), Thomas de Vio Cajetan (1468–1534), Francesco de Vitoria (1480–1546), Giordano Bruno (1548–1600), and Tommaso Campanella (1568–1639). During the same period lived several important writers, such as Desiderius Erasmus (1466–1536), Niccolò Machiavelli (1469–1527), and Thomas More (1478–1535), who though not philosophers were influential humanist thinkers.

The Renaissance cannot match the medieval and modern periods for the originality and influence of its philosophical ideas. For the most part it was concerned with the elaboration of systems of thought originating in the classical period. The main sources of philosophical inspiration were Plato and Aristotle, and although the tradition of \*scholasticism was maintained by figures such as Cajetan, de Vitoria, and Suarez, most Renaissance writers regarded the medievals as idle sophists writing a Latin that appeared barbaric by comparison with the courtly version contrived by Cicero. Throughout the Renaissance, works by classical philosophers were retranslated and new commentaries were produced. This led to the establishment of revivalist schools, the most important of which was the Neoplatonic academy in Florence founded by Ficino under the patronage of Cosimo de' Medici.

**Renouvier, Charles Bernard** (1815–1903). French personalist who used the critical method of Kant to develop a pluralism in which chance, time, novelty, and freedom are irreducible realities while absolutes and infinities do not exist. Although he never held an academic position, he was one of the most prolific philosophers in French history.

Renouvier's \*empiricism strongly influenced William James's 'radical empiricism'. A fideism in which Renouvier held that belief is voluntary (a radical form of what today is called \*doxastic voluntarism) helped James out of a suicidal depression in 1870, a crisis from which James's doctrine of 'the Will to Believe' emerged.

Renouvier's stress on freedom in belief was buttressed by an indeterminism in which chance is an irreducible aspect of nature, a rejection of determinism James endorsed too. The notion of infinity was also attacked by Renouvier, and James at his death was still struggling with his friend's claim that infinity is a self-contradictory notion.

Ralph Barton Perry, *The Thought and Character of William James* (Boston, 1936), i. 654–710.

**representation.** It is a truism that a representation is anything that represents something. Thus words, sentences, thoughts, and pictures may all be considered representations, though the manner in which they represent things is very different. Representation is a philosophically puzzling relation. To take one simple example, 'x represents y' seems to express a relation between two things. But while the existence of a relation between two things trivially entails that they exist, this is not true for the relation of representation: a picture, thought, or sentence can represent the Judgement of Paris even if there was in fact no such event. Yet who can deny that all representations do in fact represent something?

Pictorial representation seems initially to be the most straightforward form of representation, since the relation between a picture and what it represents seems so natural and obvious to us. Surely a picture represents something simply by resembling it? And isn't resemblance a perfectly natural relation? The apparent simplicity of pictorial representation might suggest that it is the most basic form of representation. A caricature of this position would be: a sentence represents something because it is associated in its user's mind with a mental picture which represents in virtue of resembling the thing represented.

But explaining pictorial representation in terms of resemblance raises many problems. While resemblance is reflexive (everything resembles itself) and symmetric (I resemble my identical twin, and he resembles me), representation is neither. Even near perfect resemblance between two things doesn't guarantee representation: my copy of today's newspaper does not represent any of the million others. These sorts of considerations have led philosophers like Nelson Goodman to deny that resemblance has anything to do with representation at all. (However, Malcolm Budd has recently come to the defence of the resemblance theory of pictorial representation.)

Resemblance is, of course, not necessary for representation; words, for example, do not resemble the things they represent. But our caricature theory explains linguistic representation in terms of associating words with mental pictures, which then represent in virtue of resemblance.

The trouble with this is that even pictures do not represent intrinsically. To take an example of Wittgenstein's, a picture of a man walking uphill could also be a picture of a man sliding backwards downhill. There is nothing intrinsic to the picture that determines that it is a picture of the first kind rather than the second. We therefore have three choices: either the picture represents what it does by being interpreted, in which case the explanation of representation is borne by the idea of interpretation, not resemblance. Or some pictures are 'self-interpreting': mental pictures or images, perhaps, determine their own interpretation. But this amounts to taking the idea of representation as fundamental and unanalysed, and leaves us without any explanation of representation at all. Finally, we could say that the picture represents everything it resembles—each picture has an indefinite number of representational 'contents'. But this too seems to leave the idea of representation entirely unexplained.

Even without this difficulty, the idea that representation is based on resemblance is untenable. For many words ('prime number', 'because') could not have mental pictures associated with them that explain their representational powers; and much thought is not pictorial or imagistic in any case. Pictures too cannot explain the logical structure of thoughts or sentences: how could a purely pictorial representation represent the thought that 'If it isn't raining next Saturday, we'll go to the sea'?

So whether or not we can explain pictorial representation in terms of resemblance, we certainly cannot explain all forms of representation in terms of pictorial representation. The various kinds of representation have distinctive features which need their own explanation. An account of linguistic representation, for instance, has to explain how the meanings of words systematically combine to produce the meanings of sentences. (\*Meaning.) In recent philosophy of mind and psychology, the notion of mental representation has become central, and many hope to explain linguistic representation in terms of it. Moreover, the hope that representation can be revealed to be a natural relation has been fuelled by the use of the notion of mental representation in \*cognitive science and psychology. t.c.

\*pictures.

H. Clapin (ed.), *Philosophy of Mental Representation* (Oxford, 2002). Robert Cummins, *Meaning and Mental Representation* (Cambridge, Mass., 1989).

Nelson Goodman, *Languages of Art* (Indianapolis, 1976).

**representation in art.** Visual \*art is markedly suited to representing things, and the way in which it does it seems irreducible to any other form of representation. In music, by contrast, representation seems peripheral, while the ability of linguistic artforms such as poetry or novels to represent is inevitably taken up with the larger question of how language itself has meaning.

Two conceptual distinctions should be borne in mind. Firstly, some representations refer to particular things, and some refer to no particular thing. For example, a

portrait has to relate to some actual person, but another picture can be a picture of a woman reading a book, without there being any particular woman or book which it is about. Secondly, there is a difference between a picture's standing for something as a symbol and its depicting something. In a painting, a lamb may *stand for* or symbolize Christ, but what is *depicted* in the painting is a lamb.

Depiction is an utterly familiar practice which proves hard to analyse. The apparently common-sense idea that the surface of a picture resembles what it depicts is usually rejected by philosophers. They try instead to specify the state of mind of someone who both sees the surface of a picture and understands what it depicts. Different accounts invoke the notions of 'seeing a woman in' the painted surface, or making believe that our seeing the picture is our seeing a woman, or experiencing a resemblance between the picture's appearance and the two-dimensional appearance which a woman would have if we saw her literally. This is a challenging area of philosophy, which has to negotiate the sophistications of contemporary philosophy of mind, while remaining alive to the history of representation in the arts and the interest which pictures actually have for their audience. c.j.

N. Goodman, *Languages of Art* (Indianapolis, 1968), ch. 1.

R. Wollheim, *Art and its Objects*, 2nd edn. (Cambridge, 1980), suppl. essay v.

**representative theory of perception.** A theory maintaining that in ordinary perception one is directly, and most immediately, aware of subjective representations (\*sense-data, \*percepts, \*sensations) of the external world. Our knowledge of objective (mind-independent) reality is, thus, derived from (based on) knowledge of facts about one's own subjective experience. Typically this view is contrasted with \*naïve realism.

A representative theorist need not (and typically does not) maintain that our knowledge of objective conditions is reached by a conscious inference from premisses describing the effects on us of this external reality. In seeing that there are cookies in the jar (an objective state of affairs), I do not arrive at my belief that there are cookies in the jar by a conscious inference from premisses describing my experience of the cookies. None the less, the belief about the cookies is based on a knowledge of a subjective condition (the sensation the cookies cause in me), in the same way that one's knowledge of a distant football game (being watched on television) is based on knowledge of what is happening on the nearby TV screen. Even if there is no conscious inference, there is a dependency of one piece of knowledge on another.

Arguments for a representative theory of perception typically appeal to hallucinations and illusions. Seeing a white rabbit is (or can be) the same from a subjective standpoint as hallucinating or dreaming of a white rabbit. The causes may be different, but the experiences are the same. Since (it is argued) one is aware of a mental representation or image in the case of hallucinations and dreams, it is reasonable to infer that in ordinary perception

one is also aware of something subjective. The only difference between seeing a white rabbit (veridical perception) and hallucinating one is the cause of the sensation. In veridical perception, the effect (the internal image of which one is directly aware) represents the cause—the white rabbit—in some more or less accurate way. In the case of hallucination the cause—drugs in the bloodstream, maybe—is misrepresented.

Arguments appealing to the fallibility of one's knowledge of the external world have also been used to support a representative theory of perception: our knowledge of reality is based on a more certain (infallible?) knowledge of the appearances (the internal representation) of reality. Even if this is, in some sense, true, it does not support a representative theory unless it is combined with the questionable premiss that knowledge of the appearances—that something looks red, for instance—requires an awareness of something that is red. This questionable premiss has been called the 'sense-datum fallacy'. If it is not assumed, the fact that our knowledge of the world's objects is based on their appearance does not imply that we are aware of anything other than the external objects themselves.

Representative theorists typically distinguish between \*primary and secondary qualities. Primary qualities are supposed to be the ones that are shared by the mental representation and the physical object it represents. The shape of an object, for instance, is represented (sometimes misrepresented) by the shape of the visual image that results from our seeing that object. Colours and sounds, on the other hand, are secondary qualities: these are properties of the sensory experience that do not resemble the objective powers in objects that cause us to experience these qualities. The greenness of grass is in the perceiver, not in the grass.

**republicanism.** To contemporary political and historical understanding, it is the doctrine of opposition to monarchy or any other form of one-person rule. In practice it first emerged in the Greek city-states after the overthrow of the tyrants. Its first fully developed expression was in the form of government of Rome, before Augustus and his imperial successors. As a theory, it is most elaborately set out in James Harrington's *Oceana* (1656). It was suppressed by Oliver Cromwell, who had by that time become an autocrat. Republicanism, following Roman practice, tends to favour a balancing of separated powers, with a ruling oligarchy mitigating institutions as safety-valves for popular discontent and swift rotation in the higher offices. The US Constitution—the work of enlightened English country gentlemen—established a scheme close in spirit to that of the Roman Republic. In Britain, since the overthrow of Stuart absolutism—in the 1640s and then again in 1689—there has prevailed what H. G. Wells called 'a crowned republic'. The chief objection to

one-person rule is the frequent descents of autocrats into megalomania, to which is added, when the post is hereditary, incompetent heirs.

James Harrington, *Oceana* (1656 and later editions).

**Rescher, Nicholas** (1928– ). An amazingly prolific contemporary American philosopher who has written over 100 books in the process of constructing a synoptic system: pragmatic idealism. The system aims at knowledge of reality. Its approach is (a) idealistic because it regards the constructive contribution of the inquiring mind as essential to knowledge, and because it regards systematic \*coherence as the criterion of truth; (b) fallibilistic because it denies that knowledge can provide more than an imperfect approximation of reality; and (c) pragmatic because it maintains that the validity of knowledge-claims depends on their utility in furthering human purposes. The epistemological part of the system aims at improving human knowledge, while its axiological part aims at deriving values from human needs and purposes and evaluating knowledge-claims in the light of them. As a whole, Rescher's development of pragmatic \*idealism is characterized by an unusually wide range of sympathy and information.

J.KEK.

\*American philosophy; pragmatism; pseudo-philosophy.

Rescher encapsulates his overall position in the trilogy *A System of Pragmatic Idealism* (Princeton, NJ, 1992–3). The coherentist aspect of his position is presented more fully in *The Coherence Theory of Truth* (Oxford, 1973). For biographical information, see his *Ongoing Journey* (Lanham, Md., 1986). Rescher founded and edited the scholarly journals *American Philosophical Quarterly*, *History of Philosophy Quarterly*, and *Public Affairs Quarterly*.

**res cogitans.** Literally, 'thinking thing'. In the Second Meditation, Descartes uses a process of systematic doubt to reach the conclusion that he is 'in the strict sense only a thing that thinks, that is, a \*mind or intelligence or intellect or reason'. In the Sixth Meditation, Descartes contrasts *res cogitans*, or mind, with *res extensa* ('extended thing', or body), and argues that the mind is 'really distinct from the body and could exist without it'.

J.COR.

\*self; dualism.

N. Malcolm, 'Descartes' Proof that his Essence is Thinking', in W. Doney (ed.), *Descartes* (London, 1967).

**resentment.** A bitter emotion based on a sense of injury, inferiority, oppression, or frustrated vindictiveness. It plays a central role in the ethics and philosophical psychology of Nietzsche as an 'act of most spiritual revenge'. The German word *Empfindlichkeit*, like the French *ressentiment* (preferred by Nietzsche), suggests an extreme sensitivity. Resentment is a 'reactionary' emotion, a bitter but frustrated response to slights, humiliation or oppression, 'submerged hatred, the vengefulness of the impotent'. In Nietzsche's view, resentment is the mark of \*slave morality', a rejection of what is noble and exceptional. As such,

it originated with and still defines the Judaeo-Christian tradition. According to Nietzsche: 'the noble man lives in trust and openness with himself, the man of *ressentiment* is neither upright nor naïve nor honest and straightforward with himself. His soul squints' (*On the Genealogy of Morals*).

Early in the twentieth century, the phenomenologist Max Scheler took on Nietzsche's psychological attack and denied that resentment was essential to Christianity or Judaeo-Christian morality. He did not, however, question the degrading status of resentment. He only shifted its locus, to the bourgeoisie. More recently still, and in a very different vein, P. F. Strawson has intricately examined the extent to which resentment presupposes free will, and John Rawls, in his *Theory of Justice*, suggests that resentment (as opposed to envy) carries with it a presupposition of \*equality and, as such, is related to our sense of \*justice.

**residues, method of:** see method of residues.

**respect.** 'Respect' is a term which has become central to the Western moral outlook since the Enlightenment. It is basically an attitude or a special kind of feeling. If we consider the deference which might be thought appropriately directed to someone of great creative ability or perhaps to a great statesman, we can say that it was the moral insight of the Enlightenment, perhaps especially that of Kant, to suggest that such deference should be accorded to persons as such. In other words, respect is an attitude of deference, or reverence, directed at persons not just for their individual gifts or status, but for being the kind of creatures they are. Kant is often rightly criticized for taking an unduly narrow view of the nature of persons by restricting it to the rational side of human beings. But he also used a more appropriate term for the object of respect—'human dignity'. Respect is not simply a transitory feeling, but, in Kant's obscure phrase, it is a feeling 'self-wrought by a rational concept'. In other words, it has both the stability of reason and the motivating force of feeling. As such, respect can plausibly be depicted as expressing the moral attitude which is basic to liberal democracy.

Nevertheless, there are two problems with the term 'respect'. First, the object of respect easily slips from human dignity to human decisions. Yet what is it to 'respect a decision'? Many writers, e.g. on bioethics, take 'respecting an autonomous decision' to mean that they must agree to it or follow it, otherwise they are violating the autonomy or human dignity of the person. More plausibly, other writers take 'respecting a decision' to mean 'taking that decision into account, or taking it seriously'. This ambiguity can have unfortunate consequences. The second problem which arises over the word 'respect' is that it tends to make morality a human-centred affair; only human beings are thought to possess the 'moral status' of

dignity. But there is no reason why the attitude of respect or reverence should not also be accorded to animals and indeed the environment. Just as respecting persons means treating them appropriately in terms of the kind of creatures they are—namely, creatures with an essential dignity—so treating animals or the environment with respect means treating them according to their essential nature. Perhaps this is all too abstract to generate moral policies but it does identify a basic moral attitude. R.S.D.

P. Taylor, *Respect for Nature* (Princeton, NJ, 1986).

**responsibility.** A term which covers a number of distinct but related notions, among the most important of which are causal responsibility, legal responsibility, and moral responsibility. To be causally responsible for a state of affairs is to bring it about either directly or indirectly, e.g. by ordering someone else to bring it about. To be legally responsible is to fulfil the requirements for accountability under the law: either the requirements for having a legal obligation, or the requirements for liability to the penalties for a particular offence (which may, but need not, consist in failing to fulfil a legal obligation). The term 'moral responsibility' covers (i) the having of a moral obligation and (ii) the fulfilment of the criteria for deserving blame or praise (punishment or reward) for a morally significant act or omission. These two notions of moral responsibility are linked, in that one can be deemed blameworthy for failing to fulfil a moral obligation. (In what follows, 'moral responsibility' will be used in its blame-deserving sense, and 'legal responsibility' in its penalty-warranting sense.)

Although there are connections between the three main kinds of responsibility, they are not necessary ones. Thus while causal responsibility is usually a criterion for legal responsibility, there are 'vicarious liability' offences with which someone can be charged without having either caused or foreseen the event in question. (For example, a tavern-keeper can be charged if, without his knowledge, an employee sells alcoholic drinks after hours.) And although causal responsibility is usually considered an essential criterion for moral responsibility, a person can be held morally responsible for deliberately *failing* to act. Since not all legal offences are moral wrongs and not all moral wrongs are legal offences, a person who is morally responsible may not be legally responsible and vice versa. On the other hand, one essential requirement for moral responsibility, that the wrong-doer should have known what he was doing and been willing to do it, is, apart from 'strict liability' offences, also essential for legal responsibility. (Bigamy and dangerous driving are examples of strict liability offences.)

The belief that, in order to be liable for \*punishment or deserving of blame, the legal or moral offender needs to have been in the state of mind described above is connected with the belief that such offenders need to be

'responsible' in yet another sense, namely that of possessing the general ability to understand what they are doing and to control their behaviour. The term 'diminished responsibility' is linked with this sense of 'responsible'.

Finally, there is one more commonly used notion of responsibility which, following H. L. A. Hart, can be called that of 'role responsibility' (see his book *Punishment and Responsibility*). This refers to the duties (often culturally determined) which are attached to particular professional or societal or (as in the case of parents) biological roles. Failure to fulfil such duties can expose the role-holder to censure which may—depending on what the roles and duties are—be of a moral or legal kind.

It is in connection with moral responsibility that the \*free will–determinism debate has traditionally arisen between compatibilists, who believe that such responsibility is compatible with the truth of \*determinism, and incompatibilists, who deny this. Incompatibilists hold that if determinism is true, then no one can be morally responsible, although they acknowledge that people may be treated as if they were, perhaps for consequentialist reasons, such as the need to deter, or to protect others. M.K.

\*compatibilism and incompatibilism; desert.

**responsibility, collective:** see collective responsibility.

**retribution:** see desert.

**revaluation of values:** see transvaluation of values.

**revelation.** The self-disclosure of God to humanity. The body of theological fact which God allows human beings to know unnaturally, especially through his 'mighty acts' (*magnalia Dei*) Acts 2: 11. Revealed theology is distinguished from \*natural theology. Aquinas distinguishes sharply between 'truths of reason' and 'truths of revelation' in knowledge of God. Karl Barth thinks that revelation is a necessary condition for any human knowing of God.

Revelation is the last book of the New Testament, authored by St John the Divine (who is almost certainly not St John the Apostle). A series of vivid visions is related, culminating in the pouring out of the wrath of God from seven bowls (14–16) and the defeat of Satan (19ff.), followed by the general resurrection of the dead and the judgement of souls. Revelation raises difficult metaphysical issues: How can a benevolent God be wrathful? What has to exist if good and evil exist? What makes some resurrection my resurrection? What is \*heaven? Do angels exist? s.p.

Aquinas, *Summa Theologica* (London, 1963–75).

**revenge.** The intentional infliction of \*punishment or injury in return for a wrong to oneself or one's family or close friends. (Compare 'vengeance', which is the satisfaction of such an intention, and 'avenge', which is to take revenge on behalf of someone else who cannot do so for him- or herself.) Revenge and vengeance have a long and controversial history in the development of retributive justice. In Homeric Greece, 'revenge' and 'justice' were more or less equivalent, but Plato's Socrates taught that 'the return of evil for evil' is always unjust. The Hebrew Bible describes a 'vengeful God' and prescribes 'an eye for an eye' (a limitation of vengeance, not an exhortation), while the New Testament encourages forgiveness, and reserves vengeance for a loving God. Modern social philosophy generally rejects the very idea of revenge as irrational and always unjustified. But among those philosophers who still defend the idea of \*retribution (as opposed to deterrence and rehabilitation), the line between revenge and retribution is not obvious. Immanuel Kant declares the latter justified and required by reason, but he dismisses the former entirely. Robert Nozick similarly suggests that revenge is emotional and merely personal, while retribution is justifiable and impersonal. In fact, revenge is sometimes justified and often deliberative, and it is a much debated question to what extent revenge should be part of the purpose of punishment in the criminal law. Nor should revenge be viewed as simply a raw, unreasonable emotion. Revenge is a dish, says one ancient proverb, which is 'best served cold'.

**revisionary metaphysics.** A term coined by P. F. Strawson to describe the philosophical efforts of Descartes, Leibniz, and Berkeley, who are contrasted with the practitioners of \*descriptive metaphysics. Revisionary \*metaphysics is said to substitute for the actual structure of the world a picture of one which is aesthetically, morally, emotionally, or intellectually preferable. The charge that philosophical systems are so many well-organized and pleasing fictions is anticipated in numerous earlier accusations of the visionary character and distance from experience of all metaphysics. Each is nevertheless deserving of study, Strawson maintained, on account of the 'intensity of its partial vision' and its utility as a source of philosophical puzzles.

The existence of revisionary metaphysics depends upon a metaphysical confusion between 'is, really' and 'ought to be', and between logical and existential concerns. Yet the satisfactions it supplies ensure that revisionary metaphysics remains a permanent temptation of philosophy, not simply a useful term for historical analysis. CATH.W.

**revolution.** A radical political upheaval or transformation. Originally understood through an astronomical metaphor, revolutions were cyclical processes moving through four stages: tyranny, resistance, civil war, and restoration. In modern times, the term has shed that reference and come to designate a change in constitution, regime, and social order. The change is intentional and programmatic, undertaken on the basis of an ideological argument painting the old regime as tyrannical, corrupt, or oppressive, promising a new age, and justifying the (usually high) costs involved.

Revolution should be distinguished from *coup d'état*, where only the rulers are changed, not the system as a whole ('palace revolution' is a *coup* in a monarchist or autocratic *état*), and also from secession and national liberation, where the goal is independence from foreign rule, not or not necessarily a radically new state and society. Hence, the justifications for revolutionary politics, once the cyclical metaphor is dropped, must extend beyond a catalogue of the crimes of a particular ruler or set of rulers, domestic or foreign. If they are to justify what needs justifying, they will have to include a detailed defence of the proposed new regime and a description of the transformations this regime will effect in society as a whole. A struggle for independence can be called revolutionary only when its protagonists defend their enterprise in this large way, aiming, like eighteenth-century Americans, at a 'new order for the ages'.

Given the scope of the changes promised, the newness of the 'new order', revolutionary politics is sometimes described as a form of secular messianism, a reproduction in political terms of Jewish and Christian visions of the end of days. Certainly, revolutionaries sometimes adapt and use religious rhetoric, but their programme, while necessarily radical in relation to the old regime, is not necessarily radical in relation to the whole of human history. It can and often does describe a particular system of oppression, not a fallen humanity, and a particular set of transformations, not a singular and universal redemption.

Nor is it the case that the transformations must be given a redemptive form in order to justify the costs of overthrowing the old regime and building the new. The standard defence of revolutionary violence probably has more to do with the supposed entrenchment of established ideologies and practices and the strength and stubbornness of the established rulers than with the glories to come. Unhappily, this defence often finds continuing uses after the overthrow of the old regime, when ideologies and practices persist and are sometimes upheld with a new stubbornness by ordinary men and women. The subsequent course of revolutionary politics is largely determined by the relation of the programmatically committed leaders (the 'vanguard') to their own increasingly reluctant followers. The hardest question for the leaders (it probably is not hard for anyone else) is whether rule by

violence is morally permitted or politically prudent during this period. How much can revolutionary aspiration justify?

A modest answer to this last question ('not much') points toward a reformist rather than a revolutionary politics. Or, perhaps, it points toward what has been called a 'long revolution', where the radical programme is maintained but a systematic effort is made to hold down the costs of achieving it. But most revolutionaries would probably argue that the changes they intend require a historical break—the total defeat of the old regime and the seizure of power by people like themselves—and in fact justify the attendant costs. M.WALZ.

**revolutions, scientific.** An idea most closely associated with Thomas Kuhn, scientific revolutions are shifts from one scientific paradigm to another, where a paradigm is a fundamental research framework that provides common methods, theories, and shared interpretations. Revolutions happen because problems arise that resist solution by methods of the existing paradigm. If the failure is perceived as serious, a crisis can arise, an alternative paradigm will be constructed, and a large-scale transition to a new paradigm may occur. Well-known examples are the change from classical mechanics to relativistic mechanics, and rule-based artificial intelligence to neural nets. Kuhn held that revolutions were discontinuities in science—paradigms are \*incommensurable, the shift is not based on rational inference from data, and cumulative progress towards the truth is destroyed. Historically, the thesis is contentious; Kuhn's historical sketches suggest less continuity than was actually present. Philosophically, the issue is arguable; one's theories of reference and meaning play a crucial role in whether the necessary semantic discontinuities exist. P.H.

Thomas S. Kuhn, *The Structure of Scientific Revolutions*, 3rd edn. (Chicago, 1996).

**rhetoric.** The art of making speeches. Learning rhetoric was prized in the Greek democracies as a means to success in public life, but criticized by Plato for being concerned with the means of persuasion, not with the ends. Aristotle's *Rhetoric* contains a fairly systematic discussion of forms of rhetorical argument (notably the \*enthymeme). For the Stoics, rhetoric became a branch of logic, and a proper study for philosophers. R.J.H.

G. A. Kennedy, *The Art of Persuasion in Greece* (London, 1963).

**Richard's paradox**, due to Jules Richard, arises from the assumption that expressions of (say) English which denote numbers can be enumerated in an alphabetical (infinite)

list *L*. If so, then a diagonal number—one differing from the *n*th number in *L* at its *n*th decimal place—can be defined (as in Cantor's proof that the reals are non-denumerable) in a finite number of English words. But then this phrase must be in list *L* as, say, entry *k* and thus must define a number differing from the one it does define, at the *k*th place. This contradiction shows there is no such list *L*. There is an enumeration of all finite strings of English letters. But whether such a string defines a number cannot be specified recursively. J.C.

Jules Richard, 'Les Principes des mathématiques et le problème des ensembles', *Revue générale des sciences pures et appliquées* (1905); tr. in J. van Heijenoort (ed.), *Source Book in Mathematical Logic 1879–1931* (Cambridge, Mass., 1964).

**Ricœur, Paul** (1913– ). French philosopher and theorist of symbolic forms. Ricœur's project since the 1950s has been to mediate in the 'conflict of interpretations' that has grown up among the various schools of linguistic, hermeneutic, and literary-critical theory. His earliest writings were mainly concerned with the debate between \*phenomenology and \*structuralism, the one aimed towards interpreting language in its creative (i.e. symbolic, metaphorical, or artistic) manifestations, the other premised on a formal methodology that took for granted, following Saussure, the priority of code and system over expressive content. This work often had a markedly theological cast, most evident in books (like *The Symbolism of Evil*) where Ricœur sought to establish links between present-day schools of thought and their various precursory movements in the history of Jewish and Christian exegetical tradition. If there is one major theme that has preoccupied his thinking since then, it is the idea that all interpretation partakes of a double ('negative' and 'positive') hermeneutic. Such is the argument of his book *Freud and Philosophy*. On the one hand psychoanalysis involves an 'archaeology' of meanings, motives, and desires, an attempt to delve back into the unconscious layers of repressed or sublimated memory. On the other—on its forward-looking or redemptive side—Freud's project points a way *through and beyond* that condition by offering the patient renewed possibilities of self-knowledge and creative fulfilment.

Ricœur finds a kindred dialectic at work within Marxist and other politically orientated theories of interpretation. Here also there is a negative (demystifying) moment of *Ideologiekritik*, joined to a positive—implicitly utopian—hermeneutics of transcendence. Given this approach, it is understandable that Ricœur should avoid the kinds of polarized thinking and attendant polemics that have characterized so much recent debate. But he does take issue with structuralism and \*post-structuralism for what he sees as their relentlessly negative stance with regard to questions of meaning, subjectivity, and truth. His recent works on metaphor and narrative again show Ricœur treating these issues through a dialogue that patiently engages all sides to the dispute while seeking a perspective atop their (often sterile) antinomies. **right**. What it is right to do, as distinct from what it is good to do. One of the traditional problems of moral philosophy is that of relating the right and the good. For the utilitarian, or more generally the consequentialist, the right is instrumental in bringing about good in the form of the best possible consequences. Other philosophers, deontologists, have held that at least some actions are right for reasons intrinsic to their own natures, and independently of 'the good'. Yet it seems hard to accept that the right has no relation to 'the good'. One solution is to suggest that the right is indeed a means to 'the good' though not an external, instrumental means as the utilitarian suggests, but an internal, component means: the very performance of the right or of duties is itself an expression of 'the good'.

R.S.D.

\*deontology; moral philosophy, problems of; right action; utilitarianism.

W. D. Ross, *The Right and the Good* (Oxford, 1930).

**right, the political:** see conservatism.

**Right, the political New.** Vague label for cluster of political doctrines emerging from \*conservatism and contrasting with it in their demand for radical change. New Right thinkers believe that political decline can be arrested only by encouraging individual initiatives and competition. This requires a reduction in the welfare provision and redistributive taxation which characterize the state influenced by \*socialism. The resulting emphasis on a minimal state distinguishes the New Right from Fascism and pushes some thinkers (e.g. Nozick) towards \*libertarianism. However, the New Right embraces \*nationalism, sometimes based, like its \*individualism, on a form of \*social Darwinism. P.GIL.

\*liberalism.

Norman Barry, *The New Right* (London, 1987).

Ted Honderich, *Conservatism* (Harmondsworth, 1990).

**right action.** No subject is more central to moral philosophy or ethics than that of right and wrong action. Although the correlative terms 'right' and 'wrong' have important non-moral uses—as, for example, when we speak of the right or wrong way to fix a car—ethicists are primarily interested in moral right and wrong, and they typically regard a theory of right and wrong in this sense as the most important element in any overall conception or view of ethics.

To be sure, there are related notions like \*'ought' and 'moral \*obligation' that play a role in any complete or overall moral theory. But it is usually assumed that such notions can be defined in terms of rightness and/or wrongness (though the definitions could also proceed in

the reverse direction). Roughly speaking, an act is (morally) obligatory or ought (morally speaking), to be done if it would be wrong not to perform it, and so a theory of right and wrong is tantamount to a theory of obligation and of what morally ought to be done. (The question whether moral goodness and praiseworthiness can also be understood in terms of rightness and wrongness is much more difficult, and some philosophers would hold that explanation should work in the opposite direction, with so-called 'deontic' notions like obligation, right, and wrong being understood as derivative from 'aretaic' notions like goodness, badness, and admirability. (\**Aretē*.)

Of course, one in any event needs to distinguish theories or conceptions of right and wrong (or of moral goodness) from analyses or definitions of the terms 'right' and 'wrong' (or 'morally good'). During the heyday of Anglo-American meta-ethics, philosophers were often on principle more interested in defining ethical notions than in offering a substantive view of what actions are right and what actions are wrong. And one can, therefore, be an emotivist, or prescriptivist, or naturalist about the meaning of (sentences or assertions involving) the terms 'right' and 'wrong', without taking sides on various issues having to do with what actually is right or wrong. But over the longer history of philosophy and certainly nowadays as well, a greater interest has been taken in giving a substantive account of rightness, as opposed to simply defining the term, and there currently are and always have been a great many opposing views about what rightness, i.e. the moral rightness of actions, substantively amounts to. (One can also talk about right attitudes and right desires, but moral philosophers have paid much, much more attention to what makes actions right.)

To a large extent, philosophers' views about right action(s) have depended on what they wanted to say about moral rules and principles. It is natural to think of morality as some kind of code containing action-guiding rules or principles and thus to think of valid morality or the true morality philosophers are seeking to formulate or describe as consisting in an appropriately ordered set of such rules or principles. Then different theories of right action would be based in differences about what were the ultimately valid principles or rules of morality. Act-utilitarianism in one standard form holds, for example, that there is one basic principle of morality, the principle of utility, which treats actions as right or wrong depending on whether they maximize the utility or welfare of the people (or sentient creatures) they affect. By contrast, Rossian intuitionism accepts a small set of basic moral principles no one of which always takes precedence over any other and regards (our knowledge of) the rightness or wrongness of particular acts (I don't think we need here distinguish actions from acts) as often a matter of delicate balancing among the different ultimate principles that apply in a given situation.

However, such a picture, though it covers most cases, is somewhat misleading as a general account of what is at

stake in theories of right action, because there are some theories, notably Aristotle's, according to which knowledge of right and wrong is not a matter of applying or weighing or balancing general moral rules or principles. The virtuous individual, for Aristotle, is capable of knowing what is right in particular circumstances by delicate perception unaided by general (even *prima facie*) principles. It is also worth pointing out that some principles of right or permissible action are not rules for the guidance of individuals *in situ*. If it is morally permissible or one has the moral right to defend oneself against deadly force, that is a right one has even and especially in situations where one is too threatened to be paying any attention to moral issues or principles. A theory of right and wrong action is not necessarily a theory of what principles should guide one in daily life, and utilitarians, for example, are fond of saying that the principle of utility is a valid *standard* of right action, but not a reasonable or useful moral guide for people to use in the course of daily life. People may be more likely to do what maximizes utility, and thus to live up to the principle of utility as a standard of moral evaluation, if they don't try to maximize utility, but instead, for example, try to help those they love or those whose distress or need immediately assails them.

Having mentioned Aristotelian, intuitionist, and utilitarian views of right action, we should complete the overview of the main competing contemporary conceptions of right action by saying something very briefly about Kantian, contractarian, and agent-based virtue-ethical theories of moral rightness. The last of these treats the rightness of actions as a matter of the motives or inner states of character they express or sustain, acts counting as right if and only if, for example, they come from sympathy or compassion or inner health or strength. Contractarians treat right action as a matter of conformity to the principles or rules that people would agree upon in some hypothetical or ideal bargaining situation. Finally, Kantians regard the rightness of an action as a matter of whether the maxim or underlying purpose of the action is one which could be consistently willed (or imagined) to govern *everyone's* behaviour—though some Kantians may prefer to say, instead, that acts are right if they don't involve treating anyone merely as a means, which idea has seemed promising to many, but is quite obviously in need of expansion. All the above-named theories have sizable or at the very least vocal followings among contemporary philosophers. M.S.

**rights.** In their strongest sense, rights are justified claims to the protection of persons' important interests. When

the rights are effective, this protection is provided as something that is owed to persons for their own sakes. The upholding of rights is thus essential for human dignity.

Although Wesley N. Hohfeld distinguished four different meanings of 'a right'—claims, liberties, powers, and immunities—claim-rights are the most important kind of rights because they entail correlative necessary duties to forbear from interfering with persons' having the objects of their rights or, in some situations, to help persons to have these objects. The general structure of a claim-right is given by this formula: *A* has a right to *X* against *B* by virtue of *Y*. There are five main elements here: first, the subject (*A*) of the right, the right-holder; second, the nature of the right; third, the object (*X*) of the right; fourth, the respondent (*B*) of the right, the duty-bearer; fifth, the justifying ground (*Y*) of the right.

Two problems about 'redundancy' are answered by reference to this formula. First, although rights are correlative with duties, rights are not redundant because their objects are benefits to the right-holder, while duties are burdens of the respondent. Second, rights cannot be dispensed with in favour of benefits or interests, because having a right adds that there is strong justification for being protected in one's benefit or interest, such that the right-holder is personally entitled to have the benefit as his due and for his own sake (as against utilitarian justifications).

The 'benefit theory' of the nature of rights emphasizes the relation between the subject and the object of rights: to have a right is to be the directly intended beneficiary of someone else's performance of a good-providing duty. The 'choice theory' emphasizes the relation between the subject and the respondent: to have a right is to be in a justified position to determine by one's choice how other persons shall act. There are arguments for and against each theory; the most acceptable account involves some combination of the two theories.

Legal rights, to be justified, must ultimately have moral justification. Because of the normative necessity involved in claim-rights, their primary justification must be found in their having as objects the goods that are necessary for human action or for having general chances of success in achieving one's purposes by action. The two main such goods are \*freedom and \*well-being, which are, respectively, the procedural and the substantive necessary conditions of action and of generally successful action. Well-being, which consists in having the general abilities and conditions needed for achieving one's purposes by action, falls into a hierarchy from life and physical integrity to education and opportunities for earning wealth and income. All actual or prospective agents have equal moral rights, positive as well as negative, to freedom and well-being; a cogent argument can be given for the moral principle that grounds this thesis. (\*Liberty.) The argument shows that every actual or prospective agent logically must accept that he and all other agents have these rights because of their enduring needs for the necessary conditions of their action and generally successful action.

Conflicts of rights can be resolved by consideration of the degrees of their objects' needfulness for action. Although \*utilitarianism can 'accommodate' rights, in that it can require that special protection be provided for persons' interests and needs, this protection would be only contingent because it would be owed to persons not for their own sakes but rather as means to the maximization of utility, so that the rights could be overridden whenever such maximization required this. On the other hand, the universality of human rights requires that each person act with due regard for other persons' freedom and well-being as well as her own.

\*ad hominem argument.

**Roman philosophy.** The distinction between ancient Roman philosophy and the Greek tradition from which it sprang and which continued alongside it can only be partial; the same is true of many other aspects of ancient Graeco-Roman culture. The term Roman philosophy will here be taken to apply (i) to philosophical writing in Latin from the beginnings to the sixth century AD, and (ii) to works which, whether in Greek or in Latin, reflect distinctive developments in the Stoic school after the Roman conquest of Greece. Here the label 'Roman' is partly a chronological one, but it also reflects distinctive emphases characteristic of Roman philosophy more generally.

Greek philosophy was initially seen as subversive of Roman customs; philosophers were expelled from Rome in 173 and 161 BC, and the \*scepticism of Carneades, who visited Rome in 155 BC, angered the elder Cato, as did other Greek cultural imports. Later in the century the Stoic Panaetius was an associate of Scipio the Younger. Philosophical writing in Latin began in the next century, with Epicurean prose writings (now lost, and scorned by Cicero), Lucretius' Epicurean poem, and Cicero's own philosophical works. The popularity of \*Epicureanism prompted Cicero to attack its recommendation of withdrawal from public life as the antithesis of Roman civic duty. In the politically unsettled times of the late Republic and early Empire there was interest in the astrological and numerological aspects of neo-\*Pythagoreanism.

Panaetius' concern with those progressing towards virtue rather than having arrived at it, with the importance of positive action, and with the relevance to ethics of individual personality have been seen as an adaptation of \*Stoicism to practical Roman interests. The extent of his divergence from earlier Stoicism has sometimes been exaggerated. Once Roman philosophy proper developed, there was an emphasis on ethics and on man's relation to the gods. Cicero himself inclined not to the Stoa but to the \*Academy—whether the epistemological scepticism of the New Academy or the more dogmatic ethics of Antiochus—but he developed the Stoic theme of the universe as common home of gods and men, and made it the basis for a theory of \*natural law. He also applied Academic suspension of judgement to theology and divination; here it should be remembered that, for ancient \*Sceptics, denial of certainty about religion, or anything else, was neither a dogmatic assertion of disbelief nor inconsistent with continuing traditional observances.

In the first century AD Stoicism became identified with the senatorial opposition to the emperors; by the second century AD there had been such a change that one of the emperors, Marcus Aurelius, is himself counted as a leading Stoic writer. Marcus, like his fellow Stoic the former slave Epictetus, wrote in Greek; Seneca, the Stoic tutor of Nero, had written in Latin. Their writings are alike characterized by concern with the practical aspects of ethics and psychology, including the notion of the \*will as distinct from the \*understanding—a specifically Roman contribution later given its fullest development in antiquity by Augustine. There is also a new stress on the divine element in each individual as the true self.

Roman philosophy was, however, still only the junior partner in the Graeco-Roman philosophical enterprise. Platonists such as Plutarch, \*Peripatetics, and Sceptics continued and developed their traditions in the first two centuries of the Empire, but, unlike the Roman Stoics, hardly count as 'Roman philosophers'; nor in the third century AD does Plotinus, the founder of \*Neoplatonism, even though Rome was where he taught. In the later Empire 'Roman philosophy' most naturally indicates that minority of philosophers who wrote in Latin; above all Augustine, and, after the western Empire had already

fallen, Boethius. Boethius began by translating and interpreting Aristotle's logic in the Neoplatonic tradition; but in the *Consolation of Philosophy* he not only gave moving literary expression, drawing on Platonic and Stoic ideas, to belief in divine providential concern and the powerlessness of wicked rulers to harm good men, but also developed a solution to the problem of reconciling divine foreknowledge and human freedom (to God all time is as the present: so his foreknowing what I will do no more removes my freedom than your seeing what I am doing now) which improved on its Greek Neoplatonist origins and was taken over by Aquinas seven centuries later.

The question why Roman philosophy has in general been less significant than Greek can be approached in more than one way, like the definition of Roman philosophy itself. On one level there was simply less Roman than Greek philosophical activity, even in the period of the Roman Empire; on another, both Greek and Roman philosophy in that period were characterized—as was much else in the culture of the time—by looking back to earlier thinkers as models, the commentary and the scholastic compendium being the characteristic forms of writing. But the contribution of Roman philosophy as here defined to the European tradition should not be underestimated.

**romantic irony:** see irony, Romantic.

**romanticism, philosophical.** The idea of Romanticism is at once indispensable and embarrassing to cultural historians. They cannot do without it; something is needed to distinguish Pope from Wordsworth, David from Delacroix, Handel from Beethoven. But they are acutely worried by the problem of defining it, which they create for themselves. Like most interesting general terms applying to human affairs, and unlike 'prime number' or 'nitrous oxide', it is not definable in a short formula made up of precisely demarcated terms. That is not necessarily a fault. Romanticism is a cluster of attitudes and preferences each of which is usually to be found with a good number of the others and, in extreme cases, with most, or even all, of them.

The Romantic favours the concrete over the abstract, variety over uniformity, the infinite over the finite, nature over culture, convention, and artifice, the organic over the mechanical, freedom over constraint, rules, and limitations. In human terms it prefers the unique individual to the average man, the free creative genius to the prudent man of good sense, the particular community or nation to humanity at large. Mentally the Romantic prefers feeling

to thought, more specifically, emotion to calculation, \*imagination to literal common-sense, intuition to intellect. This fairly coherent array of preferences is fleshed out in all sorts of specific ways: in literature, art, and music, in moral conduct and moral convictions, in religion, in politics, in the writing of history and, not least, in philosophy.

Kant created philosophical romanticism, although he was himself only very marginally and partially a Romantic. His most important contribution was inadvertent: the idiosyncratically expressed distinction he drew between \*reason and \*understanding. Kant was critical of the pretensions of what he called reason, partly for the more or less Romantic purpose of 'making room for faith', but also in the interests of the understanding, to which, in conjunction with the senses, is due, he held, all our substantial knowledge of the world. That does not make him an anti-rationalist in any ordinary sense of the word, and his ethics are even more narrowly rationalistic, since for him the supreme principle of morality is an a priori necessary truth. In the same spirit, the only kind of intuition he allows for is sense-perception. The direct apprehension of what transcends sense-experience is merely the 'dreams of a ghost-seer'.

The German Idealists who came after Kant, notably Fichte, Schelling, and Hegel, accepted his distinction between reason and understanding, but reversed the value he had ascribed to them. They saw understanding, the intellect as it works in science and everyday life, as an inferior faculty supplying useful, but distortedly abstract, opinion about fragments torn from reality for practical purposes. Reason, on the other hand, was for them intellect in its highest form as an apprehension of the totality of things in their essential interconnectedness. Coleridge, who studied Kant, Fichte, and Schelling, and lavishly borrowed from the last of them, applied their way of distinguishing reason from understanding in his own distinction between imagination, the 'esemplastic' or unifying power which fuses things together, and fancy, which merely juxtaposes 'fixities and definites'.

Non-philosophical Romanticism disdains ordinary \*rationality as a practical makeshift for the earth-bound, yielding only a truncated, superficial, and distorted picture of the world as it really is. The directly intuitive, even mystical, apprehension of the world which we owe to poets and other such creative geniuses does not stand in need of any reasoned support or articulation. A philosophical Romantic cannot be so easygoing. He has to provide the conception of the world as some kind of spiritual unity with rational credentials. These are supplied by Fichte's notion of the \*dialectic, conceived as a progressive surmounting of oppositions or contradictions and which is best known as the organizing principle of the philosophy of Hegel.

The essentially Enlightenment character of Kant's thought is shown in his rigoristic, petty bourgeois moral outlook, in his liberal, pacific, and internationalist politics, and in his religion, unencumbered with Gothic detail or liturgical tradition. The \*nationalism of Fichte and Hegel,

taking off from the more moderate celebration of cultural nationality by Herder, is another and altogether more Romantic matter. Kant was much affected by Rousseau, whose distinction between the organic general will and the mechanical will of all can properly be seen, as it was by Hegel, as another application of the reason-understanding distinction. **Romero, Francisco** (1891–1962). Argentinian philosopher, born in Seville, Spain. He began his career in the military, but taught philosophy from 1930 until his death in 1962. Romero's *Teoría del hombre* (1952) displays the influence of Max Scheler and Nicolai Hartmann. In it he develops a systematic \*philosophical anthropology within the context of a metaphysics of \*transcendence. According to Romero, reality includes physical, organic, intentional, and spiritual levels and is arranged hierarchically by degrees of transcendence. Physical objects are devoid of psychic life, whereas animals are characterized by a pre-intentional psychism but lack self-consciousness. \*Self-consciousness appears at the level of \*intentionality with man; he alone is able to view the world in terms of himself. Man reaches the level of the spiritual when he achieves absolute objectivity. The duality resulting from the merging of the intentional and spiritual levels of reality is what characterizes man. Marjorie Silliman Harris, *Francisco Romero on Problems of Philosophy* (New York, 1960).

**Rorty, Richard** (1931– ). American philosopher of mind and, subsequently, notable critic of the pretensions of traditional epistemology. Rorty did his first degree at Chicago, got a doctorate at Yale, and taught at Princeton between 1961 and 1982, in which year he moved to the University of Virginia, significantly as Professor of Humanities. He began as an able, but fairly conventionally analytic, philosopher, until the publication in 1979 of his *Philosophy and the Mirror of Nature*, whose vigorous repudiation of the idea that it is possible to pass judgement on our beliefs from some objective, transcendental standpoint excited wide attention.

Rorty's central idea, in its main outlines, repeats the objection of nineteenth-century idealists to the \*correspondence theory of truth; that there is no access, except through other beliefs, to the facts in correspondence to which the truth of our beliefs is supposed to consist. Rorty found support for this rejection of any secure touchstone or foundation for knowledge partly in the pragmatist tradition and partly in recent developments tending in the

same direction: Sellars's attack on the 'myth of the given' and Quine's attack on analyticity.

He pushed his critique of the idea that there are firm foundations from which epistemology can authoritatively pass judgement on beliefs in general to something like the extreme point of Derrida's rejection of the 'metaphysics of presence', which holds not only that there are no absolute foundations, but that no belief is more fundamental than any other. The implication he draws is that philosophy cannot establish anything and that it should be understood as a, possibly edifying, conversation, with the same sort of claim to finality as the conversations of cultural and literary critics. Heidegger, Wittgenstein, and Dewey are invoked as a kind of pantheon for this undermining of the conception philosophers have ordinarily held of their philosophical activity.

**Rosenzweig, Franz** (1886–1929). Jewish philosopher. On the point of following his cousin Rosenstock-Huessy into Christianity, Rosenzweig found that he could turn Christian only 'as a Jew'. He attended the Day of Atonement service (1913) at a traditional Berlin synagogue, discovering, to his wonder, the spirituality of his ancestral faith. Sustained study of the Jewish sources and of Hermann Cohen's work led him to the philosophical Judaism of *The Star of Redemption*, begun on postcards mailed from the Front in 1915–16. There he argues that God, world, and man cannot be explained from (or reduced to) one another but are linked in a dialogue of \*I and thou (a phrase derived from Feuerbach's critique of Hegel), by 'paths' of creation, revelation, and redemption, as if forming a shield of David, the six-pointed star of his title. Creation gives being, but also transitoriness. It is complemented by revelation, which brings man to his true self. Man responds to God's love with a love of God, which he translates into love of his neighbour, helping to lead the world to redemption. Rosenzweig's two-volume study of Hegel's political thought (1920) and his translations of Halevi's poetry and (with Martin Buber) of the Hebrew Bible show the poles that orientate him. Of the story of Balaam's ass, he said that through the year it is a fairy-tale, but when read from the scroll on the appointed Sabbath it contains the word of God speaking directly to him.

**Ross, William David** (1877–1971). Oxford philosopher and scholar. An outstanding Aristotelian and Platonic scholar, his main original, and still influential, contribution to philosophy was in ethics. Ross accepted G. E. Moore's argument that any equation of intrinsic good with a natural property commits the '\*naturalistic fallacy'.

However, Ross argues that Moore committed a similar fallacy in equating the rightness of an action with its maximization of good. That we ought always to maximize good is a synthetic and, in fact, false proposition. We have a number of distinct prima-facie \*obligations, of which this is only one and not always the most stringent. An act may be prima facie obligatory for a number of different reasons, and is *absolutely* right if the prima-facie obligation to do it is the weightiest. His attack on \*consequentialism and notion of a *prima-facie* moral obligation has had an enduring influence.

**Rousseau, Jean-Jacques** (1712–78). Rousseau is best known for his contributions to political philosophy, with his *Social Contract* (1762) being generally regarded as his masterpiece. In that he argues for a version of sovereignty of the whole citizen body over itself, expressing its legislative intent through the \*general will, which is supposed to apply to all equally because it comes from all alike. The general will tends to promote \*liberty and \*equality, in Rousseau's view, and it both arises from and promotes a spirit of \*fraternity. Rousseau is standardly seen as one of the presiding geniuses of the French Revolution, and attracts admiration or detestation accordingly. In fact, it would seem that his ideas were merely exploited opportunistically, particularly by Robespierre. One of Rousseau's most memorable epigrams, 'Man is born free; and everywhere he is in chains' comes from the *Social Contract* and has been a rallying-cry for revolutionaries and reformers ever since.

Another central thought in Rousseau's work is that man is by nature good, but he is corrupted and depraved by society. The idea of oneself as an ill-used victim, which this seems to suggest, was certainly prominent in Rousseau's personal psychology; he suffered an acute paranoiac breakdown in the late 1760s. It is doubtful, however, that this is how he wished this thought to be taken. The sources of corruption lie in the individual's own makeup, but tend to be deepened and consolidated by social processes or envious competition and desire for precedence. It is possible, none the less, to envisage a different basis for human society and hence a different destiny for men. This is most completely explained by Rousseau in his educational treatise *Émile* (1762).

Rousseau was born in Geneva, but spent twenty years of his adult life in Paris. When he first arrived there in 1742, he hoped to find fame and fortune as a musical theorist, teacher, and composer. One delightful opera, *Le Devin du village*, performed before Louis XVI at Versailles in 1745, has survived. Rousseau had, in the mean time, made friends with members of the young Paris intelligentsia, particularly Diderot. Through this relationship, he was drawn into considering social and political issues, his other major work in this area before the *Social Contract* being his *Discourse on the Origin of Inequality* (1755). After the publication of the *Social Contract* and *Émile* in 1762, Rousseau

was persecuted for his blasphemous views about natural religion, and fled Paris. He also renounced his citizenship of Geneva, where too his books were burned. After some extremely unsettled years, he was eventually permitted to resettle in France, on sufferance, and he returned to Paris in 1770. Most of the writing of his last decade is autobiographical, including his outstanding *Confessions* but also the prolix and uneven exercise in self-justification *Dialogues de Rousseau juge de Jean-Jacques*. His body was transferred to the Panthéon in 1796.

As well as his work in social and political theory, education, and music, Rousseau wrote extensively on botany (for which he had a passion), on language, on religion, and he wrote some indifferent plays and poems. He also wrote a novel, *Julie, ou la Nouvelle Héloïse*. He continues to excite great controversy as both a theoretician and a person: as a theoretician because it is possible to see him both as a great liberator of the individual or as the apologist for populist totalitarianism; as a person because it is possible to see him as an ill-starred genius or as a self-righteous bully.

N.J.H.D.

\*human nature.

Rousseau's life is recounted by M. Cranston in a 3-vol. biography (i: *Jean-Jacques* (London, 1983); ii: *The Noble Savage* (London, 1991); iii: *The Solitary Self* (London, 1996). For a general introduction, R. Grimsley, *The Philosophy of Rousseau* (Oxford, 1973) is useful. More specialist works are J. Shklar, *Men and Citizens* (Cambridge, 1969); N. J. H. Dent, *Rousseau* (Oxford, 1988); and *The Cambridge Companion to Rousseau*, ed. P. Riley (Cambridge, 2001).

**Royce, Josiah** (1855–1916). American absolute idealist philosopher, Harvard professor. *The Religious Aspect of Philosophy* (1885) is the first, and remains one of the finest, of his many major works. Royce argues for the existence of an \*absolute mind including all finite minds as the only explanation of how thought targets objects other than by description, as it must do if there is to be such a thing as error (as there must be, on pain of pragmatic contradiction). William James's pragmatism was in part an attempt to reply by showing how thought could pick out its objects purely behaviourally. This same work also contains one of the best ever statements of the basic problem of ethics, how moral thought can have the motivating force of will and still be factual, solving it by regarding facts about will itself as peculiarly motivating. Royce was important in the development of formal logic in the USA.

\*idealism.

Bruce Kuklick, *Josiah Royce* (Indianapolis, 1972).

John E. Smith, *Royce's Social Infinite* (New York, 1950).

**rule, golden:** see golden rule.

**rule of law.** A system of governmental behaviour and authority that is constrained by law and the respect for law, in contrast to despotic rule. States respecting the rule of law typically divide the powers of government among

separate branches; entrench \*civil liberties (notably, due process of law and equal protection of the law) behind constitutional walls; and provide for the orderly transfer of political power through fair elections. All versions of political \*liberalism stress the importance of the rule of law. Elements of the idea are at least as old as Pericles' Funeral Oration (431 BC). As a modern technical term, 'rule of law' was brought to prominence by A. V. Dicey in *An Introduction to the Study of the Law of the Constitution* (London, 1885).

H.A.B.

**rules.** In general, norms which either guide or constrain behaviour or thought.

Ever since Wittgenstein, philosophers have focused their interest on the notion of rule or norm which is relevant to linguistic behaviour, in particular whether our concepts or the meanings of our words are governed by rules. Kripke's commentary on Wittgenstein has done much to revive interest in this topic.

One question that has been the focus of interest is about the source of the normativity which attaches to meaning. Some, such as Kripke and Wright, have argued that meaning has a \*normative force which it gains from the linguistic practice of the community, and others, such as Blackburn, have tried to characterize the rules of meaning in terms of the dispositions of the individual. The latter view has been criticized (by Kripke himself) for leaving out the normative element in meaning. And others have applauded Kripke for stressing the normative, but criticized him in turn for eventually abandoning it for the dispositions of the individuals who comprise the community. Every one of these philosophers has sought authority for their views in Wittgenstein.

Whatever stand philosophers have taken on this dispute, there seems to be agreement among all of them that a minimal commitment to norm and rule issues from the notion of intention that goes into \*meaning. That notion is normative in that any intention divides all behaviour into correct or incorrect in the sense that any action is either a case of fulfilling that intention or failing to fulfil it. Applied to the question of meaning, this insight, it is said, amounts to the claim that if I intend in my behaviour to apply the word or concept 'stick' to sticks, then if I ever were to apply it to a rope, say (if, for instance, I were to say 'That is a stick' pointing to a rope), then I would be doing something incorrect. Only if I applied it to sticks would I be following the rule for 'stick'.

It may be questioned whether this notion of norm is relevant to the meanings of words in this way. This is not to question whether the notion of intention is a normative one in the sense just mentioned. Rather it is questionable whether the intentions involved in meaning are properly described above. The right way to describe the intention involved in meaning is to say that I intend to use the words 'That is a stick' to say something which has certain truth-conditions or assertibility-conditions or whatever we take the meaning-giving conditions to be. In other words by 'That's a stick' I intend to say something which is true

(taking \*truth-conditions to be the meaning-giving conditions) if and only if that is a stick. But this intention is fulfilled even if I say 'That is a stick' when pointing to a rope. What is not fulfilled is my intention to say something true, but that intention is not the intention relevant to the meaning of words.

It is even doubtful whether this notion of norm is relevant to \*concepts in thoughts quite apart from words in communication. Even if I were to think the thought that that is a stick and not utter any words, it would be doubtful that I am failing to fulfil an intention that I apply my concept 'stick' to sticks only. When I think that that is a stick I do not have any intention at all to apply a concept. I intend various things with my words (however tacitly) when I speak and communicate, but it seems to misdescribe things to say that I intend to apply my concept 'stick' to sticks when I *think* that that is a stick, or even that I intend to think something with certain truth- or assertibility-conditions. I have said that something like the latter intention, but not the former, is relevant to *saying* 'That is a stick' but *neither* is operative in *thinking* that that is a stick.

If the intention involved in meaning is the intention to use words with a certain meaning, it is not clear how we could fail to fulfil this intention without failing to know what we are thinking. No doubt we sometimes fail to know what we are thinking, but that is due to self-deception and other such psychological phenomena, not due to some philosophical doctrine about the normativity of meaning. So if I cannot fail to fulfil the intention involved in meaning, it is not clear whether there is even this minimal notion of correctness and incorrectness applying to meaning. The only sense in which I seem to have done something incorrect in thinking that that is a stick in the presence of a rope is simply to have thought something false (in this case due to misperception).

But if that is the only notion of incorrectness and correctness relevant to concepts and meaning, it is doubtful that there is the philosophical significance in the notion of norms or rules that these philosophers have seen in it. A standard and widely agreed upon starting-point in all of the contemporary discussion of rules and meaning thus seems to be off base.

**Russell, Bertrand** (1872–1970). Third Earl Russell, British philosopher, mathematician, Nobel Prize-winner (Literature, 1950), civil-rights activist, and public figure. His most important philosophical works date from the first two

decades of the century, and include the magisterial *Principia Mathematica* (1910–13), written jointly with Alfred North Whitehead. In the period between the world wars, he came to public notice through some influential books about morals and mores, which he claimed were written for money. After the Second World War, he was a prominent member of the Campaign for Nuclear Disarmament (and was arrested for participating in one of their protest demonstrations), and helped initiate the Pugwash conferences, international gatherings of distinguished intellectuals, mainly scientists, devoted to discussing ways to achieve and maintain world peace. His *Autobiography* caused a stir by its selective frankness, and by the rather unattractive picture it conveyed of the great man's tardy yet intense emotional development.

Russell was a marvellously wide-ranging philosopher, and it is hard to think of an area of philosophy to which he did not contribute. His best-known philosophical work, the *History of Western Philosophy*, exemplifies this breadth of interest and understanding, and shows that no two areas of philosophy can be guaranteed to be mutually irrelevant.

His own work can be presented under three headings: first, \*philosophical logic, not so much an area of philosophy as a method which influenced most of his work; second, the foundations of mathematics; third, epistemology and metaphysics. His interest in mathematics is one of his earliest, and his main idea, which came to him towards the end of the last century and was first presented in *Principles of Mathematics* (1903), was that mathematics is simply logic. Developing this line of thought led him to fundamental questions in logic, and to the approach he was to call \*'philosophical logic', which came to colour most of his work in philosophy.

*Philosophical Logic.* A good route to philosophical fame is to found a method, for then even philosophers who disagree entirely with one's results may honour one's name by working within the method. Around 1914 Russell invented the phrase 'philosophical logic' to describe the approach to philosophy which he had already been employing for some years: recasting problematic propositions in their 'logical \*form', using a language with the formal structure of *Principia Mathematica*. His motivations were various, and not very clearly articulated. He felt that ordinary language enshrines the 'savage superstitions of cannibals' ('Mind and Matter', 143) and other errors, confusions, and vagueness, and makes it impossible to give correct expression to some fundamental philosophical truths. For example, it confuses, in the word 'is', existential quantification (as in 'Serendipity is', to be formalized using '∃'), identity (as in 'Hesperus is Phosphorus', to be formalized using '='), and predication (as in 'Socrates is human', whose 'is' vanishes into the concatenation of the predicate for humanity and the name of Socrates in the formalization 'Fα'); and it is very hard to say in ordinary language that existence is not a property of individuals. An example of the way ordinary language embodies

cannibalistic superstitions is that expressions like 'Socrates' incline us to think of people and other things as simple metaphysical substances, when they are really complexes.

The best-known application of Russell's philosophical logic is to the problem of denoting phrases. The result is a general account of quantification, including the 'theory of \*descriptions' presented, in a rather clumsy form, in the famous article 'On Denoting' (1905). The problem is how to understand such phrases as 'a man', 'every man', 'no man', and 'the man'. In his *Principles of Mathematics* (1903), Russell assumed that they should be viewed in the same way as he then thought names like 'Socrates' and predicates like 'red' should be: as standing for some entity in the world. However, it is impossible to discover an appropriate entity, and the 1903 work clearly does not succeed in doing so. The 1905 theory is that these phrases should not be regarded as having any theoretical unity. They contain a quantifier, 'some', 'every', 'no', and, on Russell's view, a quantifier attaches to a 'propositional function', like '... is happy' to make a sentence (e.g. 'Someone is happy'). A quantifier attached to a predicate like 'man' (as opposed to a propositional function) in the phrase 'some man' is not an intelligible unit of language: it is essentially 'incomplete' and 'has no meaning in isolation'. A sentence like 'I met a man' is analysed as follows: 'There is some  $x$  such that  $x$  is human and I met  $x$ '. The analysis shows that what corresponds to 'a' has become 'there is some  $x$  such that' and it attaches to the propositional function ' $x$  is human and I met  $x$ '. In the analysis there is no unit corresponding to 'a man'. (See the entry 'descriptions, theory of' for the application of the approach to phrases like 'the man'.)

To feel the full impact of Russell's work on quantification, one must recall his background assumption that the fundamental way in which a word has meaning is by standing for something. Russell held to this model for many words, simple singular and general terms, like 'this' and 'red', and it led him to a corresponding view of the world: the basic constituents, the logical atoms, are the things corresponding to such words. Quantifiers, and, if Russell is right, phrases like 'the King of France', function very differently, not standing for anything in the way that the basic words do.

The logic Russell brought to bear in his philosophical logic included the apparatus of classes, originally developed in his philosophy of mathematics, and he used this to provide logical forms within which to analyse various empirical things, like material bodies. (See the section below, 'Epistemology and Metaphysics'.)

The method of philosophical logic, though it was of great significance in the twentieth century, is now, I suspect, on the wane. Russell himself took an impish and aristocratic delight in claiming that logical forms are very different from surface forms, and that the untrained cannot be expected to appreciate the real complexity of their thoughts. More recently, concern with providing explanations of how the mind actually works has made many philosophers think that one should focus closely on the

detailed workings of natural language, rather than treating it as the confused manifestation of some more orderly underlying language of logical forms.

*Mathematics.* Russell's \*logicism in the philosophy of mathematics involves two theses: (1) Mathematical truths can be *translated* into truths of pure logic; thus mathematics has no distinctive subject-matter (e.g. numbers). (2) Mathematical truths, once presented in their proper logical form, can be *proved* by logic alone. The first claim concerns the sort of meaning mathematical statements have; the second concerns how they can be established.

The key idea behind the translation is that a \*number can be treated as a class of classes, and operations on numbers can be regarded as class-theoretic ones, definable in terms of intersection, union, difference, and so on. Thus the number one can be thought of as the class of all one-membered classes, the number two as the class of all two-membered classes, and so on. In these stipulations, number-words like 'one' and 'two' figure as adjectives, and such occurrences can be treated within pure logic by means of quantification and identity. (Thus "There are two dogs" means "Something,  $x$ , is a dog, and something,  $y$ , is a dog, and  $x$  is distinct from  $y$ , and nothing distinct from either  $x$  or  $y$  is a dog".) The addition of one and two (to take an example) is thought of as the class of classes each of which is the union of a member of one with a member of two (cases in which the member of one has a member in common with the member of two to be ignored): in other words, the class of three-membered classes.

The translation assumes that logic includes the theory of classes. In general, this can be disputed; and the dispute gained special prominence from the fact, to which Russell drew attention close to the turn of the century, that the theory of classes, at least as it was understood at that time, is inconsistent. This made it unsuitable for any serious purpose, and, *a fortiori*, unsuitable for serving as a foundation in logic or mathematics.

The inconsistency arises upon the intuitively correct supposition (called, in formal dress, the comprehension axiom) that every coherent condition determines a class. Thus it seems right to say that the condition *being a man* determines the class of men, *not being a man* determines the class of non-men, *being round and square* determines the class of things which are round and square, that is, the class with no members (the empty class). On this supposition, there should be a class,  $R$ , satisfying the condition *not being a member of itself*, a class, that is, consisting of just those things, including classes, which are not members of themselves. Is  $R$  a member of itself? If it is, then it meets the condition *not being a member of itself*, and so it is not a member of itself; if it is not, then, because it meets this condition, it is a member of itself. So there is no such thing as  $R$ ; the problem is how to reconcile this with the intuition underlying the comprehension axiom, an intuition apparently forcing us to accept that there is such a class as  $R$ .

After exploring many other roads in the early years of the century, Russell finally (1908) arrived at the view that

classes are entirely dispensable: the 'no-class' theory of classes, as he called it. The idea is that although his theory has expressions which seem to stand for classes, they do not really. This is not, in itself, enough to ensure that the kind of \*paradox illustrated by the Russell class will not arise, for a similar paradox can be formulated without mentioning classes (e.g. on the basis of the property of not being self-applicable). However, the no-class theory of classes enabled Russell to bypass the intuition underlying the comprehension axiom. In his theory of \*types, things like 'x is a man', which he called 'propositional functions', cannot be applied to themselves. The grounding intuition was that self-application involves a kind of \*vicious circle', and so can justifiably be banned, with the result that the old paradoxes could not be formulated.

In 1931 Gödel published a proof that no consistent theory like Russell's in *Principia Mathematica* (one whose axioms are recursively enumerable) has every mathematical truth as a theorem. This seems to have made Russell think that his logicism had failed. In reality, however, only one component fails, the claim that every mathematical truth can be proved by logical means. It remains open whether every mathematical truth can be expressed in purely logical terms, and whether, thus expressed, it constitutes a truth of logic; for perhaps not every logical truth is provable.

*Epistemology and Metaphysics.* Russell's most important position in this area is his logical atomism, best elaborated in his lectures of that title (1918). The basic idea is that the world is composed of things like little patches of colour, their properties, and the (atomic) facts they compose. His approach is guided by the following considerations: (1) We can non-inferentially know only what is proof against Descartes's demon. (2) A view about the nature of things which vindicates our intuition that we know the things is to be preferred to one which does not. (3) Logical constructions are to be substituted for inferred entities.

The problem of 'knowledge of the external world' presented itself to him in an entirely traditional way: 'I think on the whole the sort of method adopted by Descartes is right: that you should set to work to doubt things and retain only what you cannot doubt because of its clearness and distinctness' ('Lectures', 182). This led him to the view that enduring material objects like mountains, thought of in the ordinary way as 'substances', could not be 'retained': no adequate account of how we know about such things, thus regarded, could be provided. The first two guiding considerations thus led him to favour an alternative view of the nature of mountains, one upon which we can account for our apparent knowledge of them, and this is supplied by applying the third consideration: they are to be thought of as logical constructions out of non-inferentially known entities; more specifically, as classes whose only individuals are 'sensibilia', things which, like \*sense-data, can be known in an immediate and demon-proof way.

It is open to dispute whether this view of mountains

gives a better explanation of how we have knowledge about them than the ordinary view. A mountain is construed as a very large class of sensibilia, and no one subject's experience contains them all. Thus no subject can know any proposition of the form 'This mountain is thus-and-so' merely by knowing what sense-data he has. New principles of knowledge are involved, and these principles are no more plausible when they involve extrapolation to the existence of sensibilia with which one will never be acquainted than when they involve extrapolation to material continuants which will never themselves be directly accessible to experience.

Logical atomism involves not only an account of all individuals in terms of the atomic ones, but also an account of all facts in terms of atomic ones. An atomic fact consists of a universal combined with an appropriate number of individuals. The contrast is with a molecular fact, which is expressed by means of such logical expressions as 'and' and 'not'. Russell wanted to believe that at bottom there are only atomic facts: once these are fixed, everything is fixed. Hence there is no *sui generis* fact that 'p or q', since this obtains in virtue of the existence of the fact that p or the existence of the fact that q. However, Russell argued that general facts, though not atomic, have to be added. Suppose that there are just three cats,  $c_1$ ,  $c_2$ ,  $c_3$ , and that each is hungry. This does not guarantee that there is such a fact as that all cats are hungry. To guarantee this general fact we have to add to the fact that  $c_1$  is hungry and the fact that  $c_2$  is hungry and the fact that  $c_3$  is hungry the fact that  $c_1$ ,  $c_2$ , and  $c_3$  are all the cats there are, and this is itself a general fact. Russell was also worried that one might have to add negative facts. The fact that Socrates is not alive is guaranteed by the fact that he is dead, and perhaps this is atomic. To generalize this we would have to say something like: the existence of any negative fact is guaranteed by the existence of some incompatible fact, but 'this makes incompatibility fundamental and an objective fact, which is not so very much simpler than allowing negative facts'. However, Russell's reasoning at this point is confused. Russell is happy to use disjunction when explaining what makes disjunctions true, so he should find it legitimate to use negation, or incompatibility, when explaining what makes negations true. The original aim was not to provide an explanation of the meaning of the logical constants, but to expose certain metaphysical relations.

Russell's logical atomism, in particular the technique of logical construction, is in some ways similar to \*phenomenalism, except that he did not take the atoms (sensibilia) to be mental. At other points in his development, he adopted different views. Thus in *The Problems of Philosophy*, and again in *The Analysis of Matter*, he tries to identify a kind of knowledge (merely structural) of physical continuants which could be acquired even if they are metaphysically very different from the things of which we can have non-inferential knowledge. He laid down the basic postulate that experiences are caused by something other than experiences—call the causes material events.

Implicitly assuming some principle of like cause, like effect, he says that one can infer that properties of or relations among experiences mirror properties of or relations among material events. Material continuants are constructed out of material events. The upshot is that we know the structure of matter, but not its intrinsic nature. The strategy leaves room for scepticism about the real nature of material continuants, but is supposed to capture enough for an interpretation of science upon which most scientific beliefs are true.

Yet another approach is provided in *Human Knowledge: Its Scope and Limits* (1948). Here he argues that the alternative approaches do not do justice to all our cognitive capacities. Unless we have a priori knowledge of certain substantive contingent facts, which he called 'postulates of scientific inference', then 'science is moonshine' (p. 524). One postulate is: 'Given any event A, it happens very frequently that, at any neighbouring time, there is at some neighbouring place an event very similar to A' (p. 506). Russell implies that we do indeed have a priori knowledge of such facts, of a kind which he explains in terms of 'animal expectation'. This kind of knowledge is available to non-language-users and is arguably non-propositional. This is a cognitive faculty often ignored in attempts to show how scepticism can be avoided. In this late work, Russell shows signs of breaking out of the Cartesian problematic in favour of naturalizing epistemology.

The most influential themes in Russell's work have proved those relating to \*meaning and quantification. It is hard to imagine any new work in this area not confronting Russell's idea that basic words have meaning by standing for a corresponding entity, and that quantifiers and quantifier phrases function quite differently. **Russell's paradox.** Central paradox in the theory of classes. Most classes are not members of themselves, but some are; for example, the class of non-men, being itself not a man, is a member of itself. Let R be the class of all classes which are not members of themselves. If it exists, it is a member of itself if and only if it is not a member of itself: a contradiction. So it does not exist. This is paradox-

ical, because it conflicts with the seemingly inescapable view that any coherent condition determines a class. (Even a contradictory condition, like being round and square, determines a class: the class with no members.) Standard responses, like Russell's theory of \*types, aim to find some limitation on what classes there are which is (a) intuitively satisfactory, (b) excludes R, and (c) includes all classes needed by mathematicians. **Russian philosophy.** Though a significant force in Russian history, Russian philosophy did not begin until the reign of Catherine the Great (1762–96), when Enlightenment ideas began to filter into Russia. Thereafter philosophy flourished not as an academic discipline, but in the intelligentsia's passionate debates about the liberation of humanity and the destiny of Russia, conducted in political and religious writings and most famously in the literature of Dostoevsky, Tolstoy, and others. The theories of Karl Marx gripped the radical intelligentsia in the late nineteenth and early twentieth centuries, and inspired the Bolshevik Revolution in 1917. Thereafter, Marxism-Leninism, conceived as an all-embracing world-view, was propagated by the Soviet state as its official philosophy until its collapse in 1991, while Russian religious philosophy was preserved by philosophers in exile abroad.

A defining moment in Russian philosophy was the publication of Pyotr Chaadaev's first *Philosophical Letter* in 1836. Chaadaev (1794–1856) portrayed Russia as a spiritual desert populated by nomadic souls bereft of traditions and community, who had contributed nothing to the progress of humanity. This damning vision provoked contrasting responses. The 'Slavophiles', led by Ivan Kireevsky (1806–56) and Aleksei Khomyakov (1804–60), held that Chaadaev's criticisms applied only to the 'superfluous men' of the intelligentsia. He had ignored Russia's indigenous traditions of Orthodox Christianity and the peasant commune, which jointly made possible a form of community exemplifying *sobornost'*, the free and integral unity of human beings in the love of God. Only such a genuine community promised to save world civilization from the ruinous effects of Western rationalism and individualism. In contrast, the 'Westernizers' urged the modernization of economic and political institutions and the appropriation of Western ideas of scientific progress and political liberty. The movement, originally Left Hegelian in inspiration, included literary critic Vissarion Belinsky (1811–48), Mikhail Bakunin (1814–76), and Alexandr Herzen. Though anxious for Russia to take its place among Western nations, the Westernizers were perceptive critics of capitalism.

The Westernizers' heirs in the 1860s were the Russian nihilists, so called for their denunciation of religion and traditional morality in favour of a positivistic reverence

for natural science and utilitarian ethics. (Nihilism is evocatively portrayed in Turgenev's novel *Fathers and Sons*.) Prominent was Nikolai Chernyshevsky (1828–89), whose Feuerbachian materialism and realist aesthetics influenced an entire generation of Russian radicals. Chernyshevsky believed that collective ownership would soon replace capitalism in the West and that the communal traditions of the peasantry might facilitate the immediate transition to socialism in Russia. More utopian views of the peasantry found expression in the 1870s in various forms of populism which argued that Russia must find its own way to socialism. These were in turn eclipsed by \*Marxism, with its recognition of the historical necessity of capitalism and its focus on the urban proletariat. Intriguing revisionist versions of Marxism developed, such as the neo-Kantian 'legal Marxists' and Bogdanov's empiriomonism. It was, however, Lenin's theory of revolution and Plekhanov's \*dialectical materialism that prevailed to form the core of \*Soviet state philosophy, wherein the atheism and scientific optimism of the Russian radical tradition mingled with a Slavophile belief in Russia's pre-eminent role in human emancipation.

Slavophile ideas were more faithfully pursued in the philosophy of Vladimir Solovyov in the late nineteenth century. His concern with the reintegration of humanity in the Kingdom of God on earth inspired a generation of idealist philosophers, like Nikolai Berdiaev and Lev Shestov (1866–1938), who became leading figures in the 'Russian Religious-Philosophical Renaissance'. These thinkers were also influenced by Dostoevsky (1821–81), whose novels, especially *The Devils* and *The Brothers Karamazov*, contained a prophetic critique of Russian radicalism and a profound exploration of Russian religious consciousness. In 1909, Berdiaev and a number of other former legal-Marxists participated in the *Vekhi* (Signposts) symposium, which attacked the intelligentsia's traditional allegiance to materialism as morally and intellectually bankrupt. This provoked passionate debate, interrupted only when prominent idealist philosophers were expelled from Russia in 1922 in a purge of non-Marxist intellectuals. Many became leading lights of the Russian émigré philosophical communities in Paris and Berlin.

With the idealists vanquished, Soviet Marxists energetically debated philosophy's role in the new order. Soviet 'mechanists' argued that science can in principle provide a complete account of reality. Philosophy's task is not to guide science, but to elucidate concepts and laws by generalization from scientific practice. In contrast, the 'dialecticians', led by A. M. Deborin (1881–1963), maintained that science is explained and enhanced by the correct philosophical world-view, which they identified with dialectical materialism. A philosophical stalemate, the debate was eventually resolved politically. In 1929 mechanism was officially condemned for \*'positivism' and 'revisionism'. This pattern was repeated one year later, when Deborin and his colleagues were attacked as 'Menshevizing idealists' (a heresy named after the Bolsheviks' former political rivals), whose 'formalist'

preoccupation with dialectics betrayed a lack of 'Party spirit'. The Party endorsed these charges, and the dialecticians were finished. Only Deborin himself and a handful of others survived the purges.

The 1930s saw the codification of dialectical materialism into rigid dogma. The *History of the CPSU (Bolsheviks): Short Course* (Moscow, 1938) inveighs against 'idealism' and 'metaphysics', and declares that matter is primary and spirit secondary; the phenomena of reality are interconnected; nature undergoes changes which occur, not gradually, but by 'qualitative leaps'. Historical materialism is portrayed as the application of these principles to the phenomena of social life. Striking here is not the content of the doctrine (essentially a simplification of Plekhanov's and Lenin's views), but its presentation as unquestionable truth. Stalinist Russia was deemed to be living proof of \*Marxism; hence no significant philosophical questions needed to be debated. Philosophy's role was reduced to 'a weapon in the class war'.

The brief 'thaw' after Stalin's death brought a new generation of Soviet philosophers eager to return to the critical study of Hegel and Marx. Some, such as M. K. Marmadashvili (1930–90) and E.V. Ilyenkov (1924–79), sought to develop Marx's method and his idea of social phenomena as 'objectified' activity. Ilyenkov, for example, argues that our forms of thought are objectified in our mode of interaction with nature and in the form our activity lends the world. Children acquire consciousness and selfhood through their inculturation into this externalized 'spiritual culture'. Here his views complement the 'socio-historical psychology' developed by L. S. Vygotsky in the 1920s and 1930s. Ilyenkov's critical Marxism brought him into frequent clashes with the establishment, which continued to propagate 'textbook' dialectical materialism until the *glasnost* era.

Though Marxism in some way influenced almost all Soviet thinkers, the period also produced a number of independent figures. Three such are Mikhail Bakhtin, whose 'dialogism' has enjoyed considerable influence in the West, A. F. Losev (1893–1988), author of important studies on aesthetics, myth, and ancient Greek thought, and the philosopher of culture, V. S. Bibler (1918–2000). Interestingly, the significant figures of the Soviet era, for all their diversity, can be seen as parts of a single philosophical culture unified by certain prominent themes, such as the reality of the cultural, the social nature of personhood, and the world-constituting power of human activity. Unfortunately, this culture is poorly understood, as political circumstances made it impossible for Soviet philosophers to write the history of their own tradition. It survives, however, in the imaginative philosophy of F. T. Mikhailov (b. 1930) and others.

The collapse of the USSR in 1991 stimulated numerous reflections on the fate of Marxism, followed by the emergence of a panoply of new approaches and schools. Over the following decade, notable trends include the appearance of political philosophy as an independent discipline, renewed interest in Russian religious philosophy and the

work of the émigrés, the emergence of Russian post-modernism, and attempts to blend analytic philosophy with phenomenology and hermeneutics. Many new journals have sprung into existence, but *Voprosy filosofii* (Questions of Philosophy), founded in the 1940s, remains the leading philosophy publication in Russia. Under the editorship of V. A. Lektorsky (b. 1930), the journal negotiated the collapse of the old order to become a forum for many new developments and for the introduction of hitherto neglected fields, such as bioethics and philosophy of ecology. As well as spotlighting the work of formerly forbidden thinkers, the journal has sought to preserve the best of the Soviet era.

The overarching concern of Russian philosophy is the quest for an all-embracing vision to facilitate the revitalization, even divination, of humanity, so that human beings should be at one with each other and the world. Though the Communist version is no more, the aspiration for such a vision will no doubt continue to define the Russian tradition, which promises to remain as fascinating as it is distinct from the traditional concerns of English-speaking philosophy.

**Ryle, Gilbert** (1900–76). Waynflete Professor of Metaphysical Philosophy and Fellow of Magdalen College, Oxford (1945–68), editor of the periodical *Mind* (1948–71). Probably the most conspicuous, fertile, and influential figure in a notably flourishing period of British philosophy, and in earlier years the chief instigator of the reanimation, particularly in Oxford, of the philosophical scene.

His first efforts, in the 1920s, to 'break the mould' led him into the study of continental phenomenology; but by about 1930 he came to be preoccupied chiefly with the question what philosophy itself is. If it was, as he felt and found it to be, a live subject and not merely the scholarly study of classical texts, what were its problems? What was it about? What would be distinctively philosophical methods?

His first thought was that philosophy investigates the meaning of expressions—a thought close to the idea (compare G. E. Moore and \*Logical Positivism) that philosophy's proper business is \*'analysis'. But philosophy surely is not mere lexicography; and, further, in what cases is 'analysis' philosophically called for? Ryle came to the conclusion, substantially never abandoned, that the

philosopher's business is not directly with meanings but rather with a certain kind of meaninglessness—not with what expressions mean, but with why certain combinations of expressions make no sense. Characteristic of his early work is the paper 'Systematically Misleading Expressions' (1932), which argues that some quite ordinary forms of expression are 'improper' to the states of affairs they record, invite thereby misassimilation to other forms of expression, and so tend to generate perplexity, even flat nonsense, from which it is the business of philosophical argument to rescue us.

Soon thereafter, notably in his paper 'Categories' (1938), Ryle abandoned the rather obscure notion of an expression's being 'improper' to a state of affairs in favour of the thesis that expressions can be grouped into 'types' or 'categories', and that philosophical trouble arises from attempting to handle an expression of one \*category as if it belonged to another. On this view the source of trouble is a 'category mistake'; the curative work of philosophy is to exhibit and correct categorial misassignments, it being distinctive of such misassignment that it results in a 'certain kind' of meaninglessness or, as Ryle also often put it, of 'absurdity'.

This programmatic notion is famously and extensively pursued in his major work *The Concept of Mind* (1949), an impressive but perhaps not wholly coherent book. Its milder thesis is that the many and various ways we speak about 'the \*mind' are potentially misleading; that philosophers, particularly those Ryle calls 'the Cartesians', have been misled; and that they have been misled in particular into picturing the mind as a ghostly counterpart of the body, a non-physical 'thing' mysteriously 'in' the physical body, and the scene or agent of non-physical states, happenings, and acts. There constantly obtrudes, however, a more extreme, apparently ontological thesis, that, contrary to what ordinary ways of speaking suggest, there *really are* only physical objects and physical happenings, and that all talk seemingly 'about' minds is really no more than a certain way of talking about bodies. Ryle often denied, and critics often asserted, that his book preached \*behaviourism. The fact is that it both did and did not, in different passages.

Ryle was sometimes regarded as a man of this one book, *The Concept of Mind*; but that dismissive suggestion could not survive the publication of his two-volume *Collected Papers* (1971)—fifty-seven articles (to which he later added a few more) over a period of fifty years, which leave few areas of philosophy untouched and unenlivened. *Dilemmas* (1954) and *Plato's Progress* (1966) should also be mentioned.

# S

**Saadia Gaon** (882–942). Philosopher, exegete, Hebrew grammarian and lexicographer, liturgist, translator of much of the Hebrew Bible into Arabic. Born in Egypt, Saadia became head (Gaon, lit. ‘eminence’) of the ancient Talmudic Academy located by his time in Baghdad. The first systematic work of Jewish philosophy, his *Book of Critically Chosen Beliefs and Convictions*, the book commonly known as *The Book of Beliefs and Opinions* or *Sefer Emunot ve-De’ol*, more properly, *Sefer ha-Nivhar ba-Emunot ve-De’ol*, defends creation, revelation, and a carefully balanced ethical pluralism, explains providence and the afterlife, and refutes \*scepticism, \*relativism, and dogmatism. Saadia works inductively from Scripture, using philological techniques developed after the translation of Greek works into Arabic. He favours the familiar sense of biblical expressions, except where reason, experience, authentic tradition, or another scriptural text preclude it. Then a figurative usage must be found and warranted by tight textual parallels. An intuitive psychologist, Saadia rejects asceticism for the morbid and misanthropic mood it engenders. His aesthetics celebrates contrast and diversity, arguing (as against the monism of Plotinus’ account of beauty) that God is one, but we humans are multifold and diverse.

**sacred:** see holy, numinous, and sacred.

**Sainsbury, Mark** (1943– ). English philosopher, at London and Austin, Texas, specializing in philosophical logic and the history of analytic philosophy. In particular he has developed the view that truth has degrees and that objects can be inherently vague: the border between a mountain and its plain is fuzzy, but so is the border between the mountain and that fuzzy region, and the border between the mountain and this new fuzzy region, and so on. The statement that a certain point is on the mountain may therefore be true to a certain degree, where this does *not* mean it has some true parts and some false parts. (Paradox of the \*heap.) However, this still implies a sharp trichotomy between definitely true, intermediate (of whatever degree), and

definitely false. He has therefore developed more recently a revised view whereby concepts, including those of truth and falsity, no longer have boundaries.

**Saint-Simon, Claude-Henri de Rouvroy, comte de**

(1760–1825). The father of French \*socialism, Saint-Simon was an ardent enthusiast for the philosophy of \*progress, providing the (French) link between the \*philosophes of the eighteenth century and the science and technology progressionists of the nineteenth, especially Comte, his sometime disciple and collaborator. Saint-Simon worked out his position essentially on the basis of one case, namely the rise of modern society from the feudal system of the Middle Ages. In common with many who had lived through the French Revolution, Saint-Simon did not want to deny absolutely the virtues and stability of traditional Christianity; but he saw all such societies as having the seeds of their own decay, as they fail to speak to the needs of the economic and socially dominant classes. Post-medieval Europe was a tale of the rise of independent producers and merchants, conflict with the established powers, and uneasy resolution of the struggle. That these ideas sound familiar is a direct result of their influence on Marx.

**Salmon, Wesley** (1925–2001). US philosopher of science, who devoted most of his attention to scientific explanation and the epistemology of science. Salmon rejected the Logical Positivist doctrine that the adequacy of an \*explanation depends upon whether what is to be explained can be deduced (the ‘deductive-nomological’ account) or is inductively inferable (the ‘inductive-statistical’ account) from the explanation. He first proposed that explaining an occurrence is a matter of finding factors which are statistically relevant to it (the ‘statistical relevance’ account), and later required in addition that the explanation must show the place of the occurrence in a system of real-world causal

processes and interactions (the 'causal– Mechanical' account). His epistemological studies apply Bayesian probability to traditional problems in confirmation. Salmon also worked on issues connected with space, time, and motion, as well as a variety of historical topics. J.B.B.

**salva veritate.** Literally, 'without loss of truth'. A rule of \*inference must be truth-preserving: it must take one from truths to truths. (\*Validity.)

Questions arise concerning a rule of the predicate calculus with identity which reflects a principle attributed to Leibniz, who asserted that if *a* and *b* are the same, what is true of *a* is true of *b*. The rule of the calculus is:

From ( $a = b$ ) and  $\Phi$  infer  $\Psi$ , where ' $\Psi$ ' is like ' $\Phi$ ' except that '*a*' and '*b*' have been exchanged at one or more places.

The rule seems to support substitutions that cannot be made *salva veritate* in some contexts, such as those involving \*propositional attitudes. Such contexts have been designated as indirect or \*referentially opaque. R.B.M.

**Śaṅkara** (788–820 AD). Philosopher-monk, founder of non-dualist \*Vedānta. In his fiercely polemical commentaries on the \*Upanishads and *Brahma Sūtras*, Śaṅkara rejects both pluralistic realism and subjective idealism. Using \*'third-man'-type regress arguments against causal, mereological, intentional, or any other kind of relation or difference, he seeks to show the manifold world of change to be neither real nor unreal. It is a dream *like* superimposition of contents projected by the veil of ignorance on pure unobjectified consciousness. This consciousness is the one reality behind both God (Brahman), who became the world, and the individual (Ātman). Unlike a dream-world which is nullified by 'practically true' wakeful experience, the world-appearance is dispelled only by a direct mystical dawning of the 'transcendentally true' oneness indicated by such scriptural sentences as 'You are that' and 'All this is Brahman'. **samples, explanation by.** According to Wittgenstein, a subcategory of ostensive explanations of word-meaning involves explanation by reference to a paradigmatic sample. Names of perceptual properties (e.g. colour-words), lengths (e.g. 'metre'), or weights (e.g. 'kilogram'), are (or were) introduced thus. The sample is not the property pointed at, but the *object* (the patch on the colour chart, or the metal rod) that fulfils the canonical role in the practice

of using the word. Whether something is a sample is not an intrinsic property of an object, but a matter of its *use* as a standard for the correct application of the definiendum. Hence something can be a sample only if it satisfies the conditions for such use, e.g. relative permanence or reproducibility, reidentifiability, comparability with objects that can truly or falsely be said to instantiate the feature defined.

Associated with each defining sample is a method of comparison involved in the practice of its use. Hence subjective sensations, e.g. pain, cannot fulfil the role of defining samples in a 'private ostensive definition'. What were sometimes thought to be synthetic a priori truths, e.g. that black is darker than white, or that nothing can be red and green all over simultaneously, are explained by Wittgenstein as grammatical propositions associated with the constituent expressions which are defined by reference to samples. Thus any ordered pair of samples of black and white is also used to give an ostensive definition of the relation 'darker than', and the grammatical proposition that black is darker than white is no more than a consequent rule that if *A* is black and *B* white, the inference that *A* is darker than *B* is licit. Colour exclusion is similarly explained, not as a metaphysical necessity lying in the nature of things, but as a rule that if something is rightly said to be *this* colour (pointing at a sample of red) all over, then it may not also be said to be *that* colour (pointing at a green sample), since *this* defines a different colour from *that*. **Santayana, George** (1863–1952). Born in Madrid of Spanish parents, complicated family circumstances took him to Boston at the age of 9 and an American career, though he always remained a Spanish citizen. In January 1912 he resigned his Harvard professorship and lived subsequently in Europe, mostly in hotels in Rome. All his many books were written in English, and he himself said that it was as an American philosopher that he must be counted, if he was to be counted at all. Very different from his older colleague William James, he stands with him as a major figure in 'the golden age of American philosophy'. Santayana is distinguished not only as a philosopher, but as a poet, novelist, and literary and cultural critic, famous for his characterization of what he called 'the genteel tradition' in American culture.

*The Sense of Beauty* (1896) argues that \*beauty is the pleasure of contemplating an object conceived as a quality of the object itself. Santayana did not wish to disparage beauty by thus analysing it. Indeed, he urged that the experience of beauty was the highest value in human life. (In his later treatment of art in *Reason in Art* the somewhat shifted emphasis was on the undesirability of separating the aesthetic and the practical; in the good life all human activity is both.) It was the high valuation of aesthetic experience combined with a thoroughly naturalistic

account of its basis that made an especial impression. It is perhaps (rather unfortunately) this work which has received most attention of all Santayana's work. Described as a 'pot-boiler' by Santayana, it still sounds a theme basic to his thought that the roots of good lie in man's animal nature but that its value transcends this.

*The Life of Reason; or, The Phases of Human Progress*, in five volumes, (1905–6) sketches the extent to which the main branches of human thought and activity, common-sense concepts, social organization, religious beliefs and institutions, art, and science have served the life of reason. Every impulse of a conscious being carries a sense of the goodness of its object, a goodness which, if that impulse stood alone, would be as absolute a good as there could be. \*Reason is simply a higher-order impulse whose good is the harmonization of other more particular ones and the life of reason is an ideal for all those in whom it is strong enough, but since value is relative it is not the only respectable human option. The work was an important influence on the development of American \*naturalism, and praised by Dewey.

In the next phase of his philosophy Santayana developed a form of \*Critical Realism (in fact, somewhat Thomist in character) and as such was still working in a distinctively American debate. Thus he contributed to an American philosophical manifesto called *Essays in Critical Realism* (1920) (a riposte to *The New Realism: Comparative Studies in Philosophy* (1912), the manifesto of a very sophisticated sort of naïve realism partly inspired by James). Whereas naïve realism holds that a perceived (or perhaps otherwise known) physical object is directly present to our consciousness, and indirect realism that what is directly present is particular sense-impressions from which we infer the existence of physical things, Critical Realism holds that what is directly present is an essence which characterizes the known object. Thus there is nothing from whose presented character we infer the existence of an object; rather, we are presented with a character which rightly or wrongly we take to be the character of something upon which we are intent. This intentness upon an object, considered as a purely mental phenomenon, is simply a kind of primitive preconceptual directedness on something beyond one's own mental state. What settles the object I am intent on is that I am actually physically affected by and physically adapting to it. Thus physical relations pick out the object and the essence intuited characterizes it for me (thus 'externalism' about subjects, 'internalism' about predicates).

If I am perceiving something correctly, then the essence intuited somehow applies to the physical thing on which my behavioural response is directed. If it is ever part of the very essence of the thing, then I know that thing literally (though the essence is still exemplified twice over, once for my mind, once in the object); if, as is more usual, it is simply a suitable symbol of it for human purposes, our knowledge is symbolic.

This point of view is developed most fully in *Scepticism and Animal Faith* (1923) and *Realms of Being* (1927–40) as

part of an element in an elaborate and carefully worked-out ontological system. Many admirers of *The Life of Reason* were dismayed by these works, misunderstanding them as a retreat from naturalism.

Although *Scepticism and Animal Faith* is primarily a work in epistemology, Santayana was far from thinking epistemology the core of philosophy; he is simply concerned to clear away the objections of epistemologists before presenting his ontology.

If knowledge is required, in Cartesian fashion, to be inherently certain, then knowledge, as opposed to the mere intuition of presented 'essences', is indeed impossible. But we should not pretend to a scepticism we cannot really hold, and should admit to a system of beliefs which, its truth once granted, can be seen as inevitable in a conscious animal. We rightly call this 'knowledge' because we believe it true and generated in a manner which is, in fact, reliable. This naturalistic epistemology differs from some later views, which it anticipates, by stressing that most of our knowledge is symbolic rather than literal. It provides us with a sense of how things are, adequate for practical purposes, but not revealing the real essence of the facts it registers. Such knowledge consists of 'faith mediated by symbols', the symbols being the essences, sensory and value-laden in ordinary thought, more purely structural in science, which present themselves to human perception and thought as we grapple with the world.

The four volumes of *Realms of Being* deal in turn with the four realms of being or categories of reality which Santayana distinguishes.

The character of any part of the physical world at any moment is an essence. *The realm of essence* also includes all characters which *might* have been possessed by some part of the physical world, or which *might* present themselves as possible characters of things to spirit (any mind); it is, in short, the realm of pure possibilities. There is one peculiarly basic essence, the essence of pure being. Every other essence is some determinate form of this, standing to it as all more specific colours stand to the essence of pure colour. It is a common something present in each specific essence, from which it can be abstracted and contemplated apart in one kind of mystical experience. Pure being should be distinguished from existence; it is equally present in the essence unicorn, and the essence horse, but only the latter occurs existentially.

*The realm of matter* consists of material or physical substance spread out in space and changing from moment to moment according to temporal patterns called the laws of nature. It allows essences to stand in external relations not determined by their own inherent nature as are their internal relations one to another; such standing in external relations distinguishes existence from mere being.

Certain processes in matter generate spirit. This is primarily the consciousness which some part of the physical world has of its environment, but the spirit or consciousness generated within an organism also contains much fantastic imagination, sometimes recognized and rightly enjoyed merely as such, sometimes serving as spirit's only

vaguely true grasp of the world it inhabits. The totality of spirit in the world constitutes *the realm of spirit*.

Santayana subscribes to what he calls materialism: not the doctrine that all reality is physical, but that only the physical has causal power. For spirit is simply an emanation from certain processes in the physical world, in particular the 'psyches' of animals, from which it should be sharply distinguished. Psyches consist in the genetically determined patterns of life-sustaining behaviour of organisms, adapted to changing circumstances in higher animals by physical representations of the environment in their brains, representations which should be distinguished from the non-efficacious thinking pertaining to the realm of spirit which they sustain, whose pragmatic truth therefore strictly consists not in its own usefulness but in that of the physical processes which give rise to it. But though spirit is non-efficacious, it alone brings value into the world. The tension between Santayana's \*epiphenomenalism and the pragmatic element in his account of knowledge stops short of inconsistency and is important for his value theory.

There remains *the realm of truth*. This 'is the total history and destiny of matter and spirit, or the enormously complex essence which they exemplify by existing'. \*Truth, for Santayana, is supertemporal; it is the unwritten record of all events through all times, and our truths are simply such fragments of this one total truth as we humans happen to grasp, mostly only in symbolic form. (The truth about the future is as determinate as that about the past, not because of determinism, but because the distinction between past and future has no standing for absolute truth.) His stress on the reality of such an absolutely objective truth about the world, which far surpasses any possible knowledge, represents his strongest divergence from the idealists and pragmatists who dominated philosophy in his earlier student and professorial days (and whose central claims are still very much with us in various transformations). There is, however, a strong pragmatist element in his treatment of the symbolic truth through which we deal effectively with our environment (or at least which expresses our dealing with it), which constitutes most human knowledge. This partly justifies the tendency to classify him as a pragmatist.

In *The Realm of Spirit* (1940) and other such later works as *The Idea of Christ in the Gospels* (1946) Santayana develops a somewhat Platonic account of 'the spiritual life'; one dedicated to a kind of mystical intuition of essences for their own sake, rather than as a guide to practical action; in particular those essences which can be contemplated under the form of the good. This, however, represents just one possible human option, and Santayana still declares his preference for the life of reason, in which spirituality is just one ingredient in a wider human harmony. Moreover, because Plato makes his forms efficacious agencies in the natural world, operating on it from another realm, he regards himself as finally closer to Aristotle and Spinoza. What particularly evoked Santayana's hostility was any idea that the world, and the truth about it, are some-

how a human construction. He deplored such human egotism, which he saw as the besetting sin of modern idealism and pragmatism, as expressing a dangerous resentment of our dependence on a greater non-human cosmos and unrealistic glorification of human power. In opposition to all such 'cosmic impiety' Santayana called himself a naturalist, regarding Spinoza as one of the chief teachers of this viewpoint. T.L.S.S.

**Sapir-Whorf hypothesis.** A relativistic doctrine. According to Sapir, 'We see and hear . . . very largely as we do because the \*language habits of our community pre-dispose certain choices of interpretation' ('The Status of Linguistics as a Science' (1929)). Whorf developed the idea, attempting to illustrate it from American Indian languages. The doctrine risks collapse into the truism that some things can be said more easily in some languages than in others. R.K.

**Sartre, Jean-Paul** (1905–80). Sartre's oeuvre is a unique phenomenon. No other major philosopher has also been a major playwright, novelist, political theorist, and literary critic. It is still too early to judge which facet of Sartre's extraordinary genius posterity will regard as the most important, but since his philosophy permeates his other works, its enduring interest is assured.

After a provincial childhood spent, if we can trust Sartre's captivating autobiographical essay *Words*, in his grandfather's library, Sartre studied philosophy at the École Normale in Paris. In 1931 he became a teacher of philosophy in Le Havre, which he hated (Le Havre is 'Bouville' in *Nausea*). In 1937 he moved to Paris, and the next year his brilliant philosophical novel *Nausea* was published. Many of the themes of this book recur in his first major philosophical book *L'Imaginaire* (1940) (whose botched English translation bears the title *The Psychology of Imagination*). But then the war intervened: Sartre was mobilized in 1939, and served as a meteorologist in the French Army. He later described the war as the turning-point in his life, one which changed him from an academic philosopher and avant-garde writer into an intellectual deeply committed to the fate of the 'Wretched of the Earth' (the title of the famous work by Fanon for which Sartre wrote an eloquent preface). Military service did not, however, stem the flow of words: he wrote voluminous diaries (excellently translated as his *War Diaries*), which contain early drafts of his philosophical work, mixed in with marvellous descriptions of his experiences and colleagues. In 1940 Sartre was captured and imprisoned: in prison he continued his study of Heidegger's

philosophy and wrote his first play. Released a year later, he returned to occupied Paris and to his post as a teacher of philosophy. His desire to work with the Resistance was complicated by his unwillingness to commit himself to either the Communists or the Gaullists, and in the end he devoted most of this time to writing his most important philosophical work, *Being and Nothingness* (1943).

With the liberation came instant fame, as dramatist (thanks to *Flies* and *No Exit*) and philosopher: his optimistic 1945 lecture *Existentialism and Humanism* seized the imagination of a generation. Sartre could have continued his academic career, but he chose to refuse all academic positions and to make his living as a writer, an occupation which he combined with an active concern for the political and social affairs of the day. The nature of Sartre's engagements was at first largely shaped by his complex relationships with the Communist Party, which he joined at the time of the Korean War and then left, never to return, after the Russian suppression of the Hungarian Revolution in 1956. Not surprisingly, his reflections on \*Marxism date from this period, and over the next decade he developed the 'existentialist Marxism' first expounded in his 1957 essay *Search for a Method*, and then further developed in his second large-scale philosophical treatise, *Critique of Dialectical Reason* (1960). Towards the end of this period he committed himself whole-heartedly to the struggle for liberation in Algeria (a cause which nearly cost him his life in 1961). A few years later the same passions stirred him to lead the French opposition to the American involvement in Vietnam, and these commitments are reflected in several long essays on behalf of the Third World. In 1964 he was offered the Nobel Prize for Literature, but chose to decline the offer. The student uprising of May 1968 seemed to show that Sartre's writings were still as influential as ever, as he addressed thousands in the Sorbonne; but in truth, his intellectual reputation was now eclipsed by structuralists (such as Lévi-Strauss and Althusser), and post-structuralists (such as Derrida and Deleuze). Sensing this loss of intellectual sympathy, and combating increasing blindness and other illnesses, Sartre largely withdrew from public affairs and turned his attention to the completion of his final *magnum opus*, his vast study of Flaubert, *L'Idiot de la famille*; sadly, his eyesight gave out in 1973, when only three out of five projected volumes had been completed. Yet his funeral showed that he retained an extraordinary hold on the public imagination: over 50,000 people turned up in a spontaneous demonstration of respect.

In his early philosophical writings from the 1930s Sartre was primarily concerned to develop Husserl's phenomenological methods and apply them to the study of the \*imagination. He argues that the traditional conception of mental imagery derived from the theory of \*ideas is incoherent, and needs to be replaced by a recognition that imagination, like perception, is a distinctive mode of intentional consciousness whose contents should not be treated as if they were inner objects. Sartre's special interest in the imagination derives partly from its connections

with aesthetics and the use of the imagination in creating ideal worlds which contrast with the perceived actual world (this is a prominent theme of *Nausea*); but also from the fact that he regards the exercise of the imagination as the paradigmatic exercise of freedom. He argues that, because the content of the imagination, 'the imaginary', characteristically goes beyond the actual world, there simply cannot be an adequate causal theory of the imagination, since the effects of actual causes cannot be anything but actual. This argument is unsatisfactory, for Sartre confuses the fact that what is imagined is characteristically not actual with the claim that the act of imagination itself is not actual; but we can agree with him that the imagination is a primary manifestation of human freedom without accepting his argument.

\*Freedom is not just a phenomenon of the imagination, however: according to Sartre, all consciousness is in some way free (so that the imagination is a privileged manifestation of consciousness in general). In order to understand Sartre's conception of the essential freedom of consciousness we need now to turn to *Being and Nothingness*. Sartre begins this work by arguing that consciousness belongs to a different ontological category from that of the physical world. The key premiss for this ontological distinction is an obscure thesis that consciousness is always constituted by a tacit \*self-consciousness. Sartre argues that the conception of a conscious mental state which does not include this self-conscious dimension is incoherent, since it would be an unconscious conscious state; but this argument is plainly fallacious, although there may be other reasons for thinking that consciousness implies the possibility of self-consciousness. What is distinctive about the Sartrean conception, however, is not just the association between consciousness and self-consciousness, but the claim that the self-conscious dimension is constitutive. It is not easy to see why Sartre holds this, but it seems to rest on a presumption, similar to that employed in his discussion of the imagination, that the \*intentional content of consciousness is in principle inexplicable in causal terms. If that presumption is granted, then it follows that consciousness cannot get its essential intentional content from the physical world; in which case, if there is to be an explanation of any kind for it, it is tempting to have recourse to a constitutive self-consciousness, though this requires the dubious assumption that the content of this self-consciousness is itself unproblematic.

This constitutive role for self-consciousness, however exactly it is understood, explains why Sartre now proceeds to call those aspects of human life which involve consciousness the 'for-itself' (*pour-soi*). This contrasts with all physical facts, which are independent of consciousness and comprise the 'in itself' (*en-soi*). This distinction is not, however, one between substances of two different kinds; for Sartre denies that consciousness is a substance at all. Instead, the distinction is one between types of fact. Physical facts satisfy ordinary classical logic: 'they are what they are'. But, according to Sartre, the same logic does not hold of consciousness: here things 'are what they are not and

are not what they are'. This thesis connects with the feature of Sartre's philosophy which is most difficult to come to terms with—his treatment of negation. Like other opponents of negative facts, Sartre argues that negation does not reside 'in things themselves'; instead, he holds, it is introduced into our conception of the world as a quasi-Kantian category whose transcendental justification lies in the fact that the self-conscious structure of consciousness involves negation—'the being by which Nothingness comes to the world must be its own Nothingness' (*Being and Nothingness*, 23). This baffling doctrine implies that the constitutive role of self-consciousness is at the same time self-nihilating. One would like to set this doctrine aside as a rhetorical extravagance; but this is impossible, since, according to Sartre, this capacity for reflexive self-negation is the core of human freedom and, indeed, human life. The best one can do to grasp Sartre's intention is to point to the phenomena he uses to illustrate our self-directed 'nothingness'—such facts as that we can always detach ourselves from the roles we find ourselves occupying (as in Sartre's famous example of the waiter in a café), and that in cases of self-deception we convince ourselves of something precisely because we already believe the opposite.

This theory of consciousness so far lacks any reference to the \*self, or subject of consciousness. This omission is deliberate, for in one of his first essays (*The Transcendence of the Ego*) Sartre took issue with Husserl's doctrine of the transcendental subject and argued that consciousness is fundamentally impersonal. In *Being and Nothingness* this thesis is significantly modified in the light of that of the constitutive role of self-consciousness: Sartre argues here that this self-consciousness characteristically includes a set of commitments and aspirations that gives a projective unity to the acts of consciousness that they inform, and, in doing so, strings them together as the acts of a single person—'consciousness by the pure nihilating movement of reflection makes itself *personal*' (*Being and Nothingness*, 103). In the last part of the book Sartre develops this theme in a rich and detailed elucidation of the purposive structures of psychological explanations. Two aspects of this account are specially worthy of notice. The first concerns Sartre's attitude to Freud. In an early section of the book Sartre launches a well-known critique of Freud's theory of the unconscious which is motivated by Sartre's claim that consciousness is essentially self-conscious. Sartre also argues here that Freud's theory of repression is internally flawed, but this argument is based on a misunderstanding of Freud. What is of more interest, however, is Sartre's attempt, towards the end of the book, to adapt some of Freud's ideas to his own account of human life, and thereby to develop an 'existential psychoanalysis' in which Freud's causal categories are replaced by Sartre's own teleological ones. The theme of consciousness is not so dominant here, and the method of psychological inquiry Sartre began here is one that he was to employ fruitfully in several biographical works (including *Baudelaire* (1946), *Saint Genet—Actor and Martyr* (1952), and *The Idiot of the Family* (1971–2)).

One feature of these studies is the emphasis Sartre comes to place upon the formation during childhood of a 'fundamental project' which gives unity to the person's subsequent life, and this brings me to the second notable aspect of Sartre's psychological theory. In *Being and Nothingness* Sartre writes of the formation of this fundamental project as a 'choice', and it is easy to see why he says this in the light of his emphasis on freedom—he calls this choice 'the fundamental act of freedom' (*Being and Nothingness*, 461). Sartre is here reviving a doctrine central to Kant's conception of freedom, but, like Kant, Sartre faces insoluble problems in explaining how such an act can be a choice at all, since all the subject's reasons for choice are referred back to their fundamental project. Hence it is not surprising that when Sartre attempted to apply this conception in his biographical studies, a causal mode of explanation concerning the formation in childhood of one's fundamental project appears to replace the abstract schemata of *Being and Nothingness*.

We have seen how subjectivity is achieved through the reference of acts of consciousness, through their tacit self-conscious structure, to a single project. Sartre makes it clear in *Nausea* that Roquentin's abandonment of his project brings with it the end of his subjectivity—'suddenly the I pales, pales and goes out' (*Nausea*, 241). One can ask whether subjectivity does not also involve reference to other persons, perhaps, as Hegel supposed, to their recognition of one's status as a subject. In *Being and Nothingness*, however, Sartre argues that although, for each of us, there is an aspect of ourselves that is dependent on recognition by others (our 'being-for-others'), this is an alienated conception of ourselves that we cannot integrate into our own self-consciousness; in relation to ourselves as we are for ourselves we are not dependent upon others. Sartre's discussion of this thesis includes a sustained analysis of a variety of situations in which we become aware of each other (most famously, that of the peeping Tom who hears someone behind him), and in my judgement these analyses provide the finest example of the application of phenomenological methods of analysis, not only by Sartre, but by any philosopher. Yet their conclusion is paradoxical—that we are always '*de trop* in relation to others' (*Being and Nothingness*, 410).

The ethical implication of this is that 'respect for the Other's freedom is an empty word' (*Being and Nothingness*, 409). Yet how can this be combined with the thesis which he proclaims in his 1945 lecture *Existentialism and Humanism*, that 'I am obliged to will the liberty of others at the same time as mine' (p. 52)? One part of the explanation is that *Being and Nothingness* is incomplete, and was always intended primarily as an exploration of human life as guided by illusions such as a belief in determinism and in the independent reality of ethical values. It was supposed to be balanced by a further book in which a life freed from these illusions was explored. This book was never completed, though *Existentialism and Humanism* and Sartre's 1947 notebooks *Cahiers pour une morale* (now published) reveal his broad intentions. The crucial point that emerges

from them is that Sartre maintains that although our meta-physical freedom does not depend upon others, there is another kind of freedom, moral freedom, which does depend upon others; as he puts it in the 1947 notebooks, 'morality is only possible if everyone is moral'.

Sartre's acceptance of this thesis coincides with his growing awareness of the need to fill out the rather abstract account of consciousness he had offered with an account of the relationships between an individual and their society. His approach to these relationships is, of course, deeply influenced by his study of Marx, and he likes to portray himself as a historical materialist ('I have said—and I repeat—that the only valid interpretation of human History is historical materialism' (*Critique of Dialectical Reason*, 39–40)). But in *Search for a Method* he is a brilliant critic of the reductive historical materialism familiar from orthodox Marxist theory; he offers instead a version which incorporates parts of the account of human life presented in *Being and Nothingness*. But the theme of human freedom is now given little direct emphasis: in a striking passage in the *Critique of Dialectical Reason* (pp. 233–4) he describes how workers who have some monotonous task are prone to engage in sexual fantasies—thereby contradicting his youthful insistence that the imagination is a citadel of absolute freedom. Indeed in a 1972 essay ('The Itinerary of a Thought') Sartre describes his earlier views about freedom as 'scandalous' and 'incredible'. Yet he remains as strongly committed as ever to the distinctiveness of human affairs: 'dialectical reason' is the mode of rationality characteristic of social and psychological explanations, and contrasts with 'analytical reason', which is the rationality appropriate to the physical sciences.

A central mark of 'dialectical reason' is the involvement of holistic explanations. This was already a feature of the account of psychological explanation given in *Being and Nothingness*, and to some extent the account of social explanation in Sartre's later works is an extrapolation into a broader historical and interpersonal field of the earlier account. In this case, however, the holistic theme is underpinned by an assumption basic to all Sartre's later work, that all human affairs are conducted under conditions of relative scarcity. For this implies that humans always confront each other as potential competitors, and, according to Sartre, it is this threat which both motivates all social and economic structures, and, in the end, unifies human history. This assumption of scarcity also provides one basis for the \*alienation which Sartre, like Marx, regards as an endemic feature of human history up to the present. But Sartre differs significantly from Marx in holding that alienation also arises from the fact that the realization of human purposes creates material structures (houses, machines, etc.—the 'practico-inert') that are inherently liable themselves to place further demands on people and, in some cases, to subvert the very purposes they were intended to promote. A central theme of Sartre's *Critique of Dialectical Reason* is, indeed, one of the attempt to overcome the constraints of the practico-inert through social institutions, and then of the failure of this attempt as social institutions

themselves ossify and join the practico-inert. In the *Critique of Dialectical Reason* as published, this theme is developed with particular reference to the French Revolution; in the projected second volume of the *Critique* (which was published posthumously) the same theme is discussed with reference to the Russian Revolution.

The *Critique* bears witness to Sartre's disillusionment with the fate of communist states (though not with Marxism), and in it he returns to the pessimism of *Being and Nothingness*. The kind of moral freedom that he had envisaged in *Existentialism and Humanism* is now presented as entirely utopian. Yet it was the themes of that lecture which once captivated the post-war generation, and, I suspect, it will be as protagonist of the value of existential freedom that he will be remembered. T.R.B.

**satisfaction.** The relation of satisfaction was introduced into logical investigations by Alfred Tarski. A \*formula like ' $x < 7$ ', for example, is satisfied by some values (in this case, those less than 7) of its 'free' number-variable  $x$ , and not by others. Tarski extended such an account to formulae of any degree of logical complexity, as a preliminary to defining truth for those formulae whose variables, if any, are bound by a \*quantifier. C.H.

E. Mendelson, *Introduction to Mathematical Logic*, 3rd edn. (Monterey, Calif., 1987).

**satisficing.** 'Satisficing' means 'seeking or achieving a satisfactory, but less than a maximum or optimum, result for the agent or for some group'. The term was originally introduced by economists, and satisficing models in \*economics, biology, and other sciences explain phenomena without assuming that nature or people are maximally efficient or rational. In ethics and rational-choice theory, the term refers to choices and actions that seek or achieve enough, but not maximal or optimal, well-being or desire-satisfaction, given other situational possibilities. Satisficing choice is sometimes rationally or morally recommended for cases where the calculations necessary to maximizing purposes are too difficult or costly to perform. But although such justifications are clearly *instrumental*, some ethicists hold that satisficing choices or actions can also be *inherently* admirable or rational as an

expression of moderation in one's desires and thus of admirable self-sufficiency. M.S.

\*utilitarianism.

**saturated expression:** see unsaturated expression.

**saying and showing.** For the early Wittgenstein, the logical form of a proposition, and of the reality mirrored by it, 'showed itself' in that proposition; it was not something that could be stated. At paragraph 4.1212 of the *Tractatus*, Wittgenstein wrote: 'What *can* be shown, *cannot* be said'. It is from this thought that the 'mystical' strain in the *Tractatus* really springs; Wittgenstein's remarks towards the book's end, on ethics, death, and the 'sense of the world', are all to the effect that what is at issue is something which cannot be put into words, but which makes itself manifest. That the idea expressed at 4.1212 should there relate to the logical properties of propositions thus indicates how far the author thought that the whole of philosophy (ethics etc.) could be dealt with—and to a large extent dismissed—by consideration of the nature of logic. R.P.L.T.

L. Wittgenstein, *Tractatus Logico-Philosophicus*, tr. D. F. Pears and B. F. McGuinness (London, 1961).

**Scanlon, T. M.** (1940– ). Moral and political philosopher best known for his work on contractualist moral theory. Scanlon published influential papers in the 1970s (e.g. 'Preference and Urgency', *Journal of Philosophy*, 1975, and 'Rights, Goals, and Fairness', in S. Hampshire (ed.), *Public and Private Morality*, 1978), but what established him as a leading moral philosopher was his 'Contractualism and Utilitarianism', published in A. Sen and B. Williams (eds.), *Utilitarianism and Beyond* (1982). Scanlon's contractualism held that an act is wrong if it is forbidden by any system of rules that no one could reasonably reject as the basis for informed, unforced general agreement. Books by Thomas Nagel (1991), Peter Carruthers (1992), Richard Miller (1992), and Brian Barry (1995) and a wide array of journal articles drew on Scanlon's theory. Scanlon's book *What We Owe to Each Other* (1998) not only develops his contractualism but also advances important arguments concerning normative reasons, well-being, moral motivation, responsibility, honesty, and relativism. **scepticism.** Philosophical scepticism questions our cognitive achievements, challenging our ability to obtain reliable knowledge. Global scepticism casts \*doubt upon all our attempts to seek the truth; more restricted forms of scepticism may question our knowledge of ethical matters, of the past, of other minds, of the underlying structure of matter, and so on. Since Descartes, the defence of our knowledge against scepticism has seemed to be the first task of epistemology. (\*Scepticism, history of.)

To say that sceptics deny the possibility of *knowledge* may distort the discussion: we might not feel threatened if we were capable of justified belief but not of knowledge (properly so called). Some recent writers pose the issues in terms of claims: when I put something forward as true, I present myself as making a *legitimate* claim and as able to resist intelligible challenges that may be made to it. If sceptical writings present ways of offering intelligible challenges to our claims which we cannot deal with, it seems that we cannot take responsibility for the legitimacy of any of our claims. We cannot carry out our inquiries in a responsible, self-controlled manner. It is only through tunnel vision or self-deception, closing our eyes to challenges we ought to take account of, that we are able to hold on to our opinions about the world.

The most discussed challenge in recent writing is a variant on Descartes's evil demon (\**malin génie*). Our ordinary practice of defending opinions requires us to reject explanations of our beliefs which are compatible with their falsity: if I cannot discriminate house sparrows from tree sparrows, my claim to have seen a tree sparrow should be withdrawn unless I can explain why no confusion was possible on this occasion. It is alleged that my experience may have been just as it is now had my brain been removed from my body, placed in a vat of nutrients, and wired up to a computer which was providing me with a coherent sequence of (misleading) experiences. This presents me with an analogous challenge which cannot be defeated: anything I might appeal to in order to show that I am not a \*brain in a vat could have been planted in my mind by the computer. It seems that my everyday claims are legitimate only if I can answer this sceptical challenge; and there seems no possibility of my doing this. An alternative structure of sceptical argument points out that, whenever I make a claim, I can be asked for its ground or justification. When I offer a ground, this involves making yet another claim, which can in turn be questioned. Since it is question-begging to use a circular argument to justify a claim to knowledge, my first claim is only legitimately made if I am prepared to enter an infinite regress of justifications.

Of course, such challenges have no role in our ordinary practice of making and defending views: if we were to invoke them, we would appear silly or mad. But the significance of this is unclear: it might be a sign that these sceptical doubts are unnatural or improper that the legitimacy of our beliefs is not affected by our ignoring them. If that is correct, then we could safely avoid any engagement with arguments in the sceptical canon. If, on the other hand, it simply reflects the ways in which we cope practically with the fact that scepticism is unanswerable (by ignoring it), then it would be evasion of responsibility to ignore sceptical arguments when, as philosophers, we seek an overall assessment of our cognitive position. Several contemporary philosophers, notably Barry Stroud, suspect that scepticism may be unavoidable.

In the background of much recent discussion is G. E. Moore's 'proof of the \*external world': holding his hand before him, he affirmed his knowledge that he had two

hands, and, since hands were objects in the external world, he concluded that there was an external world. Many philosophers are attracted by the robust insistence that these beliefs need no defence, but also have a strong sense that Moore missed an important point. One reaction, associated with Stroud, is that although my certainty that I have two hands needs no defence in our everyday practices, the same is not the case when we attempt a distinctively *philosophical* assessment of our position. The sense that Moore's argument settles nothing gains support from Wittgenstein's suggestion, in *On Certainty*, that talk of 'knowledge' is appropriate only when doubt is intelligible and grounds are available: if Moore claims 'knowledge', challenge and criticism is appropriate. If we are to resist the suggestion that sceptical challenges are relevant to the evaluation of our beliefs, the attractive element of the view needs a more sophisticated formulation than it received from Moore.

An influential argument that standard sceptical possibilities are irrelevant to our practice of epistemic evaluation was contained in Robert Nozick's *Philosophical Explanations*. He proposed an analysis of knowledge as belief that 'tracked the truth': simplifying slightly, my belief that Wittgenstein was Austrian counts as knowledge if it is true and if, had Wittgenstein not been Austrian, I would not have believed he was. Since, if I had been a brain in a vat, I would still have believed that I was not one, I do not know that I am not a brain in a vat. But this is irrelevant to the evaluation of more commonplace beliefs: it remains true that if my computer was not switched on, I would not believe that it was; so I do know that it is switched on. Sceptical challenges are thus of no epistemological importance.

Some are unhappy about the 'externalist' character of Nozick's approach: whether my beliefs count as knowledge may not be something I am well placed to judge. Reflection on my ways of monitoring my beliefs suggests that I cannot do this responsibly unless I can be confident of which of my beliefs are justified; or I must be able to identify which of my opinions are knowledge. Even if one of my beliefs tracks the truth, I may be in no position to tell whether it is. Nozick's claims about 'knows' need supplementing by an account of how such confidence is possible; and it is not yet obvious that sceptical challenges cannot threaten this sort of confidence in our ability to monitor our cognitive achievements.

Since Logical Positivists attempted to deny the meaningfulness of dream or demon possibilities on the grounds that we do not know what experience would be relevant to assessing their truth-value, philosophers have appealed to the theory of meaning. It is part of Donald Davidson's theory of interpretation that, when we assign meanings to someone's utterances or contents to their beliefs, we are guided by a demand that we make their beliefs largely truthful and their inferences largely sound. If that is correct, then it is impossible that someone's beliefs should be overwhelmingly false or unwarranted: that they seemed to be so would show simply that we had misinterpreted

them. If we encountered a brain in a vat, then, if we ascribed beliefs to it at all, they would be predominantly true beliefs about the 'world' created by the computer rather than predominantly false beliefs about our familiar external world. Whether or not we can conceive of the possibility that we are the victims of demons or wicked scientists, we can make no sense of our claims being both meaningful and substantially false. In that case, we can be confident of our ability to acquire information about the world, and revise our opinions in rational and defensible ways. But again, this does not satisfy those who are uneasy about the details of Davidson's account of \*interpretation\*: extrapolating from the ways we interpret our fellows to our ways of interpreting the poor brain is not easy to do; and since the 'experiences' undergone by the brain in a vat are supposedly indistinguishable from ours, we find it hard to escape the conclusion that it is indeed grossly deceived.

In an influential and controversial discussion, Hilary Putnam has argued that sceptical possibilities are self-refuting: a brain in a vat could not formulate the thought that it is one (*Reason, Truth and History*, ch. 1). Even if the brain in a vat could utter the words 'I might be a brain in a vat', they could not have the meaning they have in our speech. The argument depends (like Davidson's) on views about how words acquire reference: roughly, the sceptical use of these possibilities requires the agent to use a word 'vat' which 'refers' to a kind of thing (a real vat in the external world) which has no role in the brain's experience. Putnam rejects the claim that this rests upon a kind of 'intrinsic' or magical connection: we can make no sense of our referring to objects which have no role in the causation of our beliefs and concepts. If we understand the reference of our words and concepts in terms of their role in making sense of experience and classifying things in ways which answer to our needs, then we find that the brain in a vat uses 'vat' to refer to the 'vats' in the world of its experience rather than to these objects which are wholly independent of it. He is an internal realist rather than a metaphysical realist.

In our ordinary practice, we make 'local' challenges to particular beliefs and particular methods of inquiry against a background view of the world that stands firm and can be relied upon in meeting the challenge. Global challenges, like the 'brain in a vat' possibility, threaten this background view of the world along with more controversial claims. If Davidson's argument works, then we can legitimately refuse to take global challenges seriously: we can always trust our background view of the world in meeting any challenges that arise; and global challenges are importantly different from local ones: they are unnatural and we do not act irresponsibly in ignoring them. Many would agree that our best hope for avoiding scepticism rests on finding a way to treat global challenges as not analogous to local ones: we cannot be forced to take them into account by thinking through the consequences of our ordinary practice of challenging and defending claims and beliefs.

A major influence upon this line of thought has been Wittgenstein's *On Certainty*. Having criticized Moore's

claims to 'knowledge', he continued: 'I should like to say that Moore does not *know* what he says he knows, but it stands fast for him, as also for me; regarding it as absolutely solid is part of our *method* of inquiry' (para.151). My certainty that I have a hand is proof against sceptical arguments; and it is one of a heterogeneous group of certainties that form the background to all my ways of forming hypotheses, challenging claims, and conducting inquiries. Describing them as 'known' blinds us to the distinctive role occupied by these certainties which provide the 'scaffolding' for our inquiries. When the giving of grounds comes to an end, he urges, it is not in 'a kind of seeing on our part; it is our *acting*, which lies at the bottom of the language game' (para. 204). These certainties are manifested in the ways in which we react to evidence and to hypotheses, in our activities and our instinctive responses to the world. They are not expressed in conscious assent to propositions or in the search for evidence to support them. Local challenges are met by relying upon this scaffolding to guide our responses; since the scaffolding is not presented as 'knowledge', challenges to it cannot be posed or understood.

Whether this provides a perspective from which we can resist the traditional philosophical obsession with scepticism may still be an open question. Our best hope for doing so may well be to argue, with Wittgenstein, that the 'scaffolding' which guides us in forming and questioning beliefs cannot itself be questioned. But whether this suggestion will carry conviction for those who feel vividly the force of traditional sceptical arguments must remain uncertain.

**scepticism, history of.** The sceptical tradition questions our ability to obtain knowledge: if we are to seek the truth in a responsible manner, we need to meet challenges and difficulties to which no defensible answer is available. When we examine the history of this tradition, we study both the developments in the kinds of challenges used to unsettle our confidence, and changing views of the philosophical importance that these challenges have.

The history falls into two main periods. During the Hellenistic age, sceptical schools emerged in Greek philosophy, challenging the claims of scientists and philosophers to plumb the nature of reality. And, in the fifteenth and sixteenth centuries, new vigour was given to the question of

philosophical \*scepticism by the intellectual ferment resulting from battles between different theological positions and from the challenge posed by the new sciences to our everyday view of the world. Many date the birth of 'modern philosophy' from the time when Descartes identified the defeat of scepticism as the first task of philosophy.

Plato's philosophy bequeathed an ambiguous legacy. Socrates appeared to possess the ability to question and undermine any dogmatic assertion that was put to him, insisting that wisdom consisted in awareness of the extent of one's own ignorance. But having emphasized the importance of knowledge that was properly grounded or tethered, he explained how such knowledge was possible, suggesting that it was necessary for the exercise of virtue. During the centuries following Plato's death, his \*Academy became associated with a subtle form of scepticism, which focused more on the first part of this legacy than the second. And a breakaway sect took the name of \*Pyrrhonism', after Pyrrho of Elis, a post-Socratic philosopher whose life exhibited extreme scepticism. Our best source of Pyrrhonist thought is the writings of Sextus Empiricus, a late member of the school, whose *Outlines of Pyrrhonism* is a handbook of the position.

The Pyrrhonist 'modes' were used to challenge the beliefs of 'dogmatists': their use could supposedly force anyone to suspend judgement on any matter. Exposure to such techniques could produce a 'life without belief': a general suspension of judgement. A common objection was that without belief one cannot act, supported by the story that Pyrrho required constant support from friends to save him from natural dangers which he did not believe in. But, according to Sextus, Pyrrhonists could expect a quiet, conservative life: they passively acquiesced in 'appearances', going by perceptual information and by what appeared right and wrong; they conformed to local religious and ethical customs; and they acquired a trade. What they lacked was information about non-evident properties of things; and they accepted appearances passively, avoiding active endorsement of positions and taking no responsibility for their truth. This 'life without belief' turned out to yield the tranquillity and fulfilment (ataraxia) that others had sought through actively seeking knowledge.

Pyrrhonists challenged 'beliefs' by proposing contrasting 'appearances': when you assert that the tower is round, I point out that it does not appear round from a distance. To sustain your belief, you must propose a criterion that shows why it is correct. Since these criteria, in turn, can be challenged, your attempt to defend your view can only lead to a regress of criteria or go round in a circle, unless you stubbornly insist upon a criterion that you cannot support. If this picture of the structure of challenging beliefs is correct, it seems that you will not be able to avoid admitting that the matter is not settled.

During the sixteenth century, the writings of Sextus Empiricus and other Sceptics become more widely known, and questions about the criterion of religious truth and issues about the foundations of the new science

became pressing. Montaigne, in *Apology for Raimond Sebond*, made sceptical arguments available in the vernacular, and encouraged a more general scepticism concerning whether any system of ideas could resist doubt. An early user of sceptical themes was Erasmus, who defended the Catholic Church against Reformation ideas: he used sceptical arguments to attack Luther's doctrines and proposed (like Sextus) that we should passively conform to existing practices since no defensible criterion of truth was available which could be trusted when we try to criticize them. But at a time of intellectual and religious ferment, Pyrrhonist prescriptions about how to live yielded conflicting recommendations; and many, like Luther, insisted that conformity to prevailing customs is too tepid a style of religious observance to meet the demands of Christianity. It is no accident that epistemological scepticism came increasingly to be associated with the religious variety. And, of course, once the force of sceptical arguments is acknowledged, they cannot easily be prevented from spreading doubt to all areas of life, including the new sciences.

Descartes set out to provide secure foundations for science, metaphysics, and religion by defeating scepticism. This required him to formulate and overcome the strongest possible sceptical arguments. Rather than appealing to particular challenges, particular contrasting appearances, to question each opinion he considered, he needed systematic doubts which put all our beliefs into question. The possibility that I might be dreaming challenged all perceptual beliefs; and the possibility that I was wholly under the influence of an evil demon (*\*malin génie*) threatened logical and metaphysical principles as well. Unless Descartes could legitimately appeal to a criterion enabling him to reject those possibilities, none of our knowledge would be secure. In his *Meditations* (1641), he attempted to provide such a criterion. Since few of his contemporaries considered his attempt successful, he bequeathed to later philosophers only a more powerful battery of sceptical challenges and a greater awareness of the importance and difficulty of defeating them. His 'refutation' of scepticism left it in better shape than before, encouraging a sense of the power of scepticism which culminated in Pierre Bayle's *Historical and Critical Dictionary* (1697–1702).

Descartes transformed thought about scepticism in another way, by introducing the idea that our knowledge of the contents of our own minds is more certain than our knowledge of things outside the mind. The problem of the external world, of showing how our subjective data provide us with reason for believing that there are external things, has seemed for many modern philosophers to be the fundamental issue of scepticism, although it was unknown to ancient Sceptics. This may have distorted our understanding of the force and importance of philosophical scepticism.

Sceptical considerations had a role in the development of a new *empirical* approach to science in the sixteenth and seventeenth centuries. Many of those involved in the

development of the new science, for example Mersenne and Gassendi in France and John Locke and John Wilkins in England, would have agreed that sceptical arguments undermine the pretensions of dogmatic metaphysics and also of any scientific claim to reveal the real underlying essence of matter. Locke claimed that the study of nature yields *opinion* rather than *knowledge*, and Gassendi presented a version of the atomic theory which claimed only to accord with the patterns found in appearances. A growing modesty in the claims made for hypotheses followed sceptical awareness of the limitations of the human understanding.

This emerges clearly in the work of David Hume. Agreeing with those who reject Descartes's demand that our methods of inquiry be subjected to trial through scepticism in order to achieve certainty, Hume sought to emulate Newton and study cognition by constructing a scientific account of the mind. But he concluded that our beliefs extend beyond our own impressions and ideas only by exploiting causal inferences which have no legitimate basis. He arrives at the sceptical conclusion that the faculties giving rise to our view of the world are wholly unfitted to the task. The despair that this threatens to induce is avoided only because, when we turn aside from philosophy and science, we are psychologically incapable of taking their discoveries seriously. We are naturally drawn to philosophical investigations, but we find their results absurd and incredible.

But Hume believed that to be 'convinced of the force of the Pyrrhonian doubt, and of the impossibility that anything, but the strong power of the natural instinct, could free us from it' has a beneficial effect upon us. Inducing a sense of modesty, it discourages us from attaching too much importance to theory; we become aware of our cognitive limitations. Although we can benefit from scientific results (while sceptical that they promise the last word about things), we shall not allow them to undermine otherwise valuable beliefs and ideas. When philosophy encourages scepticism about the reliability of our knowledge, it is reasonable to extend that scepticism to philosophy: it turns into a useful activity, but not one which can provide dogmatic knowledge.

There have always been those who respond to sceptical challenges by impatiently denouncing them as absurd stratagems which no one takes seriously, and which can thus be ignored. From the time of Hume, two rationales have emerged for arguing that this response is legitimate. Since these sceptical doubts seem to be introduced in a natural way, resembling challenges we use all the time, we need to understand why they are different. We must explain how they do not show that our inquiries are governed by cognitive aims which we are incapable of achieving. The need, then, is to show that Pyrrhonist and Cartesian sceptical arguments are 'unnatural' or improper.

\*'Common-sense' philosophers, from the sixteenth century on, have insisted that demanding reasons and challenging their adequacy can distort the structure of justification. Thomas Reid is an important figure in a

tradition that also includes twentieth-century thinkers such as G. E. Moore. The belief that there is an external world, for example, is not the sort of thing which is supported by particular arguments or reasons: it has stood the test of time, and 'everything counts for it, nothing counts against it'. Sceptics force us to treat it as one hypothesis among others, thus needing the kind of defence appropriate to controversial hypotheses. But such certainties work differently from ordinary hypotheses. Indeed, anything we might introduce as an argument in their support is less certain than they are themselves: I cannot offer evidence in favour of my belief that Rome exists, because any evidence suggesting otherwise would automatically be discredited for conflicting with such an obvious truth.

Kant, by contrast, argued that sceptics posed the wrong question: we unquestionably do possess knowledge, and the philosophical task is only to explain how this is possible. He concluded that our knowledge concerns the empirical world, whose character is determined by the structuring properties of our minds. Sceptical arguments may challenge our ability to know about the noumenal world, about things as they are in themselves. But since our aim in inquiry is to develop knowledge of a world which is shaped by our cognitive constitution, these arguments do not touch the only kind of knowledge which really matters to us. **scepticism, moral:** *see* moral scepticism.

**scepticism about law:** *see* law, scepticism about.

**scepticism about religion:** *see* religion, scepticism about.

**Sceptics, ancient.** The Greek word *skeptikoi* refers to those philosophers who refused to take dogmatic positions, but rather claimed to be always engaged in 'investigation' or 'consideration' (*skepsis*) of questions. Pyrrho of Elis (c.360–c.270 BC) is generally regarded as the founder of this school. Nevertheless, later sceptics and historians of \*scepticism have often noted that a disposition to reject various claims to knowledge can be found throughout early Greek philosophy. For example, Xenophanes, Parmenides, and Democritus evince scepticism to a greater or less degree regarding claims to know reality. Thus, a denial of knowledge in one or more areas of investigation does not strictly speaking distinguish the Sceptics. Rather, they are distinguished by their adherence to certain generalized arguments against dogmatic claims and by their view of the salutary effects of a sceptical stance.

Pyrrho is said to have been a painter by training. He was probably not the author of the technical arguments that

later came to characterize the thinking of his disciples. He is reputed to have been a man of remarkable calmness and humility, and it was evidently thought by his admirers that these qualities arose from his refusal to commit himself to dogmatic claims.

The basic Sceptical strategy is to argue that the sorts of assertion dogmatists make are supposed to be inferred from elementary data such as sense-perceptions. But, the Sceptics argue, these claims are only warranted if the data entail them. Various arguments—the so-called 'Sceptical tropes'—can be employed to show that the supposed entailment is illusory. In effect, the only evidence a Sceptic will allow is entailing evidence. On this basis, one is no more justified in accepting the dogmatists' claims than their opposite. So, the only rational response is to say 'I no more accept *p* than its opposite', whatever claim *p* might express. What is the supposed result of being thus disposed to the dogmatists' claims? Tranquillity of mind and an absence of anxious attention to putatively life-enhancing knowledge.

It is not surprising that no ordinary philosophical school would be founded on the exiguous negativism of Scepticism. Pyrrho did, however, have one disciple, Timon of Phlius (c.320–c.230), who travelled to Elis as a young man and later arrived in Athens to challenge the prevailing dogmatists in the spirit of his master. Timon crafted his attacks on dogmatists in the form of *silloi*, or satirical poems, some fragments of which survive.

The principal development within Scepticism in the third century was its introduction into Plato's \*Academy by Arcesilaus. Since the prevailing dogmatism of the day was \*Stoicism, Arcesilaus and the Academic Sceptics directed their increasingly refined destructive arguments against Stoic claims in theology and ethics. We do not know to what extent Arcesilaus was influenced by Pyrrho or whether he was in contact with Timon, but the inspiration for these Sceptical attacks was not Pyrrho so much as it was Socrates, understood by the Sceptics as one of their own. He was for them, in word and deed, a model of how one ought to respond to dogmatic assertions and of the results of such a response.

The most famous of the Academic Sceptics after Arcesilaus was Carneades. The historical evidence suggests that Carneades developed an epistemological theory of probabilism which apparently aimed to mitigate the extreme alternatives—certain knowledge or ignorance—of Pyrrhonian Scepticism.

A reversion to dogmatism within the Academy, that is, to Platonism, in the first century BC ended with a revival of Pyrrhonism by Aenesidemus, whose version of Scepticism is partially preserved by the great chronicler of Scepticism, Sextus Empiricus.

Scepticism can be either global or local. That is, one can be a sceptic regarding knowledge in general or only regarding a particular area of knowledge. The later history of scepticism is replete with attempts to combine a local scepticism, say regarding religious knowledge, with vigorous knowledge-claims in other areas, such as science.

Such an approach has even been embraced by *defenders* of religion, who want to claim that religious faith is beyond the reach of that which is scientifically knowable. L.P.G.

**Schacht, Richard** (1941– ). American philosopher; Professor of Philosophy, Criticism and Interpretive Theory at the University of Illinois at Urbana-Champaign. Schacht's writings make room for some understanding between philosophers writing in the 'analytical' tradition and so-called 'modern continental philosophy'. Notably, *Nietzsche* (1983) presents arguments for and against that philosopher's perspectivism and repudiation of Western morality in an idiom that is not Nietzschean but which preserves many of Nietzsche's insights. In *Alienation* (1971), *Hegel and After: Studies in Continental Philosophy between Kant and Sartre* (1975), and *Classical Modern Philosophers: Descartes to Kant* (1984), Schacht has made Anglo-American philosophers more aware of the need to read modern European philosophers. S.P.

\*Nietzsche.

**Scheler, Max** (1874–1928). German philosopher called 'the Catholic Nietzsche'. He applied Husserl's phenomenology to ethics, culture, and religion. He was a founder of philosophical \*anthropology and of sociology of knowledge (*Problems of a Sociology of Knowledge* (1926); tr. London, 1980). In *Formalism in Ethics and the Non-Formal Ethics of Values* (1913–16; tr. Evanston, Ill., 1973), he argued (against Kant etc.) that values are objective, unchanging, a priori, non-formal, and objects of emotions and feelings rather than reason. Values form a hierarchy: (1) pleasure–pain (values of sensible feeling), (2) noble–vulgar (values of vital feeling), (3) beautiful–ugly, just–unjust, pure knowledge of truth (spiritual values), and (4) holy–unholy (religious values). Moral values consist in the realization of other values. Our feeling for values and their social embodiment, but not values themselves, vary in sociologically explicable ways. A person is not a substance nor an object, but the concrete unity of acts. He is essentially both individual and a member of a community. Most persons lack feeling for higher values, and cannot participate in the types of community devoted to them; but all should have adequate, and perhaps equal, access to what they do value. Values are better promoted by aristocracy than by liberal democracy. M.J.I.

**Schelling, Friedrich Wilhelm Joseph von** (1775–1854). German philosopher, who was the Proteus of post-Kantian \*idealism and the main philosopher of the Romantic

circle. His earliest works, from 1793 on, were variations on Fichte's \**Wissenschaftslehre*, though he contrasted idealism and 'dogmatism' less sharply than Fichte. From 1797 he produced several works on philosophy of nature, which attempt to 'construct' or 'deduce' nature as the 'objective system of reason'. For Fichte and Kant, nature, though objective in relation to the finite ego, is a product of 'consciousness in general'. Thus, as a book bears the mark of its author, \*nature will be an organic whole tending to the realization of \*reason. Fichte initially believed that Schelling was trying to establish this, as a supplement to *Wissenschaftslehre*. Nature begins in the emergence of matter from the forces of attraction and repulsion and ends in the human organism, the embodiment of practical reason: nature is the I, or mind, in the process of becoming. Every natural phenomenon has its place in a logically ordered system of development. Schelling, like Goethe, rejects quantitative, mechanical science, and stresses life, the organic, purpose, and polarity (especially electricity and magnetism).

Schelling's next (un-Fichtean) step was to view philosophy of nature and *Wissenschaftslehre* as two *parallel* sciences, respectively deriving mind from nature and nature from mind. The *System of Transcendental Idealism* (1800; tr. Charlottesville, Va., 1978) develops theoretical and practical *Wissenschaftslehre*, in which, respectively, the conscious is determined by the unconscious and the unconscious by the conscious. The theoretical self surveys the productivity of unconscious reason in feeling, perception, and thought; the practical self freely transforms this unconscious reality in individual morality, political life, and history. But both these series are endless; reason is here realized only at infinity. It is fully realized only in the unconscious, yet conscious, activity of the artistic genius: art is the true 'organ' of philosophy. He expanded this view in lectures on *Philosophy of Art* (1802–5, pub. 1859; tr. Minneapolis, 1989).

Schelling next sought a common basis for nature and the self, for philosophy of nature and transcendental idealism, i.e. a system of 'identity'. In *Exposition of my System of Philosophy* (1801), this basis is 'absolute reason', the 'indifference of nature and spirit, of object and subject'. He acknowledges its affinity to Spinoza's substance. The Absolute is the quantitative indifference of reality and ideality. Reality or objectivity predominates over ideality or subjectivity in the real series: it runs from matter, via light, electricity, and chemistry, to the organism, the most spiritual phase (or 'potency') of nature. Subjectivity predominates in the ideal series, running from morality and science to art, the most natural phase of spirit. The full manifestation of the Absolute, the universe, is a perfect organism and work of art. In *Bruno* (1802; tr. Albany, NY, 1984) the Absolute is called 'God' or the 'infinite', and the potencies are seen as (Neo)-platonian 'ideas', God's eternal vision of himself, the intermediary between the Absolute and the empirical world.

In 1804 Schelling came to believe that though the world can be shown to be rational in its content, no rational

account can be given of its *existence*, of why there is anything rather than nothing. The finite world originates from God not by a rational, comprehensible process but by a *leap*, a free (timeless) fall of the ideas from God into finite actuality. The content of reality is rational, embodying God's ideas; its being actual (nature) is apostasy, sin, unreason. Nature's essence strives to return to God, and this return is history: its goal is to reunite the ideas to God. Man's development is parallel to God's: he freely breaks loose from God and is redeemed by returning to him.

*Of Human Freedom* (1809; tr. Chicago, 1937) postulates a 'primordial ground' or 'abyss' in God, which is indeterminate, unconscious striving or \*will; all reality is ultimately will. This self-directed will creates as its self-image or self-revelation the ideas, reason. The world proceeds from the interaction between the ground and ideas. Nature reveals the conflict between irrational striving and rational purpose. History displays the triumph of man's rational universal will over his irrational particular will. Reality develops from primordial will to rational self-knowledge and self-determination.

Religion, not art, is now the organ of philosophy. God develops in the successive ideas that men have of him. In lectures on mythology (1842) and revelation (1842–3), Schelling seeks knowledge of God from the history of all religions: God's self-revelation and -development advances from primordial will to reason and love. Schelling's and Hegel's earlier 'negative philosophy' showed only that *if* God reveals himself, he does so in certain rationally comprehensible forms. The new 'positive philosophy' is needed to show *that* he reveals himself in man's religious history.

Schelling had a mind of great depth and range, capable of original insights as well as of fusing those of others (the Neoplatonists, Spinoza, Kant, Fichte, Hegel, etc.). Many of his ideas re-emerge in Schopenhauer, Tillich, and Existentialism: Schelling's God is both the will to power and existentialist man. M.J.L.

**schema.** Literally shape, pattern, form; plural, schemata or schemas. In logic a schema is an expression, often a sentence, from which certain word-groups have been removed and replaced by blanks or more commonly by 'schematic letters', the role of these being to mark places where any word-group of the type removed can be inserted: e.g. 'P', 'F', 'G' in 'If not P, P; therefore P', 'G belongs to some F',  $\exists x(Fx \wedge Gx)$  ('Something is F and G'). Some schemata are \*formulae, i.e. contain no words. But there are also formulae with meanings, e.g. the true sentence  $\forall x(x = x)$  ('Everything is the same as itself') or the functional expression ' $\pi^2$ '; whereas schemata mean noth-

ing—and so cannot, for example, be true or false—until their letters are replaced or (as some say) interpreted. The role of a schematic letter is different from that of a quantifiable \*variable, although the same letter might be assigned both roles at once. C.A.K.

W. V. Quine, *Methods of Logic*, 3rd edn. (London, 1974).

**Schiffer, Stephen** (1940– ). American philosopher (D.Phil., Oxford) currently at New York University, best known for his three books on meaning and for his quest for rigour and clarity. In *Meaning* he defended the view that \*semantics reduces to propositional-attitude psychology, by presenting an intricate version of \*Grice's intention-based semantics. He later repudiated this view in *Remnants of Meaning*, where he argued against the very possibility of a theory of \*meaning or \*propositional attitude content. He subsequently found a new possibility for such a theory, based on a distinctively deflationary but anti-reductionist, or 'pleonastic', conception of meanings and propositions. This theory is developed in *The Things We Mean*. Schiffer is also known for having introduced and later debunked the 'hidden-indexical theory' of propositional attitude ascriptions. Other papers treat such topics as the nature of desire, Descartes on his essence, rigid designation, singular thought, 'Kripkenstein' (Kripke's rendition of Wittgenstein on rules and private language), epistemic contextualism, and vagueness. **Schiller, Johann Christoph Friedrich von** (1759–1805). German philosopher, poet, and dramatist, who developed Kant's ethics and aesthetics towards post-Kantian \*idealism. His main concern was the role of art and beauty in man's rational life and its history. (He became Professor of History at Jena in 1789, and wrote several historical works, besides his inaugural lecture: *What is, and to what End does one Study, Universal History?*) On the basis of Kant's *Critique of Judgement* (1790) he argued that \*beauty is 'freedom in phenomenal appearance'. Aesthetic contemplation of an object does not involve cognitively understanding it: we do not apply concepts to it or investigate its causal conditions, but view it as if it were free. The beautiful, again, is not an object of desire or moral will. In aesthetic contemplation the 'play impulse' prevails.

\*Aesthetics, rather than (as Kant supposed) religion, plays the central part in educating the sensuous nature of man to morality. Art and beauty refine man's feelings, so that he is more inclined to act *legally*, and thus prepare him for morality. In *On the Aesthetic Education of Man* (1795; tr. Oxford, 1967) he envisaged an advance, both in the life of the individual and in the history of man, from the physical state in which man is ruled by needs and nature, by way of the aesthetic state, in which he frees himself from nature by the elimination of his sensuous will, to the moral state, in which man controls nature by his moral will. But aesthetics also perfects man's moral condition. By ennobling

his sensuous nature, beauty reconciles the conflict between it and his rational will. Thus man becomes a 'beautiful soul' (*schöne Seele*), who fulfils the moral law from inclination.

In *Naïve and Sentimental Poetry* (1796; tr. New York, 1966) he argues that different ages and types of poetry depend on different relations between nature and freedom. In the 'Arcadian' stage (Greece) nature and freedom are in primitive harmony: men act morally by unconscious instinct and poetry is naïve. Modern poetry feels a conflict between nature and freedom, the real and the ideal, and strives to reconcile it: sentimental poetry. In the 'Elysian' age to come, when harmony is reflectively restored, poetry will be at once naïve and sentimental.

**Schlegel, Friedrich von** (1772–1829). Central in the German Romantic movement and responsible for converting the classical notion of irony, as a mere figure of speech, into an entire literary or quasi-philosophical perspective that named \*Socrates among its antecedents. Early influenced by Kant and Fichte, Schlegel criticized the former for failing to bring ideas into touch with reality and the latter's world-creating ego for leaving out nature and history. Schlegel's views on irony nevertheless draw upon Fichte's view of philosophy as animated by the thoughts and counter-thoughts generated by reflection. Philosophy is a reflective art, as with Socrates, and its goal is to bring the real and the ideal into touch with each other on a broad front (poetry, art, society, politics, literary communication). Irony as reflective freedom raises the thinker to a sense of transcendence and of the divinely creative spirit. A convert to Roman Catholicism, Schlegel saw history as a process in which irreducibly single individuals, nations, and languages found their universal nature in the knowledge of God. He founded *The Athenaeum*, a periodical of the early Romantics, and was for a time a politician. A.H.

**Schleiermacher, Friedrich Ernst-Daniel** (1768–1834). German Protestant theologian and philosopher of religion. Translator of Plato. Inventor of \*hermeneutics in its modern form. Religion is properly understood by intuition and feeling (*Anschauung und Gefühl*) and 'a sense and taste for the infinite', rather than through reason or doctrine. In his philosophy of the person Schleiermacher emphasizes the dependence of each of cognition, feeling, and action on the other two. In his theology, God is the highest and only unity of what is. All particular things are disclosed only through God. The deepest awe at the existence of the universe as a whole is possible only through a feeling of devotion. The profound experience of union

with the infinite implies the existence of God. Christianity is not the only true religion, but the most complete.

Schleiermacher accepted Kant's critique of arguments for the existence of God, took seriously his construal of God, freedom, and the immortality of the soul as 'postulates', and was positively influenced by the Romantic movement, especially by \*Schlegel. Until the renewed emphasis placed upon Scripture by Karl Barth, Schleiermacher's influence on Protestant theology was immense.

**Schlick, Friedrich Albert Moritz** (1882–1936). In 1922 Schlick, a physicist turned philosopher, became Professor of the Philosophy of the Inductive Sciences in Vienna (a predecessor had been Mach), where he became the centre of a group of like-minded advocates of logical and scientific rigour in philosophy, the Vienna Circle. Out of their discussions grew \*Logical Positivism, the most profound and creative (though ultimately mistaken) school of philosophy in the twentieth century. But Schlick was not altogether typical of the Circle. Of course, he shared the view that science had a unique status, but he also included ethics in science by analysing value-judgements as desires, and therefore as psychological facts. But further development of his ideas was tragically denied to him, when in mid-career he was murdered on his way to a lecture by an insane student.

**scholasticism.** The philosophy of the 'schools', i.e. the tradition which arose in the medieval universities and is associated with the methods and theses of the major philosophers of the thirteenth and fourteenth centuries, namely, Aquinas, Scotus, and Ockham. Scholasticism remained the dominant European philosophy until the fifteenth century, when it gave way to, in turn, Renaissance humanism, rationalism, and empiricism. There have, however, been several revivals, and \*neo-scholasticism remains a feature of the philosophical landscape. J.HAL.

**Schopenhauer, Arthur** (1788–1860). German philosopher of inherited independent means, who gained distinction only towards the end of his life as a result, partly, of the notice taken of him in the British utilitarian journal the *Westminster Review*. His mother, who thoroughly disliked her son for his gloomy outlook, ran a literary salon in Weimar, frequented by Goethe, and this led to a short

period of intellectual friendship during Schopenhauer's youth, as Goethe initially thought Schopenhauer's philosophy relevant for his own theory of colours. Schopenhauer arrived at his general philosophical position very early and all his works are developments of the same basic initial ideas. His chief inspirations were Plato, Kant, and the \*Upanishads. He is, in fact, the first (and remains among the few) Western philosophers to have related his thought to Hindu and Buddhist ideas. However, his most distinctive contribution to philosophy is in his insistence that \*Will is more basic than thought in both man and nature.

1. Schopenhauer's starting-point for his solution to 'the riddle of the world' is a form of transcendental \*idealism which he owes to Kant, though he seeks to establish it in a less contorted way. The physical world is phenomenal and exists only for 'the subject of knowledge'. Only by recognizing this can we explain how we know certain necessary \*synthetic a priori truths about it. Our cognitive faculties construct the world on the basis of four versions of the 'principle of \*sufficient reason', to which all phenomena must conform. (This is elaborated most fully in the book of his early youth, *On the Fourfold Root of the Principle of Sufficient Reason* (1813).) Our *sensibility* operates with the principle that everything is situated in a space of which the parts are mutually determining according to Euclidean geometry, and a time the mutual conditioning of whose moments is the topic of arithmetic (via the temporal nature of counting); our *understanding* works with the law of causality, and yields perception of a physical world which it pictures as the cause of our sensations. Our *reason*—whose conceptual representations (*Vorstellungen*) are quite secondary to the representations which understanding produces in perception and from which they are abstracted (Schopenhauer particularly scorns the many philosophers who confuse these or, like Hegel, treat concepts as primary)—works on the principle that every judgement must have its justification. A fourth principle bids us conceive of human action as necessarily determined by  *motive*. The world constructed on these principles can only exist for the subject of knowledge to whose faculties they correspond.

2. Matters are taken further in Schopenhauer's *magnum opus* *The World as Will and Representation* (*Die Welt als Wille und Vorstellung* (1818)). Kant's greatest merit, for Schopenhauer, was the distinction of the phenomenon from the \*thing-in-itself. He was also right (though not consistently) that the thing-in-itself is not the cause of our sensations or of phenomena, since causation applies only within the phenomenal world and cannot relate it to something else. But that, for Schopenhauer, does not mean that we can form no idea of the nature of the thing-in-itself. For our perceptual experience of the phenomenal world of things in space and time is not our only experience. We are aware of ourselves, both in the perceptual fashion by which we know external things, and, quite differently, 'from within' as Will, more specifically as Will to Live. So our behaviour presents itself to us not only as the

movements of a physical object but more intimately as the phases of a Will. The latter is not, and is not felt to be, the cause of the behaviour; rather, these are the same thing known outwardly and inwardly.

From knowledge of my own nature as thing-in-itself I can infer something of the nature of the physical world in general. For while I cannot prove that the rest of nature is more than mere appearance, namely the appearance of something in itself, to deny this would be a form of \*solipsism, something which belongs only to the madhouse. If we are to look upon the world sanely, we must suppose that everything in it is the appearance of what in itself is Will in basically the same sense as is my body and its behaviour. This argument is treated by some commentators with less respect than it deserves. If it is true that my body is Will in its real inner being, then, since the physical world outwardly seems homogeneous with it, and belongs to the same unitary interacting system, it is reasonable to suppose that the same is true of physical nature, not only in other humans and animals, as is quite easily granted, but throughout. The reasonable doubt is whether Schopenhauer has shown that Will is the inner being of my organism and behaviour, rather than the justification of extending this conclusion to the world at large.

3. The natural world, then, is the appearance of Will to itself, when this generates the subject of knowledge as an affection of itself. But is it one Will or many which appears to itself as the organic and inorganic world? Schopenhauer takes the former view (as Nietzsche was later to take the latter). For, so he argues, number, as an operation of the human intellect, only applies to the world of representation and cannot be relevant to reality as it is in itself. This cannot, then, be many, but must be one, not, indeed, in the sense that this would be the upshot of a count, but in the sense that number is inapplicable. (Whether this gives him the oneness he requires is doubtful.) He could have argued more effectively, however, that since causality cannot apply to reality in itself, it cannot figure there as 'the cement of the universe' (in Mackie's phrase) and that the unity of the cosmos must not depend upon such external relations between its parts.

But if what each of us experiences as his own inner being is Will at all, surely it is Will as a series of acts of willing, something both temporal and plural? Schopenhauer, more especially in the greatly enlarged second edition (1844) of his great work, is alert to this problem. It only shows, he says, that the thing-in-itself is still revealing itself incompletely, and has divested itself only of the more external garments in which it is dressed by consciousness. In fact, there seems some oscillation between the claim (characteristic later of Nietzsche) that introspectible processes of desire, pleasure and pain, and so forth are what I find as the inner being of myself and the claim that I can detect at the core of my being a dim unvarying drive to satisfaction. No reading of the text makes him altogether consistent on such matters. But the general upshot, that the universe is a single, 'vast', cosmic Will to

Exist which experiences itself through an apparent diversity of conscious beings in a spatio-temporal and deterministic world, is clear enough and strongly argued. This Will is said to be unconscious in inanimate nature, but it is hard to see how one can understand Schopenhauer unless it is supposed that it has some sort of dumb feeling of itself, even if there is not the contrast between subject and object required for consciousness in any full sense.

4. More than anything else, Schopenhauer is famous as the philosopher of \*pessimism. The wretchedness of the world (with whose horrors he became obsessed early in life) and the nastiness of human nature, he contends, with many striking examples, is evident enough empirically. But it is also a necessary truth, following from the very nature of its underlying reality, the Will. Will seeks constantly for a quietus which from its very nature as striving it could only reach by forfeiting its main goal, existence; indeed pleasure has really only a negative character as the relief from the suffering which is its normal state. Moreover, in its apparent pluralization, each part of the phenomenal world is powered by a drive to survive at the expense of others, so that there is a universal and appalling war of all against all. This is no time to consider the psychological sources of Schopenhauer's extreme pessimism, nor weigh its pros and cons empirically; we remark only that, central as it was to his philosophy as he conceived it, it does not seem entailed by his most interesting metaphysical conclusions. It is not so obvious as he thought that a world of Will *must* have been one of misery, while some have found it possible to delight in a world thus conceived even with the miseries actually pertaining to it.

5. Glum as his view of the world is, Schopenhauer offers two ways of escape from its horrors, one temporary, the other in principle permanent.

First, there is aesthetic experience, Schopenhauer's detailed and brilliant account of which has had considerable influence. Here our faculty of knowledge, in particular perception, normally only an instrument to the Will's satisfaction, gains a certain independence as pure will-less contemplation for its own sake, freeing us briefly from our misery, while the veil which hides the true nature of reality from us is partially rent. We no longer experience ourselves as one individual standing in contrast to others, but rather as the impersonal and universal pure subject of knowledge. And with this change in our experience of ourselves goes a change in the character of the object presented to us. It is no longer particular things in space and time which present themselves, but rather the basic types and principles by which the Will manifests itself, types and principles which Schopenhauer identifies with the Platonic Ideas, believing that he is uncovering the true significance of Plato's doctrine. There is a distinct law, or system of laws, of nature which is the phenomenal manifestation of each of these (the laws of physics, of chemistry, of biology, etc., and of each animal species, a partially distinct one also for every human being constituting his innate character). The artist produces a percep-

tual representation which yields us awareness of these Ideas (*Ideen*) rather than of the particular thing before us. (Music alone depicts the Will in its various grades as it is in itself rather than as manifested in the phenomenal world.)

Aspects of this account are puzzling. Why are aesthetic contemplation, and its peaceful objects, so free of the travails essential to Will, if they really bring us closer to the reality underlying phenomena? And in what sense does the Will objectify itself in these different grades? Schopenhauer often writes as though this objectification was a kind of real entry into all the variety of the world's phenomena, but he should be referring not to a real pouring of itself into an external world, but to the way in which the one Will manifests itself to itself, *qua* subject of knowledge.

The only lasting solution, however, to our misery comes when people become so aware of the necessary wretchedness of life, of the misery of existing as futile manifestations of the cosmic Will to Live, that they lose all wish for existence and gratification. This is what happens in the case of the genuine saint, an ascetic who has no concern with living and prospering. In him the Will to Live has denied itself. Or rather, there is only a faint twinkling of it left, hardly enough to sustain the picture of a world of things in space and time. When he dies this twinkling will utterly cease, and with it the world of which he was conscious, since this consisted in nothing but his picture of it. For Will and its picture of the world cannot continue to be when it no longer desires, and the world cannot be when the Will ceases, since it is only the Will's own delusive picture of itself.

But surely the Will as personalized in me, and the world for me, end equally, when I die, whether I have reached will-denying sainthood or not, while in both cases the Will continues its life in others and in nature? The answer seems to be that, when the saint dies, his particular grade or type of Will is at an end, whereas when the ordinary man dies, though he is at an end, his type is not. (Thus suicide is self-defeating, a mere complaint over current conditions on the part of one particular grade of Will.) Moreover, universal sainthood would somehow bring everything to an end (though the real truth here must be somehow non-temporal). Will anything be left at all? Yes, Schopenhauer darkly hints, something inconceivable by us but experienced by the saint in mystic contemplation. For what is *nothing* from one point of view must always be *something* from another. The analysis of *nothing* here is similar to Bergson's.

Schopenhauer's ethics (*On the Freedom of the Will* and *On the Basis of Morality*, published together in 1841) is closely related to his metaphysics. It is prefaced by a critique of Kant's account of morality. For Schopenhauer the very idea of a categorical, as opposed to a hypothetical, imperative, is an absurdity. An intelligible imperative is normally an order given by someone who can impose sanctions on those who do not conform to it, and has the form of 'Do this . . . or else'. Schopenhauer believed that the \*categorical imperative only seemed to make sense to

Kant because unconsciously he took it as the command of God. Moreover, in spite of himself Kant comes too near to giving ethics an egoistic foundation, effectively basing it, claims Schopenhauer, on our concern with how it would affect us personally if everyone acted according to our example.

In contrast, moral goodness is identified by Schopenhauer with unselfish compassion for others. The good man is one who, not making the usual distinction between himself and others, is filled with universal compassion. Thus he acts on the principle 'Injure no one; on the contrary, help everyone as much as you can'. In doing so, he is concretely aware of what metaphysics teaches in the abstract, the oneness of the Will in all its manifestations. Thus this principle is not really an imperative but rather a description of how the good man acts. As an instruction it would really be useless, because each man acts according to his innate character anyway. So-called moral education may make men more tolerable by pointing out the advantages of co-operation with others, but our behaviour can only possess true moral worth if it stems from a moral goodness which cannot be taught. That moral worth consists in this capacity for compassion has hardly been recognized by most official moralists, but all over the world nothing is really admired in a morally relevant way except genuine concern with the welfare of others.

The compassion which constitutes moral worth manifests itself in its lesser form in justice based on the principle of non-interference with anyone's obtaining by their activity what they would otherwise legitimately achieve by it. By an illegitimate achievement is meant one made at the expense of someone else's achieving what they would otherwise—judged by the same criterion—legitimately achieve by their action. It manifests itself in a fuller form, as the loving kindness which inspires an active concern to help others in their need. It should be noted that for Schopenhauer the goal of compassion is the relief of misery and does not include the creation of positive happiness. This is partly because his pessimistic view of life implies that positive happiness, as opposed to relief from the worst sort of unhappiness, is impossible, and partly because he thinks that the kind of identification with others which constitutes compassion can only occur when one becomes aware of another as a fellow sufferer.

Schopenhauer's treatment of the freedom of the will is a brilliant (if ultimately implausible) development of Kant's. For Schopenhauer universal \*determinism holds necessarily for the phenomenal world. This follows from the fact that consciousness constructs the world on the principle of sufficient reason, in particular in its causal form. However, the thing-in-itself has freely chosen to manifest itself as a phenomenal individual answering to the particular Platonic Idea which constitutes each human being's character. This character (just like one of the laws of nature) settles just what he will do in every possible empirical circumstance. Each action is causally determined in that it flows necessarily from the combination of the agent's character and his beliefs about the conse-

quences of acting in one way rather than another. The beliefs are the cause of the action, but, like all other causes, they operate because they affect something with a determinate nature. At the level of causation specific to physics it is only the determinate nature of matter in general that is involved, while chemistry and biology explore the type of causation which arises in matter which has reached a higher level of complexity. The causation of human activity is just as inevitable, but there is no one single set of causal laws, because each single human has a quite unique determinate nature. This is his moral character, the special quality of his will. It is this which is the ultimate possessor or otherwise of moral worth. A man is blamed not so much for what he does, but for what his action shows that he is. This cannot change, because all change in a man's outward behaviour arises from causes which can only operate on him in consequence of his unchanging basic character. Causes only affect him as they do in virtue of his character and therefore cannot act on it. Nevertheless, *qua* the thing-in-itself or Will which has chosen to manifest itself in an individual with my particular character, I am to blame for what I am and do, and deserve whatever fate this brings me. The only behaviour which does not thus follow deterministically from an individual's innate character, operating in particular conditions, occurs in those rare cases when a saint reaches liberation; while his character and its consequences manifested the Will's futile but free assertion of itself, his liberation manifests the Will's wiser and equally free return to the mysterious Nothingness whence it emerged thereby.

**Schrödinger:** see cat, Schrödinger's.

**Schutz, Alfred** (1899–1959). German philosopher, who emigrated to the USA, a pupil of the phenomenologist Husserl. In the philosophy of \*social science, he is taken to be a key critic of the positivist tradition (although he saw himself as building bridges between \*positivism and the \*hermeneutic and \*phenomenological traditions). In

*The Phenomenology of the Social World* (first German edn. 1932; Evanston, Ill., 1967), Schutz analysed the process by which we typify the basic stream of meaningless sense-experience into 'stocks of knowledge', which are shared. Together all stocks of knowledge constitute the 'life-world' (our reality and our knowledge of it are one and the same). Social scientists produce 'second-order typifications'. Schutz's analysis was developed by phenomenological sociologists into a social scientific methodology which takes 'scientific knowledge' to have only the same status as the common-sense knowledge of the life-world possessed by us all.

**science, diversity of.** The tentative view that science is a network of theories that mutually support and partially explain each other and do not have a privileged foundational level—say, physics. Opposed to kinds of \*foundationalism and \*unity of science, which arrange science hierarchically, with theories at the higher levels dependent on and to be explained by those below. The view of science as diverse is thus also opposed to kinds of \*reductionism. It may, further, also resist the physicalism that reduces all science to physical science. As a full account of science, the view needs to develop generalizations about kinds of evidential relations, etc. between theories, but it remains pessimistic that true bridging laws between sciences will be established.

**science, feminist philosophy of.** Would scientists with distinctively feminist commitments do science differently? If the answer to this question is 'yes', does this mean that our conception of 'scientificity' must be adjusted?

Feminists are not the only philosophers to have questioned the demarcation of science from the ordinary run of knowledge, and therefore the philosophy of science from epistemology more generally. However, they have made a particularly significant contribution to the body of sceptical literature which asks whether conventional scientific methods and methodology are as successful at tracking or converging on truth and validity as they have claimed to be.

Feminist philosophers have also engaged with the problem of establishing what methodologies, if any, might be guarantors of good science. They have considered a number of candidates, including an adapted \*historical materialism (Nancy Hartsock), \*phenomenology (Dorothy E. Smith), and interactive observation processes (Evelyn Fox Keller). A principled rejection of a model of objectivity which relies on detachment is common to these various possibilities. Feminist philosophers do not suggest that only women could be successful scientists using such methodologies—methodology may be systematically connected with gender, but not with sex. E.J.F.

**science, history of the philosophy of.** Ancient Greek artisans, including navigators, farmers, architects, merchants, blacksmiths, shipbuilders, physicians, and chroniclers, were familiar with a great variety of materials, plants, animals, people, events. They dug tunnels, found ways to transport and to store perishable goods, and could identify and alleviate bodily and mental afflictions. They travelled across national boundaries and assimilated foreign ideas and techniques. Archaeological discoveries show how much was known, for example, about the properties of metals, their compounds and alloys, and how skilfully this knowledge was used. An enormous amount of information resided in the customs, the industries, and the common sense of the time.

Most Greeks took this abundance for granted. Not all of them were impressed by it. Aiming at something more profound, some early thinkers started the work of knowledge all over again, this time without details but with increased explicitness and rigour. They were *philosophers* because they preferred words to things, speculation to experience, principles to rules of thumb, and they did not mind when their ideas conflicted with traditions and phenomena of the most obvious kind. They were also religious and social reformers; they derided popular customs and beliefs, heaped scorn on the gods of tradition and replaced them by monsters (example: the God of Xenophanes, who is all thought and power, but lacks compassion). They were even scientists of sorts. They did not just pontificate, they argued for their views, and some of their ideas have survived until today.

Thus Parmenides claimed that the world was one, that change and subdivision did not exist, and that the lives of human beings which contained both were a chimera. The proof (which he presents as being revealed by a goddess) rests on three assumptions said to be self-evident: that \*being is (*estin*), that not-Being is not (*ouk estin*), and that nothing is more fundamental than Being. The argument then proceeds as follows: if change and difference exist, then there exists a transition from Being to not-Being (which is the only alternative); not-Being is not, hence change and difference are not either. We have here an early example of a \**reductio ad absurdum*—a type of reasoning that extended the domain of demonstrable truths and separated it from intuition. The premiss, *estin*, is the first explicit conservation law—it asserts the conservation of Being. Used in the form that nothing comes from nothing, it suggested more special conservation laws such as

the conservation of matter (Antoine Lavoisier) or the conservation of energy (Robert von Mayer, who started a decisive paper with this very principle). The uniformity of Being survived as the idea that basic laws must be independent of space, time, and circumstance. 'For us physicists', wrote Einstein, almost repeating Parmenides, 'the distinction between past, present and future has no other meaning than that of an illusion, though a tenacious one.'

A third group that affected Western science and its philosophy were the early *scientists* themselves. They differed from philosophers by favouring specifics and from artisans by their theoretical bias. With the exception of physicians like Alcmaeon of Croton, who wrote a medical textbook and who lived, probably, in the early fifth century BC, they became professionals only at the time of the Sophists. Towards the middle of the fifth century BC arithmetic, geometry, astronomy, and harmonics were already dreaded subjects of instruction (Plato, *Protagoras* 318d–f). They were also centres of intellectual activity and popular interest; even Aristophanes made fun of mathematicians. The arguments between scientists, philosophers, and those artisans who explained and defended their enterprise in writing, as well as the more specific arguments between scientific, philosophical, and practical schools, form an early, rather heterogeneous, and not always fully documented, philosophy of science.

Thus we may conjecture that the transition from a geometry and \*number theory whose propositions could be confirmed, one by one, by intuitively evident arrangements (pebble figures, drawings) to systems of statements based on principles and proofs was accompanied by a vigorous debate—but it is difficult to identify stages and individuals. In many subjects 'scientific' assumptions were closely intertwined with magical and religious ideas. This bothers historians, who want to describe the past exactly as it was but without conferring honour on what they regard as superstitious nonsense. It did not bother the author of *On the Sacred Disease*, who ridiculed temple medicine and regarded health and illness as purely natural phenomena, or the author of *On Ancient Medicine*, who rejected philosophy as being too remote for medical practice. Galen's essays on the nature of science illustrate the debate between empiricists and theoreticians in the second century AD.

In contrast with these local quarrels, Plato tried to build a philosophy that combined technical excellence with religion and an orderly politics. Outstanding scientists assisted him. Starting from the divine properties of judgement, foresight, and wisdom (*Laws* 892b2 ff.), Plato postulated that the basic \*laws of the universe must be simple and timeless. Observed regularities, he said, do not reveal basic laws. They depend on matter, which is an agent of change. Even the best-established astronomical facts do not last for ever (*Republic* 530a8 ff.). To find the principles, say, of planetary motion, it is therefore necessary to develop mathematical models 'and to leave the phenomena of the heavens aside' (*Republic* 530b7 ff.). Strangely enough, this passage was reviled by scientists, who, being

aware of the many disturbances that conceal the 'pure case' (perturbations, the effects of tidal friction, precession, atmospheric refraction, instrumental failure, subjective errors, etc., in the case of planetary motion), often started with theories and considered observations only later. It is theory that teaches us what observations are and what they mean, said Einstein. Important discoveries (the stability of the planetary system, the details of Brownian motion, the particle character of light, the \*uncertainty relations) were made by proceeding accordingly.

This was not the procedure favoured by Aristotle, however. Taking experience at face value, he tried to reconcile observations, common-sense, and abstract thought. He was the first systematic philosopher of science of the West. He raised many of the issues that constitute the subject today and suggested solutions that are still influential. He described how facts turn into concepts and, further, into principles (*Analytica posteriora* 99<sup>b</sup>35 ff.) and how things give rise to perceptions (*De anima* 418<sup>a</sup>4 ff., 424<sup>a</sup>17 ff.). For Aristotle these were natural processes which obeyed his general laws of motion and guaranteed the consistency of his empiricism. The deductive structure he proposed for \*explanations served the exposition, not the discovery, of knowledge: Aristotle had no explicit theory of research. However, he left us examples which show what he did.

He began with 'phenomena'. These could be observations, common opinions, traditional beliefs, conceptual relations, or the views of earlier thinkers. Aristotle used special teams to collect them; he established a natural history museum and a library of maps and manuscripts, and laid the foundation of all histories of Greek philosophy, mathematics, astronomy, medicine, and forms of government. Next he analysed the phenomena in a particular area; he extrapolated and removed contradictions, staying close to observation when the area was empirical, or to linguistic usage when it was abstract. His notion of place, for example, retains the idea that place is a container of sorts, but with the meaning of 'being in' freed from \*paradoxes. Finally, he formulated definitions to summarize what he had obtained. A general theory of change and interaction, the conceptual possibilities discussed, for example, in his *Metaphysics*, and a theory of mathematics which explained how mathematical concepts functioned in his largely qualitative universe served as a framework. Aristotle also started and considerably advanced the study of social, biological, and psychological phenomena. 'No one prior to Darwin has made a greater contribution to our understanding of the living world than Aristotle', wrote E. Mayr, a leading modern biologist.

The rise of modern science undermined important parts of the Aristotelian enterprise. It was a complex process which is still not fully understood. Some earlier historians and philosophers have described it in a simple and tendentious way. This is not surprising. The participants themselves misled them.

Thus Newton asserted that natural laws could be made manifest by collecting 'phenomena' (which for him were

either particular experimental findings or observable regularities like Kepler's laws), inferring conclusions, generalizing them 'by induction', and checking the result by comparing it with further facts. He thought that gravitation, the laws of motion, and the basic properties of light had been discovered and established in precisely this fashion. He added that known laws might be explained by 'hypotheses' and proposed a variety of models to make sense of the properties of light and matter.

This account suggests a hierarchy reaching from observations, measurements, low-level generalizations, and theories to entire sciences and overarching theoretical schemes. Indeed, such a hierarchy for a long time formed the background of discussions about the support, the implications, the explanatory (reductive) power, and the meaning of scientific statements. Scientists like Herschel and Whewell, and philosophers like Mill, Carnap, Hempel, Ernest Nagel, Popper, inductivists and deductivists alike, used the scheme, packing whatever fissures they perceived into 'evidence', 'initial conditions', 'auxiliary hypotheses', 'approximations', 'correspondence rules', and '*ceteris paribus* clauses'. In a purely formal way they preserved the coherence of the knowledge 'on top' and its continuity with what went on 'below'.

Kant's codification of Newtonian science, the attempt of \*logical empiricists to 'reconstruct' or 'explicate' science by translating it into a uniform language, and the idea of a uniform \*scientific method centred in physics further increased the impression of compactness. Remaining cracks were concealed by distinguishing, after Herschel, between a context of discovery and a context of justification: discovering new laws, facts, theories, may be a wildly irrational process—but establishing and presenting what has been found is subjected to strict and rational rules. This wonderfully harmonious and rather overwhelming fiction was gradually dismantled by a series of developments in the philosophy, the history, and the sociology of science as well as in the natural and social sciences themselves.

Problems occur already in Newton. Discussing the derivation of his law of gravitation, he admits that Kepler's laws are not strictly true, but decides to neglect 'those small and inconsiderable errors' (*Principia*, tr. Andrew Motte (1729), 401), which means that his empirical premisses are idealizations. Starting from here, Duhem argued that *all* experimental reports and low-level laws are idealizations and that the corresponding theories do not describe anything, while Cartwright showed that such theories are almost always false.

Newton also gave different weight to different phenomena. Being confronted with facts that contradicted his views (on light), he declared that his own results had already decided the matter. Again he admitted in practice what he had denied in philosophy, namely that the selection of data involves personal judgements. More recent research (Pickering, Galison, Rudwick, and others) has added that scientific facts are constituted by debate and compromise, that they harden with the distance from their origin, that they are manufactured rather than read

off nature, and that the activities that produce and/or identify them form complex and, with respect to theory, relatively self-contained cultures. Even laws and theories belonging to the same general field may split into separate domains with separate criteria. There are many breaks in the alleged hierarchy from fact to theory.

In the mean time historians and sociologists are taking a new look at power centres, institutions, and social groups; they point out that scientists often depend on patronage and choose their problems and their methods accordingly; they inquire how instruments like the telescope, the microscope, the air pump, or Millikan's oil-drop experiments could produce results and change views long before they were theoretically understood; they trace the changing relations between philosophers (who had defined reality), mathematicians (who had ordered events in it), and artisans (who were granted skills but denied understanding). On a more theoretical level they explore the role of terms not directly related to observation and describe how even relatively simple acts of perception (such as seeing a fly) were gradually broken up into processes (propagation of physical light; physiological reaction of eye and brain; 'mental' phenomena) whose mutual coherence is still a problem.

The role of experience turns out to be vastly more complex than empiricists up to and including the members of the \*Vienna Circle had assumed. Common-sense and sciences such as biology, meteorology, geology, medicine, provide ample evidence for regularities *and* exceptions. Nature is what happens always, or almost always, said Aristotle (*De partibus animalium* 663<sup>b</sup>27 ff.). Thus the belief in inexorable laws of nature which inspired Galileo, Descartes, and their followers, which gave rise to important theoretical developments and became a decisive ingredient of modern physics, not only was not based on experience, but clashed with it in many areas. This further widened the gap between common-sense, qualitative knowledge, and the gradually emerging edifice of modern science.

The edifice started falling apart in the twentieth century. \*Mathematics, apparently the most secure and well-founded science, divided into schools with different philosophies and different conditions for acceptable results. Logicians argued that mathematics was part of logic and therefore as unambiguous and compelling as that discipline. Intuitionists interpreted mathematics as a human enterprise and inferred, for example, that some of Cantor's theorems and methods could not be accepted. Trying to save these and other parts of classical mathematics, Hilbert and his collaborators formalized the relevant proofs and examined the resulting structures in a way that satisfied the intuitionists' criteria. The programme collapsed when Gödel showed that the idea of mathematics as a comprehensive and provably consistent system was incoherent. Following Einstein, Reich-enbach, Grünbaum, and Michael Friedmann developed new philosophies of \*space, \*time, and \*confirmation, while quantum mechanics opened a gulf between space-time and matter

and closed the traditional gulf between observer and reality in ways that keep troubling scientists and have philosophers in a tizzy. Wittgenstein and Quine revealed the wishful thinking implicit in logical empiricism; biologists, chemists, historians, social scientists, aided by philosophers, reasserted an independence they had possessed in the nineteenth century, while the 'New History' reached levels of concreteness unimagined before. Surrounded by the ruins of once well-established patterns of knowledge, Kuhn, in 1962, proposed a new and, to most philosophers, rather upsetting account of scientific change. Like Aristotle, Kuhn emphasized the collaborative character of science and the role of shared facts, concepts, procedures. But he also asserted that change ('progress' in the older philosophical versions) might sever all logical connections with the past. Adopting his views, one could no longer assume that science accumulates facts, or that theories can be reduced, by approximation, to their more precise and more comprehensive successors.

Kuhn's book, *The Structure of Scientific Revolutions*, was the last major attempt so far to subject a complex practice, science, to abstract thought. It clashed with important ingredients of \*rationalism. After 1962 philosophers tried either to reinforce these ingredients or to show that they were not in danger, or they introduced less binding rules, or else they concentrated on problems apparently untouched by Kuhn. Older approaches are still producing interesting results (example: Achinstein's Bayesian reconstruction of nineteenth-century debates about light and matter, which seemed to call for a less orderly account). The issue between \*realism and \*empiricism, which changed with the arrival of \*quantum mechanics and was sharpened by the interventions of G. Maxwell, Richard Boyd, Ernan McMullin, Putnam, van Fraassen, Cartwright, and others, is as alive as ever. Already before Kuhn some writers had opted for cognitive models of scientific knowledge which are naturalistic—they do not distinguish between logical and empirical \*'laws of thought'—and based on only partly rational patterns of adaptation. Others had emphasized details and objected to premature generalizations. These researchers appreciate what Kuhn did, but think that his approach is still far too abstract. They study particular events, conduct interviews, invade laboratories, challenge scientists, examine their technologies, images, conceptions, and explore the often glaring antagonisms between disciplines, schools, and individual research groups. Summarizing their results, we can say that the problem is no longer how to articulate the monolith SCIENCE, but what to do with the scattered collection of efforts that has replaced it.

A topic that was often neglected or dealt with in a dogmatic way is *the authority of science*. Is science the best type of knowledge we possess, or is it just the most influential? This way of putting the question has by now become obsolete. Science is not one thing, it is many; it is not closed, but open to new approaches. Objections to novelty and to alternatives come from particular groups

with vested interests, not from science as a whole. It is therefore possible to gain understanding and to solve problems by combining bits and pieces of 'science' with prima facie 'unscientific' opinions and procedures. Architecture, technology, work in \*artificial intelligence, management science, ecology, public health, and community development are examples. Purely theoretical subjects have profited from foreign invasions. One can even succeed by altogether staying outside 'science'. Numerous non-scientific cultures supported their members materially and spiritually. True, they ran into difficulties—but so did our science-based Western civilization. The old antagonism between practice and theory and the related antagonism between 'scientific' and 'unscientific' approaches may still survive in practice, or in some archaic slogans; however, it has lost much of its philosophical bite. P.K.F.

\*medicine, philosophy of; revolutions, scientific.

The many aspects and schools of ancient science are discussed, with ample literature, in the books and articles of G. E. R. Lloyd. Ernan McMullin, *The Inference that Makes Science* (Milwaukee, 1992) is a concise account that includes the medieval period. For the changing ways of dealing with scientific practice see A. Pickering (ed.), *Science as a Practice and Culture* (Chicago, 1992). I. Hacking, *Representing and Intervening* (Cambridge, 1983) describes the fruitful confusion of post-Kuhnian thought, to which Hacking himself has made important contributions.

**science, problems of the philosophy of.** The philosophy of science can be divided into two broad areas: the epistemology of science and the metaphysics of science. The epistemology of science discusses the justification and objectivity of scientific knowledge. The metaphysics of science discusses philosophically puzzling aspects of the reality uncovered by science.

Questions about the epistemology of science overlap with questions about knowledge in general. A central issue is the problem of induction. \*Induction is the process which leads us from observations of particular cases to such universal conclusions as that 'All bodies fall with constant acceleration'. The problem is that such arguments are not logically valid. The truth of the particular premisses does not guarantee the truth of the universal conclusion. That all bodies observed so far have fallen with constant acceleration does not guarantee that all future ones will do so too.

One popular response to the problem of induction is due to Karl Popper. In Popper's view, science does not rely on induction in the first place. Rather it puts forward hypotheses in a conjectural spirit, and then strives to refute them. Popper argues that as long as such hypotheses are falsifiable, in the sense that there are possible observations that would disprove them, then the objectivity of science is assured.

Critics of Popper's 'falsificationism' complain that it offers no account of our entitlement to believe in the truth of scientific theories, rather than their falsity. Popper only accounts for negative scientific knowledge, as opposed to positive knowledge. He rightly points out that a single

counter-example can show us that a scientific theory is wrong. But he says nothing about what can show us that a scientific theory is right. Yet it is positive knowledge of this latter kind that is supposed to follow from inductive inferences. What is more, it is this kind of positive knowledge that makes induction so important. We can cure diseases and send people to the moon because we know that certain causes do always have certain results, not because we know that they don't. If Popper cannot explain how we sometimes know that 'All A's are B's', rather than just 'It's false that all A's are B's', then he has surely failed to deal properly with the problem of induction.

An alternative response to the problem of induction is offered by \*Bayesian confirmation theory. Bayesians argue that our beliefs come in degrees, and that such degrees of belief, when rational, conform to the probability calculus. In itself, this does not imply that any particular degree of belief in universal scientific theories is mandated—only that an individual's degrees of belief must respect the axioms of probability. However, Bayesians also argue that \*Bayes's theorem implies a rational strategy for updating our degrees of belief in response to new evidence, and in particular that it implies we should increase our degree of belief in a scientific theory when its predictions are confirmed. On this basis they argue that everybody ought to come to attach a high credence to any universal generalization that is repeatedly borne out by experience. The idea is thus that, given enough evidence, everybody will eventually end up believing true universal generalizations, even if they attach different degrees of belief to them to start with. However, this doesn't work for all possible initial degrees of belief. Some eccentric initial degrees of belief are consistent with the axioms of probability, but will not lead to eventual convergence. So, for example, Bayesians don't explain what is wrong with people who never end up believing universal generalizations because they always think it is probable that the course of nature is going to change tomorrow. This shows that Bayesianism provides at best a partial solution to the problem of induction. Bayesianism may show us how our initial degrees of belief constrain the way we should respond in response to new evidence. But it needs to be supplemented by some further account of why some initial degrees of belief are objectively superior to others.

Another central problem in the epistemology of science is the possibility of knowledge of unobservables like viruses and electrons. Instrumentalists deny that scientific theories about unobservables can be accepted as true descriptions of an unobservable world. Rather they hold that such theories are at best useful instruments for generating observational predictions. They are opposed by those who take the realist view that science can and does discover truths about unobservables.

Some instrumentalists defend their view by appeal to the underdetermination of theory by data. According to this claim, any given body of observational data will always be compatible with a number of mutually incom-

patible theories about unobservables, and so cannot compel the choice of any particular such theory. This claim can be defended in turn by appeal to the 'Duhem–Quine thesis', which says that you can always retain any particular theoretical proposition in the face of apparently contrary evidence, by making adjustments to other auxiliary hypotheses in your overall theory. An alternative route to the underdetermination of theory by data is to observe that, given any successful theory that explains the observational data, we can always 'cook up' an alternative theory which explains the same observational facts. For example, Darwinism may successfully explain the fossil record, but so does Philip Henry Gosse's hypothesis that God put the fossils there in order to test our faith.

The doctrine of \*instrumentalism rests on a distinction between what is observable and what is not. This distinction is not unproblematic. Some philosophers of science, most notably T. S. Kuhn and Paul Feyerabend, argue that observation is 'theory-laden', by which they mean that our prior theories influence what observations we make and what significance we attach to them. They infer from this that different scientific theories are often 'incommensurable', in the sense that there is no theory-neutral body of observational judgements to adjudicate between them. Kuhn argues that the history of science displays a succession of 'paradigms', sets of assumptions and exemplars which condition the way scientists solve problems and understand data, and which are only overthrown in occasional 'scientific revolutions' when scientists switch from one theoretical faith to another.

Kuhn and Feyerabend thus in effect generalize the instrumentalists' doubts about scientific truth. Whereas instrumentalists hold that claims about scientific unobservables cannot be accepted as true descriptions of reality, Kuhn and Feyerabend say the same about observational claims too. Not all epistemologists of science accept Kuhn's and Feyerabend's \*epistemological relativism. On the issue of observational claims, most would maintain that, even if the line between observables and unobservables is neither sharp nor immutable, basic observational judgements can still provide an impartial test of a theory's predictions. And, on the issue of theories about unobservables, many would maintain that, even if theories are always underdetermined in the sense that a number of different theories will always be *compatible* with any given body of data, it does not necessarily follow that we cannot rationally choose between such theories, for some of those theories may be better *supported* than others by that body of data.

There is, however, another powerful argument against the realist view that scientific theories are true descriptions of an independent reality. This is the poor past form of such theories. Many past scientific theories, from Ptolemaic astronomy to the phlogiston theory of combustion, have turned out to be false. So it seems we should infer, by a 'pessimistic meta-induction', that since past scientific theories have normally been false, present and future scientific theories are likely to be false too.

In response, it can be argued that even false past theories contained a large element of truth, and therefore that present and future theories can be expected to *approximate* to the truth. Moreover, some philosophers detect a pattern of convergence, and argue that the succeeding scientific theories are moving *closer and closer* to the truth. These views, however, presuppose a notion of 'likeness to truth', or \*verisimilitude. It has proved surprisingly difficult to give a clear meaning to this notion. The earliest attempts to define this notion, due to Popper and others, have proved incoherent, and it is not clear whether a satisfactory clarification of this notion is possible.

During the 1980s a number of philosophers adopted a *naturalized* approach to the epistemology of science. Rather than seeking to identify \*a priori rules of scientific method, they look to the history of science and other \*a posteriori disciplines to show which methodological strategies are in fact effective means to the achievement of scientific goals. It is possible to combine this naturalized approach with the realist view that the goal of scientific theorizing is to uncover the truth. However, in the light of the arguments mentioned above, most naturalized epistemologists of science reject truth as a sensible goal for science, and instead investigate strategies for achieving such theoretical goals as simplicity, predictive success, and \*heuristic fertility.

Turning now to the metaphysics of science, a central issue is the analysis of \*causality. According to \*David Hume, causation, as an objective relation, is simply a matter of constant conjunction: one event causes another just in case events of the first type are constantly conjoined with events like the second. This analysis, however, generates a number of problems. First, there is the question of distinguishing genuine causal \*laws of nature from accidentally true constant conjunctions: being a screw in my desk could well be constantly conjoined with being made of copper, without its being true that those screws are made of copper *because* they are in my desk. Second, there is a problem about the direction of causation: how do we tell causes from effects, given that a constant conjunction of *A*-type events with *B*-type events immediately implies a constant conjunction of *B*-type events with *A*-type events? And, third, there is the issue of probabilistic causation: do causes have to determine their effects, or is it enough that they are probably (rather than 'constantly') conjoined with them?

Many philosophers of science this century have preferred to talk about \*explanation rather than causation. According to the popular \*covering-law model of explanation, developed by Carl Hempel, a particular event is explained if its occurrence can be deduced from the occurrence of other particular events, with the help of one or more laws. But this is little different from Hume's account of causation, and not surprisingly faces essentially the same problems. How do we tell laws from accidents? Can't we sometimes deduce 'backwards', from causes to effects—as when we infer the height of the flagpole from the length of the shadow—even though we don't want to

say that the length of the shadow explains the height of the flagpole? And aren't there cases where we can explain one event—Mr X contracting cancer, say—by another—his smoking sixty cigarettes a day—even though we can't deduce the former from the latter, since their connection is only probabilistic?

On the question of distinguishing laws from accidents, there are two possible strategies. The first remains faithful to the Humean view that law statements assert nothing more than constant conjunction, and then seeks to explain why some statements of constant conjunction—the laws—are more important than others—the accidents. The best-known version of this Humean strategy, originally proposed by F. P. Ramsey and later revived by David Lewis, argues that laws are those true generalizations that can be fitted into an ideal systematization of knowledge—or, as Ramsey put it, laws are a 'consequence of those propositions which we should take as axioms if we knew everything and organized it as simply as possible in a deductive system'. The alternative, non-Humean strategy, whose most prominent defender is D. M. Armstrong, rejects the presupposition that laws involve nothing more than constant conjunctions, and instead postulates a relationship of 'necessitation' which obtains between event-types which are related by law, but not between those which are only accidentally conjoined.

On the question of the direction of causation, Hume himself simply said that the *earlier* of two constantly conjoined events is the cause, and the *later* the effect. But there are a number of objections to using the earlier–later asymmetry of time to analyse the cause–effect asymmetry. For a start, it seems to be at least conceivable that there should be causes that are simultaneous with their effects, or even causes that come after their effects. In addition, there seem to be good reasons for wanting to run the analysis in the opposite direction, and use the direction of causation to analyse the direction of time. If we do this, then we will want some time-independent account of the direction of causation. A number of such accounts have been proposed. David Lewis argues that the asymmetry of causation derives from the 'asymmetry of overdetermination': while the \*overdetermination of effects by causes is very rare, it is absolutely normal for causes to be 'overdetermined' by a large number of chains of independent effects, each of which suffices for the earlier cause. Other writers have appealed to a related probabilistic asymmetry to explain causal asymmetry, pointing out that the different causes of any given common effect are normally probabilistically independent of each other, but the different effects of a common cause are normally probabilistically correlated.

The rise of \*quantum mechanics, and in particular the experimental disproof of Bell's inequality, has persuaded many philosophers of science of the falsity of \*determinism. In line with this, they have sought to develop models of causation in which causes only probabilify, rather than determine, their effects. The earliest such models, influenced by Carl Hempel's account of 'inductive-statistical'

explanation, required that causes should give their effects a *high* probability. However, while smoking unequivocally causes cancer, it never makes it highly probable. So more recent models simply require that causes *increase* the probability of their effects, even if this is merely from a low figure to a slightly less low figure. Models of probabilistic causation need to guard against the possibility that probabilistic associations between events may be *spurious* rather than genuinely causal, like the association between barometers falling and subsequent rain. It is an open question whether such spurious associations can be ruled out by purely probabilistic means, or whether further non-probabilistic criteria need to be introduced.

The notion of \*probability is of philosophical interest independently of its connection with causation. There are a number of different ways of interpreting the mathematical calculus of probability. *Subjective* theories of probability, which developed out of J. M. Keynes's logical theory of probability, understand probabilities as subjective degrees of belief. This is the interpretation assumed by Bayesian confirmation theorists. However, most philosophers of probability argue that we need an *objective* interpretation of probability in addition to this subjective account. According to the *frequency* theory of Richard von Mises, the probability of any given type of result is the limit of the relative frequency with which it occurs in longer and longer sequences drawn from some infinite 'reference class'. One difficulty facing the frequency theory is that it will ascribe a different probability to a given single-case result when that result is considered as a member of different reference classes. To rule this out, Karl Popper proposed that probabilities should be regarded as *propensities* of specific experimental set-ups, in the sense that only frequencies in reference classes generated by repetitions of the same experimental set-up should count as genuine probabilities. Later versions of this *propensity* theory dispense with the reliance on infinite reference classes, and simply take probability to be a quantitative feature of particular set-ups, which is evidenced by frequencies in repetitions of those set-ups, but cannot be defined in terms of frequencies.

The philosophical interpretation of objective probability is tied up with our understanding of modern quantum mechanics. The interpretation of quantum mechanics, however, is still an open problem in the \*philosophy of physics. Taken at face value, quantum mechanics says that when physical systems are measured, they suddenly acquire definite values of observable parameters which they did not have before. The theory specifies the probabilities of different such values, but cannot predict with certainty which will be observed. Albert Einstein's response was that quantum mechanics must therefore be incomplete, and that a future theory would identify the 'hidden variables' which do determine observed results. However, since Einstein's time new evidence against such hidden-variable theories has emerged. John Bell showed that any version of such a hidden-variable theory that respected the principles of special relativity would contra-

dict the observational predictions of quantum mechanics; moreover, experiments have now confirmed that these quantum-mechanical predictions are correct. True, this does leave the possibility of hidden-variable theories that do not respect special relativity and allow faster-than-light causal influences, like David Bohm's version of quantum mechanics, but these now have only minority support. If hidden variables are rejected, quantum mechanics then faces the problem of making sense of quantum \*measurement as a process in which a previously indeterminate reality somehow 'collapses' into some definite observable state. It is not obvious that it can answer this challenge. Even though measurements are themselves physical processes, orthodox quantum mechanics offers no theory of why measurements precipitate definite observable values, but instead simply assumes this. It thus seems likely that a satisfactory understanding of quantum measurement will depend on some radically new interpretation of the theory. According to one increasingly popular view, it is an illusion that prior indeterminacies 'collapse' into a definite state when measured; rather, reality 'branches' into a plurality of distinct non-interacting futures, one for each possible result of the measurement.

A further metaphysical aspect of the philosophy of science is the issue of \*teleology. This is mainly a topic in the philosophy of \*biology, since it is in the biological realm that we find the paradigm examples of teleological explanation, as when we say, for example, that chlorophyll is present in plants *in order to* facilitate photosynthesis. Explanations like these are of philosophical interest because they explain causes by effects, and so seem to run counter to the normal pattern of explaining effects by causes. Carl Hempel argued that such explanations are simply a species of covering-law explanation in which the fact used to explain—the photosynthesis—happens to come later in time than the fact which gets explained—the chlorophyll. However, there are counter-examples to this proposal, and attempts to tighten it up by requiring that the items involved be parts of some self-regulating system have proved problematic. The majority of philosophers of science would probably now favour a different approach, according to which teleological explanations in biology are a form of disguised causal explanation, in which implicit reference is made to a hypothesized history of natural selection during which the trait in question—chlorophyll—was favoured because it produced the relevant effect—photosynthesis. Some philosophers would question whether such 'backward-looking' explanations really deserve to be called 'teleological', since they do not in fact explain the present by the future, but by past histories of selection; this issue, however, is essentially a terminological matter.

'Special sciences' like biology, chemistry, geology, meteorology, and so on raise the question of \*reductionism. One science is said to be 'reduced' by another if its categories can be defined in terms of the categories of the latter, and its laws explained by the laws of the latter. *Reductionists* argue that the sciences form a hierarchy in

which the higher can be reduced by the lower: thus biology might be reduced by physiology, physiology by chemistry, and eventually chemistry by physics.

The issue of reductionism can be viewed either historically or metaphysically. The historical question is whether science characteristically progresses by later theories reducing earlier ones. The metaphysical question is whether the different areas of science describe different realities, or just the one physical reality described at different levels of detail. Though often run together, these are different questions. Taken as a general thesis, historical reductionism is false, for reasons relating to the 'pessimistic meta-induction' discussed above: while there are some historical episodes where new scientific theories have reduced old ones, there are as many where new theories have shown old theories to be false, and so eliminated rather than reduced them. This does not mean, however, that metaphysical reductionism is false. Even if science proceeds towards the overall truth by fits and starts, there may be general reasons for expecting that this overall truth, when eventually reached, will reduce to physical truth.

One possible such argument stems from the *causal interaction* between the phenomena discussed in the special sciences and physical phenomena. Thus biological, geological, and meteorological events all unquestionably have physical effects; this might seem to require that they be made of physical components. It is doubtful, however, whether this suffices to establish full-scale reductionism, as opposed to the thesis of supervenience, which holds that special properties are determined by physical properties, even though they are not identical with them as types. For example, whether or not some being is adding 2 and 2 is arguably determined by its physical make-up; yet the property of adding 2 plus 2 cannot be identified with any specific physical property, for many different beings, with different physical constitutions, are in principle capable of adding 2 plus 2. If we accept supervenience, and reject the stronger claim of 'type identity' between special and physical properties, then we will also reject the reductionist thesis that all special laws can be explained by physical laws. Instead we will hold that there are *sui generis* special laws, patterns which cover special types which vary in their physical make-up, and which therefore cannot be explained in terms of physical law alone. **science, pseudo:** *see* pseudo-science.

**science, social philosophy of.** General term for the investigation of moral and political issues in the practice of sci-

ence. These issues are very varied, ranging from the morality of animal experimentation to the accusation that science promotes a reductive, disenchanting world outlook. There are two overall questions: whether scientists should subscribe to an ethical code (like the Hippocratic Oath); and whether there is a clear distinction between cognitive ('purely scientific') and ethical values in science.

**science and knowledge:** *see* knowledge and science.

**science and life:** *see* life and science.

**science and philosophy:** *see* philosophy and science.

**science, art, and religion.** The theories of science aim at accounts of the world which depend on no particular perspective on the world and no particular type of observer. Though in practice they never completely abstract from idiosyncratically human perceptions and forms of thought, their success, or otherwise, depends on how they fare against a nature which is impervious to our feelings and perceptions. \*Art, by contrast, works with visions of the world expressed in concrete form, adapted precisely to human sensory faculties and emotional sensibilities. Works of art are judged by their success over time in evoking responses to human perceivers.

Religion shares the scientific aim of giving an account of the world as it is in itself, not as it is for us. But, unlike science, and closer to a work of art, it reveals the world as informed by purpose, will, and personality, as expressing the intentions of a transcendent being. In presupposing a transcendent being, religion avoids the possibility of direct refutation by empirical or scientific evidence. Even the facts of evil and suffering are normally, and from his point of view not unreasonably, taken by the religious believer to be consistent with a divine purpose which, being transcendent, we cannot fully fathom. But equally, although religion provides an answer to the questions of the meaning and ultimate genesis of the world's totality, which science raises but cannot answer, at least while staying within a strictly empirical framework, religion's appeal to transcendence deprives it of any direct empirical support. Religion, properly conceived, is based on the experiences of meaning and value which it is the province of art rather than science to express and explore. In seeing value and personality written into the very fabric of the world, in a way which does not depend on our wishes or desires, is the religious believer indulging in mere projection or wish-fulfilment? In considering this question, we should remember that science as such cannot pronounce on the questions relating to the world as a whole, and also reflect on how hard it is to live as if our values were just projections of human feeling, individual or collective. **scientific determinism:** *see* determinism, scientific.

**scientific method.** Although the question of scientific method is generally thought to resolve itself into two parts—the problem of discovery and the problem of justification—it seems fair to say that philosophers have felt significantly more comfortable with the latter than the former. Indeed there are those (like Karl Popper) who have argued that philosophy can say nothing of value about discovery and that the whole topic is best left to the historian or psychologist.

Certainly it seems the case that the problem of justification lays itself more readily open to the forming of rules and criteria for identifying and producing the best kind of science. Traditionally, the discussion has been located against the ideal of an \*axiom system, a powerful model set by the successes of Greek geometry. Transcending mere common-sense knowledge, science shares with mathematics some elements of its necessity and universality, although what distinguishes science from pure thought is its mandate to understand the world of empirical experience.

How does one establish the truths of science? Francis Bacon argued that scientific knowledge is gained and confirmed by a process of \*induction. Precisely how this should be understood and performed has been a matter of ongoing debate. Many, although not Bacon himself, have argued that the process of induction is merely one of simple enumeration, where essentially what one does is count the cases favourable to a particular hypothesis. But this suggestion can be faulted on at least two grounds. First, it is simply false of the way in which real science proceeds. No one just goes out and counts instances, without a prior theory for inspiration. Second, no matter how much one counts, the result will always be in doubt, because of the ever-present possibility of counter-examples.

Seizing on this second point, a number of philosophers have made a virtue out of necessity, arguing that the aim of science is never to achieve certain knowledge. Rather, in the light of intuitions and previous understanding, one proposes hypotheses which one then judges against experience. Inasmuch as they stand the test of time, understanding advances; but since all scientific claims are by their very nature falsifiable (to use Popper's term), there is always the possibility of disconfirmation and the need for replacement by a more powerful hypothesis.

An important body of scientific claims are causal, meaning that in some sense they tell us why things work. Newton set the modern agenda for discussion about \*cause, arguing that the best causes are *verae causae*. This claim has been variously interpreted. The English empiricist philosopher John Herschel argued that one must aim always for analogical support, based on everyday easily understood and encountered examples. The English

rationalist philosopher William Whewell argued that one should aim to locate one's causes at the focus of a 'concurrence of inductions', where many different pieces of evidence combine to point to one true explanation. To use a detective-story analogy, whereas Herschel argues that to pin the guilt on a suspect one must have eyewitness testimony, Whewell preferred circumstantial evidence, where the clues all pointed to the guilty party.

This century's advances in the understanding of the micro-world beyond the senses have led to refinements in discussions of method, as have the successes of the non-physical sciences. Much effort has been given to the question of whether there is one method uniquely for all science. Although Bacon argued strongly against teleology in science, many biologists would still claim that their material demands an understanding in terms of purpose or final cause. This is neither something theological nor something demanding causes acting out of the future and on to the present. It is something which recognizes the distinctively adapted nature of organic beings. One has a metaphor of design—a metaphor because the work of organic organization is being done by Darwin's mechanism of natural selection rather than a conscious being—which yet forces one to think of the ends that features serve, rather than merely their material causes.

Although discovery may be problematic, there are always those who try to approach it philosophically. Many have thought that Mill's so-called methods are a good start, for here one has a number of recipes for working out the existence and nature of causes. (For example, the \*method of agreement claims that if one has a number of different cases of the production of an effect and only one antecedent phenomenon in common, then it is the cause.) However, as Whewell pointed out, although Mill's methods may be valuable in the discerning of causes, they are not very helpful in deciding initially what phenomena are worth explaining and what different circumstances lead to these phenomena. In other words, their virtue lies truly in the context of discovery.

In recent years, there have been renewed attempts to crack the discovery problem. Working from insights of the \*pragmatists, Norwood Russell Hanson argued that one needs a kind of logic of \*abduction, which throws up plausible hypotheses. Some have been attracted to the nature of analogy in their quest for insight. And yet others have turned to the newly developed power of computers for clues to a logic and method of discovery. But although certainly much has been learned thereby about the nature of human creative reasoning, it seems fair to say that, in the search for formal rules of method, we are little further ahead than we were when we began. Perhaps there are some things which simply do not yield to philosophical analysis, and Popper's conclusion is less one of despair than of realism. Or perhaps the very distinction itself is ill-taken, and (as various historians and sociologists would argue) the very act of scientific creativity can take place only within a certain culture and against a background of already held belief. Hence, there never can be a claim which is

epistemically neutral nor can there be a discovery except some commitments have already been made. M.R.

\*methodology; scientism.

J. Losee, *The History of the Philosophy of Science* (Oxford, 1972).

K. Popper, *The Logic of Scientific Discovery*, Eng. tr. (London, 1959).

**scientism.** 'Scientism' is a term of abuse. Therefore, perhaps inevitably, there is no one simple characterization of the views of those who are thought to be identified as prone to it. In philosophy, a commitment to one or more of the following lays one open to the charge of scientism.

- (a) The sciences are more important than the arts for an understanding of the world in which we live, or, even, all we need to understand it.
- (b) Only a scientific methodology is intellectually acceptable. Therefore, if the arts are to be a genuine part of human knowledge they must adopt it.
- (c) Philosophical problems are scientific problems and should only be dealt with as such.

A successful accusation of scientism usually relies upon a restrictive conception of the sciences and an optimistic conception of the arts as hitherto practised. Nobody espouses scientism; it is just detected in the writings of others. Among the accused are P. M. and P. S. Churchland, W. V. Quine, and \*Logical Positivism. P.J.P.N.

T. Sorell, *Scientism* (London, 1991).

**scope.** Many words have the syntactic role of building one or more expressions of some type into another expression of some type, as 'but' can build the sentences 'Bill is rich' and 'Jill is stinking rich' into the sentence 'Bill is rich but Jill is stinking rich'. The scope of such a word is the immediate outcome of this process. For example, the scope of 'fashion' in 'He kept his house Bristol fashion' is the adverbial phrase 'Bristol fashion', but in 'The Bristol fashion experts were wrong' it is the noun phrase 'fashion experts'. Some structural ambiguities are ambiguities of scope, for example 'superfluous' in 'Try our superfluous hair remover'. A virtue of the \*artificial languages of logic is to represent many structural ambiguities of English, e.g. 'Some professors get drunk every night', as demanding a decision on the scope of some logical \*constant. C.A.K.

R. M. Sainsbury, *Logical Forms: An Introduction to Philosophical Logic* (Oxford, 1991).

**scope fallacies.** Scope fallacies are endemic in philosophy and in ordinary language. 'If it snows the crops will inevitably fail' suggests misleadingly that the scope of 'inevitably' is the consequent rather than the whole conditional. A standard example is to be found in proofs of God's existence which move from 'For every contingent being there is a time when it does not exist' to 'There is a time when every contingent being does not exist'. Subtler is 'Statements of identity are, when true, necessarily true. Therefore since Elizabeth is the Queen of England, neces-

sarily Elizabeth is the Queen of England'. It is true, of the person who is, contingently, the Queen of England that, necessarily, she is identical with Elizabeth, but it is not true of that person that, necessarily, she is Queen of England.

**Scottish philosophy.** Scottish universities had, until recently, a traditional reverence for philosophy, which was compulsory for every degree. The tradition began in the University of St Andrews, founded in the fifteenth century. Initially the universities relied on their seniors in England and France to train their teachers. But by the end of the sixteenth century they were ready to provide their own. The subject was divided into logic, pneumatology (psychology), moral philosophy, and natural philosophy (physical science). There was no idea of exclusive specialization, let alone that the best results require it. The policy of non-specialization allowed Hume, Smith, and Reid, at the tradition's high point, to variously combine psychology, moral philosophy, optics, mechanics, economics, history, and jurisprudence. Philosophy and science were taken to be one. But, as physical science advanced and the mind-body distinction took a firmer grip, philosophers in Scotland, as elsewhere, increasingly doubted the philosophical competence of science and instead concentrated on developing metaphysical \*idealism.

The earliest Scottish philosophers of note came from the south-east. They were Duns Scotus (c.1266–1308), the 'subtle doctor', and John Mair (or Major) (c.1467–1550). The former was a Franciscan academic who lectured in Cambridge, Oxford, and Paris. Primarily a theologian, he had a distinctive doctrine of \*free will, emphasizing the possibility of genuine altruism, a view subsequently resumed by Hutcheson and his followers. John Mair, educated in Cambridge, also lectured in Paris, before returning to take up teaching and administrative posts in his native land. His approach seems to have been logico-linguistic.

Lacking a conception of intellectual progress, Scottish philosophy of this period assumed that anything worth knowing had already been divinely imparted to the ancient Jews or discovered by the ancient Greeks. The Reformation did not dispel this prejudice, but, if anything, reinforced it, favouring classical writers, like Plato and Cicero. The prevailing practice was to comment on whatever texts could be retrieved from ancient times, whether in Latin, Greek, or Hebrew. Thus the seventeenth century produced no original philosopher in the universities educating the professional classes. Scottish academics, by no means insular, were conscious of continental and English genius, like that of the Dutch lawyer Grotius, the French mathematician and natural philosopher Descartes, and the English natural philosophers Newton and Boyle. They

also admired John Locke, who based his epistemology on physical science.

The time was ripe to earn the benefit of an educational system which was non-specialist yet capable of imparting the latest discoveries in mental and natural philosophy. The results were impressive. In mental philosophy emphasis on feeling and sensation as sources of belief produced the great works of Hutcheson, Hume, Smith, and Reid. Hutcheson showed that moral approval is a kind of pleasure, and therefore is not purely rational. Hume accepted this and went on to extend anti-rationalism in a unique claim that important beliefs, in causes, in the \*external world, and in \*personal identity, are instinctive and non-rational. He showed that a cause can never be completely proved and that belief in a cause is a conditioned reflex, not a logical deduction. Belief in the external world, and in personal identity, is also the result of conditioning and cannot be proved; so is belief in God. His views were widely misunderstood as being sceptical about any kind of unperceived existence, whereas he was only pointing out that beliefs about the world, causes, and personal identity go beyond any evidence. Reid, using contemporary science to develop indirect realism, and seeing Hume as a sceptic, blamed him for saying that we mistake sensations for external objects and that beliefs are images of sensations. Though critical of Hume, he agreed that the mind generates beliefs from materials which are logically inadequate—and a good thing too, he thought. Whereas Hume and Reid were not sceptical about the mind's irrational usefulness, they were sceptical about philosophy's power to do any better. It was felt by some that they had downgraded reason and the nobility of their subject. Kant disparaged them, while thanking them for waking him from his dogmatic slumber, and argued that philosophy can justify belief in the external world, in causality, and in personal identity, as necessary presuppositions for objective understanding. Hume and Reid had never doubted the need for such presuppositions, but thought it obvious, as indeed it is, that such need is no evidence of truth.

Reid's philosophy had critics, beginning with Dugald Stewart who made minor refinements. William Hamilton went further, declaring that the cause of sensation cannot be known. James Frederick Ferrier, an idiosyncratic idealist, proposed that sensations have a dual nature as occurring in perceptible sense-organs, while at the same time presenting themselves to consciousness as external objects, a view not unlike Hume's. Later, Andrew Seth, the first non-professorial lecturer appointed in Scotland (thanks to A. J. Balfour), attacked Hamiltonian agnosticism. He proudly defended what he called 'the Natural Realism of the Scottish philosophy', arguing that substance and quality are not distinct: sensation of qualities must be of substance, revealing what it is. Henry Langueville Mansel, an English theologian and pupil of Hamilton's, used his philosophical agnosticism to defend revealed religion, as Hume's agnosticism had been used for the same purpose in Germany. Anti-Hamiltonianism flared up in Glasgow, led by Edward Caird, Professor of

Moral Philosophy, who had imbibed German idealism at Balliol, to whose Mastership he gratefully returned.

In the twentieth century England escaped into empiricism, and the canny Scots concentrated on the history of philosophy. The early tradition of combining philosophy and science, weakened by idealism, had ended, though there was still a strong connection between philosophy and psychology, felt of all the sciences to be closest to spiritual reality. This may explain the subsequent appearance in Hume's university of a chair of paranormal psychology.

**sea battle:** see Łukasiewicz; many-valued logic.

**sea-battle argument.** Argument criticized by \*Aristotle in *De Interpretatione*, book ix. Either there will be a sea battle tomorrow or there will not. These possibilities are mutually exclusive and jointly exhaustive. It seems, therefore, to be a necessary truth that there will be a sea battle tomorrow or there will be no sea battle. The future is inevitable now, it is just that we are presently ignorant of which future events will happen. The argument putatively establishes the fatalistic conclusions that everything that happens happens necessarily, and that it was always true that those events that do happen would happen.

In criticism, Aristotle argues that from the necessity of the disjunction ( $p \vee \neg p$ ) it does not follow that the disjunct  $p$  is necessary nor that the disjunct  $\neg p$  is necessary. Although it is necessary that either a sea battle take place tomorrow or not, it is not necessary that it should take place tomorrow, and is it not necessary that it should not take place tomorrow. Therefore the argument does not validly establish that future events are inevitable. This is consistent with its being a necessary truth that either there will or will not be a sea battle tomorrow. s.p.

\*future contingents.

*Aristotle's Categories and De Interpretatione*, tr. J. L. Ackrill (Oxford, 1963).

**Searle, John R.** (1932– ). Philosopher of mind and language at the University of California at Berkeley. The mind, for Searle, is \*intentional (*à la* Brentano) in that perceptions, memories, imaginings, desires, and many other mental states take objects (e.g. I see *the car* and I remember *Aunt Fanny*). Language, seen by Searle mainly from the \*speech-act tradition of J. L. Austin, is also intentional, but derivatively so. His intentional theory, and the

emphasis he places on \*consciousness as an intrinsic feature of the mind, put him at odds with behaviouristic, functional, and other materialistic theories of mind. For Searle, although the mind emerges from the body, it possesses an ineliminable subjective character with which materialistic accounts cannot adequately deal. In relation to this claim, he uses his famous \*Chinese room argument to show that even though a 'system' (a computer and a person) inside a room can manipulate Chinese symbols, it does not necessarily operate on the level of meaning. To do that, mental (intentional) concepts need to be introduced into the system.

**secondary qualities:** see primary and secondary qualities.

**seeing as.** In his later writings, Wittgenstein showed an interest in the phenomenon to which the *Gestalt* psychologists had drawn attention, of seeing (or hearing, or, . . .) something *as* something. The \*duck-rabbit is an example: a picture that can be seen either as a duck or as a rabbit. Part of Wittgenstein's interest in this phenomenon had to do with his rejection of a naïve account of \*perception; he took the interpretation of what is seen to be less separable from seeing itself than empiricist philosophers had been wont to think. But perception was not his only concern. We see one continuation of a number-series as 'more natural' or 'simpler' than another; see one grouping of objects in a class as 'cutting Nature at the joints', another not; and so on. Our use of concepts depends on 'seeing as'.

R.P.L.T.

\*illusion, arguments from.

L. Wittgenstein, *Philosophical Investigations*, tr. G. E. M. Anscombe, 3rd edn. (Oxford, 1967).

**self.** The term 'self' is often used interchangeably with \*person', though usually with more emphasis on the 'inner', or psychological, dimension of personality than on outward bodily form. Thus a self is conceived to be a subject of consciousness, a being capable of thought and experience and able to engage in deliberative action. More crucially, a self must have a capacity for \*self-consciousness, which partly explains the aptness of the term 'self'. Thus a self is a being that is able to entertain first-person thoughts.

A first-person thought is one whose apt expression in language requires the use of the first-person pronoun 'I', or some equivalent \*indexical expression. However, it may not be right to insist that a self be capable of expressing its thoughts in language—even its first-person thoughts. Happily, we possess locutions for ascribing first-person thoughts to others without implying that they are capable of articulating those thoughts. One such locution is the 'he himself' construction. Thus if I ascribe to Fred the thought that *he himself* is fat, I ascribe to him a thought whose apt expression in English by Fred would be 'I am fat', though I do not imply that Fred is capable of so expressing that thought. Note that we must distinguish

this thought from a similar *third*-person thought that Fred might have about himself, whose apt expression in English by Fred might be 'Fred is fat' or 'That person is fat' (the latter said by Fred in reference to a person he sees reflected in a mirror, not realizing that it is himself that he sees).

It is plausible to require of a self not only a capacity to entertain first-person thoughts but also the possession of certain kinds of first-person knowledge. For example, it seems right to insist that a self must know, of any of its present, conscious thoughts, experiences, and actions, that they are *its own*. This is why the response of Mrs Gradgrind (in Charles Dickens's *Hard Times*), when asked on her sick-bed whether she was in pain, strikes us as so bizarre: 'I think there's a pain somewhere in the room, but I couldn't positively say that I have got it.' Our possession of such self-knowledge is connected with the phenomenon of 'immunity to error through misidentification' (Sydney Shoemaker). An example involving memory is provided by the apparent absurdity of supposing that I might accurately remember (as it were, 'from the inside') a meal in a restaurant attended by a number of people, and yet be in some doubt about whether *I* was one of those people. (As against this, however, Derek Parfit has argued that we could in principle inherit 'quasi-memories' from other people, including first-person 'memories' of what they, but not we, had done.)

So far we have largely been concerned with the *meaning* of the term 'self', that is, with the essential characteristics of selfhood. But metaphysicians are also interested in exploring the *nature* of the self, that is, what sort of \*thing the self is, if indeed it is a 'thing' at all. In traditional terms, a distinction may be drawn between substantival and non-substantival theories of the self, the former contending that the self is a \*substance, either physical or non-physical, the latter that it is a mode of substance. Philosophers like Hume, who regarded the self as 'nothing but a bundle of different perceptions', effectively treat the self as belonging to the category of modes. A problem with the Humean approach is that perceptions—that is, thoughts and experiences—seem to depend for their identity upon the identity of the selves who possess them, which implies that perceptions are modes *of selves* and hence that the latter have the status of substances *vis-à-vis* their thoughts and experiences, rather than being reducible to them.

B. Williams, *Problems of the Self* (Cambridge, 1973).

**self, bundle theory of the:** see bundle theory of the self.

**self-consciousness.** One view of self-consciousness would be that it is the \*consciousness of a special kind of object, 'the \*self'. In reply, it has been claimed that just as the eye cannot see itself, so the self, understood as a subject of awareness, cannot be aware of itself as an object. According to Schopenhauer, for example, the suggestion that a

subject can be an object to itself would be 'the most monstrous contradiction ever thought of'. More cautiously, it might be argued that the core of the intuitive notion of self-consciousness is what might be called *introspective* self-awareness, and that one cannot be introspectively aware of oneself as an object. Sydney Shoemaker's defence of this view of introspective self-awareness is to point out that in those cases in which one might be said to be conscious of oneself as an object—seeing oneself in a mirror, for example—one always has to identify the presented object as oneself. Since identification always carries with it the possibility of misidentification, first-person statements based on such awareness are not 'immune to error through misidentification' relative to the first-person pronoun. Yet, it seems to be a requirement on introspective self-awareness that it is capable of grounding first-person statements that are immune to this kind of error.

To say that a statement of the form 'I am *F*' is immune to error through misidentification relative to the first-person pronoun is to say that the following is not possible: one knows that someone is *F*, but one's statement is mistaken because, and only because, the person one knows to be *F* is not oneself. For example, if one were to judge 'I am in pain' on the basis of feeling pain, it could not happen that the person one knows to be in pain is not oneself. If self-ascriptions of mental states are immune to error through misidentification, then the awareness on which they are based may be introspective, but could not be awareness of oneself as an object.

Kant expressed this point by saying that the self as it is in itself cannot be 'intuited' or perceived by means of \*inner sense. Since, for Kant, knowledge of an object requires both a concept and an intuition of it, he concluded that knowledge of the self as it is in itself is impossible. Kant did not, however, accept the Humean idea that there is no more to self-consciousness than consciousness of subjectless mental occurrences. Instead, he argued that consciousness of self consists in an ability to ascribe one's thoughts and experiences to oneself. The self-ascription of experiences was in turn claimed to require experience and knowledge of objects other than oneself. A variation on this suggestion is the idea, associated with P. F. Strawson, that for one to be able to ascribe experiences to oneself, one must also be able to ascribe them to subjects other than oneself.

A somewhat different approach would be to claim that self-consciousness necessarily involves awareness of one's own body. Since bodily self-ascriptions such as 'My legs are crossed' appear to be immune to error through misidentification when based on awareness of one's own body 'from the inside', this makes it plausible that such awareness is a genuine form of self-consciousness. If bodily awareness is also awareness of oneself as an object, then Shoemaker's argument may not, after all, be decisive. On the other hand, some have argued that the peculiarities of bodily awareness are such as to cast doubt on the idea that it is awareness of oneself as an object. The suggestion that self-consciousness requires bodily awareness is also controversial.

Q.C.

\*introspection.

**self-control.** Traditionally, a capacity to conduct oneself as one judges best when tempted to do otherwise. Self-control is the contrary of weakness of will or \**akrasia*. Aristotle distinguishes self-control (*enkrateia*) from temperance (*sōphrosunē*). The latter, a moral virtue, is possessed only by individuals who have no improper or excessive desires regarding bodily pleasures and pains; self-controlled individuals have such desires, but they characteristically resist them, acting as they judge best. On more recent views, self-control may be exhibited in any sphere in which motivational states compete with a person's values, principles, or practical judgements, including practical and theoretical reasoning and the gathering and assessment of evidence for motivationally attractive or unattractive hypotheses (e.g. the hypothesis that one is popular or that one's spouse has been unfaithful). A.R.M.  
 A. R. Mele, *Autonomous Agents: From Self-Control to Autonomy* (Oxford, 1995).

**self-deception.** Everything about the concept of 'self-deception' is controversial among philosophers, beginning with its definition. That human beings play a large and often wilful role in perpetuating their own ignorance and befuddlement is beyond dispute; but how legitimate is the traditional characterization of the activities subsumed under this role as 'self-deception'?

Dictionaries define the term unilluminatingly as the act of deceiving oneself or the state of being deceived by oneself. Since deception involves intentional misleading, such a definition invites the question precisely how one can both intend to be misled by oneself and succeed in such an endeavour. Can the \*self perhaps be divided into a deceiving and a deceived part, as in Freud's view of the unconscious keeping information from the conscious self? Or must one adopt Sartre's paradoxical view, in *Being and Nothingness*, that 'I must know, as deceiver, the truth that is masked from me as deceived'?

Many reject such views as logically or psychologically impossible. Some claim that 'self-deception' refers to one or more of four restrictions on perception, none of which need involve the paradox of simultaneously deceiving and being deceived: first, the ignorance resulting from our necessarily limited capacity to respond to incoming information; second, the 'psychic numbing' that constitutes a reflex response to prolonged exposure to facts which would, if truly confronted each time, be difficult to bear—as when children shield themselves from fully responding

to the violence they witness within the family or on television; third, mechanisms of denial whereby we may end up deceived about information that would otherwise be too painful to confront, even though we are not consciously deceiving ourselves; and, fourth, processes of more conscious avoidance such as procrastination, rationalization, and compartmentalization.

Advocates of political and religious doctrines have further disputed the nature of what we hide from ourselves. The greater their zeal in promoting particular truths, the more tempting it becomes for them to assume that non-believers are not merely in error but actually engaged in blocking truths they would otherwise have to acknowledge as utterly self-evident. In practice, this assumption easily leads to indoctrination and worse, as witch-hunts ancient and modern make clear.

A final controversy about self-deception, however defined, has to do with its desirability. The injunction of the Delphic Oracle—"Know thyself"—that underlies much philosophy has long been pitted against dismal suspicions of what we would find if we took the Oracle seriously. The drive for attaining greater understanding about ourselves and our role in the world has clashed with the fear of inviting revulsion or misfortune by probing too deeply. Some have further claimed that judicious self-deception is conducive to better mental and physical well-being, as if to underline Jonathan Swift's (ironical) remark, in *A Tale of a Tub*, defining happiness as 'the perpetual Possession of being well Deceived'.

The continuing debate over the desirability of self-deception reveals two incompatible views of optimal human functioning. These views, in turn, generate incompatible conceptions of the role of all involved in therapy: to what extent and by what means should they encourage fuller self-understanding, or on the contrary promote in patients what they take to be life-enhancing false beliefs? If therapists choose the latter path, they run up, once more, against one of the paradoxes of self-deception: for how can they be honest with patients about their intent and about any illusory belief they wish to encourage? But if they cannot, why should their patients trust them? S.B.

**self-defeating theories.** In the simplest sense, a theory is self-defeating if the truth of the theory would imply the falsity of the theory. However, the expression is usually applied to theories that purport to guide action in some sense—particularly normative ethical theories. A theory is self-defeating if attempting to achieve what the theory says ought to be achieved is bound to fail because of that attempt. The best-known example is sometimes referred to as the paradox of hedonism. Hedonism tells us that hap-

piness is the ultimate goal, but clearly if we spend our lives single-mindedly seeking happiness, we are unlikely to achieve it. \*Parfit introduces distinctions between individually self-defeating theories (self-defeating when one person acts according to the theory) and collectively self-defeating theories (self-defeating when a group of people act according to the theory), and between indirectly self-defeating theories (self-defeating when the aims of the theory are consciously adopted by the agent) and directly self-defeating theories (self-defeating when the aims of the theory are successfully achieved by the agent). Some forms of consequentialism seem to be indirectly self-defeating in the same way that hedonism is indirectly self-defeating. E.J.M.

D. Parfit, *Reasons and Persons* (Oxford, 1984).

**self-determination, political.** The rule of a particular group of people—nation or religious community or, more simply, the residents of a place—over their own affairs. Self-determination is not the same as self-government, which usually implies some version of \*democracy. A group of people, freed, say, from imperial rule, might choose the government of a king, an oligarchy, or a clerical élite and, assuming that the choice is not coerced from outside, this would still be called self-determination. A right to self-determination is a right to make choices of that sort. In recent times, this right is most often claimed on behalf of a nation. (\*Nationalism.) But the character and standing of the 'self' in 'self-determination' is often a matter of dispute. In principle, the right was invented for the sake of existing collective selves, but it may also happen that collectivities are invented in order to exercise the right. M.WALZ.

\*liberty; state intervention; public and private.

J. S. Mill, *On Liberty*.

**Sellers, Roy Wood** (1880–1973). American critical realist, evolutionary naturalist, materialist, and socialist who taught at the University of Michigan. Knowing, for Sellers, is an activity which, in disclosing objects by means of

ideas, is about external things and consequently transcends the cognitive organism. 'The sensory complex arises in the brain under patterned stimulation of the sense organs and has the role of guidance of response. Such guidance is a transcending role . . . we do not need to get mystical about transcendence.' Evolutionary \*naturalism is not reductive, since nature undergoes cumulative change in which new patterns emerge. 'Matter is . . . existent in its own right. And I shall think it in terms of the category of substance', not process. For Sellars, '\*socialism is a democratic movement whose purpose is in securing of an economic organization of society which will give the maximum possible at any one time of justice and liberty.' His son, Wilfrid Sellars, acknowledged close philosophical affinity with his father, though he wrote in the idiom of a different generation. P.H.H.

\*Critical Realism; materialism.

*Symposium in Honor of Roy Wood Sellars (Philosophy and Phenomenological Research, 15; 1954).*

**Sellars, Wilfrid** (1912–89). American philosopher notable for his thoroughgoing investigations in metaphysics and the philosophy of mind. He distinguishes between the manifest image of man as a being with beliefs, desires, and intentions, and the scientific image of him as an embodied being subject to study by physicists, biochemists, and physiologists. The task of reconciling those two images is a major problem in the philosophy of mind. Typical of Sellars's own approach to the problem is his verbal behaviourist account of thought and meaning in terms of the functional role of linguistic items. (\*Functionalism.) Thought is inner speech which is modelled on overt speech, and overt speech is the exercise of a capacity to use words and sentences appropriately in relation to the world and to each other. Thus nothing repugnant to the scientific image is invoked. O.R.J.

\*myth of the given.

**semantic ascent.** The move from talk about the world to talk about the semantic properties of a language (e.g. the move from 'Snow is white' to "'Snow is white" is true'). This is said to involve *ascent* because of the doctrine that the semantic properties of a language *L* cannot, in general, be expressed in *L* itself, but only in a higher \*metalanguage. The move is useful because ascent to a semantic level enables one to express certain kinds of generalizations that are otherwise inexpressible. Thus, the sentence 'Every axiom of Peano arithmetic is true' makes, it is argued, a claim about numbers. But, since Peano arithmetic contains infinitely many axioms, the claim cannot be expressed, without resorting to semantic ascent, by any finite sentence. A.GUP.

W. V. Quine, *Philosophy of Logic* (Englewood Cliffs, NJ, 1970).

**semantics.** In *Foundations of the Theory of Signs* (1938) C. W. Morris divided the general study of signs (\*semiotics) into three branches. These are \*syntactics, or the study of the relation of signs to other signs; semantics, or the study of the relation of signs to the things they represent; and \*pragmatics, or the study of the relation of signs to their users. Semantics is thus the general study of the interpretation of \*signs, and in particular the interpretation of the sentences and words of languages. Following Carnap, it is commonly divided into pure semantics, or the study of artificial and formally specified languages in the abstract, and applied semantics, or the study of natural, empirically given languages such as English or French. The language studied is called the \*object language, and the language in which interpretations are given, the \*metalanguage. A semantic statement typically mentions a sentence or other term of the object language, and says what it means, or refers to, or what otherwise provides its interpretation using the metalanguage. An object language can function as its own metalanguage, at least to an extent circumscribed by the need to avoid semantic \*paradoxes. A \*formal semantics is a fully systematic description of the way in which an object language is to be interpreted, standardly given by a recursive account of the way in which larger meanings or truth-conditions for entire and progressively more complex sentences depend upon the interpretations assigned to their elements.

The fundamental problems for semantics are first to discover what linguistic categories we need to distinguish, and then the *kind* of description of the function of terms that is appropriate. The great advances in the subject came with realizing, for instance, that 'Some men are mortal' is semantically quite different from 'Aristotle is mortal': the phrase 'some men' does not function as a name or 'term' interpreted as referring to some men. The difference in function is clearly seen when we look at the different kinds of inference such expressions create. The theory of this difference (quantification theory) is well understood, but other semantic problems have proved less tractable. Are we content to say of a \*name, for example, that it refers to its bearer? In that case we see no difference between two names that have the same bearer. Or is some more fine-grained description needed, separating what is said about each of two such names? The former option makes for a more simple and logically more tractable system (extensional semantics) while the latter initiates a search for principles governing the more fine-grained (intensional) features that separate terms with the same extension, but which mean different things. Controversies in semantics frequently centre on the use of various devices, such as possible worlds, to provide the necessary interpretations. But it is generally accepted that the more fine-grained the discriminations or contexts that a language permits, the richer are the categories and descriptions that a semantics must adopt in representing its structure.

Even when these problems are solved, others remain for a full philosophical semantics. For any semantics is apt to deal in terms such as \*reference, predication, and

\*truth, and perhaps in addition the richer intensional concepts of \*meaning, \*sense, and \*synonymy. And even if we are quite happy using such terms, the question remains *in virtue of what* they apply (for instance, do predicates mean what they do in virtue of shared universals, and what are \*universals and how do we apprehend them?). If we consider a pure or formal specification of a language as an abstract structure, then the equivalent problem will be the question what is necessary for it to be correctly attributed to a population. Divisions rapidly arise over whether the appropriate empirical grounding is given by one kind of fact or another. These problems separate semantics in a narrow sense from the wider concerns of the philosophy of language. s.w.B.

\*semiotics; language, problems of the philosophy of; Montague.

R. Carnap, *Introduction to Semantics* (Cambridge, Mass., 1947).

P. Ludlow (ed.), *Readings in the Philosophy of Language* (Cambridge, Mass., 1997).

**semantics, formal:** *see* formal semantics.

**semantic theory of truth.** This theory was developed by Tarski, who was particularly concerned to overcome the semantic \*paradoxes to which talk of \*truth gives rise in natural languages, such as the \*liar paradox. He held that truth could only be adequately defined for a language which did not contain its own truth-predicate. Calling such a language, *L*, the object language, Tarski undertook to provide a definition by \*recursion of truth-in-*L*, the definition being formulated in an appropriate \*metalinguage. For such a definition to be satisfactory, Tarski held, it would have to enable one to prove all true equivalences of the form ‘*S* is true-in-*L* if and only if *p*’, where ‘*S*’ is a structural specification of a sentence of *L* and *p* constitutes the correct translation of that sentence into the metalinguage. He showed how this task could indeed be carried out for certain artificial, formalized languages, but believed that the method could not be extended to provide a definition of truth for any natural language, such as English. E.J.L.

\*snow is white.

S. Haack, *Philosophy of Logics* (Cambridge, 1978).

**semiotics.** General theory of \*signs. Peirce distinguished three kinds of sign: icons, which are like the objects signified (e.g. naturalistic paintings); natural signs (e.g. clouds signify rain); and conventional signs (e.g. red for danger, and at least the majority of words). Semiotics is usually divided into three fields: \*semantics, the study of meaning; \*syntactics, the study of (surface ‘grammatical’ and also ‘deep’) structure; and \*pragmatics, which deals with the extra-linguistic purposes and effects of communications. A.J.L.

C. W. Morris, *Signification and Significance* (Cambridge, Mass., 1968).

**Sen, Amartya K.** (1933–). Indian economist and philosopher at Harvard, winner of the Nobel Prize for Economics in 1998. Working on the foundations of welfare and development economics, Sen is a leading theorist of social choice. In the debate following \*Arrow’s paradox, Sen has been a critic of \*welfarism, which appraises the value of outcomes wholly in terms of individuals’ preferences between them. Sen has argued for a consequentialist ethics that incorporates respect for rights in its doctrine of the good. He raised the ‘paradox of the Paretian liberal’—an inconsistency, given plausible background assumptions, between the welfarist claim that if everyone prefers an *A* to a *B*, then *A* must rank above *B* in a social ordering, and a condition of minimal liberty that each agent possess a personal sphere where her preferences dictate the social ordering. Sen has worked on the nature of personal \*well-being and the measurement of poverty. T.P.

A. K. Sen, *Choice, Welfare and Measurement* (Oxford, 1982).

— *On Economic Inequality*, new edn. (Oxford, 1997).

**Seneca, Lucius Annaeus** (c.2 BC–AD 65). Stoic, tutor to Nero, chief administrator of the Roman Empire with Burrus AD 54–62, and author of ten *Moral Discourses*, 124 *Moral Epistles*, a satire on Claudius, nine tragedies, and a work on natural philosophy. At worst Seneca is an unoriginal philosopher and a contrived stylist. At best, in the *Epistles* and *Discourses* (note particularly ‘De providentia’, a Stoic dissertation on suffering, and ‘Ad Marciam de consolatione’, addressed to a mother on the death of her sons), he writes with a vividness of illustration and a persuasive brilliance unrivalled in philosophy: philosophy is practical goodness; excessive passion is evil; external goods are ultimately valueless; life is infinitely worth while; tragedy can be overcome or endured. Driven to suicide by Nero, his reputation and his life alike were blighted by his infamous pupil. J.C.A.G.

\*Stoicism.

V. Sørensen, *Seneca: The Humanist at the Court of Nero* (Edinburgh, 1984).

**sensation.** The subjective aspect of \*perception—usually taken to denote the sensory (as opposed to conceptual) phase of a perceptual process. In hearing a concert, for instance, the sensation is the conscious auditory event preceding whatever thoughts and beliefs (if any) the sensation arouses in the perceiver. One might hear—thus have a sensation caused by—a French horn without coming to know or believe that it is a French horn. One might misidentify it as a trombone or not have any thoughts at all about it. This, presumably, is what happens with animals and young children. They can hear French horns. They can, therefore, have sensations—perhaps even sensations similar to ours—without these sensations necessarily producing beliefs similar to ours. Perhaps (though this is controversial and depends on just what is meant by having a \*belief) they can have sensations (be sentient) without having any beliefs at all.

Aside from the sensations (visual, auditory, olfactory, and so on) associated with the various sense modalities, there is also a wide variety of other sensory-like phenomena that are ordinarily classified as sensations: twinges, tickles, pains, itches, thirst, hunger, feelings of sexual arousal, and so on. If there is any feature that distinguishes this odd assortment of mental entities, it is, perhaps, their introspectively salient quality. The sound of a French horn is utterly unlike the look or feel of a French horn. If the sensation is identified, as it typically is in the case of perceptual awareness, with the way things sound, look, and feel, then these sensations, though they are all of the same thing (a French horn), have an intrinsic, an introspectively obvious, quality that distinguishes them from one another. This is quite unlike such \*propositional attitudes as thought, belief, judgement, and knowledge. Beliefs differ only with respect to their content—the proposition believed—not in their intrinsic quality or ‘feel’ to the person having them. Sensations, on the other hand, can be of, about, or directed upon the same thing (a French horn)—thus having, in this sense, the same content—and yet remain entirely different. As a result, thoughts are classified in terms of their \*intentionality, what they are of or about, while sensations are specified in terms of their intrinsic character, what they feel or seem like to the person having them, quite apart from what, if anything, they are of or about.

A second feature of sensations that sets them apart from such discursive events as reasoning, thinking, knowing, and remembering is that sensations are, in the first instance at least, independent of the conceptual or intellectual assets (if any) of the subject. One cannot want chocolate, believe that there are chocolates in the box, or remember that one ate chocolate without understanding what chocolate is. One can, however, taste chocolate, smell it, and see it—and in this sense have chocolate sensations—while remaining completely ignorant of what chocolate is. In this way sensations constitute a primitive level of mental existence. They occur at a level—presumably in certain animals—at which discursive thought and reason are, if possible at all, not well developed. One does not need the concept of an itch or a pain, the capacity to have itch-thoughts and pain-beliefs, in order to *feel* itches and pains.

Though sensations, unlike thoughts, differ from one another in some intrinsic way, their epistemological status remains moot. Is one directly aware of (say) a visual sensation when one perceives, in a perfectly normal way, an external object? If so, is one aware of two things in normal perception—the external object (we say we perceive) and the internal sensation which it (the object) arouses in us? Or is one directly aware of only one thing, the sensation, while the external object is reached (known? perceived?) by some inferential or constructive mental process (thus being known or perceived indirectly) as the \*representative theory maintains? Or is one only aware of the external object, the internal sensation being known only by inference, as \*naïve realism asserts? If so, how is one’s

knowledge—which seems direct—of the character of sensations to be understood? F.D.

**sense, manifold of:** see manifold of sense.

**sense and reference.** Standard translations of Frege’s terms *Sinn* and *Bedeutung*, originating in his 1892 paper ‘Über Sinn und Bedeutung’. The reference of an expression is the entity it stands for: referring expressions stand for objects, predicates stand for \*functions (in the mathematical sense, which Frege called ‘concepts’), and sentences stand for truth-values. Referring expressions and predicates combine to form whole sentences, whose references are a function of the references of their parts. Senses are ‘modes of presentation’ of \*references: the terms ‘Cicero’ and ‘Tully’ have the same reference but different senses. Sense was initially introduced by Frege to solve the puzzle of identity: if ‘Cicero’ has the same reference as ‘Tully’, then how can ‘Cicero is Tully’ be informative when ‘Cicero is Cicero’ is not? The senses of the parts of sentences combine to form the senses of sentences, which Frege called ‘thoughts’. T.C.

\*connotation and denotation; meaning.

Gottlob Frege, ‘On Sense and Meaning’, in *Translations from the Philosophical Writings of Gottlob Frege*, ed. P. T. Geach and Max Black (Oxford, 1980).

**sense awareness:** see awareness, sense.

**sense-data.** Subjective entities (allegedly) having the properties the perceived external object (if there is one) appears to have. In seeing a white circle under red light and at an oblique angle, the sense-datum would be red and elliptical (the way the white circle looks). According to sense-data theorists, one perceives an external object, a white circle, but what one senses (is acquainted with, directly apprehends) is a red ellipse: the subjective sense-datum. Then, if one is clever (and knows about the funny lighting), one infers, on the basis of the sense-data one directly apprehends, that there is (probably) a white circle causing the red, elliptical sense-datum. In this way our knowledge of sense-data is supposed to provide a foundation for all empirical knowledge. F.D.

\*perception; phenomenalism; representative theory of perception.

B. Russell, *The Problems of Philosophy* (New York, 1959), ch. 1.

C. D. Broad, *Scientific Thought* (London, 1923), chs. 7 and 8.

**sensibility.** In one sense this can mean a set of individual or collective dispositions to emotions, attitudes, and feelings. As such, sensibility is relevant especially to value theory, including ethics, aesthetics, and politics. Arguably, there are at least three important interrelated types of judgement one

can make about a sensibility: that some constitutive emotions can be criticized or justified against criticism in various ways (e.g. are 'irrational', 'exaggerated', 'well-founded', etc.); that some constitutive emotions ought to be regulated in certain ways, in light of criticism; and that individual or collective responsibility is appropriate for some of the emotions, in light of the possibility of regulation. E.T.S.

\*aesthetic attitude; taste.

Ronald B. De Sousa, *The Rationality of Emotion* (Cambridge, Mass., 1987).

**sentences:** see statements and sentences.

**sentential calculus.** Where a \*proposition is understood to be a completely interpreted indicative sentence of a language, 'sentential calculus' and \*'propositional calculus' may be used interchangeably.

Where, as in Frege, a proposition is an abstract entity which is the sense or content of a sentence, those objects are *represented* by sentences. Different sentences in a given or a different language may express the same proposition. Given the elusiveness of such entities, the logic of interpreted sentences remains the vehicle for presenting the logic of propositions as in the propositional calculus.

R.B.M.

B. Mates, *Elementary Logic* (Oxford, 1972).

**sentential function.** An expression which can be joined to another expression or expressions to form a sentence. Sentential functions include \*connectives, such as 'and', which form a complex sentence from a sentence or sentences. Predicates are also counted as sentential functions since, for example, the predicate '... is wise' when joined with the singular term 'Socrates' forms the sentence 'Socrates is wise'.

A.D.O.

**sentimentalism:** see moral sense.

**sentiments.** A sentiment is an attitude, in favour of or against people and their actions, which may involve both \*judgement and \*emotion. The term 'sentiment' has also been used, as by Hume and Smith, to refer to a possible basis for our moral attitudes. In this use sentiment is a feeling which the objects of moral appraisal evoke in us; as a possible basis for our moral attitudes, sentiment is opposed to reason.

### Serbian philosophy.

1863–1945. Emerging after the foundation of Belgrade University in 1863, Serbian philosophy gained a reputation through the work of Branislav Petronijević, whose articles were later cited as authoritative in such works as Lee's *Zeno of Elea* (Cambridge, 1936) and Boyer's *The Concepts of the Calculus* (New York, 1939).

1940s–1960s. The philosophical tradition was dismantled in post-war Yugoslavia by the communist regime. The

official establishment of 'humanist Marxism' followed the 1953 ideological cleansing of 'dogmatists'. The critical attitude of members of the 'Praxis Group' such as Svetozar Stojanović to the governing regime led to their dismissal from Belgrade University in 1975. The international reputation of 'Praxis Marxism' partly rests on non-philosophical grounds. Non-Marxist approaches were not tolerated and Alexandar Kron's work in formal logic represents the only such achievement of that time.

1970s and since. Although both politicians and Marxist academics became more tolerant in the early 1970s, it is hard to understand how a critical mass of analytically oriented, practically self-taught non-Marxist students was reached so quickly. The 'September Meetings' in Dubrovnik, established in the early 1980s by David Charles, Timothy Williamson, and their Belgrade colleagues, resulted in what was later called the 'England–Belgrade axis'. The distinctively analytic character of Serbian philosophy is underlined in that fourteen of the sixteen Yugoslav contributors to the collection cited below are, or have been, active at Belgrade University. Hopefully, though now either spread throughout the world or still working at home under unfriendly conditions, some will make important contributions to metaphysics, logic, epistemology, philosophical psychology, ethics, philosophy of action, and philosophy of science. Very well trained in philosophical analysis and symbolic logic, they are particularly successful in using thought experiments and the \**reductio ad absurdum* method. M.A.

**set theory.** The property of being human is said to 'pick out' or 'determine' the *set* of all human beings. This has *subsets*—the sets of Scots, English, etc.—and *members*—e.g. David Hume and Jane Austen. At least normally, if not always, a set is not a member of itself: thus the set of City University philosophers is not itself, alas, another philosopher, who could help increasing numbers of students. It is an abstract object.

Our basic logical thoughts often embody relations between sets, subsets, and members, for example in syllogistic argument. Thus 'All robots are musical' says 'The set of robots is a subset of the set of musical things'; or, every member of the first set is a member of the second. Between 1874 and 1897 Cantor developed an astonishingly rich theory of infinite sets, including ones whose members are ordered, and sets having even more members than the so-called 'denumerably' infinite set of all integers—thus proving the existence of 'higher' infinities. Later, Russell and Whitehead tried to show that pure mathematics is a branch of the logic of sets, and is thus \*analytic. Set theory has applications within many areas of mathematics.

It is therefore extremely embarrassing that our simplest intuitive thoughts about sets very quickly lead to contradiction. For if every property determines a set, then the set

(R) of all 'normal' sets, namely, 'those which are not members of themselves' is, if a member of itself, then not, and vice versa (\*Russell's paradox). Alternative set theories are formal, symbolic expressions of relationships between sets which attempt to avoid contradictions with minimal loss of intuitive acceptability. The Russellian approach rejects as malformed symbolic expressions of both 'S is a member of itself' and its denial. Sets are put in hierarchies, and one can only meaningfully express membership relations between sets of immediately neighbouring levels. Such an axiomatization may be consistent, but only through inordinate loss of expressive power. Zermelo–Fraenkel–Skolem set theory only allows the *construction* of sets from properties when certain other conditions obtain: these entail the non-existence of *R*. Von Neumann–Bernays–Gödel set theory is more comprehensive but even more complex. It allows the existence of *R*, but it is not a member of any other set (it is then called a 'class'). This seems counter-intuitive: for if *R* exists, then why should there not be a merely two-membered set containing, say, *R* plus the set of all philosophers?.

**sex.** Biological feature distinguishing males and females in respect of their reproductive roles (contrast \*gender). Thus, by extension, sex is thought of as a biological drive which gives rise to activity that typically results in reproduction, or as that activity itself. This suggests that the kind of explanation required for such activity is a biological one, occasioning such protestations as 'My sex life is not my fault: I'm programmed by my genes'. As well as presupposing a crude determinism, this underplays the role of \*culture in giving rise to multifarious forms of sexual activity (e.g. \*homosexuality). Yet sexual desire has usually been viewed as a *blind* desire, i.e. one the desirability of whose object is not apparent to reason. It is perhaps for this reason that the character of Freudian explanations of behaviour in terms of sexual desire (and their scope) remains mysterious.

P.G.

\*sexual morality.

Roger Scruton, *Sexual Desire* (London, 1986).

**sex, philosophy of.** The theoretical examination of human sexuality, desire, and pleasure. Analysis has focused on the attempt to establish non-moral standards to rank sexual behaviours as 'natural' or good, as opposed to perverse or bad. Central to this examination is determining whether sexual desire is localized simultaneously within the phantasmatic as well as the sensory boundaries of the skin. Thomas Nagel reworks Sartre's notion of 'a double reciprocal incarnation' into an account of sexual desire as a serial unfolding of nested desirings of two reflective persons. On this view, the category of perverted sex would extend to include any solitary sexual practice.

This analysis of sexual desire in terms of reciprocating psychic structurings has ramifications for justifications of sado-masochism. Patrick Hopkins argues that rape simulations are logically distinct from rapes, since certain sexual behaviours cannot be properly individuated except by their links with a shared sexual imaginary. Robert Solomon not only continues this mentalist reading of sexual desire, but refigures bodily gestures as having semantic content: an intimate behaviour is a 'natural expression' that can be perverse if untruthful or feigned. Alan Goldman, on the other hand, rejects any account of sexual desire that is not straightforwardly 'bodily'. For Goldman, sexual desire is directed toward the physicality of another person and involves only a minimal, short-lived psychological component. On this account, the deliberate delay of coitus and bestiality each count as perverse. Other issues involve Kant's claim that objectification is necessarily involved in any sexual relation between persons. Martha Nussbaum separates 'benign' objectification from the malignant sorts marked by one or more of the following: viewing the desired other as essentially replaceable, lacking 'boundary-integrity', and failing to be the possessor and owner of a unique personal narrative.

Michel Foucault challenges this entire analytic schema by running a genealogy of sex. On his view, sex for modern subjects in the West is discursive: subjectivities, bodies, and pleasures are produced by the operations of a particular regime of knowledge/power/pleasure. Foucault delineates 'a *scientia sexualis*' that naturalizes the phenomena it extracts and organizes through medicalizing the confession, replacing the priest with the psychoanalyst. He claims that any natural/unnatural schematic is a mythic construction, since there is no non-linguistic access to any pre-social human nature.

**sexism.** Thought or practice which may permeate language and which assumes women's inferiority to men. The existence of sexism is acknowledged from a variety of ideological perspectives, and sexism may be conceived either as something one encounters instances of, or as a pervasive phenomenon endemic to society. Thus 'sexist' is applied pejoratively to individuals and to institutions both by liberal feminists and by feminists who advocate a radical transformation of existing \*gender relations.

J.HORN.

\*feminism.

Mary Vetterling-Braggin, Frederick A. Elliston, and Jane English (eds.), *Feminism and Philosophy* (Totowa, NJ, 1977).

**Sextus Empiricus** (AD c.200). Sceptic and physician. Sextus, about whose life we know practically nothing, wrote a number of works on the complex history of the Sceptical movement. The surviving works are: *Outlines of Pyrrhonism*;

*Against the Dogmatists*; and *Against the Professors*. The second two are usually coupled together and titled *Against the Mathematicians*, that is, all those who profess any sort of technical knowledge. *Outlines of Pyrrhonism* provides an account of the philosophy of Pyrrho, including a comparison of \*Pyrrhonism with versions of Academic \*scepticism. The other works examine at considerable length various dogmatic claims in the arts and sciences and sceptical strategies that may be employed to undermine confidence in them. These works are therefore a mine of information on many ancient philosophical schools. Sextus argues for the superiority of Pyrrho's Scepticism to that of the \*Academy, although the difference between these are disputed in the scholarship. Although Sextus is unrelentingly critical of all other philosophical positions, he believes that Scepticism has a positive practical purpose, namely, the tranquillity of soul arising from abandoning the quest for knowledge of any sort.

**sexual morality.** Principles of right conduct in matters of \*sex, or their observance. Two questions arise: *What* sexual acts are morally permissible? *With whom* are they permissible?

The view that some kinds of sexual act are morally wrong can spring from several sources. The most obvious employs the \*consequentialist test of whether they cause harm. Thus some sexually sadistic acts may, by this criterion, be condemned, though de Sade himself would reply that they cause less harm than the acts resulting from their repression. In the absence of reliable empirical evidence on the effects of sexual behaviour (e.g. of reading pornography), non-consequentialist criteria may be turned to. One employs the notion that some kinds of sexual acts are unnatural and therefore wrong. Two problems arise. First, the mere fact that many sexual acts are not conducive to reproduction (or to other biological purposes) does nothing to show that they are unnatural, in the sense of tending, or intended, to frustrate what, if anything, is \*natural to human beings. Second, even if they were, they would not thereby be shown to be immoral without further premisses such as the Roman Catholic belief that what is contrary to created nature's purposes is wrong because contrary to its Creator's will.

A more widely acceptable criterion condemns some kinds of sexual acts as failing to treat those with whom they are performed, or oneself, as \*persons rather than as objects. Kant seems to have treated all sex like this, holding that 'sexual love makes of the loved person an object of appetite; as soon as that appetite has been stilled, the person is cast aside as one casts away a lemon which has been sucked dry'. Sartre thinks of ordinary sexual desire as aiming to avoid this, but failing, so that either one makes

the other an object, as in sadism, or one becomes an object for the other, as in masochism. With Sartre's pessimism discarded, this has provided an influential criterion, particularly for \*feminism. It does, however, require additional argument to conclude that depersonalized sex is morally impermissible.

The view that a sexual partner should be treated as a person offers one in a series of answers to the question *with whom* one may, morally, have sexual relations. The most stringent answer restricts sex to \*marriage partners, ruling out, *inter alia*, \*homosexuality; the next to those in a relationship of \*love, ruling out casual sex; then to those desired and respected as persons, excluding, perhaps, prostitution; and uncontroversially, to consenting adults, ruling out sex with children and animals, who are incapable of informed consent. The first three answers correspond roughly to three general approaches in moral philosophy. The ban on extramarital sex goes with an ethics of \*duty. The restriction of sex to love implies an ethics of \*care. And the person-centred approach emphasizes an ethics of \*virtue, of self-creation rather than spontaneity. It may not be fanciful to suggest that the application of each approach here is a reaction to viewing sex as a potentially disruptive force—disruptive, respectively, to society at large, so that exceptionless formal restrictions need to be imposed; to personal relationships, so that sex must be tied to concern for another's welfare; and to the individuals themselves, whose integrity as persons is put at risk by it.

Few philosophers have, by contrast, developed an ethics of sexuality as something other than an appetite requiring regulation. They have, however, attacked the first two moral restrictions—on consequentialist grounds, like Plato, as socially dysfunctional; on the grounds that they inhibit individual \*autonomy in relationships; and on feminist grounds that they impose a pattern of relationships which actually benefits men at the expense of women. As to the third restriction, Nagel bravely maintains that 'bad sex is generally better than none at all'.

Yet such \*essentialist assumptions about sexuality run counter to currently popular views, deriving from feminism and \*post-structuralism, which see different sexualities as constitutive of people's identities as e.g. a lesbian woman or a straight man. These identities, like those of any cultural minority, are regarded as prior to and formative of the particular moralities which apply to them. Thus the attempt to formulate general principles of sexual conduct is viewed (as in a wider \*ethical relativism) as the imposition of the morality of one identity group—typically that of straight men—at the expense of members of others. There are, however, many difficulties with this approach: how fine-grained are the relevant sexual identities? Are *all* identities (e.g. paedophile) to be tolerated, and, if not, why not? Is the implied \*libertarianism compatible with social organization? Can the objections to a general ethical relativism be evaded? The absence of a middle way between universalizing and relativizing approaches to sexual morality is sympathetic to contemporary practical, as well as philosophical, uncertainties in this area of life.

**Shaftesbury, third Earl of** (1671–1713). Named Anthony Ashley Cooper, like his descendant, the nineteenth-century philanthropist, he is normally known simply as Shaftesbury. Partly educated under the politically radical Locke (though he later criticized Locke on both ethics and epistemology), he was an early, if not always consistent, representative, in his *Characteristics of Men, Manners, Opinions, Times* (1711), of the \*'moral sense' doctrine in ethics, inventing that phrase. For much of the time, though not all of it, he emphasized feeling rather than reason as the source of morality: we approve of, or take pleasure in the contemplation of, virtue, and this is because we are by nature altruistic and not just selfish. Morality with him becomes human-orientated rather than God-orientated, though religion can motivate us further towards it. He also foreshadowed to some extent \*utilitarianism, which came to prominence later in the eighteenth century. A.R.L.

S. Grean, *Shaftesbury's Philosophy of Religion and Ethics* (Athens, Oh., 1967).

**shame.** An emotion that serves as the focal point of ethics in many ancient and non-Western philosophies, but its comparative neglect in many ethical theories is illustrative. The Judaeo-Christian tradition and many modern theories place considerable emphasis on \*guilt, but the difference between shame and guilt is profound and symptomatic of a larger omission in ethics. Guilt (not causal or legal guilt, but the feeling of guilt) is a highly individualistic emotion, a matter of self-scrutiny and self-condemnation. Shame, by contrast, is a highly social \*emotion, and it has to do with violating a common trust, 'letting the others down'. Like guilt, it is self-accusatory, but it is so through the eyes of others, as an inextricable member of a group or a community. The capacity to feel shame has thus been cited as a pre-condition of all the virtues, as in the Ethiopian proverb 'Where there is no shame, there is no honour'. Thus Aristotle, in his *Ethics*, takes shame to be a 'quasi-virtue'. It is not good to feel shame, because it is not good to have done something about which to be ashamed, but to do something wrong and not feel shame is the ultimate proof of a wicked character. R.C.SOL.

Aristotle, *Nicomachean Ethics* (Indianapolis, 1985).

**Shoemaker, Sydney** (1931– ). American philosopher at Cornell, known principally for his work in metaphysics and the philosophy of mind. In the former he has argued for the possibility of time without change. He has defended a causal theory of properties, which has as a consequence that the laws of nature are a posteriori necessary rather than contingent; and a causal theory of identity over time.

In the philosophy of mind he is a vocal proponent of analytic \*functionalism, in defence of which he offers a subtle discussion of \*qualia: he denies the possibility of absent qualia, that someone might be functionally identical to us, yet lack qualitative mental states; but accepts the possibility of inverted qualia, that two people may be functionally alike but differ in their qualitative mental states. In addition, his work has covered personal identity, memory, self-consciousness, and dualism. M.G.F.M.

**side constraints:** see ends and means.

**Sidgwick, Henry** (1838–1900). British moral philosopher, who developed the most sensitive, sophisticated (and complicated) account of \*utilitarianism in the nineteenth century. Sidgwick was educated as a classical scholar at Cambridge, resigned his college position because of religious doubts in 1869, but later became the first secular Professor of Philosophy at Cambridge (1883). He was the professor when McTaggart, Russell, and Moore were philosophy students. Sidgwick wrote on many areas, but his only great work is *The Methods of Ethics* (1874; and then five other editions in his lifetime). This is not intended as a defence of utilitarianism so much as an account of the ways in which it is possible to reach a rational basis for action. Starting with common sense, Sidgwick identifies three such methods: \*intuitionism, universal hedonism (i.e. utilitarianism), and individual \*hedonism (i.e. \*egoism). He finds that the particular maxims of common-sense morality do not meet the criteria he lays down for something being an intuitively self-evident principle; but that these are met by certain 'absolute practical principles' of a more abstract nature, such as that future good is as important as present good, or 'that the good of any one individual is of no more importance, from the point of view (if I may say so) of the Universe, than the good of any other'. With such principles he manages to reconcile intuitionism and utilitarianism. However, he thinks that egoism is also an intuitive principle of action, which would only be made compatible with utilitarianism by the work of God. Being reluctant to introduce God for this purpose, Sidgwick had no solution for what he called the 'dualism of \*practical reason', and hence ended the first edition with the sombre words that 'the prolonged effort of the human intellect to frame a perfect ideal of rational conduct is seen to have been foredoomed to inevitable failure'. R.H.

**sign and symbol.** A distinction first explored in these terms by C. S. Peirce. Signs are a highly general category, including natural indications of things. Spots are a sign of measles, clouds a sign of rain to come. A sign of a state of

affairs or event may be any indication, evidence, manifestation, portent, trace (which seems to be what Peirce called an 'index'), or mark that is regularly correlated with it, and hence can be used to infer its presence. In that case, to take something as a sign of something else is to use it to infer the presence of the other thing. This is the use of natural signs, but we can of course invent signs or signals: in heraldry specified emblems indicate the identity of the person wearing them; or a picture of a man with a shovel on the roadside indicates the presence of roadworks; or the picture of beans on the can indicates beans within. In Peirce's view the latter signs work as *icons*, by bearing a natural resemblance to what is depicted. Icons are signs that work in virtue of sharing properties with what is signalled. But most such signals work by \*convention, and it requires a process of being inducted into the convention to learn to interpret them.

Peirce may have supposed that a symbol was a manufactured sign. He defines a symbol as a 'sign which is constituted a sign merely or mainly by the fact that it is used and understood as such' (*Collected Papers*, ii. 307). But this is quickly seen to be inadequate. With symbols we enter a different domain from that of the sign, since the role of a symbol is not that of correlating with the presence of the thing signified. There is no regular correlation of this kind in question. A portrait is not a signal that the sitter is near, but a representation of her. A symbol is not used as a mark that something else is present, but in place of the something else, to bring it to mind, or to identify it as a topic (or, of course, to elicit the emotions and reactions that are supposed appropriate to that other thing, as when a flag is a symbol of a country). Certainly, if we are to think of words as symbols, it is hopeless to see them as kinds of signal or sign of whatever it is they represent. The presence of the word 'giraffe' on a page is no sign that there are giraffes about. A symbol is not something that is used as a sign of things, given the function of signs that we have sketched.

The alternative position is that words and symbols do function as signs, but of states of their producers rather than the states of the world that they signify. Thus Locke took it that words are external signs, in the signalling sense, of ideas in the mind of the person producing them. But this can only be one part of an overall theory, since it requires a supplementary story about the way in which ideas serve as symbols or representations of whatever it is that we end up talking about. Peirce himself was driven to the regressive suggestion that as well as a sign and its object we need to postulate a 'more developed sign' or *interpretant* in the mind of the user. The problem of how such things represent substitutes for the problem about how words represent. A more modern view is that they may be signs of the beliefs or intentions of the person, but the question arises how the presence of belief or other intentional states can consist in the presence of something invested with representative power. s.w.b.

\*representation; semantics; meaning.

C. S. Peirce, *Collected Papers* (Cambridge, Mass., 1932–5), ii.

**simplicity.** Sometimes thought to provide a criterion for choice among scientific theories, with varying accounts of how simplicity might be measured. If simple theories are easier to use, their adoption might be on pragmatic grounds. Poincaré, in contrast, identified mathematical simplicity as a marker for *truth*, which makes sense only if one believes that nature is simple, and will appear so through the filter of theory and language. N.C.

**simulation.** How best to understand the nature and basis of folk-psychological predictions, explanations, and descriptions of human behaviour and mentality couched in terms of belief, desire and the like? Theory theorists maintain that in such activities folk psychological ascriptions are underwritten by the tacit grasp of a theory specifying the use of notions such as belief and desire—informally much like theoretical explanation in the sciences. Simulation theorists claim that we understand one another by using our own minds in a process of simulation, generating processes in ourselves similar to those in other people, informing ourselves of the mental states of others by running our own cognitive machinery 'offline'. This is in contrast to the positing by theory theorists of a system of laws and logical relations which connect beliefs, desires, and the like with behaviour. But if we can use our own minds to simulate the minds of others without invoking such laws, parsimony counsels against theory theory. Much is made of the pretend play of young children, and the importance of simulation in ethical evaluation, empathy, fictional narrative, and aesthetics. Whether this amounts to new interpretations of phenomena or genuine arguments for the view remains unclear. J.GAR.

— (eds.), *Mental Simulation* (Oxford, 1995).

**sin** is moral wrongdoing, or in some cases the omission of what one ought to do. It is usually thought of as the violation of natural law or the commands of a deity. A person's sins are ordinarily characterized in terms of actions or omissions, but in some cases sin can be more meaningfully construed in terms of faults of character or in terms of states, such as a state of rebellion against God or estrangement from God. From medieval times the Church has distinguished mortal sins from venial, or less serious, sins. More controversial is the notion of \*original sin, or guilt inherited from Adam, the first man. Those who take seriously the notion of original sin place great emphasis upon the effects of sin in the world. Some religious traditions allow for the possibility of the forgiveness of sin. G.F.M.

L. Berkhof, *Systematic Theology* (Grand Rapids, Mich., 1939).

H. Davis, *Moral and Pastoral Theology*, 4th edn. (London, 1945), vol i, treatise 4.

**sin, original:** *see* original sin.

**sincerity.** In his *History of England* Hume described men as given to 'feigning'. Sincerity implies by contrast that we have given a full and frank account of ourselves and have not added anything extra. So philosophers have debated whether true morality requires sincerity, or simply appropriate conduct and the 'external' performance of one's duties, and how sincere anyone can be morally required to be. Kant's discussion, 'Concerning Lying', in the *Groundwork of the Metaphysics of Morals* concludes that insincerity with oneself 'deserves the greatest censure, for . . . from such a rotten spot . . . the evil of untruthfulness spreads itself also into one's relationships with other men'.

The special problem of philosophical insincerity arises because of the dual role of the philosopher as custodian of the virtues and critic of orthodoxies. Thus Descartes has been accused of hypocrisy in disguising his hostility to religion and pandering to the Sorbonne, and Hume's *Treatise of Human Nature* invites us to reflect on whether a philosopher can be a sincere and believing sceptic.

CATH. W.

\*lying.

**Singer, Peter A.** (1946– ). Best known for his writing in areas of \*applied ethics, starting with his best-selling *Animal Liberation* (London, 1976), in which he argues that most treatment meted out to animals is morally intolerable. He has continued to write about such issues, but has also put the ideas and theories of moral philosophy to work to provide assessments of the morality of euthanasia, *in vitro* fertilization, the distribution of world resources, and many allied topics (see especially his *Practical Ethics* (Cambridge, 1979)). His work is marked by a strong commitment to \*utilitarianism and by a wish to displace the morality of what he has referred to as the 'Judaean-Christian inheritance'. He lived and worked for many years in Australia, along the way serving on government committees and running a Centre for Human Bioethics, but in 1999 took a professorship at Princeton.

**Sinn:** *see* sense and reference.

**Skolem paradox.** A collection is *countable* if it is either finite or has the same size as the natural numbers, the smallest infinite set. It is a theorem of standard \*set theory, due to Cantor, that the set of real \*numbers is not countable—there are more real numbers than natural numbers. However, the Löwenheim–Skolem theorem states that if

a countable set of (first-order) sentences has a model at all, then it has a model whose domain is at most countable. The 'paradox' is that if real analysis is consistent, it has a countable model. Similarly, if set theory is consistent, it has a countable model that satisfies an assertion that one of its members is not countable. Such models are called 'non-standard'. The fact that a model of set theory satisfies an assertion that a set is uncountable only entails that there is no function in the model that maps the natural numbers on to the 'members' of the set. It does not rule out the existence of such a function—outside the model. The 'paradox' has been thought to raise doubts concerning the referents of expressions like 'natural number' and 'finite'. In what sense can we say that the aforementioned non-standard models are 'unintended'? s.s.

\*satisfaction.

Thoralf Skolem, 'Einige Bemerkungen zur axiomatischen Begründung der Mengenlehre'; tr. as 'Some Remarks on Axiomatized Set Theory', in Jean van Heijenoort (ed.), *From Frege to Gödel* (Cambridge, Mass., 1967).

**slave morality.** Nietzsche's designation of one basic type of morality which he contrasts with another he calls 'master morality'. Whereas 'master morality' is fundamentally a morality of self-affirmation on the part of the powerful, 'slave morality' is a reactive morality originating in resentment of the powerful on the part of the powerless. The qualities of the powerful which they affirm as 'good' are deemed 'evil' by the powerless, for whom 'good' is derivatively conceived in terms of the absence or repudiation of those qualities. Nietzsche contends that this reactive, fearful, and resentful type of morality (and its 'good versus evil') has triumphed over its ancient rival (and its contrasting opposition of 'good versus bad', i.e. superior versus inferior) in the modern world, to the detriment of the quality of human life. (See *Beyond Good and Evil*, sects. 260–8; *Genealogy of Morals*, First Essay.) r.s.

Richard Schacht, *Nietzsche* (London, 1983), ch. 7.

**slave of the passions:** *see* reason as slave of the passions.

**slime.** Sartre invokes *le visqueux* (slime, stickiness, the viscous) in discussing how feelings, acts, character traits, are 'charged with something material', while, equally, material substance is engrained with 'affective meaning'. The disgustingness of slime seems to have an objective quality, neither physical nor psychic but transcending both. Slime's connotations cannot be derived from slime as brute fact, but they cannot be a projection of our feelings either, since to establish the connection between literal physical sliminess and the slimy quality of a person requires us to recognize baseness *already* in sliminess, and sliminess in a type of baseness: there is 'pre-ontological comprehension'. However experienced, slime is compromising, duplicitous, 'leechlike', the potential 'revenge of the in-itself' on the \*for-itself it seeks to engulf. J.O.G.

**slingshot arguments.** Such arguments purport to show that distinct true sentences  $p$  and  $q$  (or nominalizations of them, such as ‘the fact that  $p$ ’ and ‘the fact that  $q$ ’) can never have different references. Assuming, as seems plausible, that any sentence logically equivalent to  $p$  has the same reference, and that the reference of a sentence is not altered by replacing any term in it by another term with the same reference, it appears to follow that the reference of  $p$  is the same as the reference of any other true sentence  $q$ . This seems to spell trouble for the \*correspondence theory of truth and for an \*ontology of \*facts, but it is thought by many that the fault lies more with slingshot arguments than with their targets. E.J.L.

S. Neale, *Facing Facts* (Oxford, 2001).

**slippery slope.** The ‘slippery slope’ is the name of an argument based on a certain view of human nature, not on logic, and commonly used in non-philosophical discussions of moral issues. The reasoning is that, though a practice may be unobjectionable in one type of case, if it is once permitted, its use will inevitably be extended to other more morally dubious cases. Thus it is argued that, though research using human embryos immediately after fertilization may be morally defensible, the period for research will inevitably be extended, until we shall find ourselves using children and adults for research, without their consent. The inevitability here supposed is not logical inevitability, but is thought to result from people’s always wanting more than they have. In fact legislation or other forms of regulation can usually control an undesirable slide down the slippery slope. M.WARN.

**Slovene philosophy.** Its main areas of activity have been ethics, natural philosophy, and philosophical psychology, while the Aristotelian and Thomistic traditions have been the principal influences.

Medieval disputes in ontology and logic were chiefly concerned with the meaning, interpretation, and definition of terms; in the twelfth century, Hermanus de Carinthia wrote a treatise on essences.

At the time of the Slovene Cultural Revival (the late eighteenth century) the most prominent philosopher was Franc Samuel Karpe (1747–1806), whose central philosophy was associative psychology in the tradition of Locke. His empirical psychology distinguished between the lower epistemic capabilities, such as sensations and presentations, and the higher epistemic powers including the ability to form concepts, conceptual association, memory, speech, and prediction. Others followed a psychological approach to epistemic certainty.

Ethics was empirically and psychologically based, taking as its starting-point the needs of human beings and their desire for survival as the spur to cultural development. Morality was felt to be required where life does not follow the exigencies of nature. For Karpe, moral philoso-

phy was an extension of thought and imagination by the introduction of the emotive element. Reflexes determine personal behaviour, but human beings also possess the power of decision and free will. Whereas the pure qualities of mind are measurable, a particular soul may only be compared to them. Also in the period of the Cultural Revival mathematical metaphysics aimed to replace verbal argumentation by a system of mathematically based pictorial argumentation.

Starting from Meinongian theory of objects, France Veber developed his idea of knowledge of reality with the help of basic sensory experience. Recently the Veberian tradition has seen a revival with meetings of the Slovene–Austrian Philosophical Society (Ljubljana and Graz), and with *Acta Analytica*, an international journal dedicated mostly to the philosophy of psychology, edited by the Ljubljana-based Slovene Society for Analytical Philosophy, one of several active Slovene philosophical societies. Important work is also being done in the philosophy of science. M.POT.

**Smart, J. J. C.** (1920– ). Emeritus Professor of the Australian National University and the University of Adelaide, Companion of the Order of Australia, Cambridge-born, educated at Glasgow and Oxford, and since the early 1950s a leading Australian philosopher, widely recognized for contributions in the philosophy of mind, philosophy of science, metaphysics, and ethics. Smart was an original architect of the brand of tough-minded \*realism nowadays associated with philosophy in Australia. His realism, like his uncompromising \*materialism, is the product of a conviction that philosophical theories are constrained by their scientific plausibility. This conviction underlies Smart’s defence of a ‘non-cognitivist’ account of the basis of moral judgement and an advocacy of utilitarian normative principles, which are recommended by their simplicity and generality, features they share with an appropriately modest scientific perspective on the world. J.HEIL

J. J. C. Smart, *Philosophy and Scientific Realism* (London, 1963).

**Smith, Adam** (1723–90). The famous economist was born in Kirkcaldy and educated at Glasgow and Oxford. Between 1751 and 1763 he was Professor of Logic and then of Moral Philosophy in Glasgow. He became tutor to a Scottish nobleman, whom he accompanied to Europe, returning to Kirkcaldy in 1767 where he lived with his mother. Latterly he was a Customs Commissioner in Edinburgh. He was intimate with Hume, whose views on morals and economics he shared. A Stoic rather than an Epicurean, he inherited the spectator theory of virtue from his teacher Francis Hutcheson. The theory is a form of psychological \*naturalism, explaining moral good as a

particular kind of pleasure, that of a spectator watching virtue at work. Smith suggested that the reason for the pleasure is the similarity between the virtue of the agent and that of the spectator himself. What makes the spectator's pleasure moral is its object, the agent's motive of consciously conforming with agreed standards of not harming the innocent, benefiting oneself, one's family and friends, and the societies to which one belongs, and being grateful to one's benefactors. v.H.

**snow is white.** "Snow is white" is true if and only if snow is white' was Tarski's celebrated example of what he called an equivalence of the form *T*. He showed how truth, for sentences of a formalized language *L*, could be defined in such a way that an equivalence of the form *T* for each sentence of *L* is a consequence, and yet without generating the notorious \*liar paradox. Some, notably Davidson, have attempted to exploit Tarski's ideas to provide an analysis of the \*semantics of natural language. The interpretation of Tarski's results in the context of natural languages, as a theory of meaning, or as a diagnosis and solution of the liar paradox, has attracted criticism, however, largely because of what are seen as strong disanalogies between the structures of formalized and natural languages. C.H.

**social change, means of.** In a democracy, ideally speaking, citizens produce social change by bringing problems to the attention of a government, which then gathers evidence and expert opinion. All important social issues are addressed, evidence is publicly discussed, and decisions are made by the people as a whole. Transparency and maximum citizen participation characterize all stages. Reasoned, just, and non-violent social change is the result.

Since this ideal process is realizable only in democracies, and achieved only rarely there, activists have used extra-governmental means to try to bring about change. Social movements, which may include demonstrations, heroic or self-sacrificial acts, advocacy and organizational groups, spokespeople, promotional writings, and artistic expressions, have brought important reform. Such movements—e.g. those for women's rights and for civil rights—typically go through many stages over long periods of time. They may be limited to civil disobedience and other non-violent tactics to appeal to conscience and generate sympathy, or they may employ violence to retaliate for perceived wrongs or to weaken opposing forces and compel negotiations. More extreme are revolutions attempting to alter basic social institutions and not work within them; proponents justify them as the only means of eliminating pervasive and destructive conditions (e.g. a repressive regime, an exploitative economic system).

One country may try to produce social change in another by diplomatic means, by imposing economic sanctions, or by supporting revolutionary movements or terrorist activities within it. Even more direct is the invasion and subjugation of another country, defended as alone effective in eliminating great evils within that country or in preventing it from causing enormous harm to others. These methods are increasingly controversial, as they appear to violate moral standards, international law, or the United Nations Charter.

Attempts at reform always face the conservatism of the public media, controlled by the state in authoritarian regimes and strongly constrained by financial pressures in liberal ones. The media are usually part of the very power structure being challenged. Recognizing that media have a central role in shaping public opinion, activists use mass demonstrations, art, sympathetic publishers, and 'alternative' media developed by the activist community itself to gain a public voice. c.c.

**social constructionism.** Analysis of 'knowledge' or 'reality' or both as contingent upon social relations, and as made out of continuing human practices, by processes such as reification, sedimentation, habitualization. Schutz's \*phenomenology—the analysis of the structure of the common-sense world of everyday life—is an important influence, although current exponents draw on a variety of sources including \*hermeneutics, the later Wittgenstein's intersubjective theory of meaning, and the Marxist conception of \*praxis (which emphasizes how knowledge and politics are contingent upon work and economic relations). Social constructionists do not believe in the possibility of value-free foundations or sources of knowledge, nor do they conceptualize a clear objective–subjective distinction, or a clear distinction between 'knowledge' and 'reality'. The position, therefore, has profound implications for the practice and philosophy of science, and for political philosophy. E.J.F.

\*social facts; communitarianism.

**social contract:** see contract, social.

**Social Darwinism.** Social Darwinism is a diverse collection of nineteenth- and early twentieth-century doctrines that enjoyed considerable popularity and that interpreted various human social phenomena in the light of (what was taken to be) Darwinian evolutionary theory. Perhaps the most influential form of Social Darwinism viewed society

and the economy as a competitive arena in which the 'fittest' would rise to the top. With this doctrine went the worry that various cultural practices and social reforms meant to provide for the least well-off in fact lessen this 'natural selection' and promote instead a 'degeneration' of the species. From a contemporary perspective, Social Darwinists conflated social success with reproductive fitness (wealth and education in fact tend to be inversely correlated with birth-rate) and questions of moral rightness with matters of a supposed 'natural order'. P.R.

\*evolution.

**social engineering.** Concept popularized by Karl Popper's critique in his *Open Society and its Enemies* (Princeton, NJ, 1950), it takes two forms. *Utopian* social engineering, associated with Plato, Hegel, Marx, and their totalitarian heirs, is committed to the wholesale transformation of society through central planning according to a comprehensive ideal plan and unlimited by any constraints from competing social institutions (e.g. the church). *Piecemeal* social engineering involves only 'searching for, and fighting against, the greatest and most urgent evils of society'. Popper's distinction aside, social engineering as a legitimate activity of government is essential to the welfare state and to all versions of \*socialism and \*communism. It is anathema to \*libertarianism but endorsed under constraints by modern \*liberalism. H.A.B.

Friedrich A. Hayek, *The Road to Serfdom* (Chicago, 1944).

Barbara Wootton, *Freedom under Planning* (Chapel Hill, NC, 1945).

**social epistemology.** Two distinct, but not unrelated, fields of study compete for this label. The first is a version of the theory of knowledge which fully acknowledges our dependence on other people in this matter, and does not relegate it to the marginal or supplementary status of 'testimony'. All but the most elemental knowledge—of the sort possessed by infants and animals—presupposes the mastery of the indisputably social institution of language. The second, and less philosophical, is a concern with the social determinants of belief. It has obvious relevance to moral and political convictions. Attempts to apply it to the findings of natural science—let alone those of mathematics—are less persuasive. A.Q.

\*sociology of knowledge.

Alvin Goldman, *Knowledge in a Social World* (Oxford, 1999).

**social facts.** A \*fact is a social fact when it is a statement concerning the forms of organization present in a society or it ascribes an irreducibly social property to an entity. According to Durkheim, social facts result from treating social phenomena, including ourselves, as *things*; they can therefore be approached, it is claimed, in the same objective way as the facts with which the natural sciences deal.

Social facts, such as 'George W. Bush is President of the

United States' and 'France is a charter member of the United Nations', are the concern of sociologists, whose task it is to attain a body of knowledge on the basis of which the actions of human beings as members of society can be understood. The main question in this area concerns the relationship of such facts to facts about individuals: are social facts reducible to, or explained solely by, facts such as the beliefs and desires of individuals, i.e. non-social facts? Methodological individualists have answered in the affirmative, insisting that there are not both societies and their members, and that everything that happens can be explained without recourse to social entities and social properties. Methodological holists, on the other hand, claim that understanding some types of behaviour necessarily depends upon understanding the holistic phenomena of social structures.

The debate about social facts has thus centred on ambiguities in the important but unclear concept of 'reduction' and is bound up with the question of the merits and demerits of functionalist explanations in sociology. Clearly, it is also a debate about the purposes of social science. P.W.

**socialism.** It is difficult to subsume all the various socio-economic beliefs that have been referred to as 'socialism' under one definition. In its broadest sense, socialism refers to the views of those who: (1) claim that \*capitalism has grave moral flaws and (2) advocate some revolutionary socio-economic reform to remedy these flaws.

Certain elements of what is typically thought of as socialist thought appear throughout the entire history of philosophy, such as in Thomas More's *Utopia* and even Plato's *Republic*. But the term 'socialism' was first used in connection with the views of early nineteenth-century social critics, such as Robert Owen, Saint-Simon, Charles Fourier, and Pierre Proudhon. These social critics were reacting to the excesses and injustices of early capitalism, and advocated reforms such as the transformation of society into small communities in which private \*property was to be abolished and the radical redistribution of wealth. Socialism is also an important part of the philosophy of Karl Marx and \*Marxism. For Marxists, socialism is viewed as a stage in history characterized, in part, by state ownership of all capital goods and central planning of the economy. This stage in history they see as transitional between capitalism and the final stage of history, \*communism, which will be characterized by the absence of differing social classes and thus the end of class warfare.

Among the grave moral flaws that socialists typically claim to be inherent in capitalism are vast, unjust inequalities in wealth, income, opportunities, and power. Other moral flaws seen in capitalism include excessive individualism, competition and materialism, and the

\*exploitation of ordinary working people. Perhaps more than anything else, however, socialists oppose the unjust oppression of one group by another, whether through class domination, discrimination, or an unequal distribution of power. In short, socialism, in the broad sense, champions the 'underdogs' of society. The revolutionary socio-economic reforms that have been proposed by socialists for remedying the declared moral flaws of capitalism are so diverse as to defy any precise characterization. Typically, these reforms involve radical changes in the ownership or distribution of property throughout society. It is questionable, however, whether 'socialism' in this broad sense is a specific enough term to be very useful. Moreover, not all those who see grave moral flaws in capitalism and call for major reforms, or who have joined the fight against oppression, consider themselves to be socialists; to call them 'socialists' anyway invites confusing their views with socialism in the narrower sense to be considered next.

The narrower, and thus perhaps more useful, sense in which the term 'socialism' is often used is to refer to an economic system which features: (1) state ownership of the means of production and control over investment throughout the economy; (2) a more equal distribution of income and wealth than typically found in capitalism; and (3) democratic election of government officials responsible for economic decisions. Those who advocate a system with the above three features have, in the past, often advocated a fourth feature as well: government planning of not just investment, but the entire economy; that is, government planning of what goods and services are to be produced, how they are to be produced, in what quantities, and at what prices they are to be sold, rather than simply allowing these matters to be determined by the market through supply and demand. If the economic system includes this fourth feature, it is referred to as 'central-planning socialism'.

The most significant of these features for defining socialism in the narrow sense is state ownership of the means of production and control over investment; this is, arguably, the only feature that qualifies as being both a necessary and a sufficient defining characteristic. The second feature, that of income and wealth under socialism being distributed more equally than under capitalism, is something about which socialists generally agree, although there is much disagreement about what principle, exactly, should govern this distribution. A number of alternatives that have been advocated, including, for example, 'To each equally', 'To each according to his or her effort', and 'To each according to his or her need'. The third feature, democratic elections, is one that most socialist theorists insist upon, although whenever socialism of the central-planning variety has been put into effect in a country, \*democracy has not flourished. The fourth feature—namely, government planning of the entire economy—has been, perhaps, the most controversial feature. Advocates of this feature argue that central-planning remedies well-known flaws of capitalism, such as monop-

olies, business cycles, unemployment, vast inequalities in the distribution of wealth, and the mistreatment of workers. On the other hand, conservative economists, such as Ludwig von Mises and Friedrich Hayek, argue that central-planning can never come close to matching the efficiency of the \*market, because central-planners can never match the overall information inherent in the decision-making throughout a market economy, nor can business managers in a centrally planned economy ever match the motivation of entrepreneurs in a market economy, who are driven by private profit.

The arguments of these conservative economists, as well as the relatively poor performance of economies that, for the most part, have been centrally planned, have led many socialists to abandon feature four, and to propose instead a reliance upon the market for almost everything other than investment. State control over investment, combined with a reliance upon the market for almost everything other than investment, will, these new socialists argue, remedy the main flaws inherent in capitalism while, at the same time, retaining the productivity advantages of the market. The economists Oskar Lange and Fred M. Taylor were early proponents of such an approach, which is referred to as 'market socialism'. Recent proponents of a similar approach, such as the philosopher David Schweickart, have added the feature of \*worker control to the general idea of market socialism to form a system often referred to as 'worker-control socialism'. With worker control, the workers of each business enterprise are to manage it themselves through direct democracy or, as will more often be the case, are to elect, periodically, a team of managers who then manage the enterprise for them. An advantage of worker control is claimed to be that managers who must face workers in periodic elections will therefore be motivated, above all else, to do what is *beneficial* for workers, rather than exploiting them. Still other reformers propose an economic system featuring worker control, but without state ownership of the means of production and control over investment; rather, the workers of each business enterprise are themselves to own its means of production, and investment is to be left to the market. But since, with such an economic system, all the means of production are privately owned and the market prevails throughout the entire economy, this system is more appropriately referred to as 'worker-control capitalism', not socialism.

**social philosophy.** The term ‘social philosophy’ does not have a fixed meaning in current philosophical circles. Sometimes it is used as more or less equivalent to ‘political philosophy’: that is, to the normative discussion—analytical or substantive—of questions about how society should be organized. But usually it is taken to be the non-normative discussion—again, analytical or substantive—of what is involved in having social organization: the non-normative discussion of what sorts of entity appear with the onset of society and of how they relate to individual human subjects. I shall take social philosophy in this latter sense, as a sort of social ontology: as an account of what there is in the social world.

Social philosophy in the ontological sense takes as granted that there is no society without individual intentional agents: without subjects who apparently act, other things being equal, on the basis of their beliefs and desires, and who are capable of exhibiting rationality—and of seeking to exhibit rationality—in the formation and maintenance of those beliefs and desires (Pettit, *The Common Mind*, pt. 1). The question which it raises bears on what more we should include in our ontological stock-taking of society; and of how the more we should include, if there is any, relates to individual intentional subjects.

This question may be raised on the basis simply of our everyday experience and understanding of social life: on the basis of our commonplace sociology, as we might call it. But it is usually raised not just on this basis, but equally on the basis of what the best social science—whatever that is taken to be—tells us about the social world. Social philosophy becomes in good part an ontology of social science. (\*Social science, philosophy of.) Consider an analogy. The philosophy of mind seeks to tell us what is involved in a creature’s being a psychological subject, as social philosophy tries to say what is involved in an arrangement’s being a social form of organization. In raising the psychological question, the philosopher will take account of all that we know, in our experience of ourselves and others, of human psychology. But if he is serious, he will also take account of what the best psychology and neuroscience, as he sees it, says about psychological subjects. Similarly, the social philosopher who is anxious to provide an ontological inventory of the social realm will take account not just of the sociological commonplaces, but also of the scientific verities—as he sees them—about the social realm.

We should note, in passing, that the stock of commonplaces that a social philosopher recognizes may vary, depending on the scientific verities that he recognizes. Someone who takes a radical Marxist view of social science, for example, is likely to be less impressed than someone of a more conservative bent about the alleged commonplace status of the claim that people generally know the reasons why they do things: that they are not generally ignorant or deceived about their motivations. The situation here is again parallel to the situation in psychology. As there are rival theories in social science, so there are competing stories in psychology and neuro-

science; and as the social-scientific variation impacts on what sociological commonplaces are recognized, so the psychological and neuroscientific diversity correlates with a variation in what are taken to be commonplaces about psychological subjects.

What we have been saying bears on the \*dialectic whereby a particular social philosophy, a particular ontology of society, will be defended. The dialectic will involve arguing for a particular trade-off of apparent commonplaces for alleged social-scientific verities and investigating what the preferred package of commonplaces and verities suggests about the ontology of the social world. But what are the different social philosophies between which we are to judge? What are the main lines of division in the area?

There are two aspects to social life. There is the social *interaction* between individuals in virtue of which various relationships get formed: relationships involving communication, affection, collaboration, exchange, recognition, esteem, or whatever. And there is the social *aggregation* of individual attitudes and actions in virtue of which various institutions get established: these institutions will include common instrumentalities such as languages, cultures, and markets; groups, like the club or union or party, whose essence it is to have a mode of collective behaviour; groups that may have only a non-behavioural collective identity like genders, races, and classes; and shared resources of the kind illustrated by museums, libraries, and states.

Social philosophy concerns itself both with issues raised by interaction and with questions associated with aggregation. I will look at the interaction area first and then at that of aggregation. But before going on, one preliminary comment. Interaction need not involve people’s intentional attitudes: after all, my breathing the oxygen that you would otherwise consume is a form of interaction. And, equally, aggregation need not involve such attitudes either: aggregation accounts for the fact, for example, that together you and I weigh twenty stone. When I speak of social interaction and social aggregation, I assume that these are forms of interaction and aggregation that require the people involved to have certain intentional attitudes; I ignore interaction and aggregation of the purely physical, and certainly non-social, sort.

On the side of interaction, the main issue in social philosophy is that which divides so-called atomists from non-atomists (Taylor, *Philosophy and the Human Sciences*). The atomist holds that individual human beings do not depend on social relationships for the appearance of any distinctive human capacities. The non-atomist holds that they do. The atomist defends an image of human beings under which they come to society with all the characteristic properties that they will ever display; social life does not transform them in any essential manner. The non-atomist denies this, believing that it is only in the experience of social relationships that the human being comes properly into his own.

This formulation of the issue is crucially vague, in at least two respects. First, it is not clear what sort of social

dependence is in question; and second, it is not obvious what are to count as distinctive human capacities. The traditional resolution of the second vagueness is to nominate the relevant capacity as the ability—the actualized, concrete ability—to reason and think. And this resolution prompts a resolution of the first vagueness. It suggests that the question cannot be whether human beings depend causally on their relationships with one another for having the capacity to think. If that were the question, then the atomist's position would be extraordinarily weak; all the evidence of children raised in isolation, as well as our sense of what we learn from our parents and teachers, argues against it. Thus the issue must be whether individual human beings depend on their relationships with one another in a non-causal way for having the ability to reason and think (Pettit, *The Common Mind*, ch. 4).

It is plausible that individuals depend on social relationships in a non-causal way for having the ability—the actualized, concrete ability—to speak the local language; without other individuals, or without social relationships to such individuals, it is unclear how a person could count as speaking a language shared with them. The non-atomist holds that the same sort of social dependence governs the ability of an individual to reason and think: the ability, as we may take it, not just to have beliefs and desires, but to act with a view to having rational beliefs and desires. The atomist denies this, sticking by the view that all that is involved in reason and thought, all that is non-causally required for their appearance, is available to the individual outside society.

The debate between atomists and non-atomists has centred around the connection between thought and language. Atomists have taken their lead from Hobbes, who argues that, however useful language is for mnemonic, taxonomic, and communicative purposes, thinking is possible without speech, even without any inchoate form of speech. Non-atomists have tended to follow Rousseau and the Romantic tradition with which he is associated—a tradition also encompassing Herder and Hegel—in arguing, first, that language is social and, second, that thought requires language.

The atomist tradition has been dominant in English-speaking philosophy, while the non-atomist has had a considerable presence in France and Germany. One source of non-atomism in the English-speaking world has been the work of the later Wittgenstein, in which it is suggested that following a rule—and, therefore, thinking—is possible only in the context of social practices and relationships. This very strong non-atomist thesis may also be weakened, so that the claim is that following a rule of a characteristic kind—say, a suitably scrutable kind—requires such a social context (Pettit, *The Common Mind*, ch. 4). Another source of non-atomism in recent English-speaking philosophy has been the argument that the content of a person's thoughts is fixed not just by what goes on in his head, but by the linguistic community to which he belongs and to which he aspires to remain faithful (Hurley, *Natural Reasons*).

So much for the main question raised in social philosophy by the interactive side of social life. What now of the issues generated by the aggregative aspect of society? There are a number of interesting questions raised by the aggregative structure of society (\*methodological holism and individualism), but one issue is of striking importance. This is whether the entities that appear with the social aggregation of individual attitudes and actions give the lie to our ordinary sense of intentional agency: whether their presence means that our commonplace psychological sense of one another—our sense of one another as, most of the time, more or less rational creatures—is unsound; whether it means that, contrary to appearances, we are in some way the dupes of higher-level patterns or forces (Pettit, *The Common Mind*, ch. 3). The individualist, to use a name that also bears further connotations, denies that aggregate entities have this effect; the non-individualist insists that they do.

One extreme sort of individualism would say that intentional agency is not compromised by any aggregate, social entities, because in strict truth no such entities exist; they have the status of logical fictions, as it is sometimes put, or something of the kind. This doctrine is not very plausible, for who can sensibly deny, at least for reasons specific to the social domain, that there are languages and organizations and collectivities and the like? The more appealing form of individualism would say that while there are indeed a variety of aggregate entities, there is nothing about those entities that suggests that our received, commonplace psychology is mistaken. True, there are aggregate regularities associated with such entities: for example, a rise in unemployment tends to be followed by a rise in crime; the fact that something is in an organization's interest generally means that agents of the organization will pursue it; and the optimality of a certain procedure in certain contexts—say, an economic decision-making procedure—often ensures its stability. But the individualist will argue that the obtaining of those regularities does not signal the presence of forces unrecognized in commonplace psychology, nor the operation of any mechanism—say, any selection mechanism—that belies the assumptions of that psychology. That the regularities obtain can be explained within that psychology, given the context in which the relevant agents find themselves and given their understanding—perhaps involving relevant aggregate-level concepts—of that context.

The issue between individualism and non-individualism, as this should make clear, ties up closely with questions of social explanation: questions in the philosophy of social science about the resources required in order to make sense of social happenings and regularities (James, *The Content of Social Explanation*; Ruben, *The Metaphysics of the Social World*). The individualist may admit that social explanation can happily invoke structural or aggregate factors, but he must be able to argue that the causal relevance ascribed to those factors is not inconsistent with the assumptions of commonplace psychology. The non-individualist will maintain that, on the contrary, aggregate

factors have causal relevance in such a predetermining way, or on the basis of such a predestining form of selection, that our commonplace psychology has to be seen as deeply misleading (Pettit, *The Common Mind*, ch. 3). P.P.

**social science, philosophy of.** The philosophy of any science comes in two varieties, as the methodology or as the ontology of the discipline. The methodology looks at questions to do with the nature of observations, laws and theories, the logic of induction and confirmation, the requirements of understanding and explanation, and so on. The ontology looks at questions to do with what the discipline posits—what it says there is—and with whether those posits are consistent with more or less commonplace beliefs.

The philosophy of social science, as this distinction would lead us to expect, has both a methodological and an ontological aspect; we might do better, indeed, to regard it as two disciplines, one methodological, the other ontological. The methodology of social science concerns itself with the implicit claim of social science to be able to generate knowledge, especially knowledge otherwise unavailable, of the social world; in particular, it has tended in recent years to focus on the claim of social science to be able to provide distinctive explanations (James, *The Content of Social Explanation*; Ruben, *The Metaphysics of the Social World*). The ontology of social science concerns itself with the sorts of entity that the discipline posits—entities like aggregate regularities and structural constraints—and at how far those entities are consistent with our more or less commonplace view of human beings and their relationships. I will discuss only the methodology of social science here, as the ontology of social science is covered under the heading of \*social philosophy. (See Ryan, *The Philosophy of the Social Sciences*, for an overview.)

The methodology of social science may be motivated in one of two ways: internally or externally. The externally motivated methodology of social science sees its job as the replication, in the social area, of the methodological discussion of natural science. Every methodology of natural science will offer an account of observation, induction, explanation, and related topics. The externally motivated methodology of social science looks at social science with a view to seeing how far that account is borne out there, and with what nuances. In principle, the possibility is open that the account will be revised in the light of reflection on social science. In practice, the lessons from the area of natural science are often taken as more or less canonical.

The upshot of this approach to the methodology of social science may be conservative or critical. The conservative methodologist holds that, in general, social science conforms to the canonical methods and that it deserves to be treated as seriously as natural science (Papineau, *For Science in Social Science*). The critical methodologist, on the other hand, argues that at least in some cases social science deviates from the standards fixed by the natural sciences and to that extent should be regarded as something less than science: as pseudo-science, for example, or common sense. The dominant methodology of natural science in this century has been associated with the positivist movement and with post-positivist variations such as that developed by Karl Popper and his school. It is striking that such positivists and post-positivists have sometimes been conservative in their methodological reflections on the social sciences, sometimes critical. Among the critical trends, we find a tendency to see history and ethnographic anthropology as exercises in common sense rather than science, and a disposition to dismiss speculative theories influenced by the work of Marx and Freud as pseudo-scientific.

So much for the externally motivated methodology of social science. What now of the internally motivated variety? This alternative approach, unparalleled in the methodology of natural science, has its source in a peculiar feature of the social sciences. The social sciences were conceived and pursued, from the very beginning, under the influence of ideals, particularly ideals of scientific objectivity and progress, deriving from the eighteenth-century \*Enlightenment movement. The first social scientists were economists and sociologists, as we would call them today, and they were self-consciously concerned about producing something that would count not as philosophy, not as literature, not as common sense, but as science: as a project faithful to the image forged by natural science.

The scientific intention—the intention to make science—has remained characteristic of work in the social sciences. It puts social scientists, paradoxically, under an obligation of a philosophical kind: the obligation to show that the sort of analysis they pursue is of a properly scientific kind. And in this way it gives rise to the internally motivated approach to the philosophy—strictly, the methodology—of social science. Under this approach, the task for the methodology of social science is not primarily to map the practices of the social sciences, as if they were on a par with the natural sciences, but rather to interrogate and assess the philosophies or ideologies whereby the social sciences try to legitimize what they do: that is, try to show that what they do is genuinely scientific in character.

It is not usual to present things in this way, but, broadly speaking, there are three main ideologies that have been invoked—individually or in various combinations—by social scientists, in the scientific legitimization of their enterprise. These each mark a feature that putatively distinguishes social science from mere common sense, mere social lore. The first ideology hails social science as an explanatory enterprise of culturally universal validity; the second as an enterprise that is interpretatively neutral, not

being warped by people's self-understanding; and the third as an enterprise that enjoys evaluative independence: value-freedom. The universality, neutrality, and independence claimed are each meant to establish social science as objective, and therefore scientifically respectable, in a way in which social lore is not; each notion offers an explication of what scientific objectivity involves.

Social lore is always lore about a particular social milieu and culture, and an aspiration to cultural universality, if it can be vindicated, would certainly give social science a distinctive status. Such an aspiration is supported in a variety of traditions: among anthropologists and sociologists of a Durkheimian cast, among many Marxist scholars, and among those economists who think that all human behaviour, and the patterns to which it gives rise, can be explained by reference to *Homo economicus*. But methodologists of social science have claimed many reasons to question the possibility of any universalist, or at least any straightforwardly universalist, theory. The hermeneutic tradition that has long been dominant in Germany and the analytical tradition sponsored by the work of the later Wittgenstein both suggest that any explanation of human behaviour has to start with the culturally specific concepts in which people understand their environment and cannot aspire, therefore, to a substantive universality. The debate on these questions ranges widely, encompassing issues to do with cultural and other forms of relativism (Winch, *The Idea of a Social Science and its Relation to Philosophy*; Hollis and Lukes, *Rationality and Relativism*).

Social lore is not only particularistic, it is also designed to represent people as subjectively understandable or interpretable. We, the local consumers of such lore, know what it is like to be creatures of the kind represented and know how we would go about communicating with them. The second, and perhaps least persuasive, ideology of social science suggests that this disposition to represent people as subjectively understandable comes of a limited perspective which social science transcends. It suggests that social science can aspire to an objective explanation of people's behaviour without worrying about whether the explanation fits with their self-understanding: without being anxious to ensure that it makes native sense of them and facilitates interpersonal communication. The ideology suggests that social science, in the received phrases, can aspire to a form of *Erklären*, or explanation, that need not service the needs of interpersonal *Verstehen*, or understanding. Methodologists of social science have claimed many reasons to question this aspiration to *Verstehen*-free explanation. The hermeneutic and Wittgensteinian thinkers mentioned earlier both reject the idea that people can be properly understood without facilitating communication (Winch, *The Idea of a Social Science*). And the many philosophers who follow the lead of Donald Davidson on interpretation argue that there is no interpreting human subjects without representing them as more or less rational and more or less interpersonally scrutable (Macdonald and Pettit, *Semantics and Social Science*).

Social lore is often evaluatively committed, as well as being particularistic and orientated to subjective understanding. It takes a form which is premised on an evaluative characterization of the status quo. Thus it may characterize the beliefs, and explain the behaviour, of rulers on the assumption that the regime they sustain is unjust. The third and most common legitimizing ideology of social science, one associated in particular with the German sociologist Max Weber, holds that in this respect—and perhaps in this respect only—social science can do scientifically better than social lore. It can acknowledge that the agents in the society have evaluative beliefs, and it can take account of these in its explanation of what they do, without itself endorsing any such beliefs; it can be objective, in the familiar sense of remaining uncommitted on evaluative questions. Methodologists of social science have also sought reasons to doubt this claim, but the debate has been confused by differences over what sorts of evaluative commitment would really be damaging to the pretensions of social science (Macdonald and Pettit, *Semantics and Social Science*, ch. 4). **society.** A set of individuals and/or institutions in relations governed by practical interdependence, convention, and perhaps law—which relations may vary from the local to the international. The modern concept emerged in later eighteenth-century Europe (in arguments against absolutism and civic republicanism) to denote a supposed sphere of causal and moral self-sufficiency lying between the political and the personal. The concept was the ground for the new 'science' of 'sociology'. It later came to be used more loosely to include the political and the personal. Many \*liberalisms have resisted the idea of 'the social', preferring to see individuals as self-sufficient. Some philosophers, however, including Williams and Rawls, as well as some critics of liberalism, like MacIntyre, have recently reasserted conceptions of the social as the ground of moral possibility and moral judgement. G.P.H.

**society, organic:** see organic society.

**sociobiology.** Sociobiologists attempt to explain patterns of interaction in group-living organisms ranging from ants to human beings within the categories established by Darwin's theory of natural selection and the mathematical theory of genetics. Of particular interest is the behaviour involved in herding, co-operation, aggression, altruism, mate selection, and sexual exclusivity or non-exclusivity. Sociobiology is often criticized on the grounds that its explanatory hypotheses are not easily verified, or that they reflect conventional, unexamined, or impossible assumptions, especially about natural patterns of behaviour for human beings.

**sociology:** see Adorno, Comte; Durkheim; Mead; Spencer; Weber.

**sociology of knowledge.** This explores the social causes of the formation and diffusion of beliefs. Forerunners include Bacon, Comte, Nietzsche, Marx, and Engels. It was established as an independent discipline by Scheler and Mannheim, and also by anthropologists, such as Durkheim and Lévy-Bruhl, studying the social causes of religions and ideologies. Natural science was generally credited with privileged access to reality and thus immunity to sociological explanation. This discrimination is unwarranted. If sociology gives sufficient conditions for beliefs without reference to their truth-value, it undermines their claim to truth, leading to scepticism or relativism. But this consequence is avoided if it gives only necessary conditions for the formation and spread of beliefs, conditions which need not determine the content of beliefs in detail, or if it explains the emergence and acceptance of a theory despite its being underdetermined by the evidence. In these cases, the truth of beliefs and/or evidence for it remains an essential part of their explanation, supplemented, but not excluded, by social factors.

**Socrates** (470–399 BC). Athenian philosopher, teacher of Plato. Socrates is one of the most significant yet most enigmatic figures in the history of philosophy: significant because his relation to Plato was crucial to the development of the latter, and thus indirectly to the development

of much later philosophy; enigmatic because he wrote nothing himself, and therefore presents the challenge of reconstructing him from the evidence of others. It is therefore necessary to start with a brief account of that evidence.

*Sources.* Assuming the truth of the generally (though not universally) accepted view that all Plato's dialogues were written after Socrates' death, the only evidence from his own lifetime consists of references to him in Athenian comedy from the last quarter of the fifth century BC. While most of these are very brief, a sentence or so mentioning some singular trait such as Socrates' loquacity, or his going barefoot, we have a full-scale portrayal in Aristophanes' *Clouds*, first produced in 423, in which Socrates is a central character. Though this portrayal does preserve some traits of the actual Socrates as recorded elsewhere, such as his peculiar gait, it is recognized that the Socrates of the play is not a realistic portrait but a caricature of a representative 'Sophist' combining features of various individuals (e.g. the theory of the divinity of the air propounded by the contemporary natural philosopher Diogenes of Apollonia) and of stock comic types, such as the half-starved Pythagorean ascetic. The fact that Aristophanes chose Socrates as a peg on which to hang this caricature shows that he was by then a comparatively well-known figure, and the dramatic circumstances of his condemnation and death (see below) gave rise to a considerable Socratic literature, comprising both imaginative reproductions of his conversations and controversial works (some hostile, some favourable) focusing on his trial. Apart from fragmentary remains of some other authors (e.g. Aeschines of Sphettus), the only substantial survivors of this literature are the dialogues of Plato and the Socratic writings of Xenophon, which include a version of his speech at his trial and purported 'memoirs' of various conversations. While these are in broad agreement with Plato in attributing to Socrates certain modes of argument (e.g. inductive arguments) and certain specific doctrines (e.g. that virtue is knowledge), their tone is much less speculative and their picture of Socrates much more conventional and practically orientated than Plato's, reflecting the different characters and interests of the respective authors. While Plato's dialogues present a consistent and compelling portrait of Socrates' highly individual personality, his primary purpose in writing them was not that of a biographer (at least on the modern conception as a chronicler one of whose primary aims is historical accuracy). Rather, he writes as a philosophical apologist, who seeks to present Socrates as the ideal embodiment of philosophy, unjustly traduced by confusion with bogus practitioners (\*Sophists) and unjustly condemned for his dedication to the philosophical life. It is, therefore, quite natural that he should in some places put into the mouth of Socrates doctrines of his own which the historical Socrates did not hold (see below). In what are standardly regarded as his later dialogues the importance of the figure of Socrates diminishes, and his role as a figure of philosophical authority is taken over by others, in some cases by impersonal figures

such as the Eleatic Visitor of the *Sophist* and *Statesman* and the Athenian of the *Laws* (traditionally regarded as Plato's last dialogue, and the only one in which Socrates does not figure at all). It is reasonable to explain this progressive disappearance of Socrates as a reflection of the development of Plato's views and methods in directions independent of the elder philosopher. Aristotle, who was born in 384 and came to Athens to study in the Academy in 367, must have derived his knowledge of Socrates primarily (though doubtless not exclusively) from Platonic sources. That is not, of course, to say that his only information was Plato's dialogues; though some of his references to Socrates are clearly, and others possibly, to passages in the dialogues, there is ground for thinking that some are independent (see below).

*Life.* Socrates spent all his life in Athens, apart from military service abroad. The sources represent him as spending his time in philosophical discussion, and how he made his living is unclear; while there is a tradition that he followed (at least for a time) his father's trade as a stonemason, he may have depended largely on support from friends. Plato is emphatic that he never took money for philosophizing, and makes that a central point of differentiation between him and the (professional) Sophists. He was married to Xanthippe, whose bad temper (together with Socrates' equanimity in putting up with it) became a stock element in a comic tradition which endured from antiquity to at least the nineteenth century. (For instance, Chaucer's *Wife of Bath* tells how Socrates sat quietly when Xanthippe 'caste pisse upon his heed', merely remarking mildly, 'Before the thunder stops the rain starts.'). If there is any factual basis to this legend it is worth noting that Xanthippe, who, as Plato recounts in the *Phaedo*, had two infant children at the time of Socrates' death, must have been least thirty years younger than her husband, and also that Socrates' life-style can hardly have made him a reliable bread-winner. Some ancient sources mention a second wife, or perhaps concubine, named Myrto; the comic tradition represents Socrates as living bigamously with her and Xanthippe (doubtless another source of irritation to the latter), but the historical basis is very dubious.

The 'intellectual autobiography' which Plato puts into Socrates's mouth in the *Phaedo* represents him as having been at one time keenly interested in natural philosophy, but as having become disillusioned by the neglect of teleological explanation by its leading theorists. Assuming the historical accuracy of that account, his interests seem to have shifted to questions of conduct and especially of its fundamental principles, while the magnetism of his personality attracted to him a circle of mainly younger men, some of whom, including Plato and some of his relatives, were opposed to the Athenian democratic system. It is impossible to determine how far Socrates himself shared such views; however critical he may have been of democracy in theory, he was in practice a loyal citizen, serving with distinction on the battlefield and adhering strictly to

his ideals of legality and justice under severe pressure, once under the democracy, when he was alone in opposing an unconstitutional proposal in the Assembly, and once under the tyrannical regime which briefly ousted the democracy at the end of the Peloponnesian War, when he refused an order to participate in the arrest (and subsequent death) of an innocent man. None the less, his association with notorious anti-democrats, especially Alcibiades and Plato's relatives Critias and Charmides, probably contributed, after the restoration of the democracy, to his indictment on vague charges of neglect of the state religion and corruption of the young, and to his condemnation to death. In addition to Xenophon's account of his trial (mentioned above) the events of his trial and its aftermath are immortalized in three of Plato's works, the *Apology* (Defence) an idealized version of Socrates' defence at his trial, *Crito*, which gives his reasons for refusing to take the opportunity (which was apparently available) of escape from prison, and *Phaedo*, a moving re-creation of his final hours, containing first a Platonic treatise on the philosophy of life, death, and immortality and then a depiction of the ideal philosophic death.

*Philosophy.* It cannot be doubted that Socrates was a major, perhaps the most significant, influence on Plato's philosophical development, but the nature of this influence is not altogether easy to determine. Because our main access to Socrates is via the works of Plato, we have the problem of determining what, if any, doctrines Socrates himself held (see above). One extreme position is that we can know nothing whatever about the views of the historical Socrates, another that whatever views Plato ascribes to Socrates in any dialogue were actually held by him. Neither seems to me tenable. Aristotle distinguishes the views of Plato from those of Socrates (*Metaphysics* 1078<sup>b</sup>27–32) by attributing to the former the theory of separate \*Forms, which, he says, Socrates did not hold. Since Socrates is represented as expounding that theory in the *Phaedo* and other dialogues, it is clear that Aristotle does not derive that information from the dialogues, and it is therefore plausible that he learned either from Plato himself or from other sources in the Academy that the theory was Plato's own. So not everything in the dialogues is Socratic. But is anything Socratic? In the same passage Aristotle ascribes to Socrates an interest in general definitions and the practice of inductive arguments, both of which we find attributed to Socrates by both Plato and Xenophon. Both the latter also attribute to Socrates the 'Socratic paradoxes' that virtue is wisdom or knowledge and that no one does wrong willingly. Though it is likely that Xenophon's portrayal of Socrates is not totally independent of Plato's, it is at least plausible that those methods of argument were employed, and those doctrines held, by the historical Socrates.

Though Socrates is represented as maintaining these doctrines by Plato, he figures in the dialogues, especially those generally regarded as early, not primarily as a dogmatic philosopher (indeed he was famous for claiming

that he was not wise in any respect), but as a critic, eliciting opinions from his interlocutors and subjecting them to critical scrutiny, usually producing a refutation by showing the doctrine in question to be inconsistent with other propositions agreed by both parties to be true. This 'method of \*elenchus' (a Greek word meaning 'examination') has obvious affinities with the argumentative strategies employed and taught by the Sophists, and Plato is concerned to stress that in Socrates' hands it was intended not to produce victory in a debating contest, but to lead to genuine understanding by purging the person subjected to it of false beliefs. Philosophical inquiry conducted by this method is supposed to be not a contest between opponents (eristic), but a co-operative search for truth and understanding (\*dialectic). Though Plato's conception of the methods of dialectic clearly developed considerably in the course of his life (see above) the ideal of a co-operative critical inquiry, conducted by the spoken word, remained his paradigm of philosophy, and we have every reason to think that it was his memory of the power of Socratic conversations which gave that ideal its perennial attractiveness for him.

*Later influence.* The influence of the figure of Socrates did not cease with Plato. In the Hellenistic and Roman periods the various schools (with the exception of the Epicureans) each sought to appropriate him as a patron saint, the Cynics appealing to his ascetic mode of life, the Sceptics and sceptical Academics to his profession of ignorance (see above), and the Stoics, notably Epictetus, to his alleged claim that virtue is the only intrinsic good. The Christian apologist Justin (second century AD) claimed him as a forerunner of Christ, a characterization which was revived in the fifteenth century by Neoplatonists such as Marsilio Ficino. In medieval Islam he was revered (though not well understood) as a sage and upholder of monotheism against idolatry. In the later Renaissance and in the eighteenth-century Enlightenment he came to be seen as a paradigm of human virtue and a martyr to rationalism at the hands of superstition. In different ways Hegel, Kierkegaard, and Nietzsche saw him as a pivotal figure in the development of human thought and constructed central aspects of their own thought in reaction to him, and in our own day he has been an important influence on the later work of Foucault. It is no exaggeration to claim that as long as personal and intellectual integrity remain compelling ideals, Socrates will be a suitable embodiment of them. C. C. W. T.

**Socratic method.** The question-and-answer method of philosophizing (dialectic) used by Socrates in Plato's early dialogues (e.g. *Euthyphro*), often in conjunction with pretended ignorance (Socratic irony), whereby a self-professed expert's over-confident claim to knowledge is subverted. Sometimes the idea is to clear the mind for the subsequent development of more adequate views. More generally, Socratic method is any philosophical or pedagogical method that disinterestedly pursues truth through analytical discussion. A. BEL.

\*philosophical inquiry.

Leonard Nelson, *Socratic Method and Critical Philosophy* (New York, 1965).

**Socratic paradox.** Several claims put by Plato in the mouth of Socrates have been called 'Socratic paradoxes', but the one which the description fits best is the dictum 'No one does wrong voluntarily'. This is more plausible in its Greek original, where the word translated 'does wrong' can also mean 'misses the mark'. It implies that all wrongdoing is due to lack of knowledge, so that another version of the paradox is 'Virtue is knowledge'. C. J. F. W.

**Sohravardī, Shihāb al-Dīn Yahyā** (?–1191). Persian thinker whose Philosophy of Illumination was the first attempt to construct a consistent non-Aristotelian system in \*Islamic philosophy. His intention was to improve upon the Avicennan system by avoiding its logical gaps; to uphold the rational validity of revealed knowledge; and to construct a unified epistemological system that would include 'scientific' explanations of inspirational as well as sense-perceived knowledge.

The Philosophy of Illumination employs a specifically defined symbolic 'language of Illumination'. Objects, depicted as lights, are inherently knowable because, as part of the propagated whole as continuum, they include essential light that may be 'seen' by subjects who, recovering their own essential lightness, become self-cognizant and capable of 'seeing' the object's manifest light-essence.

Sohravardī redefined and refined problems pertaining to every domain of philosophical investigation. In logic, he defines the modal 'necessary' as an independent operator to construct a superiterated modal proposition to which all other propositions are reduced. Most critically, he argues that Avicenna's complete essentialist definition, deemed the first step in science, cannot be constructed, thus refuting the basis of Peripatetic scientific method. Similar to the impossibility of definition by extension through exhaustive enumeration of elements, he argues

that the thing's essentials may not all be known when constructing the formula. Further, he criticizes the universal proposition on the grounds that universal validity must be necessary and always true; but because of necessary future contingency (possible worlds), the formal validity of a 'law' deduced 'now' may be invalidated at some future time by the recovery of exceptions. The most prior, necessary, and always true knowledge thus cannot be predicative. Rather, it is \*'knowledge by presence' when the 'illuminationist' relation between the subject and the object is actualized in durationless time. However, foundations must be renewed in all future time, or in other possible worlds, based on future or other knowing subjects' 'observations', thus according a principal role for the enlightened 'observer'.

**solipsism.** The view that only oneself exists. 'Is anybody there?' asks the visitor trapped in the waxworks museum after closing time, 'Or is there only me?' Philosophers raise eyebrows by discussing similar-sounding questions when there are no special circumstances. One debate is whether other creatures have an inner life (thoughts, wants, feelings) of the kind which makes the subject a person. Even if they do, is the inquirer in a position to know or reasonably believe that? This 'problem of \*other minds' presents solipsism as an apparently inescapable conclusion from certain (Cartesian) assumptions, whereby access to others' mental states is indirect, involving a dodgy inference from behaviour.

A more radical version is that one's own immediate experience has a fundamental, self-certifying reality and that comparable knowledge of 'physical' or 'public' items is unobtainable. This is sometimes anchored in the thought that, when a person loses consciousness, his whole world crashes. Arguments that cast doubt on the existence or accessibility of a mind-independent world leave us with no lifeline to the presence of others, no defence against the threat of solipsism.

Characteristically, these sceptical arguments take a yet more radical turn when the link between grasping the meaning of words and being presented with examples is remembered. If I am never acquainted with your experience and can gain no knowledge about it, how can I understand the words that allegedly refer to it? It seems to a solipsist that I have to learn what words refer to by connecting them with items of my own experience. How can I even get the idea that there are things outside that experience? The world has to be my world.

Counter-attacks often focus on what the sceptic keeps. In stating his view he may use 'I' or 'my', thus assuming a distinction between himself and others. But, if there are no other takers, what is meant by claiming that experience is *mine*? Where there is no possibility of others, the idea of

signalling one person rather than another, presupposed in the normal use of 'I', seems to fail. For this reason, Lichtenberg's famous suggestion that we should do better to say 'It thinks' rather than 'I think' finds favour with solipsists. (Also, presumably, 'It hurts', 'It chooses', and so on.)

In *Philosophical Investigations*, §§243ff., Wittgenstein seeks to undermine this further position by questioning the possibility that anyone could acquire a \*private language. The need to observe a distinction between correct and incorrect judgement finally forces us to admit that language itself is essentially social. This seems to allow a return to the common-sense position that if the solipsist says *anything*, this ought to be an intelligible communication; but that the thesis should be understood seems to be a possibility which it itself rules out.

But if solipsism is absurd, discussing it is not. Solipsistic conclusions may be used as powerful *reductio ad absurdum* arguments against some common assumptions, and the interesting mistakes that generate solipsism also embody real insights into our language and thought. It leads us to reconsider how the words 'I' and 'mine' work, what the relation is between the relatively permanent objects around us and the testimony of our senses, and how we learn to speak about sensations. It also leads us to question common ideas about the primacy of private experience in fixing the meaning of words in general. There is method in the madness of losing your head when all about you are keeping theirs.

**Solovyov, Vladimir Sergeevich** (1853–1900). Idealist philosopher and poet. Solovyov's lectures on \*'Godmanhood' at St Petersburg University in 1878 established him as Russia's first significant academic philosopher (though he was forced out of academe after appealing for clemency for Alexander II's assassins). Influenced by German idealism, Solovyov saw development as a progression from primitive unity through differentiation to a higher reintegration. The world of spatio-temporal objects was created when Sophia, or the world-soul, separated from God. Reintegration requires the establishment of 'all-unity': the reuniting of the world with God in a kingdom of heaven on earth. For a time, Solovyov envisioned a theocratic utopia with all Churches and nations united under the Pope and the Russian Tsar. His later philosophy is more contemplative and less dogmatic, though prey to pessimism. Solovyov inspired a significant revival in Russian religious philosophy and influenced the Russian symbolist poets.

**sophism.** A sophism is a type of \*fallacy that is not just an error of reasoning, or an invalid argument, but a kind of tactic of argumentation used unfairly to try to get the best of a speech partner. Aristotle called these kinds of tactics *sophistic elenchi*, or sophistical refutations. For an example of a sophism, see the entry 'straw man fallacy'. D.N.W.

\*fallacy.

Douglas Walton, *The Place of Emotion in Argument* (University Park, Penn., 1992).

**Sophists.** Itinerant professors of higher education. From its original senses of 'sage' and 'expert' (lit. 'one who is wise', from *sophizesthai*, cognate with *sophos*) the word came to be applied in the fifth century BC in the technical sense given above to a number of individuals who travelled widely through the Greek world, giving popular lectures and specialized instruction in a wide range of topics. They were in no sense a school, or even a single movement. They had neither a common set of doctrines nor any shared organization, and while our evidence indicates that some of them knew one another, their attitude to one another was rather that of professional rivals than colleagues.

Their intellectual activities included the popularization of the Ionian tradition of inquiry into nature (which was concurrently being developed by more original thinkers such as Anaxagoras and the \*Atomists) and mathematics. The polymath Hippias included both in his range of expertise, and Protagoras is reported to have written a work on mathematics, which may have included criticism of mathematics from the standpoint of his subjectivist epistemology. The fifth century saw the development of what might broadly be called the 'social sciences' of history, geography, and speculative anthropology, as represented, for example, by the works of Hecataeus, Herodotus, and Thucydides; Hippias and probably Protagoras were also active in these fields. Another significant development in this period was the systematic study of techniques of persuasion and argument, which included the beginnings of the study of language in various forms, including grammar, literary criticism, and semantics. In all these areas Protagoras seems to have been a pioneer; he was reputedly the first person to write a treatise on techniques of argument, and was notorious for his claim, reported by Aristotle, to be able to 'make the weaker argument the stronger', a claim apparently based on the view that to every thesis there was opposed an equipollent contrary thesis. If all these have equal evidential support (a thesis logically independent of, but doubtless psychologically connected with, the famous doctrine that 'Man is the measure of all things' (cf. Protagoras)), then it is an appropriate task for the technique of persuasion to devise arguments on either side sufficient for their political or forensic function.

This side of their activities brought the Sophists into the public arena, where it is clear that they aroused strong reactions, both positive and negative. On the positive side,

the long and financially highly successful careers of the most celebrated testify to a considerable demand for their services, both in satisfying the educational aspirations of the well-off, especially in Athens, then at the height of its prosperity and political and cultural influence, and in providing rhetorical and forensic training for aspiring politicians. On the negative side, they were regarded as socially and morally subversive, especially by those of conservative views. Suspicion focused both on their naturalistic outlook, especially in its application to morality and theology, and on their teaching of techniques of argument, which could be seen as encouraging those who acquired them, especially the young, to subvert sound morality and hallowed tradition by clever cavilling. The caricature of sophistic education given by Aristophanes in his *Clouds* brings the two points together; Socrates, who is presented as the representative of sophistry, first replaces the traditional gods by naturalistic processes such as 'Swirl', and then provides his pupils with arguments, including arguments from the non-existence of the gods, to the conclusion that they can welsh on their debts. Criticisms of traditional theology were not, indeed, introduced by or restricted to the Sophists. In the previous century Xenophanes had ridiculed anthropomorphism and maintained the existence of a single cosmic deity, and Heraclitus had castigated certain rituals as absurd and obscene, and that tradition was continued by Plato's demand for the suppression of all mythical accounts of divine wrongdoings. In the fifth century we see the rise of a climate of thought which casts doubt on religion itself, either on epistemological grounds, as in Protagoras' agnostic writings, or by providing naturalistic explanations of the celestial phenomena traditionally regarded as divine, and of the origins of religion itself. Anaxagoras famously taught that the sun was a molten rock, while Prodicus (otherwise chiefly known for his technique of distinguishing near-synonyms, parodied in Plato's *Protagoras*) is said to have maintained that the gods were either personifications of natural objects of special importance in human life, e.g. the sun, or benefactors of earlier generations deified after death.

In this climate of thought, morality was no more immune from critical scrutiny than was religion. Various positions may be distinguished. Protagoras maintained (apparently inconsistently with his universal subjectivism) a form of \*moral relativism, in which moral beliefs are true for those communities in which they are maintained. Plato's dialogues provide evidence of more radical challenges to morality associated with Sophists. In the *Republic* the Sophist Thrasymachus (a historical person) argues that, since it is contrary to self-interest to accept the constraints of morality, immorality is a virtue and morality a defect (\*aretē; \*eudaimonia), while in the *Gorgias* Callicles, a pupil of Gorgias, maintains yet more radically that conventional morality is in fact a form of injustice, since it attempts to deprive the strong of their natural right to exploit the weak. It is, however, over-simplified to regard the Sophists collectively as having had a common doctrine, or even as having shared a generally sceptical or

radical outlook on morality. Xenophon, for instance, reports Hippias as maintaining the traditional doctrine that there exist certain natural laws, e.g. that one should worship the gods and honour one's parents, which are common to all societies, while Protagoras, in Plato's dialogue of that name, holds that the educational function of the Sophist is continuous with that of the traditional educational institutions of the community, namely, to impart the basic social virtues of justice and self-control.

The writings of the Sophists, which were in some cases voluminous, are lost, with the sole exception of a substantial papyrus fragment from a work by Antiphon, critical of conventional morality on the grounds of its conflict with self-interest. The principal source of our information is Plato, who is a hostile witness, partly on the grounds that he believed the Sophists to have claimed an educational role to which they were not entitled, perhaps even more because he believed, very probably truly, that the suspicion which certain Sophists had attracted had contributed to the unpopularity and ultimately to the condemnation of Socrates, whose critical stance and destructive methods of argument were no doubt hard to distinguish from typically Sophistic tactics. Plato is therefore at pains to depict the Sophists as bogus practitioners of philosophy, in contrast to Socrates, the paradigm of true philosophy. The gravamen of his charge is not that they were subversive (though, as pointed out above, he does reflect that aspect), but that they pretended to knowledge that they did not possess, and that they sought popularity and success by dressing up popular prejudices with a specious appearance of novelty. At the same time his portrayal of Protagoras in the *Protagoras* and his detailed critique of his subjectivism in the *Theaetetus* show that he regarded him as a figure of major intellectual stature (his portrayals of some other Sophists are decidedly less friendly). The complexity of Plato's attitudes should remind us of the complexity of the subject, and put us on our guard against uncritical acceptance of an over-simplified stereotype. C.C.W.T.

**Sorabji, Richard Ruston Kharsedji** (1934– ). Based in London and Oxford, Sorabji has written widely on all periods of ancient Greek philosophy, linking it with contemporary issues, especially in metaphysics, philosophy of mind, and ethics, and contributing substantially to the current revival of post-Aristotelian philosophy. In this last respect he has aimed to take the story beyond the Stoics and Epicureans, where it usually stops, to the end of Greek philosophy around AD 600, thereby showing its continuity with the succeeding philosophies of the Arabs, the Middle Ages, and the Renaissance. In particular he has used ancient writers to support the claims that causation is more closely linked to explanation than to necessitation,

and that time could in principle be circular, so that any given event may lie both in the past and in the future. He is the originator and general editor of a major edition, in English translation, of the ancient commentators on Aristotle. He is also concerned with the rationality of animals, both in ancient thinkers and in fact. A.R.L.

**Sorel, Georges** (1847–1922). It was only after his retirement from working for the French government as an engineer that Sorel began to publish the idiosyncratic views on politics which have earned him a permanent, if minor, place in the annals of revolutionary theory. Drawn initially to an ethical interpretation of Marxism and the reformist ideas of Bernstein, he became disillusioned following the Dreyfus affair and emerged as the leading exponent of revolutionary \*syndicalism. In his most famous work, *Reflections on Violence* (1906), Sorel argued that the main doctrines of Marxism, and in particular the general strike, should be seen as myths capable of inspiring the working class to violent acts of revolution that alone would be capable of effecting a fundamental transformation of society. Towards the end of his life Sorel became an admirer of Lenin and, to a lesser extent, of Mussolini. D.McL.

**sortal.** A type of term, usually a noun, e.g. 'cat' or 'person', that supplies a single principle of individuating and counting the instances it applies to. A sortal contrasts with characterizing terms, e.g. 'red', with material names, e.g. 'butter', and with terms like 'thing', 'action', 'place', none of which, unless variously completed (as in 'red chair' 'pat of butter', the place we are in), supply such a principle. s.w.

**Sosa, Ernest** (1940– ). Romeo Elton Professor of Natural Theology at Brown University, recognized for contributions in epistemology, metaphysics, and the philosophy of mind. Sosa is best known for 'virtue perspectivism', an attempt to reconcile traditional 'coherentist' and 'foundationalist' epistemological concerns. On this view, whether a belief constitutes knowledge depends both on how it was produced and on the believer's perspective on his own situation as knower. To be candidates for knowledge, beliefs must be products of truth-conducive intellectual virtues. Elsewhere, Sosa argues that belief (*de re*) about a referent is a kind of propositional belief that picks out its object from the believer's perspective, some propositions being 'indexical' and perspective-dependent. Sosa

has also defended a broad Aristotelianism against the charge that it implies that one's survival cannot matter rationally even to oneself.

**soul.** The human soul is that which gives life to the human being. For Aristotle, the soul was simply the form of the body, i.e. the way the body behaved, and thus not capable of existing separately from it; plants and animals also had souls of their own kinds. For Plato, most Christian theologians of the first millennium AD, Descartes, and many others, the soul was the essential immaterial part of a human, temporarily united with its body. Aquinas also held this, while emphasizing that union with a body was the natural state for a soul. Most modern philosophers deny the existence of an immaterial soul. (\*Mind-body problem.) One strong argument for the existence of such a soul given in essence by Descartes is this. I am now conscious. But it is logically possible that my body should suddenly be destroyed and yet I continue to be conscious and so to exist. But a thing such as I am can only continue to exist if some part of the thing continues to exist. So I must now already have an essential non-bodily part, i.e. a soul, if my continued existence is to be logically possible.

**sovereignty.** The right, by a governing power, held against other powers, to rule a designated territory, people, and their resources—a jurisdiction—and defend these from incursion. It requires, first, criteria for according the right, and secondly, correlative duties on the part of other states. Until the Treaty of Westphalia (1648), after the Thirty Years War, the accepted sources of the right were principally religious. Post-Westphalia a secular basis for the right became established, granting sovereignty to *de facto* independent political entities. The corresponding duties developed to include equal treatment and respect in international relations, and non-interference by other states in affairs internal to the jurisdiction, save for extreme circumstances. Recently, 'liberal internationalists' have argued that justice demands that sovereignty be conditional on democratic self-governance and respect for basic rights. Thus, whilst a degree of self-determination is accepted, powers failing to uphold citizens' basic rights and democracy are said to be illegitimate whatever their *de facto* status. Westphalia sovereignty is, on this argument, wrong, and one extreme version adds that liberal states should act on illiberal states to export rights and democracy.

**space.** We all ask where things are, how big they are, and what room there is for them or in them. Classifying these enquiries generates the concepts of extension in one or more dimensions, distance, direction, and emptiness; and discussions of these more sophisticated concepts may be grouped together as philosophizing about space.

The first Greek Atomists conceived the void through which their atoms moved as having positive reality, and called it 'the empty' or 'that which is not'. The latter phrase may have been intended to provoke the Eleatics, who wished to impose a veto on saying 'That that which is not, is'. A term closer to our 'space' is introduced by Plato. In the *Timaeus* he applies '*khōra*' to a confessedly weird medium in which simple numerical ratios are represented by tiny polyhedra whose fluctuations constitute the fabric of the perceived world. To modern readers he may seem to have grasped the notion of space dominant in our thinking. But Aristotle interprets him as proposing a (bad) theory of matter, drops the technical use of '*khōra*', and discusses place instead of space. Influenced, perhaps, by Plato's *Parmenides* (138a–b etc.), he analyses this in terms not of distance and direction but of containment. Later Greek writers take '*khōra*' to signify a special kind of place or extension (*diastēma*) and speak chiefly of those. Neglect of space persists through the Middle Ages. Perhaps interest in it goes with the belief, which Aristotle's authority opposed, that mathematics is the paradigm for all knowledge and illuminates the heart of reality. If reality consists of geometrical solids or, as modern physics suggests, of punctiform events fixed by four spatio-temporal coordinates, space is just about all there is.

Anyhow it makes a joint comeback with mathematics in the seventeenth century. Newton's description of it (*Principia*, definition 8, scholium) as an eternal, infinite, isotropic continuum (like air, only thinner) captivates philosophers like the Sirens' song. He held that spatial relations are mind-independent and that objects stand in them not just to one another but to subregions of this continuum. Most people wonder about the second contention: he wants space to be a physical reality that can neither affect other things nor be affected by them, and that sounds like a contradiction in terms. Leibniz rejected both claims about spatial relations, and Kant only the first. We conceive objects, Kant argues, as products of a perceiver's imagination; what makes them non-identical is occupying non-identical chunks of space; space is unique in that there could not be two unrelated systems of spatial relations; but our idea of it is an idea, not of an individual we experience, but of how we experience other things as individuals.

Philosophers still debate Kant's and Newton's claims, and have developed a literature of metaphysical fiction in which people visit spaces with unconventional numbers of dimensions or pass from one spatial system to another

by means that defy physical laws. But they also study the conceptual demands of modern physics. Until 1900 people assumed that space and time are measurable independently. According to the special theory of \*relativity, if two events are distant from each other in space, their distance apart in time will vary with the frame of reference we select; relatively to one frame they might be simultaneous and relatively to another, an hour apart; and these differences in temporal separation are not independent of differences in spatial separation. It also used to be assumed that things in space satisfy Euclid's theorems—that if three events are connected by straight lines, the triangle enclosed will be Euclidean. The general theory of relativity makes the geometry of space dependent on the distribution in it of matter, and thereby forces us to reconsider the status of Euclid's theorems. w.c.

**space-time.** The set of all events occurring in \*space and \*time, like the explosion of a fire-cracker or the snapping of one's fingers. Space-time is four-dimensional, in that each event can be located by four numbers, three for its position and one for its time of occurrence. In the space-time underlying Newtonian physics, spatial separations and temporal durations between events are independent of an observer's state of motion. But in Einstein's \*relativity theory, these measures cease to be absolute—the length of a rigid rod will be judged shorter when moving than if stationary, and similarly a moving clock runs slower. Nevertheless, there is still an absolute measure in the form of the space-time interval between events, which moved the mathematician Minkowski to remark: 'Henceforth space by itself, and time by itself, are doomed to fade away into mere shadows, and only a kind of union between the two will preserve an independent reality.' The space-time interval not only determines by how much a rod will be seen to contract, or clock run slow, but whether or not a pair of events can be causally connected, that is, whether a signal not exceeding the speed of light can be sent from the (space-time) location of one event to the other—an 'invariant' fact independent of one's state of motion. **Spanish philosophy.** Although notable Roman and medieval philosophers, such as Seneca, Averroës, Ramon Llull, and Maimonides, were born in the territories of Spain long before it appeared as a unified state in 1492, it is more appropriate to think of Spanish philosophy as the philosophy produced in Spain after its political constitution. As a matter of fact, 1492 is also the year of the discovery of America, and the starting-point of its

domination and colonization, which turned Spain into a worldly empire. It marked as well an extraordinary flourishing of Spanish culture, which made the sixteenth century the Golden Age of Spanish culture.

Philosophy was not alien to this flourishing. Most philosophical trends of this epoch are well represented. \*Scholasticism received a strong impulse at the University of Salamanca. Vitoria, Suárez, and Molina developed a metaphysics separate from theology. Their main contribution, though, was their argument for a right of peoples, a *ius gentium*, which later became the basis for our current international law. Challenged by the problems of legitimacy that the conquest and domination of 'The New World' raised, Vitoria and Suárez argued against the legitimacy of war to impose a faith, and contended that native American peoples, as humans, had rights to property and self-government.

\*Humanism and \*Neoplatonism were also well represented at that time. The humanist J. L. Vives (1492–1540), a close friend of Erasmus, defended the importance of human subjectivity as the ground of human dignity and religious life. Moreover, during turbulent years of wars of religion in Europe, he argued in favour of peace and concord, as higher standards of human dignity. On the other hand, the philosopher-physician Francisco Sánchez (1550–1623), in his work *That Nothing is Known*, developed the humanist themes of distrusting authority and tradition as foundations of knowledge, and proposed a principle of 'methodical doubt' as the right way of inquiry, which was later to influence Descartes.

Spanish Neoplatonism of the time finds perfect expression in the Jewish writer Leo Hebraeus, whose *Dialogues on Love* continue the themes of Marsilio Ficino, and culminates in the poetry of the great Spanish \*mystics, Teresa de Jesús (1515–82) and Juan de la Cruz (1542–91), whose central idea was that of love as the path to an intimate knowledge of God.

The commitment of Spain to the defence of orthodox Roman Catholicism against the Reformation, and the converted Jews and Muslims, brought about a long period of persecution of free thought, exercised by the infamous and powerful Inquisition. By the beginning of the seventeenth century, even study abroad was forbidden. It took 300 years for philosophy to become invigorated again, at the end of the nineteenth century, when it started a new period of cultural flourishing; a period that was to be dramatically interrupted by the Spanish Civil War (1936–9).

Since academic philosophy at that time was in the hands of the Church, this new philosophical movement found expression in a literary genre, the novel. Unamuno (1865–1936) is the most notable writer of this philosophical bent, whose works depict characters deeply influenced by the sort of existential worries first formulated by Kierkegaard. But a powerful character was to appear in the next generation, Ortega y Gasset (1883–1955), called to renew academic philosophy in Spain. Under German influence he opted for the essay genre. His philosophy is called ratio-vitalism, a variety of Husserlian phenomenism,

according to which the self is conceived not in the abstract, but in the context of the circumstances of the individual life. Accordingly, truth is perspectival.

The defeat of Spanish democracy in 1939 forced into exile most of the intellectuals and scientists of the time (Ferrater-Mora can be considered the best representative of Spanish philosophy in exile). By the end of the Sixties, though, some academic philosophers played an important role in introducing current European philosophical styles and ideas, as a form of dissidence. In large part, the task was one of translation, but some names deserve mention as much for their intellectual contribution in renewing Spanish philosophy as for their ethical attitude of vindication of intellectual, and political, freedom: J. M. Valverde and J. L. López Aranguren. Since the restoration of democracy, in 1978, this pluralist reception of philosophical traditions has continued, but it is on the analytical side that contributions of international significance can be found. Philosophy of mind and of language, and logic, are the more active areas.

**Spencer, Herbert** (1820–1903). English evolutionist, father of sociology, and self-appointed philosopher, Spencer enjoyed immense popularity in his own time, especially in America. His huge output, the 'Synthetic Philosophy', was made possible by the fact that he troubled himself little with the writings of others, claiming indeed that the reading of books with which he disagreed gave him headaches. Sinking in esteem by the century's end to hitherto unfathomed depths, Spencer is today remembered primarily as the enthusiast for extreme *laissez-faire* or \*Social Darwinism, and the classic exemplar of the \*naturalistic fallacy as he attempted to derive the force of morality from the fact and course of \*evolution. In his day, however, he was far more popular as the prophet of progress, claiming that nature tends always towards equi-

librium and that this sparks an upward evolutionary move from homogeneity to heterogeneity. One suspects that, even to this day, the unsung figure of Spencer rides on, paradoxically among both right-wing politicians decrying the dangers of state interference and left-wing ecologists hymning the virtues of balance.

**Speusippus** (c.410–337 BC). An Athenian philosopher who was Plato's nephew and successor as head of the \*Academy. He wrote extensively on topics in metaphysics, the philosophy of logic and language, philosophy of nature, and ethics; but his thoughts have reached us only in tantalizingly incomplete and obscure form. There is some evidence for attributing to him a nominalist, anti-essentialist tendency in his theorizing on semantics, mathematics, and natural kinds. Thus he is reported by Aristotle as denying independent, substantive existence to numbers, and as maintaining that things should be defined not by their own intrinsic characters but rather in terms of their relations of similarity and dissimilarity to other things. If more were known about these ideas, it might illuminate many aspects of Aristotle's theorizing about essence.

J.D.G.E.

Speusippus' writings have been collected and discussed by P. Lang, *De Speusippi Academici Fragmenta* (Bonn, 1911) and more recently by L. Tarán, *Speusippus of Athens* (Leiden, 1981).

**Spinoza, Baruch (or Benedictus)** (1632–77). Dutch Jewish philosopher. Spinoza's family were Portuguese Judaizing Marranos (forced converts to Christianity living secretly as Jews). His father had emigrated to Amsterdam to avoid persecution, where he built up a successful merchant business. Spinoza's mother died when he was 6 and his father when he was 22. Spinoza continued for a time as a respected member of his synagogue, running the family business with his brother. However, a crisis arose when he would not renounce the heterodox opinions he had been heard to voice, and, after unsuccessful efforts to buy his silence, he was cursed and excommunicated from the Jewish community. Opinions differ over why such strong action was taken against him. One view is that the peculiar religious position of the Marranos had encouraged scepticism and laxity in Jewish practice and that the rabbis felt that they must affirm the religious unity of their community (there were some other similar instances of *herem*). Others emphasize the need to reassure the city fathers that the Jewish community was committed to the same basic theism as Christianity.

A few years after the ban Spinoza (with the family business wound up) left Amsterdam and lived for some years in Rijnsburg, near Leiden, lodging with a member of the Collegiant sect, with which he was developing an association. After four years he moved to Voorburg and then to The Hague, living in modest lodgings. (The houses at Rijnsburg and The Hague now contain the library and offices of the Dutch Spinoza society, the *Vereniging het*

*Spinozahuis*.) He was a skilled optical lens grinder and some of his income came from this, though he also accepted some small financial support from his followers. He acquired international fame, and, with the publication of the *Tractatus Theologico-Politicus* in 1670, notoriety. Among his friends and frequent correspondents was Henry Oldenburg, Secretary of the Royal Society in London. Oldenburg and some other Christians may have hoped that Spinoza would lead that mass conversion of the Jews to Christianity which their millenarian beliefs led them to expect. However, Spinoza conceived Jesus as at most the last of the great Jewish prophets.

Spinoza only published two books in his lifetime: *The Principles of Descartes's Philosophy* (written initially for a young man he was informally tutoring, published 1663) and the *Tractatus Theologico-Politicus*. The latter was published anonymously at Amsterdam, though for reasons of prudence with a falsely titled frontispiece and binding. It soon became explosively infamous and Spinoza, once he became known as the author, much reviled for it.

It is part biblical study, part political treatise. Its overriding goal is to recommend full freedom of thought and religious practice, subject to behavioural conformity with the laws of the land. As virtually the first examination of the Scriptures (primarily the Pentateuch) as historical documents, reflecting the intellectual limitations of their time, and of problematic authorship, it opened the so-called higher criticism. What is important, claims Spinoza, is the Bible's moral message; its implied science and metaphysics can stand only as imaginative adjuncts for teaching ethics to the multitude. Though Spinoza unobtrusively identifies \*God and \*nature, one of the opinions leading to his excommunication (as he was already doing in his work in progress on the *Ethics*), he writes in a seemingly more orthodox vein, even while denying the genuinely supernatural character of reported miracles. It is much debated whether this shows that those who now read the *Ethics* in too secular a way are misunderstanding it, or whether Spinoza was adapting his presentation not indeed to the masses, but to conventionally religious intellectuals of his time, among whom he wished to promote tolerant liberal ideals. The study of the Bible is designed to show that there is nothing in it which should sanction intolerance within Judaism or Christianity, or between them, and to illustrate certain political facts by reflections on Jewish history, such as the desirable relations between Church and State. Spinoza's political theory owes a good deal to Hobbes, utilizing similarly the idea of a \*social contract, but deriving a more liberal and democratic lesson from it. Spinoza was personally committed to the republican policies of the De Witt brothers in Amsterdam, was outraged at their murder, and was against the royalist ambitions of the House of Orange.

Shortly after his death *Opera Postuma* was published by his friends, containing the *Ethics*, one of the major and most influential works of Western philosophy, the unfinished *Tractatus Politicus*, some lesser works, and some important correspondence. So notorious had Spinoza's

opinions become that they still only gave the name of the author as B.D.S. (Two other works have come to light since.)

Spinoza has been more variously interpreted than most philosophers. Perhaps this only shows his system's resemblance to the universe it mirrors. A less contentious explanation is that, depending on the reader's starting-point, it may come either as a call to abandon traditional Jewish or Christian religious belief and practice, or as a revitalization of the conception of a God who seemed to be dying. In the seventeenth and eighteenth centuries he was widely regarded with horror as a scarcely covert atheist, in the nineteenth as a precursor of absolute \*idealism. Some twentieth-century thinkers interpreted him, rather one-sidedly, as a precursor of a \*'cognitive science' interpretation of mind, others almost as a logical atomist, while others again hailed his \*pantheism as providing a metaphysical foundation for 'deep ecology'. Among the many very different thinkers who have either regarded themselves as, in a broad sense, Spinozists, or as strongly influenced by him, are Goethe, Lessing, Heine, Nietzsche, George Eliot, Einstein, Freud, Bertrand Russell, and George Santayana, while Hegel saw Spinoza's philosophy as a particularly important dialectical stage on the road to his own absolute idea. Historically, Spinoza was strongly influenced by Descartes, though the upshot of his thought is markedly different, and, to a debatable degree, by various Jewish thinkers.

Spinoza's great work, the *Ethics*, is presented as a deductive system in the manner of Euclid. Each of its five parts ('Concerning God'; 'On the Nature and Origin of the Mind'; 'Concerning the Origin and Nature of the Emotions'; 'Of Human Bondage, or the Strength of the Emotions'; 'Of the Power of the Intellect, or of Human Freedom') opens with a set of definitions and axioms and is followed by a series of theorems proved upon the basis of what precedes them, with more informal remarks in scholia and appendices.

In part 1 Spinoza proves (understand henceforth: or intends to prove) that there is only one substance (in the sense of genuinely individual thing with an intelligibility not derivative from that of other things), and this answers both to the traditional meanings of 'God' (for example, its existence follows from its essence) and of 'nature' (that of which the laws of nature are the operations). (Thus God did not create but *is* nature.) Spinoza derives this claim by pushing the traditional notion of an individual substance to its limit in a complex argument roughly as follows.

1. First we must note some of his opening definitions: 'By \*substance I understand what is in itself and is conceived through itself, i.e. that whose concept does not require the concept of another thing, from which it must be formed.' 'By \*attribute I understand what the intellect perceives of a substance, as constituting its essence.' 'By \*mode I understand the affections of a substance or that which is in another thing through which it is also conceived.' 'By God I understand a being absolutely infinite,

i.e. a substance consisting of an infinity of attributes, of which each one expresses an eternal and infinite essence.'

2. After certain initial moves Spinoza proves proposition 5, 'In the universe there cannot be two or more substances of the same nature or attribute', by considering what could possibly distinguish two such substances. It could not be their affections or modes, because they must be different in order to have different affections (just as two men could not be distinguished by the fact that one was angry and the other not, for this possibility rests upon their being different men—compare some recent arguments for bare particulars). However, on the only alternative, that they are distinguished by their natures or attributes, they would not be instances of what is denied. Why Spinoza did not consider the apparently obvious objection (noted by Leibniz) that they might share one but not all their attributes has been debated. The solution recommended here is that, since an attribute is simply a way of conceiving the essence or nature of a substance, any shared attribute implies a shared essence which in turn implies the same set of attributes as ways of conceiving it.

3. The next crucial proposition (part 1, proposition 11) affirms the necessary existence of God as we have seen him (or it—to say 'her' would be wildly anachronistic) defined. Spinoza's \*ontological argument for this is derived with peculiar abruptness from proposition 7, according to which existence appertains to the nature of substance (and so must pertain to the divine substance), this being derived in turn from the impossibility, established in previous propositions, of one substance producing another (because such causation requires a community of nature that is impossible granted that two substances cannot share their nature).

One might think that this only shows that if a substance exists at all, then it must exist of its own nature, and does not tell us which if any substances do exist. However, the underlying thought seems to be that any coherently conceivable substance (with a possibly actualizable essence) must exist, since the conception of it cannot be derived from anything but its own existing self. In the case of that which could only exist as the modification of something else, the case is different, for the conception of it may be derived from the conception of that of which it is a possible modification. Thus (my examples) the conception of Horatio's bravery in some non-actual situation may be derived from a proper conception of Horatio himself, and the conception of a unicorn may be derived from the conception of the universal space within which it could figure as a possible form. But in the case of a coherently conceivable substance, such as God, there can be no such derivation, and its coherent conceivability must derive from its own actual being. (Leibniz's claim that the ontological argument should first establish the coherent conceivability of God is apt here. In fact in the course of the first of two further proofs Spinoza does try to show this.)

4. Since a perfect substance exists possessing all attributes, and since there cannot be more than one substance possessing the same attribute, it follows that this perfect

substance is the only substance, since there are no attributes left for any other substance. Thus (part 1, proposition 14) 'Except God, no substance can be or be conceived.'

We must continue in even less detail. All ordinary finite things are modes of this one substance, that is, stand to it as, say, an emotion pertains to a person or a movement to a moving thing. Thus the existence of a person consists in the one substance being in a certain state, just as the existence of my anger consists in my being in a certain state. (This traditional reading of Spinoza is sometimes challenged.) In effect, my anger is the mode (Spinoza says 'affection') of a mode.

Some commentators resist the usual idea that for Spinoza God simply is the universe, insisting that he is rather the one substance in which all natural phenomena inhere. But though we should distinguish between the essence-and-attributes-of-God and his modes, that still leaves all natural phenomena as his states just as my moods are mine. However, certainly God is not merely the physical universe for Spinoza. (Though that God was, among other things, physical, was, indeed, one of his most shocking claims.) For the essence of God is expressed in an infinite number of attributes of which physical extension is just one. Thus the physical world is God's body, God in his physical aspect, rather than the totality of what God is. Humans, as it happens, only know of one other of these attributes, namely thought. God or the universe is thus both an infinite physical thing and an infinite thinking thing (as well as an infinite number of other infinite things the nature of which is hidden from us).

The one substance and its modes exhaust the things which are. But where does that leave the essence and attributes of the one substance and the essences-of-its-modes (of which Spinoza also makes much)? On the face of it, these seem additional sorts of entity. However, this is not really so.

(i) The essence of a finite thing (that is, a finite mode) is simply the thing itself (or rather that core thereof which must endure so long as the thing exists at all) *qua* possibility whose actualization constitutes it an existent or whose non-actualization leaves it merely as something which might exist (so far at least as the general character of the universe goes). The essence of the one substance is similarly one with the substance itself, that core of the universe which must endure so long as anything does and of which all finite things are passing states. However, there is no question of its ever having or having had status as a mere possibility and it is a necessarily actualized essence. That something is possible but non-existent must be a fact about something which does exist. The non-existence of unicorns is the fact that nature has no place for them, but there is nothing which could have no place for Nature, that is, the one divine substance. There is an implied further proof of God's existence here.

(ii) Much discussion has centred on how Spinoza conceived the relation between the essence of the one substance and its attributes. The 'subjective' interpretation

regards them as the subjective appearances to a mind of some unknown ultimate noumenal essence. Modern commentators mostly prefer the objective interpretation according to which they are genuine constituents of the essence rather than a veil behind which it hides. There are difficulties in both accounts, both as interpretation and as philosophy. This writer holds the intermediate position that each attribute is one of various alternative ways of conceiving the essence correctly. (Among other reasons for this are the justification we have seen that it provides of part 1, proposition 5.) Thus the world can be truly seen either as a physical system (the attribute of extension) or as a mental system, that is, a system of ideas (the attribute of thought) while there are other in principle possible ways of seeing it (the unknown attributes) beyond human mental capacity.

In short, neither the essence of substance nor its attributes are items in addition to substance itself.

*Qua* system of thought God, or Nature, is the idea of itself *qua* physical system, and every finite thing, as mode of the one substance, is both a physical thing and the idea of that physical thing, that is, that component of God's mind which is his awareness of it. Thus every genuine unit in physical nature, animal, plant, or ultimate particle, has its mental counterpart, that is, may be conceived not as a physical thing but as the idea of a physical thing. The human mind is the idea of the human body (of how it functions as a whole, rather than of its every detail). Here again commentators interpret Spinoza somewhat divergently, but most agree that this implies that every physical thing has some kind of sentience. However, it is only in so far as a physical thing has a certain wholeness to it that its mental counterpart constitutes a mind with much distinctness from the rest of cosmic mentality.

Every finite thing has a built in *conatus* (striving or endeavour) to persist in its own being, that is, to keep its own essence actualized (in fact, the *conatus* simply is the essence with its own tendency to persist) until it is defeated in so doing by external causes. This produces self-preserving behaviour suited, to the extent that it can internally register them, to current circumstances. The human mind-body is especially apt in such registration, which constitutes its own ideas of its current environment. (Its ideas of its environment are part of God's current idea of it as affected by this.) Pleasure and pain are the mental analogues of an increase or decrease in the effectiveness of its *conatus*, differing in character with the thing's essence. Spinoza defines all the emotions in terms of pleasure, pain, and the basic *conatus* they manifest. He aims to study human psychology dispassionately 'just as if it were an investigation into lines, planes, or bodies', in contrast to those 'who prefer to abuse or deride the emotions and actions of men rather than to understand them'. For only by understanding ourselves can we win freedom in Spinoza's sense.

Spinoza is an uncompromising determinist. Everything that happens is determined by two factors, in the manner of Hempel's account of scientific explanation, the standing

nature of God, that is, the laws of nature, and previous conditions likewise determined back through infinite time. There is no human 'freedom of indifference' but there are various degrees of human freedom in a more worthy sense. The physical and mental behaviour of a human being (or, in principle, of any other finite thing) may be active or passive to various degrees. The more it stems distinctively (or creatively) from its own *conatus*, the more active it is; the more it is merely acted on by external things, the more passive it is. The active behaviour of the mind consists in what Spinoza calls adequate ideas, the passive behaviour in inadequate ideas; adequate ideas necessarily constitute more genuine knowledge. Knowledge has three main grades, in order of its adequacy: (1) knowledge by hearsay and vague experience; (2) knowledge by general reasoning; (3) intuitive rational insight. The first type of knowledge yields emotion and activity of an essentially enslaved sort; human liberation consists in movement through the second to the third type of knowledge. Only at that level do we cease to be victims of emotions which we do not properly understand and cannot control. The third type of knowledge ultimately yields the 'intellectual love of God', Spinoza's version of salvation.

More informally put, Spinoza regards us in bondage so far as we are under the control of external things (in a sense which includes especially mental processes of our own which we do not properly understand) and as free to the extent that we meet life with creative understanding of what will best serve the purposes that adequate ideas will determine in us.

One may still wonder how far Spinoza is really committed to what one might call a religious view of the world.

Well, he was certainly against all forms of religion which he regarded as life-denying and which view the present life as a mere preparation for a life to come; rather, our primary aim should be joyous living in the here and now. This, however, should ideally culminate in that quasi-mystical grasp of our eternal place in the scheme of things, and oneness with God, or nature, which he calls the intellectual love of God. Love of God, in this sense, should be the focal aim of the wise man's life.

So far as religion, as most people conceive it, goes, he clearly thought that a good deal of it was mere superstition, fomenting intolerance and in many ways unhelpful as a basis for a genuinely good life. But he also thought that for the mass of people, who are incapable of the philosopher's intellectual love of God, a good popular religion could act as a morally worthy substitute, providing a less complete form of salvation available to all who live morally and love God, as they conceive him, appropriately, provided only that their love of God is of a type which promotes obedience to the basic commands of morality.

Spinoza is arguably the only really great 'modern' Western philosopher who develops what can be properly called a personal \*philosophy of life.

**spirit.** Spirits hover between \*minds, \*souls, and vapours. The original idea of a spirit is of a disembodied agent, as an immaterial soul or a non-material intelligent power. In the seventeenth century and earlier there was a belief in spirits as gaslike substances intermediate between matter and mind. For all his dualism Descartes in *Les Passions de l'âme* uses the idea. When we talk now of the spiritual we refer to neither of these but typically to the kind of emotion one might have towards God or some other factor beyond one's material life. An image common to all three of these seems to be one of distillation, of a more refined product of a crude original. A.M.

\**pneuma*.

Richard Burton, *The Anatomy of Melancholy* (1621).

**spontaneity and indifference.** These medieval terms are used for two kinds of liberty or freedom. The two kinds continue to be discussed, under the names 'voluntariness' and 'origination', the first sometimes being denied to be real liberty or freedom. To have liberty of spontaneity is to be able to do as you choose. That is, unlike a man in jail, or a man with a gun at his head, you are unconstrained or uncompelled to act as you do. To have liberty of indifference is to be able, given things exactly as they are, to choose or originate another action different from the one you actually choose. If determinism is true, we still often enjoy liberty of spontaneity, because our actions still result from our own choices, but not liberty of indifference, because the choices themselves are caused or deter-

mined. According to the doctrine of \*compatibilism, spontaneity is the freedom that is important, and is sufficient for moral responsibility. According to incompatibilism, the only true freedom is indifference, and it is necessary for moral responsibility. R.C.W.

\*freedom and determinism; origination; embraced and reluctant desires.

**sport.** Despite Plato's reputation as a wrestler, the worlds of philosophy and sport have rarely collided. Unlike other social practices such as art, education, or medicine, sport's characteristic conceptualization as 'non-serious' reinforces scepticism as to the possibility of genuine philosophical interest therein. As a professional field of some thirty years, philosophy of sport has analysed key concepts such as 'competition', 'game', 'play', and 'sport', and explored more generally their nature and significance. As a field of applied philosophy, it has often drawn from work in other fields such as aesthetics, epistemology, and the philosophy of rules. Only in ethics does sport give rise to issues of substantial and original interest, where research might contribute to new thinking in the parent discipline. Sports ethics is certainly the most vibrant dimension of the philosophy of sport, where analytical and normative issues surrounding practices such as doping, cheating, gamesmanship, and genetic manipulation are widely disputed, though largely from within a deontological framework. **Sprigge, Timothy L. S.** (1932– ). British idealist philosopher, formerly at the University of Edinburgh. In *The Vindication of Absolute Idealism* (1983) he argues that the reality which appears to us as the physical world of daily life, and of which physical science specifies the abstract structure, is 'in itself' (or 'noumenally') a system of mutually interacting centres of experience. Thus he defends a form of \*panpsychism. This conclusion is supported by an argument that a totally unexperienced reality is impossible. Reflections on relations and on temporality suggest that the system must have its own overall consciousness, as an eternal changeless unity within which temporal processes occur. This position is Spinozistic in that the universe is held to be both a mental and a physical totality, though on Sprigge's view the mental is its inner essence and the physical only its structure.

In his moral philosophy Sprigge defends a qualified moral realism and utilitarianism which is not only consistent with his metaphysics but depends upon it for premisses. It is entailed by his moral philosophy that non-human animals have rights, and Sprigge is known as a defender of \*animal rights through both publications and active campaigning. S.P.

**square of opposition.** Traditionally ‘All men are mortal’ and ‘No men are mortal’ are \*contraries, meaning that they cannot both be true but may both be false; and ‘Some men are mortal’ and ‘Some men are not mortal’ are \*subcontraries, meaning that they cannot both be false but may both be true. ‘All men are mortal’ and ‘Some men are not mortal’ (like ‘No men are mortal’ and ‘Some men are mortal’) are \*contradictories, meaning that one must be true, the other false. The square is a traditional diagram summarizing these ‘oppositions’:

In traditional logic ‘Some men are mortal’ is entailed by ‘All men are mortal’, and ‘Some men are not mortal’ is entailed by ‘No men are mortal’. Though it is implausible to regard this subalternation as a variety of opposition, it was sometimes included in the diagram too. C.W.

\*traditional logic; subaltern.

C. Williamson, ‘Squares of Opposition’, *Notre Dame Journal of Formal Logic* (1972).

**stadium or moving rows paradox.** The most mysterious of \*Zeno of Elea’s paradoxes of motion. The rows are like trains of coaches; the train of A-coaches is stationary, those of B-coaches and C-coaches are moving past it at equal speeds in opposite directions. Zeno seems to infer that a B takes as long, and also half as long, to pass a moving C as to pass a stationary A; hence that a time is equal to its half. One suggestion is that he is attacking the idea of a minimum time-stretch: a B’s A-passing time is supposed for argument’s sake to be such a minimum; but if so, even though two C-passing times evidently equal that minimum, one C-passing time cannot be less. Another suggestion has him ignore the relativity of motion: since the coaches are equal in length, it *must* take the same time for a B to pass one A as to pass one C. C.A.K.

W. C. Salmon (ed.), *Zeno’s Paradoxes* (Indianapolis, 1970).

**Stalnaker, Robert C.** (1940– ). American philosopher who is especially noted for his work on \*conditionals. Like David Lewis, but independently of him, Stalnaker has devised an analysis of conditionals in terms of \*possible worlds. Loosely, Stalnaker regards a conditional of the form ‘If *p*, then *q*’ as being true in the actual world if and only if *q* is true in the closest possible world in which *p* is true. There are important differences between Stalnaker’s and Lewis’s systems of conditional logic, the most notable

being that only Stalnaker’s supports the principle of conditional \*excluded middle, that is, the principle that ‘Either if *p*, then *q*, or if *p*, then not *q*’ is true of \*logical necessity. Apparent counter-examples can be deflected by denying that the principle of bivalence holds for conditionals.

Stalnaker has also done influential work on the ontological status of possible worlds, the theory of mental content, the nature of belief, and the problem of how beliefs undergo rational revision. E.J.L.

**State, the.** The political organization of a body of people for the maintenance of order within its territory by coercion, or, more loosely, the body of people so organized or its territory. There have been *stateless* societies, characterized by lack of a definite territory or, perhaps, by the absence of a form of government with coercive powers for securing obedience. The State, however, is taken to have the \*power to regulate the behaviour of all individuals and of any other organizations within its boundaries. For this purpose the State has, or at least claims, a monopoly on the use of force.

Among several theories of the nature of the State the simplest holds that it is simply an organization for subordinating the many to the will of a dominant few. But even on this account a distinction has to be drawn between the *private* acts of individuals and their *public* acts as agents of the State. This is done through marking out the latter as the exercise of power through the administration of the law and the maintenance of security for a territory within which the law can be administered. But is the State more than simply ‘a conspiracy of the rich who call their intrigues laws’ (Sir Thomas More)?

\*Anarchism denies that it is, holding that the State lacks any necessary or desirable function in regulating society. Other theories characterize the State in terms of one. According to Hobbes it prevents a ‘warre of every man against every man’, and is legitimized by a \*social contract between citizens to submit to it in order to secure this benefit. This leads naturally to a view of the State as a voluntary association for mutual protection. Under the theory of \*democracy such an association will be governed legitimately only if in accordance with the electorally expressed wishes of its members.

In democracies decisions may be made which apparently involve the State in going beyond its role of maintaining social order. Is this admissible? Under \*conservatism, the State’s provision of welfare or even its redistribution of wealth can be viewed as simply averting strife, or otherwise as inadmissible. This reflects the doctrine of the ‘minimal’ State. The State’s prevention of discord may, however, be viewed as only an example of its general provision of public benefits. Thus according to \*socialism the task of the State is the creation of a

good life for all, towards which radical social policies are permissible.

All the above theories view the State as conducing to the satisfaction of *individual* wishes, which are logically prior to it. Under some forms of \*communitarianism, however, the State is itself the condition of any rational choice. Thus 'the Fascist conception of the State is all-embracing: outside it no human or spiritual values can exist, much less have value' (Mussolini). \*Fascism legitimizes the State by according it the role of supreme moral arbiter.

The theory of the State as an association and some theories of nationalism have different approaches to the question which territory should make up the State. For example, the former should be sympathetic to well-supported secessionist movements, while the latter may regard them as a threat to national unity. However, although the rights of a State to self-preservation against internal threats are unclear, their right and duty to defend themselves against external ones is readily conceded. Indeed, in the absence of international government, Hobbes viewed the relation between States as one of perpetual war.

**statements, basic:** see basic statements.

**statements and sentences.** Most modern logicians maintain that statements are distinct from sentences, citing the fact that not all sentences are used to make statements or arguing that the same statement may be expressed by different sentences. Some use 'statement' and \*'proposition' interchangeably, regarding them as alternative names for what is 'expressed' by an indicative sentence or 'asserted' when such a sentence is used. Others distinguish between the two, so that a proposition is what is asserted when such a sentence is used to make a statement. Some—Strawson, for example—have held that statements must be distinguished from sentences because mere sentences cannot contradict one another. We imagine that 'I am under six foot tall' and 'I am over six foot tall' are inconsistent, the argument runs, only because we think of them being uttered by the same person in the same breath, i.e. being used to make contradictory statements. What this argument really shows, however, is the importance of taking context into account. Adding the sentence–statement distinction is arbitrary, but it reflects a deep-seated tendency to incorporate in a separate entity what properly belongs to the way that a sentence is used in some particular setting.

P. F. Strawson, *Introduction to Logical Theory* (London, 1952), 3–4, 9–12, 174–6.

**state of nature.** This notion was employed by \*social contract theorists to indicate the condition of human beings prior to or without government. By showing what

was lacking in this natural condition, or state of nature, they hoped to demonstrate the benefits of politically organized society and the rationality of accepting governmental authority. The state of nature was characterized by certain deficiencies for which government was said to be the proper remedy. It is therefore rational for individuals to pull themselves out of this condition by agreeing among themselves to accept some form of political authority. However, social contract theorists differed sharply with one another about what kind of government provides the best remedy, and this disagreement stems largely from how each characterizes the state of nature. Hobbes, for example, characterized it as an utterly lawless state of affairs in which 'the notions of right and wrong, justice and injustice . . . have no place', and where each man has the right (or liberty) to do whatever he deems necessary to preserve himself. Such a condition, he says, is 'called war; and such a war as is of every man against every man'. He observes that under such circumstances 'the life of man [is] solitary, poor, nasty, brutish, and short'. Thus, Hobbes concludes that the only kind of political authority strong and stable enough to safeguard us from ever falling into such a horrible condition again is unlimited political authority, preferably an absolute monarchy. The authority of such a sovereign must be unconditional and indissoluble; the right to rule conferred on the sovereign must be such that 'whatsoever he doth, it can be no injury to any of his subjects, nor ought he to be by any of them accused of injustice'. Locke, on the other hand, characterized the state of nature as a pre-political state, but insists that 'the state of nature has a law of nature to govern it, which obliges everyone; and reason, which is that law, teaches all mankind who will but consult it that, being all equal and independent, no one ought to harm another in his life, health, liberty, or possessions'. Because of this he views the state of nature as merely involving certain inconveniences. These inconveniences consist in (1) the lack of an established, known law that gives an authoritative interpretation of the law of nature, (2) the absence of an impartial judge to determine violations of the law and their proper punishment, and (3) the want of a power sufficient to ensure enforcement of the law. Thus, while granting that 'civil government is the proper remedy for the inconveniences of the state of nature', Locke also admonishes us 'to remember that absolute monarchs are but men' and asks, 'if government is to be the remedy of those evils which necessarily follow from men's being judges in their own cases, and the state of nature is therefore not to be endured, I desire to know what kind of government that is, and how much better it is than the state of nature, where one man commanding a multitude, has the liberty to be judge in his own case, and may do to all his subjects whatever he pleases . . . and in whatsoever he does, whether led by reason, mistake, or passion, must be submitted to'. Locke concludes that the proper remedy for the state of nature must place ultimate political authority in the will of the majority, who will then entrust political power to governmental officials only under the condition

that the latter promote the common good, reserving the right to remove them if they violate this trust. R.D.M.

Jean-Jacques Rousseau, *The Social Contract* (1762).

**Stevenson, Charles L.** (1908–79). Stevenson is the best known, and arguably the most compelling, exponent of what is known as the \*emotive theory of ethics. In two papers written in the 1930s ('The Emotive Meaning of Ethical Terms' (1937), 'Persuasive Definitions' (1938), collected in his *Facts and Values* (New Haven, Conn., 1963)) Stevenson presented this theory, that moral judgements do not describe properties of people or actions but express approval or disapproval and seek also to influence the feelings of approval and disapproval of others. He worked out his ideas in detail in *Ethics and Language* (New Haven, Conn., 1944), a substantial work of considerable depth and originality. The emotive theory of ethics is sometimes taken to encourage, or to imply, immorality, and because of this (wholly unwarranted) idea Stevenson was discharged from a university post in 1945. However, he subsequently worked at the University of Michigan until his retirement in 1977. He is certainly one of the most influential ethical theorists of this century, for all that the emotive theory continues to be widely criticized. N.J.H.D.

**Stewart, Dugald** (1735–1828). Son of a professor of mathematics in Edinburgh, for whom he deputized, and pupil of Ferguson, he heard Reid lecturing in Glasgow and was persuaded that mind can be studied scientifically. Clarifying Reid's principles of common sense, he saw the difference between the axiomatic deduction of mathematics and natural generation of belief about the world. Such existential belief had to be governed by laws, not operating as deductive premisses but as constituents of human reason. As Ferguson's successor to the Chair of Moral Philosophy, Stewart argued, as had Reid, that moral qualities really exist independently of perception. He proclaimed his philosophy in extensive writings, promoting Adam Smith's science of legislation, or political economy, which he believed to presuppose moral philosophy. He foresaw that British liberty would develop among 'the oppressed and benighted nations around us'. Although James Mill was one of his students, M'Cosh applauded him for saving England from 'low sensational, materialistic, and utilitarian views'. V.H.

— *Outlines of Moral Philosophy*, with a memoir by J. M'Cosh (London, 1864).

**Stich, Stephen** (1944– ). American philosopher. Stich's work in philosophy of psychology and theory of know-

ledge uses results from cognitive psychology to question the view—called \*'folk psychology'—that intentional behaviour is to be explained by appeal to the agent's beliefs and desires (where beliefs and desires are construed as attitudes toward propositions) along with traditional accounts of what it is for a method of inquiry to be rational. Cognitive psychological evidence has suggested to Stich that people often do not act in ways that fit what they sincerely claim they believe or desire, and therefore that there may be no such things as beliefs or desires whose contents can be determined as required by folk psychology explanations of behaviour. Further evidence that people often make up their minds in violation of standards of rationality derived from elementary logic and probability theory has led Stich to a radical critique of the notion of rational belief and the goals of inquiry. J.B.B. Stephen Stich, *The Fragmentation of Reason* (Cambridge, Mass., 1990).

— *Deconstructing the Mind* (New York, 1996).

**Stirner, Max** (1806–56), pseudonym of Johann Kaspar Schmidt. German philosopher who heard Hegel lecture and became a Left Hegelian. In his major work, *The Ego and his Own* (1845), he attacks the 'new radicalism' of Bauer, Feuerbach, and Marx as much as the 'old orthodoxy'. The only reality, he argues, is the individual ego, and things have value only in so far as they serve the ego. The individual must become conscious of his power over his own ideas. Once ideas escape the ego's control, they become 'ideals' and dominate the ego that produced them. This is true not only of the old ideas of Church and State, but of the new ideas of humanism and socialism. This, like Bauer's, exaltation of individual self-consciousness is a reversion to pre-Hegelian romanticism. Marx and Engels attacked 'Saint Max' (Stirner) in *The German Ideology*. M.J.I.

\*romanticism, philosophical.

**stochastic process.** Any sequence of trials the outcomes of which are only probabilistically determined. The term is usually applied to sequences of trials ordered in time. As an example consider a time-ordered sequence of tosses of a fair die with specified probabilities for any given face coming up in a given toss. Two fundamentally important kinds of stochastic processes are Bernoulli sequences, in which the trials are all probabilistically independent of one another, and Markov processes. In a Markov process the probabilities for the outcome of a trial may depend conditionally on the outcome of the previous trial, but they are probabilistically independent of the outcomes of any trials before the one immediately preceding the trial in question. L.S.

\*chance; probability.

W. Feller, *An Introduction to Probability Theory and its Applications* (New York, 1950), vol. i, ch. 15.

**Stoicism.** Philosophical tradition founded by Zeno of Citium, developed by Cleanthes and Chrysippus, and

named from the *Stoa poikilē* or 'Painted Porch' in Athens where they taught. The last major figure in antiquity to have Stoicism as his primary allegiance was the emperor Marcus Aurelius in the second century AD, but the influence of the school's ideas lived on, and 'stoical' has become a common expression to indicate acceptance of misfortune without complaint.

Stoicism placed ethics in the context of an understanding of the world as a whole, with reason being paramount both in human behaviour and in the divinely ordered cosmos. The Stoic view of divinity and its relation to the world has been historically influential, contributing to the context in which \*Neoplatonic and Christian thought developed, and especially to \*theodicy; but it is perhaps Stoic ethical views that are of most immediate philosophical interest to us today, and it is these that have been given most prominence in what follows. The systematic nature of Stoic philosophy indeed reflected the school's view of the systematic nature of the world itself, which it sought to explain without recourse to a Platonic other-worldliness. Some of the paradoxes for which Stoicism was notorious were deliberately adopted for the sake of a striking exposition; but the system was ultimately unable to succeed in explaining everything without internal incoherences.

Stoic ethics indicated that if a perfectly wise, i.e. virtuous, man saw his child in danger of drowning (say), he would try to save it; but that if he failed he would accept this without feeling distress or pity, and without his happiness being diminished. Since everything that happens is governed by divine providence, his failure must have been for the best, even if he could not understand why. Moreover, moral virtue is the only good, and wickedness the only evil; so the child's death was not itself an evil. Furthermore, since moral virtue is the only good, and being perfectly virtuous the wise man will by definition have done the best he could, there is nothing for him to regret. (This example is adapted from Long, *Hellenistic Philosophy*, 197–8; it is not based on any single ancient text, but brings out the implications.)

Such a view may seem repellent, even incomprehensible, especially as the Stoics made 'following \*nature' the centre of their ethics, explaining the development of moral awareness by the individual's progressive realization of what was naturally appropriate for him (*oikeiōsis*). But context and motivation are important. Ancient Greek society placed considerable emphasis on material achievement, and in spite of Socrates' insistence on the importance of moral goodness, Aristotle had maintained the relevance of bodily and material goods, as well as virtue, to human happiness (*\*eudaimonia*); indeed some Aristotelian virtues require considerable resources and social standing. The Stoics reacted against such views, still within a eudaemonistic framework, by insisting that all that matters is our attempts to do what is right; health and wealth are naturally *preferable* to sickness and poverty, and we should *pursue* them if we do not wrong others thereby, but *achieving* them is beyond our control. A slave, as Epictetus had been, can be as virtuous as a free man.

Stoicism did not teach withdrawal and inaction (the Stoic school, unlike others, was in the Athenian city centre); but the wise man, while doing the best he can in the circumstances as he sees them, is prepared to accept the eventual outcome as the will of providence, and thus he alone is free. He is like an archer who cares less about actually hitting the target than about doing the best he can to hit it, and his wisdom includes understanding the difference between what is in his power and what is not. (That Chrysippus was a thoroughgoing compatibilist, holding that our actions are predetermined but still our responsibility, is a separate issue; what is important—from his point of view—is that the actions are still ours.)

Only the perfectly wise man is good—and he is as rare as the phoenix; all others are both mad and bad, and all crimes are equal. Like the insistence that virtue alone is good, this can be seen as straining language to make a serious point; all imperfection is imperfection, and one can drown an arm's length from the surface as well as 500 fathoms down. The paradox was lessened by recognition of a class of those not yet virtuous but 'making progress'. The actions which such people should perform are 'proper' (*kathēkonta*, often rendered 'duties'); it is only when such actions are performed by the wise man that they count as virtuous. \*Emotions are interpreted in intellectual terms; those such as distress, pity (which is a species of distress), and fear, which reflect a false judgement about what is evil, are to be avoided (as also are those which reflect a false judgement about what is good, such as love of honours or riches). It is for such emotions as these that the Stoics reserved the usual Greek term *pathē*. They did, however, allow the wise man such 'good feelings' as 'watchfulness' or kindness, the difference being that these are based on sound (Stoic) reasoning concerning what matters and what does not. The wise man will thus be *apathēs*, 'without *pathē*', but not in our terms 'apathetic'. The experience of internal conflict which Plato had interpreted as a struggle between rational and irrational parts of our psyche was for the early Stoa rather a rapid wavering between conflicting judgements.

By taking nature as a moral guide (like their Cynic predecessors, for whom, however, 'following nature' meant little more than rejecting the institutions of the city state), the Stoics founded the tradition of \*natural law. In the Roman period Stoicism became linked with the senatorial opposition to the autocratic rule of emperors like Nero and Domitian. The Stoics were pantheists; \*God not only orders everything for the best, but is present in everything as \*'spirit', conceived in corporeal terms (as fiery air), because only what is corporeal exists, and determining the character of each thing by its degree of physical 'tension'. In animate beings spirit is present as psyche, in plants as 'nature', and in inanimate things as their 'state' (*hexis*). But God exists in a special way in the fiery heavens, and at fixed periods the whole world becomes fire (an apotheosis, rather than a destruction) before again repeating its predetermined history.

The Stoics developed \*propositional logic; they engaged in epistemological debate with the sceptical

\*Academy, and partly anticipated Frege's distinction between \*sense and reference. In spite of their influential attempts to reconcile providence and \*evil, they could not adequately explain why, when virtue was the only good, divine providence should bring it about that almost everyone is bad. Theism eventually proved more congenial than pantheism, and a psychology of conflict than the unity of the psyche; Stoicism declined as Neoplatonism developed.

**stories and explanation.** Narrative understanding is our most primitive form of explanation. We make sense of things by fitting them into stories. When events fall into a pattern which we can describe in a way that is satisfying as narrative then we think that we have some grasp of why they occurred. It is not obvious what makes a satisfying story, but at the very least a story requires purposes fitting into a time-frame. Religions sometimes make sense of the whole world and of individual lives by fitting them together as connected stories. Nations tell stories of their past in terms of which they try to shape their futures. (Such a story is based on a chronicle of real or imagined facts, but adds to it national aims, and the idea of victory and defeat.) Scientific understanding is different. It finds patterns that are not narratives, and forces us to see the stories of our lives as patterns that we make for ourselves, which do not fit into any bigger story.

**Stout, George Frederick** (1860–1944). Taught philosophy and psychology at Cambridge, Aberdeen, Oxford, and finally St Andrews, where he established an experimental laboratory. His central work, however, was in 'armchair' philosophy of psychology. He held that *every* experience embraces a 'thought reference' to a real object, for even in illusions and hallucinations there is reference to *something* other than the experiencing subject. We do not need to impose Kantian categorical conceptions of space, time, causality, etc. on to our experiences, for we have a natural disposition to experience things in these ways.

The subject of mental attributes—cognition, feeling, and 'conation' (\*intention)—is not a Cartesian ego or a mere material object, but a unitary 'embodied \*mind' which has both physical and mental attributes occurring in parallel.

**straw man fallacy.** The straw man fallacy is the tactic in argument of misrepresenting an opponent's position, making it appear more implausible, so that it can more

easily be refuted, then going ahead and arguing against the imputed position as though it were really that of your opponent. For example, against an opponent who has taken a 'green' position, an arguer might reply that she wants to make the earth into a natural place like it was hundreds of years ago, and that therefore her argument would require the elimination of industrial production.

D.N.W.

Douglas N. Walton, *Informal Logic* (Cambridge, 1989).

**Strawson, Peter F.** (1919– ). British philosopher of logic and metaphysician, noted also for his exposition of Kant. Many of the themes which run through his work are to be found in his most influential book, *Individuals* (1959). Those themes include: the problem of \*individuation, the distinction between \*subject and predicate, the ontological status of \*persons, and the possibility of objective knowledge—all of which Strawson handles in a way which is coloured by his respect for Kant's approach to metaphysics. Strawson characterizes his own approach to metaphysics as '\*descriptive' rather than '\*revisionary', aspiring to articulate the fundamental structure of our common-sense conceptual scheme rather than to reject it in favour of a radically new vision of reality.

In an early but highly influential paper, 'On Referring' (1950), Strawson attacks Russell's theory of definite \*descriptions as unnecessarily revisionary of our ordinary modes of speech. On Russell's account, a sentence of the form 'The *F* is *G*' (for instance, 'The present Prime Minister of the UK is grey-haired') is not really of subject–predicate form, but is equivalent rather to an existentially quantified sentence of the form 'There is one and only one *F* and it is *G*'. Thus, for Russell, 'the *F*' is never a referring expression, having as its \*reference a particular object. Strawson complains that Russell fails to distinguish between *sentences* and the \*statements made by speakers in uttering them, arguing that whenever a speaker makes a statement by uttering a sentence of the form 'The *F* is *G*', he uses 'the *F*' to make reference to a specific object which has the property of being *F*. That there *is* such an object is, according to Strawson, a *presupposition* of the speaker's statement rather than, as Russell implied, part of what is being stated.

In *Individuals*, Strawson explores the Kantian claim that our ability to reidentify \*things over time presupposes the locatability in space of at least some of those things as objects existing independently of our subjective experiences of them. Although he suggests that this claim is in some respects too strong, he is broadly sympathetic to its thrust. He contends that certain privileged kinds of objects—namely, material bodies and persons possessing such bodies—constitute 'basic' \*particulars in our common-sense conceptual scheme. It is ultimately by reference to particulars of these kinds that we are able, in general, to individuate and identify items of other kinds, such as events.

It is noteworthy that Strawson assigns equal weight to both material bodies and persons, rather than regarding the latter as merely a species of the former. For Strawson,

persons constitute a fundamental and irreducible category of being, distinctive in having both physical and psychological characteristics predicable of them. A person is not simply a physical thing, nor yet a combination of a physical body and a mind: rather, the notion of a whole person, as a psychophysical being, is conceptually prior both to the notion of a person's body and to the notion of a mind.

In his contributions to epistemology, Strawson argues for \*direct realism in perception but concedes that scepticism concerning the external world is not conclusively refutable. At the same time, he contends that such scepticism is literally unbelievable, endorsing a view which he describes as 'naturalism'. His book on Kant, *The Bounds of Sense*, though widely admired, is seen by some as being unduly dismissive of Kant's doctrine of transcendental idealism and over-optimistic in its suggestion that many of the central arguments of Kant's critical philosophy can survive the repudiation of that doctrine. Strawson has also written influentially on the problem of \*freedom and determinism, notably in a paper entitled 'Freedom and Resentment' (1962).

**stream of consciousness.** William James's famous metaphor for the way \*consciousness seems. In *The Principles of Psychology* (1890) the metaphor is introduced in a chapter entitled 'The Stream of Thought'. Two years later, in *Psychology: The Briefer Course*, the corresponding chapter is entitled 'The Stream of Consciousness'. It may be that James, who devotes much of his psychology to unconscious processes, changed the title, and thus the metaphor, in order to emphasize that the metaphor is a purely phenomenological one—consciousness seems streamlike. Since only part of thinking, the conscious part, seems any way at all, the metaphor is restricted to this part, to consciousness. The conscious stream, according to James, is personal, feels continuous, forward-moving, and in constant change. We tend to speak and focus on particular contentful states. But the metaphor is designed to draw our attention to the deep and wide currents that surround, and render meaningful in particular ways, these thoughts. The 'halo of relations' surrounding and constituting each image or thought, James called the 'penumbra' or 'fringe of consciousness'.

**strict implication:** *see* implication.

**Stroud, Barry** (1935– ). A Canadian by birth and citizenship, Stroud has lived in the United States since studying at

Harvard in the early 1960s. He has been a Professor of Philosophy at the University of California at Berkeley since 1974. Stroud's philosophical interests range widely, but he has been particularly concerned with epistemology, certain aspects of the philosophy of language, and with the thought of Hume and Wittgenstein. His philosophy is more exploratory than system-building, and his outlook is broadly Humean, in that he has little sympathy for rationalistic approaches to philosophy. He has written influentially on transcendental arguments, and his early article 'Wittgenstein and Logical Necessity' has been extensively anthologized.

**structuralism.** An interdisciplinary movement of thought which enjoyed a high vogue through the 1960s and early 1970s—when it acquired a certain radical cachet—but which has left its most durable mark in the fields of linguistics, anthropology, and literary theory. What unites structuralists in these different fields is the principle, derived from Ferdinand de Saussure, that cultural forms, belief systems, and \*'discourses' of every kind can best be understood by analogy with language, or with the properties manifest in language when treated from a strictly synchronic standpoint that seeks to analyse its immanent structures of sound and sense.

In literary criticism, theorists now rejected mere interpretation as a fruitless endeavour subject to all the vagaries of *ad hoc*, intuitive response. Only by examining the structural features of texts—poetic devices, narrative functions, techniques of linguistic 'defamiliarization'—could criticism place itself on a firm (inductive and adequately theorized) methodological footing. In this sense the movement is a part of that wider formalist enterprise which started out with Aristotle's *Poetics* and has since then enjoyed periodic revivals, mostly—as now—in response to new ideas about language, rhetoric, or the function of criticism *vis-à-vis* other disciplines. Where structuralism can claim to represent a real advance is in its highly sophisticated treatment of rhetorical figures like metaphor and metonymy, figures which (according to Roman Jakobson) are the structural axes of all linguistic communication, and which are raised to their highest expressive power in poetry and other art-forms.

**structural violence.** Popularized by the Norwegian sociologist Johan Galtung, the idea of structural violence involves a wide construal of violence aimed at showing that its menace is present in institutional ways even where no literal or 'narrow' \*violence occurs. Structural violence does not involve agents inflicting damage by force, but is equivalent to social injustice. Apart from its potentiality for confusion, a key problem with the concept is its

dubious suggestion that a variety of apparently quite different social problems are all essentially the same and will therefore yield to the one approach.

J. Galtung, 'Violence, Peace and Peace Research', *Journal of Peace Research* (1969).

**structure, deep and surface.** Originally used by Chomsky as part of a theory of \*grammar that would generate all and only the grammatical sentences of a speaker's language. The deep structures of sentences (e.g. 'Bill saw whom') were akin to their \*logical forms: the level of semantic interpretation. Surface structures (e.g. 'Whom did Bill see?') were derived by transformation rules which moved constituents to new positions, sometimes adding structure, sometimes deleting it. In Chomsky's current theory, mappings from deep to surface level preserve structure. Moved items (like 'whom') leave traces at S-structure to mark their original positions (e.g. direct object) at D-structure. The presence of traces indicate that S-structures are not surface forms: they are shallow structures occurring just below the level of perceived speech. S-structures or logical forms replace D-structures to become the levels where semantic interpretation occurs. B.C.S.

**Suárez, Francisco** (1548–1617). Jesuit philosopher and theologian, born in Granada, Spain. He taught primarily at Salamanca and Coimbra. Suárez's metaphysics, epistemology, and philosophy of law, though influenced by Aristotle and Aquinas, challenged traditional scholastic views. His *Disputationes Metaphysicae* (1597) was the first systematic and comprehensive work of metaphysics written in the West that was not a commentary on Aristotle's *Metaphysics*. For Suárez, metaphysics is the science of 'being in so far as it is real being' (*ens in quantum ens reale*) and its proper object of study is 'the objective concept of being'. This doctrine is regarded by some as having contributed to the development of mentalism in early modern philosophy. Suárez's theory of individuation reveals the influence of Ockham. The principle of individuation is 'entity', which Suárez identifies with 'essence as it exists'. Existing reality is composed exclusively of individuals.

**subaltern.** 'Some *S* are *P*' was traditionally said to be the subaltern of 'All *S* are *P*', 'Some *S* are not *P*' the subaltern of 'No *S* are *P*', meaning that the first proposition is in each case entailed by the second. The second was sometimes called the 'superimplicant' of the first, the first the 'subimplicant' of the second. A \*syllogism which draws a conclusion about *some* things from premisses which merit a conclusion about *all* of them was said to be in the 'subaltern mode'.

C.W.

J. N. Keynes, *Formal Logic*, 4th edn. (London, 1906), ch. 3.

**subconscious mind:** see unconscious and sub-conscious mind.

**subcontraries.** Two propositions *p* and *q* are subcontraries when, as with 'There are fewer than 5 million unemployed' and 'There are more than 3 million unemployed', they cannot both be false (so the falsity of one entails the truth of the other) but the truth of one does not entail the falsity of the other, i.e. when 'Either *p* or *q*' is true. Traditionally 'Some *S* are *P*' and 'Some *S* are not *P*' were called subcontraries. C.W.

\*square of opposition.

J. N. Keynes, *Formal Logic*, 4th edn. (London, 1906), ch. 3.

**subject:** see self.

**subject and predicate.** Grammatically, a subject–predicate sentence consists of any noun phrase and verb phrase in combination, the constraints on the combination being syntactic rather than semantic. Of greater interest to philosophers has been the narrower notion of a 'logical' subject–predicate sentence, where the eligible noun phrases are restricted to those having a certain semantic function, namely, that of \*referring to something or someone. Thus, whereas 'Nothing dies' and 'Nero fiddled' would both satisfy the grammatical description, only the latter would be reckoned a logical subject–predicate sentence. More precisely, the predicate in such a sentence is described as a 'first-order' predicate, whereas a predicate which attaches not to a name but to a first-order predicate is known as a 'second-order' predicate. The logical variety is in question when it is said that 'exists' is not a predicate. In saying, for example, 'The Loch Ness monster does not exist' we can hardly be referring to a monster in the loch, so the grammatical subject is not a logical subject, and the predicate accordingly not a logical predicate. The hierarchy of predicates indicated is also thought important to an understanding of related terms, as 'there is' and 'something'. Starting with 'atomic' sentences, as 'Rome burned' and 'Vesuvius is a dormant volcano', we can derive the forms 'Something burned' and 'There is a dormant volcano'. 'Something' and 'there is' are not logical subjects, but are predicates of a predicate, or second-order predicates. This whole mode of classification calls for scrutiny.

Consider 'Here is a key'. This provides a good contrast to a subject–predicate sentence in that we are not saying of something named 'here' that it is a key, but the adverb simply demarcates the locality where the description ostensibly applies. Similarly with 'There is a key', and not merely when this features 'there' as an adverb of place. In the existential reading what we have is a variation on this pattern, even though 'there' now lacks demonstrative force, approximating more to 'somewhere': provided a key is somewhere to be found, the form is in order. At all events, so long as the behaviour of 'is a key' can be reckoned the same whether it follows 'here' or 'there', we have reason not to think of 'There is a key' as in some way

deriving from particular predications, as 'This is a key'. Since we do not then have a predicative use of 'a key' in 'There is a key', nothing which can be attached to the former phrase can be described as a predicate of a predicate.

It can also be queried whether 'Something is a key' features a second-order predicate, but now because 'is a key' may be said to function in just the same way as in 'This is a key', despite the absence of any namelike term. More generally, there is good reason for broadening the category of subject to include a greater range of noun phrases than is customary, even those that are negative, as 'nothing' or 'no one'. So we might include here 'Every dog has its day', 'Gentlemen prefer blondes', and 'Nothing surprises him any more'. In 'Every dog has its day' the phrase 'every dog' is a genuine unit, relevantly on a par with 'Fido', though of course not a name. It is relevantly on a par in so far as we can say: 'has its day' is true of every dog. Similarly, 'prefer blondes' is true of gentlemen and 'surprises him any more' is true of nothing. The contrast here continues to be with 'Here is an *F*', where we cannot say: 'is an *F*' is true of here.

**subjective truth.** This self-consciously paradoxical description was employed by the Danish philosopher Søren Kierkegaard to describe the force of passionate conviction and commitment, particularly with reference to religion. The intended contrast, obviously, is objective truth, scientific truth, matters which can be verified or established by proof. But 'subjective truth', although conscientiously 'unscientific', is not therefore meaningless or irrational, as some later positivists would argue (and as Kierkegaard sometimes suggests himself). Subjective truth is a commitment to believe, in the face of 'objective uncertainty', in matters which cannot be demonstrated or verified, such as the existence of God. The defence of such convictions, in so far as there can be such, are strictly personal, a matter of personal passion (not mere 'preference'), and refer to an outlook on life, a way of 'existing', rather than a set of cognitive or ontological commitments.

R.C.SOL.

\*double truth.

S. Kierkegaard, *Concluding Unscientific Postscript* (1846; Princeton, NJ, 1944).

**subjectivism:** see objectivism and subjectivism.

**subjectivity.** Pertaining to the subject and his or her particular perspective, feelings, beliefs, and desires. The term pervades modern philosophy, usually contrasted with 'objectivity', but it plays various and sometimes ambiguous roles in epistemology, in contemporary Continental philosophy, and in cognitive science. In casual philosophical and other conversation, the term often refers to unargued or unjustified personal feelings and opinions as

opposed to knowledge and justified belief. In epistemology, especially since Descartes, the term is often used to refer to the realm of experience, however circumscribed and defined, and is typically defined with reference to the first-person standpoint. The project of much of modern epistemology, accordingly, has been the attempt to argue from this admittedly limited standpoint to objective knowledge, whether by ingenious deduction (Descartes), causal inference (Locke), transcendental argument (Kant), dialectical development (Hegel), or phenomenological analysis (Husserl). In recent Continental philosophy, the subject of subjectivity has been under severe scrutiny, and the very idea has been rejected by more radical recent opinion. Revolting against Jean-Paul Sartre, who followed Descartes in insisting that free subjectivity (as \*'consciousness') was the ontological essence of being human, such thinkers as Michel Foucault and Jacques Derrida have rejected the notion of 'the subject' altogether and insisted that what is mistakenly identified by that name is a 'construction' of politics, language, and culture. In cognitive science, subjectivity has been argued, e.g. by Thomas Nagel, to be the ultimate obstacle to any reduction of the mental to the physiological. Subjectivity, on this account, is phenomenological experience, or 'what it's like to be' a certain conscious being (for example, a man, a woman, or a bat), the tendency to project (and take one's own attitudes as properties of the world). The notion of subjectivity is also used, particularly in multicultural contexts, to underscore the importance of perspective, the fact that everyone sees the world from his or her (or its) individual vantage-point, defined in part by nature, by culture, and by individual experience. Philosophers have often asked, Can we 'escape' our subjectivity? But what would it mean to do so? What would it mean *not* to do so?

**sublime.** The concept of sublimity is seen by some aesthetic theorists as of only historical interest, but by others as a lastingly important mode of response to basic items of human experience. From the later seventeenth century there developed accounts of experience of objects that exceeded our perceptual and imaginative grasp, and defied neoclassical conceptions of form and \*'beauty. Although these objects were daunting and dreadful, they were nevertheless exhilarating to contemplate: Alpine crags and ravines, storms at sea, the sky at night . . . Given this duality, writers differed over the source of our resilience *vis-à-vis* such intimidating phenomena. For Kant, for example, despite the failure of imagination's synthesizing powers (we cannot *realize* the interstellar distances), our reason and our status as free moral beings

allow us to cope with the sheer magnitudes and energies of phenomenal nature and to be aware of a personal value that these do not threaten. A religious note was, and is, never very far from many accounts of sublimity: its dual quality can be analogous to experience of the divine—a *mysterium tremendum et fascinans*, as Rudolf Otto famously described it in *The Holy*.

**substance and attribute.** The idea of substance has been widely and differently used throughout the history of philosophy from the time of Greeks onward—by Plato, Aristotle, Locke, Descartes, Spinoza, Kant, and many other philosophers. What is perhaps the main distinction between substance and attribute originally gave support to the feeling that reality is independent and objective, robust and solid, that there is something out there which is abiding and remains the same in spite of varieties and changes encountered in the world. Substance was taken as the abiding and constant, while attributes and properties changed. However, if changing, the attributes and properties were objective as a result of their association with and dependence on the substance. Without an underpinning substance or substratum to which to belong, could they have reality? Originally, the distinction between substance and attribute was taken literally, but subsequent revisionism has often made it almost grammatical or functional (e.g. Leibniz, Hume).

There is indeed reason to believe that the substance–attribute distinction, like the object–property distinction, is parasitic on some other distinction. One reason is that when we see an apple, for instance, we grasp it at once as a whole object. We do not see it, as it were, compositionally, first seeing its red shape, then conjoining with this a taste, a texture, etc., and finally proceeding to unify these elements into a single apple. We do not perceptually grasp an apple through the distinction between substance and attribute. Perception seems not to be the source of the distinction.

With the imposition of the substance–attribute distinction, objects which initially were perceived as wholes now come to be analysed or restructured. The need to do so seems to be pressed upon us by various considerations. But the manner of the restructuring appears to be suggested not by reality, so to speak, but by the linguistic distinction between subject and predicate, this being the very means available to us for describing objects in their varieties and alterations. Whereas the perception of objects is as wholes, speech, on the other hand, is almost always construed from parts, and is in this sense compositional. Conceiving the unitary apple in terms of the distinction between substance and attribute or object and property

seems to be parasitic on, and a suggestion from, the linguistic distinction between subject and predicate.

Three considerations or aims have moved philosophers to engage in the restructuring of things in terms of substance and attribute. The first aim is to secure the ability to speak of similar objects whose features are nevertheless being contrasted (e.g. a green banana and a yellow banana). This aim encourages the idea of the object as comprising a thoroughly denuded substance (often called the ultimate subject of properties) on to which the attributes which it shoulders, and with respect to which object and object can be compared, are grafted. This view of things was held by John Locke, who made famous the phrase 'substance or something-I-know-not-what'. It was also formulated by Aristotle in terms of 'primary substance'. It was accepted by philosophers for centuries.

While the first aim addresses static and compositional aspects of the existence of objects, the second addresses dynamic aspects of the existence of objects, thereby involving a reference to time, as Kant noted. It secures the ability to speak of an object remaining the same yet different, invoking the idea of \*change. In this context, substance is proclaimed to be the perdurant in change, the absolutely unchanging core, the ground which enables an object to be the same in spite of the newness of its features. The third aim also involves a reference to time, and addresses intra-active and interactive aspects of the existence of objects. It imbues an object with the active power to initiate change in itself (Leibniz) or in another object (Locke and Kant) and the passive power to allow change to be initiated in it (Locke and Kant). In this sense, substance is seen as the ultimate centre of force used in grounding change-producing actions and causalities.

It is customary to think of substance and attribute in terms of ordinary things. But it needs to be noted that two sorts of primary substance have been discussed historically: material substances for the extended physical world, and spiritual substances for the non-physical, unextended world (Descartes). Spiritual or mental substances enter into the attempted solution of the mind–body problem in terms of substance \*dualism.

All of this still leaves disagreement possible over the necessity of a conception of substance. There is also the question of the precise nature of its supposed relations with the properties of an object. Why do the properties of an object hang together? How should one think of the relation between an object and its properties so that properties do not simply fall off and scatter, but are instead collected in the object? Think of the difference between a fruit with a pit (where the flesh corresponds to the properties of an object and the pit corresponds to the primary substance) and a vegetable like an onion whose layers aggregate without a supporting pit. This difference between the two is over a sort of metaphysical arithmetic: would subtracting just its properties from an object leave anything behind, the substance or something-I-know-not-what of John Locke, or would it leave absolutely nothing behind?

**substratum:** *see* substance and attribute.

**sufficient condition:** *see* necessary and sufficient condition.

**sufficient reason, principle of.** Leibniz held that the principle of sufficient reason is fundamental to all reasoning. It states, in his own words, that 'there can be found no fact that is true or existent, or any true proposition, without there being a sufficient reason for its being so and not otherwise, although we cannot know these reasons in most cases'. In short, the principle is that nothing is without a reason for its being, and for being as it is: *nihil fit sine ratione*.

Schopenhauer devoted his earliest philosophical work to discussion of the principle, which he characterized as what 'authorizes us everywhere to search for the *why*'. He rightly criticized his predecessors, Leibniz included, for misunderstanding it, chiefly by confusing the notions of *reason* and *cause*. Schopenhauer himself distinguished four distinct explanatory applications of the principle: the physical (in explaining change in the natural world), the logical (in deriving truths a priori), the mathematical (in giving geometrical demonstrations), and the moral (in explaining actions in terms of motives). This classification might be unsatisfactory, but the principle itself captures something intuitively compelling, in having it that whatever is or happens must from some point of view be finally explicable. A.C.G.

G. W. Leibniz, *The Monadology* (1714), sects. 31, 32.

A. Schopenhauer, *The Fourfold Root of the Principle of Sufficient Reason* (1813).

**Sufism.** A variety of Muslim \*mysticism characterized by the concept of a union of the human being with God through the power of love. The union was thought by many to be of the will and it was held that suffering, as well as love, was a necessary condition of the union. Its days as a major force in Islam are long since past. A.BRO.

A. J. Arberry, *Sufism* (London, 1950).

**suicide.** The most conventional definition of 'suicide' is intentionally caused self-destruction. However, several problems for this simple definition arise from sacrificial death, martyrdom that could have been avoided, actions that risk near-certain death or mutilation, refusals of medical treatment with foreknowledge of death, addiction-induced overdosing, coercion to self-caused death, and the like. Some definitions of 'suicide' have tried to take account of these cases by not requiring suicidal intent, but only foreknowledge of death or the acceptance of a risk of death. These different definitions have led to disagreements over cases—for example, whether Socrates and Samson committed suicide.

Starkly different views about the moral justifiability of suicide have also been defended in the history of philosophy. Debates traditionally centred on whether suicide violates one or more of three types of obligation: to oneself, to others, or to God. St Thomas Aquinas's arguments are typical (*Summa Theologiae* II. ii, q. 64, Art. 5):

It is altogether unlawful to kill oneself, for three reasons: [1] everything naturally keeps itself in being . . . Wherefore suicide is . . . contrary to the natural law and to charity. [2] Because . . . every man is part of the community, and . . . by killing himself he injures the community. [3] Because life is God's gift to man, and is subject to His power . . . Hence whoever takes his own life, sins against God.

In a famous rebuttal of such traditional views, David Hume identified with a handful of pre-Christian classical writers who considered suicide an honourable and sometimes praiseworthy act. An autonomous suicide, from Hume's perspective, is permissible (and on occasion laudable) if, on balance, more value is produced for the individual or more value is produced for society than would be produced by not performing the act of taking one's life ('Of Suicide', posthumous, although suppressed by Hume in 1757).

Sir William Blackstone (1723–80), codified English law by using arguments similar to Aquinas's to explain the state's right to prevent and punish suicide. Blackstone categorized suicide as 'self-murder' and a grave felony (*Blackstone's Commentaries*, ch. 14). But when laws against suicide progressively fell, Hume's theses came to prevail, both in Britain and in North America.

Philosophical controversy has recently centred on (1) \*paternalism in suicide intervention and (2) the justification of assisted suicide. Regarding (2), see the entry on euthanasia. Regarding (1), if individuals have a *right* to commit suicide, then others appear to have a correlative obligation not to intervene to prevent the suicide. Yet we often do intervene, either by reporting a suicide threat or preventing a suicide attempt. Many believe that we are justified in intervening in these ways and possibly are *obligated* to do so or at least to report suicide threats. But if there is a *right* to commit suicide, are we as justified in intervening as we commonly think? In the case of almost any similarly intrusive, liberty-limiting action, the person impeded could successfully sue those who intervene.

No one doubts that we should intervene to prevent suicide by incompetent persons. But if we accept an unrestricted, free-choice principle, the imprudent but competent suicide who would want to live under more favourable circumstances could not legitimately be prevented from committing suicide. Both law and philosophy continue to struggle with issues about the extent to which paternalism is justified in such cases, if it is. T.L.B.

John Donnelly (ed.), *Suicide: Right or Wrong?* (Buffalo, 1991).

**summum bonum:** *see* good, greatest.

**supererogation** occurs when one's action goes beyond the demands of duty. Supererogatory acts are praiseworthy to perform but not blameworthy to omit. Saintly or heroic acts are generally considered to be paradigm examples. However, some philosophers (for example, strict act-utilitarians) and theologians (for example, those who emphasize that God demands our best at every moment) hold that there is no possibility of performing good or praiseworthy actions which exceed the demands of duty, and on their view acts of supererogation are not possible.

G.F.M.

\*ideals, moral.

D. Heyd, *Supererogation* (Cambridge, 1982).

**superman** (or overman). Nietzsche's image conveying the idea of human life enhanced and transformed in a manner sufficient to render it worthy of affirmation, in contrast to all that is 'all too human' about it, dispensing with all other-worldly hopes and illusions, and overcoming all disillusionment. The apotheosis of human vitality and creativity, this image functions as a guiding idea by reference to which 'higher' and 'lower' human types can be distinguished, and as the locus of meaning ('the meaning of earth') in Nietzsche's naturalistic reassessment of this life in this world. It has élitist rather than racist overtones and implications for Nietzsche, emphasizing the importance of the respects in which human beings individually differ in their abilities, and of the manner in which their differing abilities are cultivated and employed. This reflects his fundamental conviction that what matters most, and so what is decisive with respect to human worth and 'rank' alike, is 'the enhancement of life', which he conceives above all in terms of the flourishing of cultural life. (See e.g. *Thus Spoke Zarathustra*, prologue; *The Antichrist*, sect. 4; *The Will to Power*, sect. 866.)

R.S.

\*slave morality; great-souled man.

Arthur Danto, *Nietzsche* (New York, 1965), ch. 7.

**superstructure:** *see* base and superstructure.

**supervaluation.** A method of valuation that supervenes on several different lower-order valuations. A statement is super-true (or super-false) if it is true (or false) on all admissible valuations. Otherwise it is neither super-true nor super-false. Statements in which the components have no determinate truth-value can thus themselves be super-true or super-false. 'This is a really big book, or it's not', for example, is super-true because it is true on all admissible valuations, even if 'This is a really big book' is too vague to have a single admissible precise valuation.

James D. McCawley, *Everything that Linguists have always Wanted to Know about Logic (but were Ashamed to Ask)* (Chicago, 1993).

**supervenience.** A kind of dependency relation. One set of properties is supervenient on a second set when they are so related that there could not be a difference in the first without there being a difference in the second, though there could be a difference in the second with no difference in the first. It has been argued that mental properties are supervenient upon, rather than nomically identical with or related to, physical properties.

\*psychophysical laws.

David Charles and Kathleen Lennon (eds.), *Reduction, Explanation and Realism* (Oxford, 1992).

**supposition theory.** Medieval philosophers developed supposition theory in the late twelfth century to specify the \*reference of a term in various propositional contexts. A term has personal supposition when it is used to talk about what it signifies, for example 'lion' in 'She is feeding the lion now'. A term has material supposition when it is used autonomously to talk about its inscription or utterance, as in 'Lion has four letters'. A term has formal supposition when it stands for a concept or a \*universal, as in 'Lion is a species'. The modes of personal supposition specify how many objects a term is used to talk about: either exactly one (discrete supposition) or at least one (determinate supposition); if the latter, either all instances (distributive supposition) or several (non-distributive confused supposition). Supposition theory was used to codify and explain the inferential relations among sentences. It was an important part of medieval theories of \*truth, \*quantification, \*entailment, and \*fallacy.

**survival:** *see* immortality.

**Swedish philosophy.** The history of Swedish philosophy contains few really original or pioneering achievements. To a large extent it has mirrored the general philosophical development of Europe, though in a way that has been marked by national prejudices and national concerns.

It was Christianity that first brought Sweden into contact with the higher European culture. In the later Middle Ages we find Swedish scholars who had studied at Italian or French universities and were familiar with the best contemporary culture. Perhaps the most important figure was Matthias Ovidi (d. 1350). He was the confessor of St Bridget but also a learned philosopher and theologian. His commentary on the Book of Revelation (*Expositio super Apocalypsin*) was studied all over Europe.

When Sweden became a great power in the seventeenth century it became more interesting to the philosophers of Europe. René Descartes went to Stockholm to give lessons to Queen Christina—and to die. Samuel Pufendorf became professor at the newly founded university of Lund (1668). And Swedes began to take a keener

interest in philosophy. The heavy hand of Lutheran orthodoxy lay over all intellectual life in Sweden, so out of necessity philosophical questions also became theological ones. The adherents of Aristotle fought a bitter battle with the adherents of Peter Ramus. The main question was which philosophy would best serve the purposes of theology. When the new philosophy of Descartes reached the Swedish universities it was at once suspected of theological heresy. Indeed \*Cartesianism was officially condemned by Charles XI in a decree of 1689. Perhaps the suspected role of Descartes in converting Queen Christina to Catholicism had some part in the prejudice against Cartesianism.

The most original philosopher and one of the most fascinating personages of the Swedish seventeenth century was George Stiernhielm (1598–1672). His unfinished work *Monile Minervae* (The Necklace of Minerva) contained the fragments of his philosophy, where hermetic \*mysticism was mingled with Neoplatonic \*humanism. His theory of language stressed the non-arbitrary nature of words. According to Stiernhielm etymology is the key to deep insights into the essence of things.

At the end of Sweden's period as a great power there appeared another mystic and philosopher who was destined to fame. Emanuel Swedenborg (1688–1772) began his career as a natural scientist, but was later captivated by theology and religious speculation. Swedenborg's visions from the world of the spirits were scornfully dismissed by Kant as *Träume eines Geistesehers* ('dreams of a spirit-seer'). But to the philosophers of the Romanticism Swedenborg was an inspired genius. He was not typical of Swedish eighteenth-century philosophy, however. The philosophy taught at the universities was sterner and drier. The arid rationalism of Christian Wolff for a long time held academic philosophy in its thrall. Later the empiricism of Locke and Hume found some adherents.

The era of Romantic idealism was pioneered by the Uppsala philosopher Benjamin Höijer (1767–1812). Höijer was influenced by Kant and Fichte, but developed their ideas in an original way. His *Ahandling om den filosofiska konstruktionen* (Dissertation on Philosophical Construction, 1799), anticipated some of Schelling's theories. It was also favourably reviewed by the German philosopher. At the same time its emphasis on the liberty of the thought and the activity of the spirit was regarded with suspicion by the authorities. Höijer's academic career was for a long time held in suspense. His importance to the Swedish philosophy of the next century was nevertheless immense. The transcendental idealism that Höijer had introduced held the stage for more than a hundred years.

The dominant Swedish philosopher of the nineteenth century was Christoffer Jacob Boström (1797–1866), who was professor at the university of Uppsala. Boström has been described variously as 'the Plato of the North' and as 'the Swedish Hegel'. His sternly rational \*idealism made no concessions to empirical reality—material things didn't exist. According to Boström true reality was

identical with God and his ideas. Boström worked out his metaphysical system in great detail. It proved to have important implications for every sphere of human life, not least the political one, where Boström's conclusions were strictly conservative. Boström had many clever disciples. In fact 'Boströmianism' dominated Swedish academic philosophy until the turn of the century.

During the first part of the twentieth century Swedish philosophy was torn between rival schools. Particularly important was the feud fought between the Uppsala philosophy of Axel Hägerström (1868–1939) and the Lund philosophy of Hans Larsson (1862–1944). Hägerström was famous for his \*emotive theory of ethics. He denied the possibility of practical knowledge and the existence of objective values. According to him values were just projections of emotional attitudes. Ethical propositions were said to be neither true nor false, being in fact just noises indicative of certain emotional states.

Larsson, on the other hand, upheld the \*objectivity of values. But his most important contribution to philosophy lay in the field of aesthetics. His book *Poesiens logik* (The Logic of Poetry, 1899), was intended to show that logical reasoning and poetic intuition are compatible and indeed complementary.

After 1945 the strong German influence on Swedish philosophy was broken and was replaced by an Anglo-Saxon one. Swedish philosophers began to call themselves 'analytical philosophers'. Among the most influential philosophers of the first post-war generation were Ingemar Hedenius and Anders Wedberg.

Ingemar Hedenius (1908–82) became the best-known philosopher of his generation through his book *Tro och vetande* (Belief and Knowledge, 1949). The book contained a savage attack on Christian dogma and on contemporary Swedish theology. Hedenius formulated a 'maxim for intellectual morality' (to some extent inspired by Russell), saying that you should only believe what there are rational grounds for believing. As Christian belief is muddled, contradictory, and incompatible with modern science, it has to be rejected. Some theologians argued that religious faith is atheoretical and does not aspire to say something that is true or false. Hedenius rejected this view and tried to show that Christianity is indeed making statements about reality and is thus open to philosophical or scientific refutation.

Anders Wedberg (1913–78) is best known for his work on the history of philosophy. His *Plato's Philosophy of Mathematics* (1955) is still useful. But his most ambitious work in the field was his *Filosofins historia*, i–iii (1958–66, translated into English as *A History of Philosophy* (1982–4)). Wedberg's aim was to write the history of philosophy in a new way. He carefully distinguished the philosophical way of writing history of philosophy (which he chose) from the historical way (which he left to others). The philosophical way of doing history of philosophy was to treat the philosophers of the past as contemporaries, to look out for what might still be interesting in their theories from a philosophical point of view, and to interpret them

in a way that would make their arguments as coherent and as plausible as possible, as seen by a modern analytical philosopher. This should be done, Wedberg argued, even at the price of the occasional anachronism.

Nowadays Swedish philosophers to a large extent publish their results in English. Logic, decision theory, and applied ethics are among the areas where Swedish philosophers have been particularly successful in recent decades.

\*Danish philosophy; Norwegian philosophy.

R. E. Olson, and A. M. Paul, *Contemporary Philosophy in Scandinavia* (Baltimore, 1972).

**Swinburne, Richard** (1934– ). Nolloth Professor of the Philosophy of the Christian Religion at Oxford from 1985 to 2002. His chief contribution has been to philosophical theology. Perhaps his most interesting achievement is a rigorous formulation of a cumulative case for \*God's existence. In *The Existence of God* (1979), he used Bayesian reasoning to argue that the probability of theism is raised by such things as the existence of the universe, its order, the existence of consciousness, human opportunities to do good, the pattern of history, evidence of miracles, and religious experience. He also argues that the existence of \*evil does not count against the existence of God. His conclusion is that on our total evidence theism is more probable than not. Swinburne's more recent investigations have focused on distinctively Christian doctrines such as sin and atonement, sanctification, and revelation. He has also contributed to philosophy of science through work on confirmation and on space and time.

**syllogism.** Originally defined by Aristotle as 'discourse in which, certain things being posited, something else necessarily follows', it came to have the narrower meaning typified by 'All men are mortal; Greeks are men; therefore Greeks are mortal'. Until the revolution in logic in the late nineteenth and early twentieth centuries, most logicians regarded four types of 'categorical' proposition as lying at the heart of proper reasoning: 'All *S* are *P*', 'No *S* are *P*', 'Some *S* are *P*', and 'Some *S* are not *P*'. A syllogism is an inference made up of three propositions of these types. Propositions not obviously of these forms (e.g. singulars like 'Socrates is a man') were generally regarded as mere variants on them, just as apparently non-syllogistic inferences were analysed, and sometimes distorted, to fit the orthodox structure. A syllogism may be defined as a piece of reasoning analysable into:

1. three categorical propositions such that the third (the *conclusion*) is presented as following from the first two (the *premisses*), and
2. three terms such that one of them (the *middle term*) is common to the premisses, the second is common to

the conclusion and one of the premisses, and the third is common to the conclusion and the other premiss.

The first term (the *subject*) of the conclusion is called the *minor term*, the premiss containing it the *minor premiss*; and the second term (the *predicate*) of the conclusion is called the *major term*, the premiss containing it the *major premiss*.

Inferences like 'All men are mortal; all Greeks are men; all Athenians are Greeks; therefore all Athenians are mortal' were called *polysyllogisms*. Polysyllogisms contain more than two premisses but are analysable into a sequence of two or more conventional syllogisms.

Syllogisms were classified according to their *figure* and *mood*, and various rules were invoked to distinguish between valid and invalid forms.

\*logic, traditional.

I. M. Bochenski, *Ancient Formal Logic* (Amsterdam, 1951), 36–54.

W. D. Ross (ed.), *Aristotle's Prior and Posterior Analytics* (Oxford, 1949).

**symbol:** see sign and symbol.

**symbolic logic:** see logic, formal or symbolic.

**symbols, logical:** see Appendix on logical symbols; notations, logical.

**symmetric relation.** A binary, i.e. two-term, \*relation is symmetric, or symmetrical, when it holds both ways if at all, i.e. if it holds from *x* to *y*, it holds from *y* to *x* (in symbols, *R* is symmetric if and only if  $\forall x \forall y (Rxy \rightarrow Ryx)$ ); for example, *living with*. 'Asymmetric' means: if it holds from *x* to *y*, it does not hold from *y* to *x*; for example, *being half of*. 'Non-symmetric' may mean either 'not symmetric' or 'neither symmetric nor asymmetric'.

C.A.K.

W. Hodges, *Logic* (Harmondsworth, 1977).

**sympathy.** (a) Emotional affinity between two or more persons similarly affected by a given circumstance or (b) disorder occasioned in one living entity by the disorder of another. In moral philosophy, (b) is developed by Hume to provide a quasi-mechanical psychological explanation of why the well-being or misery of one person is of concern to others. Adam Smith takes Hume's ideas further in his *Theory of Moral Sentiments* (1759), in which sympathy is the analogous feeling that is experienced by the impartial observer at the *thought* of the situation of the other person.

J.C.A.G.

Philip Mercer, *Sympathy and Ethics* (Oxford, 1972).

**syncategorematic.** Literally, what is predicated together with (sc. some other predicate). So traditional logic defined as syncategorematic a word that converts one or more simple predicates into what was thought to be a complex predicate, as in 'no man', 'white and shiny'. The word now has no technical utility, but is sometimes

applied to logical \*constants or other \*topic-neutral expressions, such as 'not', 'every', 'if', 'is', 'was', 'must', 'the'.

**syndicalism.** Late nineteenth- and twentieth-century revolutionary movement among industrial workers aiming at transferring ownership and control of the means of production and distribution from the capitalist class to unions of workers (*syndicats*) by means of strikes. Syndicalism traditionally marched with \*anarchism to produce anarcho-syndicalism. \*Sorel misappropriated this term for his quasi-fascist theory of action through irrational \*violence, but mainstream syndicalism continued as a radical-left workers' movement.

A.BEL.

\*worker control.

Rudolf Rocker, *Anarcho-Syndicalism* (London, 1938).

**synonymy.** Identity of \*meaning. Different occurrences of the same expression (e.g. word, phrase, sentence) are all synonymous unless the expression has more than one meaning. Occurrences of different expressions, in the same or different languages, may also be synonymous: e.g. 'bucket' with 'pail', 'j'ai froid' with 'I am cold', 'gift' with some occurrences of 'present'. Expressions that *apply* in some situation to the same thing or things need not be synonymous: e.g. 'I' and 'you' when the former is said by, and the latter to, someone, or 'boiled water' and 'pure water' when boiling and nothing else purifies. Conversely, in some situations synonymous expressions are forced to apply to different things: e.g. 'I' said by different speakers. The view sometimes held that synonymy of expressions is the same as necessary identity of application seems incorrect.

s.w.

B. Mates, *Synonymy*, University of California Publications in Philosophy (Berkeley, Calif., 1950), repr. in L. Linsky (ed.), *Semantics and the Philosophy of Language* (Urbana, Ill., 1952).

**syntactics.** The study of syntax, i.e. of the kinds of expression in a language, and the rules which govern how they combine together. In developing modern logic, Frege suggested a theory of syntactic categories which is also applicable to natural languages. In Ajdukiewicz's notation, the two basic categories are sentences (S), and singular terms (N); from any categories A and B we can form the new category A/B, containing all those expressions which can be combined with Bs to form As.

**synthetic a priori judgements.** The classification 'synthetic a priori' applied to judgements, or to true judgements, owes its origin to Kant's *Critique of Pure Reason* (Introduction, B 1–19). It is a hybrid form constructed from the separate distinctions between analytic–synthetic and a posteriori–a priori truth. Kant held that we were able to know some truths a priori rather than a posteriori, independently of sense-experience, such as mathematical truths, and that there was a separate contrast to be drawn between analytic and synthetic truths. Analytic truths involved judgements in which the predicate was semantically contained in the subject-term or alternatively those whose denial yielded a contradiction. With these separate classifications four hybrid forms can be theoretically constructed, although Kant believed that one (analytic a posteriori) was impossible and two others (synthetic a posteriori and analytic a priori) were uninteresting standard cases. The remaining hybrid, synthetic a priori truth, was an important innovation, but both controversial and variously understood. For the Logical Positivists the classification was contradictory, since they treated the two basic classifications as equivalent; for Quineans the classification was flawed since the analytic–synthetic distinction was ambiguous and rested on an unelucidated notion of 'semantic containment'. More recently Kripke's separate classifications of necessary–contingent and a priori–a posteriori truth, and the resulting hybrids necessary a posteriori and contingent a priori truth, have been thought to parallel Kant's innovation. Kripke shares with Kant the idea that one of the basic classifications (analytic–synthetic) is semantic, or logical, while the other (a posteriori–a priori) is epistemic, but their conception of the resulting hybrids is not the same. Kant's case for the existence of synthetic a priori truth rests essentially on the idea that not all a priori truths owe their status to their analytic character. If it is allowed that a priori truth is not necessarily analytic, then some room is available for synthetic a priori truth.

# T

**tabula rasa.** A phrase (meaning blank writing-tablet) from the Latin translation of Aristotle's *De anima* (430<sup>a</sup>). It does *not* occur in Locke's *Essay* (1690), though it is present in Pierre Coste's French translation (1700). The *Essay*, in its statement of the empiricist thesis that there is nothing in the mind that was not previously in the senses, speaks rather of the mind at birth as 'white paper' (ii. i. 2), awaiting ideas from experience.

R.S.W.

\*empiricism.

R. I. Aaron, *John Locke*, 3rd edn. (Oxford, 1971), 32, 35, 114.

**tacit knowledge.** Thinkers often perform complex rule-governed tasks even though they have no conscious or explicit knowledge of the rules involved. To explain these capacities, philosophers and psychologists have supposed that thinkers have unconscious or tacit knowledge of the rules for executing the tasks. A prominent example is speakers' ability to produce and understand indefinitely many grammatical sentences of their language even though they cannot state the rules of grammar they conform to. To credit speakers with tacit knowledge of grammar is to suppose they have information-bearing states of mind—inaccessible to consciousness—that encode the rules of their language and enable speakers to produce and comprehend grammatical speech. To say that thinkers are able to perform tasks described by a theory because they tacitly know the theory is to say that they encode the information recorded by the theory but not necessarily in the form in which the theory represents it.

**Tagore, Rabindranath** (1861–1941). Poet, novelist, playwright, literary critic, painter, composer, and educationist. He won the Nobel Prize for literature, and refused a knighthood. Although he deeply influenced the Indian nationalist movement, he himself embraced a humanist inter-nationalism. This \*humanism also coloured his metaphysics, in which the universal I of the human enjoyer bestows beauty and hence truth on an otherwise valueless universe. The Absolute Person who craves for the love of a human other remains unknown like the protagonist of *King of the Dark Chamber* (Tagore's play which

Wittgenstein retranslated). Apart from love of nature and humanity, the highest religion of man, according to Tagore, is to try to enhance our creativity, which is 'the surplus in man' allowing us an occasional glimpse of the deeper truth that 'each of us is King, in our King's Kingdom'. Thus, we can communicate with God, the cosmic artist, only through our individual artistic freedom. A.C.

Rabindranath Tagore, *The Religion of Man* (London, 1988).

**Tanabe Hajime** (1885–1962). Widely regarded as Japan's next greatest thinker after Nishida, Tanabe is remarkable for the immense compass of his thought, which ranges from the philosophy of science and mathematics, through the philosophy of history, to major works dealing with ideas from Shin Buddhism and Christianity. Having studied with Husserl and Heidegger in the mid-1920s, Tanabe became increasingly influenced by Hegel and Kant; and during the 1930s he developed a 'logic of species' (*shu no ronri*), which emphasized the role of the nation (as species) as mediating between humankind (as genus) and the historical individual. Increasingly concerned with philosophy of religion, Tanabe wrote towards the end of the Second World War his major work, *Philosophy as Metanoetics*, in which he presented a 'philosophy without philosophy' based on the phenomenon of 'repentance' (*zange*) and a way of thinking purged of the nationalistic elements that he felt had vitiated the logic of species.

**Tantra.** Ancient and medieval Sanskrit texts containing somewhat unorthodox guidelines, followed by Hindus, Buddhists, and Jains, for rituals, meditation, and life-orientation. The Tantras are deeply monistic and idealistic in spite of positing numerous female and male deities as immediate objects of worship. Some celebrate the body, esoteric geometric patterns, and sexuality as instrumental to spiritual transcendence. Elaborating a transformationist account of \*causality, tantra identifies the cosmic knowing-wishing-acting power which has become the universe with the energy that lies latent in the human

body. This feminine power is represented as a coiled snake at the base of the spinal cord—waiting, as it were, to be woken up and eventually united with the Supreme Male Spirit in the cortex. The task is to *recognize* oneself as identical with this pulsating all-pervasive World-spirit. This recognition-philosophy was developed into a full-fledged metaphysics and epistemology by the great aesthete of Kashmir Abhinavagupta (AD 980). A.C.

\*Indian philosophy; Buddhist philosophy.

**tao:** see Confucianism.

**Taoism.** Major school of thought in China which has been influential on various aspects of Chinese culture, such as art, literature, and religion. The two best-known Taoist texts are the *Chuang Tzū* and the *Lao Tzū*, both probably composite and compiled in the fourth and third century BC. Other texts traditionally regarded as Taoist include the syncretic *Huai Nan Tzū*, composed in the second century BC, and the *Lieh Tzū*, compiled in the second or third century AD. Taoist thought further developed in the third and fourth century AD, such development being often referred to as neo-Taoism. Better-known texts of the period include Wang Pi's (226–49) commentary on the *Lao Tzū*, and Kuo Hsiang's (d. 312) commentary on the *Chuang Tzū*, which either borrowed from or built on a commentary by Hsiang Hsiu (fl. 250). Development of Taoist ideas in this period subsequently exerted influence on the Chinese interpretation of Buddhism as well as on the later development of Confucian thought.

A basic tenet of Taoist thought is that the operation of the human world should ideally be continuous with that of the natural order, and that one should restore the continuity by freeing the self from the restrictive influence of social norms, moral precepts, and worldly goals. The Taoist ideal is often characterized in terms of *wu wei* (non-action, not-doing); the *Chuang Tzū* presents it as involving one's responding spontaneously to situations with no preconceived goals or preconceptions of what is proper, while the *Lao Tzū* presents it as involving few desires and absence of striving after worldly goals. The actual way of life involved is subject to different interpretations. For example, some scholars interpret the *Chuang Tzū* as advocating a withdrawal from social life, while others interpret it as advocating a relaxation of concern which is compatible with ordinary social activities. Subsequent developments of Taoist thought likewise took different directions. For example, while some Taoist thinkers of the third century AD advocated a life of disregard for established social conventions and values, others such as Wang Pi and Kuo Hsiang regarded the Taoist ideal as compatible with ordinary ways of life, including social and political participation. For Kuo Hsiang, the Taoist ideal is, for certain individuals, even compatible with their being sages in some more ordinary sense, such as that advocated by the Confucians—it is in the nature of some (but not all) to become such sages.

Taoist thought also has implications for politics. *Wu wei* can characterize the ideal form of government, which does not teach or impose on the people standards of behaviour, including those of conventional morality, and which provides conditions making possible their functioning in a way continuous with the natural order. With regard to the relation between states, the *Lao Tzū* regards non-contention as enabling a state to outlast competitors. There is also a metaphysical dimension to Taoist thought. For example, the *Lao Tzū* portrays *tao* (the Way) as a metaphysical entity which is the source of all things and which is characterized by *wu* (non-being, vacuity), an idea further developed in Wang Pi's commentary. According to Wang Pi, *tao* is the ultimate reality which transcends all distinctions and conceptualizations. Its substance is *wu* and its function *wu-wei*; that is, it does not create or do anything, but just lets things follow their natural course. Similarly, the sage has *wu* as substance and *wu-wei* as function in that he has eliminated all attachments of the self and just lets everything follow its natural course, without devising and imposing a way of life on himself or others.

**Tarot.** The Tarot pack, in its original form, was invented in the early fifteenth century, at the Court either of Milan or of Ferrara. It consists of seventy-eight cards, being essentially an ordinary pack of cards (save for having four instead of three court-cards in each suit) to which twenty-two additional picture-cards, not belonging to any of the four suits, have been added; the suit-signs are those then ordinarily used in Italy, and still used in many parts of it, for ordinary playing-cards. The only use for these cards recorded before the eighteenth century was to play a particular type of card-game, still played in numerous versions in many parts of Europe: one of the picture-cards, the Fool, or Matto, is a kind of wild card, and the remaining ones, which form a sequence and depict standard subjects such as Love, the Devil, the Star, and so forth, are permanent trumps. In 1781 Antoine Court de Gébelin propounded the theory that the cards had been invented by ancient Egyptian priests as a symbolic expression of their beliefs; the theory was rapidly exploited by professional fortune-tellers. In the mid-nineteenth century the French writer Éliphas Lévi incorporated 'the Tarot' into his cloudy brand of occultist doctrine, principally by entwining its images with the Kabbalah, with which they had in origin had nothing to do. In the last twelve years of the nineteenth century these ideas were taken up in Britain, and in the early years of the twentieth century spread throughout the world. M.D.

**Tarski, Alfred** (1902–83). Tarski was born in Poland, and taught mathematics at the University of Warsaw until he emigrated to the United States in 1939. Appointed Professor of Mathematics at the University of California at Berkeley in 1946, he made important contributions to the subject. It is for his work in logic that he is best known to philosophers, for it established the foundations of modern logical theory.

The seminal ideas appear in an early paper (tr. as 'The Concept of Truth in Formalized Languages' (1935), repr. in *Logic, Semantics, and Metamathematics*), whose goal was a definition of truth for sentences, in a way that both ensures satisfaction of the schema of type *T* (\*'snow is white') and avoids the \*liar paradox. In this paper Tarski distinguishes between a formalized language *L*, on the one hand, whose sentences meet a purely syntactical criterion of well-formedness, and an *interpretation*  $\mathfrak{I}$  of *L*, a structure consisting of domains of individuals and predicates and relations defined in these domains, on the other. The domains supply the values of variables of appropriate type in the language, and the predicates and relations of  $\mathfrak{I}$  are correlated with predicate and relation symbols of *L*. A general characterization of \*truth in  $\mathfrak{I}$  for sentences of *L* can then be specified in terms of the inductively defined relation of \*satisfaction. Tarski showed also that this definition could not be carried out in *L* itself, but required the resources of a richer metalanguage (Tarski's theorem).

If each of a set *Q* of sentences of *L* is true in  $\mathfrak{I}$ ,  $\mathfrak{I}$  is said to be a *model* of *Q*. In his 1936 paper 'On the Concept of Logical Consequence' (reprinted in *Logic, Semantics, and Metamathematics*), Tarski founded what quickly became the accepted theory of logical consequence on the model concept: a sentence *s* is a consequence of a set *P* of premisses just in case, when both are formalized, every model of *P* is a model of  $\{s\}$ . Such has been the comprehensiveness of the Tarskian revolution in logic that only recently have dissenting voices been raised (for example, Etchemendy, *The Concept of Logical Consequence*). C.H.

\*semantic theory of truth.

**tar-water.** Made by stirring together tar and cold water, and drawing off the impregnated water after the solid residues have settled. Advocated by Berkeley in his strange work *Siris: A Chain of Philosophical Reflexions and Inquiries* (1744) for its 'extraordinary virtues' as an all-purpose medicine. His enthusiasm, though excessive, was widely shared in the later eighteenth century and, as a mild antiseptic, tar-water was probably not entirely useless. G.J.W.

A. A. Luce, *The Life of George Berkeley* (London, 1949), 196–206.

**taste.** The appreciative \*sensitivity of observers who experience delight when disinterestedly contemplating certain

natural and artefactual objects ranging from meteoroid showers over Death Valley to performances of *Der Rosenkavalier*. This concept evolved from Dominique Bouhours's use of 'la délicatesse' in 1687 to mark the importance of emotion in aesthetic appreciation and the ultimacy of individual response over classical canons of correctness. In England, taste was first modelled as a quasi-perceptual inner sense of beauty not involving judgement (Hutcheson). Hume expected standards to be established by isolating features which pleased most serene, experienced observers. Kant argued that taste judgements were subjective and universally valid. In the twentieth century taste was redefined by some as a discriminatory sensitivity to aesthetic qualities of artworks by insightful percipients. The correct perception is triggered by knowledge of history, biography, intention (Croce), or boosted by use of simile and metaphor like 'His canvasses are fires, they crackle, burn, and blaze' (Frank Sibley). B.T.

Harold Osborne, *Aesthetics and Art Theory* (New York, 1970).

**tautology.** A \*well-formed formula  $\phi$  of the \*propositional calculus is a tautology if the formula is true whatever truth-values are assigned to its basic (atomic) propositional components. This can be determined by \*truth-tables. (\*Decision procedure.) Tautologies in the predicate calculus can be determined by treating quantified formulae as if they were basic components of well-formed formulae and testing for tautologousness. For example,

$$((x)Fx \vee \sim(x)Fx)$$

is a tautology, corresponding as it does to  $(P \vee \sim P)$ , whereas

$$((x)Fx \vee (x)\sim Fx)$$

is not a tautology.

In an earlier use, the entire set of logically valid propositions or analytic truths were sometimes designated as tautologies.

On still another use, the theorems of the propositional calculus

$$\phi \equiv (\phi \vee \phi)$$

$$\phi \equiv (\phi \cdot \phi)$$

are sometimes described as principles of tautology. R.B.M.

**Taylor, Charles** (1931– ). Canadian philosopher and political theorist (primarily at Oxford and McGill) whose writing includes a critique of behaviourism in psychology (*The Explanation of Behaviour* (1964)), work in and about political science, and support for the general view that the methodology of natural science and that of \*social science (the latter centring on interpretation) differ fundamentally. He has defended positive freedom, contributed to theory of responsibility, and written on Hegel. Though not reducible to one theme, Taylor's work often criticizes

\*naturalism'. His active as well as scholarly engagement with politics is evident in his life and writings. Most recently, he has produced a major volume on modernity (*Sources of the Self*), in which the self is conceived as constituted by a relation to the good; an essay on 'multiculturalism'; and *The Ethics of Authenticity*, readily accessible but also of scholarly interest. E.T.S.

Charles Taylor, *Sources of the Self* (Cambridge, Mass., 1989).  
—*The Ethics of Authenticity* (Cambridge, Mass., 1992).

**Taylor, Richard** (1919–2003). Taylor, an American philosopher who held professorships at Brown and Columbia, was among those who saw common sense as the basis for reasoning. He was particularly known for his well-written prose, shrewd dialectics, iconoclasm and, especially in his later writings, advocacy of \*wisdom over mere learnedness. Among his main works are *Action and Purpose* (Englewood Cliffs, NJ, 1966), *Metaphysics* (4th edn., Englewood Cliffs, NJ, 1992), *Good and Evil* (Buffalo, NY, 1970), and *With Heart and Mind* (New York, 1973).

To illustrate Taylor's approach, common-sense yields that it is up to us what we do *and* that every event is caused. These apparently conflicting claims are reconciled by saying that a person is an agent, a substantial self, and not a bundle of events (as Hume thought); and agency is outside the scope of the claim that all events are caused. This approach to the conundrum of \*free will, however, faces serious challenges in specifying the nature of an agent and in explaining how an agent can be influenced by external events without being caused to act. **te** : see Confucianism.

**teaching and indoctrinating.** Indoctrination is the teaching of what is known to be false as true, or more widely the teaching of what is believed true in such a way as to preclude critical inquiry on the part of learners.

Teachers are thus in a strong position to indoctrinate, as their pupils are usually in no position to judge the truth or reasonableness of what they are being taught. While in the *Republic* Plato advised the guardians to teach the people a \*'noble lie' to get them to accept their station in life, few teachers actually teach things they believe untrue or unfounded. Although non-believers often accuse Catholic teachers of indoctrinating because they teach Catholic dogma as true, they are not guilty of Platonic insincerity. They might, though, be teaching in such a way as to preclude inquiry on the part of pupils. To avoid indoctrinating, teachers must ensure that at some stage in a course of study pupils will hear competing points of view on disputed questions. Judgement, though, will still be required as to just which questions are really disputed, which points of view are worth considering, and when young pupils are ready to consider alternatives without becoming utterly confused. A.O'H.

I. A. Snook (ed.), *Concepts of Indoctrination* (London, 1972).

**teaching philosophy.** Teachers teach two things: what the results of inquiry are, and how to get more of them. Teachers of \*philosophy want to find and pass on philosophical truths and, more importantly, the knack of both getting them and distinguishing them from competitors such as nonsense and falsehood. Two near-paradoxes result.

Philosophical results are important, and philosophers typically have firm and, they hope, well-thought-out views on philosophical issues. But they want students to acquire the ability to form justified beliefs for themselves, even if the cost is occasionally going astray. So good philosophers typically do not mind students rejecting their beliefs; indeed they positively welcome it, as long as the disagreement is well supported. As all good teachers know, this feature of the pedagogical process makes certain students very nervous. Actually, as all good students know, it also makes certain teachers very nervous.

The second semi-paradox concerns the tension between what is taught and the way it is taught. Philosophers emphasize \*rational persuasion, rational discourse, and rational examination. As Robert Boyle said, 'Philosophy, when it deserves that name, is but Reason, improv'd by Study, Learning, and the use of things.' However, the way in which the importance of rational persuasion is instilled may have very little to do with rational persuasion. Humour, irony, analogy, intonation, sentence structure, allusion, arguments *ad hominem* and from authority, the perceived enthusiasm and confidence of the speaker, the amount of self-motivation required of the student, and a host of other factors, including even the very order in which opposing views are presented, all affect the likelihood of students' accepting or even comprehending the points presented. Even intellectually extraneous factors such as the room's light or the presence of moving air affect uptake and acceptance. Preaching the primacy of reason involves a host of non-rational methods.

Plato believed that philosophy could only be taught soul to soul, and encounters in small groups provide the best way to convey both the excitement involved in, and the abilities required for, the practice of philosophy. In such settings, the student can try out ideas *en route* to truth which will then be subjected to detailed constructive scrutiny by herself, her teachers, and her peers.

However, the realities of teaching often make this wildly utopian. It is difficult for soul to speak to soul when the souls are clustered in groups of up to 300. What one politician has called 'negative increases' in educational funding, and the consequent deterioration in the educational process, ensure that the Platonic ideal is seldom realized before the graduate stage. (Detailed discussions concerning real-world teaching are offered quarterly in *Teaching Philosophy*. Also of interest is *Thinking*, a journal concerned with philosophy for children.)

Plato also believed that students need a rigorous educational background for philosophy: something contemporary educational systems find difficulty in providing. Many first-year university students do not know so much

as the *names* of Archimedes or Newton. However, such gaps can be filled, and many universities offer general introductory courses to attempt just that. More pernicious is the deliberate inculcation of irrationality. Unsure of how to cope with multiculturalism, many teachers and too many academics retreat into the relativism they confuse with tolerance. Schools now turn out a host of contemporary Averroists, prepared to say straightfacedly, 'Well, it's true for you, but not for me.' Thus, in addition to the more or less standard familiarly inspired religious, political, and moral prejudices, contemporary education adds another, moral and epistemological relativism, impressed in the schools, and reinforced by a number of non-philosophical disciplines, which the working philosopher is called upon to remove before the real business of education can begin. J.J.M.

**technology:** see Frankfurt School.

**teleological argument for the existence of God.** A world-based line of argument appealing to special features, those aspects of the world which appear to be designed and purposive, analogous to cases of human design. It is usually put probabilistically, arguing that the most plausible explanation is that of a world designer and creator, with intelligence, purposes, etc.

The theory of \*evolution, suggesting an alternative explanation for some kinds of order, has sapped some of the persuasiveness of older versions, and has incited the formulation of more broadly based versions of this argument, such as those of F. R. Tennant and Richard Swinburne. G.I.M.

David Hume, *Dialogues Concerning Natural Religion* (1777).

Richard Swinburne, *The Existence of God* (Oxford, 1979).

F. R. Tennant, *Philosophical Theology* (Cambridge, 1968).

**teleological explanation.** From the Greek word for goal, task, completion, or perfection. Teleological explanations attempt to account for things and features by appeal to their contribution to optimal states, or the normal functioning, or the attainment of goals, of wholes or systems they belong to. Socrates' story (in Plato's *Phaedo*) of how he wanted to understand things in terms of what is best is an early discussion of teleology. Another is Aristotle's discussion of 'final cause' explanations in terms of that for the sake of which something is, acts, or is acted upon. Such explanations are parodied in Voltaire's *Candide*.

There are many cases in which an item's contribution to a desirable result does not explain its occurrence. For example, what spring rain does for crops does not explain why it rains in the spring. But suppose we discovered that some object's features were designed and maintained by

an intelligent creator to enable it to accomplish some purpose. Then an understanding of a feature's contribution to that purpose could help us explain its presence without mistakenly assuming that everything is as it is because of the effects it causes. There are many things (e.g. well-designed clocks in good working order) known to have been produced by intelligent manufacturers for well-understood purposes, whose features can, therefore, be explained in this way. But if all teleological explanation presupposes intelligent design, only creationists could accept teleological explanations of natural things, and only conspiracy theorists could accept teleological explanations of economic and social phenomena.

Teleological explanations which do not presuppose that what is to be explained is the work of an intelligent agent are to be found in biology, economics, and elsewhere. Their justification typically involves two components: an analysis of the function of the item to be explained and an aetiological account.

Functional analysis seeks to determine what contribution the item to be explained makes to some main activity, to the proper functioning, or to the well-being or preservation, of the organism, object, or system it belongs to. For example, given what is known about the contribution of normal blood circulation to the main activities and the well-being of animals with hearts, the structure and behaviour of the heart lead physiologists to identify its function with its contribution to circulation. Given the function of part of an organism, the function of a subpart (e.g. some nerve-ending in the heart) can be identified with its contribution—if any—to the function of the part (e.g. stimulating heart contractions). Important empirical problems in biology and the \*social sciences and equally important conceptual problems in the philosophy of science arise from questions about the evaluation of ascriptions of purposes and functions.

Functional analysis cannot explain a feature's presence without an aetiological account which explains how the feature came to be where we find it. In natural-selection explanations, aetiological accounts typically appeal to (a) genetic transmission mechanisms by which features are passed from one generation to the next and (b) selection mechanisms (e.g. environmental pressures) because of which organisms with the feature to be explained have a better chance to reproduce than organisms which lack it. The justification of teleological explanations in socio-biology, anthropology, economics, and elsewhere typically assumes the possibility of finding accounts of transmission and selection mechanisms roughly analogous to (a) and (b). **tender- and tough-minded.** 'The history of philosophy is to a great extent that of a certain clash of human temperaments', said William James in *Pragmatism* (1907), listing typifying characteristics of each as below. An almost perfect example of the second is A. J. Ayer; pure forms of the first are scarcer.

<i>The tender-minded</i>	<i>The tough-minded</i>
Rationalistic	Empiricist
(going by 'principles')	(going by 'facts')
Intellectualistic	Sensationalistic
Idealistic	Materialistic
Optimistic	Pessimistic
Religious	Irreligious
Free-willist	Fatalistic
Monistic	Pluralistic
Dogmatical	Sceptical

T.L.S.S.

T. L. S. Sprigge, 'A. J. Ayer: An Appreciation of his Philosophy', *Utilitas* (1990).

**tense.** Grammatically, tense is a feature of verbs, exemplified by the past, present, and future forms 'he went', 'he is going', and 'he will go'. Philosophers think of tense in broader terms, to include any kind of temporal expression whose reference is dependent on its time of utterance, such as 'yesterday', 'now', or 'next week'. Thus, 'yesterday' refers to the day before the one on which it is uttered. The truth-values of tensed sentences can change over time: on one day it may be true to say 'Yesterday it rained', while on the next day it may be false to say this. Adherents of tensed theories of \*time hold that tensed sentences are made true by tensed \*facts, and that facts change as time passes, whereas adherents of tenseless theories of time hold that tensed sentences are made true by unchanging, tenseless facts. For the tenseless theorist, tense is merely a feature of our language or thought about the world, not a feature of temporal reality itself. E.J.L.

D. H. Mellor, *Real Time*, 2nd edn. (London, 1998).

**term.** A word or phrase denoting an individual or class, or the propositional component it expresses. Thus 'John is a man' contains two terms, 'John' and 'man' (or 'is a man'), denoting John and the set of men respectively. More generally, any word or phrase that determines the proposition expressed. In this sense, the above sentence contains the \*syncategorematic term 'is', which does not denote an individual or class. W.A.D.

H. W. B. Joseph, *An Introduction to Logic* (Oxford, 1916), ch. 2.

**terrorism.** 'Terrorism' is a highly emotive, pejorative label, originally applied to the Reign of Terror following the French Revolution, but now most commonly used of \*political violence as employed by insurgents against a \*state, unless specifically qualified as 'state terrorism'. Its definition has proved philosophically elusive, depending, as it does, on whether, and, if so, how, the pejorative force is to be captured definitionally; or, in other words, on whether terrorism is to be viewed as *ipso facto* unjustifiable, and, if so, why, which evidently raises substantive philosophical issues.

Broadly speaking, there are two approaches to characterizing terrorism in a way that views it as, *ceteris paribus*, morally wrong. One regards it as not just any tactic which induces terror by the use of violence, for such terror is routinely employed in wartime by the use of military force, which is not thereby terroristic. Rather, it is the use of force of a military character in contravention of the rules of war as adumbrated in the theory of the just \*war. Thus, on the one hand, terrorism may be seen as the use of such force without a \**ius ad bellum* because its perpetrators—as non-state actors—lack proper authority. To this criticism those dubbed terrorists typically reply that the states they oppose have forfeited authority over them by their unjust behaviour, which furnishes them with a just cause (an argument advanced by John Locke). It is this line of thought that commonly leads so-called terrorists to view themselves as 'freedom fighters'.

On the other hand, however, what may be attributed to terrorists is a failure of \**ius in bello*, resulting from breaches of the principle of non-combatant immunity by the targeting of civilians. One response to this charge (adopted by Sartre in his defence of FLN violence in Algeria) is that the civilians targeted are not innocent of the injustices combated. Another is that the exposure of civilians to injury through terrorism is no greater, and perhaps less, than that routinely accepted in conventional wars.

The major drawback of this unjust war model of terrorism is that, in regarding terrorism as *prima facie* wrong because contrary to the rules of war, it concedes that terrorism is indeed a form of war; albeit often one in which terrorist tactics are employed precisely because the resources for a conventional war are lacking, and therefore, since military victory is impossible, success can be achieved only by terrorizing a people and its government into submitting to demands. Yet, though terrorists usually claim to be fighting a war, this is exactly what governments are loath to allow, since this would give terrorists the same protections as soldiers against the operation of the ordinary criminal law.

A second approach to terrorism is, therefore, to view it as wrong for the same sort of reason as any violent crime is wrong, and distinguished from other such crimes only by having a political motive. The usual anti-terrorist strategy is thus to employ a criminal justice rather than a military approach, though this can prove problematic in the case of international terrorists operating from beyond the attacked state's jurisdiction. So-called terrorists will deny that their

violence is morally wrong just because contrary to the laws of a possibly unjust government, however, and will go on to repudiate the pejorative label. It may still be applied to them, Michael Walzer argues, if they contravene a 'political code' of anti-state violence by targeting civilians rather than, on this account, only politicians and the like.

These definitional problems may, perhaps, be overcome by using the word 'terrorism' without pejorative force and viewing it as a species of political violence not accorded the legitimacy of war. Then the substantive question comes to the fore of when such violence (including the violence of the state) is justified. p.g.

\*political violence; war, just.

**tertium non datur**: see excluded middle, law of.

**testimony.** The role of testimony in getting and spreading reliable belief or \*knowledge has been a relatively neglected epistemological issue. Traditional epistemology has had a marked individualist flavour in its stress upon the status and vindication of information gleaned from individual perception, memory, or inference. But it is clear that most of what any given individual knows comes from others: palpably with knowledge of history, geography, or science, more subtly with knowledge about everyday facts such as when one was born. Recently, more attention has been paid to this topic, and amongst the problems discussed are the scope of the dependency each of us has on the word of others, the difficulty of validating the dependency via inferences from an individual's experience of witness reliability, and the problems of expert evidence. C.A.J.C.

C. A. J. Coady, *Testimony: A Philosophical Study* (Oxford, 1992).

**test of time.** For a work or idea of any sort to evoke admiration or agreement over many generations implies that it transcends fashion and can be appreciated from different standpoints. In the aesthetic realm, where what is at issue is particular objects for which there can be no universally applicable standard of taste, the test of time may be the best, if not the only, determinant of ultimate quality. In politics, too, where knowledge of the effects of institutions and policies may be hard to gauge directly, the test of time becomes a strong criterion of value, particularly for \*conservative thinkers. A.O'H.

\*tradition.

**Thales of Miletus** (6th century bc). By tradition he was the first philosopher and the founder of the Ionian School.

According to Herodotus, Thales predicted (within a year) the solar eclipse of 585 bc. Aristotle attributes to him the conjecture that (1) water is the material principle of all things and that (2) a soul (\*psyche) is a sort of 'motor' (*kinētikon*), for he said that a magnet has a soul because it moves iron. G.B.M.

G. S. Kirk, J. E. Raven, and M. Schofield, *The Presocratic Philosophers*, 2nd edn. (Cambridge, 1990).

**theism**: see God.

**theodicy.** A justifying explanation of why God permits \*evil, responding to the problem of evil. The theodicist puts forward what he or she takes to be the *actual* purposes, rationales, etc. that explain and justify the divine actions, and inactions, with respect to evil. It contrasts with a defence, which has a more modest project, that of refuting atheistic arguments from evil without committing to a positive claim about the divine reasons. John Hick, for example, proposes a theodicy, while Alvin Plantinga formulates a defence. The idea of human \*free will often appears in a both of these strategies, but in different ways.

John Hick, *Evil and the God of Love* (London, 1968).  
 Alvin Plantinga, *God and Other Minds* (Ithaca, NY, 1967).

**theology and philosophy.** That the two have important overlapping concerns seems beyond question. A systematic philosophy that fails to give any thought to the question of \*God's existence could be judged seriously incomplete: likewise a theology that fails to enter into discussion with opposed views of the world, or to explore whatever philosophical support is available for its principal claims.

Other and related topics that have clearly both philosophical and theological relevance include questions, for example, of personal identity—in relation to life beyond the death of the body, metaphysical questions about time and eternity (God's relation to time), and moral questions about the Christian doctrine of \*Atonement.

Theologians sometimes claim that philosophical appraisal has no legitimacy in relation to what they see as a 'revealed' system of belief. But surely this cannot be right. First: to preface a statement of doctrine with such words as 'It is divinely revealed that . . . ' cannot confer coherence on what is logically incoherent or make a contradiction come out as true. There is therefore legitimate work for logic and philosophy of language in the analysis of such doctrinal claims. Second: however much of his religious beliefs a theologian regards as revealed, that cannot constitute a complete theistic system. The revealed totality has to be intelligibly related to the deity who allegedly revealed it, imparted it to mankind; and its authority needs to be more convincingly established than that of rival claimants. What is taken to be the essential nature of that deity, *qua* revealer, cannot itself be derived from revelation. It is a proper topic for philosophical (metaphysical) inquiry. A philosophical component—an

epistemology of belief—is thus vitally necessary to a revealed theology.

There is, of course, one route of escape from that model of ‘revealed package plus metaphysical account of its divine origin’: namely, to see the ‘revealed’ package as a set of ‘pictures’, stories, parables, by which to regulate human life, and for which no further grounding is possible or appropriate. The religious authority and the efficacy of these pictures, however, when taken in that way, become enigmatic—and questionable.

**Theophrastus** (c.371–c.287 BC). Younger colleague of Aristotle, his partner in his researches and his successor as head of the Lyceum, the school Aristotle founded. Theophrastus wrote on everything from \*modal logic (where he introduced the rule that the conclusion cannot be stronger than the weakest premiss) to penalties for gazumping. His surviving writings include sketches of (faulty) human character-types, fundamental works on botany, and shorter pieces, including a *Metaphysics* which contains more questions than solutions. He has been seen as rejecting Aristotelian positions for increased \*mechanism and \*materialism; but the differences can be exaggerated, and he is best regarded not as deliberately rejecting Aristotelian positions but as continuing Aristotle’s own procedure of questioning and criticism, influenced by his own preferences and inclinations.

W. W. Fortenbaugh et al. (eds.), *Rutgers University Studies in Classical Humanities*, ii, iii, v, vii (New Brunswick, NJ, 1985, 1988, 1992, 1995).

**theorem.** In an \*axiomatic system a theorem is the last of a sequence of formulae or propositions each of which is an axiom or follows from preceding steps in accordance with specified rules. Such a sequence is a proof or a derivation. A proof is clearly formal where the entire process is syntactical and can be employed without further attention to meanings, as in a computer computation.

In some formal systems of logic using \*natural deduction, theorems of logic can be generated without recourse to axioms. In such cases a theorem of logic is one which is derivable from the empty set of premisses.

R.B.M.

B. Mates, *Elementary Logic* (Oxford, 1972).

**theory.** A scientific theory is an attempt to bind together in a systematic fashion the knowledge that one has of some particular aspect of the world of experience. The aim is to achieve some form of understanding, where this is usually cashed out as explanatory power and predictive

fertility. The traditional analysis, going back to the Greeks and most recently championed by such logical empiricists as Carl Hempel and Ernest Nagel, sees theories as ‘hypothetico-deductive systems’, meaning that one has sets of laws bound together through the fact that, from a few high-powered axioms or hypotheses, everything else can be shown to follow as a deductive consequence. Explanation therefore is a matter of showing how things happened because of the laws of the theory. Prediction is a matter of showing how things will happen in accordance with the laws of the theory. Most significant is the fact that really successful theories bind together information from many hitherto disparate areas of experience, thus exhibiting what the philosopher William Whewell characterized as a \*‘consilience of inductions’.

In recent years, this picture of theories has come under some considerable attack. Although it may apply fairly well to such a theory as Newton’s theory of gravitational attraction, something like Darwin’s theory of \*evolution through natural selection seems not to be as tightly integrated (deductively) as is supposed. Moreover, while such a theory as Darwin’s certainly has some predictive power, it can hardly be said that this is a compelling attraction. Hence, rather than relying on the traditional excuses (‘biology is immature’ and so forth), an increasing number of thinkers have started to promote a view of theories which (they claim) pays far greater attention to the actual practice of science. Supporters of this ‘semantic view’ of theories argue that theories should not be seen as overall systems trying to cover, at one move, major areas of experience. Rather, more informally, they should be considered as sets of theoretical \*models which are given empirical meaning only inasmuch as they can be applied directly (semantically) to certain limited areas of empirical reality. The virtues of the theory (like explanation and prediction) are not prescribed beforehand, but are very much a function of the particular model in use at the time.

Debate continues, but undoubtedly at least part of the divide is between an older philosophy of science which sees the task to be that of *prescription* of the ideal form of science, and a newer philosophy of science which rests content with a *description* of the way in which science is actually performed.

M.R.

\*observation and theory.

R. B. Braithwaite, *Scientific Explanation* (Cambridge, 1953).

R. Giere, *Explaining Science* (Chicago, 1988).

**theory-ladenness.** The idea that all observations are interpreted through the medium of theories. The position has three versions. The first insists that when observations are described, the description inescapably involves some theoretical perspective. Thus, observations will report the ant species *Solenopsis invicta* engaged in foraging rather than as red objects moving along linear paths. More dramatic is the claim that what is sensed is affected by one’s theory—that our conceptual frameworks affect the sensory inputs. With the appropriate knowledge base, we see

the Old Bailey as a criminal court rather than as a building inhabited by oddly garbed humans engaged in hectoring and wheedling. A contemporary version of theory-ladenness asserts that 'observations' are constructed—one counts certain observations as being of psi particles rather than as blips on a cathode-ray tube because there is general agreement in the relevant social community on the former interpretation. Theory-ladenness has been widely used as a reason to question the objectivity of observational data.

P.H.

Ian Hacking, *Representing and Intervening* (Cambridge, 1983), ch. 10.

**theory theory of mind.** Humans have a natural ability to attribute mental states to one another in order to explain and predict behaviour. This common-sense psychological reasoning enables us to make sense of what others do and say. To the extent that this reasoning consists in a body of knowledge about the workings of people's minds and their connection with their acts and utterances, we can call such reasoning a theory; although the term 'theory of mind' is often used just to refer to the ability to attribute mental states to others. To explain this ability, many philosophers and psychologists have supposed that humans are equipped, perhaps innately, with a theory of mind which they deploy to make sense of others as rational agents. Such a theory is not consciously or explicitly known, but it is said to be tacitly known. This is the theory theory of mind. The rival view of how we attribute mental states to others is \*simulation theory. According to this view, we work out what others think and feel, or might do and say, by using ourselves to simulate their predicament and discovering what we would think or feel, do or say, were we in their predicament, subject to the same factors. Simulation theory privileges the first-person point of view in our understanding of others, whereas 'theory' theory privileges the third-personal observation of others.

M. Davies and T. Stone, *Folk Psychology: The Theory of Mind Debate* (Oxford, 1995).

**theosophy.** In a broad sense, theosophy is the mystical doctrine of various German thinkers of the later \*Renaissance period, most notably Jakob Boehme. It holds that man can have knowledge of God only by some kind of mystical acquaintance. More narrowly, and comically, it is the name of a movement led by Madame Blavatsky and Mrs Annie Besant in the late nineteenth century which sought to bring enlightenment to the Western world from Eastern religion and metaphysics.

A.Q.

**thing-in-itself.** This is Kant's expression for the object considered as it is independently of its cognitive relation to the human mind. It is contrasted with the object as it appears, or phenomenon, which is the object *qua* given to the mind in accordance with its sensible forms. Although Kant denies that we can know the thing-in-itself, he maintains that we must think of it as the ground of appearance.

H.E.A.

\*phenomena and noumena.

H. E. Allison, *Kant's Transcendental Idealism* (New Haven, Conn., 1983).

**things.** 'Thing', in its most general sense, is interchangeable with 'entity' or '\*being' and is applicable to any item whose \*existence is acknowledged by a system of ontology, whether that item be particular, universal, abstract, or concrete. In this sense, not only material bodies but also properties, relations, events, numbers, sets, and propositions are—if they are acknowledged as existing—to be accounted 'things'. In this sense, then, the statement 'Everything is a thing' amounts to an analytic triviality. However, it is more common for philosophers to use 'thing' in a more restricted sense, in which it is interchangeable with 'object' and stands in opposition to such terms as \*'property', \*'relation', and \*'event'. In the restricted sense, things are items which possess properties, stand in relations to one another, and undergo the changes which constitute events. Thus understood, the notion of a thing is closely linked to the traditional notion of a \*'substance'. As such, it is a notion also linked to the grammatical and logical notion of a \*subject (as opposed to a predicate). Indeed, Frege's well-known distinction between 'objects' and 'concepts' precisely mirrors the subject–predicate distinction (at least as it is employed in logic).

What, then, is the hallmark of thinghood in this restricted sense? Two competing answers to this question dominate current debate. One, the linguistic answer, espoused by Frege but also by more recent philosophers such as Quine, holds that an object is whatever may be referred to by a proper \*name or can be made the value of a variable of quantification. But a problem with this answer is to specify without circularity what constitutes a genuine proper name (or, more generally, a genuine singular term) or variable of quantification. For instance, when a soldier is described as having died for the sake of his country, should the noun phrase 'the sake of his country' be regarded as genuine singular term naming some object or thing? Surely not: but it is arguably only because we already believe, on independent grounds, that there are no such things as 'sakes' that we refuse to regard this noun phrase as a genuine singular term. Here an adherent of the linguistic answer may follow the lead of Frege and Quine by insisting that the application of genuine names or variables of quantification demands the provision of criteria of identity for the things named or quantified over: in Quine's words, 'No entity without identity'. But this suggests that in fact metaphysical rather than linguistic considerations lie at the root of our concept of thinghood, and more particularly that the hallmark of thinghood consists in the possession of determinate and objective identity conditions. This is the contention of the alternative, metaphysical answer to the question 'What is a thing?' By this account, a thing is any item falling under a sortal concept supplying a criterion of identity for its instances. Thus shoes and ships and sealing-wax are things, but certainly not sakes and probably not propositions.

There is a special sense of the term 'thing' or 'object' in which it is used to draw a contrast with the term 'subject', in the sense of the latter in which it is used to denote a subject of consciousness or experience, that is, a person or \*self. Of course, in a broader sense subjects or persons are themselves 'things', and indeed apparently things with determinate identity conditions, however difficult it may be to specify those conditions satisfactorily. What chiefly motivates the subject-object or person-thing distinction is the fact that objects or things in this sense are thought *about* rather than thinking, that is, are passive rather than active relata of consciousness. This fact is mirrored in the grammatical structure of statements of cognition, which typically feature transitive verbs taking a grammatical object—statements like 'I see a tree' or 'You are reading this book'. Indeed, the terminology of 'subject' and 'object' clearly draws on these grammatical categories.

**thinking.** In its diverse forms—as \*reasoning, believing, reflecting, calculating, deliberating—thinking appears to enjoy an intimate connection with speech, but just what that connection might be is difficult to establish. It is seldom, as Plato would have it, a matter of an inward dialogue carried on by the mind with itself. Not only is wordless thought possible, as when we think how a room would look with the furniture rearranged; it does not even require attention to the matter in question for us to have thought that something was so, as when, tripping on a stair, we say we thought there was one fewer stair than there in fact was.

Is thinking that *p* a matter of being disposed to say that *p*? This is tempting through making reliance on the spoken word basic, but it does not get us far as it stands. First, while thinking that *p* we need have no inclination whatsoever to say that *p*; at best, the disposition must be restricted by an appropriate condition, as 'if asked to give our opinion'. Even then there is a supposition that we are speaking truthfully, and this would seem to be a matter of saying what we really think. A more satisfactory characterization might run: to think that *p* is to be in a state of mind expressible by saying that *p* with an intention to speak the truth. The latter condition is not 'intending to speak truthfully', which would again reintroduce thinking, but 'intending to say something that is in fact true'.

This characterization allows for a suitably loose connection between thought and speech in several respects: those who cannot in fact speak are not being denied the capacity to think, and indeed it is possible that someone should suggest a form of words which better expresses another's thought than the words originally used. It is also allowed that there should be a range of quite different propositions to which one might assent as expressing

one's thought. You ask whether I thought the window was dirty. Yes indeed, I reply, but I could also have agreed if you had asked whether I thought there was a smudge on the window-pane, this being equally adequate to conveying how things struck me at the time. It is not as if the formulation ventured has to match unspoken words. I did not think in words. On the other hand, the characterization is also congenial to the idea that there are limits to the range of thoughts possible without language. Lacking the relevant vocabulary, a person could hardly be in a state of mind expressible by saying, with the relevant intention, that Sofia is the capital of Bulgaria.

Can animals think? We might say of a monkey which takes refuge from a snake by going up a tree that it knows that it is safe there. We might say this, because the monkey no longer behaves as if in imminent danger, but observes the snake in a detached fashion. However, while we may be prepared to say that it knows, we may be less happy to say that the monkey *thinks* that it is safe. That threatens to demand more of the monkey's mental capacities than we are willing to concede. On the other hand, we need a description for the case where there would be knowledge that *p* but for the fact that *p* is false, and while 'thinks that *p*' has the disadvantage of suggesting a mastery of concepts, an inner mental response, which it would be fanciful to attribute to the animal, so long as 'knows that *p*' can be affirmed solely on the strength of observed behaviour, the same status can be extended to the ascription of thought.

B.B.R.

\*belief; cognition; deliberation; understanding; language of thought.

P. M. S. Hacker, *Wittgenstein: Meaning and Mind* (Oxford, 1990).H. H. Price, *Thinking and Experience* (London, 1953).G. Ryle, *On Thinking* (Oxford, 1979).**thinking, critical:** see critical thinking.

**thinking causes** are causally efficacious \*propositional attitudes. Conflict arises over what is required for thinking causes to be causally efficacious. For instance, Donald Davidson only requires that the event be causally related to another event, and that the correct application of mental predicates ascribing propositional attitudes supervenes on the correct application of physical predicates. Others argue that something can only be a thinking cause if the event in question is causally efficacious in virtue of its \*intentional properties and believe that Davidson's approach does not capture this requirement.

P.J.P.N.

\*mental causation.

D. Davidson, 'Thinking Causes', in J. Heil and A. Mele (eds.), *Mental Causation* (Oxford, 1993).

**third man argument.** Aristotle coined the expression 'third man' (which refers to an extra entity beyond the individual man, such as Socrates or Plato, and the general kind man) to designate a notorious ontological-regress argument which first appears in Plato's *Parmenides* and has

impressed philosophers ever since. Apparently directed against Plato's own earlier theory of \*Forms, the argument shows that the premisses which are needed to entail the existence of a Form can then be reapplied to entail the existence of further Forms in infinite regress. The nerve of the argument is whether a Platonic Form (or other similar entity) is or is not to be counted in with the other objects which are related to it. There has been vigorous debate about the effectiveness of the argument; a majority maintain that it exploits genuine deficiencies in Plato's earlier thought, while a minority argue that he would reject its premisses or reasoning.

J. D. G. E.

A judicious article from the heyday of modern interest in this argument is Colin Strang, 'Plato and the Third Man', *Proceedings of the Aristotelian Society*, supp. vol. (1963).

**Thomism.** A philosophical-theological movement based upon leading ideas of St Thomas Aquinas. Successive generations have taken his philosophy as a starting-point for their own speculations and have developed his ideas in many directions. Thomism, an ongoing enterprise with its own schools and disputes, is particularly associated with the Catholic Church, although much of his theology has proved acceptable to Christians of a wide variety of denominations and his theological teachings are by no means peculiar to the Catholic Church. Indeed philosophical parts of Thomism, for example on predication, on being, on the nature of mind, and on the relations between law and human nature, do not depend logically upon Christian \*dogma and can appeal to people of any religion or none. It should be added that Aquinas's philosophy was never universally accepted by his own Church, and a number of his propositions were denounced in Paris and Oxford in 1277 shortly after his death.

In due course while Thomism was establishing itself its proponents, such as John Capreolus, whose title was *Princeps Thomistarum* (chief of Thomists), had to defend themselves against other movements, especially those based on the ideas of Duns Scotus and of Ockham. In the sixteenth century, in the face of the Protestant Reformation, Thomism, represented by men such as Domingo de Soto, held a prominent place in the armoury of the Counter-Reformation, and in the nineteenth century, after a period of decline, it gained renewed vigour as a result of a papal bull commending the study of Aquinas. \*Neo-Thomism, which was in part a result of that bull, is still with us. Among its exponents are Jacques Maritain and Étienne Gilson. We shall consider here three topics which at different times have been high on the agenda of Thomists, namely, the doctrine of analogy, the relation between free will and grace, and probabilism.

Thomas de Vio (1468–1534), Cardinal Cajetan, was perhaps the greatest of the Thomists during the earlier stages of the Reformation. His finest work was his commentary on the *Summa Theologiae* of Aquinas, but in many other books also, such as his *De nominum analogia* (The Analogy of Names) he attended directly to Aquinas's doctrines. In that latter work he developed Aquinas's doctrine of anal-

ogy far beyond anything to be found in Aquinas's writings. The question at issue was the meaning of terms predicated affirmatively of \*God, terms such as 'good', 'wise', and 'powerful'. Aquinas had said that they should be understood neither literally nor negatively but analogically, and though deploying widely the concept of analogy he did not expound it systematically or in detail. Cajetan filled that gap.

The crucial move in his systematization was to identify a jointly exhaustive set of three heads of division for analogy. Any instance of analogy was an analogy either of inequality, or of attribution, or of proportionality. The first two, however, turn out to be analogies by an improper use of the term 'analogy'. Only analogy of proportionality is analogy properly speaking. Two things are analogous by proportionality if they have a common name and the notion expressed by this name is proportionally the same. For example, to see by corporeal vision and to see by intellectual vision are instances of seeing, for just as corporeal seeing presents something to the living body so also the faculty of intellect presents something to the mind. Thus there is a kind of act which is related to the intellect as seeing is related to the living body, and that kind of act is therefore a seeing, analogically speaking, where the analogy is that of proportionality. This kind of analogy is commonly deployed in metaphor, as when we speak of a smiling meadow, on the analogy of a smiling face, for in general people look most attractive when smiling, and a meadow, when looking its best, can therefore be described, by analogy of proportionality, as smiling. But it was upon the non-metaphorical uses of analogical terms that Cajetan concentrated, and in so doing he shed a good deal of light on Aquinas's problem of how we are to make sense of affirmative terms predicated of God in the Bible. God's goodness, wisdom, and so on are to be understood on an analogy of creaturely goodness and wisdom: as our goodness and wisdom are proportional to us so are God's proportional to him. There is considerable dispute among Thomists over whether Cajetan's teaching on analogy faithfully reflects, as he intended, the mind of Aquinas, but there is no doubt that his *De nominum analogia* is a major Thomist document.

A second major area of Thomist thought concerns the relation between human \*free will, divine foreknowledge of human acts, and God's grace. Aquinas had seen the need to refute the argument that God's foreknowledge of human acts implies that we humans cannot do otherwise than we do. He had no doubt that God knows human acts that lie in the future in relation to us now. This doctrine does not, however, imply that God determines those human acts. He knows them not because he has determined them but because he sees them happening as present to him, though future in relation to us. Aquinas had also seen the need to deal with the closely related question of whether God's grace by which a person is saved is something that the recipient freely accepts, or whether his acceptance is determined by God. If his grace is not freely accepted, then a question arises of the contribution if any

that a person can make towards his own salvation or damnation. In the latter part of the sixteenth century a major dispute arose in this area, particularly between Dominican thinkers, whose chief spokesman in this matter was Domingo Báñez, and Jesuits, whose chief spokesman was Luis de Molina. As part of his rejection of Aquinas's teaching Molina developed the doctrine of *scientia media* (middle knowledge) and the associated concept of a 'free futurible', which is an act with a conditional existence, not an act that will be performed or one that might be but in fact will not be, but instead one that would be freely chosen if certain conditions were satisfied. God, as omniscient, must know eternally not only all events (including all free human acts) past, present, or future in relation to us, but also all events which would happen given the satisfaction of certain conditions. God's middle knowledge of human acts is his knowledge of acts which have this metaphysical status of a 'would-be'. These acts are the 'free futuribles'. Amongst them are the acceptance by human beings of God's saving grace. According to Molina God, in an absolutely free act, gives grace in the light of his middle knowledge that the recipient would accept it, and the recipient accepts that grace with an entirely free consent. Thus the doctrine of 'determinism by grace' is totally rejected by Molina. Against this teaching Domingo Báñez and his fellow Dominicans deployed the concept of *praemotio physica* (physical pre-motion) and argued, in the spirit of Aquinas, that a person cannot freely accept the grace that God offers unless moved by God to do so. This is a difficult doctrine to maintain, in its own way as difficult as the doctrine of middle knowledge, and the consequent dispute between Dominican Thomists and Jesuit anti-Thomists rumbled on for decades. There is some point to the claim that the Jesuits were standing dangerously close to the Pelagian heresy, and that the Dominicans were standing dangerously close to Calvinist teaching on predestination.

In the course of his commentary (1577) on a part of the *Summa Theologiae* of Aquinas, Bartholomew Medina presents a doctrine which he thought of as according to the mind of Aquinas and which has been disputed by Thomists ever since. The doctrine is probabilism. If a person wishes to perform a given act and is in doubt over whether the moral law forbids that act, then he is morally at liberty to perform it on condition that the opinion that he is at liberty to perform it is supported by a probable argument, that is, by an argument whose conclusion has some degree of probability, and even if the argument supporting the claim that the moral law forbids the act is more probable. There is an evident danger of probabilism leading the unwary into the vice of laxity, when a barely probable opinion on the side of liberty will be followed in preference to a highly probable opinion on the side of the moral law. It was because of this danger that some insisted that the opinion on the side of liberty had first to be shown to be soundly based; shaky grounds for acting on the side of liberty are never sufficient. At the other extreme is the vice of rigorism, associated especially with the Jansenists,

who argued that in the face of a probable argument on the side of the moral law and another probable argument on the side of liberty, there was always a presumption on the side of the law. Given that probabilism occupies an intermediate position between the two extremes of laxity and rigour, there was room for dispute, which duly took place, over how nearly a probabilist may approach one extreme or the other without straying into moral error. There is no doubt that probabilism has its roots in Aquinas's writings, and the fact that the doctrine is still a matter for dispute is due in part to the very fact that the protagonists in the dispute see themselves as enjoying the support of Aquinas. It is precisely this that makes them Thomists. A.BRO.

\*Thomism, analytical.

Good accessible material is hard to come by. The following are relevant:

É. Gilson, *The Spirit of Thomism* (New York, 1964).

B. Hamilton, *Political Thought in Sixteenth Century Spain* (Oxford, 1963).

Thomas de Vio (Cardinal Cajetan), *The Analogy of Names* (Louvain, 1959).

**Thomism, analytical.** A broad philosophical approach that brings into mutual relationship the styles and pre-occupations of recent English-speaking philosophy and the concepts and concerns shared by Aquinas and his followers. This approach bears some relation to that of those post-war Oxford philosophers, e.g. Austin and Ryle, who sought to reintroduce certain concepts into the analysis of thought and action, such as those of capacities and dispositions, which are prominent within Aristotelian philosophy. In the case of analytical Thomists the primary areas of interest have been intentionality, action, virtue theory, philosophical anthropology, causation, and essentialism. The expression 'analytical \*Thomism' is rarely employed, but it usefully identifies aspects of the writings of philosophers such as Anscombe, Donagan, Geach, Grisez, Kenny, and MacIntyre. J.HAL.

P. T. Geach, 'Form and Existence', in *God and the Soul* (London, 1969).

A. MacIntyre, *First Principles, Final Ends and Contemporary Philosophical Issues* (Milwaukee, 1990).

**Thomism, neo-:** see neo-Thomism.

**Thomson, Judith Jarvis** (1929– ). American philosopher best known for her use of hypothetical examples to elicit intuitions that help to reveal the structure of common-sense morality. The most influential of her arguments of this sort grants the assumption that the foetus is a person but defends the permissibility of \*abortion by appealing to an analogous case in which a person can stop providing life support for another innocent person, to whom she has been involuntarily connected, only by killing that person. Thomson believes that rights, which she analyses as non-absolute constraints on the behaviour of those against whom they hold, are the central components of morality. So, for example, she argues that self-defence is permissible

if and only if the person one defends oneself against would otherwise violate one's rights; for such a person cannot have a right not to be prevented from violating one's rights.

J.M.C.M.

J. J. Thomson, *Rights, Restitution, and Risk*, ed. William Parent (Cambridge, Mass., 1986).

**Thoreau, Henry David** (1817–62). \*New England Transcendentalist, natural historian, and social critic, Thoreau proclaimed, in *Walden*, that most people spend their lives superficially, by pursuing wealth and following custom. Genuinely encountering reality is to be found only by separating oneself from the artificialities of city, economic, and family life and communing directly with nature, where one could 'front only the essential facts of life'. Nature preserves a spontaneity and wildness that civilization suppresses; the civil liberties democracy provides are far less important than the spiritual freedom nature embodies and inspires: 'all good things are wild and free'. \*'Civil disobedience' is the classic defence of conscience above unjust law. One must not support an immoral law and can protest by, for example, not paying taxes that implement it, or refusing to obey it and accepting a jail term. This appeals to the conscience of others and so begins a social movement.

**thought:** *see* thinking; cognition; language of thought.

**thought, language of:** *see* language of thought.

**thought, laws of:** *see* laws of thought.

**thought experiments** are employed both by philosophers and by theoretical scientists to examine the implications of theories and to explore the boundaries of concepts. They are controlled exercises of the imagination in which test cases are envisaged with a view to establishing their conceptual coherence or their compatibility with some proposed theory. For example, in assessing the merits of rival theories of \*personal identity, philosophers commonly propose thought experiments envisaging the consequences of procedures which would apparently result in the fission or fusion of persons—for instance, brain bisection followed by transplantation of the two cerebral hemispheres into separate bodies.

Some philosophers object vehemently to the philosophical use of thought experiments as substituting fantasy for reality, but since philosophical argument is often concerned to establish precisely what is *possible*, it is hard to see how philosophy could do without them altogether.

R. A. Sorensen, *Thought Experiments* (New York, 1992).

**Thrasymachus.** Notable figure in Plato's *Republic*. Having had enough of the preceding high-minded, convivial but thin discussion of justice, Thrasymachus falls on Socrates

and his interlocutors like a beast, arguing that justice is nothing else than the advantage of the stronger. Some interpret Thrasymachus as claiming that justice is nothing deeper than the bare fact that those in power enact laws which protect their interests—justice is nothing more than the weak obeying the will of the strong. Some see Thrasymachus as arguing for more: it is just that the strong ought to rule the weak, and justice consists in the strong holding sway. Might makes right. Thrasymachus is claimed as spokesman by nihilists, ethical egoists, relativists, and realists.

J.GAR.

Plato, *Republic* 336b–354c.

**threats and offers.** Threats express intentions to inflict injury or damage. They are menacing proposals, paradigmatically expressed in 'Your money or your life'. Offers, by contrast, are proposals that expand opportunities: 'I'll pay you \$10 to weed the garden.' Threats can masquerade as offers. Since they present pairs of options, their surface grammar can suggest expansion of opportunity. Such proposals none the less are threats just in case either option would leave one worse off than one would otherwise have been. In standard cases, such a set-back is measured relative to the welfare one would have enjoyed had one not encountered the robber in the first place. In other cases, the set-back is measured against a morally defined baseline, which includes the welfare one should enjoy as one's due: a proposal to stop beating you if you weed the garden constitutes a threat. Thus threats, in contrast to offers, are coercive, which is not to say that all offers are morally innocent—they may be disrespectful, exploitative, or exert undue influence.

\*coercion.

A. Wertheimer, *Coercion* (Princeton, NJ, 1987).

**time.** The dimension of \*change, a fact which distinguishes it from the three dimensions of \*space. But how does genuine temporal change differ from mere variation as exhibited in space? When a road is said to change in breadth along its length, 'change' is being used only metaphorically, in contrast to its literal use when a child is said to change in height as it becomes older. Some theories of time and change do not really accommodate this distinction, and as such are sometimes accused of 'spatializing' time or denying the reality of temporal 'becoming'. Some philosophers believe, indeed, that developments in physics connected with the theory of \*relativity necessitate this denial, because they seem to demonstrate that the notion of an absolute 'now' must be abandoned along with the Newtonian notion of the absoluteness of simultaneity. Events deemed 'past' in one frame of reference must be deemed 'future' in other frames, apparently indicating that the distinction between past and future is only a subjective, experientially based one rather than reflecting a genuine ontological divide. Philosophers of this persuasion adopt what is commonly called a 'static' view of

time, thus partaking in a tradition stretching back to Parmenides and Zeno, who held the appearance of temporal change to be an illusion.

In opposition to the 'static' view stands the 'dynamic' view of time, traceable back to Aristotle and before him to Heraclitus. By this account the future lacks the reality of the past and present, and indeed reality is continually being added to as time passes. The objection mentioned earlier is not difficult to overcome, since even the theory of relativity acknowledges that some events are past and others future, no matter which frame of reference is selected, and these may be said to lie in the absolute past or future. The relativity of simultaneity only requires us to revise our conception of the present, allowing it to embrace all events not causally connectable to us by a physical signal. A more serious challenge to the dynamic view of time comes from an argument of J. M. E. McTaggart, who claimed that the notion of temporal becoming (bound up with the \*A-series of past, present, and future) leads to contradiction. But it seems fair to protest that McTaggart's argument demonstrates not so much the absurdity of the notion of temporal becoming as the incoherence of his representation of that phenomenon. According to McTaggart, the phenomenon supposedly consists in future events 'becoming present' and then 'receding into the past', whence it apparently follows, absurdly, that all events are past, present, and future. But the lesson is just that we should not think of 'the present' as somehow 'moving' along the sequence of events from past to future. In denying the reality of the future, we may appeal to the fact that not all future-tensed statements appear to be determinately true or false.

The asymmetry of time is perhaps its most striking feature and the most difficult to explain. The fundamental laws of physics are time-reversible, and yet complex macroscopic processes like the growth of a tree or the breaking of a glass could not happen in reverse save by a miracle. This is often supposed to be explicable by reference to the second law of thermodynamics, which implies that closed systems tend to evolve from conditions of less to greater disorder, or 'entropy'. But why should the universe have been created in a particularly low state of entropy—or was this just an accident without which time might have been isotropic? And how does the asymmetry of time as we know it relate to the apparent non-existence of phenomena involving \*'backwards' causation, such as \*time-travel? These are problems which are still very little understood by either metaphysicians or physicists. E.J.L.

\*endurance and perdurance; persistence through time; presentism; space-time; specious present; tense.

J. R. Lucas, *The Future* (Oxford, 1989).

R. Le Poidevin and M. MacBeath (eds.), *The Philosophy of Time* (Oxford, 1993).

**time preference.** We are often prepared to opt for a good thing now even if we know that a better thing can be obtained later with at least as much probability. This sort of attitude is known by decision theorists as time prefer-

ence, and the question of its rationality is much debated. Some suggest that time preference is a biologically evolved strategy to discount future goods—a sensible enough one for creatures for whom the calculation of future probabilities would be too difficult or a waste of cognitive resources.

E.J.L.

\*decision theory.

R. Nozick, *The Nature of Rationality* (Princeton, NJ, 1993).

**time's arrow.** Time has, it seems, both a 'forward' and a 'backward' direction, unlike any of the dimensions of space. But is this a feature internal to \*time itself? Is it related to \*causal asymmetry? If an event *e* is earlier than another event *d*, then, unless time is circular, *d* is not also earlier than *e*. But in virtue of what is one event or moment of time earlier, rather than later, than another? Some philosophers attribute time's 'arrow' or directionality to the Second Law of Thermodynamics, which says, in effect, that complex systems become increasingly disordered over time: glass vases frequently break into fragments, but fragments of glass never reassemble themselves into intact glass vases. However, the fundamental laws of physics appear to be time-symmetric, which makes the Second Law appear to be a contingent consequence of the fact that the physical universe came into existence at the Big Bang in a highly ordered state. Why, though, should we say that the Big Bang was at the *beginning*, as opposed to the *end*, of time? E.J.L.

S. F. Savitt (ed.), *Time's Arrow Today* (Cambridge, 1995).

**time-travel.** The philosophy of time-travel is a serious subject with a burgeoning literature. Early objections to the logical possibility of time-travel have now been answered. For instance, there is no contradiction in saying that the time-traveller has gone back 100 years in time but become a day older in the process, provided we distinguish between 'external' or 'historical' time and the 'personal' time of the traveller. Again, it is no objection to say that if time-travel were possible the time-traveller could murder his own grandparents and thus prevent his own birth: for time-travel is not a licence to *change* the past, but at most to *affect* it—and, given that the time-traveller was born, no effect he has on the past can alter that.

The philosophical value of imagining cases of time-travel lies in what such \*thought experiments reveal about our concepts of time, \*causality, \*personal identity, and the like. E.J.L.

P. Horwich, *Asymmetries in Time* (Cambridge, Mass., 1987).

**'to be', the verb.** Russell declared that it was 'a disgrace to the human race' that it used the same word in such different contexts as the following: 'John is bald', 'There is a robin on the lawn', 'A dolphin is a mammal' and 'The square of three is nine'. These uses of 'be' have been called respectively the copulative, the existential, the class-inclusion, and the identity use of 'be'. Aristotle too had affirmed that the Greek equivalent of 'be' was used in more than

one way (*Metaphysics* v. 7), although his list of the different ways is not the same as Russell's. Medieval philosophers were divided on the matter, Aquinas following Aristotle and maintaining that being was 'analogical', i.e. had different though connected senses, and others such as Duns Scotus insisting on the univocity of being, i.e. that 'be' had only one sense. Arguably all these senses can be reduced to two, the copulative and the existential sense. In its existential sense 'be' seems to be doing work otherwise done by 'some': "There are blue buttercups" means 'Some buttercups are blue'. In its copulative sense 'be' seems to have the purely syntactic function of converting a non-verbal expression into the equivalent of a verb: 'is a smoker' is an alternative to 'smokes'. These two uses seem to have little to do with each other, and it is tempting to regard the verb as used in these two ways as purely equivocal, i.e. as having two unconnected senses. But this plurality of senses is a phenomenon which occurs in practically all languages (see John M. W. Verhaar (ed.), *The Verb 'Be' and its Synonyms* (Dordrecht, 1967–72)), so it is difficult to regard it as accidental. For one attempt to explain it, see C. J. F. Williams, *What is Existence?* (Oxford, 1981), chapters 1 and 12.

C.J.F.W.

\*being; existence.

**token.** Contrasted with 'type', originally in semiotics, and nowadays in the formulation of identity theses in philosophy of mind.

A 'token' was said by Peirce to be a 'replica of a symbol'. Tokens, then, are particular meaningful items, which belong to the same type (or replicate the same symbol) if and only if (very roughly) they have the same significance. Following Peirce it can be said, for example, that there are three tokens of the word 'the' (that type) in the previous sentence, and that the actual book you're now reading is a token of the type *Oxford Companion to Philosophy*.

In recent philosophical usage of 'type' and 'token', different kinds of abstraction from that which concerned Peirce are thought to relate tokens (particulars) to types (abstract things). It is said, for instance, that the event which is your now reading is a token of the type *reading*, and that the event which is Jane's believing that *p* is a token of the type *belief that p*.

**Toland, John** (1670–1722). A radical thinker, born a Roman Catholic in the north of Ireland, who, after abandoning Catholicism at 15—by 'his own reason and such as made use of theirs'—moved from latitudinarianism, to \*deism, and finally to a materialistic form of \*pantheism, coining the word 'pantheist' in 1705. Toland's deism is most evident in his *Christianity not Mysterious* (1696), a seminal work in both free thought and Irish philosophy.

His pantheism is developed esoterically in *Letters to Serena* (1704)—which contains an acute attack on Spinoza's theory of matter—and more openly in *Pantheisticon* (1720). He was a prolific controversialist and scholar. His *Tetradymus* (1720) contains the first published essay on the esoteric–exoteric distinction, a distinction important for understanding his own views as well as those of his fellow free thinkers, such as Anthony Collins.

R. E. Sullivan, *John Toland and the Deist Controversy* (Cambridge, Mass., 1982).

**tolerance, principle of:** see Carnap.

**toleration.** Requires people to coexist peacefully with others who have fundamentally different beliefs or values. Within Western political philosophy, toleration was first discussed during the Wars of Religion between Catholics and Protestants. When the attempt to impose a single religion failed, the assumption that political stability required a common religion was replaced by the principle of toleration. This principle has now been extended to other areas of moral disagreement, including sexual orientation and political belief. Why should we tolerate those whom we see as mistaken, or as heretics? Arguments for toleration include the fallibility of our beliefs, the impossibility of coercing genuine religious belief, respect for autonomy, the danger of civil strife, and the value of diversity. These parallel the arguments for liberalism. Theorists of toleration include Spinoza, Locke, Voltaire, and Mill; critics include Rousseau and Comte.

**tone.** Used by philosophers to translate Frege's *Beleuchtung* and *Farbung*. Followers of Frege and J. L. Austin distinguish three ways in which a word or construction can have \*meaning: by determining what the speaker says; by indicating whether the utterance is a statement, order, promise, or what not; and (thanks, perhaps, to its sound or associations) by making the utterance more or less apt to affect the state of mind of someone who understands what is said—to illuminate or confuse, to arouse or quiet a feeling. This last is its contribution to tone.

M. Dummett, *Frege: Philosophy of Language* (London, 1973), ch. 5.

**topic-neutral.** The term was introduced by Ryle for expressions that indicate nothing about the subject-matter, for example, 'inside' indicates place, and so is not topic-neutral, but 'of' is topic-neutral. Smart introduced a much more specific sense in which a topic-neutral analysis of a property term entails neither that the property is physical nor that it is non-physical. He gave topic-neutral analyses of mental terms which were the first functionalist identity-claims. Further, he argued that anyone who accepts an empirical physicalist or functionalist identity

thesis (e.g. pain = c-fibre stimulation, or pain = such-and-such a computational state) should also accept a topic-neutral (functionalist) conceptual analysis of mental-state terms. Suppose  $S_{17}$  is a brain state or a functional state and that the claim that pain =  $S_{17}$  is offered as an empirical identity-claim. Then the terms flanking the '=' must pick out the common referent via different modes of presentation. The mode of presentation of 'pain', however, presumably will be something mental, even something phenomenal, requiring the empirical identity theorist to claim that the mode of presentation is also a physical-functional state, say,  $S_{18}$ . A regress can be avoided only by accepting an a priori identity, and the only candidate is a topic-neutral analysis of mental-state terms in terms of the states' normal causes and effects. (Only in an a priori identity will the terms flanking the '=' refer via the same mode of presentation.) Thus, according to Smart's argument, empirical identity-claims engender topic-neutral analyses.

N.B.

\*identity theory; functionalism.

Stephen White, 'Curse of the Qualia', *Synthese* (1986).

**tradition.** Customary sets of belief, or ways of behaving of uncertain origin, which are accepted by those belonging to the tradition as persuasive or even authoritative and which are transmitted by unreflective example and imitation.

It is a conceptual joke for a school to announce that as from June it will be a tradition that . . . The nature of traditions is such that they cannot (logically) be willed; rather they have grown up. Traditions exist in all areas of life—literature, religion, legal institutions, and so on—but the term is of particular interest in political philosophy. For those political philosophers hostile to the idea of tradition it is perceived as representing entrenched privileges holding back political and social progress, and it is to be contrasted with a vision of human beings controlling their own destinies with rational decisions and asserting rationally based rights. This latter was the position of revolutionary political thinkers such as Rousseau, Tom Paine, and Richard Price. Their position was opposed by thinkers such as Edmund Burke, who had less faith in reason. For traditionalists like Burke social life is kept going not mainly by rational decision-making but by feeling, habit, emotional attachments, and conventions.

R.S.D.

\*conservatism; revolution; reform.

Charles Parkin, *The Moral Basis of Burke's Thought* (Cambridge, 1956).

**tragedy.** Philosophical reflection on tragic drama is as old as tragedy itself. Plato found tragedy antithetical to philosophy, claiming that it nourishes an irrational part of the soul which takes pleasure in empathizing with fierce emotions. Indeed, only by opposing tragedy's pre-eminence, and its claim to provide a comprehensive ethical education, could Plato establish philosophy's claim to be uniquely concerned with truth and the good. Aristotle, in response,

saw tragedy as a representation of universal truths which engages our pity and fear in a beneficial way. Of later views, Nietzsche's is the most well known. For him, tragedy unites a terrifying insight into the destructibility of the individual (associated with Dionysus) with the beautiful dream-image (associated with Apollo), producing a uniquely powerful form of art. Tragedy continues to fascinate philosophers interested in aesthetics and moral psychology.

C.J.

Aristotle, *Poetics*.

**transcendence.** Existence beyond; independent existence. For example, God, numbers, and universals are sometimes held to exist beyond space, time, the physical world, or experience (in some non-spatial sense of 'beyond'). In theology, the transcendence of God is contrasted with his immanence or pervasion of the world. In medieval philosophy, the transcendentals are notions that are too fundamental to be accommodated in Aristotle's ten categories: for example, unity, truth, goodness, and being. In Kant's critical philosophy, 'transcendent' knowledge of non-spatio-temporal reality that cannot be subsumed under the \*categories is impossible; 'transcendental' knowledge, \*a priori knowledge of how knowledge is possible, is possible and is the content of the critical philosophy.

One of the most fundamental and persistent divisions within philosophy is between philosophers who think there is a transcendental reality and those who do not. Indeed, the history of philosophy can be understood as the recurrent advocacy and repudiation of transcendence. A clue to understanding belief in metaphysical reality lies in taking the world with which we are acquainted as only part of a greater whole. The known arguably depends upon the unknown, because metaphysical questions can be raised within and about the empirical world but cannot be answered by any further empirical inspection: Why is there a universe? Why is a particular person oneself? Why is it now, now? What is being? Is there life after death?

*Immanuel Kant's Critique of Pure Reason*, tr. Norman Kemp Smith (London, 1978).

**transcendental analytic.** This is Kant's title for the portion of the *Critique of Pure Reason* dealing with the nature and function of the understanding. Kant argues that the understanding is equipped with a set of \*a priori concepts or \*categories, including substance and causality, which are required for the knowledge of an object or an objective realm. From this he concludes that all objects of possible experience must conform to these categories.

H.E.A.

H. J. Paton, *Kant's Metaphysic of Experience* (New York, 1936).

**transcendental arguments.** Anti-sceptical arguments of the form: There is experience; the truth of some

proposition *p* is a conceptually necessary condition of the possibility of experience; therefore *p*. Kant, with whom transcendental arguments are mainly associated, regarded them as only capable of providing \*synthetic a priori knowledge of the world as it appears rather than as it is in itself.

Q.C.

I. Kant, 'The Discipline of Pure Reason in Regard to its Proofs', in *Critique of Pure Reason*, tr. N. Kemp Smith (London, 1929).

R. Stern (ed.), *Transcendental Arguments: Problems and Prospects* (Oxford, 1999).

**transcendental deduction.** Kant's name in the *Critique of Pure Reason* for the reasoning which simultaneously justifies both the applicability of the pure concepts of the understanding (\*categories) to objects of experience and the objectivity of experience itself. The term 'deduction' here is borrowed from contemporary jurisprudence regarding the need to address matters of right as well as of fact. Starting from the fact that all my representations are grasped together in one consciousness (the unity of apperception), the argument asserts that such unity is possible only because synthesized according to the rules contained in the pure concepts.

A.H.

H. E. Allison, *Kant's Transcendental Idealism: An Interpretation and Defense* (New Haven, Conn., 1983), ch. 7.

**transcendental idealism** is Kant's name for his overarching metaphysical doctrine. Some commentators confine the name to Kant's own version of the doctrine, while some extend it to other self-proclaimed versions, notably Schopenhauer's, and even to positions, like Śāṅkara's, that anticipated Kant's. Transcendental idealism maintains, in Kant's version, that the world as known to creatures like ourselves, who rely on perceptual experience and conceptual understanding, is not the world of \*things-in-themselves—of things as they are independently of cognition— but of 'appearances'. We have knowledge only of \*phenomena (things in the sensible realm), and not of the \*noumena which are knowable only by a being, like God, capable of a non-sensory 'intellectual intuition'. For example, we experience the world as spatio-temporal, even though space and time are 'forms of (our) sensibility', not features of reality-in-itself. Kant favourably contrasts his transcendental idealism with transcendental realism and empirical idealism, which respectively hold that our knowledge extends to things-in-themselves, and that objects of experience are not grounded in extra-mental reality. Schopenhauer criticized Kant for overlooking a non-representational mode of knowledge whereby we are acquainted, albeit imperfectly, with reality-in-itself as \*will.

H. E. Allison, *Kant's Transcendental Idealism: An Interpretation and Defense* (New Haven, Conn., 1983).

A. C. Ewing, *Idealism: A Critical Survey*, 3rd edn. (London, 1974).

**transcendentalism.** The word 'transcendentalism' can be applied either to something large, shapeless, and generic or, more straightforwardly, to something historically and

geographically distinctive, which willingly accepted the name. In the larger sense transcendentalism is belief in the existence of things that transcend sense-experience or, more reflectively, belief in the possibility of transcendent metaphysics, that is to say, philosophical reasoning which aims to establish beliefs about transcendent entities. \*God might seem an obvious example of a transcendent, but those who accept religious or mystical experience as a source of knowledge might resist that. The \*Forms or Ideas of Plato, which are not in space and time and not encountered in the world of the senses, are more uncontestedly transcendent. Some have said, or, like Berkeley, implied, that Locke and representationalists generally, who take our beliefs in the existence of material things to be causal inferences from our sense-experiences, are transcendent metaphysicians. Many philosophers of science, along similar lines, have said the same about belief in the literal existence of such theoretical entities as atoms and subatomic particles.

Transcendent metaphysics has been attacked in two main ways. In the first place it can be argued that there can be no rational warrant for the inferences that transcendental metaphysicians make from experience to what transcends it. Secondly, it has been argued by positivists of various kinds that since the terms that figure in the utterances of transcendent metaphysicians have no criteria of empirical application, those utterances are devoid of meaning. The philosophy of Kant contains elements of both approaches. He does not deny meaning to the theses that the world is infinite in size or has a first cause (and their opposites), but he holds them to be undecidable or unknowable for the reason that the concepts employed in them are being used outside the sphere of their legitimate application, which is within experience. To make things more complicated he also holds that there are transcendent things-in-themselves, noumenal objects or selves, indeed, perhaps, that these are the only truly real things that there are. With a final turn of the screw he describes his own inquiries and their results as transcendental, meaning by this not that they are concerned with the transcendent, but that they are concerned with the possibility of knowledge.

More definite in outline, if not in content, is \*New England Transcendentalism. This was the body of ideas elaborated by Emerson and a group of associates—among them Thoreau, George Riley, Orestes Brownson, and Bronson Alcott—who lived in or met at Concord, Massachusetts between about 1830 and 1860. It was a very diluted variety of philosophical thought. Plato and Plotinus, Coleridge and Carlyle, Eastern scriptures, German mystics like Boehme and the Romantic German idealists, all contributed to a doctrine which stressed the spiritual unity of the world (thus interpreting God in an untranscendentally pantheistic way) and the superiority of intuition as a source of knowledge as opposed to logical reasoning and sense-experience. They relied heavily on the distinction of true reason from the merely analytic understanding, the doctrinal cornerstone of \*philosophical Romanticism. It supplied a foundation for the

'spiritual religion' they upheld against the natural religion of the Enlightenment and the revealed religion of Calvinism.

As important deliverances of intuition they affirmed the natural goodness of man and his freedom, in opposition to the emphasis of \*Calvinism on original sin and predestination. Many of the Transcendentalists had started out as Unitarians. Rejecting the Calvinist orthodoxy of their time and place, they were equally hostile to scientific materialism, the conception of the world formed by the mere understanding.

New England Transcendentalism was more a social movement than a philosophical school. It expressed itself in the formation of ideal communities such as Brook Farm—the inspiration of Hawthorne's *Blithedale Romance*. Its adherents took progressive positions on the emancipation of women and the abolition of slavery.

**transcendental unity of apperception:** *see* apperception.

**transitive relation.** A binary, i.e. two-term, \*relation is transitive when if anything  $x$  has it to anything  $y$ , and  $y$  to anything  $z$ , then  $x$  has it to  $z$  (in symbols,  $R$  is transitive if and only if  $\forall x\forall y\forall z((Rxy \wedge Ryz) \rightarrow Rxz)$ ); for example, *being older than*. 'Intransitive' means: if anything  $x$  has it to anything  $y$ , and  $y$  to anything  $z$ , then  $x$  does not have it to  $z$ ; for example, *being twice as old as*. 'Non-transitive' may mean either 'not transitive' or 'neither transitive nor intransitive'.

C.A.K.

W. Hodges, *Logic* (Harmondsworth, 1977).

**translation, indeterminacy of.** W. V. Quine argued that there are no uniquely correct translations between languages. This is not the banal point that languages contain words with no precise equivalents in others, but the extraordinary claim that there is *no such thing, ever, as a uniquely correct translation of a word*. It forms part of Quine's argument that 'there is no objective matter to be right or wrong about' where the \*meaning of words is concerned (*Word and Object*, 73), and it has implications in the philosophy of mind: if words have no meaning, then beliefs and other \*propositional attitudes do not exist. Quine sees this as an acceptable result of behaviourist psychology; the apparatus of stimulus and response will not vindicate common-sense views about meaning, and 'the very question of conditions for identity of propositions presents not so much an unsolved problem as a mistaken ideal' (*Word and Object*, 206).

The doctrine arises from Quine's dissatisfaction with the Logical Positivists' version of the distinction between \*analytic and synthetic statements, which requires the meanings of words to be explained in terms of the experiences appropriate or inappropriate to their use. Quine

retorts that single words cannot be paired with experiences, since they confront experience in clusters. His celebrated illustration involves an imaginary community who say 'gavagai' when confronted by a rabbit. Other things being equal, it is natural to translate the word as 'rabbit'. But why not translate it as, say, 'undetached rabbit-part'? For any experience which makes the use of 'rabbit' appropriate would also make that of 'undetached rabbit-part' appropriate.

One reply is that we should discover what their word for 'same' is (let us say 'emas') and then point to different parts of a rabbit and see if the community's members keep agreeing that this is the 'emas gavagai'. One would expect them to dissent at some point if this phrase translates 'same undetached rabbit-part'. However, how are we to obtain the translation of 'emas'? It seems that this awaits translation of words like 'gavagai'. For if this translates as 'rabbit', then their failure to dissent from 'emas gavagai' indicates that the latter may translate as 'same rabbit'. But if 'gavagai' translates as 'undetached rabbit-part', then their failure to dissent indicates that 'emas gavagai' should translate as, say, 'part of the same group of undetached rabbit-parts'. We are trapped in a circle, and Quine contends that this always happens if we try to translate 'gavagai' by translating other words first. Since experience is not enough to tie down individual words, there is no initial point on which to base a uniquely correct translation.

A different reply is that finding out more about the brains and nervous systems of the members of the community would indicate which translation is correct. But Quine argues that the indeterminacy thesis holds even given all facts about the world (past, present, and future) that could be stated in terms of physics. The situation here is delicate: on the one hand, Quine's critics accuse him of unfairly restricting the range of facts relevant to translation, while he on the other replies that such critics beg the question by smuggling in assumptions about meaning and translation.

The imaginary community is only a metaphor. If there is nothing to choose between linguist  $A$ 's translation of 'gavagai' as 'rabbit', and linguist  $B$ 's translation of it as 'undetached rabbit-part', then why should not  $B$  translate  $A$ 's uses of 'rabbit' as 'undetached rabbit-part'? Hence, if the argument works, it works within a single language.

Responses tend to involve attacks on Quine's \*behaviourism. But this is not the best approach to his nihilism about meaning, given the currency of nihilism in philosophy of mind (and critical theory). The root of the trouble lies in attempts to give 'scientific' accounts of language and thought, and Quine's outlook is more typical of its time than some treatments indicate.

**transparency:** *see* opacity and transparency.

**transposition** (also known as \*contraposition). The rule in classical logic whereby we derive 'If not- $q$  then not- $p$ ' from 'If  $p$  then  $q$ '. While admitting its occasional acceptability, many find transposition ('an antiquated notion': Dudman) deeply suspect. Difficult cases include 'There's cake if you want it', and Prior's 'If God exists, go to church'. Transposition is the sentential-logic analogue of the argument form \**modus tollens*, and of traditional logic's contraposition (whereby from a given sentence we infer another whose subject is the contradictory of the original's predicate). J.J.M.

V. H. Dudman, 'Parsing "If"-Sentences', *Analysis* (1984).

**transvaluation of values** (or **revaluation of values**). Nietzsche's project of reassessing the worth of things commonly valued positively or negatively. He proposed and undertook to revalue them in terms of their 'value for life', i.e. the extent to which they are conducive or detrimental to the preservation and enhancement of various types of human beings and of human life more generally. This is neither to devalue nor to reverse all prevailing \*value-determinations, but rather to revise them in a naturalistic manner sensitive to the varying requirements of human flourishing. (See e.g. *Beyond Good and Evil*, sect. 4; *Genealogy of Morals*, preface; *The Antichrist*, sects. 1–7.) R.S.

George Morgan, *What Nietzsche Means* (New York, 1965), ch. 5.

**traversal of the infinite**. An argument for the finitude of the world's past which originated with Philoponus (490?–575?). An infinite series cannot be completed (the infinite cannot be traversed). But if the world were infinite in past time, then 'up to every given moment an eternity has elapsed' (Kant) and thus an infinite sequence would have been completed. Therefore the world is finite in past time. This argument has been offered by, among others, al-Ghazālī, St Bonaventure, and Kant. It was, however, decisively refuted by Aquinas and, somewhat more subtly, by Ockham. Aquinas pointed out that traversal requires *two* termini: a beginning and an end. But any past time which could count as a beginning is only a finite time ago. Consequently we do not, in the required sense, have a traversed infinity. J.J.M.

\*infinity.

Norman Kretzmann, 'Ockham and the Creation of the Beginningless World', *Franciscan Studies* (1985).

**triangulation**. Davidson invokes this puzzling notion while arguing that thought is an essentially social phenomenon. The content of our thoughts, he contends, is determined by their causes. Yet, when you see, and think, there is a table before you, many causal factors contribute to your having this thought. What makes it a thought about the *table* as opposed to some other link in the causal chain (e.g. your retinal image)? Davidson maintains that this question cannot be answered if we consider you in isolation. Once we introduce another person, it becomes evi-

dent that communication is possible only on the assumption that your respective thoughts converge on public objects of a shared world. The 'triangle' <person-person-object> is essential to the determination of the mental content and thus, as Davidson puts it, there can be no first person without a second person. D.BAK.

Donald Davidson, *Subjective, Intersubjective, Objective* (Oxford, 2001).

**trolley problem**. Suppose you are driving a trolley whose brakes have failed. Ahead of you five people are standing on the track. But here the track forks, and on the alternative path one person stands. Is it morally permissible, or even required, to divert the trolley to save the five from death, at the cost of one? Most people's intuition is that this is at least morally permissible. Why, then, do we not think it permissible for a surgeon, in urgent need of five different organs to save five patients, to kill a healthy patient to procure them? S.D.R.

**trope**. The term 'trope' was introduced into philosophy by D. C. Williams to mean a particular unrepeatable property, like the particular blueness of a blue patch that cannot be shared by any other patch, not even a patch that *exactly* matches the blue patch in colour. Other patches may nevertheless share the same shade of blue by virtue of the fact that their particular bluenesses resemble one another. Tropes are to be contrasted with \*universals, which are repeatable properties, like a specific shade of blue that can be shared by many different patches. A particular property may be thought to be a complex of a particular (a patch) and a universal (a shade of blue). By contrast, trope theory claims, a trope is not complex but simple. F.MacB.

\*properties, individual; universals.

**Trotsky, Leon** (1879–1940), real name Lev Davidovich Bronstein. The most famous of the Bolshevik leaders after Lenin, Trotsky played a prominent role in the 1917 Revolution and its aftermath, only to be subsequently exiled and murdered by Stalin. Although less interested in philosophy than most of his fellow Bolsheviks, Trotsky did address himself to these matters on two occasions. First in the 1920s he became interested in the philosophy of science. He defended the heterogeneity of the sciences, argued against those who assimilated the method of social science to that of natural science, and refused to claim that dialectical materialism was integral to the creativeness of science. Trotsky displayed the same approach in psychology through his continued preference for the

imagination and enterprise of Freud over the plodding behaviouralism of Pavlov.

Towards the very end of his life, however, Trotsky dealt more systematically with philosophical questions—but with regrettable results. Prompted by the attack on Marxist philosophy by his hitherto loyal lieutenants Burnham and Shachtman, Trotsky wrote *In Defence of Marxism* which consisted in a dogmatic insistence on the essentiality of \*dialectical materialism to Marxism. For Trotsky here, the politics and economics of Marxism had to be ensconced within the framework of a consistent and well-defined philosophical outlook. Anyone who divorced sociology from dialectical materialism and politics from sociology would, in the end, lose any capacity for political activity.

**true for me:** see relativism, epistemological.

**trust.** Whether one trusts a specific other commonly depends on whether one thinks the other is trustworthy in the relevant circumstances. This depends on what knowledge one has of the other's future commitments to behave as one trusts. Some writers treat trust as a matter of rational assessment and rational choice on the parts of both the truster and the trusted. Perhaps because of its relation to trustworthiness, some theorists treat trust as inherently normative—even to the point of assigning an obligation of trustworthiness to one who is trusted. John Locke thought trust central to consensual government. Contrary to the purely rational-choice vision, many theorists suppose that only a normative commitment to some degree of trustworthiness can explain the success of many institutions and organizations in serving their clientele.

\*consent; testimony; loyalty.

Diego Gambetta, *Trust: Making and Breaking Cooperative Relations* (New York, 1988).

**truth.** The term 'truth' seems to denote a property, one which is also expressed by the truth-predicate 'is true'. But if so, of *what* is truth a property? What are the primary 'bearers' of truth, and of its counterpart, falsity? (Whether truth and falsity are indeed polar opposites, as the principle of \*bivalence implies, is itself a disputed issue.) At least three candidates can be put forward: sentences, \*statements, and \*propositions. Loosely, a *sentence* is a linguistic token or type, such as the string of written words 'This is red'. A *statement* is the assertoric use of a sentence by a speaker on a particular occasion. A *proposition* is what is asserted when a statement is made—its 'content'. Thus two different speakers, or the same speaker on two different occasions, may assert the same proposition by making two different statements, perhaps using sentences of two different languages. And the same sentence (conceived of as a linguistic type) may be used in two different statements to assert two different propositions.

In addition to speaking of sentences, statements, and propositions being true or false, we also speak of *beliefs* (and other \*propositional attitudes) being true or false. So is the notion of truth ambiguous, or is there a primary notion which attaches to just one of these classes of items? Opinions differ, but a broad division can be drawn amongst theories of truth between those that regard truth as being a property of *linguistic or mental representations* of some sort—such as primarily sentences, statements, and beliefs—and those that regard truth as primarily a property of *propositions*, conceived as items that are *represented or expressed* in thought or speech, but exist independently of mind and language. Disputes between theorists of truth are sometimes confused by a failure to discern this division.

The best-known theory of truth is the \*correspondence theory. On this view, a candidate for truth is true if and only if it 'corresponds to a fact'. Some objectors complain that the notion of a \*fact is itself only to be explained in terms of truth (for instance, as being the worldly correlate of a true sentence or proposition), so that the theory is vitiated by circularity. Others complain that the notion of 'correspondence' is either vacuous or unintelligible. It is hard to say which philosophers have really held this theory. Aristotle is sometimes said to intimate allegiance to it in his remark that 'to say of what is that it is, and of what is not that it is not, is true'. Wittgenstein's 'picture' theory of the *Tractatus* is often cited as exemplifying it. Even Tarski's \*semantic theory of truth has been described as a version of it. But in modern times its clearest advocate has perhaps been J. L. Austin. The theory is often thought to be vulnerable to devastating criticism in the form of the so-called \*slingshot argument. This argument seems to show that, given any two truths *p* and *q*, the expressions 'the fact that *p*' and 'the fact that *q*' must have the same reference, the implication being that there cannot be more than one fact—sometimes ironically called 'the Great Fact'. The problem is that correspondence theorists typically maintain that distinct truths correspond to *different* facts, but it now appears that these supposed differences between facts inevitably collapse. Very arguably, however, the proper lesson to draw is not that there is something wrong with the correspondence conception of truth as such, but rather that not just its enemies but even some of its friends have unnecessarily embroiled it in bad metaphysics.

Almost equally well known is the \*coherence theory, whose proponents are usually led to it by the perceived difficulties of the correspondence theory. Accepting that truth cannot consist in a relation between truth-bearers and items which are not themselves truth-bearers (such as 'facts'), these theorists propose instead that it consists in a relation which truth-bearers have to one another—such as a relation of mutual support amongst the beliefs of an individual or a community. Opponents object that this leads to an unacceptable \*relativism about truth, since many different and mutually incompatible systems of belief could be internally consistent and self-supporting. They also sometimes complain that advocates of the

theory are guilty of a confusion between stating a *criterion* of truth—that is, a rule for the evaluation of a belief as being true—and stating what truth *consists* in.

In order to overcome the objection of relativism, some advocates of the coherence theory suggest that the notion of truth is a regulative ideal, which could only be fully realized in a unified and completed science far in advance of the fragmented and partial belief systems of any human community that actually exists or is ever likely to. In this guise, the theory overlaps with some versions of the so-called \*pragmatic theory of truth, associated with the American philosophers Peirce, James, and Dewey. The latter theory—particularly in the hands of James—urges a connection between what is true and what is useful, pointing out, for instance, that one mark of a successful scientific theory is that it enables us, through associated developments in technology, to manipulate nature to our advantage in ways hitherto unavailable to us. Detractors protest that this (alleged) conflation of truth with utility is pernicious, because the ethics of belief require us to pursue the truth with honesty even if its consequences should prove detrimental to our material well-being.

All the theories of truth so far mentioned may be called *substantive* or *robust*, as opposed to \**deflationary*, in the sense that they all take truth to be a real and important property of the items—whatever they are—that the theories take to be the primary bearers of truth. But in recent times deflationary theories of truth have become quite popular, the earliest example being the \**redundancy theory* (a later variant of this being the so-called *prosentential theory of truth*). This theory, building on the apparent equivalence between asserting a proposition *p* and asserting that *p* is true, holds that the truth-predicate ‘is true’ exists only in order to enable economy of expression, and that what is said with its aid could in principle be said without it. A closely related view is that the truth-predicate plays a performative role, enabling speakers to express their approval or endorsement of the assertions of other speakers. Serious-minded philosophers will deplore such views for taking truth to be so flimsy.

Some theorists in the pragmatic tradition, such as Stephen Stich, now urge that truth as such has no cognitive value—that we literally should not care whether our beliefs are true or false, but only whether they enable us to achieve more substantive goals such as happiness and well-being. However, \**Sophists* were urging much the same in the time of Plato and—fortunately!—it seems unlikely that philosophers will ever entirely give up asking ‘What is truth?’ and assuming that the answer is something of importance. Quite apart from anything else, giving up the question of truth would deprive them of the endless enjoyment to be derived from attempting to solve the various paradoxes, such as the \**liar paradox*, which the notion of truth throws up.

In recent years, metaphysicians have been emphasizing again the connection between \**realism* and truth that seems to have inspired many advocates of the correspondence theory. This attitude often finds expression in some

version of the so-called truth-maker principle—the principle that every truth (or, at least, every contingent truth) must be *made* true by the existence of something in reality. Some advocates of the principle, such as David Armstrong, maintain that truth-makers are *states of affairs*, others that they are particularized \**properties*, or *tropes*. So, for example, on the former view it is *Mars’s being red* that makes true the proposition that Mars is red, while on the latter it is *Mars’s redness* that makes this true. Both approaches contend that the world contains a multiplicity of truth-makers, but neither insists, as some versions of the correspondence theory do, that there is a one-to-one correlation between truths and truth-makers. Indeed, truth-maker realism is not committed to the claim that truth *consists* in, or is definable in terms of, any independently specifiable relation between truth-bearers and other entities of any specific kind. For this reason, it is not vulnerable to many of the objections traditionally raised against the correspondence theory of truth, while at the same time inheriting the attractive realist and anti-relativist implications of that view.

**truth, semantic theory of:** *see* semantic theory of truth.

**truth, subjective:** *see* subjective truth.

**truth and truthfulness.** The assumptions that one is truthful when speaking truly, and that truthfulness is a virtue, because truth is valuable, are both questionable. True statements can be intentionally misleading (e.g. ‘Someone stole your book’, said by the culprit), and a would-be liar may, through ignorance, inadvertently say something true. In neither case would we describe the

speaker as being truthful. In *The Gay Science* (§344), Nietzsche denies that truthfulness is admired because it helps disseminate truth, for 'truth at any price' may be 'inimical to life'. Rather, we admire truthfulness, irrespective of practical benefits, on the 'moral ground' that 'I will not deceive, even myself'. The virtue of truthfulness is therefore relatively independent of the value of truth. D.E.C.

B. Williams, *Truth and Truthfulness: An Essay in Genealogy* (Princeton, NJ, 2002).

**truth-conditions.** Usually short for 'truth- and falsity-conditions'. The truth-conditions of an indicative sentence are the conditions under which it would be true, or false: e.g. 'I'm exheredated' is true if the speaker is at the time of speaking exheredated, and false otherwise. The truth-conditions of a word or phrase are its contribution to the conditions under which an indicative sentence containing it would be true, or false: e.g. (for the word 'exheredated') any sentence 'a is exheredated' is true if 'a' in it refers to something exheredated, and false otherwise. (These are very simple examples; even so, it is not implied that they are necessarily accurate, especially over falsity.)

C.A.K.

D. K. Lewis, 'General Semantics', in *Philosophical Papers*, i (New York, 1983).

**truth-function.** A proposition is a truth-function if its truth-value is determined by the truth-value of its components (or arguments). In the standard \*propositional calculus (PC), propositions have truth-values True or False exclusively. The logical constants  $\sim$ ,  $\vee$ ,  $\cdot$ ,  $\supset$ ,  $\equiv$  (in one standard notation), which approximate to the English 'not', 'or (inclusive)', 'and', a use of 'if', and 'if and only if', respectively, are so defined that a \*well-formed formula of PC which is a proposition is a truth-function.

For example, where  $\phi$  and  $\psi$  are propositions,

- $\sim\phi$  is true if and only if  $\phi$  is false,
- $(\phi \vee \psi)$  is true if and only if  $\phi$  is true or  $\psi$  is true or both are true,

and so on as given in the \*truth-tables for the logical constants.

There is therefore an effective procedure for determining the truth-value of any PC proposition given the truth-value of its basic (atomic) propositional components.

R.B.M.

B. Mates, *Elementary Logic* (Oxford, 1972).

**truth-table.** In the \*propositional calculus, if  $\phi$  and  $\psi$  are propositions, then the truth-value True or False of the truth-functions  $\sim\phi$ ,  $(\phi \vee \psi)$ ,  $(\phi \cdot \psi)$ ,  $(\phi \supset \psi)$ ,  $(\phi \equiv \psi)$  may be determined from the following matrices:

$\phi$	$\sim\phi$
T	F
F	T

$\phi$	$\psi$	$(\phi \vee \psi)$	$(\phi \cdot \psi)$	$(\phi \supset \psi)$	$(\phi \equiv \psi)$
T	T	T	T	T	T
T	F	T	F	F	F
F	T	T	F	T	F
F	F	F	F	T	T

where ' $\sim$ ', ' $\vee$ ', ' $\cdot$ ', ' $\supset$ ', ' $\equiv$ ' may be translated as 'not', 'or', 'and', 'if... then ---', and '... if and only if ---' respectively.

The truth-value of truth-functions constructed out of  $n$  basic (atomic) propositions can be determined from a truth-table of  $2^n$  lines by systematic application of the matrices.

For example, if  $p$  and  $q$  are basic or atomic propositions, then the truth-table for  $((p \cdot q) \supset p)$  may be given as follows.

$p$	$q$	$((p \cdot q) \supset p)$
T	T	T
T	F	F
F	T	T
F	F	T

and translated as: If  $p$  and  $q$ , then  $p$ .

R.B.M.

B. Mates, *Elementary Logic* (Oxford, 1972).

E. L. Post, 'Introduction to the Theory of Elementary Propositions', *American Journal of Mathematics* (1921).

**truth-value.** The truth (T or 1) or falsity (F or 0) of a proposition is its truth-value. In \*propositional calculus, propositions are regarded primarily as the bearers of these two values: the \*truth-table method is used to calculate the value of compound expressions. Systems using more than two such values have been developed by some modern logicians, e.g. Łukasiewicz. C.W.

A. N. Prior, *Formal Logic*, 2nd edn. (Oxford, 1962), pt. III, sect. 2.

**trying,** or attempting; phenomenon whose relation to \*belief, \*desire, \*intention, is investigated in philosophy of action.

Some philosophers accord trying a prominent role in action's elucidation, believing both that someone who does something intentionally tries to do it, and that trying marks a point where *mental* and *physical* concepts meet in their application. A person's trying to do something is naturally thought of as 'mental'; but an event of a person's trying to do something is, arguably, usually the same as a 'physical' action of hers. J.HORN.

\*volition.

Jennifer Hornsby, *Actions* (London, 1980), ch. 3.

**Tugendhat, Ernst** (1930– ). One of the most important contributors to the re-establishment of \*analytic philosophy in Germany after the Nazi period, in which almost all

analytic philosophers had to leave the country. Tugendhat, born in Brno as a Jew, emigrated to Venezuela, received his BA at Stanford 1949, his Ph.D. in Freiburg 1956, and his Habilitation in Tübingen 1966. He has held professorships in Heidelberg, Starnberg, and Berlin.

Trained by Heidegger in the Aristotelian and phenomenological tradition, he argues in an original way that analytic philosophy of language is the culmination of Aristotle's ontological project. Throughout Tugendhat's work the central characteristic of philosophy is 'the idea of organizing life as a whole in accordance with truth, i.e. the idea of a life of critical responsibility'. Along the same lines, he argues that Wittgenstein's view of self-knowledge and Heidegger's account of practical self-understanding are intrinsically connected because consciousness of the self arises only when I ask the question what kind of human being I aspire to be. This question also plays a central role in ethics as Tugendhat conceives it: morality can only be justified relative to conceptions of good personhood. s.g.

E. Tugendhat, *Traditional and Analytical Philosophy: Lectures on the Philosophy of Language*, tr. P. A. Gornier (New York, 1982).

**Turing, Alan** (1912–54). English mathematician best known for the \*Turing machine and the Turing test, both concerned with the relation between computation and mind. Turing's work in mathematical logic in the late 1930s systematized ideas of Gödel and Church in the form of an abstract description of what an idealized finite agent could compute. During the Second World War Turing worked on deciphering German codes, and in particular on the computational machinery required. After the war he worked on early digital computers and in 1950 published 'Computing Machinery and Intelligence' in *Mind*. In this article he proposes a test for thought: a machine can think if its replies to questions are indistinguishable from those of a human. A.M.

\*computers.

Andrew Hodges, *Alan Turing* (London, 1985).  
*The Essential Turing*, ed. B. J. Copeland (Oxford, 2004).

**Turing machine.** A Turing machine is an idealization of an ideal finite calculating agent. It is usually described as if it were a mechanism, but a description as an ideal clerk would also be possible. So a Turing machine has an infinite tape (or notepad), a head which reads or writes symbols from a finite list to it (or pen), and a finite number of states. A machine-table specifies what, given a state and a symbol, will be overwritten at that point, and the next state. It can calculate anything any digital computer can. Three fundamental facts are (a) the characterization does not depend on details of how many symbols etc. there are; (b) there is a 'universal' Turing machine which can mimic the output of any other machine; (c) there is no Turing machine which, given a specification of any arbitrary Turing machine and an input, will halt when that machine halts, given that input. The last, (c), is closely related to

Gödel's theorem. Turing machines can give substance to \*functionalism in the philosophy of mind. A.M.

*The Essential Turing*, ed. B. J. Copeland (Oxford, 2004).

**Twardowski, Kazimierz** (1866–1938). Polish philosopher who became the father of Polish \*analytic philosophy. Twardowski studied in Vienna with Brentano (Ph.D. 1891, Habilitation 1894). In 1895 he was appointed a professor of philosophy at the University of Lvov. Twardowski was a distinguished teacher who trained many Polish philosophers and logicians, including Ajdukiewicz, Kotarbiński, Leśniewski, and Łukasiewicz. In his essay *Zur Lehre vom Inhalt und Gegenstand der Vorstellungen* (1894) Twardowski introduced a distinction between the content and the object of presentations which completed Brentano's earlier analysis of psychic phenomena in terms of acts and objects. Twardowski also argues for the thesis that there are no objectless presentations and develops a theory of objects. His *Habilitationsschrift* considerably influenced Meinong's ontology and Husserl's preparatory studies to *Logische Untersuchungen*. The actions-products distinction is another of Twardowski's conceptual clarifications which deserves to be mentioned. J.WOL.

K. Twardowski, *On the Content and Object of Presentation*, tr. H. Grossmann (The Hague, 1976).

**twin earth.** Imaginary counterpart to earth introduced in thought experiments in philosophy of mind and language.

In Putnam's famous example, on twin earth the stuff which falls from the sky, comes out of taps, and constitutes oceans, etc. is XYZ, not H<sub>2</sub>O. Putnam argued that a person's meaning what she does cannot be 'in her head', since twin earth's inhabitants' heads are not relevantly different from earth's, but what they mean by 'water' is different from what earth's inhabitants mean. J.HORN.

John Heil, *The Nature of True Minds* (Cambridge, 1993), ch. 2.

**two-envelope paradox.** Imagine that you are offered a choice between two envelopes, each containing money. One has twice as much money as the other, but you are not told which. Once you have selected an envelope, A, you are offered a further choice. You can either open the envelope or swap it for the other, B. You reason as follows.

Let the amount of money in A be  $x$ . The other envelope, B, contains either  $2x$  or  $x/2$ . The two possible outcomes are equally probable. Therefore, the expected value of swapping A for B is  $(0.5 \times 2x) + (0.5 \times x/2) = 5/4x$ . Since the expected value of hanging on to A is  $x$  (given that it is certain that A contains  $x$ ), if I want to maximize expected value, I ought to swap A for B.

This is paradoxical because, once I have swapped A for B, a similar line of reasoning will show that I ought to swap back—and so on indefinitely. J.BER.

\*decision theory; paradoxes.

Timothy J. McGrew, David Shier, and Harry S. Silverstein, 'The Two-envelope Paradox Resolved', *Analysis* (1995).

**tychism:** *see* Peirce.

**type:** *see* token.

**types, theory of.** Let  $r$  be the set of all sets that are not members of themselves:  $\{x \mid x \notin x\}$ . It follows that  $r \in r$  if and only if  $r \notin r$ , a contradiction. This is known as \*Russell's paradox. A similar result can be obtained from the property of those properties that do not hold of themselves (i.e.  $R(P)$  if and only if  $\neg P(P)$ ). Type theory avoids these consequences by segregating properties, relations, and sets into 'types'. Type 0 items are ordinary objects, which are not properties. Type 1 items are properties of ordinary objects; type 2 items are properties of type 1 properties, etc. 'Personhood' is type 1, and 'holding of

exactly six objects' is type 2. Things get more complex when relations are considered. There is, for example, a type of relations between type 1 properties and ordinary objects. In 'ramified type theory', types are further segregated into levels. Type 1, level 0 properties are those that can be defined with reference to type 0 items (ordinary objects) alone. Type 1, level 1 properties are those that can be defined with reference to type 0 items and type 1, level 0 properties, etc. In general, each property must be defined with reference to only properties of lower type and properties of its type but lower level. 'Simple type theory' does not employ levels, and allows unrestricted, or impredicative, definitions. s.s.

\*higher-order logic; vicious circle; reducibility, axiom of; logic, history of.

# U

**ugliness.** The property of having aesthetic disvalue, eliciting not indifference but discomfort or misery. Modes of ugliness in art correspond to the various modes of beauty or aesthetic value. If the mode is formal, ugliness is the ill-formed or deformed, misshapen, ill-placed. If the mode is expressive, the ugly may be the sentimental, the mawkish, clichéd, sickening; or it may arise from uncontrolled emotion—bombastic, ranting, or hysterical. If considered from a representational point of view, the objects represented may be judged unrelievedly disagreeable or painful to contemplate. Nevertheless, art can make use of the ugly; and the question must always be asked: Does this *prima facie* ugly work possess any justifying, compensating features—perhaps social or moral point? Or has this ugly component been transformed—by the medium—by the context—to be an ingredient in a new whole with positive aesthetic value?

R.W.H.

\*beauty.

There is a dearth of recent substantial discussions. One *locus classicus* is Plotinus, *Enneads*, I. 6. See also Bernard Bosanquet, *Three Lectures on Aesthetics* (London, 1915).

**Unamuno, Miguel de** (1865–1936). Multi-faceted Spanish writer (novelist, poet, essayist) and professor (philologist). Deeply concerned about the meaning of life and death, which inspired all his writings, and dissatisfied by the sceptical answers of science and reason as regards eternal life, Unamuno argued for an existential attitude—the ‘tragic sense of life’—consisting in acting as if human life has in fact a transcendent significance, even given our uncertainty that it has.

Unamuno found this attitude exemplified in lonely heroes such as Don Quixote and Jesus: men who, despite their respective folly and doubts (or maybe because of them), carried out their missions, thus redeeming themselves and others. This attitude has a clear religious dimension, closer to Protestant spirituality than to Spanish orthodox Catholicism. In fact, some of Unamuno’s works were included in the Index, until the Second Vatican Council.

A.GOM.

R. R. Ellis, *The Tragic Pursuit of Being: Unamuno and Sartre* (Tuscaloosa, Ala., 1988).

**uncertainty principle.** Also called the indeterminacy principle, it is based on the orthodox (‘Copenhagen’) interpretation of a set of mathematical inequalities entailed by \*quantum mechanics, called uncertainty relations. Roughly, these put a fundamental limit on the accuracy with which one can simultaneously predict the values of certain pairs of physical magnitudes (termed ‘incompatible’), such as the position and momentum of a particle. More precisely, if one can predict that a particle’s position will (most probably) be found on measurement to fall within some narrow range of values, then accuracy in predicting its momentum to fall within a similarly narrow range must be sacrificed, and vice versa. Orthodoxy interprets this as more than just a limitation on the statistical spread of measurement results, but as a principle governing what can be said about a single particle. Heisenberg mainly argued that the limitation is epistemic, preventing the simultaneous determination of a particle’s position and momentum (and so forever blocking the possibility of predicting its future behaviour); while Bohr argued that the limitation is also ontic, rendering inapplicable the classical concepts of ‘position’ and ‘momentum’ to a particle.

**unconscious and subconscious mind.** Although Freud claimed to have discovered the unconscious mind, there is little doubt that the view that there are aspects of our mental life to which we are not privy was widely available throughout the nineteenth century. Anticipations are to be found in Leibniz, Schelling, and Nietzsche. Freud’s own preference was for the term ‘unconscious’ rather than ‘subconscious’, which was also widely used, on the grounds that the latter term encourages the equation of the psychical with the conscious. His conception of the unconscious allows that we may possess wishes which may be inaccessible to us. Freud believed that we need assistance from \*psychoanalysis to recover them.

R.A.S.

H. F. Ellenberger, *The Discovery of the Unconscious* (New York, 1970).

**undecidability.** Term not only used in the philosophy of mathematics but also deployed by Jacques Derrida and those who have adopted his heterodox procedures in the deconstructive reading of philosophical and literary texts. Here it signals the impossibility of deciding between discrepant (often contradictory) orders of meaning, as for instance between the constative and performative, the literal and metaphoric, or the overt and the latent orders of sense.

C.N.

\*deconstruction; *différance*; logocentrism; decidability.

Jacques Derrida, *Margins of Philosophy*, tr. Alan Bass (Chicago, 1982).

**underdetermination.** The *problem of underdetermination* concerns the relationship between \*theory (scientific theory, or any generalization) and the \*empirical data. For any given theory, the evidence will never determine the choice between that theory and some rival theory. The problem then is to show how theory choice can ever be rational.

R.L.E.P.

W. H. Newton-Smith, *The Rationality of Science* (London, 1981).

**understanding.** What it is about humans, uniquely so far as is known, that enables us to understand other minds, do mathematics and science, cheat evolution by manipulating our environment, and speculate about itself in philosophy. Philosophers debate about the limits of understanding—for instance, how could we know either that there are or that there are not things for ever beyond our grasp? But it is easier to be amazed at its scope. Why should an average mammal on a peripheral planet be able to fathom the nature of preceding creatures millions of years back, the interior of stars, the laws of nature, the early moments of the whole universe? That is far in excess of what we need in order to get by, as the other animals (who do not reciprocate our interest in them) get by. The most astounding thing in the world, it may seem, is that we can understand it and the creatures within it. So much understood so recently. Yet the brains of Stone Age people were as capacious as ours. I wonder if they felt the same awe.

**underworld of philosophy:** see philosophy, world and underworld.

**undistributed middle.** It was a rule of traditional logic that the middle term of a valid \*syllogism (the term common to the premisses) must be distributed in at least one of its occurrences: not meeting this requirement was the fallacy of undistributed middle. (\*Distribution of terms.) On this view

All who train regularly are fit

All Olympic athletes are fit

Therefore, all who train regularly are Olympic athletes

is invalid because the middle term ('those who are fit') is in both instances the predicate of a universal affirmative (\*logic, traditional) and therefore undistributed. The uneasy wording of the rule, which permits the middle term to be distributed either once or twice, reflects weaknesses in the standard doctrine of distribution.

**unhappy consciousness:** see alienation; Feuerbach.

**uniformity of nature.** Newton stated that certain qualities (such as inertia and impenetrability) 'which are found to belong to all bodies within the reach of our experience, are to be esteemed the universal qualities of all bodies whatsoever'. Such an inference must be based, Mill said, on the 'ultimate major premise' that 'the course of nature is uniform'. Taking that to mean that 'whatever is true in any one case, is true in all cases of a certain description', Mill thought that 'the only difficulty is, to find what description'. But any doubts about the truth of such generalizations are not settled by invoking as an assumption the alleged 'uniformity of nature': without the relevant descriptions the principle is empty, while with them it says no more than the generalizations themselves.

M.C.

\*grue; induction.

E. Nagel, *The Structure of Science* (London, 1961).

**union theory.** The union theory concerns the relation between mental events and neural events, and their combined causal efficacy. It holds that all types of mental event are nomically correlated with types of neural event, that the correlation is most likely to be that of one type of mental event with one of many types of neural event, and that these 'psychoneural' correlates are pairs. The last idea is the most distinctive and original component of the theory. Psychoneural pairs are thought to function as a causal unit, in other words as a single cause and effect of things, rather than being separable into individual causes and effects. The principal recommendation of the theory is that it allows for the irreducibility of the mental while avoiding \*epiphenomenalism.

P.J.P.N.

\*consciousness, its irreducibility.

T. Honderich, *A Theory of Determinism* (Oxford, 1988), chs. 2 and 3.

**unity of science.** The unity of science, in its traditional positivistic formulation, is the view that all science is reducible to physics, in that lawful relations for any science can be derived in an appropriate way from the laws of physics. Alternatively, the unity of science might be understood as a methodological constraint on scientific-theory formation, where reduction to physics plays a

regulatory role in scientific practice. Many philosophers (e.g. Fodor) argue that the special sciences, such as psychology, are legitimate even though they cannot in principle be so reduced.

M.B.

\*reductionism.

A classical statement is R. Carnap, *The Unity of Science*, tr. Max Black (London, 1934). Cf. J. Fodor, *The Language of Thought* (Cambridge, Mass., 1979), ch. 1.

**universal grammar.** A set of principles true of all human languages and thought to be mentally represented in the minds of language-users. The principles characterize the genetically determined initial state of the language faculty—a biological endowment, specific to the human species, which provides the innate conditions for the growth of linguistic knowledge in the individual. Grammars for particular languages result from the exposure of the language faculty to the available linguistic data.

B.C.S.

\*grammar.

V. Cook, *Chomsky's Universal Grammar* (Oxford, 1988).

**universalizability.** A judgement about an individual instance of a certain kind is universalizable if it applies also to every relevantly similar instance of that kind. An assumption of universalizability underlies appeals to the \*golden rule (in ethics), the uniformity of nature (in science), equality before the law (in jurisprudence), logical form (in deductive proof), reasonableness (in common-sense inference), etc. In sum, all arguments about individual things ought to be universalizable.

L.J.C.

R. M. Hare, *Moral Thinking: Its Levels, Method and Point* (Oxford, 1981), 107–29.

**universalizability, moral.** The concept of \*universalizability has been thought by some philosophers to provide a rational basis for moral principles of impartiality and justice. It is suggested that, if I maintain that I ought to act in a certain way towards others, the universalizability of 'ought' requires me to accept that others ought to act in the same way towards me. This then commits me, it is said, to accepting only those 'ought' judgements which give the same consideration to others' interests as to my own.

Critics have retorted that this is an attempt to build too much on the purely formal requirement of consistency. I can be a consistent egoist; if I think that I ought to pursue my own interests, universalizability commits me only to accepting that others ought also to pursue their own interests. And why should I not accept this?

R.J.N.

R. M. Hare, *Freedom and Reason* (Oxford, 1963).

**universal proposition.** In traditional logic propositions construed as having the form 'All S are P' or 'No S are P' (which implies 'All S are not P') were called universal and

contrasted with the particular forms 'Some S are P' and 'Some S are not P'. In \*predicate calculus, propositions like 'All men are mortal' are represented as having the form 'For all x: if x is S, x is P', which may be symbolized as  $\forall x(Sx \rightarrow Px)$ .

**universal quantifier:** see quantifier.

**universals.** Universals are the supposed referents of general terms like 'red', 'table', and 'tree', understood as entities distinct from any of the particular \*things describable by those terms. But why should we suppose that such entities exist, and what must be their nature if they do? One traditional argument for their existence, traceable to Plato, is that they are needed to explain why all and only the particular things correctly describable as red, say, are indeed correctly describable as such. Surely all these distinct particular things must have something identifiable in common in order to be legitimately classified alike?—and that which is common to all and only red things is precisely the universal red. Red things are all red by virtue of their relationship to this one universal, according to traditional 'realism'. As to the nature of this relationship and the nature of universals themselves, however, realists are divided. 'Platonists' hold that the universal red has a non-spatio-temporal existence distinct and separable from all particular red things, which need not even exist in order for that universal to exist. 'Aristotelians' hold, conversely, that the universal red only exists inseparably from the existence of particular red things. But the Platonic view creates difficulties concerning the relationship between particular red things and the universal red, while the Aristotelian view seems to render the sense in which universals are 'real' somewhat tenuous. Furthermore, the argument just mentioned for the existence of universals is not entirely convincing. 'Conceptualism' holds that our classification of particulars under general terms is a product of our selective human interests rather than a reflection of metaphysical truth, while \*'nominalism' holds that resemblances between particulars are sufficient to justify our application of the same general term to them without appeal to any additional entity.

However, the failure of one traditional argument for realism and internal difficulties in certain realist positions do not suffice to undermine the realist case. In recent years new arguments for realism have emerged which invoke universals to explain the status of natural laws and causal generalizations. Philosophers like D. M. Armstrong urge that natural necessity is to be explained as a relationship between universals, and that only by appeal to this notion can the logical distinction between lawlike and accidental generalizations be captured. On this view, it is not necessary to suppose that every meaningful general term refers to a real universal, since only those universals need be admitted that play a role in scientific laws. Hence this view need not be embarrassed by Wittgenstein's observation

that there are general terms like 'game' for which it seems impossible to isolate any single feature common to all and only the particulars to which it applies.

Another reason why a realist need not be totally indiscriminating about general terms is that such terms clearly fall into a number of distinct semantic categories, not all of which equally invite a realist treatment. Thus, of the three general terms mentioned at the outset—'red', 'table', and 'tree'—only the latter two are \*sortals, and of these only the last is a natural-kind term. Sortals differ from general terms like 'red' in that they convey not only a criterion of application but also a criterion of identity for the particular things to which they apply. Since particulars cannot be individuated at all save relative to an appropriate sortal classification, it is arguable that realism with regard to particulars demands realism with regard to at least some universals, namely, those that are the putative referents of *bona fide* natural kind terms.

**unlikely philosophical propositions.** Perhaps most philosophers are ready enough to make a list of these. Certainly in their talk they give evidence of having the materials ready to hand. Philosopher-editors, being accessories to the publication of much that by their lights is unlikely to be true, maybe even a thing or two that are just confused, are readier to make a list. It may be a *cri de cœur*. Here is mine.

1. *Philosophy is one subject in which formal logic is fundamental.* This book is a proof that philosophy is a family of subjects, indeed an unruly one. In that family, as the book also demonstrates, formal logic is neither father nor even elder brother. (Maybe philosophical logic has more claim to such a position, but still not a large claim.) How many large philosophical problems have been solved or made more tractable by formal logic? Have any? Why is there no formal logic to speak of in the greatest works of philosophy?

2. *A service is done to students or other innocents, or to logic, by those logicians who allow it to be thought that the ordinary 'If . . . then . . .' thoughts that we depend on in life and science somehow come down to a thing, fundamental to a basic part of logic and called a material implication, which by definition is true except when its first part is true and its second part false.* If you are tempted to go along with the idea, reflect on 'If Hollywood is in California, then Edinburgh is in Scotland.' Do not neglect, either, 'If Edinburgh is in California, then Aristotle was a photographer'.

3. *Our own conscious thoughts and feelings are not different from electrochemical events in our brains. They are nothing but electrochemical events which are causally or logically related to*

*certain other things, notably what is called input and output.* This is the root proposition of functionalism, cognitive science, and much psychologized and computerized philosophy of mind in so far as it applies to us rather than computers, Martians, or whatever else. If it is true, then what we are most sure about does not exist.

4. *If you and I both see the same copy of this book, there are two objects of awareness in question—each of us is just aware of a subjective thing, a 'sense-datum' or whatever.* Great philosophers have thought so. They have thought in this way about the external world in general. If so, as far as perception goes, each of us is in a kind of perpetual solitary confinement. No books, either. There's got to be something wrong with *that*, doesn't there, even if perceptual consciousness like the rest of consciousness somehow has a subjective side?

5. *The truth of a statement about the world, say about the weight of this book, does not consist in the statement's corresponding to actual things, but in some quite different relation, maybe one of coherence with other statements.* If so, whatever the attractions of anti-realism for mathematics and logical systems, the world is as incidental to truth as it is to consistent imagining. Nor, by the way, can difficulties in getting clear about the general relation between language and the world, or the mistake of talking about facts rather than things, reduce us to the deflationary policy of saying ' "Snow is white" is true if and only if snow is white', and a like thing about any other proposition—and saying no more than that.

6. *In the possible world where I'm wearing brown shoes and a hat . . . ' can mean something other than and grander than 'In this world, if I were wearing brown shoes and a hat . . . '.* Some who want to give a helping hand to modal logic think so, and some others, a lot more, mystify the impressionable by joining into the talk. Conditional statements, and notably the counterfactual ones, aren't easy to explain, but we can get somewhere without the science fiction.

7. *An effect is not something that had to happen or was necessitated, but just an event which was preceded by something necessary to it, something without which the event wouldn't have happened.* If so, we can say our choices and decisions are effects without getting worried about whether we have free will. But effects aren't what we thought they were, which is things that actually have explanations.

8. *An effect by itself, as distinct from a thought of it in advance or earlier similar effects or anything else, sometimes explains why its cause happened.* This, the ancient and wonderful idea of teleological or functional explanation, is sometimes veiled by technicalities, sometimes turns up in Marxist reflections on base and superstructure, and is sometimes discerned in biology. The idea is aided by the example, about which it is a good idea to think again, that birds have hollow bones because that enables them to fly better.

9. *Moral judgements, say the judgement 'Socialism is morally right', are not a matter of our disputable attitudes or inclinations, but are like "That rose is red", which, although it is somehow dependent on our perceptual apparatus, is definitely true or*

*false in the plain sense.* This, too good to be true, has stolen the name of moral realism. Maybe moral judgements can be rooted in real truths of human nature. That is a different realism, less dramatic but more reassuring.

10. *There are moral reasons for actions that do not rest on consequences of those actions. So consequentialism as it is called is a mistake, a low one.* The idea is edifying but surely it can't be right. A moral reason, like any reason, is a kind of desire that an action is to satisfy. How could there be such a desire without reference to consequences of or in the action? How could the reason 'He's my son' be such? Supposedly non-consequentialist reasons are about somehow self-serving consequences, aren't they?

11. *To argue for punishment by saying, in one way or another, that it is deserved or is a retribution is to give some reason for it other than the disagreeable one that it satisfies grievances—desires for the distress of offenders.* What is offered instead in analysis or explanation of arguments of desert or retribution is usually high-minded, but not such as to provide an actual reason.

12. *There is some principle of justice or equality or well-being, or some other principle of political morality, that should have priority over this: that we must seek by rational means to make well-off those who are badly off, one of our means being the reducing of demands for rewards by larger contributors to society.* I don't think we'll find anything closer to true than the Principle of Humanity. In liberalism or anything else.

13. *Philosophy, to come back to that whole subject, has less to contribute to the understanding of realities of one kind and another than science, literature, economics, history, or narrower specialities.* You can think instead that there is a division of labour in thinking about consciousness, the world of which Quantum Theory as interpreted is a theory, time, free will, genes, terrorism, and more. There are scientific and other disasters in those neighbourhoods. Decent philosophy's contribution, as essential as any, is a general logic—a clarity, consistency and completeness. We can't get along without it. There should be a book, too, on why science regularly gets philosophical subjects so wrong.

Why are philosophers not detained by the certainty that their published or unpublished lists of unlikely philosophical propositions have no chance of being widely accepted as unlikely? (There is *some* philosopher, decent enough and paid for his work, whose list contains exactly the contradictories of the propositions above.) Does this show that philosophy is the particular line of life whose questions are hardest, and that surviving in its resulting climate of uncertainty brings out bumpiness? T.H.

\*Honderich.

**unsaturated expression.** An expression that needs supplementation before it has what Frege calls a complete sense; an expression that refers to functions, not objects. Frege views an expression such as 'Caesar conquered Gaul' as analysable into two sorts of constituents, one complete in itself and the other unsaturated. 'Caesar' and

'Gaul' are of the first sort; these refer to objects. '—conquered —' is of the second sort; it must have its blanks 'saturated' before it can express a complete sense. Other examples of unsaturated expressions are 'the father of —' and 'either — or —'. Observe that the notion of unsaturated expression is quite different from Russell's notion of 'incomplete symbol'. Frege explains the notion in, among other places, 'Function and Concept', in *Collected Papers on Mathematics, Logic, and Philosophy* (Oxford, 1984). A.GUP.

**Upanishads.** Theoretical sections of the orally transmitted corpus of sacred Sanskrit literature called 'Veda' and traditionally believed to have no beginning in time. The Upanishads were compiled in India 400 to 500 years before Socrates. These parts of the Vedic corpus were so named because pupils had to sit (*śad*) down (*ni*) close (*upa*) to their teacher to learn them. There are nearly 100 of them, many of which are apocryphal. The twelve principal ones include texts called 'The Lord', 'By Whom?', 'Questions', 'The Big Forest', etc. Commenting upon these major Upanishads was essential for a philosopher starting a new school of \*Vedānta. The Upanishads use the forms of dialogue, anecdote, parable, and allegory to make their point.

For example, we find a dialogue in the court of philosopher-king Janaka between Yājñavalkya and a woman philosopher Gārgī about the phenomenology of dreams and deep sleep; the anecdotes of the candid son of a prostitute who was treated as belonging to the highest caste of priests because of his love of truth, and of the young lad Nachiketas walking up to the palace of Death to ask about the afterlife; a parable of ten people who could never find the tenth because no one counted himself; the allegory of transcendental and empirical selves as two birds on a branch, one watching the other nibble at objects of experience. There are also pieces of straightforward reasoning like 'Fear and constraint come from a second, therefore to realize that the self alone is real without a second, is to be fearless and free'.

By distinguishing pleasure from the good, the Upanishads claim self-knowledge to be the ultimate good. The notion of the Self or *Ātman* is analysed in much detail, with accounts like that of the 'five sheaths' of food, breath, mind, intellect, and bliss being the progressively subtler individuators of consciousness yielding progressively deeper notions of a person. True self-knowledge is attained by philosophical reflection supported by greedless performance of social duties. A virtue ethics enjoining truthfulness, universal love, self-control, and inwardization of the senses is developed with a liberating union of the self with the world-spirit Brahman, as the final goal of life.

The notion of a world-spirit is arrived at by ignoring structural and functional differences and reducing effects to their material causes. The appeal here is to intuitions like 'What is the nail-clipper except the steel?' Such reductive logic is then applied to resolve all objects into intentional transformations of the knowing consciousness.

This witnessing consciousness, like the watching bird mentioned in the allegory above, can never really be made an object. Since the real is that which stays the same through change and cannot be thought away, the undifferentiated unlimited pure Consciousness is arrived at as the stuff of which both we and the world are made.

This Supreme Reality is also pure Being and pure Bliss. It is essentially formless and indescribable in words, but when personalized it is called God or the Lord. At its monistic height, meditation on this first philosophy shows that I am Brahman, which is all there is. Wittgenstein's remark that 'the spirit of the snake . . . is *your* spirit for it is only from yourself that you are acquainted with spirit at all' (*Notebooks*, 85e) reveals the impact of the Upanishads, which trickled down to him through Schopenhauer, who admits to being deeply influenced by them. A.C.

\*Indian philosophy.

Paul Deussen, *Philosophy of the Upanishads* (New York, 1966).

**use and meaning.** What gives words their \*meaning? According to Wittgenstein, in his later writings, what breathes life into dead signs is their use. His thesis that meaning is use replaces views of word meaning as ideas in the minds of speakers, or as the things words stand for. But what is the relationship between meaning and use? Not every way of using a word is part of its meaning. There are correct and incorrect uses of words. Wittgenstein saw the correct use of a word as governed by a rule, and supposed that it was the existence of common rules of use for words that guaranteed them a meaning among a linguistic community. On this account, meaning does not precede use but is constituted by rule-governed use of a word. Equally, meaning cannot transcend use: there can be no more to the meaning of an expression than can be discerned by observing the use that speakers make of it. Thus Wittgenstein treats meaning as a public not a private matter. However, problems remain. Rules extend beyond any instance we reach, but how can their indefinite application be extrapolated from current use? Furthermore, rules suggest a normative dimension to meaning, but which features of use reveal these linguistic norms? These problems remain matters of intense philosophical scrutiny. B.C.S.

P. Horwich, *Meaning* (Oxford, 2001).

**use and mention.** A distinction between talk about the world by means of a word and talk about that word. For example, in 'Numbers are abstract objects' the word 'number' is used, but in "'Number" has six letters' the word 'number' is mentioned. To mark the distinction, it is customary to place a word in quotation marks in cases where it is being mentioned. As a test for the distinction, translate the sentence embedding the word into another language. If the word is mentioned, it is appropriate to leave it untranslated; if used, inappropriate.

It is important to observe the distinction to avoid confusion between ascribing properties to language and ascribing properties to non-linguistic reality. s.p.

\*formal and material mode.

**utilitarianism** is an approach to morality that treats pleasure or desire-satisfaction as the sole element in human good and that regards the morality of actions as entirely dependent on consequences or results for human (or sentient) well-being. Utilitarianism has its origins in late seventeenth-century Britain, received its 'classical' formulations in the work of Bentham, Mill, and Sidgwick, and has continued to have a prominent place in the English-speaking philosophical world up to the present day. Bentham and most subsequent utilitarians discard religious traditions and social conventions in favour of treating human \*well-being or \*happiness as the touchstone for all moral evaluation; and in the nineteenth century, in Britain and elsewhere, the doctrine played an important role in democratic and humane political reforms.

Present-day utilitarianism is best understood by breaking it down into its separable elements, by focusing on certain formal and controversial aspects of utilitarian thought, and by indicating important variations and disagreements within utilitarianism itself. In its earliest and best-known examples, utilitarianism is a *hedonistic* doctrine: it treats pleasure and pain as the sole good and bad things in human lives. This \*ethical hedonism was originally tied to \*psychological hedonism about human motivation. Bentham assumed that all humans are basically and exclusively motivated by the desire to gain \*pleasure and avoid \*pain, but it is possible to maintain ethical hedonism while rejecting, as most present utilitarians are inclined to do, psychological hedonism. However, certain later and contemporary versions of utilitarianism broaden the notion of ethical hedonism so that human or personal good is understood to be constituted by whatever satisfies people's desires or preferences or makes people *happy*.

Utilitarians nowadays also typically accept some form of *outcome utilitarianism* (Amartya Sen's term), according to which, roughly, the goodness of any state of affairs is solely a matter of how much overall (or average) well-being people (or sentient beings generally) are enjoying in that state of affairs. But the major ethical element in most contemporary utilitarianism is *direct \*consequentialism*, the view that the rightness and goodness of any action, motive, or political institution depends solely on the goodness of the overall state of affairs consequent upon it (this state of affairs includes the act or motive itself). Combining these elements (and adding the assumption that morality requires us to *do our best*), most current direct (or act-) utilitarians want to say that an act is morally obligatory if and only if it produces a greater balance of pleasure over pain, or of desire satisfaction, than any alternative action available to the agent. An act is then morally right, or not wrong, if it produces as great a balance of pleasure over pain as any alternative action open to the agent. (An act may be right but not obligatory if it is tied for first place with one or more alternatives.) These general claims about rightness and obligation are often referred to as (forms of) the principle of \*utility.

## BRITISH POLITICAL THINKERS

JEREMY BENTHAM did not invent the principle of utility, but he devised the first comprehensive theory of utilitarianism and urged its practical application.

JOHN STUART MILL, famous first for his system of logic, then for his moral philosophy, devoted himself largely to political reform after the death of his wife Harriet, who had shared his work and influenced him greatly.

MARY WOLLSTONECRAFT was one of the 'English Jacobins'; social reformers of the revolutionary era at the end of the eighteenth century. She envisioned a new social order which would free every person to develop her or his own capabilities.

EDMUND BURKE, aesthetician, parliamentarian, Conservative icon, scourge of the French Revolutionaries, advocate of independence for Britain's overseas territories.

On a direct utilitarian view, moral evaluation is a form of instrumental evaluation: acts are not right or obligatory because of their inherent character, their underlying motives, or their relation to divine or social dictates, but because of how much overall human or sentient well-being they *produce*. Moreover, if one thinks one should produce the best state of affairs one can, but believes, for example, that equality (rather than sheer quantity) of well-being or (unobserved) natural beauty makes a fundamental difference to the goodness of states of affairs or situations, then one may be a consequentialist but one is not a utilitarian. (According to an older, now discarded usage, such a position would be characterized as 'ideal utilitarianism'.)

Some utilitarians reject direct consequentialism in favour of 'rule-consequentialism', according to which the rightness of an action depends on the consequences not of the action itself, but of various sets of rules. Such indirect consequentialism says, for example, that an act is right if it accords with a set of rules whose being accepted, or followed, would have consequences as good as those that would result from any other set of rules' being accepted, or followed. Act-consequentialism, by contrast, evaluates actions directly in terms of *their own* consequences. The chief advantage of rule-consequentialism is that its evaluations of actions accord better with ordinary moral beliefs and intuitions than familiar forms of act-consequentialism do. For direct (or act-) consequentialism, any means can be justified by a good-enough end, and if framing an innocent person will almost certainly prevent race riots and many consequent fatalities, act-utilitarianism and most other forms of direct consequentialism tell us it is (or may well be) our obligation to frame the innocent person. But this seems morally unacceptable to most people, and rule-consequentialism can avoid such a result by claiming that any accepted set of social rules that permitted framing innocent people would be more destructive of social harmony and well-being than could possibly be made up for by the occasional prevention of a race riot, and then saying that the act of framing an innocent person is wrong because it fails to accord with that set of social rules that would best produce overall social harmony and well-being. However, rule-consequentialism has been criticized on the theoretical grounds that it offers no adequate or consistent reason why rules should be evaluated by *their* consequences but acts should *not* be, and most present-day utilitarians accept direct consequentialism, while at the same time in one way or another attempting to reduce or play down the importance of the divergence between utilitarian moral views and common-sense moral thinking.

By contrast with ordinary or common-sense morality, utilitarianism is an *impartial* or *impersonal* moral view. Ordinarily, we think a person is morally entitled to favour herself or her family (to some extent) over other people, but direct (or act-) utilitarianism claims that our obligations depend on an impersonal assessment of the consequences of our actions, and if we have a choice between

doing more for strangers or less for ourselves and/or our friends and relations, then we must give preference to the strangers. Ordinary morality is 'agent-relative' and allows each person to favour those near and dear to him, but for utilitarianism each person is fundamentally morally equal to every other, and any favouritism must be justified by overall good consequences for people generally. This ends up making direct (or act-) utilitarianism a rather demanding moral doctrine, and opponents of such utilitarianism often criticize it for being too demanding. But this charge can be evaded or rendered less damaging if one adopts a form of direct utilitarianism that doesn't require the production of as much good/pleasure as possible as a condition of right action. Utilitarians must hold that producing more good is always *better*, but Bentham (in his earlier years), Karl Popper, and (more recently) Judith Lichtenberg, Michael Slote, and Michael Stocker have all formulated versions of act-utilitarianism allowing for an act to count as morally (all) right if it produces *enough* on-balance good/pleasure, even if the agent could have produced *more* on-balance good/pleasure. Such '\*satisficing\*' utilitarianism allows for moral \*supererogation and is therefore less demanding than more standard optimizing/maximizing versions of act-utilitarianism. But recent theorists such as Peter Railton, Samuel Scheffler, and Shelly Kagan have questioned whether the charge of over-demandingness really can be made to stick against standard forms of act-utilitarianism (and act-consequentialism).

Ordinary morality is also agent-relative in a way not mentioned above: it allows us to do to and against ourselves what we are not morally permitted to do to and against others. We are allowed to throw away our own possessions, but not those of others, and negligent self-damage is not criticized the way the negligent damaging of others is. Utilitarianism allows of no such moral distinctions. And, furthermore, in keeping with the justification of means by ends, act-utilitarianism treats it as morally permissible and even obligatory to kill or injure people in order to prevent other people from killing or injuring some greater number of people (or in order simply to prevent a greater number of deaths overall). Common sense, again, balks at such an instrumental view of morality, but although utilitarians have been much criticized for this aspect of their doctrine, defenders of common-sense (or of Kantian prohibitions on using people as means) have not found it easy to pinpoint what is morally indefensible in utilitarian instrumentalism. The utilitarian can say, for example, that although she sometimes recommends using people as means to the general or overall (greatest) welfare of human beings, such 'using' is not morally objectionable because (unlike most ways people use other people) it acknowledges the value of each individual human and her happiness. The topic is a subject of continuing philosophical debate.

The great strength of utilitarianism as an ethical theory lies in its ability to replace the hodgepodge (and, arguably, inconsistency) of our common-sense moral intuitions with a unified system of thought that treats all moral questions

in uniform fashion and in relation to an ideal, human happiness or desire-satisfaction, that is both less obscure and more attractive than most alternatives. M.S.

J. J. C. Smart and B. A. O. Williams, *Utilitarianism: For and Against* (Cambridge, 1973).

**utility** refers in philosophy to what is of use to human beings (or sometimes, more generally, to all sentient creatures). It therefore denotes what is good for humans, most frequently welfare. Argued to be of fundamental importance for ethics by Cicero and Hume, it was promoted by Bentham as the sole end of right action; hence the doctrine known as \*utilitarianism. For Bentham utility meant \*happiness or \*pleasure; a more particular sense which has sometimes been preserved by later philosophers.

R.H.

R. D. Collison Black, 'Utility', in John Eatwell et al. (eds.), *The New Palgrave*, iv (London, 1987).

**utility, principle of:** see greatest happiness principle; utilitarianism.

**utopianism.** Critical and creative thinking projecting alternative social worlds that would realize the best possible way of being, based on rational and moral principles, accounts of human nature and history, or imagined technological possibilities. Utopian thinking invariably contains criticism of the status quo. It aims to overcome social \*inequality, economic \*exploitation, sexual repression, and other possible forms of domination that make well-being and happiness in this life impossible; death is thus often seen as its critical limit. Utopian thought like Plato's *Republic*, Thomas More's classic *Utopia* (1515–16), Tommaso Campanella's *La Città del Sole* (1623), and the social utopianism of Saint-Simon, Fourier, and Owen, concentrates on conceptions of an ideal commonwealth.

While both criticizing social life and aiming at new forms of it, utopianism nevertheless attempts to transcend the boundaries of so-called realistic and pragmatic considerations. The tension thereby created between utopian thought and social reality has led to harsh criticisms of its fantastic character. The derivation of 'utopia' is Greek words meaning 'not-place', and utopianism is generally identified with unrealistic speculation, providing the adjective 'utopian' with its everyday pejorative meaning. While Marx and Engels, for example, emphasized utopianism's positive function of relativizing existing social reality, they nevertheless criticized its lack of a thorough comprehension and analysis of current society that alone would make concrete political action possible. Thus

utopianism is rejected by Marxism not because of its potential in alternative imaginative thinking but rather because of its theoretical unconnectedness with the social status quo.

Thinkers like Bloch and Marcuse, however, distinguish between 'abstract' and 'concrete' utopias. The former are mere dreams and fantasies, while the latter are based on insights derived from critical social theory. Utopian thought is seen as springing from the unconscious, whose imaginative capacity confronts, challenges, surpasses, and overrides conscious reality by means of projected counter-pictures containing hopes, desires, and wishful thinking. This utopian faculty, however, is only critical if disconnected from existing \*ideologies, and based on an understanding of social totality and the means of realizing better conditions of existence. As Mannheim points out, utopian thought is directed toward change of existing social structures while the function of ideologies is the preservation of the status quo. Of course, utopias as private or unrealizable fantasies may take on an ideological function of preserving what is, while religious or 'bourgeois' ideologies contain a utopian core by confronting existing suffering and injustice with the ideal of paradisaic or just forms of being.

Accordingly, utopianism is limited neither to a literary genre nor to specific conceptions of the good life. It rather plays a genuine role in relation to possible or intended change in existing social conditions. To be sure, the identification of utopian thinking with socialism has often led to an over-hasty dismissal of utopianism as such. Today, for instance, post-Marxist social theory tries to use 'the utopia of an ideal communication community' (Habermas) merely as a 'counterfactual' standard to judge existing reality, while post-structuralist philosophers like Foucault criticize even this ideal as 'utopian', describing modern society as a dystopia of all-pervasive power relations. Social movements like \*feminism, the civil rights movement, and multiculturalism, however, seem to require—and allow!—more concrete alternatives to the existing state of affairs.

Concrete and responsible utopian thinking may thus be an indispensable part of social criticism. First, the projection of alternative worlds helps to relativize the present; it creates distance and estrangement from the realm of assumed necessities of social life. Second, it explores concrete alternatives and realizable possibilities that could lead to practicable changes and improvements. And third, utopias seem indispensable for motivation. The sense of a better, realizable state of affairs not only gives meaning and significance to critical engagement, but also encourages interest in and hope of achieving real change in political action.

# V

**vagueness.** Words like 'smart', 'tall', and 'fat' are vague, since in most contexts of use there is no clear line separating them from 'not smart', 'not tall', and 'not fat' respectively. Vagueness needs to be distinguished from \*ambiguity, which is a property of a word with two distinct meanings. Whereas 'is drunk' is vague; 'is at the bank' (river? commercial?) is ambiguous. Vague terms are said to be tolerant, in that they are used in settings where small changes (e.g. in colour) often make no difference to us. How we react to vagueness can vary. We can tolerate or even approve of vagueness, as when we engage in diplomatic negotiations. Or we can react less tolerantly by viewing vagueness as a kind of language failure ('I can't tell where your land ends and mine begins').

N.F.

Rosanna Keefe and Peter Smith (eds.), *Vagueness: A Reader* (Cambridge, 1997).

**vague objects.** If they exist, they challenge the common idea that reality itself is not vague, only our representations of it being so. If, for example, Mount Everest is a vague object, it has vague boundaries; some rocks are neither clearly part of it nor clearly not part of it. Thus the vagueness is not blamed on the name 'Everest', which is allowed to refer determinately to a unique, vague mountain. Vagueness may also infect temporal boundaries (e.g. the moment of death). Vague objects are identical only if they have the same clear parts and the same clear non-parts; it is controversial whether this relation too can be vague. One can suppose an object vague without supposing it indeterminate, if one (controversially) regards its vagueness as the impossibility of finding its sharp boundaries.

T.W.

T. Williamson, *Vagueness* (London, 1994).

**Vaihinger, Hans** (1852–1933). German philosopher, who from his study of Kant and Nietzsche derived the *Philosophy of As If* (*Die Philosophie des Als Ob* (1911; tr. London, 1924)). Sensations and feelings are real, but the rest of human knowledge consists of pragmatically justified 'fictions'. The laws of logic are fictions that have proved their indispensable worth in experience and are thus held to be undeniably true. Of a religious or metaphysical doctrine, we should ask not whether it is true in some non-pragmatist sense (we cannot discover this), but whether it

is useful to act *as if* it were true. (The concepts of fiction and as-if vary, Vaihinger concedes, according to different types of truth, e.g. logical, scientific, religious.)

The theory involves familiar, though not necessarily insurmountable, difficulties. In saying that we should act as if a doctrine were 'true', it presupposes a perhaps ineliminable non-pragmatist notion of truth. (If we explicate this occurrence of 'true' in pragmatist terms, we fall into an infinite regress: 'We should act as if we should act as if, etc.'). According to the theory, claims about the utility of holding doctrines, and indeed the theory itself, will themselves be no more than useful fictions.

M.J.I.

\*pragmatism.

A. Seidel (ed.), *Die Philosophie des Als Ob und das Leben: Festschrift zu Hans Vaihingers 80 Geburtstag* (Berlin, 1932).

**validity.** In logic, validity is most commonly attributed to either:

1. Deductive arguments, which are such that if the premisses are true the conclusion must be true. Traditional logic studies the validity of syllogistic arguments. Modern logic, more generally, identifies as valid those arguments which accord with truth-preserving rules. (\**Salva veritate*.) Any argument is valid if and only if the set consisting of its premisses and the negation of its conclusion is inconsistent.

2. Propositions which are semantically valid, i.e. are true under any alternative interpretation of the non-logical words.

In a formal uninterpreted system of logic a derivation is (syntactically) valid where it is in accordance with specified axioms or rules.

R.B.M.

\*completeness; theorem; logic, traditional.

B. Mates, *Elementary Logic* (Oxford, 1972).

**Valla, Lorenzo** (c.1407–57). Italian humanist who promoted rhetoric, grammar, and philology at the expense of scholastic logic and metaphysics. He reduced logic to a tool of rhetoric and held that most metaphysical terminology was nothing more than ungrammatical jargon which should be replaced by a philosophical discourse based on the accepted usage of the best ancient Latin

authors. Highly critical of the philosophical theology of medieval thinkers such as Aquinas, he wanted to return to the rhetorical theology of the Church Fathers. For Valla certain issues, such as the compatibility of divine predestination and human \*free will, had to be accepted as matters of faith and were not open to rational investigation. In ethics, he championed a Christianized version of \*Epicureanism, which saw the highest good in the pleasure which the soul attains in the afterlife. J.A.K.

O. Besomi and M. Regoliosi (eds.), *Lorenzo Valla e l'umanesimo italiano* (Padua, 1986).

**value.** Philosophical concern with value has focused on three connected issues: first, on what sort of property or characteristic of something its 'having value' or 'being of value' is; second, on whether having value is an objective or subjective matter, whether value reposes in the object or is a matter of how we feel towards it; third, on trying to say what things have value, are valuable. These concerns closely parallel concerns with the nature of good, from which value is seldom carefully distinguished in philosophical discussion, though the terms are clearly not synonymous.

In regard to the first concern, the value something has is clearly not a property of it which can be discerned by the senses or by scientific measuring instruments. This may be because it is a *sui generis* property, requiring a special sort of awareness or thought process to detect it. Or it could be a relational property of things, such as their meeting human needs; or not a property of things at all but rather a matter of the loving regard we pay to things. Something would thus be called 'valuable' in so far as we cherish it, though common-sense might well say that this gets matters the wrong way round: we cherish it because it is valuable.

Plainly, the view reached about what sort of characteristic having value is will strongly influence any view about whether it is an objective or subjective matter. Presumably if having value is a *sui generis* property, then whether or not something has value cannot depend on human opinion, but is a matter of fact. On the other hand if to bear a cherishing regard towards something is what thinking it valuable consists in, then it would seem that whether something has value is a subjective issue. It can be argued that such regard could be appropriate or inappropriate, and thus some standard of correctness of attitude could be introduced, giving some measure of objectivity.

On the third matter, of what things have value, clearly the list is endless. Many things have value to people because of a special role they play in their lives. This is not to be confused with a subjective theory of the nature of value. It could be an objective truth that something which holds special significance in the life of a person will have value for that person. Other things, such as human life, are sometimes said to have absolute value. Value may be inherent or intrinsic or relational, extrinsic.

The task of a 'valuer' of jewellery or property is an interesting one. Does he, like Oscar Wilde's cynic, 'know

the price of everything and the value of nothing'? Or does he have more discerning judgement than the rest of us? Or perhaps indeed his approval helps to *set* the value of the thing he is looking at. N.J.H.D.

\*good; axiological ethics; ethics and aesthetics; super-valuation.

Notable discussions of these, and, many related topics are:

J. N. Findlay, *Values and Intentions* (London, 1966).

N. Hartmann, *Ethics* (London, 1932).

J. Laird, *The Idea of Value* (Cambridge, 1929).

C. I. Lewis, *An Analysis of Knowledge and Valuation* (La Salle, Ill., 1946).

**value, aesthetic.** We say that the performance of an opera was good, that one painting is a finer example of a certain style than another, or that a combination of colours looks just right. The 'good', 'fine', and 'right', in these cases appear to concern a kind of value which is neither moral value, nor utility value, nor the rightness of being true. We have to acknowledge that there is a peculiarly aesthetic way of being 'good' or 'right', or at least that people talk as if there is. The traditional way of marking out aesthetic value from truth, goodness, or utility is to provide an account of \*beauty.

With all \*value, philosophers will sooner or later ask whether it is objective or subjective, whether it is really in the objects of which we appear to predicate it, or only a product of the mind of the judging subject. If the former, it is arguable that what is 'in' the object will be a power to affect the mind in a certain way, so that a thing may have a real value in a way parallel to its having a real colour, as some would see it. In the history of aesthetics, views range from the notion that beauty resides as an objective property in objects, through to ideas more akin to the popular saying 'Beauty is in the eye of the beholder'. Philosophers should be wary of subscribing to this slogan. For there is public discourse about aesthetic standards, and \*aesthetic judgements are usually put forward as true, not merely as reports of one person's subjective response. The central problem concerning aesthetic value is that it is not merely in the eye of the beholder, while yet it seems to require the eye of the beholder in order to exist. C.J.

**van Fraassen, Bas C.** (1941–). Princeton logician and philosopher of science who, in *The Scientific Image* (1980), develops a well-reasoned anti-realist empiricist alternative to both the \*Logical Positivism of

Rudolf Carnap and the scientific realism of Wilfrid Sellars and Hilary Putnam. For the realist, the point of constructing scientific theories is to 'aim to give us a literally true story of what the world is like'. So accepting any scientific theory is supposed to involve, automatically, belief that terms describing postulated structures and processes have existential import. Van Fraassen attacks this position and defends an alternative: empirical adequacy is the only aim of scientific theorizing. The belief that the theory fits the observable phenomena is the only belief involved in accepting a scientific theory; explanatory power is not grounds for believing that all theoretical terms refer. In *Laws and Symmetry* (1989), van Fraassen argues against a realist construal of \*laws of nature and natural necessities.

**variable.** A letter substituted for one or more occurrences of an expression in a wider expression, as in 'x admires x'. When a \*quantifier is prefixed to this, the variable is 'bound'. Only if repeated variables or two or more quantifiers are involved is this apparatus necessary, the letter attached to each prefixed quantifier indicating which variable it binds in the remaining sentence. See the example given in the entry 'quantifier'.

C.J.F.W.

W. V. Quine, 'Variables Explained Away', in *Selected Logic Papers* (New York, 1966).

**variable realization.** An argument of Hilary Putnam's against the type-\*identity theory of mind: the theory that mental properties are physical properties. On this view, every instance of a mental property is an instance of the physical property with which that mental property is identical. But it seems very unlikely that every instance of pain is an instance of the same brain property. A creature could have a very different physical nature from us, yet still be in pain: this possibility renders the type-identity theory empirically implausible.

T.C.

\*realization.

Hilary Putnam, 'The Mental Life of Some Machines', in *Mind, Language and Reality: Philosophical Papers*, ii (Cambridge, 1975).

**Vattimo, Gianni** (1936– ). A scholar of nineteenth- and twentieth-century German philosophy, which he teaches at the University of Turin, he is the leading Italian theorist of \*post-modernism. Vattimo believes that the modern, \*Enlightenment project of human emancipation as the unfolding of reason through the self-conscious appropriation of nature and the rational organization of society, has been undermined by the effects of new technology and the mass media upon contemporary societies. These developments have produced a complex and fragmented

world, in which the continual elaboration of numerous heterogeneous interpretative schemata has removed the possibility of any privileged or 'objective' point of view upon which to build a unitary or progressive conception of human history. He argues that this situation produces a 'weak ontology' that demands a corresponding weakening of philosophy's traditional metaphysical aspirations in the direction of 'weak thought' (*pensiero debole*), an approach he associates with the notions of \*nihilism and difference elaborated by Nietzsche and Heidegger.

**Vedānta.** End or cream of the revealed scriptures of the Hindus (collectively called 'Veda'), which traditionally includes the more philosophical \*Upanishads, a root-text called *Brahma Sūtras*, and the ethico-religious text \**Bhagavadgītā*. The philosophy contained in the Upanishads is polemically distilled in the *Brahma Sūtras*, which are aphorisms regarding the Supreme Reality. These aphorisms, ascribed to Bādarāyaṇa (second or first century BC) controvert heterodox views like atheism, and respond to the problem of evil, naturalism, no-self theories, etc. They seek to establish God as the material and efficient cause of the cosmos, they analyse dreaming, deep sleep, life after death, re-embodiment, and the state of liberation, and they prescribe techniques of meditation leading to that state. Competing commentaries on the *Brahma Sūtras* engendered schools of Vedānta such as the non-dualism of \*Śaṅkara, the qualified monism of \*Rāmānuja, the dualism of \*Madhva, the identity-in-difference of Nīmbarka, etc.

Non-dualist Vedānta upholds absolute subjective consciousness as the only reality, regards the external world of plurality as false appearance, and establishes that the individual self is strictly identical with that absolute consciousness. This eventually enables each of us to realize the Vedic truth 'I am all that exists'. Qualified monists and dualists reject the above monistic views and interpret the *Brahma Sūtras* differently.

In the late nineteenth century Śrī Ramakrishna, an unlettered mystic saint, rejuvenated Vedantic Hinduism, winning over Christian missionaries and Unitarian-influenced reformers by reaffirming the catholic Vedic truth that the same spiritual goal of God-realization can be attained through many alternative routes adopted by different religions of the world. His disciple Swami Vivekānanda stole the show at the 1893 Parliament of Religions in Chicago by his eloquent opposition to sectarian exclusivism and advocacy of what he later called 'practical Vedānta', i.e. an active recognition of the divinity in every living being to be achieved by serving each living being like God. This is more than altruism or social service because it has to be based on contemplative faith in the spiritual oneness of all.

Among professional philosophers the influence of Kant and Hegel mingled with the resurrection of Vedānta to

produce neo-Vedāntists like K. C. Bhattacharya, whose strikingly original phenomenology of bodily, introspective, and spiritual subjectivity yields a very subtle but ill-understood theory of the 'unmeant' self as freedom from all objectification. A.C.

Eliot Deutsch, *Advaita Vedānta: A Philosophical Reconstruction* (Honolulu, 1969).

**Veda, Vedic:** see Indian philosophy; Vedānta.

**vegetarianism.** The view that we should avoid eating meat or fish has ancient philosophical roots. In the Hindu \*Upanishads (about 1000 BC) the doctrine of reincarnation leads to opposition to eating meat. Buddha taught compassion for all sentient creatures. Buddhist monks were not to kill \*animals, nor to eat meat, unless they knew that the animal had not been killed for their sake. Jains hold to *ahimsa*, or non-violence toward any living creature, and accordingly do not eat meat.

In the Western tradition, Genesis suggests that the first diet of human beings was vegetarian, and permission to eat meat was given only after the Flood. After that, vegetarianism gains little support from either the Jewish or Christian scriptures, or from Islam. Philosophical vegetarianism was stronger in ancient Greece and Rome: it was supported by Pythagoras, Empedocles, Plutarch, Plotinus, Porphyry, and, in some passages, Plato. Pythagoreans abstained from eating animals partly because of their belief that humans and animals share a common soul, and partly because they appear to have considered the diet a healthier one. Plato shared both these views to some extent. Plutarch's essay *On Eating Flesh*, written in the late first or early second century of the Christian era, is a detailed argument for vegetarianism on grounds of justice and humane treatment of animals.

Interest in vegetarianism revived in the nineteenth century, on grounds of health and humanity towards animals. Notable vegetarian thinkers included the poet Percy Bysshe Shelley, Henry Salt (who wrote a pioneering volume entitled *Animals' Rights*), and George Bernard Shaw, who said that he put into his plays the ideas that he learned from Salt. In Germany Arthur Schopenhauer urged that ethically we should become vegetarian, were it not for the fact that the human race cannot exist without animal food 'in the north'!

Since the 1970s vegetarianism has gained strength from three major lines of argument: health, ecology, and concern for animals. The first of these grounds rests on a scientific, rather than philosophical, claim and will not be discussed further here. Ecological concerns about eating meat arise from the well-documented inefficiency of much animal-raising. This applies especially to intensive farming, in which grain is grown on good agricultural land and fed to animals confined indoors, or in the case of cattle, in crowded feed-lots. Much of the nutritional value of the grain is lost in the process, and this form of animal

production is also energy-intensive. Hence concern for world hunger, for the land, and for energy conservation provide an ethical basis for a vegetarian diet, or at least one in which meat consumption is minimized.

Arguments for a reassessment of the moral status of animals have also given support to vegetarianism. If animals have rights, or are entitled to have their interests given equal consideration with the similar interests of human beings, it is easy to see that there are difficulties in claiming that we are entitled to eat non-human animals (but not, presumably, human beings, even if through some accident they are at a similar mental level to the animals we do eat). These ethical arguments for vegetarianism may be based on the view that we violate the rights of animals when we kill them for our food, or on the more utilitarian grounds that, in raising them for our food, we cause them more suffering than we gain by eating their flesh. P.S.

**veil of ignorance.** The setting-aside of all information about your distinguishing social characteristics, to ensure a fair choice of principles of justice. In Rawls's theory, it is a feature of the \*original position, an imaginary situation in which you are supposed to make a blind choice of principles, as if not knowing what position you occupy in society—not knowing your race, sex, religion, wealth, talents, or ultimate values and aims in life. The idea is that this will force you to choose as if you might be in any social position, so that you must take into account the interests of everyone equally, thus ensuring fairness to all. T.N.

J. Rawls, *A Theory of Justice* (Cambridge, Mass., 1971).

**veil of perception.** This is a sceptical problem that arises for a certain analysis of perception. If our senses only reveal knowledge about how things *seem*, how can we hope to use them to find out how things really *are*? The appearances are in danger of obstructing rather than helping us in our attempts to discern the nature of reality.

The obvious way to escape this difficulty is to hold that in perception we are directly aware of material things, not just of appearances; the name for such a position is \*naïve or direct realism. Something still needs to be said about appearances. One promising line is the adverbial theory, which holds that appearances themselves are not the primary objects for the mind, but the way in which our primary objects are presented. J.D.

F. Jackson, *Perception* (Cambridge, 1977).

**vengeance:** see revenge.

**verifiability:** see verification principle.

**verification principle.** This, also called the Verifiability Principle, has two forms: (1) The meaning of a statement is the method of its verification. (2) A statement is meaningful if and only if it is in principle verifiable. (1) implies (2) but not all recognize the converse implication. Verification may cover only observational procedures, in which case the principle is applied only to 'factual' statements, allegedly analytic statements (including pure mathematics), somehow true by definition, receiving a separate treatment. Alternatively, verification may cover calculations for establishing these. The verification principle was a main tenet of the original Logical Positivists, inspired by remarks of Wittgenstein. Prominent supporters have included Moritz Schlick and A. J. Ayer. Problems have been its judgement on itself and the fact that any statement will have verifiable implications if conjoined with suitably chosen others. None the less the general idea that genuinely factual knowledge must increase our powers of empirical prediction has influenced many. T.L.S.S

\*Logical Positivism; verificationism; nonsense.

**verificationism.** Any view which embraces some version of the \*verification principle. Verificationists characterize the meaning of a proposition, or the conditions required for a proposition to have meaning, in terms of the difference its truth makes to the senses, the conditions under which it is verified (or falsified) by empirical test. Variations on both the principle itself and its implications are possible. Perhaps the most influential thinkers in this neighbourhood are gathered together under the banner of \*Logical Positivism—A. J. Ayer, Rudolph Carnap, Herbert Feigl, Ernest Nagel, Otto Neurath, Moritz Schlick and others—all offering articulations of both the verification principle and its implications for metaphysics, aesthetics, and ethics. Some phenomenalist philosophers have derived from verificationism the view that statements about physical objects are reducible to talk of sense-data, actual and possible sense experiences. The difficulty, which most take as decisive, is that the list of conditional observation statements for any reduction would be very long and worryingly vague. Abandoning reduction, Carnap was led to conclude that the best one can hope for is a specification of the observation statements implied by particular non-observation statements. Quine, holding that theories are underdetermined by evidence and following Duhem's claim that non-observation sentences cannot be verified individually, did not on those grounds reject verificationism, but instead concluded that a non-observation sentence has no meaning in isolation, has no empirical consequences of its own, makes no difference to our senses individually. Individual sentences mean what they do only against the backdrop of the theory in which they are embedded. J.GAR.

R. Carnap, *The Logical Structure of the World* (London, 1967).

W. V. O. Quine, *From a Logical Point of View* (Cambridge, Mass., 1953).

**verisimilitude.** A concept of central importance within Popper's anti-inductivist philosophy of science, but also of independent interest. Given a view of science as a paradigm of rational activity, it seems natural to take its goal to be the production of true theories. But all past \*theories have turned out to be false, and only wild immodesty could let us suppose that currently accepted theories will escape such an ultimate fate. How can it be rational to pursue an unattainable goal? How can there be scientific progress in these circumstances? One answer is to suggest that science has the more limited goal of developing theories which approximate more closely to the \*truth, i.e. possess increasing verisimilitude. However, there are severe problems involved both in defining and in developing a measure or ranking-mechanism of, verisimilitude. J.L.

W. H. Newton-Smith, *The Rationality of Science* (London, 1981).

**Veritatis Splendor.** The title, taken from its opening words, 'The Splendour of Truth', of the most widely discussed of recent papal encyclicals. In it Pope John Paul II responds to \*subjectivism, \*relativism, and \*consequentialism, and reaffirms traditional Catholic teaching that there is an objective universal moral order (\*natural law) involving intrinsic goods and evils. The philosophical exposition and argument draw primarily upon Thomist and neo-Kantian moral theories. The main philosophical discussion is in a section called 'The Moral Act', where it is argued that 'The rational ordering of the human act to the good in its truth and the voluntary pursuit of that good, known by reason, constitute morality. Hence human activity cannot be judged as morally good merely because it is a means for attaining one or another of its goals, or simply because the subject's intention is good.' J.HAL.

*Veritatis Splendor: Encyclical Letter Regarding Certain Fundamental Questions of the Church's Moral Teaching* (London, 1993).

**Verstehen.** Although this is the ordinary German word for understanding, philosophers have often invested it with special senses. For Kant, understanding is the faculty, distinguished from sensibility and reason, whereby sensory items are brought under concepts. Within \*hermeneutics (the study of interpretation) and the \*social sciences, however, it usually has the sense given it by Wilhelm Dilthey: an interpretative understanding sharply distinguished from the explanatory understanding, in terms of natural laws, sought in the natural sciences. *Verstehen* is therefore confined to the humane sciences (*Geisteswissenschaften*). While, for Dilthey, *Verstehen* requires an empathetic 're-living' of the 'mental life' of those whose 'expressions'—texts, actions, etc.—we seek to interpret, his main emphasis is upon identifying the expressions' meanings by locating them in larger cultural wholes. 'Meaning means nothing except belonging to a whole' (1968, p. 233). An expression is only fully understood when referred back to the total cultural 'life-form' (\*form of life) that it manifests. The distinctive character

of *Verstehen* informs the writings of such social theorists as Alfred Schutz and Peter Winch. D.E.C.

W. Dilthey, *Dilthey: Selected Writings*, tr. H. P. Rickman (Cambridge, 1968).

A. O'Hear (ed.), *Verstehen and Humane Understanding* (Cambridge, 1996).

**vices.** States of bad or undesirable character, definable partly in contrast to \*virtues. The favoured list of vices varies across time and place, depending on differences in corresponding conceptions of virtue. Thus, the change from classical pagan to medieval Christian morality brought with it a change of emphasis from the virtues of courage and temperance to the virtues of love and charity, with corresponding vices being defined in contrast to these virtues. On the classical Aristotelian view, a paradigmatic vice consists in the possession of some character trait out of proportion to the nature of its associated object. Thus, a coward is someone who fears what is not dangerous. On this view, vice is understood negatively in terms of a failure to possess virtuous character traits. One limitation of this view is that it fails to fully account for such bad character traits as cruelty, maliciousness, and spite, which consist partly in an agent consciously aiming for the bad. H.L.

\*virtue.

M. Midgley, *Wickedness* (London, 1984).

**vicious circle.** An argument assuming its conclusion as a premiss (\*begging the question), or a definition of an expression in terms of itself. Russell argued that paradoxes in the foundations of mathematics—for example, his paradox of the class of all classes that are not members of themselves—depend on a kind of vicious circularity, violating the maxim 'Whatever involves all of a collection must not be one of the collection'. M.C.

\*vicious-circle principle.

**vicious-circle principle.** First propounded by Poincaré in 1906 as a diagnosis of the contradictions then besetting logicism. The basic idea is that a vicious circle is involved if, in the definition of an object of some kind, we quantify over all objects of the same kind. Definitions with this feature are called 'impredicative', others 'predicative'. (For example, the set of all natural numbers is commonly defined as the *least* set containing 0 and containing the successor of everything it contains. But this definition is impredicative, since the 'least' such set means the one that is a subset of *all* such sets.) Russell claimed to base his theory of \*types upon this principle, but that claim can hardly be upheld. Gödel observed that from a Platonist standpoint there need be nothing wrong with impredicative definitions, though they should be suspected by the conceptualist, who holds that abstract objects exist only as a result of our constructions. D.B.

\*predicative theories; constructivism; impredicative definition.

**Vico, Giambattista** (1668–1744). Arguably the most significant Italian philosopher, he was Professor of Rhetoric at the university of his native Naples from 1699. Underlying Vico's thought is the principle that 'the true (*verum*) and the made (*factum*) are convertible', so that we can only know for certain that which we have created. The natural sciences can only yield approximate truths based on our attempts to imitate nature in experiments, whereas the human sciences can offer exact knowledge because societies are our own creations. Vico used this thesis in his *The New Science* of 1725 to develop a whole philosophy of history that anticipated many of the central tenets of nineteenth-century \*historicism. He argued that historical change parallels the passage of the individual from birth to maturity and ultimately death, so that history follows a cyclical pattern of *corsi* and *ricorsi* in which linguistic, cultural, intellectual, political, and economic development are all interrelated. Past societies had to be understood in their own terms, and social change was to be seen as the unintended and providential product of the evolving needs, reason, and interests of essentially egoistic individuals. R.P.B.

L. Pompa, *Vico* (Cambridge, 1975).

**Vienna Circle** (Wiener Kreis). A group whose work was central to the development of \*Logical Positivism. The Circle emerged from discussions, beginning in 1907, between Otto Neurath, a sociologist, Hans Hahn, a mathematician, and Philip Frank, a physicist. Like its founders, most Circle members, including its philosophers, had considerable scientific and mathematical training. The Circle flourished under the leadership of Moritz Schlick, who filled Ernst Mach's chair at the University of Vienna in 1922. But the rise of Nazism in the 1930s led to a diaspora of the Circle's members, many of whom were Jewish, Marxist, or both. Herbert Feigl left in 1931, arriving eventually at the University of Minnesota, where he helped build an influential philosophy of science programme. Rudolf Carnap, who came to Vienna in 1926, left in 1931. He was installed at the University of Chicago in 1936, the year Schlick was assassinated in Vienna on the university steps. In 1938 the Circle's last Vienna organization was officially dissolved, Neurath and Friedrich Waismann went to Oxford, and Kurt Gödel went to Princeton.

Tarski's work on the semantics of formal languages and Popper's attempts to explain the difference between real and spurious science were important influences on the Circle. Another was the work of Wittgenstein. His *Tractatus* was read aloud and studied line by line by Vienna Circle members, a few of whom were allowed to meet him—in diminishing numbers, and varying configurations and degrees of discomfort—from 1927 into the

early 1930s. From these discussions emerged a strong version of the ‘\*verification principle’ according to which the significance of non-analytic sentences depends upon whether they can be tested, and utterances which are neither analytic nor empirically testable are meaningless. Different versions of this principle are distinguished by the strengths of their testability requirements.

Vienna Circle philosophizing utilized logical machinery invented by Frege, Russell, and Whitehead (long before its general acceptance) and formal techniques in semantics and inductive reasoning, many of which were invented or enriched by its members. These tools were applied to classical philosophical issues concerning the nature and possibility of knowledge. The main examples of knowledge the Circle urged philosophers to study came from the exact sciences, which it supposed were models of properly conducted inquiry whose epistemic standards should be extended to the social sciences. This, along with its demanding formalisms, helped make Vienna Circle philosophy unpopular among academics who considered their work more humane. So did the Circle’s crusade against ‘metaphysics’, its derogatory term for discourse which purports to make substantive claims but which is susceptible neither to rigorous empirical testing nor to formally rigorous explication. It offended intellectuals to have words they lived by (and made a living from) condemned as metaphysics.

Others were unhappy for political reasons which should be taken seriously by anyone interested in the history of analytic philosophy. A host of German philosophers—Heidegger, for one—were promoting the idea that only pure Germans could understand, and should be allowed to teach, subjects bearing on German history and culture. Hitler, supported by no less than Nobel Laureate physicist Philipp Lenard, vowed to save German youth from un-German science, including relativity and quantum physics. The discourse used to justify such positions included some targets of the Circle’s war against metaphysics. ‘The tear is running . . . It’d be to throw up, if one didn’t have to laugh . . . behind it all stands Hitler . . . Here come God, and Religion . . . and ancestral truths, and the German *Volk*, and what you need to stab a Jewish socialist . . . between the ribs . . . Oh Carnap! Oh World!’ That was Neurath in 1932 (quoted in Gallison, ‘Aufbau/Bauhaus’, 742), describing the situation the Vienna Circle and other positivists faced as they developed and promulgated formal methods in philosophy, set the agenda for twentieth-century philosophy of science, and helped to invent \*analytical philosophy.

**violence, democratic:** see democratic violence.

**violence, political.** Resort to force for political ends, outside its normal use in international warfare or in the internal administration of justice. Political violence covers a wide spectrum from stone-throwing at demonstrations to \*revolution and civil war. Violence is conventionally distinguished from force in general as unlawful; thus political violence oversteps the limits placed upon the lawful pursuit of political purposes. Indeed the breaking of laws is sometimes part of the point of violent protest, as it is in \*civil disobedience; for political violence is characteristically expressive of its political purposes (e.g. by challenging the authority of the \*state to enforce its laws) rather than simply instrumental in achieving them (e.g. by undermining the power of the state).

\*Terrorism is the paradigm of political violence, but it eludes easy definition. One type of analysis views it as political killing rendered illegitimate, in contrast to tyrannicide, either by the availability of peaceful alternatives or by its targeting of innocent citizens rather than responsible politicians. Another type regards terrorism as low-level warfare directed, contrary to the principles of the \*just war, against harmless civilians, often owing to the terrorists’ lack of adequate resources to defeat a military force. Neither analysis seems adequate to cover what is regularly referred to as terrorism, namely, activity which is regarded by its protagonists as part of a war and by its opponents as common crime (or, perhaps, as a crime against humanity but not, strictly speaking, as a war crime).

Characterizing terrorism in these terms we can sensibly ask: When, if ever, is terrorism justified? On some theories of deontological ethics it is never justified, either because it inevitably involves the death of innocents, or because it is in breach of political obligations. Under \*utilitarianism, however, it may be justified if it is likely to avert a greater evil. Typically terrorists not only appeal to utilitarian considerations but also answer deontologists by arguing either that innocents are unintended victims who suffer no more, and perhaps less, than in conventional war, or that the citizens who are targeted have collective responsibility as members of an oppressor group. Terrorists also deny the existence of political obligations to a state which is oppressive or which they refuse to recognize, e.g. when they are actuated by \*nationalism. In neither case, they argue, are there adequate alternatives to the adoption of military means for pursuing their political goals. As a result, terrorists, under the influence of one or other of the analyses mentioned above, deny that they *are* terrorists, rather than freedom fighters etc., since on these analyses terrorism is always unjustified.

Political violence includes not only the use of force against the state, but also some of its uses by, or on behalf of, the state, e.g. state terrorism, as directed against minority groups under Fascism. Though the law may be changed to accommodate it, it still has the criminal character of terrorism, since ‘unjust law is not law’, while it is

intended as part of a war against those to whom the state recognizes no obligation of care. The distinction between political violence and the ostensibly legitimate use of force may itself be called into question if the actions of some, or all, states are thought of as aimed at terrorizing their subjects into submission. Such ‘structural violence’ is, in a loose sense, criminal, through infringing natural rights, and warlike, since ‘government is begotten of aggression and by aggression’ (Herbert Spencer). It may be held to justify a response comprising more overt political violence. p.g.

Ted Honderich, *Terrorism for Humanity* (London, 2004).

**violence, structural:** see structural violence.

**virtue, unity of.** This doctrine is advanced by Plato, Aristotle, and other ancient philosophers, although its correct interpretation has been the subject of much scholarly debate. Understood as the claim that having one virtue entails having them all, it is defended in many recent formulations of virtue ethics.

The following line of thought seems to support the doctrine: the proper scope of each virtue is determined collectively by the others. We would not describe someone’s action, motivated by the desire to spare *x*’s feelings, as ‘kind’ if it involved his knowingly being unfair to *y*. Against this, opponents claim that one can, without contradiction, describe a villain as brave. And do we not observe, in different individuals, that people may excel in some virtues while lacking others?

While the doctrine appears to require empirical confirmation, its defenders typically appeal to conceptual constraints, such as the claim that virtue must issue in right conduct. s.d.r.

Philippa Foot, ‘Virtues and Vices’, reprinted in her *Virtues and Vices* (Oxford, 1978, 2002).

John McDowell, ‘Virtue and Reason’, reprinted in his *Mind, Value and Reality* (Cambridge, Mass., 1998).

**virtue epistemology.** Virtue epistemologists attempt to apply to epistemology the insights of virtue ethics. Virtue epistemologists do not say that a justified belief is one suitably related to something foundational, or one that is a member of a coherent set; they say that it is one that a virtuous cognizer, someone with the cognitive virtues, would have. They tend then to give a complex picture of cognitive virtues; the virtues of the rational enquirer need not be restricted to (say) the ability to discover truths and avoid errors, but are many and various, perhaps including such traits as imaginativeness, a sense of the absurd, and some blend of epistemic stubbornness and modesty. j.d.

G. Axtell (ed.), *Knowledge, Belief and Character: Readings in Virtue Epistemology* (Oxford, 2000).

**virtues.** Almost all systematic approaches to ethics have something to say about what traits count as virtues and

about the character of virtue as a whole. A distinction is typically made between intellectual and moral/ethical virtues, but there is an important difference also between those traditions of moral theory that highlight and focus on virtue—which can be classed together under the title ‘virtue ethics’—and approaches to ethics that make room for an account of virtue(s) only alongside, and by way of supplementing, the main business of formulating the ultimate principles or rules of morality. For the latter, virtues and virtue are effectively the internal analogue of (a set of) moral principles—they amount to dispositions to obey or follow what the rules prescribe (as, mainly, with \*Kantianism) or else (as with direct \*utilitarianism) to dispositions whose existence furthers the same goals as are specified in principles of right action.

By contrast, various forms of virtue ethics play down the importance or even deny the existence of generally valid moral rules or principles, and claim that morality is most fundamentally to be understood in terms of inner traits, virtues, that cannot be cashed out in terms of rules or goals. Aristotelian virtue ethics regards matters of right and wrong as unencapsulable in rules, and describes the virtuous individual as someone who perceives and fairly effortlessly acts upon situationally unique moral requirements. And philosophers such as Elizabeth Anscombe, Philippa Foot, Rosalind Hursthouse, John McDowell, Martha Nussbaum, Amélie Rorty, Michael Stocker, and Michael Slote have sought to develop versions or aspects of \*Aristotelianism that are sensitive to the current situation in ethical theory. Other forms of virtue ethics—arguably those defended, for example, by Plato and James Martineau (a nineteenth-century British ethicist)—think of the virtuous agent not as perceiving what is independently right or noble to do, but as having independently admirable motives or other inner states whose very expression in her actions serves to *make* those actions right or admirable. For Plato, virtue is an inner state, is the harmony, health, beauty, or strength of a soul made up of interacting parts or aspects, and right or just action is action that sustains or enhances inner virtue. Such a view treats the morality of actions as derivative from the morality or ethics of agents’ inner states (in a way that Aristotle’s theory of situationally perceived right or noble actions arguably does not), and one also finds such ‘agent-basing’ in Martineau’s view, according to which there is an intuitive hierarchy of moral motives (reverence, followed by compassion, being at the top) and the rightness of actions depends on which of possibly conflicting motives determines one’s actions. More recently, Michael Slote and Jorge Gracia have, respectively, begun to explore updated versions of Plato’s inner-strength approach and Martineau’s intuitive hierarchy.

Let us turn now to the discussion of particular virtues, which has varied over the centuries in a number of important ways. Ancient (virtue) ethics recognized four cardinal ethical virtues: temperance, justice, courage, and (practical) wisdom, but in the Middle Ages Christian philosophers tended to add three theological virtues: faith, hope,

and charity or love, to the list of major virtues. In the ethics of Socrates, Plato, and Aristotle, a thesis of the *unity of the virtues* emerged as a pivotal doctrine, the idea being (very roughly) that each virtue requires that one be sensitive to potentially inconsistent claims deriving from the other virtues, so that in the end one cannot really possess one virtue without possessing them all. However, this doctrine is not widely accepted by those who have treated the virtues during the modern period. What is accepted and goes back to ancient times is the idea of virtues as dispositions, rather than skills or capacities. Someone who is *able* to control his appetites but in fact does not cannot be regarded as having the virtue of temperance or moderation. But there has, over the millennia, been strong disagreement about whether it is more virtuous and admirable to overcome strong temptations or to lack such temptations altogether. And in discussions of virtue(s) there has also been much disagreement over whether conscientious adherence to duty is morally preferable to 'natural' motivations like compassion or love as a basis for actions (Kant gives preference to the motive of conscientiousness and even says that other motives have no moral value, but in recent years a whole host of philosophers, including Philippa Foot, Michael Stocker, Lawrence Blum, and Bernard Williams, have opposed this view).

In recent years, the whole topic of virtue and the virtues has been of increasing interest to moral philosophers, and there are more and more philosophers who think a focus on virtue can form the basis for an entire free-standing account of morality and ethics. M.S.

**virtues, doxastic.** Breaking down traditional barriers between epistemology and ethics, some philosophers stress the central roles of virtue and character in the evaluation of our doxastic life (believing, doubting, etc.). An assumption is made that doxastic states are voluntary in at least a weak sense. A person of virtuous doxastic character habitually avoids the vices of \*scepticism and dogmatism while exhibiting such virtues as intellectual impartiality and courage. The doxastic states (e.g. beliefs) of such a balanced personality come about through a process that is responsible in a sense of 'responsible' similar to its sense when we speak of a father's parenting as responsible.

P.H.H.

\*voluntarism, doxastic.

Jonathan L. Kvanvig, *The Intellectual Virtues and the Life of the Mind: On the Place of the Virtues in Contemporary Epistemology* (Savage, Md., 1992).

**virtues, intellectual.** The intellectual, or epistemic,

\*virtues are those character traits of an agent that are conducive to the agent forming true beliefs and, thereby, gaining \*knowledge. The character traits of being open-minded or conscientious could thus be regarded as intellectual virtues (though perhaps not exclusively: they may also be thought to be moral virtues). Although discussion of the intellectual virtues has always been a part of epistemology, in recent years it has come to the fore with the development of so-called virtue epistemologies, where the intellectual virtues take centre stage. For example, Linda Zagzebski offers a broadly Aristotelian account of the intellectual virtues which presents an integrated account of the moral and intellectual virtues in terms of the kind of character that an agent needs if she is to lead the good life. This is in contrast to the type of \*reliabilism proposed by Ernest Sosa, who argues that an intellectual virtue might merely be a reliable cognitive faculty of the agent, such as the faculty of sight, and thus need not be part of the agent's intellectual character at all.

**virtuous circle.** Particular deductions must conform to general logical principles; but such principles must conform to accepted deductive practice. For Goodman, this circularity is virtuous and means only that our principles and practices should be brought into agreement. But if this involves the amendment of both principle and practice, it is not clear that what we have here is properly speaking a circle at all. M.C.

\*vicious circle.

N. Goodman, *Fact, Fiction, and Forecast* (London, 1957).

**viscous:** see slime.

**vitalism.** The idea that life cannot be explained in material terms stems from Aristotle, but life as a potent explanatory and evaluative concept rose to importance in the late nineteenth century in reaction to scientific \*materialism and Kantian \*idealism. It appealed, among others, to Bergson, Nietzsche, and Dilthey. While vitalists differ in detail, they share some general beliefs: Life, and reality in so far as it is living, consists in movement and becoming, rather than in static being. Reality is organic, not mechanical: biology, and often history, are more central than physics. Life is known empirically or by intuition, rather than by concepts and logical inference. Life is objective and transcends the knowing subject. Vitalism stresses the diversity of life and tends towards pluralism, and occasionally relativism, rather than monism. It is not sharply distinct from philosophical \*anthropology. M.J.I.

H. Schnädelbach, *Philosophy in Germany 1831–1933* (Cambridge, 1984).

**Vitoria, Francisco de** (1480–1546). A member of the Dominican Order, he was a student at Paris, and later lectured at Salamanca. He wrote lengthy commentaries on theological writings of Thomas Aquinas but is most famous for his political and legal writings, and especially for his contribution to international law. He believed in *jus gentium*, a 'law of nations' established on the basis of natural law and universally valid. Living at the time of the conquest of the Americas, Vitoria developed his teaching partly in the context of his discussions on the appropriate treatment of the native peoples of the New World.

**void.** This word (Greek *kenon*, Latin *vacuum*) was a term of art in ancient philosophy of nature, used to designate utterly empty space or extension. Some philosophers (notably Aristotle, perhaps also Plato) rejected the notion as incoherent. Others (the Stoics) gave it a marginal role in ontology; it enabled them to posit a limited universe, for which the external void supplied a defining condition. But for the fifth-century Atomists and the Epicureans it was a key component in ontology. They used the idea to underpin the possibility of a universe which contains many objects undergoing change: void effected the separation of one object from another, and the distinctness of an actual state of affairs from its non-existent successor. The explanatory adequacy of this ontology was also used, particularly by the Epicureans, to bring out the ethical implications of their materialism. Since the only alternative to an existing object was empty space, the option of survival in the form of an incorporeal \*soul was excluded.

J.D.G.E.

\*atomism; Epicureanism.

For a thorough and penetrating survey of the void and related notions in ancient philosophy of nature, see R. R. K. Sorabji, *Time, Creation and the Continuum* (London, 1983).

**Voidism:** see Buddhist philosophy; Nāgārjuna.

**volition.** The faculty of the \*will; or an item (sometimes

alternatively called an act of will) conceived as the product of such a faculty.

In many dualist and empiricist accounts of \*action, volitions are mental items that cause bodily motions on occasions of human agency. Ryle criticized such accounts. In recent philosophy, volitions are introduced in various roles, sometimes as a species of \*intention. It remains controversial exactly what Ryle's arguments rule out, and whether volitions can or ought to play any role in explicating \*agency.

R. Kane (ed.), *The Oxford Handbook of Free Will* (Oxford, 2001).

**Voltaire, François-Marie Arouet de** (1694–1778). Though not an original thinker, Voltaire was in his time a major playwright and novelist, and a brilliant scientific and philosophical popularizer. After exile in England, Voltaire communicated Locke's philosophy and Newton's science through his *Lettres philosophiques* (1734). With strong and lifelong social concerns, Voltaire used the letters to praise what he portrayed as English constitutionalism and freedom of thought, and so criticize their lack in France. Voltaire controversially shared Locke's agnosticism about the immateriality of mind. He believed that God's existence could be proved by the \*cosmological and \*design arguments. However, he was hostile to Leibniz's theodicy, and denied any particular providence. A believer in natural religion, Voltaire condemned the social effects of revealed religion as pernicious. He campaigned energetically for freedom of religion and judicial reform.

F.-M. de Voltaire, *Philosophical Letters on the English Nation* (Indianapolis, 1961).

**voluntariness:** see compatibilism and incompatibilism; embraced and reluctant desires; freedom; spontaneity and indifference; voluntarism, doxastic.

**voluntarism, doxastic.** The question whether doxastic states (e.g. beliefs) are voluntary is important because such voluntariness seems to be assumed by any ethics of belief or theory of doxastic virtue. Doxastic voluntarists from René Descartes to Roderick M. Chisholm have held that believing is a voluntary act. Opponents from David Hume to Bernard Williams have argued that it makes no sense to speak of deciding to believe—the concept of voluntary belief is simply incoherent. A plausible form of doxastic voluntarism is developed by conceding that \*beliefs cannot be voluntary acts because they are not acts at all, while insisting that genuine acts of assent and other of the myriad acts involved in acquiring, sustaining, and removing doxastic states are often voluntary in a sense robust enough to justify holding a person responsible for being in such states.

P.H.H.

\*virtues, doxastic.

Peter Kauber, 'Does James' Ethics of Belief Rest on a Mistake?', *Southern Journal of Philosophy* (1974).

**voluntarism, ethical.** Voluntarism can be characterized as any philosophical view in which prominence is given to the \*will over against one's other mental faculties. Ethical voluntarism is the view that whether an act qualifies as right or wrong depends primarily upon how the act is willed and that the consequences of one's act are judged good or bad primarily in accord with the goodness or badness of the will which produces the act. In general, Kantian ethics is quite hospitable to ethical voluntarism. Ethical voluntarists are inclined to doubt that there is such a thing as moral luck, since fortuitous circumstances are unrelated to whether one's will is good and hence to whether one can be judged as having done right or wrong.

G.F.M.

D. Statman, *Moral Luck* (New York, 1993).**von Hartmann, Eduard:** see Hartmann, Eduard von.**von Neumann, John:** see Neumann, John von.

**von Wright, Georg Henrik** (1916–2003). In 1939, G. H. von Wright, a member of Finland's Swedish-speaking minority, went from Helsinki to Cambridge to pursue his interest in induction and probability. He met Ludwig Wittgenstein, who influenced him greatly, and in 1948, at the age of 33, von Wright succeeded Wittgenstein as Professor of Philosophy at Cambridge University. He resigned the chair in 1951 to return to Finland. From 1961 to 1986 he was Research Professor at the Academy of Finland. Besides editing many of Wittgenstein's works, he produced biographical, expository, and critical writings about Wittgenstein. A survey of the three volumes of his *Philosophical Papers* indicates the scope of his interests: *Practical Reason* (vol. i, 1983) continues themes from *The Varieties of Goodness* (1963), *Norm and Action* (1963), *An Essay in Deontic Logic* (1968), and *Explanation and Understanding* (1971). *Philosophical Logic* (vol. ii, 1983) continues themes from *A Treatise on Induction and Probability* (1951) and *Logical Studies* (1957) and includes essays on paradoxes, preference, and tense logic. *Truth, Knowledge, and Modality* (vol. iii, 1984) continues themes from *Causality and Determinism* (1974) and *Freedom and Determination* (1980) and includes essays on propositions, causal knowledge, and modality.

**Vorstellung.** German for 'putting forward', hence 'representation' or 'idea' as used by British Empiricists. Like 'idea', *Vorstellung* has a narrow and a wide sense. (1) It is a mental \*image, picture, or conception produced by prior perception of an object or objects. It contrasts with 'sensation', 'intuition', and 'perception', since these require the actual presence of an object, and also with 'thought', 'concept', and 'idea (*Idee*)', since these need no pictorial component and are more objective than *Vorstellungen*. (One speaks of *my Vorstellung* (\*idea, conception) of God, but the

\*concept (*Begriff*) of God.) *Vorstellungen* are involved in memory, imagination, etc., and are, in the view of older psychologists, subject to laws of 'association'. (2) In a wide sense, a *Vorstellung* is any mental item that refers to an intentional object. Hence a thought, a concept, or a perception is also a *Vorstellung*.

Some idealists argued that we cannot know objects in themselves, but only 'the *Vorstellungen* that they produce in us when they affect our senses' (Kant), or that 'the world is my *Vorstellung*' (Schopenhauer). Hegel's \*idealism depends on thought, the 'concept', and the *Idee*, rather than *Vorstellungen*. In his view, religion presents in *Vorstellungen* (in the narrow sense of 'pictorial imagery') the 'content' that art presents in sensory intuitions (*Anschauungen*) and philosophy in thoughts.

**voting paradox.** Suppose that three people, Alice, Brian, and Cait, are choosing between three candidates, Primus, Secunda, and Tertius, for a job. Alice prefers Primus to Secunda to Tertius. Brian prefers Secunda to Tertius to Primus. Cait prefers Tertius to Primus to Secunda. So a majority prefer Primus to Secunda, and a majority prefer Secunda to Tertius, and, paradoxically, a majority prefer Tertius to Primus. So preferences obtained by majority voting between pairs do not give a coherent ranking. Or, to put it differently, the outcome depends on the order in which the options are presented. If the first choice is between Primus and Secunda then Secunda will be eliminated and Primus will win when compared with Tertius. But if the first choice is between Primus and Tertius then Primus will be eliminated and then Secundus will win when compared with Tertius. These facts are special cases of Arrow's theorem, which shows that there can be no perfect voting system.

**Vygotsky, Lev Semenovich** (1896–1934). Innovative Russian psychologist and philosopher who argued that only by understanding the role of culture in psychological development can we attain an account of consciousness that overcomes the shortcomings of \*behaviourism and \*reductionism without embracing \*dualism. While human beings are endowed with elementary mental functions that can be explained naturalistically, the higher mental functions are mediated by psychological tools, such as language and other externalized systems of representation, which the individual acquires, not naturally, but through the internalization of social activity. Each

child therefore attains consciousness as she is inaugurated into human culture. Shortly after Vygotsky's death from tuberculosis in 1934, the Stalin regime blacklisted his works for many years, but his ideas were preserved by his collaborators, especially A. R. Luria and A. N. Leontiev, and formed the foundation of Soviet 'socio-historical

psychology'. His thought has also been influential in the West, particularly among educationalists. D.BAK.

**Walton, Kendall** (1939– ). American philosopher. Walton's work in philosophical aesthetics makes him one of the most influential thinkers in that field since Monroe Beardsley and Nelson Goodman. One of Walton's early contributions (1970) was to show that the aesthetic properties of works of art were not intrinsic to them, but were instead relative to the medium, style, and genre categories in which those works were correctly perceived, and thus that, as a consequence, strong versions of formalism and anti-intentionalism regarding works of art must be mistaken. Walton's major contribution to aesthetics, however (1990), consists in his elaboration of a general theory of representations or fictions, which are treated as equivalent, in terms of an activity of prop-guided imagination, or 'make-believe'. In subsequent important papers Walton has addressed issues concerning the aesthetics of photography, the aesthetics of music, the embedding of moral perspectives in literature, and the role of simulation in aesthetic appreciation. J.LEV.

Kendall Walton, 'Categories of Art', *Philosophical Review* (1970).  
— *Mimesis as Make-Believe* (Cambridge, Mass., 1990).

**Walzer, Michael** (1935– ). American political philosopher who has specialized in the study of democracy, justice, and ethical relativism. He is particularly interested in the processes through which each community arrives at its own shared understanding of justice and the good society. Walzer believes that these processes and understandings are necessarily community-specific, and hence a certain degree of cultural relativism must be respected. However, Walzer also recognizes a non-relativist 'minimal code', prohibiting slavery, genocide, and gross cruelty in any community. His most important works include *Just and Unjust Wars* (1977), *Spheres of Justice* (1983), and *Interpretation and Social Criticism* (1987). Walzer has been variously described as a liberal, a communitarian, and a radical democrat, but the originality of his thought makes him difficult to label. Walzer is currently a professor at the Institute for Advanced Studies in Princeton. W.K.

Michael Walzer, *Spheres of Justice: A Defence of Pluralism and Equality* (Oxford, 1983).

**Wang, Hao** (1921–95). American mathematical logician and philosopher of mathematics, born and educated in

China. He supplied the axioms of membership for Quine's \*set theory in *Mathematical Logic*, replacing an earlier inconsistent version. He extended Russell's ramified type hierarchy to infinite levels. He was the first to write (in 1959) a computer program which efficiently proved all the first-order theorems of Whitehead and Russell's *Principia Mathematica*. His contributions to mathematical philosophy often took the form of historical analyses of major figures; his reports of his discussions with Gödel in the 1970s are a main source for Gödel's unpublished philosophical views on truth and the nature of mathematics. Wang argued that philosophers of mathematics should take mathematical knowledge and intuition as given, and seek to describe their structure and their place in life. W.A.H.

Hao Wang, *Beyond Analytic Philosophy: Doing Justice to what we Know* (Cambridge, Mass., 1986).

— *A Logical Journey: From Gödel to Philosophy* (Cambridge, Mass., 1996).

**Wang Yang-ming** (1472–1529). Confucian thinker in China, also known as Wang Shou-jen. His thinking partly drew inspiration from that of Lu Hsiang-shan (1139–93), and scholars speak of a Lu–Wang school which competed for influence with the Ch'eng–Chu school of Ch'eng I (1033–1107) and Chu Hsi (1130–1200). Wang's fundamental ideas are contained in the work *Ch'uan-hsi-lu (Instructions for Practical Living)*. Though sharing Chu Hsi's view that human beings already have a fully virtuous disposition which has been obscured by distortive desires and thoughts, he opposed Chu on various issues. For example, for Wang, self-cultivation should involve one's directing attention to the mind, constantly watching out for and eliminating distortive desires and thoughts, rather than engaging in such inquiries as the study of classics and historical records. K.-L.S.

\*Confucianism.

*Instructions for Practical Living and Other Neo-Confucian Writings by Wang Yang-ming*, tr. Wing-tsit Chan (New York, 1963).

**war, just.** The tradition of 'just war' theory has aimed at identifying those conditions which make it morally legitimate to wage war. It was developed originally by the Christian Church, and more recently has been expressed in the conventions of international law. The early

Christian attitude of abstention from involvement in war was difficult to sustain when Christianity became the established religion of the Roman Empire, and thinkers such as Augustine turned to the idea that the waging of war was a legitimate exercise of the authority of rulers. As the ruler may justly punish wrongdoing on the part of his subjects, so likewise war could be 'just' if it was waged to punish external wrongdoers.

Over the centuries this position was elaborated in detail, and divided into the theory of *jus ad bellum*—what makes it right to go to war—and the theory of *jus in bello*—what it is right to do in war. Typical conditions laid down for *jus ad bellum* were that war may be undertaken only by a legitimate authority, it may be waged only for a just cause, it must be a last resort, there must be a formal declaration of war, and there must be a reasonable hope of success. The two most important conditions for *jus in bello* were that the means employed should be 'proportional' to the end aimed at (that is, the war should not be fought in such a way as to constitute a greater evil than the evil it was intended to remedy), and that it was not permissible to kill 'the innocent' (understood to mean non-combatants, civilians).

More recent versions of 'just war' theory have focused especially on two ideas: (i) that war can be justified only as a response to aggression (this is presented as the principal condition for *jus ad bellum*); and (ii) the idea of non-combatant immunity as the principal condition for *jus in bello*. The difficulty with both ideas is their dependence on an analogy between individuals and communities. The right to resist aggression is standardly compared to individuals' right of self-defence. However, even if it is permissible for an individual to kill his attacker in order to defend his own life, is it equally justifiable to kill thousands of people in order to defend the borders of a nation? It can be argued that individuals have a right of self-defence because the attacker has forfeited his own right to life by threatening someone else's life. It does not follow, however, that the inhabitants of a country, or even its military personnel, have forfeited their right to life because their country's rulers have decided upon aggression against another country.

The application of the principle of non-combatant immunity raises similar problems. Even if a nation waging war is not 'innocent', most of the individual combatants would seem to be, in any morally relevant sense, just as 'innocent' as non-combatants. They are not responsible for the war. They may have been compelled to fight, and if civilians are in an appropriate sense 'innocent', then most individual combatants would seem to be no less so. Moreover, the nature of modern societies and the immensely destructive power of modern weapons makes it very difficult in practice to discriminate between combatants and non-combatants. In most modern wars it is virtually impossible to target a country's military forces and military installations without attacking centres of population and killing large numbers of civilians. In that case no modern war can be waged with-

out killing the innocent. Perhaps we should conclude that no war can be 'just'.

**war and philosophy.** Philosophers of every era have tried to understand the nature and problems of war—from Heraclitus' conception of war as the father of all things to Kant's treatise on eternal peace. Philosophers have debated the value of war as a school for virtue, the misery of war, the causes of war, the \*just war, and the possibility of creating peace and universal brotherhood. But war has been important to philosophy in other ways too. The disastrous Peloponnesian War certainly influenced Plato's bad opinion of Athenian democracy. The capture of Rome by Alaric made St Augustine write *Civitas Dei*. Montaigne's scepticism was strengthened by the religious wars of the sixteenth century. The Civil War of seventeenth-century England gave Hobbes the problematic of *Leviathan*.

In modern times too, war has influenced philosophy, sometimes in unexpected ways. Some illustrations of this can be drawn from the First World War. In quite a new way the First World War made scholars and scientists participate in the war of propaganda. The role of the philosophers was important. They contributed grand metaphysical interpretations of the war aims of their own nations. In Germany philosophers like Paul Natorp, Max Scheler, and George Simmel, to name a few, did their bit for the Vaterland. The war was depicted as a struggle between profound German 'culture' and shallow Anglo-French 'civilization'. The value of war as existential experience was stressed. All the German philosophical heritage was mobilized for the fight. 'Send Fichte to the trenches!' became a catchword. The French philosophers were not to be outdone. In his *La Signification de la guerre* (1915; tr. into English the same year) Henri Bergson explained that the war was one between 'life and matter'. It takes no deep knowledge of the philosophy of Bergson to guess which among the combatants in the war represented 'life' and which represented 'matter'. Those French historians of philosophy who had taken Fichte or Hegel as their subject had an unpleasant choice before them. Should they sacrifice thinkers, whom formerly they had venerated, on the altar of patriotism? Or should they try to make a distinction between the old good Germany and the new bad one?

Nor did the philosophical struggle in Great Britain escape the bitterness of war. Until its outbreak \*Hegelianism had been firmly entrenched in the universities of England and Scotland. Now everything emanating from the enemy was seen as highly suspect. One victim of this wave of hatred against all things German was the philosopher-statesman R. B. Haldane. Haldane was a Hegelian philosopher and a follower of T. H. Green. He was also a liberal

politician. When the war broke out Haldane was Lord Chancellor in Asquith's Cabinet. In 1916 he was forced to resign. A hue and cry had been raised against this statesman who had once said that Germany was his 'spiritual home'. Wartime animosity against German philosophy is exemplified in another way by L. T. Hobhouse in his *The Metaphysical Theory of the State* (1918). The book is a critique of Bernard Bosanquet's Hegelian political philosophy. In his preface Hobhouse dedicated it to his son, who was fighting in the trenches against the very enemy whom his father tried to overcome with philosophical arguments—the German spirit.

Of course there were other, more subtle ways in which the war influenced philosophy. One of the most important works of twentieth-century philosophy, Ludwig Wittgenstein's *Tractatus Logico-Philosophicus*, was prepared and written while its author was an active combatant or a prisoner of war. Does not the agonized tone of this strange and remarkable work bear some relation to that biographical background?

The First World War had the effect of making philosophy more national and the differences between national traditions in philosophy more important. The Second World War and the ensuing Cold War had similar consequences, national and ideological cleavages parting philosophers and other scholars from each other. Philosophical arguments had their share in the wars of propaganda. World congresses of philosophy were held and other efforts made to bring philosophers together in amicable discussions. But there was great difficulty in finding a way back even to the climate of discussion of the nineteenth century. The Stoic utopia of a peaceful world state of philosophers seems very distant. S.N.

Robert Wohl, *The Generation of 1914* (Cambridge, Mass., 1979).

**Warnock, Geoffrey J.** (1923–96). Warnock's first major publication was a monograph on Berkeley (*Berkeley* (Harmondsworth, 1953)) in which he brought some of the tools of modern 'linguistic philosophy' to bear on Berkeley's ideas, to considerable effect. The bulk of his subsequent work concentrated on moral philosophy, including an incisive critique of developments in that subject this century (*Contemporary Moral Philosophy* (London, 1967)), and an exposition of his own developed theory (*The Object of Morality* (London, 1971)). Warnock takes a broadly naturalistic approach to the phenomenon of morality, arguing that it exists to help regulate conflict and promote social stability. He was the husband of Mary Warnock, and spent his working life in Oxford, where he was Vice-Chancellor from 1981 to 1985. He was knighted in 1986. N.J.H.D.

\*Berkeley.

**Warnock, Mary** (1924–). Baroness Warnock has done notable work in at least four fields: academic philosophy (narrowly conceived); the theory and practice of educa-

tion; the morality and legality of new methods of embryo fertilization; public service associated with these concerns. In academic philosophy, she has written extensively on ethics, and particularly existentialist ethics. Other work has been in the philosophy of mind, with monographs entitled *Imagination* (London, 1976) and *Memory* (London, 1987). She chaired a government inquiry into special educational needs, in the mid-1970s, and has written widely on educational issues, at both school and university level. She additionally chaired the Committee of Inquiry into Human Fertilisation in the early 1980s. Much of her working life was spent in Oxford, as college tutor but also Headmistress of Oxford High School. She was Mistress of Girton College, Cambridge, 1985–91. She was created a life peer in 1985 and was married to Geoffrey Warnock. N.J.H.D.

**war of all against all:** *see* state of nature.

**Watson, John Broadus** (1878–1958). An American psychologist, Watson was the father of \*behaviourism, the dominant theory of psychology through most of the early and middle decades of the twentieth century. For Watson, if psychology is to be scientific, its data must consist of external (public) stimuli and external (behavioural) responses; and not introspective (private mental) reports. Introspective reports give psychologists only indirect access to whatever data they need to develop their science. In contrast, behavioural reports give psychologists access to data that are as direct as those found in the physical sciences. As a method for how the science of psychology should proceed, Watson's (as well as Clark Hull's and B. F. Skinner's) behaviourism should be distinguished from logical or conceptual behaviourism, which argues that the meaning of mental terms is wholly or primarily analysable behaviourally and/or dispositionally. N.F.  
John Broadus Watson, *Behaviourism* (London, 1925).

**Watsuji Tetsurō** (1889–1960). A prominent philosopher associated with the Kyoto School, Watsuji proposed the East Asian idea of *ningen*—'human-beings-in-representation'—as the basis for a philosophical anthropology. Torn in his youth between attractions to philosophy and literature, Watsuji produced early works on Schopenhauer, Nietzsche, and Kierkegaard, before turning to a study of Asian traditions of thought. A polymath like many of his colleagues, he continued to write on such topics as Homer, Greek politics, and early Christianity, but devoted most of his energies to writings on Buddhism and the cultural history of Japan, with special emphasis on ethical thought. In his works on cultural anthropology—of which *Climate* (1935) has been translated into English—Watsuji criticized Heidegger for neglecting human spatiality in *Being and Time* and for making his notion of *Dasein* overly individualistic. G.R.P.

**weakness of will:** *see akrasia.*

**Weber, Karl Emil Maximilian (Max)** (1864–1920). German sociologist, whose polymathy defied his characterization of our age as one of specialization and bureaucracy. Men attach meanings to their actions and these become embodied in social norms. Hence sociology involves ‘understanding’ (*Verstehen*). But it can causally explain social phenomena by the comparative method and by ‘ideal types’. Ideal types include the three types of authority: traditional, charismatic, and legal-rational or bureaucratic (which prevails in both \*capitalism and \*socialism). Social phenomena, e.g. the rise of capitalism, depend not only on economic factors but on ideas, e.g. Calvinism’s ‘Protestant ethic’. Status groups are as important as Marx’s economic classes. In response to the political upheavals of 1919 he distinguished the ‘ethic of responsibility’ from the ‘ethic of conscience’ and quoted Goethe’s *Faust*: ‘The devil is old; you must become old to understand him’. M.J.I.

R. Bendix, *Max Weber: An Intellectual Portrait* (London, 1960).

**Weil, Simone** (1909–43). A pupil of the radical individualist philosopher Alain, Simone Weil evolved a Platonic interpretation of the world with strong mystical leanings. Her ideals, which first lay in the direction of anarcho-syndicalism, she pursued with a consistent eccentricity. After her conversion to Christianity, she combined her strong commitment to many of its Catholic forms with a thoroughgoing interpretation of its main themes—God, creation, redemption—through the concepts of ancient Greek philosophy. This involved an emphasis on the impersonal and the contemplative. Always a political activist, she also attempted to sketch the politics of a society equal to these aspirations. As such she represents the most striking example of twentieth-century Christian \*Platonism. D.McL.

D. McLellan, *Simone Weil: Utopian Pessimist* (London, 1990).

**welfarism.** A view which assigns to the state the function of looking after the well-being or welfare of the people.

In the seventeenth and eighteenth centuries liberal-democratic theorists (such as Adam Smith) held that the state had a largely negative function of protecting security from outside or inside and only a minimal welfare function, such as the provision of large works which individuals could not manage on their own or the ensuring of minimum standards of education. Welfarism became a large function of the state in Britain after the Beveridge Report (1942), which propounded state responsibility for individual welfare ‘from the cradle to the grave’. Other European states adopted the idea of welfarism to a greater or lesser extent. Indeed, Germany pioneered both modern social insurance in the 1880s and the concept of *Wohlfahrtsstaat* in the 1920s. The USA has been much less influenced by these

ideas. At the moment there seems to be a move away from welfarism in the UK and other parts of Europe, partly on the grounds that it is difficult to sustain the expenditure involved in such welfare concerns as the National Health Service, and partly on broader moral grounds, that welfarism saps the moral fibre of the people and is really massive state paternalism or, as it is often described by its opponents, that it constitutes the ‘nanny state’. R.S.D.

\*conservatism.

R. Hattersley, *Choose Freedom: The Future for Democratic Socialism* (Harmondsworth, 1987).

R. Nozick, *Anarchy, State and Utopia* (Oxford, 1974).

**well-being.** Various interpretations of ‘living and faring well’ or ‘flourishing’, the notion of well-being is intricately bound up with our ideas about what constitutes human \*happiness and the sort of life it is good to lead. Well-being is said to be both a condition of the good life *and* what the good life achieves.

However, the phrase ‘the good life’ is ambiguous between the morally good life and the sort of life most people aspire to, a life in which comfort and enjoyment have a large part. Indeed we may even suspect that the two sorts of life are mutually exclusive—and that well-being belongs firmly in the latter, or would be a surprising *central* feature of the former. It seems that the ambiguity can at least be taken as an indication of how unclear we find the connection between being morally good and possessing health, wealth, and happiness, and the other components of well-being.

Some philosophers have, nevertheless, objected to the suggested dichotomy between what is morally good and what is enjoyable. Aristotle, for example, insists in his discussion of *eudaimonia* that the morally good life is essential to human flourishing and, conversely, that being good is possible only for a person who has well-being. Thus, according to this view, well-being is a notion which spans both the moral and non-moral aspects of life. It follows that any adequate conception of a good life *cannot* be limited to either a narrowly moral, or a non-moral, account. It will be a highly complex account, akin to the answer a parent might give when asked ‘What sort of life do you wish for your children?’, with all the intricacies such an answer would involve.

Furthermore, because a good person cannot enjoy well-being in conditions of poverty or oppression, it is clear that well-being is also a political notion. It must therefore be explicated in both moral and political terms, with the focus of interest placed firmly on the interdependence of these. While common sense accords with this view of the matter, the notion of well-being has tended to be the subject of much dispute, and prey to the conflicting conceptions of what enables human beings to flourish which are provided by different moral and political philosophies.

Nevertheless, it seems possible to specify, as Rawls and Honderich do, the primary goods which are necessary, if

not sufficient, conditions of well-being, and the political arrangements which will therefore facilitate it. The question of the distribution of well-being will then be essentially a matter of social justice. Since it is hard to justify inequalities of well-being even when it seems possible to justify inequalities of socio-economic goods, the question will be best answered, perhaps, by some principle of equality which gives priority to policies whose end is to make well-off those who are badly off in terms of well-being.

**well-formed formula.** A formal calculus has a basic vocabulary and rules for forming acceptable sequences (well-formed formulae or wffs) of that vocabulary. Well-formed formulae are analogues of grammatical sentences in natural language. The rules for well-formedness are analogues of rules of grammar. For example, for a version of the \*propositional calculus where

(1)  $\sim$  and  $\vee$  are basic logical constants ('not', 'or'),

(2)  $A_1, A_2, \dots, A_n$  are atomic propositional expressions,

the set of wffs is defined as follows:

(3) wffs are either atomic propositional expressions or molecular, i.e. of the form  $\sim \phi$  or  $(\phi \vee \psi)$ , where

(4)  $\sim \phi$  is a wff if and only if  $\phi$  is a wff,

(5)  $(\phi \vee \psi)$  is a wff if and only if  $\phi$  and  $\psi$  are wffs. ('(' and ')') are analogues of punctuation.)

(1)–(5) provide a \*decision procedure for well-formedness.

**Weyl's paradox** is a name that has been used for the paradox concerning the term 'heterological', which is supposed to apply to all and only terms which do not apply truly to themselves. The problem is that it then seems that 'heterological' is heterological if and only if it is not. This

paradox was originally presented in 1908 in a paper by Kurt Grelling and Leonard Nelson, so that the term 'Weyl's paradox' is incorrect. Herman Weyl (1885–1955) was a German-American mathematician, physicist, and philosopher of science.

J.C.

\*Grelling's paradox.

**wff:** see well-formed formula.

**Whewell, William** (1794–1866). Influential Cambridge philosopher, mineralogist, and educational reformer. Son of a Lancaster carpenter, Whewell became Master of Trinity College in 1841. In his *The Philosophy of the Inductive Sciences Founded upon their History* (London, 1840) he sought to update the methodology advocated programmatically in Francis Bacon's *Novum Organum*, and to base this updating on consideration of how science had actually progressed—a consideration made possible by his own *History of the Inductive Sciences from the Earliest to the Present Time* (London, 1837). He asserted a fundamental antithesis between the facts studied by a scientist and the concepts that a scientist invents in order to colligate the facts, and owed to Kant the idea that certain very general laws are presuppositions of empirical inquiry. Correspondingly he opposed J. S. Mill's views about the epistemology of such general laws.

\*natural law.

M. Fisch, *William Whewell: Philosopher of Science* (Oxford, 1991).

**Whitehead, Alfred North** (1861–1947). British mathematician and philosopher who spent his later and philosophically most productive years in the United States at Harvard University, where he and his wife hosted legendary Sunday teas. *Principia Mathematica* (1910–13), his three-volume attempt in collaboration with his former student Bertrand Russell to show that mathematics can be reduced to logic (i.e. to establish \*logicism), is considered by many to be one of the great intellectual achievements of all time. *Process and Reality* (1929), a metaphysical system in which substance (as traditionally conceived in Western philosophy) is rejected in favour of process, is regarded as having importance in the history of metaphysics comparable to the significance of his earlier work for logic and the foundations of mathematics.

Whitehead's work is usually divided into three periods: before 1914, mathematics and logic; 1914–24, philosophy of physical science; and 1924–47, metaphysics and the historical role of metaphysical ideas in civilization. Although during most of his life he considered himself and was considered by others to be a mathematician, study of his intellectual development reveals it to be unified by philosophical concerns (e.g. 'modes of togetherness').

In *Science and the Modern World* (1925), his first metaphysical work, Whitehead rejected the idea of 'simple location' presupposed by scientific materialism. Everything, he said, is a field spread out temporally and spatially; every object, from a human body to an electron, is

composed of events or processes. In *Process and Reality* he systematically elaborated this metaphysics, in which the basic unit is an experiential event called an 'actual entity'. An actual entity is a unifying of its relations to the other actual entities of the world it appropriates. These appropriating relations are 'prehensions', vectors which transform everything experienced into that entity's distinctive actuality.

God plays a central role in this appropriating process. In his 'Primordial Nature' God orders possibilities ('eternal objects') to make them relevant to the becoming of an entity. In his 'Consequent Nature' God preserves the immediacies of all past actual entities and unites them with his envisionment of the primordial unity of all eternal objects. God is not only necessary to every becoming; becomings are necessary to the development of God as Consequent. Like any actual entity, God is a process of becoming.

Whitehead's books after *Process and Reality* avoid technicalities in exploring imaginatively the significance of his metaphysical ideas. *Religion in the Making* (1926) is a richly suggestive discussion of the nature of religion; *Adventures of Ideas* (1933) presents, for example, his conception of experience in luminous prose; and *Modes of Thought* (1938) is intended as 'a free examination of some ultimate notions, as they occur naturally in daily life'.

Paul Arthur Schilpp (ed.), *The Philosophy of Alfred North Whitehead* (New York, 1941).

**why.** The question 'Why . . . ?' is answered by explaining why, which is stating a reason why (explaining-what is different). Often such reasons are causes, but even when 'cause' is not the natural description, 'Because ---' is the natural formula for answering 'why' questions. Other idioms do exist, as in: 'Why did she flood the bathroom?'—'Out of mischief'; 'Why do animals have hearts?'—'For pumping the blood'; 'Why walk?'—'To save money'. But such answers can always be expanded into 'Because ---' answers, usually becoming more informative in the process (the expansion will often indicate that the thing to be explained does some good, or—differently—aims at some good, these being two kinds of \*teleological explanation).

A 'why' explanation must, first, state a *reason for thinking* that the matter to be explained is true: for example, 'Bangkok is hot because it is in the tropics'. This may, secondly, need amplification—different things go without saying in different contexts of 'why' inquiry. The amplification may fill the reason out, for example by adding that most tropical cities are hot, or strengthen it, for example by substituting 'Because it is at sea-level in the tropics, and all sea-level tropical cities are hot', or extend it, for example by explaining why sea-level tropical cities are hot (this last

process is potentially endless). But thirdly, some 'why' questions do not need, or even cannot get, answers—for example, 'Why is Bangkok a sea-level tropical city?' Finally and crucially, many reasons for thinking fail to be *reasons why* even after these amplifications. For example—an example of Aristotle's—'Because they do not twinkle' does not begin to explain why the planets are near us (here the explanation goes the other way round). The question what extra is required connects with the mysterious question what \*causality is.

**Why be moral?** *see* moral philosophy, history of.

**Wiggins, David** (1933– ). Oxford philosopher specializing in metaphysics, philosophical logic, and ethics, noted for his work on \*identity. He challenges P. T. Geach's doctrine of the relativity of identity, advancing instead an 'absolute' conception whereby if particulars are identical under one \*sortal concept, then they are identical under any other that applies to them. Geach's supposed counterexamples are dismissed as turning on equivocation. Thus Geach suggests that *x* and *y* might be the same *river*, but different *bodies of water*. Wiggins's response is that rivers are not identical with bodies of water, but rather *constituted* by them.

One consequence of Wiggins's position is that two different \*things—for instance, a river and the body of water currently constituting it—may exist in the same place at the same time. This may seem odd, but is unobjectionable provided, as here, the things in question are of different kinds.

**will.** Traditionally the will was taken to be a mental faculty responsible for acts of volition such as choosing, deciding, and initiating motion. This faculty of the soul or mind was taken as one of the characteristics, the most important, separating us from animals and inanimate objects. Usually the will was explicitly taken to be capable of \*origination—the creation of a new beginning and escape from the past. Kant stressed the moral importance of acts of will, as opposed to practical consequences of actions, but the will reached its philosophical apotheosis in Schopenhauer's *The World as Will and Idea* (1818, 1844). Contemporary philosophy of mind is less accepting of ontologically real mental faculties, although the will has continued to have attention paid to it. The traditional problem of the freedom of the will concerns itself partly with (a) the possible incompatibility between free will and determinism, and (b) the alleged dependency of moral responsibility upon free will.

**William of Ockham:** *see* Ockham.

**Williams, Bernard A. O.** (1929–2003). Bernard Williams was one of the leading British intellectuals of the late twentieth century. Among philosophers he is best known for his work in moral philosophy and on the metaphysics of mind, especially in connection with issues of personal identity. He also made contributions to classical philosophy, notably *Shame and Necessity* (Berkeley, 1993), and wrote an important book on Descartes (*Descartes* (Harmondsworth, 1978)), in which he gives prominence to the idea of there being an 'absolute conception of reality' inherent in Descartes's philosophical project.

Williams's work on \*personal identity resists easy summary. In general, though, it is marked by a particular inventiveness in devising examples or possible cases to refute or to develop these about the physical or mental bases of personal identity, and by great fertility and incisiveness in seeing new ways of approaching issues. This freshness in tackling problems is a notable feature of much of Williams's work, which is widely influential. His papers on this topic are collected in *Problems of the Self* (Cambridge, 1973).

In moral philosophy, Williams argued against both Kantian and utilitarian approaches. In both cases, he objects that these views require agents to view themselves unrealistically as simply one person among others, which neglects to acknowledge the special significance that a person's own projects must have for them. In particular, he gives emphasis to the role of emotions in moral responsiveness. Williams is also sceptical that many of the claims morality makes for itself (that it is universal, absolutely binding, and so on) can cogently be justified. Many of these themes are prominent in his *Ethics and the Limits of Philosophy* (London, 1985).

Williams chaired the government Committee on Obscenity and Film Censorship in the late 1970s. He held professorships in London, Oxford, and Berkeley, California, and was Provost of King's College Cambridge from 1979 to 1987. Not long before his death he completed a long-awaited book on *Truth and Truthfulness* (Princeton, NJ, 2002).

N.J.H.D.

\*moral luck; reasons, internal and external.

**Williamson, Timothy** (1955– ). British logician and epistemologist, currently Wykeham Professor of Logic at the University of Oxford.

Williamson defends the epistemic theory of \*vagueness. Vague terms have borderline cases. Most philosophers assume that there is no fact of the matter about whether a vague term can truly be applied in a borderline case. Williamson, however, maintains that vague terms have sharp boundaries, which are in principle inaccessible, even though they are determined by the ways in which language is used. Since Williamson understands know-

ledge in terms of margin of error principles, which require that *p* must be true in all cases sufficiently similar to cases in which *p* is known, it remains possible to apply vague terms knowledgeably. In more recent work Williamson has developed a broader epistemological perspective. Taking knowledge to be conceptually prior to belief, he offers new perspectives on the plausibility of scepticism, the nature of evidence, the accessibility of our own mental states, and the limits of knowledge.

J.BER.

T. Williamson, *Knowledge and its Limits* (Oxford, 2000).

**will to believe.** In his 1897 article entitled 'The Will to Believe', William James said that, under certain specified conditions, we have a right to let our passionate nature decide which of two alternative hypotheses to adopt. These are that the matter cannot be settled on intellectual grounds, and that the choice between them is *living* (we find each credible), *forced* (we must act in the light of one or the other), and *momentous* (really important). Examples are the choice between theism and atheism or free will and determinism.

T.L.S.S.

\*voluntarism, doxastic.

Richard Schacht, *Nietzsche* (London, 1983), ch. 4.

**Wilt Chamberlain argument.** In what is his best-known argument from *Anarchy, State and Utopia* (New York, 1974), Robert Nozick asks us to imagine that we are in a society that has just distributed income according to some ideal pattern, possibly a pattern of \*equality. We are to further imagine that in such a society someone with the talents of Wilt Chamberlain offers to play basketball for us provided that he or she receives a small fraction of the proceeds from every home game ticket that is sold. Suppose we agree to these terms, and a large number of people attend the home games to watch this super-talented player, thereby securing for him or her a sizeable income. Since such an income would surely upset the initial pattern of income distribution whatever that happened to be, Nozick contends that this illustrates how an ideal of \*liberty upsets the patterns required by other political ideals, and hence calls for their rejection.

J.P.S.

\*libertarianism; conservatism.

**Winch, P. G.** (1926–97). A prominent Wittgensteinian, whose writings explore the implications of the claim that to understand a language is to understand a \*form of life. His most influential work, *The Idea of a Social Science*, was highly critical of received empiricist anthropological and sociological conceptions of understanding human action. It stimulated extensive debate about the methodology of the social sciences. Subsequent writings on the understanding of primitive societies were equally influential. Winch's ethical writings are distinguished not only by their seriousness, but also by the concreteness of examples and the attention to the context of moral predicaments, as well as the texture of life in which they are embedded.

**wisdom.** A form of understanding that unites a reflective attitude and a practical concern. The aim of the attitude is to understand the fundamental nature of reality and its significance for living a good life. The object of the practical concern is to form a reasonable conception of a good life, given the agents' character and circumstances, and to evaluate the situations in which they have to make decisions and act from its point of view. These evaluations are often difficult because many situations are complex, conceptions of a good life are incompletely formed, and the variability of individual character and circumstances render general principles insufficiently specific. Wisdom may be identified then with good judgement about the evaluation of complex situations and conceptions of a good life in the light of a reflective understanding of the human condition.

Although wisdom is what \*philosophy is meant to be a love of, little attention has been paid to this essential component of good lives in post-classical Western philosophy. It is perhaps for this reason that those in search of it often turn to the obscurities of oriental religions for enlightenment.

J.KEK.

\*understanding.

**Wisdom, John** (1904–93). Professor of Philosophy at Cambridge 1952–68, and at Virginia and Oregon. Wisdom was enormously appreciative and yet critical of the anti-metaphysical arguments of both G. E. Moore, with his emphasis on common sense, and the later Wittgenstein, who claimed that metaphysical theories are basically misconceptions caused by our failure to appreciate the variety of functions of ordinary language. Wisdom argued on the contrary that the extraordinary, paradoxical-sounding claims of poets and scientists, theologians, and metaphysicians can be illuminating as well as misleading, and are often both. Plain thought can conceal what extravagant

metaphor reveals—but also vice versa. Thus insight can often be obtained only by appreciating the dialectical argument between the apparently obvious and the flamboyantly surreal, each of which may have something to be said for it.

In *Other Minds* (1952) Wisdom particularly applied these insights to \*scepticism and the philosophy of mind.

John Wisdom, *Philosophy and Psycho-analysis* (Oxford, 1953).

**Wissenschaftslehre.** German for the 'theory of science or knowledge'. For Fichte, it is simply philosophy, since no opponent of the enterprise is a philosopher; it derives all knowledge and science from a self-evident axiom: 'All other propositions will have only a mediate certainty, derived from it, while it must be immediately certain.' Bolzano's *Wissenschaftslehre* (1837) argues (and helped to convince Husserl) that logic has nothing to do with psychology; it studies non-temporal, non-spatial, ideal objects: proofs, propositions, concepts.

**Wittgenstein, Ludwig Josef Johann** (1889–1951). The leading analytical philosopher of the twentieth century, whose two major works altered the course of the subject. Whether by agreement or by disagreement, whether through understanding or misunderstanding, his influence has moulded the evolution of philosophy from the 1920s.

Born in Vienna, he studied engineering, first in Berlin, then in Manchester. Gravitating towards philosophy, he went to Cambridge in 1912 to work with Russell. He served in the Austrian army in the First World War, and while on active duty completed his first masterpiece (and only book published in his lifetime) the *Tractatus Logico-Philosophicus* (1921). From 1920 to 1926 he worked as a schoolteacher. The next two years were occupied with designing and building a mansion in Vienna for his sister. During this period he came into contact with the \*Vienna Circle, a group of philosophers much influenced by his early ideas, which, sometimes through misunderstanding, were the mainspring of their Logical Positivism. In 1929 he returned to philosophical work at Cambridge, where he spent the rest of his teaching life. Between 1929 and 1932 his ideas underwent dramatic change, which he consolidated over the next fifteen years. Reacting against his own early philosophy, he developed a quite different viewpoint. Initially communicated only through pupils, these ideas revolutionized philosophy in mid-century. They were given definitive expression in his second masterpiece, the *Philosophical Investigations* (1953), published two years after his death. Over subsequent decades, a further dozen unfinished books and four volumes of lecture notes taken by pupils were published.

Wittgenstein's greatest contributions to philosophy can be classified under five headings: philosophy of

language, philosophy of logic, philosophical psychology, philosophy of mathematics, and the clarification of the nature and limits of philosophy itself. In each of these his views are revolutionary and virtually without precedent. On every subject he tackled, he eschewed received positions and rejected traditional alternatives, believing that where philosophy was caught between apparently unavoidable poles, e.g. realism and idealism, Cartesianism and behaviourism, Platonism and formalism, it was the common presuppositions of both that need to be rejected.

The *Tractatus* is a mere seventy-five pages long, written in syllable, marmoreal sentences. It ranges over metaphysics, logic, and logical truth, the nature of representation in general and of propositional representation in particular, the status of mathematics and of scientific theory, solipsism and the self, ethics and the mystical.

According to the *Tractatus*, the world is the totality of \*facts, not \*things. The substance of all possible worlds consists of the totality of sempiternal simple objects (e.g. spatio-temporal points, unanalysable properties, and relations). The form of a simple object consists in its combinatorial possibilities with other objects. The possible concatenation of objects constitutes a state of affairs. The obtaining of a state of affairs is a fact. A representation of a state of affairs is a model or picture. It must possess the same logical multiplicity as, and be isomorphic with, what it represents. Propositions are logical pictures. They are essentially bipolar, i.e. capable of being true and also capable of being false. In this their nature reflects the nature of what they represent, since it is of the essence of a state of affairs that it either obtains or does not obtain. An elementary proposition depicts an (atomic) state of affairs. Its constituent names (unanalysable, logically simple names) go proxy for the objects in reality which are what they mean. The logico-syntactical form of a simple name must mirror the metaphysical form of the object that is its meaning. Hence the combinatorial possibilities of names mirror the combinatorial possibilities of objects. It is the fact that the names in a proposition are arranged as they are, in accord with the rules of logical syntax, that says that things are thus-and-so in reality. The sense of a proposition is a function of the meanings of its constituent names. Sense must be absolutely determinate; so any vagueness betokens analysability, and will disappear on analysis. The essence of the proposition is given by the general propositional form, which is: "This is how things are", i.e. the general form of a description of how things stand in reality. A proposition is true if things in reality are as it depicts them as being.

The logical analysis of propositions must yield propositions which are logically independent of each other, i.e. elementary propositions whose truth depends only on the existence or non-existence of (atomic) states of affairs. Elementary propositions can be combined to form molecular propositions by means of truth-functional operators—the logical connectives. These, contrary to Frege and Russell, are not names of anything (logical objects, functions).

They are merely truth-functional combinatorial devices, which generate truth-dependencies between propositions. All possible forms of truth-functional combination can be generated by the operation of joint-negation on a set of elementary propositions. All logical relations between propositions turn on the inner complexity (the truth-functional combination) of molecular propositions. The only (expressible) form of necessity is \*logical necessity. Two limiting cases of combination are senseless (not nonsense): tautologies, which are unconditionally true, and contradictions, which are unconditionally false. In an ideal notation their truth-value would be perspicuous from mere inspection of the symbolism. The necessary truths of logic are not, as Russell thought, descriptions of the most general features of the world; nor are they descriptions of relations between logical objects, as Frege thought. They are \*tautologies, molecular propositions which are so combined that bipolarity, and hence all content, cancels out; they all say the same thing, namely nothing. They are 'degenerate' propositions in the sense in which a point is a degenerate conic section. So the truths of logic are not a domain for pure reason alone to attain knowledge about reality, since to know a tautology is to know nothing.

Metaphysical utterances, by contrast, are nonsense—violations of the bounds of sense. For the apparent categorical concepts that occur in them, e.g. 'proposition', 'fact', 'object', 'colour', are not genuine concepts at all, but unbound variables that cannot occur in a well-formed proposition. But what one tries to say by means of the pseudo-propositions of metaphysics (e.g. that red is a colour) is *shown* by features (forms) of genuine propositions containing substitution-instances of these formal concepts (e.g. 'A is red'). What is shown by a notation cannot be said. Truths of metaphysics are ineffable; and so too are truths of ethics, aesthetics, and religion.

Hence there are no philosophical propositions, i.e. propositions describing the essential natures of things or the metaphysical structure of the world. So the very propositions of the *Tractatus* itself are finally condemned as nonsense—attempts to say what can only be shown. The task of the *Tractatus* was to lead one to a correct logical point of view. Once that is achieved, one can throw away the ladder up which one has climbed. Philosophy is not a science; nor is it in competition with the sciences. It is not the accumulation of knowledge about a subject-matter. Its sole function is to monitor the bounds of sense, to elucidate philosophically problematic sentences, and to show that attempts to traverse the bounds of sense are futile.

The achievement of the *Tractatus* is manifold. (a) It brought to full fruition the atomist and foundationalist traditions, the conception of philosophy as analysis of hidden logical structures, the venerable quest for an ideal language or notation, the logico-metaphysical picture of language and logical form as a mirror of the logical structure of the world. Thenceforth these were ripe for demolition—a task that was carried out in the *Investigations*. (b)

Its numerous criticisms of Frege and Russell were definitive. (c) The radical conception of philosophy it propounded initiated the so-called \*'linguistic turn' characteristic of modern analytical philosophy, and paved the way for the similar, but immeasurably richer, conception of philosophy delineated in the *Investigations*. (d) Its elucidation of the nature of logical necessity and logical truth, though still to be modified and elaborated in the later *Remarks on the Foundations of Mathematics*, was its crowning achievement.

Although the *Philosophical Investigations* was meant to be seen against the backdrop of the *Tractatus*, it is the whole tradition of which the *Tractatus* was the culmination that is being criticized. The criticisms are often indirect, confronting not doctrines and theses, but the presuppositions that inform them.

In his philosophy of language, Wittgenstein now rejected the assumption that the meaning of a word is the thing it stands for. That involves a misuse of the word 'meaning'. There is no such thing as *the* name-relation, and it is confused to suppose that words are connected with reality by semantic links. That supposition rests on a misconstrual of ostensive definition. Not all words are or need to be sharply defined, analysable by specification of necessary and sufficient conditions of application. The demand for determinacy of sense was incoherent. Vagueness is not always a defect, and there is no absolute standard of exactness. The very ideal of analysis (inherited from the Cartesians and Empiricists, and developed afresh by Moore and Russell) was misconceived. The terms 'simple' and 'complex', which are relative, were misused. Many concepts, in particular philosophically crucial ones such as 'proposition', 'language', 'number', are united by family resemblance rather than by common characteristic marks. The thought that all propositions share a common essence, a general propositional form, was misguided. Not all propositions are descriptions, and, even among those that are, there are many different logical kinds of description. It was an error to suppose that the fundamental role of the proposition is to describe a state of affairs. It was a mistake to think that the meaning of a sentence is composed of the meanings of its constituents, and confused to think that truth consists in correspondence between proposition and fact. The institution of language can only be elucidated by attending to the use of words and sentences in the stream of life.

In opposition to the conception that makes truth pivotal to the elucidation of meaning, letting understanding take care of itself, Wittgenstein argued that \*meaning is what is given by explanations of meaning, which are rules for the use of words. It is what is understood when one understands what an utterance means. Understanding is an ability, the mastery of the technique of using an expression. It is exhibited in using an expression correctly, in explaining what it means, and in responding appropriately to its use—which are severally criteria of understanding. Forms of explanation are diverse, formal definition being

only one among many, e.g. ostension, paraphrase, contrastive paraphrase, exemplification, explanation by examples, etc. Ostensive definition, which looks as if it links word and world, in fact introduces a sample providing a standard for the correct application of the definiendum. The sample belongs to the method of representation, not to what is represented; hence no link with reality, i.e. with what is represented, is thereby forged.

Consequently the central thought of the *Tractatus*, that any form of \*representation is answerable to reality, that it must, in its formal structure, mirror the metaphysical form of the world, is misconceived. Concepts are not correct or incorrect, only more or less useful. Rules for the use of words are not true or false. They are not answerable to reality, nor to antecedently given meanings. Rather they determine the meanings of words, are constitutive of their meanings. Grammar is autonomous. Hence what appear to be necessary metaphysical truths (e.g. that red is a colour), which the *Tractatus* held to be ineffably shown by any symbolism (e.g. any language for the description of coloured things), are actually no more than rules for the use of words in the guise of descriptions (e.g. that if anything can be said to be red, it can also be said to be coloured). What seemed to be a metaphysical co-ordination between language and reality, e.g. between the proposition that *p* and the fact that *p* which makes it true, is merely an intragrammatical articulation, namely that 'the proposition that *p*' = 'the proposition which is true if it is a fact that *p*'. The apparent harmony between language and reality is merely the shadow cast upon the world by grammar. Hence too, puzzles about the intentionality of thought and language are not to be resolved by means of relations between word and world, or thought and reality, but by clarifying intragrammatical connections within language.

Running through the mainstream tradition of European philosophy is the thought that what is given is subjective experience, that a person knows how things are with him (that he is in pain, is experiencing this or that), but must problematically infer how things are 'outside' him. So the private is better known than the public, mind is better known than matter. Subjective experience was conceived not only as the foundations of empirical knowledge, but also as the foundations of language, i.e. that the meanings of words are fixed by naming subjective impressions (e.g. 'pain' means *this*, which I now have). Wittgenstein's \*'private language arguments' mount a comprehensive assault on the presuppositions of this conception.

Conceiving of one's current experience as an object of subjective knowledge is misleading, since the ability, for example, to avow one's pain does not rest on evidence, and one does not find out or verify that one is in pain. Being ignorant of or doubting one's own pain makes no sense, nor therefore does knowing or being certain that one is in pain. To say 'I know I'm in pain' is either an emphatic avowal of pain or a philosopher's nonsense. The

thought that no one else can have what I have when I am in pain, hence that I enjoy an epistemically privileged position, is confused. For it rests on the assumption that the pains of different people are at best qualitatively, but not numerically, identical. But that is a distinction applicable to substances, not to impressions. Two people have the same pain if their pains tally in intensity, phenomenological features, and occur in corresponding locations of their bodies. The whole traditional picture is a distortion of the 'inner', under the pressure of misleading pictures embedded in our language and of misconstruals of grammatical asymmetries between first- and third-person psychological sentences. Hence we misconstrue the 'outer' likewise. We do often know that others are in pain on the basis of their behaviour, but this is not inductive or analogical evidence. It is a logical criterion for their pain. Although such criteria are defeasible, in the absence of defeating conditions, it is senseless to doubt whether the sufferer is in pain. The behavioural criteria for the application of a psychological predicate are partly constitutive of its meaning. For expressions signifying the 'inner' are not given their meaning by a private ostensive definition in which a subjective impression functions as a sample. There can be no such thing as a logically private sample, and a sensation cannot fulfil the role of a sample. The elaborate argument to establish this negative conclusion undermines the conception of the 'inner' as a private domain to which its subject enjoys privileged access by means of a faculty of introspection construed on the model of perception.

Contrary to the dominant tradition, Wittgenstein argued that \*language is misrepresented as a vehicle for the communication of language-independent thoughts. Speaking is not a matter of translating wordless thoughts into language, and understanding is not a matter of interpreting—transforming dead signs into living thoughts. The limits of thought are determined by the limits of the expression of thoughts. The possession of a language not only expands the intellect, but also extends the will. A dog can want a bone, but only a language-user can now want something next week. It is not thought that breathes life into the signs of a language, but the use of signs in the stream of human life.

Wittgenstein also worked extensively on the philosophy of mathematics. His *Remarks on the Foundations of Mathematics* is as original and revolutionary as everything else he wrote. He developed further his earlier account of logical truth, cutting it free from the metaphysical apparatus of the *Tractatus*. He rejected \*logicism, \*formalism, and \*intuitionism alike. In their place he delineated a normative conception of mathematics. Arithmetic is a system of rules (in the form of descriptions) for the transformation of empirical propositions about the numbers or quantities of things. The propositions of geometry are not descriptions of the properties of space, but are rather constitutive rules for the description of spatial relations. A mathematical proof is misconceived as a demonstration of *truths* about the nature of numbers or geometrical forms. It determines

concepts and so too forms of inference. It is a matter of invention (concept-formation), rather than discovery. To truth in mathematics corresponds sense in inferences among empirical propositions about numbers and magnitudes of things. Wittgenstein's views here, however, have proved to be too radical and difficult for the age, and have met largely with incomprehension and misinterpretation.

The revolutionary conception of philosophy propounded in the *Tractatus* finds its counterpart in Wittgenstein's later philosophy. Philosophy, he continued to argue, is not a cognitive discipline. There are no philosophical propositions and no philosophical knowledge. If there were theses in philosophy, everyone would agree with them, for they would be mere grammatical truisms (e.g. that we know that someone is in pain by his behaviour). The task of philosophy is to clear away the conceptual confusions that stand in the way of accepting these rule-governed articulations in our language. There is no room for theories in philosophy, for in philosophy we are moving around within our own grammar, dissolving philosophical questions by examining the rules for the use of words with which we are familiar. For there are no such things as hidden rules which are followed, or discoveries about the real meanings of expressions in use which are unknown to all users. Philosophical problems stem from entanglement in linguistic rules, e.g. projecting the \*grammar of one kind of expression upon another (the grammar of 'pin' on to 'pain'), or projecting norms of representation on to reality and thinking that we are confronting metaphysical necessities in the world (e.g. 'Nothing can be red and green all over'), or placing demands upon certain concepts, e.g. that they lend themselves to certain kinds of explanation, which are only appropriate for concepts of a different category. The methods of philosophy are purely descriptive. The task of philosophy is conceptual clarification and the dissolution of philosophical problems. The goal of philosophy is not knowledge but understanding.

**Wittgenstein, the new.** In recent years a revisionary view of Wittgenstein's thought has emerged, championed by Cora Diamond, Stanley Cavell, Hilary Putnam, and others. Its two central tenets are that the early and late work of Wittgenstein (respectively and chiefly the *Tractatus* and the *Philosophical Investigations*) are continuous with each other, and share a fundamental purpose in common, which is a 'therapeutic' one, aimed at curing the philosophical disease of creating problems where none exist by misunderstandings about the way language works.

The standard view repudiated by proponents of the 'new Wittgenstein' is a familiar one. It says that in the *Tractatus* Wittgenstein set out a view of the relation between language and the world in which the structure of each mirrors the other, as a result of a denoting relation between the simplest elements of language ('names') and the world ('objects'). His later philosophy is premised on an emphatic rejection of this view in favour of the idea that meaning is a function of use within 'language-games' embedded in 'forms of life'. In the earlier philosophy, accordingly, his account can be described as truth-conditional and realist, while in the latter it is closer to an assertibility-conditions account, and is anti-realist.

The 'new Wittgenstein' advocates reject this story completely. They argue instead that Wittgenstein's aims were the same throughout his earlier and later work, and that its basis is the rejection of the idea that language can be understood from an external point of view. Grasping this cures one (hence the invocation of the idea of 'therapy') of the temptation to undertake traditional philosophical inquiry. The principal concerns of the *Investigations* are thus to be found in the *Tractatus*, and vice versa, and this—so these advocates urge—requires a radical new view of Wittgenstein's philosophy. A.C.G. Cora Diamond, *The Realistic Spirit* (Cambridge, Mass., 1991).

**Wittgensteinians.** Wittgenstein's impact upon analytical philosophy is second to none. Although he did not, nor indeed did he wish to, found a philosophical school of thinkers, the evolution of twentieth-century philosophy would be as unintelligible without his work as would that of twentieth-century art without Picasso's. His influence is marked by two waves and their aftermath. The *Tractatus* (1921) was the leading text of \*logical atomism and the main inspiration of the \*Vienna Circle (and acknowledged as such in their Manifesto). The positivists' conception of philosophy as analysis, of logical truths as vacuous tautologies, and of metaphysical assertions as nonsense, was derived from the *Tractatus*. The \*principle of verification was derived from discussions with Wittgenstein, and so too, with considerable misunderstanding, was their conventionalism in logic and mathematics. Although Carnap could not be called 'a Wittgensteinian', he acknowledged Wittgenstein's formative influence, and his *Logical Syntax of Language* is heavily indebted to the *Tractatus*. Logical

Positivism developed its own momentum in the 1930s, and, through A. J. Ayer in Britain and Carnap in the USA, became extremely influential. M. Schlick and F. Waismann, however, were more influenced by the second phase of Wittgenstein's thought, and their work, from the early 1930s onwards, bears its hallmark.

While the Circle was developing their *Wissenschaftliches Weltauffassung*, a research programme for a 'scientific world-outlook', Wittgenstein, then teaching in Cambridge, was moving off in fresh directions, which led to the *Philosophical Investigations*. He repudiated much of his earlier philosophy, replacing it with a very different viewpoint. His main work in this second phase of his career focused upon philosophy of language and logic, philosophy of mind, and philosophy of mathematics. In each of these he adopted revolutionary and wholly original positions. His primary influence was exerted through his teaching. Among his pupils in the 1930s were A. Ambrose, M. Black, D. A. T. Gasking, M. MacDonald, N. Malcolm, G. A. Paul, R. Rhees, C. L. Stevenson, G. H. von Wright, and J. Wisdom. During the post-war years, G. E. M. Anscombe, P. Geach, N. Malcolm, I. Murdoch, and S. Toulmin attended his classes. Through these and others, and through the circulation of unpublished dictations, the influence of Wittgenstein's later philosophy spread.

The scene was transformed by the publication of the *Investigations* (1953), which was followed by further unfinished works and lectures. This made his thought available to a wider philosophical public. From the 1960s a fresh generation of philosophers followed Wittgenstein's footsteps. They, together with Wittgenstein's pupils, contributed to the elucidation and extension of Wittgenstein's ideas. The clarification and interpretation of his thought has been a major task occupying numerous writers. More than 7,000 books and articles have been published on his work. The extension and further application of his ideas has borne a rich harvest. Important work was done in the philosophy of mind, repudiating empiricist conceptions of the mental as well as behaviourist and materialist ones, and developing teleological, anti-causalist, accounts of action and its explanation: on intention, action, and the will, Anscombe, A. J. P. Kenny, F. Stoutland, and von Wright; on consciousness and memory, Malcolm; on psychoanalysis, F. Cioffi, I. Dilman, and Wisdom; on sensation and perception, P. M. S. Hacker and B. Rundle; on aspect-perception, S. Mulhall; on personal identity and the first-person pronoun, Anscombe, Kenny, S. Shoemaker, and P. F. Strawson. Noteworthy applications of Wittgenstein's ideas to anthropology and the social sciences were made by Cioffi and P. Winch, to philosophy of religion by D. Z. Phillips. In philosophy of language, Wittgenstein's views were very influential during the 1950s and 1960s, emphasis being placed upon use rather than on logical form, on description rather than on theory-construction. Anscombe's and Geach's work here was broadly Wittgensteinian (though also Fregean). Other extensions of his philosophy of language were made by J. Hunter and Rundle. It was applied in criticism

of contemporary linguistic theory and philosophical theories of meaning by G. P. Baker and Hacker. Wittgenstein's philosophy of mathematics received least attention, but important attempts to come to grips with it were made by Waismann, Ambrose, and S. Shanker, who has also applied Wittgenstein's ideas in criticism of cognitive science and artificial intelligence. Although Wittgenstein wrote little on ethics, attempts to elaborate his ideas were made by P. Johnston, and to apply them by Winch. A highly original application of Wittgensteinian methodology to general value-theory was made by von Wright.

Disagreements among Wittgensteinians, over both the interpretation and application of his ideas, has been almost as extensive as the disagreements between Wittgensteinians and other philosophers. Some main areas of controversy among his followers have been: (a) the interpretation of the private-language arguments, in particular whether they commit one to the view that the concept of a language and hence of a language-user is internally related to that of a linguistic community; (b) the interpretation of his discussion of following a rule, in particular whether his purpose was to resolve a paradox about rule-following by reference to community agreement in acting on a given rule, or to show that the paradox itself rests on a philosophical confusion; (c) the elucidation of his concept of a \*criterion, which has been variously interpreted as a necessary condition, necessary and sufficient condition, or as necessarily, but defeasible, good evidence for that for which it is a criterion; (d) whether his discussion of ostensive definition is intended to show that it is a defective form of explanation of word-meaning, or rather to show that it is not a privileged form of explanation which links language to reality; (e) how much continuity there is between his early and later philosophy; (f) whether his later philosophy consists of systematic argument which purports to demonstrate the incoherence of opposing positions, or whether it consists of unsystematic *aperçus* designed to effect a *Gestalt*-switch.

Critics of Wittgenstein's later philosophy have argued that he must, in the private language arguments, rely on a principle of verification, that he is a crypto-behaviourist, that he is committed to a form of linguistic idealism or anti-realism, that his philosophy of mathematics involves a 'full-blooded' or 'existentialist' form of conventionalism, or that he is propounding a use-theory of meaning. These criticisms demonstrably rest on misunderstandings and misinterpretations. More serious criticisms, still currently debated, turn on whether his general conception of philosophy justifiably excludes theory-construction in philosophy, whether his philosophy of mathematics does not neglect the extent to which mathematical proof is predetermined by antecedent commitments of axioms and proven theorems, and whether his animadversion to the construction of a theory of meaning and his elucidations of meaning in terms of use are defensible.

P.M.S.H.

A more comprehensive delineation of his impact can be found in P. M. S. Hacker, *Wittgenstein's Position in Twentieth-Century*

*Analytic Philosophy* (Oxford, 1996), the fifth and final vol. of his *Analytical Commentary on the Philosophical Investigations*.

**Wolff, Christian** (1679–1750). German philosopher who presented much of Leibniz's philosophy in the format of Protestant scholasticism. The dominant doctrine and ideology of the German Enlightenment before Kant was the so-called Leibniz–Wolffian philosophy; but both Leibniz and Wolff objected to this name, rightly, because Wolff was ignorant of, or rejected, some of Leibniz's main teachings, and besides was closer to Descartes than to Leibniz. Wolff was banished from the University of Halle (1723) for denying the necessity of a Christian foundation for ethics and for allegedly teaching a fatalistic ethics. He then had a successful career at Marburg until recalled to Prussia by Frederick the Great (1740). He was a prolific and verbose (and ruthlessly boring) writer in both Latin and German, and his most lasting contribution was in establishing German as a language for philosophy. His many disciples were among Kant's foremost critics.

—'From Leibniz to Kant', in *Routledge History of Philosophy* (London, 1993), vol. vi, ch. 1.

**Wollheim, Richard** (1923–2003). English philosopher (at University College London and at Berkeley) who wrote on philosophy of mind, ethics, aesthetics, political philosophy, and history of philosophy. Wollheim worked on, *inter alia*, the ontology of art and the nature of painting. He was a sympathetic interpreter of Freudian ideas, especially as developed by Melanie Klein. Wollheim's interest in \*psychoanalysis is basic to much of his philosophy, including his ethics. He described his attraction to 'moral philosophy . . . pursued as moral psychology', both 'the study of those mental processes which are involved in moral deliberation, moral decision, and moral action . . . moral reasoning, its nature and the defects to which it is susceptible', and especially the study of 'the growth of the moral sense'.

— *On the Emotions* (New Haven, Conn., 1999).

**Wollstonecraft, Mary** (1759–97). Political writer and novelist, sometimes (inaccurately) called the first feminist. A *Vindication of the Rights of Woman* (1792) expresses the liberal longing for, and belief in the possibility of, a social order in which every individual is free from the shackles of superstition and false authority. Wollstonecraft believed that the moral and intellectual capacities essential to such an order are latent in humanity, their actual presence thwarted by male power. Reason has been involved in error, having been confined to partial, male experience; the truth of which men pretend to judge in relation to women has been shaped to their convenience. Women, deprived of education, taught to defer to men, and appraised according to the double standard of morality,

have been prevented from exercising genuine judgement or attaining genuine virtue.

J.HORN.

\*feminism.

Claire Tomalin, *The Life and Death of Mary Wollstonecraft* (Harmondsworth, 1985).

**women in philosophy.** Women philosophers seem to be largely absent from the history of philosophy, according to many philosophy department syllabuses. In fact, women have been practising philosophers for many centuries, but a great deal of research has had to be dedicated to recovering their work in order to be able to evaluate it; see e.g. Mary Ellen Waithe (ed.), *A History of Women Philosophers*, 4 vols. (Dordrecht, 1984).

The apparent invisibility of women in philosophy or lack of 'great' women philosophers has been attributed to many causes. One reason is the selection process which has been used to construct the canon of philosophy, a framework which has used certain criteria to determine which topics, individuals, or texts can be defined as philosophical and included in the canon. Women have tended to fare badly in this selection process in the past because social perceptions of their basic abilities have affected assessment of their philosophical achievements.

Such perceptions of women's abilities are also to be found within philosophy. Many philosophers have written *about* women; much of what has been said has been largely derogatory or dismissive. For example, Plato, Aristotle, Kant, Rousseau, Schopenhauer, and Nietzsche all discuss the topic of women, often with regard to women's capacity for philosophical rationality, and frequently find them inferior in this respect.

Although it is easy to document examples of misogynistic remarks, it is only comparatively recently that their implications have been considered, in the context of feminist reappraisals of philosophy and attempts to explain women's invisibility in philosophical history. Because such remarks may be seen as embarrassing, irrelevant, or outdated historical prejudice, they have often been disregarded in the overall assessment of a philosopher's work. Such remarks may have been discounted because it is assumed that liberal intellectuals no longer hold such views. Or it may be that such passages are seen as irrelevant to real philosophical matter and can be easily discarded. But this position assumes (i) that we can clearly identify first-order philosophical problems and (ii) that such passages are independent of what the philosopher says elsewhere (for example, about human nature in general), and can be removed without affecting the overall framework.

If the exclusion of women from philosophy is merely a social-historical accident and due to lack of opportunity, then it may be corrected with time. But the problem may run much deeper. The association of philosophy with a professional, public practice of rationality may mean women have tended to avoid such a 'masculine' role and have chosen more characteristically 'feminine' interests.

Within philosophy, the identification of certain dominant topics or interests with 'masculine' values may have implicitly or explicitly excluded women: ways of looking at knowledge, the self, reason, and ethics which seem to reinforce 'masculine' values may discourage or exclude women, either by implying that they are less able practitioners, or by valuing their work on alternative topics as 'less' philosophical.

But despite such discouragement, and as a result of social and economic changes, many more women were professional philosophers in the last century than in previous centuries. Well-known examples of recent women philosophers include Philippa Foot, Iris Murdoch, Elizabeth Anscombe, and Luce Irigaray, and earlier thinkers include Hannah Arendt, Simone Weil, Simone de Beauvoir, and Mary Wollstonecraft. Not all of these philosophers would necessarily describe themselves as feminists, but it may be as a result of feminist arguments in favour of their worth that they are given more prominence. Debates are continuing over whether there are specifically female, feminine, or feminist viewpoints within philosophy, what characteristics they might display, and whether they help or hinder women philosophers in their work.

**worker control.** An economic system that is characterized by (1) each individual business enterprise being managed democratically by its workers, and (2) the economy as a whole relying upon the market—that is, upon supply and demand rather than central planning—for determining the prices of all goods and services and the incomes people get for producing them. Democratic management by the workers may take the form of direct democracy, but, for larger enterprises, it will usually take the form of representative democracy where the workers, periodically, elect a management team, and the management team will then control the everyday affairs of the enterprise. Worker-control systems can be classified as either *worker-control \*socialism* or *worker-control \*capitalism*. Worker-control socialism (sometimes referred to as *market socialism*) is characterized by public ownership of the means of production and government planning of most new investment throughout the economy. Worker-control capitalism is characterized by the means of production for each business enterprise being owned privately by the workers of that enterprise themselves, and by the absence of any government planning of investment, which is to be left to the market.

Among the advantages that advocates of worker control claim for this system are greater worker autonomy and a more equal distribution of income. With worker

control, income, being market-determined, will not be distributed equally. Since, however, investment income will no longer be concentrated largely in the hands of just a relatively few wealthy individuals, and since control of each business enterprise will be in the hands of its workers, incomes will, so it is argued, be distributed more equally than in traditional capitalism. But perhaps the greatest alleged advantage is that worker-controlled enterprises are structured so that management, having to face workers in periodic elections, will thus be motivated primarily to please *them*, which will lead to safer, more pleasant working conditions, less tedious, more challenging work, a more favourable balance between work and leisure, and any number of other benefits for workers. **world philosophy.** The first important European philosopher seriously to consider the philosophical traditions of other civilizations, Hegel, viewed them as episodes in a development that culminated in his own metaphysics. While some recent books on world philosophy share Hegel's comparative concerns, their authors eschew his teleological predilections and reject his disdainful attitude to non-Western traditions. Instead, they write from the conviction that these traditions, especially \*Chinese, \*Japanese, and \*Indian, are sophisticated ones that have been wrongly ignored by Western philosophers. (Sometimes the expression 'world philosophy' is confined to non-Western thought.) At a minimum, examination of these traditions acquaints us with thinkers of genius and challenging ideas, and may, in addition, contribute fruitful perspectives on live philosophical issues that know no geographical or cultural boundaries. A matter which divides advocates of world philosophy is whether the belief systems of non-literate civilizations, such as some African ones, should be included in its purview. D.E.C.

D. E. Cooper, *World Philosophies: An Historical Introduction*, 2nd rev. edn. (Oxford, 2002).

E. Deutsch and R. Bontekoe (eds.), *A Companion to World Philosophies* (Oxford, 1997).

**world-soul.** Hegel was living in Jena in 1806 when Napoleon crushed the Prussian army at the battle named after that city. He wrote in a letter: 'The Emperor—this world-soul—I saw riding through the city to review his troops. It is indeed a wonderful feeling to see such an individual who, here concentrated into a single point, reaches out over the world and dominates it'. Since history has, for Hegel, a goal, the world-soul is the instrument of a larger destiny. P.S.

G. W. F. Hegel, *Lectures on the Philosophy of History*, tr. J. Sibree (New York, 1956).

**Wright, Chauncey** (1830–75). American pragmatist and enthusiast for \*evolution, Wright so impressed Darwin that the Englishman had his writings on the subject

reprinted and published in book form as a refutation of critics. Wright was nevertheless a stern critic of Spencer, especially the way in which the latter was trying to make a world philosophy from an amalgam of progressivist evolution, Lamarckian inheritance of acquired characters, and a misunderstanding of the second law of thermodynamics. Never a prolific writer, and better in tutorial than lecture theatre, Wright nevertheless influenced many of the better-known pragmatists, especially James. His own most original contribution was in an analysis of \*causality, distinguishing between those causes which entirely explain their effects and those where something new appears. In this second category, Wright was clearly hinting at doctrines of \*emergence (like that of Alexander) that were to become so popular fifty years after his death. Whether so clear-headed a thinker would have welcomed so fuzzy a philosophy is another matter. M.R.

E. H. Madden, *Chauncey Wright* (New York, 1964).

C. Wright, *Philosophical Discussions* (New York, 1877).

**Wright, Crispin** (1942– ). British philosopher who has written extensively on the work of the later Wittgenstein, Frege, the debate between realists and anti-realists, vagueness, and scepticism.

The most notable aspect of Wright's work has been his attempt to develop and defend his anti-realist position, according to which whatever is true must be in some sense knowable. In this area Wright is deeply influenced by Dummett, who has been engaged in the same enterprise. However, the views of the two philosophers are not identical, and there are definite disagreements concerning, for example, the revisionary consequences of an anti-realist theory of meaning for logic.

In his work on Wittgenstein, Wright has been centrally concerned with the rule-following considerations and has developed a sophisticated interpretation not identical with, but in many ways similar to, that of Kripke. H.W.N.

\*realism and anti-realism.

Crispin Wright, *Realism, Meaning and Truth*, 2nd edn. (Oxford, 1993).

**Wyclif, John** (before 1330–after 1380). A student at Oxford, and Master of Balliol (1360), he wrote widely on philosophy and theology, and made a major contribution to the first English translation of the Bible. His writings contain strong criticisms of Church teachings and practice, and those criticisms plus his contribution to the translation of the Bible led to his being termed, with some justice, 'the Morning Star of the Reformation'. His chief philosophical work, the *Summa de Ente*, contains a treatise on the problem of \*universals, in which he presents and defends a strongly realist position, maintaining that the common nature in virtue of which something is a member of its species must have an existence entirely independent of any mind. A.BRO.

A. Kenny (ed.), *Wyclif in his Times* (Oxford, 1986).

# X

**Xenocrates** (396–314 BC). Successor to Speusippus as head of Plato's Academy. Xenocrates wrote treatises in which he attempted to systematize Platonism. These treatises are lost, but the range of his work may be guessed at from a list of titles contained in the brief biography by Diogenes Laertius. Xenocrates was the first of the school of Plato to attempt to respond to Aristotle's criticisms. His formulation of Platonism was to become highly influential in the later tradition. In particular, Xenocrates' division of philosophy into three branches, physics, ethics, and logic, helped shape Hellenistic philosophy and its understanding of its fourth-century predecessors. L.P.G.

John Dillon, *The Middle Platonists 80 BC to AD 220* (Ithaca, NY, 1977).

**Xenophanes of Colophon** (c.560–c.470 BC). Pre-Socratic philosopher, cosmologist, and theologian; author of the first known discussion of epistemology. He made the fundamental point that, to claim knowledge, it is not suffi-

cient to 'speak what is completely true', and seems have to have thought that there was no possibility of knowledge outside the realm of direct experience. In its place he proposed to put 'opinions resembling the things which are true', which must mean that they are straightforwardly extrapolated from the world of direct experience. What is known of his cosmology seems to show that he practised what he preached.

In theology he satirized traditional anthropomorphism, remarking that each race represented its gods in its own image, and concluding that, if horses could draw, they would draw their gods looking like horses. He also attacked the traditional stories about the Greek gods as immoral. In its place he proposed a transcendent monotheism. He seems to have deduced the properties of his god from an overall principle of what is 'fitting'; the first known attempt at philosophical theology. E.L.H.

J. H. Lesher, *Xenophanes of Colophon* (Toronto, 1992).

# Y

**yin and yang:** *see* Chinese philosophy.

**Yoga:** *see* Aurobindo; Hindu philosophy.

**Yugoslav philosophy:** *see* Croat philosophy; Serbian philosophy; Slovene philosophy.

# Z

**Zeitgeist.** In retrospect, ages seem to have spirits, which historians identify. But is it possible to identify the spirit of a present age, and, if so, what if anything should we do as a result? Talk of the spirit of the age in the twentieth century was often used by tyrants and bureaucrats to suppress criticism from those who objected to their vision of the age. We should remember that individuals create their ages, and that individuals of \*genius transform them. A.O'H.

K. R. Popper, *The Poverty of Historicism* (London, 1957).

**Zen.** A form of Buddhism that developed in China and spread to Japan which gives central importance to meditation and to the idea that the world, seen through eyes unclouded by desire, is beautiful. It is like a philosophical iceberg: almost all of the philosophy is beneath the surface. Buddhism in general is dedicated to the proposition that desires (i.e. strong preferences that involve attachment) are the primary cause of suffering, and that liberation will be the result of shedding the illusion of a substantial self and losing one's desires; this is generally implicit rather than explicit in Zen texts. They also take from the Mādhyamika school of Buddhist philosophy the anti-realist claim that there is no objectively correct and definitive perspective on anything. This is dramatized in the Zen literature, rather than argued for, by use of puzzles (*Koans*) for which there could be no literally correct solution and by amusing exchanges intended to undercut any tendency to believe in, or take seriously, the literal truth of anything. J.J.K.

\*Buddhist philosophy.

An examination of Zen that is more philosophically probing than most is to be found in D. T. Suzuki, *The Zen Doctrine of No-Mind* (York Beach, Me., 1972).

**Zeno of Citium.** This Zeno (334–262 BC) must be distinguished from the earlier (fifth century) Pre-Socratic Zeno of Elea. Zeno of Citium was the founder of the Hellenistic school of Stoic philosophy. The main features of early Stoic thought were a corporealist and dynamic philosophy of nature, an empiricist epistemology, an absolutist conception of moral duty, and an internationalist theory of social organization. Zeno's writings are all lost; but his contribution to this complex system seems to have been

particularly in the areas of epistemology and political philosophy. He wrote a widely admired *Republic*, which expounded such key Stoic themes as the importance of the rule of law and the universality of human political institutions. In epistemology and ethics he is explicitly associated with the absolutist view, according to which a person either completely attains or totally misses scientific knowledge and virtue. J.D.G.E.

\*Stoicism.

For a judicious assessment of the distinctly Zenonian features of early Stoicism, see A. A. Long and D. N. Sedley, *The Hellenistic Philosophers*, 2 vols. (Cambridge, 1987).

**Zeno of Elea** (c.470 BC). Fellow citizen and associate of Parmenides; admired by Plato as 'the Eleatic Palamedes' and by Aristotle as the inventor of philosophical dialectic. Zeno is not known to have advanced any positive views. He devised an arsenal of destructive arguments, directed against opponents of Parmenides. (Some seem to be *ad hominem*.) These exploit properties of the infinite, and use (perhaps for the first time) \*infinite regress as an argumentative device. Those for which there is evidence may be grouped as: (1) arguments against plurality (against the thesis 'There are many things'); (2) arguments against the possibility of motion; (3) others.

1. The arguments against plurality systematically deduced contradictions from the premiss that 'There are many things'. Three survive in whole or in part. (a) 'If there are many things, they must be both great and small: so small as to have no size, so great as to be infinite.' The second limb of the argument employs the 'dichotomy' principle: anything with size can be divided into two things each with size; hence there is a process which never terminates. (b) If there is plurality, the total of things must be both finite and infinite in *number*: finite because a plurality implies a definite and therefore a finite number; infinite because two or more things require boundaries or more generally distinguishing marks, and here again a progression to infinity sets in. (c) 'If there are many things they must be both like and unlike.' The supporting arguments are not recorded.

(2). The famous '\*paradoxes of motion', recorded by Aristotle, use assumptions about the spatial and temporal

properties of change to demonstrate that change is impossible. (a) The 'race-course' (also known as the 'stadium' or 'dichotomy'). A runner has to run a given length. Before running the whole length, he must have run half of it. Then, before running the second half, he must have run half of that half. And so on. Since the division again never terminates, the whole stretch is composed of infinitely many successive pieces, each of some length. But the runner cannot finish the task of traversing infinitely many substretches in succession. (b) The 'Achilles'. A slow runner is given a start by a fast runner. The fast one can never catch up: again he has to traverse infinitely many successive stretches, first to the slower runner's starting-point, then to the point the slow runner has reached by then, and so on. (c) The 'arrow'. In any indivisible instant of its flight, is a flying arrow moving or at rest? If the former, how can it move in an instant? If the latter, it is never moving, and therefore is at rest. (d) The 'moving rows' (also known as the 'stadium') A paradox involving relative motion; the details are unclear.

(3). Other arguments recorded are: (a) one about 'place', again constructing an infinite progression (if everything that is in a place, and place is, then a place is in a place, and so *ad infinitum*); (b) possibly the first sorites argument (about the smallest \*heap of grain to make an audible noise when dropped; details unreliable). E.L.H.

G. Vlastos, 'Zeno of Elea', in P. Edwards (ed.), *The Encyclopedia of Philosophy* (New York, 1967).

**zombies.** The zombies of Haitian voodoo lore and horror movies are the 'living dead', but the philosopher's zombies are merely the stuff of \*thought experiments. A zombie, if there could be such a thing, would be a living

creature that was indistinguishable in its physical constitution and in terms of its outward appearance and behaviour from a normal human being, but in whom the light of \*consciousness was completely absent: a being with no inner, conscious mental life, no first-person point of view, no \*qualia—in short, a being such that there would be *nothing it was like* to be that being. But could there be such a being? It is not enough to point out that we can *imagine* there being zombies, because not everything that we can imagine is really possible (\*time-travel may be an example). It may be difficult to determine whether zombies really are possible, but the issue undoubtedly has far-reaching implications for the metaphysics of mind.

E.J.L.

D. J. Chalmers, *The Conscious Mind* (Oxford, 1996).

**Zoroastrianism.** An ancient Persian religion, most likely to be known to philosophers either in connection with Nietzsche's naming the central character of *Thus Spoke Zarathustra* after its founder or because Pierre Bayle in his *Dictionary* (1697) presented it as a key to the problem of evil. Zarathustra is now thought to have flourished in the middle of the second millennium bc. In an audacious transvaluation, he proclaimed the gods (*daevas*) worshipped by the very ancient Persians to be evil. The leader of the *daevas* is the eternal opponent of the one good God, Ahura Mazda. The feature of Zoroastrianism that attracted Bayle is that the forces of good and evil are about equally matched. At the end of time Ahura Mazda will score a final victory, but until then he often fails to control events. Consequently Zoroastrianism, unlike Christianity, Judaism, and Islam, escapes the paradox of an all-powerful God who is responsible for what many people take to be unnecessary \*evil.

Mary Boyce, *Zoroastrians: Their Religious Beliefs and Practices* (London, 1979).

## APPENDIX

# Logical Symbols

A book like this cannot define the logical symbols precisely, both because they may have somewhat different definitions in different logical systems, and because the methods of definition used by logicians cannot be explained in a few words. The following list merely offers rough equivalents in English for symbols and letters that are used in the *Companion*, with a few comments. For a more generous list of some of the alternatives see the entry 'notations, logical'. And do note that any explanation given within a particular article overrides what is said here.

$\sim$ or $\neg$ or $-$ or $N$	not
$\cdot$ or $\&$ or $\wedge$	and
$\vee$	or
$\supset$ or $\rightarrow$	if (i.e. ' $P \supset Q$ ' and ' $P \rightarrow Q$ ' mean 'If $P$ , $Q$ '; signs for material implication)
$\rightarrow$	if (similarly; a sign for strict implication)
$\equiv$ or $\leftrightarrow$	if and only if (material equivalence)
$=$	is the same as, or if and only if (strict equivalence)
$\forall$	all (' $\forall x$ ' etc. are sometimes written ' $(x)$ ' etc.)
$\exists$	some, at least one, there exists, i.e. not $\forall$ not
$\square$ or $L$	necessarily
$\diamond$ or $M$	possibly, i.e. not $\square$ not
$\in$	is a member of (a set or class)
$\notin$	negates $\in$
$\neq$	negates $=$
$\cap$	indicates intersection
$\cup$	indicates union

Letters are very variously employed, and the following is no more than a guide to usage in the *Companion*. What are here called schematic letters (\*schema) are sometimes brought under the general label \*'variables'.

$P, Q$ or $p, q$ , etc.	schematic letters for replacement by indicative sentences, or by names of such sentences
$F, G$ , etc.	schematic letters for replacement by predicates (e.g. 'is a swan', 'laughs', 'is to the left of'), or by terms (e.g. 'swans', 'black things')

$R$	schematic letter for replacement by two-place predicates (e.g. 'is to the left of'), or by indicative sentences
$S, P$	schematic letters for replacement by terms
$a, b$ , etc. or $X, Y$	schematic letters for replacement by singular names or referring expressions (in predicate logic these are written after predicate letters, e.g. 'Fa', 'Rba'), or by terms
$x, y, z$ , etc.	individual variables
$\alpha, \Gamma, \Delta$ , etc.	variables used informally, i.e. not as parts of a logical language, for talking about—usually generalizing over—expressions of a logical language, or sets of them
$n, m$	the same for talking about numbers
$t, t_1$ , etc.	the same for time instants
$w, w_1$ , etc.	the same for possible worlds
$E, F$	the same for events
$\phi, \psi$	like $\alpha, \Gamma, \Delta$ etc. or general like $x, y, z$ , etc.
$A, B$ , etc.	very general—used <i>either</i> like $S, P$ , etc. or like $\alpha, \Gamma$ , etc. or like $a, b$ , etc. or even like $P, Q$ , etc.

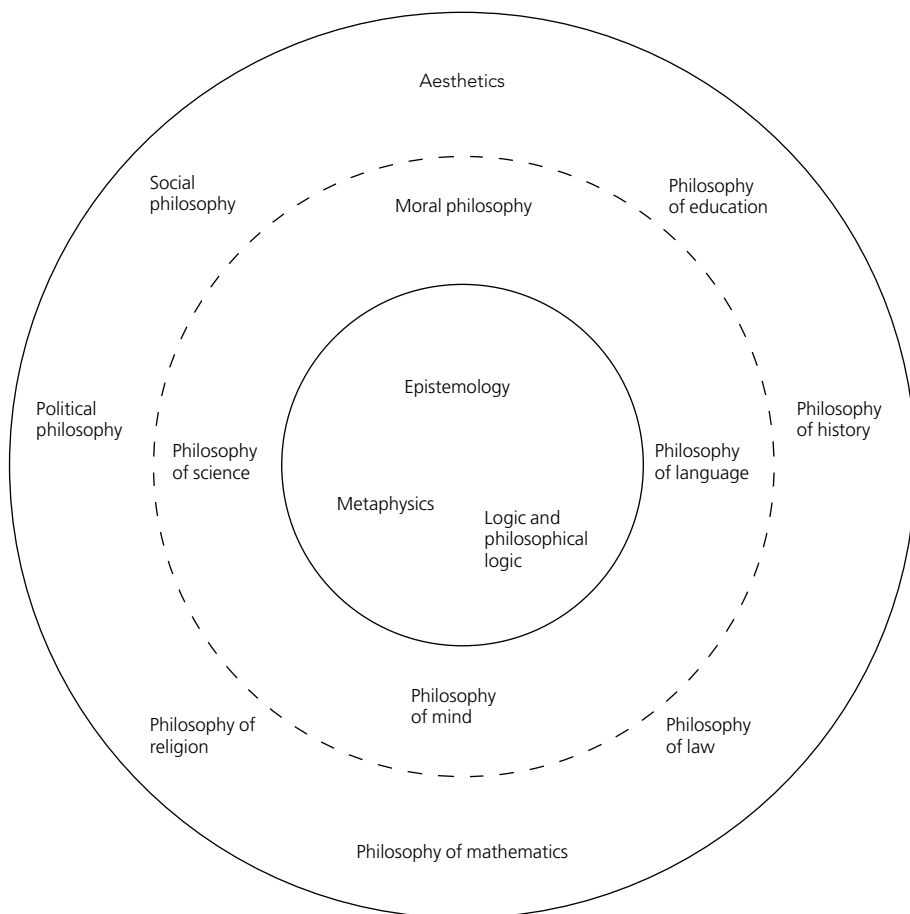

Other letters are explained in their places in the book, or are self-explanatory.

C.A.K.

## APPENDIX

# Maps of Philosophy

Mapping philosophy is as difficult as mapping the world. Asia and Alaska are likely to be a whole map-width apart, despite the mere 56 miles that really separates them. On one projection Africa will look like a squashed-up kidney bean, on another like a woebegone banana. On one the world itself will appear as an ellipse, on another as two circles. The world has two hemispheres (east and west) but also two other hemispheres (north and south). Equal-area and equal-population maps (where equal areas on the page represent equal areas on the ground, or equal populations, respectively) may be almost unrecognizable as

**Inner and outer circles of philosophy**

referring to the same planet. Yet maps are made and are useful. Most normal maps (though not all possible ones) will show London as between Cambridge and Brighton. The situation is the same in philosophy. There is no one way of mapping it. Different, perhaps overlapping, perhaps inconsistent, maps may be used for different purposes, and will all be horribly misleading unless used merely as over-simplified rough guides. It is essential that the reader remember these points when looking at the following pages.

### Inner and Outer Circles of Philosophy

Philosophy can be thought of as concerning what in the most general sense there is, what we can know and how, and the most general conditions that must be satisfied by any coherent thought. This gives us the three items in the central circle. The items in the outer circles are less general and concern limited areas. They also tend to depend on the central items in ways that those do not depend on them in return. For instance, moral philosophy often depends on theories of implication, which belong in logic and philosophical logic, but logic and philosophical logic do not themselves depend for their tools on moral philosophy. The relation between the two outer circles is somewhat similar, though less markedly so. Political philosophy, for instance, seems to presuppose moral philosophy without being presupposed by it. No doubt for these reasons philosophers have given more attention to the more central items, so that the diagram also to some extent maps popularity. However, both the circles themselves and the regions within them should be thought of as only rather vaguely delimited. There are multiple overlaps, and in particular no attempt has been made to order the items within each ring, which are arranged alphabetically, reading clockwise from the top; no significance attaches to co-radiality.

### Groups of Parts of Philosophy

#### I

Epistemology  
Philosophy of science

#### III

Aesthetics  
Moral philosophy  
Political philosophy

#### V

Philosophy of education  
Philosophy of history  
Philosophy of law  
Social philosophy

#### II

Metaphysics  
Philosophy of mind  
Philosophy of religion

#### IV

Logic  
Philosophical logic  
Philosophy of language  
Philosophy of mathematics

Any grouping is bound to be somewhat arbitrary and roughshod, but the reader may find it helpful for certain similarities to be pointed out, bearing in mind

always that the grouping presented here, though it has the rationale explained below, is certainly not unique.

Group I has in common a concern with the conditions under which we can know something, the justifications that we can offer for claims to know it, and the methods that may help us to come to know it.

Group II asks primarily about what there is, either completely generally or in certain obviously important spheres such as that of beings as developed as ourselves or that of the ultimate power, if any, behind the universe. It then asks about the nature of these various things.

Group III combines various questions concerned in one way or another with value: what sorts of value there are, what things are valuable in these various ways, and what connection there is between value and a duty to produce it, as well as the question what alternatives, if any, to value can be offered as a foundation for our duties.

Group IV mainly concerns abstract structures, and in particular the structure of any coherent thinking and the tools that are essential for such thinking—since presumably we could not think in any effective way without language.

Group V, finally, is a bit of a ragbag since it consists of philosophical problems directed at various particular subject areas. The list could be extended almost indefinitely, since there are usually at least some philosophical problems attached specifically to each of the special sciences or other major areas of human activity. Those mentioned have achieved a certain entrenchment, presumably because, although each of them has connections with various items in the other four groups, they are thought to raise more problems of their own than the philosophies of, say, physics or economics. One special case deserving mention is the subject often called philosophy of action: its subject is quite general and not a *particular* sphere of human activity; but in fact it is usually regarded as a branch of philosophy of mind.

## Parts of Philosophy and Philosophical Positions and Doctrines

In what follows, those diagrams headed ‘Epistemology’, ‘Metaphysics’, ‘Logic and philosophical logic’, ‘Philosophy of mind’, ‘Moral philosophy’, ‘Political philosophy’, ‘Philosophy of language’, and ‘Philosophy of science’ represent the parts of philosophy, or questions that can be asked, while the others represent philosophical positions and doctrines, or answers that might be given. Solid lines represent relations in a tree diagram. Dotted lines represent connections, as when in the former group the ‘main related subjects’ are listed, or else emphasize that the items they connect share a greater than usual degree of overlap, or merge into each other and cannot be sharply distinguished. For instance, in ‘Theories on mind and body’ property dualism, though presumably to be classified under dualism, is closely bound up with certain monist views. The lists of ‘main related subjects’, and items linked only by dotted lines to the main subject, are not always limited to subjects within philosophy itself. The few attributions of views to named figures should be regarded as approximate, sometimes controversial, and of course not exhaustive. There are more philosophers who might be mentioned in connection with each view.

## APPENDIX

# A Chronological Table of Philosophy

Any table of this nature must reflect a certain arbitrariness. The left column represents philosophers or events of philosophical importance. Some attempt has been made to list philosophers in the order in which they produced their main work or had their main influence; normally each philosopher is listed once only, at the time when he was most active or most influential. Titles are given in the language in which they are most familiar. Similar considerations in general apply to the right column, which lists, with considerably greater arbitrariness, public events or people, partly to give a general temporal framework and partly to pick out items that might be thought to have some relevance to the development of philosophy. The correlation between the columns, however, cannot be anything but very rough and approximate.

600 BC	First flourishing of Greek philosophy (Thales, Anaximander, Anaximenes) through the sixth century in the town of Miletus in Asia Minor	Zoroaster c.630–c.553	THE ARCHAIC PERIOD IN GREECE
	Pythagoras and his followers found religious movement in southern Italy	Solar eclipse, allegedly predicted by Thales, 585	
	Xenophanes criticizes anthropomorphic religion	Beginnings of Greek mathematics, attributed to Thales	
	Heraclitus propounds a bold metaphysics in Ephesus	Buddha c.563–?	
500 BC	Confucius c.557–479	First systematic edition of <i>Iliad</i> and <i>Odyssey</i> (probably composed two or three centuries earlier)	EASTERN CHOU ERA IN CHINA
	Parmenides discusses philosophical method in verse	Cleisthenes expels tyrants from Athens 510, and introduces democracy 508	
	Lao Tsū founds Taoism	Ionian revolt against Persia 499–494	
	Zeno of Elea develops Parmenides' ideas	Persian wars unite Greece, temporarily; Persia effectively defeated in 479	
	Empedocles in Sicily; Anaxagoras in Athens; Melissus in Samos	Persian-war veteran Aeschylus becomes first great European dramatist	
	Protagoras, the leading Sophist, visits Athens	Athens founds Delian League as bulwark against Persia, but uses it for imperialist purposes (and to finance building of Parthenon, completed 438)	
		Periclean age c.460–429, ending with plague which killed Pericles	
	Sophocles writes prize-winning tragedies from 468 until his death in 406	THE CLASSICAL PERIOD IN GREECE	

400 BC	<p>Democritus develops early atomism</p> <p>Socrates (469–399)</p>	<p>Abortive attempt to found Panhellenic colony at Thurii in Italy 444, with Protagoras invited to write its laws</p> <p>Herodotus presents a panorama of the world known to the Greeks in his <i>Histories</i></p> <p>Peloponnesian War between Sparta and Athens, 431–404, ends in defeat of Athens, which quickly revives</p> <p>Earliest of many medical treatises attributed to Hippocrates (c.450–c.370)</p> <p>Euripides' tragedies show Sophists' influence</p> <p>Aristophanes mocks Socrates in his comedy <i>Clouds</i></p> <p>Thucydides examines political behaviour and motivation in his history</p>	THE CLASSICAL PERIOD IN GREECE EASTERN CHOU ERA IN CHINA		
	300 BC	<p>Death of Socrates, 399, has profound effect on Plato and others</p> <p>'Socratic schools' (Megarians, Cynics, Cyrenaics) form</p> <p>Plato (427–347) founds Academy c.380</p> <p>Plato's <i>Republic</i> c.380–370</p> <p>Diogenes the Cynic c.400–c.325</p> <p>Aristotle (384–322) enters Academy 367, tutors Alexander c.343–339, founds Lyceum c.336, writes main works c.350–323</p> <p>Headship of Academy falls to Speusippus 347, and then Xenocrates</p> <p>Theophrastus (Aristotle's successor in Lyceum) 370–c.288</p> <p>Pyrrho the Sceptic c.365–c.275</p> <p>Epicurus (341–270) founds Epicurean school</p> <p>Zeno of Citium (335–263) founds Stoic school</p>		<p>Pentateuch of Old Testament receives definitive form</p> <p>Xenophon (c.428–c.354), historian and one source for our knowledge of Socrates</p> <p>Greek mathematics flourishes under Theodorus and Theaetetus</p> <p>Greek oratory and rhetoric flourish under Isocrates, Demosthenes, Aeschines</p> <p>Aristoxenus, theorist of Greek music</p> <p>Second battle of Chaeronea 338 ends independence of Greek city states, thereafter under Macedonian rule</p> <p>Greek comedy turns, especially with Menander, from political and social to domestic satire</p> <p>Alexander succeeds Philip of Macedon 336</p> <p>Death of Alexander 323</p> <p>Euclid the geometer active</p>	THE HELLENISTIC PERIOD HAN DYNASTY IN CHINA
200 BC		<p>Mencius (c.372–289) and Chuang Tzú active</p> <p>Arcesilaus (c.316–c.242) founds 'Middle Academy', representing Sceptical rival to Stoics</p> <p>Cleanthes and Chrysippus (c.280–207) second and third heads of Stoic school</p>	<p>Aristarchus presents heliocentric hypothesis</p> <p>Septuagint (Greek version of Old Testament) written</p> <p>Scientist-engineer Archimedes c.287–212 (killed at fall of Syracuse)</p> <p>Asoka emperor and law-giver in India</p> <p>Eratosthenes (c.276–194) makes good estimate of earth's circumference</p> <p>Hannibal in Italy; finally defeated at Zama (near Carthage) 202</p>		
		<p>Carneades (c.214–c.129) founds 'New Academy', continuing Sceptical tradition</p>	<p>Plautus and Terence develop Roman comic theatre</p> <p>Sack of Corinth by Rome finally ends Greek independence of Rome 146</p>		

100 BC	Panaetius the Stoic c.185–109	Political reforms attempted by the Gracchi in Rome	THE HELLENISTIC PERIOD
	Posidonius the Stoic c.135–c.51	Aristotle's works brought to Rome by Sulla 84, and subsequently edited by Andronicus Rebellion of slaves under Spartacus defeated 71	
	Cicero 106–43	Caesar crosses Rubicon and starts civil war 49 Julian calendar adopted 46	
	Lucretius (98–c.51) publishes poetic version of Epicureanism c.60	Library of Alexandria wholly or partially destroyed 47 Battle of Actium ends Roman republic and independence of Egypt (where defeated parties, Antony and Cleopatra, were based), thereby closing the Hellenistic or Alexandrian period, 31 Augustan or Golden Age of Roman literature: Virgil, Livy, Horace, Ovid, <i>et al.</i>	
AD BC	Seneca c.1 BC–AD 65	Jesus Christ 4 BC–AD c.29 Augustus dies 14; succeeded by Tiberius	HAN DYNASTY IN CHINA
	Beginning of Nyāya philosophy (Hindu logical school) in India	Nero (emperor 54–68) orders suicide of Seneca and persecutes Christians Naturalist Pliny the Elder dies while investigating eruption of Vesuvius which destroyed Pompeii 79 Silver Age of Roman literature begins: Tacitus, Suetonius, Pliny the Younger, Martial, Juvenal, Quintilian, <i>et al.</i> Greek historian Plutarch of Chaeronea	
100	Epictetus c.55–135	Trajan (emperor 98–117) extends Roman Empire to its greatest size	ROMAN EMPIRE
200	Marcus Aurelius 121–80	Encyclopaedic medical writer Galen 129–99	
	Mahāyāna Buddhism inaugurated by Nāgārjuna Alexander of Aphrodisias lecturing in Athens	Origen (c.185–254) tries to reconcile Christianity with Platonic philosophy by interpreting the Bible Diogenes Laertius, important source for history of philosophy, writing	
300	Sextus Empiricus active	Diophantus the mathematician active c.250 Manichean religion founded by Mani	
	Plotinus (205–c.269) introduces Neoplatonism Porphyry c.232–c.305	Roman Empire begins to be invaded from the north-east Roman Empire first divided into east and west by Diocletian 285	
		Constantinople founded 324, becoming seat of Roman Empire 331 First Council of Nicaea condemns Arians (who stressed God's unity and so gave Christ subordinate status) in favour of Athanasius 325	

400		Books start to replace scrolls c.360 Roman Empire finally divided into east and west after death of Theodosius 395	BREAK-UP OF ROMAN EMPIRE
500	Augustine (354–430) composes his major philosophical works Proclus c.410–85	Western Roman Empire falls to Germans under Odoacer 476 First schism between Eastern and Western Churches 484	OLD MAYAN EMPIRE IN CENTRAL AMERICA
600	Boethius c.480–524 Philoponus (c.490–570) and Simplicius active, Simplicius being the last main Neoplatonist, and Philoponus helping to replace Neoplatonism with Christianity in Alexandria	John Stobaeus' literary anthology, of some importance as source for history of philosophy Closing of Athenian schools by Justinian 529 Simplicius temporarily migrates to Persia Justinian promulgates legal code	OLD MAYAN EMPIRE IN CENTRAL AMERICA
700	Nestorians translate ancient Greek philosophers into Syriac	Hegira: flight of Muhammad (570–632) from Mecca to Medina, 622; start of Muslim Calendar Islam replaces Zoroastrianism in Persia 641	OLD MAYAN EMPIRE IN CENTRAL AMERICA
800		Muslim Empire reaches its height, with capital first at Damascus and then at Baghdad Beginning of Arabic science and philosophy at Baghdad 'Arabic' (in fact Indian) numerals known in Baghdad 760	BYZANTINE ERA
900	Al-Kindī c.801–66 John Scotus Eriugena active	Charlemagne crowned at Aix (Aachen) as first Holy Roman Emperor 800 Revival of classical learning at Aix	ARABIC INTELLECTUAL FLOWERING
1000	Al-Fārābī 870–950	Buddhist influence in India starts to decline Start of Christian reconquest of Spain Cordoba becomes centre of Arabic culture in Spain, with university founded 968	ARABIC INTELLECTUAL FLOWERING
1100	Avicenna (Ibn Sīnā) 980–1037 Avecebról (Ibn Gabirol) 1020–c.1070 Anselm 1033–1109 Al-Ghazālī 1058/9–1111 Arabic philosophers start to be translated into Latin	Norman Conquest of England 1066 Greek medicine brought to West by Constantine the African 1071 First Crusade launched by Pope Urban II 1095	ARABIC INTELLECTUAL FLOWERING
	Abelard 1079–1142	First modern European university founded at Bologna 1113 Arabs in Spain manufacture paper 1150	ARABIC INTELLECTUAL FLOWERING

1200	Averroës 1126–98	University of Paris founded 1150	BYZANTINE ERA	
	Maimonides 1125–1204	University of Oxford founded 1167 Thomas à Becket murdered at Canterbury 1170		
1300	Albert the Great c.1200–80	Francis of Assisi 1182–1226	BYZANTINE ERA	
	Roger Bacon c.1214–c.1292	Magna Carta 1215		
	Bonaventure 1221–74	Genghis Khan (c.1162–1227) establishes Mongol Empire		
	Thomas Aquinas c.1224–74	Fourth Crusade captures Constantinople 1204, giving West access to Greek writings		
1400	Duns Scotus c.1266–1308	Cordoba falls to Spain 1236	BYZANTINE ERA	
	William of Ockham c.1285–c.1349	Dante (1265–1321), one of the earliest writers in Italian rather than Latin, writes <i>Divine Comedy</i>		
		Black Death ravages Europe, killing one-third of English population 1347–51		
1500	Nicholas of Cusa c.1400–64	Boccaccio (1313–75) publishes <i>Decameron</i> 1348–53	EUROPEAN RENAISSANCE	
	Marsilio Ficino 1433–99	Chaucer (1340–1400) writes <i>The Canterbury Tales</i>		
		Constantinople falls to Ottomans 1453, ending Byzantine era		
1500		Caxton prints Chaucer's <i>Canterbury Tales</i> 1477	EUROPEAN RENAISSANCE	
		Granada falls to Spanish, ending Moorish power in Spain, 1492		
		Columbus crosses Atlantic 1492		
	Erasmus 1465–1536	Leonardo da Vinci 1452–1519		MOGUL EMPIRE IN ASIA
	Machiavelli (1469–1527) writes <i>Il Principe</i> 1513	Raphael 1483–1520		
		Michelangelo 1475–1564		
		Physician and alchemist Paracelsus 1493–1541		
		Luther (1483–1536) instigates Reformation at Wittenberg 1517		
		Rabelais (1494–1553) publishes <i>Pantagruel</i> 1532		
		St Ignatius Loyola founds Society of Jesus 1534		
	Copernicus (1473–1543) publishes heliocentric theory 1541–3			
	Calvin 1509–64			
Suarez 1548–1607	Montaigne (1533–92)			
	Queen Elizabeth I crowned 1558			
	First microscope invented by Janssen 1590			

1600	<p>Thermometer invented by Galileo</p> <p>Edict of Nantes, tolerating Huguenots, issued by Henri IV 1598</p> <p>Shakespeare (1564–1616) writes <i>Hamlet</i> c.1600</p>	
1600	<p>Francis Bacon (1561–1626) publishes <i>Advancement of Learning</i> 1605, <i>Novum Organum</i> 1620</p> <p>Philosophy starts to be written in the vernacular rather than in Latin</p> <p>Gassendi 1592–1655</p> <p>Descartes (1596–1650) publishes <i>Meditations</i> 1641, <i>Principles of Philosophy</i> 1644</p> <p>Hobbes (1588–1679) publishes <i>Leviathan</i> 1651</p> <p>Spinoza (1632–77) publishes <i>Ethics</i> 1677</p> <p>Cambridge Platonists (Whichcote (1609–83), More (1614–87), Cudworth (1617–88), <i>et al.</i>) active</p> <p>Locke (1632–1704) publishes <i>Essay Concerning Human Understanding</i> 1690, <i>Two Treatises of Government</i> 1690</p> <p>Malebranche (1628–1715) publishes <i>De la recherche de la vérité</i> 1674</p>	<p>Telescope invented by Dutch 1600</p> <p>Bruno (born 1548) accused of heresy and burnt by Inquisition 1600</p> <p>Kepler (1571–1630) discovers elliptical orbits of planets</p> <p>Harvey discovers circulation of blood 1628</p> <p>Galileo sentenced by Inquisition 1633</p> <p>Harvard University founded 1636</p> <p>English Civil War 1642–6</p> <p>Louis XIV (1638–1715) becomes King of France 1643</p> <p>Charles I executed 1649, inaugurating eleven-year Commonwealth period under Puritans in Britain</p> <p>Fermat (1601–65) and Pascal (1633–62) inaugurate study of probability 1654</p> <p>French drama flourishes with Corneille (1606–84), Molière (1622–73), Racine (1639–99)</p> <p>Plague in England 1665</p> <p>Great Fire of London 1666</p> <p>Milton (1608–74) publishes <i>Paradise Lost</i> 1667</p> <p>Decline of Latin as a language in which the educated are fluent</p> <p>Bunyan (1628–88) publishes <i>The Pilgrim's Progress</i> 1678–84</p> <p>Newton publishes <i>Principia</i> 1687</p> <p>'Glorious Revolution' rids Britain of Stuart monarchs 1688</p> <p>Dryden (1631–1700), poet, dramatist, and critic</p>

	Hegel (1770–1831) publishes <i>The Phenomenology of Mind</i> 1800	American Declaration of Independence 1776	
	James Mill 1773–1835	Lavoisier (1743–94) analyses air into oxygen and nitrogen, opening the way for overthrow of phlogiston theory of combustion (dominant since early in the century) 1777	
	Schelling 1775–1854	Mesmerism practised in Paris 1778	
		French Revolution 1789	
		Burke (1729–97) publishes <i>Reflections on the Revolution in France</i> 1790	
		Tom Paine (1737–1809) publishes <i>The Rights of Man</i> 1791–2, <i>The Age of Reason</i> 1794–5	
		French Reign of Terror 1793, followed by Napoleonic wars	
	Goethe 1749–1832		
	Schiller 1759–1805		
	Malthus (1766–1834) publishes <i>Essay on the Principle of Population</i> 1798		
	Dalton (1766–1844) introduces atomic theory c.1800		
	Wordsworth 1770–1850		
	Coleridge 1772–1834		
	Thomas Jefferson (1743–1836), third President of USA 1801–9		
	Battle of Waterloo brings comparative stability to Europe 1815		
	Byron 1788–1824		
	Shelley 1792–1822		
	Ricardo writing on economics 1809–17		

- Schopenhauer (1788–1860) publishes *The World as Will and Representation* 1819
- John Austin (1790–1859) publishes *The Province of Jurisprudence Determined* 1832
- Comte 1798–1857
- Feuerbach 1804–72
- Hamilton (1788–1856), philosopher criticized by J. S. Mill
- Whewell 1794–1866
- John Stuart Mill (1806–73) publishes *A System of Logic* 1843, *On Liberty* 1859, *Utilitarianism* 1863
- Kierkegaard 1813–55
- Engels (1820–95) publishes *The Condition of the Working Class in England* 1845
- Marx (1818–83) publishes *Manifesto of the Communist Party* (with Engels) 1848, *Das Kapital* 1867, 1885, 1893
- Emerson 1803–82
- Spencer 1820–1903
- Dilthey 1833–1911
- Sidgwick (1838–1900) publishes *The Methods of Ethics* 1874
- Mach (1838–1916) publishes *The Science of Mechanics* 1883, *Popular Scientific Lectures* 1894 (or 1896)
- Brentano (1838–1917) publishes *Psychology from an Empirical Standpoint* 1874, *The Origin of our Knowledge of Right and Wrong* 1889
- Peirce 1834–1914
- Nietzsche (1844–1900) publishes *Thus Spake Zarathustra* 1883–5, *Beyond Good and Evil* 1886
- Lamarck (1744–1829) propounds theory of inheritance of acquired characteristics
- Non-Euclidean geometries developed by Lobachevsky (1793–1856) and Riemann (1826–66)
- Faraday (1791–1867), experimental physicist
- Carnot (1796–1832) propounds second law of thermodynamics
- Carlyle (1795–1841) publishes *The French Revolution* 1837
- British franchise widened to include male middle class 1832, and much of male working class 1867
- Dickens 1812–70
- Pre-Raphaelite Brotherhood founded by Hunt, Millais, Rossetti 1848
- Major unrest in Paris. Louis-Philippe abdicates throne and Louis-Napoléon elected President 1848
- Louis-Napoléon largely reverses reforms of 1848 in 1851
- Great Exhibition in London 1851
- Thoreau 1817–62
- Dostoevsky 1821–81
- Ruskin (1819–1900) publishes *Modern Painters* (1843–60)
- Crimean War 1854–5
- George Eliot 1819–80
- Indian Mutiny repressed 1857
- Darwin publishes *The Origin of Species* 1859
- American Civil War 1861–5
- Cardinal J. H. Newman (1801–90) publishes *Apologia pro vita mea* 1864
- Courbet (1819–77) promotes realist movement in painting
- Women get the vote in the American state of Wyoming 1869
- Franco-Prussian War 1870–1
- Matthew Arnold 1822–88
- Tolstoy 1828–1910
- William Thomson, Lord Kelvin (1824–1907), physicist
- Maxwell (1831–74) unites electricity and magnetism 1873
- Impressionist exhibitions in Paris 1874–86

William James (1842–1910) publishes *The Principles of Psychology* 1890, *The Varieties of Religious Experience* 1902, *Pragmatism* 1907

Bradley (1846–1924) publishes *Appearance and Reality* 1893

Frege (1848–1925) publishes *The Foundations of Arithmetic* 1884, 'On Sense and Reference' 1892

Poincaré 1854–1912

Husserl (1859–1938) publishes *Philosophy of Arithmetic* 1891, *Logical Investigations* 1900–1, *Cartesian Meditations* 1931

Bergson (1859–1941) publishes *Time and Free Will* 1889, *Matter and Memory* 1896, *Creative Evolution* 1907, *The Two Sources of Morality and Religion* 1932

Dewey 1859–1952

Meinong (1853–1920) publishes *On Assumptions* 1902, 'On the Theory of Objects' 1904

Croce (1866–1952) publishes *Aesthetic* 1902

Scheler 1874–1928

Moore (1873–1958) publishes *Principia Ethica* 1903, 'Refutation of Idealism' 1903

Russell (1872–1970) publishes *The Principles of Mathematics* 1903, *Principia Mathematica* (with Whitehead) 1910–13, *Our Knowledge of the External World* 1914

Duhem (1861–1916) publishes *The Aim and Structure of Physical Theory* 1906

Santayana 1863–1952

Alexander (1859–1938) publishes *Space, Time and Deity* 1920

McTaggart (1866–1925) publishes *The Nature of Existence* 1921

Wittgenstein (1889–1951) publishes *Tractatus Logico-Philosophicus* 1921

Schlick 1882–1936

Cantor, mathematician, 1845–1914

Michelson–Morley experiment shows that speed of light is unaffected by direction of travel, 1888 and after

Oscar Wilde 1854–1900

Boer War 1899–1902

Freud (1856–1939) publishes *The Interpretation of Dreams* 1900, *The Psychopathology of Everyday Life* 1905, *Totem and Taboo* 1913

Bloomsbury Group of intellectuals including the Woolfs, the Bells, J. M. Keynes, Lytton Strachey, E. M. Forster, etc., influenced by Moore's *Principia Ethica* 1903, comes into existence c.1905

Einstein (1879–1955) devises special relativity theory 1905

Bohr (1885–1962) publishes theory of hydrogen atom 1913

First World War 1914–18

Einstein (1879–1955) introduces general relativity theory 1915, confirmed by solar eclipse 1919

Jung, psychologist, 1875–1961

Lenin (1870–1924) masterminds Bolshevik Revolution in Russia 1917, inaugurating communism there

Treaty of Versailles, imposing crippling war reparations on Germany 1919

J. M. Keynes (1883–1946) publishes *The Economic Consequences of the Peace* 1919; start of Keynesian economics

Mussolini (1883–1945) forms Fascist government in Italy 1922

T. S. Eliot (1888–1965) publishes *The Waste Land* 1922

Ramsey 1903–30	James Joyce (1882–1941) publishes <i>Ulysses</i> (burnt by American Post Office) 1922, <i>Finnegan's Wake</i> 1939
Broad (1887–1971) publishes <i>The Mind and its Place in Nature</i> 1925, <i>Five Types of Ethical Theory</i> 1930	General strike in Great Britain defeated 1926
Heidegger (1889–1976) publishes <i>Sein und Zeit</i> 1927	Trotsky (1879–1940) expelled from Russian Communist Party 1927
Whitehead (1861–1947) publishes <i>Process and Reality</i> 1929	Heisenberg's uncertainty principle 1927
Carnap (1891–1970) publishes <i>Der Logische Aufbau der Welt</i> 1928, <i>The Unity of Science</i> 1932, <i>Meaning and Necessity</i> 1947, <i>Logical Foundations of Probability</i> 1950	Eddington (1882–1944) publishes <i>The Nature of the Physical World</i> 1928
Gödel (1906–78) publishes his incompleteness theorems 1931	Fleming (1881–1954) discovers penicillin 1928
Maritain 1882–1973	Economic depression hits Europe and America 1929
Jaspers 1883–1969	
Bachelard 1884–1962	
Marcel 1889–1973	
Reichenbach 1891–1953	Roosevelt elected US President 1932
H. H. Price (1899–1984) publishes <i>Perception</i> 1932	Karl Barth, theologian, 1886–1968
Popper (1902–94) publishes <i>The Logic of Scientific Discovery</i> 1935, <i>The Open Society and its Enemies</i> 1945	
Ayer (1910–89) publishes <i>Language, Truth and Logic</i> 1936	Hitler (1889–1945) takes power 1933 and annexes Austria 1938, causing exodus of many intellectuals including philosophers
	Alan Turing (1912–54) conceives universal digital computing machine
	Franco (1892–1975) gains power in Spain after Civil War 1936–9
	Munich Agreement offers 'peace in our time' 1938
Collingwood (1889–1943) publishes <i>An Essay on Metaphysics</i> 1940	German–Soviet pact 1939

# Index and List of Entries

The headings in this index include all the headings of the entries in the book. So the index is also a list of the entries. To look up any subject, turn first to the main entry under the capitalized index heading (e.g. ABANDONMENT) and then to the entries under the following headings (e.g. authenticity).

Where an index heading is from an entry which is a bare cross-reference to another entry, the index indicates this by following the same form (e.g. ABSTRACT IDEAS *see* IDEAS).

In order not to submerge the significant entries on a subject in a host of others, the index does not include every mention of a subject in the book, but rather the more significant ones.

The few headings in the index which are not also headings of entries in the book are in large capitals. These are to AESTHETICS and so on—main parts of philosophy, which in the book are divided into one entry on the history of the part of philosophy and one on its problems. The few references in the index to such entries are also in large capitals.

- ABANDONMENT authenticity; autonomy and heteronomy; despair; existentialism
- ABDUCTION induction; inference to the best explanation; Peirce; scientific method
- ABELARD Héloïse complex; logic, history of; medieval philosophy; metaphysics, history of; philosophy, history of departments and centres of
- ABLEISM disability and morality; discrimination; equality; justice
- ABORTION applied ethics; double effect; killing; medical ethics; Thomson
- ABSOLUTE, THE Bosanquet; Bradley; German philosophy; Hegel; idealism, philosophical; James; metaphysics, history of; relations, the nature of; Royce; Schelling
- ABSOLUTISM, MORAL consequentialism; deontological ethics; ideals, moral; lying; sexual morality
- ABSTRACT ENTITIES mathematics, history of the philosophy of; nominalism; ontology; proposition; universals
- ABSTRACT IDEAS *see* IDEAS
- ABSTRACTION ideas; Locke
- ABSTRACT PARTICULARS *see* PROPERTIES, INDIVIDUAL
