CONTINENTAL EUROPEAN PHILOSOPHY IN THE NINETEENTH CENTURY

J. G. FICHTE developed Kant's epistemological and ethical ideas at the end of the eighteenth century, and became an apostle of Prussian nationalism.

SØREN KIERKEGAARD gave deliberately anti-academic expression (witness the peculiar forms, titles, and pseudonyms of his works) to a powerful defence of human freedom against systems, rules, and rationalizations.

ARTHUR SCHOPENHAUER's academic career at the University of Berlin floundered when he opted unwisely to deliver his lectures at the same times as Hegel's; the resulting resentment, and many others, find expression in his writings. In his work Eastern religious traditions first exert a significant influence on Western philosophy.

FRIEDRICH NIETZSCHE's iconoclastic brilliance brought him international fame too late for him to know it. His unpredictable influence has coursed through modernism and postmodernism.

The transcendental method is connected with several other features of German thought. First, transcendental philosophers regard idealism as entirely compatible with objectivity. While idealists such as Hume and Mill tend to see values and the truths of logic and arithmetic as dependent on our psychological states (or, later, on our language), German idealists often, though not invariably, regard them as wholly objective, albeit transcendently determined. The transcendental lies deeper than our customary distinction between the subject and the object, the subjective and the objective. Second, since the transcendental I is neither psychological subject nor physical object, and since it is, on some accounts, prior even to the distinction between different people, it tends to be equated with, or to turn into, the Absolute or God; it met with this fate in Fichte and Schelling, if not in Husserl. By contrast, Hume and Mill incline to atheism, since there is little temptation to deify the psychological I. (Berkeley's theology depends on a combination of the psychological and transcendental methods.) Third, psychological or subjective idealism is inimical to a sense of history. If I focus on my own mental states and the laws governing them, I have little reason to suppose that others may have, or have had, mental states of a different type, governed perhaps by different laws. It is even hard to see how the historical past can be more than a dubious inference from my present mental states or a logical construction out of them. \*Transcendental idealism, by contrast, presents no such difficulties in the view of its adherents. Indeed, it is plausible to suppose that it favoured historicism: if one pares oneself down to one's bare I, shorn of historically determined physical and psychological contingencies, it is easier to range in imagination over other times and places. What I then find in the past may be as independent of my present mental states as are the laws of logic and mathematics.

The transcendental method is also related to the tendency of German philosophers to reject individualism. Psychological states are decidedly the states of a single individual, and the single individual is, on the whole, what concerns British empiricists. An individual is conceived as a complete person prior to relations with other individuals. The acquisition of concepts and knowledge is regarded as a solitary enterprise, with little attention to the education of children into a shared language and culture. There then arises the problem of other minds: How can I know that there are any other minds or, if there are, what goes on in them? How can there even be psychological states that are not experienced by *me*? (Little attention was paid to this problem before J. S. Mill, however.) Individualism also inspired social contract theories: people are conceived as fully formed individuals, capable of making contracts, etc., prior to relations with others, independently of any shared culture or tradition. The transcendental I, by contrast, is less obviously a complete individual, or even an individual at all. To the questions 'Why can there not be just one person? Why does the I splinter into many individuals?', Fichte and Schelling reply that without others I would not be complete. I would lack moral

constraints and thus be unable to display my (Kantian) freedom. Bereft of others and confined to my own perspective on the world, I could hardly extricate the world from myself: it would be *my* world, not an *objective* world. Hegel develops their thought in his concept of *Geist*, a word for 'mind' that expands, more readily than its English counterpart, into a shared mind or 'spirit', into an 'I that is We and a We that is I'. Heidegger too, with his concepts of 'being-with-others' and the *They*, insists that a shared world and a complete human being require a deep interconnection between individuals, not just a plurality of solitary individuals. Such philosophical anti-individualism converges with the German propensity for cultural history (Herder, Dilthey) and sociology (Weber).

The history of German philosophy is more complex than these generalizations suggest. The first strictly German philosophers, writing in German as often as in Latin, were the mystics, the earliest of whom were nuns, such as Hildegard of Bingen (1098–1173) and Mechthild of Magdeburg (1212–85). These prepared the ground for Meister Eckhart (1260–1337), Heinrich Seuse (1300–66), Johann Tauler (1300–61), and Thomas à Kempis (1379–1471). The mystics were not wholly divorced from scholastic philosophy. Eckhart, for example, made use of \*Neoplatonism and of Aquinas, and his thought is essentially scholastic, even if his style and devotion are shaped by earlier mystics. The mystics were much admired by Leibniz, and their influence, especially on the Romantics, but also on, for example, Heidegger, is pervasive. The greatest German philosopher of the Renaissance, Nicholas of Cusa (1401–64), was influenced by Eckhart, as well as by medieval logic, in arguing that the universe flows out of and returns to an unknowable God. Several aspects of his thought, especially his principle of the coincidence of opposites, anticipate Leibniz and Hegel. (Hegel, however, nowhere mentions Nicholas.) Among later mystics, the shoemaker Jakob Böhme (1575–1624) had a large impact on later philosophers, including Hegel and Schelling (who called him a 'miraculous phenomenon in the history of humanity').

Böhme was persecuted by the Protestant orthodoxy established by Martin Luther (1483–1546), who rejected the metaphysical element in German philosophy, attacked Aristotelianism and Thomism, and advocated conceptual and verbal clarity. Philip Melancthon (1497–1560), who was entrusted by Luther with the task of systematizing the thought of the Reformation, paradoxically returned to Aristotle as the foundation of his system, thus establishing what came to be known as Protestant neo-scholasticism.

The first indisputably great German philosopher is Leibniz, who, although he did not teach philosophy and published relatively little, decisively shaped the future course of philosophy in Germany and was in a sense the founder of German idealism. Christian Wolff, who was a follower of Leibniz, achieved enormous popularity in the late eighteenth century and was largely responsible for establishing a clear, stable philosophical vocabulary in German. Other rationalist philosophers were Mendelssohn and Alexander

Gottlieb Baumgarten (1714–62), who first gave aesthetics its name and established it as a distinct department of philosophy, and whose *Metaphysica* (1739) was used by Kant as the basis for his lectures.

The German \*Enlightenment reached its climax with Kant, who initiated the most important period of philosophical activity in modern times. He generated a host of followers, attempting to explain, systematize, and develop his thought: among others, Karl Leonhard Reinhold (1758–1823), Solomon Maimon (1753–1800), J. S. Beck (1761–1840), and Jakob Friedrich Fries (1773–1843). Schiller gave Kantianism a distinctive historical and aesthetic bias that contributed to the growth of post-Kantian idealism. But other forces worked to the same end: for example, Johann Georg Hamann (1730–88), the ‘magus of the north’, a Protestant mystic who disliked the analytical rationalism of the Enlightenment and saw more creative power in feeling, language, and especially poetry, the ‘mother-tongue of the human race’. Friedrich Heinrich Jacobi (1743–1819) argued that our knowledge of mundane and divine matters rests, not on argument, but on feeling and faith. He also initiated the revival of Spinoza, a crucial influence on Herder, Goethe, and the post-Kantian idealists: Fichte, Schelling, and Hegel. The Romantic circle, especially Novalis (1772–1801) and Schlegel, made perverse use of Fichte’s doctrines, cultivating the aphoristic style later adopted by Nietzsche. Schelling was seen as their official philosopher. Schleiermacher was another member of the circle. Hegel admired his *On Religion: Speeches to its Cultured Despisers* (1799), but later came to hate him, avowedly because he rejected his view that religion rests on a feeling of ‘absolute dependence’ (in which case, Hegel said, a dog is the best Christian), but perhaps also because he envied his work on Heraclitus, Plato, and dialectic.

With the death of Hegel in 1831 the period of German idealism, which has no parallel elsewhere, came to end. The growth of the natural sciences cast suspicion on philosophical systems and favoured \*naturalism and \*materialism. The view of man as essentially rational gave way to the view that he is primarily a biological creature, dominated by will rather than reason. Schopenhauer forms a bridge between idealism and naturalism, shifting freely from the ‘I’ to the ‘brain’, and Nietzsche moved further in the direction of naturalism. The best of the Hegelians followed this trend: Feuerbach, Stirner, and Marx. Schelling’s late philosophy, essentially an elaboration of idealism, was regarded as an anachronism. Three other developments which began in the nineteenth century contributed to the upsurge of German philosophy in the twentieth. First, the neo-Kantians appealed to Kant both to oppose metaphysical idealism and to supply a more adequate foundation for the sciences. They later included Cassirer and Heidegger’s teacher Heinrich Rickert (1863–1936). Second, Dilthey and Georg Simmel (1858–1918) advanced the philosophy of history, making more use of the concept of life than of reason. (History and ‘life’ are also central in Nietzsche’s thought.) Third, Brentano laid the foundations of phenomenology.

The main philosophical trends of the early twentieth century, a period of creativity almost equal to the age of idealism, emerged from these beginnings. Husserl and Scheler developed \*phenomenology, though Scheler (as protean as Schelling) moved closer to Nietzsche and Dilthey when he championed philosophical \*anthropology. Nicolai Hartmann abandoned neo-Kantianism to establish an empirically grounded ontology. All of these tendencies, along with Kierkegaard, contributed to the *Existenzphilosophie* of Jaspers and Heidegger. Most of these trends continued after the Second World War, but with several additions. Heidegger’s thought developed away from, or at least beyond, his pre-war writings. Gadamer elaborated Heidegger’s \*hermeneutics into a hermeneutical philosophy. The neo-Marxian critical theory of the \*Frankfurt School, originated in the 1930s by Adorno and Horkheimer, continued to flourish after their return from exile and has been developed by Habermas. Finally, analytical philosophy prospers in Germany, especially under the influence of the Vienna Circle, Popper, Wittgenstein, and Anglo-American philosophers, but utilizing also the fertile resources of the German heritage.

**German philosophy today.** Contemporary philosophizing in the German-speaking realm is characterized by a ‘new obscurity’ (*neue Unübersichtlichkeit*, Jürgen Habermas). The decline of previous philosophical systems within and after the two World Wars led to a *plurality* of coexisting approaches and directions. They are often in opposition to the idealistic and transcendental traditions which had been dominant for a long time and are still influential (especially the writings of Immanuel Kant and Georg Wilhelm Friedrich Hegel). What appeared in the twentieth century as a revolution or break became established as branches of new traditions, which will likely continue for quite a while. They are of no less importance than the extensive investigations of the history of philosophy and the interpretation of classical texts, the treasures of which are made fruitful for contemporary thinking. Three main currents are characteristic today: (1) the *hermeneutic current*, which evolved out of the plurality of interpretations and deals with them; (2) the *post-modern current*, which is brought about by the plurality of life-forms, partially leading to an extreme relativism, and giving special emphasis to aesthetic points of view; and

(3) the *scientific and science-oriented current*, which reacts to the growth of knowledge and the increase in specialization, and carefully considers the theoretical and practical conditions and consequences of the scientization and mechanization of the world we live in. A shared core of these three main currents is *anthropology* in all its different aspects—a reflection about man as an interpreting, social, and natural being that searches for orientation in an increasingly complex world.

1. *Hermeneutic philosophy* is the only main current today that has persisted relatively intact since before the Second World War, and is the deepest continuation of traditional philosophy in the German-speaking realm. It builds especially upon the analyses of understanding by Wilhelm Dilthey, phenomenology (Edmund Husserl), analyses of being (Martin Heidegger), and subsequent philosophical hermeneutics in a narrower sense (Hans-Georg Gadamer). At the centre of this 'art of understanding' are philosophical, literary, and theological texts and their historical horizon, as well as the methods of the humanities, and everyday life as a whole. This approach is chiefly about interpretations and hence also about the phenomenon of language (which rose—but for different reasons and especially with the aim of a theory of meaning—to be a main subject of analytical philosophy as well). The conditions and features of the communicative society, as well as linguistic practice itself, are analysed (with natural connections to speech-act theory, structuralism, and general semiotics). Not the individual consciousness but, rather, intersubjectivity is regarded as constitutive for reason and the truth of statements. Contrary to the coherence and correspondence theories of truth, which are dominant in scientific philosophy, consensus theories of truth are favoured, and the concept of explanation is confronted with the concept of understanding. The underlying motivations for thought and action are analysed, leading to discourse ethics (Jürgen Habermas, Karl-Otto Apel) and a strong tendency to investigate and criticize social mechanisms (with connections to sociology) and the tradition of philosophical enlightenment. Sometimes social theory has almost demanded the status of a *prima philosophia*. Before the reunification of Germany, Marxist philosophy also had a shaping influence: in West Germany (FRG) as a critical instance within the scope of the Frankfurt School (Theodor W. Adorno, Max Horkheimer, Herbert Marcuse, Jürgen Habermas, etc.), and quite differently in East Germany (GDR) as a state doctrine. Today, the spectrum of the hermeneutic current extends from the attempting of ultimate explanations in ideal-communicative and transcendental-pragmatic contexts, to a 'farewell to principles' (*Abschied vom Prinzipiellen*, Odo Marquard). The search for anthropological and social guide-lines for managing one's own existence took the place of systematizing objective truths in a *philosophia perennis*. This pragmatic turn led to a self-restriction of philosophy. Ludwig Wittgenstein's later investigations of the philosophy of language gave many impulses for the analysis of everyday

communication and the life-world. In taking very different historical, geographical, but also individual ways of life into consideration, the 'new obscurity' is also reflected in the second contemporary main current:

2. *Post-modern philosophy* which, in the broader sense, separates itself from ways of thinking which are orientated towards strict methods, rationality, linguistic analyses, and the search for objective knowledge. It has been influenced partly by twentieth-century French philosophy. So-called post-modernism (a somewhat misleading term which expresses, quite appropriately, a certain insecurity within this current) tries to interpret the plurality of approaches and perspectives affirmatively and as progress, contrary to sceptical objections. At the same time, earlier philosophical systems and traditions are considered 'grand narratives' among others. Some aspects of the modern are preserved, however, which is why Wolfgang Iser spoke of 'our postmodern modern age'. Here one continues to emphasize human autonomy; on the other hand, belief in the progress of science and society is questioned or criticized as a form of totalitarianism. The aim is a 'narrative philosophy' similar to Richard Rorty's in the USA.

Questions about forms of life, and how to conduct one's own life, are the focus of interest in this divergent current of thought, which exceeds post-modernism in a narrower sense; traditional philosophizing with its demand for ultimate obligations recedes into the background. Culture and art critics, journalists, artists, movie directors and talk-show hosts now consider themselves competent to answer philosophical questions. The result is a popularization of philosophical topics in philosophical cafés, feature pages, and on television. Aesthetics, philosophy of art, and the search for meaning, happiness, and an art of living become more and more important; occasionally there are even attempts to apply philosophy therapeutically. A philosophy of the media has developed, where virtual reality, simulation, and surrogates acquire paradigmatic status. There is a far-reaching scepticism about metaphysics and rationality, attacking social taboos (e.g. in the evaluation of mental diseases and criminality) and cultural bias. There is an increased exploration of ways of thinking from other cultures, especially Asia. Finally, some post-modern philosophers oppose metaphysical or scientific realism, justifying this with historical investigations of era changes and paradigm shifts, as well as studies of the sociology of science; they argue for diverse forms of anti-realism and relativism. This is in sharp contrast to the third main current:

3. *Scientific and science-oriented philosophy*, which has mostly been influenced by the Anglo-American world, and can be subdivided into a theoretical and a more practical, applied part. The *theoretical side*, with its emphasis of the significance of logic, language analysis, and empiricism, is dominated by analytical philosophy and philosophy of science. It is in the tradition of Cambridge philosophers like G. E. Moore, Bertrand Russell, the early Ludwig Wittgenstein, and especially the Vienna Circle.

Historically its reception did not begin until the emigration of many of its proponents to the USA, and the subsequent radiation of their teachings. Additionally, Karl Popper and his successors had a formative influence on philosophy of science and political philosophy (fallibilism, criticism of totalitarianism). Also initiated by Popper, and in conjunction with biological discoveries, evolutionary epistemology was developed. Here the nature and capacity of our epistemological faculties are viewed objectively in the light of the Darwinian theory of selection. Contrary to this, radical constructivism takes a more relativistic and subjectivistic view, culminating in quasi-idealistic epistemological schemes. It is inspired by cybernetics and neurobiology. In the framework of the Erlanger school (Paul Lorenzen), constructivist approaches also exist in philosophy of science (especially of physics) and mathematics. The focus of interest here is the process and methods of gaining knowledge: philosophy of science is transformed into a theory of action, and laws of nature are interpreted as instructions to act. Structuralism (Wolfgang Stegmüller and successors) is another prominent current in philosophy of science; its focal point is, the formal description and reconstruction of scientific theories. Finally, those working within the framework of modern philosophy of nature reflect on scientific knowledge and interpret its implications for an extensive philosophical world-view. Partly this has the character of a counter-movement to post-modern pluralism and splintering, striving for orientation by means of a unification of science and world interpretation. It has, however, by now reached its own high degree of differentiation and, thus, complexity or obscurity. The central issue being dealt with is naturalism (physicalism, materialism). It is both elaborated and stated in rigorous forms, and also criticized. Especially influential upon philosophy of nature and mind are discoveries in physics (cosmology, chaos theory, particle physics) and biology (evolutionary theory, neuroscience). As in the Anglo-American world, the mind-body problem, consciousness, intentionality, personal identity, free will, and artificial intelligence have long been central issues, with interdisciplinary connections to evolutionary and cognitive psychology, linguistics, and computer science. A new topic is evolutionary ethics, which combines sociobiology, ethnology, and behavioural ecology to explore possible biological foundations of morality.

The *applied side* of scientific philosophy is concerned with the decisions required by new results and opportunities of science and technology. There is a political dimension to this, and that is why philosophers participate in advisory boards and parliamentary decision-making. Particularly urgent and controversial are the different domains of bioethics, especially because of the new possibilities in genetics and medicine. Another focus of interest is philosophy of technology. Here, quite pragmatic tendencies are common, which accompany technological developments mainly reflectively and try to evaluate their effects and implications.

The three main currents outlined are not unrelated and separate from each other. There were and are connecting topics, attempts at mediation, and more or less fruitful controversies (e.g. the positivist dispute). Within the philosophy of mind, for instance, phenomenological and analytical approaches are linked to each other, post-modern ideas are discussed ('the end of the subject'), and some aspects of traditional German idealism are maintained (e.g. self-consciousness in the work of Dieter Henrich and Manfred Frank). Philosophers of technology have to deal with the critical hermeneutical tradition since Martin Heidegger. Philosophers of nature derive some inspirations (e.g. for the problem of emergence) from the organismic conceptions of nature which go back to German idealism and romanticism. There is interpollination between hermeneutical and analytical schools, especially in discussions of ethics and ecology. In general pragmatics, there are efforts to integrate hermeneutic, relativistic, and naturalistic perspectives. Whatever its different currents and points of view, philosophy should, after all, always be indispensable as a means for conceptual analysis and reflection, as well as being a critical authority, for science and society.

**Gestalt theory.** A psychological theory which tried to explain various aspects of psychology in terms of structures (*Gestalten*), particularly in relation to the tendency of forms of \*perception to conform to 'good' structures (the so-called law of *Prägnanz*). The movement was initiated by Max Wertheimer (1880–1943), Wolfgang Köhler (1897–1967), and Kurt Koffka (1886–1941) in reaction against earlier sensationalist psychological theories which tried to break down the mental life into atomic sensations and ideas. The Gestaltists emphasized 'wholes' and structures which could not be broken down into elements. Initially the movement was concerned with perception, starting from the phi-phenomenon, the apparent movement of alternating points of light; but gradually other aspects of psychology, including both their physiological and their philosophical backing, were brought within the same principles, especially by Köhler.

**Gettier, Edmund** (1927– ). Gettier is famous in Anglo-American epistemology for one three-page paper in which he attacks the tripartite definition of \*knowledge. This defines 'S knows that *p*' as:

1.  $p$  is true.
2.  $S$  believes that  $p$ .
3.  $S$ 's belief that  $p$  is justified.

Gettier showed by counter-example that this definition is insufficient; there are cases where the three clauses are all true, but  $S$  does not know. The general idea was that one's true belief might be justified in a way that depends too much on luck, as, for example, when a clock which is normally accurate happens to have stopped, but its hands indicate the very time at which one glances at it. In a case like this, one has a true belief which is justified, but is not knowledge. (Russell made the same point some decades earlier.) Considerable effort has been spent, especially in the USA, on repairing the definition. Counter-examples to suggested repairs are known as Gettier counter-examples.

**Geulincx, Arnold** (1624–69). An occasionalist, a modified Cartesian, and an anti-Aristotelian, Geulincx moved from Louvain to Leiden, and simultaneously from Catholicism to \*Calvinism, in 1658. Using the analogy of two synchronized but otherwise unconnected \*clocks which strike simultaneously, he pointed out the possibility of there being two law-governed areas with no causal interaction. Applying this to the general case he held that though God acts immediately and in a lawlike manner in the realms of both thought and extension, there is no interaction between the two. Like Descartes, Geulincx was a plenist who held that *body* and *extension* are coextensive. Hence, given his supposition that the universe is infinite, so is matter. Motion, however, may not be. Beyond the universe of events lies infinite space: 'completely solid, completely dark, harder than any adamant'.

**Gewirth, Alan** (1912–2004). Gewirth did important work on Descartes's theory of knowledge and medieval political philosophy, especially Marsilius of Padua, but he is best known for his attempt to develop a stringently rational foundation for morality in *Reason and Morality*. The central argument of this book begins with a claim that every rational agent must accept, which is that he or she must have freedom and well-being. Gewirth claims that when the implications of this claim are fully worked out, it follows that every rational agent must also accept the claim that all prospective purposive agents have a *moral* \*right to freedom and well-being. Professor Gewirth spent most of his career at the University of Chicago.

**Ghazālī, al-** (1058/9–1111). Persian Abū Ḥāmid Muḥammad Ghazālī (Algazel in Latin texts) was the most

influential Ash'arite theologian of his time. His role as head of the state-endowed Nizāmiyya Madrasa, his monumental work *Revival of Religious Sciences*, and his autobiographical account *Deliverance from Error* (often compared to Augustine's *Confessions*) furthered the triumph of revelation over reason. His specifically anti-philosophical works, *Intentions of the Philosophers* and *Incoherence of the Philosophers*, called on theologians to use philosophical technique to oppose 'heretic' arguments. However, the effects on philosophy proved positive. The study of logic gained widespread theological acceptance. The identification of twenty philosophical problems argued to be false (including eternity, immortality, and rational causality) were brilliantly rebutted by Averroës, thus leading to refinement of Aristotelian arguments, and Sohrawardī's philosophy.

**ghost in the machine.** Gilbert Ryle in his book *The Concept of Mind* held that the 'Cartesian' tradition represents the human body as a purely physical thing (the machine), and the human \*mind as a purely non-physical thing (the ghost) somehow inhabiting the body and 'operating' it from inside. 'The ghost in the machine' is his derisive title for this—as Ryle argues—fundamentally misleading picture.

G.J.W.

G. Ryle, *The Concept of Mind* (London, 1949), 15ff.

**Gibbard, Allan** (1942– ). American philosopher, professor at the University of Michigan, who has developed a general theory of normative judgement. According to this expressivist theory, to cite a reason for action or judgement is to accept norms that give it weight in deliberation. Norms serve the biological function of social co-ordination, and Gibbard offers naturalistic accounts of their force and degree of objectivity. Morality concerns the rationality of feelings such as guilt and anger that sanction uncooperative actions. Feelings have rationales stating that the circumstances that elicit them call for the actions they prompt, and moral norms endorse or alter the rationales for these moral feelings that have naturally evolved.

**Giles of Rome** (c.1247–1316). A member of the Order of the Hermits of St Augustine, rising to become General of the order in 1292. He studied at Paris, possibly under Aquinas, and eventually taught theology there. He produced a number of commentaries on Aristotle's writings, though his most famous treatise *Errors of the Philosophers* was a different sort of work, in which he attacks Aristotle and a number of major Muslim and Jewish thinkers. His aim is, however, not always accurate. For example, although he singles out Maimonides for censure partly on the grounds that the latter taught that some terms

predicated affirmatively of \*God have to be understood by way of causality, Maimonides did not in fact teach such a doctrine. For example, he did not (*pace* Giles) say that 'God is alive' means 'God is the cause of living things'. For some years Giles was thought theologically unsound, because of his unequivocally stated teaching on the question whether the individual soul has a plurality of forms, but he eventually retracted.

Giles of Rome, *Errores Philosophorum*, ed. J. Koch, tr. J. O. Riedl (Milwaukee, Wis., 1944).

**Gilson, Étienne** (1884–1978). French historian of medieval philosophy who was particularly dedicated to rescuing the philosophy of Thomas Aquinas from what he viewed as centuries of distortion foisted on Aquinas by friend and foe alike. He sought to recover an authentic version of Thomism which he understood to focus on the primacy of existence in the account of being. Gilson's first work was a dissertation on Descartes (1913). After the First World War, at the University of Strasbourg and then in 1921 at the University of Paris, Gilson devoted himself to research on the medieval background to modern philosophy. He arrived in North America in 1927 to deliver a course of lectures at Harvard, and in 1929 he founded the Institute of Medieval Studies in Toronto. For nearly a half century after, Gilson divided his teaching between Europe and North America. He produced an extraordinary number of seminal studies on virtually all the major figures and movements in medieval philosophy.

**given, the.** The epistemological sceptic notes that our faculties of knowledge, in short reason and the senses, are fallible. Fallacious reasoning occurs, just as sensory illusions and hallucinations occur. On account of this fallibility of our faculties of knowledge, the sceptic is disposed to conclude that through reliance on them nothing can be known with certainty. There are many ways in which attempts have been made to answer the epistemological sceptic. Sometimes, the sceptic's claims have been said to be incoherent in the sense that to be true, or even to make sense at all, they require assumptions which make them false. Alternatively, the claims have been said to be unintelligible in the sense that facts about the nature of language and its use preclude them. Also, the sceptic's arguments themselves have been challenged on the score of invalidity—it is denied that they succeed in showing what they purport to show. More and more today, it has been maintained that the sceptic is misdirected about the nature of existence and of knowledge.

There is one other way, different from all of these, in which the sceptic's position has been opposed. This involves a direct challenge to the sceptic's contention that nothing can be known with certainty. Here, an attempt is made to show that there *is* something whose existence cannot be denied and which is such that we can and do

know it with certainty. It is commonly referred to as 'the given'. It is what is immediately presented to consciousness. Even in erroneous perception, we are told, *something* is still perceived. Neither illusion nor hallucination is characterized by perceptual vacuity—there always is something given. Berkeley spoke of 'the proper object of the senses', and A. J. Ayer and others of '\*sense-data'. When one supposedly sees a penny, according to these philosophers, one sees not the penny itself but an elliptical sense-datum.

This view of sense-data as the incorrigibly given in perception is connected with \*foundationalism. Beginning from sense-data, foundationalism seeks to show how, from such elements, we construct objects like the penny. The methods of construction are intended to transfer to our knowledge-claims concerning three-dimensional objects something of the certainty of knowledge associated with sense-data. Rudolf Carnap made strides towards bringing about such a construction, but W. V. Quine's systematic criticisms of the programme and its devices have made it evident to many that it will not be completed. And the assumption of sense-data known incorrigibly has not been without its critics (e.g. the later Wittgenstein and J. L. Austin).

**globalization, morality, and politics.** Although 'globalization' can refer to an increase in international co-operation as represented in organizations such as the United Nations and the European Union, it usually designates the world-wide expansion of market capitalism in the 1990s. This resulted from international agreements reducing barriers to trade and capital flow, the development of information technology, and, with the collapse of the USSR, the seeming elimination of any practical alternative to corporate capitalism. The consequence was a global search for markets, inexpensive labour and production costs, and natural resources, leading to rapid industrialization of Third World countries and the international spread of technology.

Advocates argue that free trade has reduced the cost of living, made available a greater variety of goods to consumers, stimulated economic growth, and increased wealth. Multinational corporations, helped by favourable governmental policies, have been the chief instruments of these changes; the 'invisible hand' has produced world-wide social progress and also immense profits to its corporate owners. Values such as greed and self-interest have come to be seen as promoting social good; corporations are now considered important instruments for international development. Corporate success has given enormous economic and military power to the industrialized West, particularly to the United States.

Yet for non-industrial countries economic globalization has brought imports that undercut prices for locally produced goods; this in turn has forced workers to move to urban centres for jobs. These are often available only for very low pay with long hours and harsh working conditions, and without union representation. While salaries for management and technically trained professionals have greatly increased, pay for untrained labour has declined sharply. These changes have increased the gap between rich and poor.

Although underdeveloped countries can qualify for loans from the International Monetary Fund and the World Bank, usually they must agree to trade deregulation, privatization of state industry, reductions in public welfare, limited government, and fewer environmental restrictions and protections for workers' rights—restricting the authority of borrowing countries in these areas. The World Trade Organization, which oversees economic globalization, can require compensation from member nations, including wealthy ones, for loss of profit due to e.g. laws protecting the environment or health, thus further eroding local democratic control.

**Glover, Jonathan** (1941– ). Professor of Ethics at King's College London, formerly at Oxford, Glover has been a seminal figure in the emergence of 'applied ethics' as an area of vigorous philosophical inquiry. A theorist of broadly utilitarian sympathies, he developed an account of the wrongness of killing that rejects traditional notions of the sanctity of life and instead appeals to the intrinsic value of life that is worth living, respect for autonomy, and side-effects. This account has been influential in its rejection of the moral significance of the distinction between \*killing and letting die and in its implication that abortion and infanticide are, except perhaps where side-effects are concerned, morally equivalent to the failure to cause a person to exist. His more recent work on \*personal identity argues that the popular conception of the unity of the self is mistaken and that our distinctiveness and value as persons is in part the result of self-creation, which is itself a phenomenon that should be encouraged by social institutions.

**gnoseology** (or, gnosiology). From the Greek *gnōsis*, a word for 'knowledge'. Any philosophy or branch of philosophy concerned either with solving problems about the nature and possibility of \*knowledge, or with delivering knowledge of ultimate reality especially in so far as this is not available to sense-experience. 'Gnoseology' is an

archaic term and has been superseded in the former sense by 'epistemology' and in the latter sense by 'metaphysics'.

s.p.

**gnosticism.** The teachings of a family of sects which flourished from the second to the fourth centuries AD, combining elements of Christianity with \*Platonism, drawing in particular from the creation myths of Genesis and of Plato's *Timaeus*. Gnosticism was dualist, distinguishing the spiritual and good world from the evil and material world. Matter was the creation of a wicked demiurge. But a spiritual saviour had come to offer redeeming *gnōsis*, or knowledge, of our true spiritual selves. The gnostic would be released from the material world, the non-gnostic doomed to reincarnation. Gnosticism initially threatened what survived it as orthodox Christianity, stimulating the latter to define its teaching on the nature of authority and revelation. Having been outlawed by the Christian Roman emperors, gnostic teachings survived in Syria and Persia and were absorbed into \*Manicheism.

**God.** The three main Western religions—Christianity, Judaism, and Islam—have all claimed that God is the supreme reality. Sometimes their thinkers have said that God is so great that we cannot say anything in human words about what he is like. All we can say is what he is not—he is not evil, he is not foolish, and so on. This approach known as the *via negativa* was especially prominent in the period AD 500–1000. But if that is all we could say about God, there would be no content to religious doctrines adequate to justify religious practice, such as the worship of God. Hence most philosophical theologians have tried to say something about what God is like. In so doing, they have generally regarded him as a personal being, bodiless, omnipresent, creator and sustainer of any universe there may be, perfectly free, omnipotent, omniscient, perfectly good, and a source of moral obligation; who exists eternally and necessarily, and has essentially the divine properties which I have listed. Many philosophers (influenced by Anselm) have seen these properties as deriving from the property of being the greatest conceivable being. God is the greatest conceivable being and so he has all the great-making properties. Within each of the religions, however, and especially within Christianity, there have been somewhat different ways of understanding some of the divine properties.

God's being omnipresent, present everywhere, is his knowing what is happening everywhere and being able to act everywhere—directly, in the way in which we act on our bodies. To say that God is creator and sustainer of any universe there may be is to say that anything else which exists depends for its existence from moment to moment on God's sustaining action. If the physical universe had a beginning of existence (as Western religions have usually claimed), God caused that beginning; but if not, then God has kept it in being for all past time. God is perfectly free if

nothing acts from without to cause or even influence how he chooses to act.

To say that God is omnipotent would seem, literally, to mean that he can do whatever he chooses to do. But how is 'whatever' to be understood? Can God change the rules of logic—can he make  $2 + 2 = 5$ , or make a thing exist and not exist at the same time, or change the past? Descartes seems to have claimed that he can do all these things; but theists have more usually claimed that it makes no sense to say that God can do the logically impossible, and they have then tried to spell out carefully what that rules out. A chapter (2.25) of Aquinas's *Summa contra Gentiles* is entitled 'How the omnipotent God is said to be incapable of certain things', and goes on to list some twenty such things.

God's being omniscient is (literally) his knowing everything, i.e. every true proposition. But how is that to be understood? It looks as if there are some propositions which can only be known by certain persons or at certain times. Only I can know that I am ill; others can know only that *S* is ill. So how could God know the true proposition which I know? One response is that what is known by me and others is the same, even if it is differently expressed, and God can know the thing in question. Can God know in advance how free agents will choose to act—if so, how can their choices be free? While some theists have denied that humans have free will, most have affirmed that they do, and they often seem to have affirmed \*free will in the libertarian sense in which an action is free if the agent's choice so to act has no total cause, whether brain-state or God. Consider then an agent *S* at a time *t* choosing freely whether to do *X* or not-*X*. Whatever God or anyone else believed beforehand about what *S* would do, *S* has it in his power so to act as to make that belief false. How then can God be essentially omniscient? The answer invariably given by theologians in the Middle Ages was that God's being \*eternal is to be understood as his being outside time. It follows that he does not know anything before or after it happens, but knows events only by seeing them happen from his standpoint outside time. But God's seeing us act in no way makes us less free. However, this notion of eternity may not be a coherent one, and in that case God's being eternal is to be understood as his being everlasting, i.e. as existing at each moment. In that case theism needs to construe God's omniscience not as knowledge of every true proposition, but as knowledge of every true proposition which it is logically possible to know. It is not logically possible to know in advance how agents with libertarian free will will act. Hence God by creating us with such free will limits his own knowledge.

God is a source of moral obligation if his commands make actions right or wrong for humans when they would not be otherwise. This suggestion raises immediately the Euthyphro dilemma. Some (e.g. Kant) have claimed that God's commands cannot make any difference to what is right or wrong; others have claimed that nothing would be right or wrong but for God's command. A midway position is that of both Aquinas and Duns

Scotus that there are very general first principles of morality which it is not logically possible that even God could change. Among those very general first principles is the duty to please benefactors. God is our supreme benefactor, and hence his commands impose on us obligations to obey. Such a command could not make it obligatory to do anything contrary to any other first principle of morality (e.g. to torture children just for fun); but God's being essentially good would not command us so to act.

God is supposed to exist 'necessarily'. Some have understood this to mean 'of logical necessity', i.e. it would be incoherent to suppose there to be no God. \*Atheism does, however, seem to be a coherent position, even if false; and so other theists have understood God's being necessary as his being the ultimate brute fact on which all other things depend. In all these ways theists have tried to spell out an internally coherent understanding of God broadly consonant with the tradition of Western religion; while some (but not all) atheists hold that such attempts all fail.

**God, arguments against the existence of.** The most popular line of argument against God's existence involves the problem of \*evil. This argument is the inverse analogue of the \*teleological argument. Some versions are deductive in form, others are probabilistic.

A rather clear version of the deductive form is given by J. L. Mackie in 'Evil and Omnipotence'. He claims that the propositions *God is omnipotent*, *God is wholly good*, and *Evil exists* form a logically inconsistent triad, and that therefore some important part of theistic belief is false. This seems to be equivalent to an argument which takes *Evil exists* as its main premiss, and the other two propositions as analytic truths expressing (part of) the concept of God. The intended conclusion would be that God does not exist—i.e. that no actual entity satisfies that concept.

Deductive arguments from evil have recently been subjected to very intensive criticism, and enthusiasm for them seems to have waned somewhat. But there has been some increase of interest in probabilistic versions. These acknowledge the logical possibility of God along with evil. But they argue that in view of the amount of evil in the world, its horrific nature, the implausibility of the available theodicies, etc., it is improbable that God exists. Discussion of these attempts, both pro and con, suffer from the comparative obscurity of inductive logic.

Another line of atheological argument claims that the concept of God is *internally* incoherent, rather than incompatible with an obvious fact about the world. This is the inverse analogue of the ontological argument. Some, for example, have argued that being worthy of worship is a necessary condition of divinity, and this requires

necessary existence. But nothing, so they say, can exist necessarily. Ergo . . .

Others argue that one or another of the attributes traditionally assigned to God—e.g. omnipotence, omniscience, eternity—cannot be given a coherent sense. There arguments invite responses of two sorts. One may produce even more careful and subtle analyses to show that they are coherent after all. Or one may argue that they are not essential to the concept of God and can be replaced—e.g. God may be everlasting rather than eternal, almighty instead of omnipotent.

A third general line, vigorously proposed by Antony Flew, argues that atheism is the proper 'fall-back' position. In the absence of satisfactory arguments for theism, atheism should be accepted, even without any positive arguments in its favour. This has some similarity to the claim of some theistic philosophers that belief in God is legitimate, even if it is not supported by positive argument.

**God, arguments for the existence of.** Most theistic arguments fall into one of two classes—the a priori or purely conceptual arguments, and the world-based arguments. The various versions of the ontological argument constitute the first class. These have a specially 'philosophical' flavour, and give rise to difficult questions in modal logic. They have the advantage of concluding straightforwardly to the *necessary* existence of God, a feature which many take to be essential to the concept of a divine being.

In the other class belong the \*cosmological arguments, appealing to general features of the world, and \*teleological arguments, based on more special features. These lines of argument are more generally accessible, and have been more widely popular. And there are some even more special arguments (perhaps versions of the teleological family)—arguments based on the demands of morality, the existence of beauty, the normativity of human rationality, religious experience, etc.

Most of these lines of argument have a long history, and they have avid defenders and critics among contemporary philosophers. A crucial question, often ignored in these controversies, is that of the proper standards to be applied to such arguments. Presumably, they should be valid and their premisses true. But if God exists, these requirements are trivially easy to satisfy. What else is needed? If, for example, we require that their premisses be universally accepted, indubitable, etc., then probably no theistic argument will pass muster. (Probably no interesting argument for anything will measure up to this standard.) If, on the other hand, we require only validity, truth, and that the premisses be acceptable to some intended audience, then many of these arguments may be satisfactory. But they will not be universally persuasive. Their effectiveness

will be limited to those for whom their premisses are acceptable.

There are other lines of argument which are not really intended to establish the truth of God's existence, but rather the rationality, the intellectual permissibility, etc. of theistic belief. Pascal's wager is an example, and the rather similar 'will to believe' of William James. A different approach to this question of rationality is that of Alvin Plantinga and other contemporary 'Calvinians' (or 'reformed epistemologists') who argue that theistic belief is properly basic, and can be properly adopted and held without any inferential justification, though it may well be grounded in the occurrence of genuine (divinely initiated) religious experience.

**God and the philosophers.** The beliefs of most people in the West who have been brought up in the Christian or Jewish religions can be summarized in the following propositions: the natural universe has not always existed; it was created out of nothing by a purely spiritual being; this purely spiritual being known as \*God has always existed; this being not only created the universe but has continued to be its ruler ever since the creation, interfering in the course of events from time to time by working miracles; this being, furthermore, has the attributes of omnipotence, omniscience, and perfect goodness. The leading Christian and Jewish philosophers—St Augustine, St Anselm of Canterbury, St Thomas Aquinas, William of Ockham, and Maimonides—supported all these propositions. Ockham did not think that they could be proven, but the other great figures in the Judaeo-Christian tradition maintained that they are backed by decisive evidence.

Plato and Aristotle believed in gods who played a far less central role in the universe than the God of the Christians and Jews. In the *Timaeus* Plato introduces the Demiurge, a kind of cosmic architect or engineer who brings order into a chaotic universe. Aristotle's God is a 'prime mover'—we have to appeal to such a being to explain motion, but the material universe itself is eternal and uncreated. It should be mentioned that although Aquinas believed, on the basis of Scripture, that the universe was created by God out of nothing, he did not think that any of his 'proofs' established this conclusion. They only established God as the *sustaining* cause of the universe, and this conclusion is entirely compatible with the eternity of the world.

We now know that, aside from Ockham, quite a few medieval philosophers were in varying degrees sceptical of the official theology. However, since it was protected by what Voltaire called the 'logic of the sword', heresies were infrequent. In Muslim countries, where there was far greater freedom of thought, several of the leading

## LATE ANCIENT AND EARLY MEDIEVAL PHILOSOPHY

AUGUSTINE rose to eminence as the leading churchman in North Africa in the early fifth century; meanwhile he developed his Platonic Christian philosophy in private contemplation.

ABELARD, legendary French lover—but philosophers are more interested in his theory of universals. His teachings on atonement and on the role of intention in human conduct were also influential.

ANSELM, born in Italy, was Archbishop of Canterbury at the end of the eleventh century. He produced rational investigations of the foundations of Christian belief, and is famous for his ontological argument for the existence of God, which holds that it is implicit in the very idea of God that he exists.

BOETHIUS, a Roman politician of noble family, might have made Greek philosophy known in western Europe centuries earlier than its eventual promulgation in Latin, but his translation of Plato and Aristotle was brought to an abrupt end by his execution c.526.

philosophers, most notably Averroës, openly accepted Aristotle's teaching of God as the Prime Mover and of the eternity of the world.

Much of the philosophy of the last 300 years is the story of the attacks on the Judaeo-Christian view and its replacement by a naturalistic outlook which completely dispenses with theological explanations. Some of the great philosophers of the modern period, notably Descartes and Leibniz, offered arguments for traditional theism, but several others were in varying degrees critical of the old scheme. Foremost among the critics were Spinoza, the deists, Hume, and Kant. Spinoza is usually classified as a pantheist who maintained that God and the universe are identical. Voltaire and Frederick the Great regarded him as an atheist who retained theological language, while Goethe, who was himself a pantheist, called Spinoza 'God-intoxicated'. Be this as it may be, Spinoza taught that the natural universe was uncreated, and he was also most emphatic in his rejection of miracles.

\*Deism, which began in England in the late seventeenth century, was primarily a rebellion against revealed as distinct from natural religion. The deists did not deny a creator of the universe, but they were highly critical of the Bible, regarding all stories of divine intervention as superstitious and often immoral nonsense. In arguing for the existence of God they preferred the teleological argument to the a priori arguments of earlier believers. Some of them questioned the perfect goodness or indeed any of the moral attributes of the Deity. In his *Poème sur le désastre de Lisbonne* and in *Candide*, Voltaire, the most influential of the eighteenth-century deists, tried to show the absurdity of any cosmic optimism without, however, abandoning belief in a Designer.

Hume has sometimes been called a deist, but in fact he was what we would now call an agnostic. His posthumously published *Dialogues Concerning Natural Religion* contain some of the most incisive criticism of the cosmological and the teleological arguments. In connection with the former he observes that a causal series is nothing over and above the members of the series, so that if we have explained the origin of each member, there is nothing left to explain. As for the teleological argument, we have no reason to suppose that there was a time when order of the kind described in our scientific laws did not characterize the universe. Although not as radical as Hume, Kant had much greater influence on subsequent developments. His *Critique of Pure Reason* contains a devastating examination of the \*ontological, \*cosmological, and \*teleological arguments. Hume's discussion of the latter two arguments was greatly superior, but Kant's refutation of the ontological argument, which Hume barely touched, was masterful.

The work of Hume and Kant no doubt helped to pave the way for agnosticism and \*theism, but it also had a significant impact on Christian and Jewish philosophy, resulting in the widespread adoption of a position known as 'fideism'—belief in God (or other religious propositions) on the basis of faith alone. Fideistic believers are

ready to concede that the arguments for the existence of God are not valid, but they commonly add that this is not necessarily a cause for concern. Faith, in the words of John Hick, 'stands ultimately upon the ground of religious experience and is not a product of philosophical reasoning'. Kierkegaard, a leading figure in the fideist tradition, went so far as to maintain that those who tried to prove the existence of God are enemies of true faith. Faith, on Kierkegaard's view, involves risk, but there would be no risk if the existence of God or immortality were as solidly established as mathematical theorems and scientific laws.

\*Fideism flourished in the nineteenth century and is still widely adopted at the present time, but it goes back at least as far as Blaise Pascal (1623–62), who, in a famous passage in his *Pensées*, asserted that 'the heart has reasons which reason knows not of'. Pascal's heart, needless to say, told him that there is a God, that there is life after death, and that he himself was going to inherit eternal bliss. It did not occur to him that other people's hearts might tell them very different things and that we would then have the problem of whose heart is to be trusted. Rousseau, too, was a champion of faith and the heart. 'I have suffered too much in this life not to expect another', he wrote in a published rebuttal to Voltaire's *Poème sur le désastre de Lisbonne*—'all the subtleties of metaphysics will never make me doubt for a moment the immortality of the soul and a beneficent providence. I feel it, I believe it, I want it, I hope for it, I will defend it to my last breath.' Sceptics have generally not been unduly impressed by such outbursts and have dismissed fideism as nothing but a species of wishful thinking which ought to have no place in serious philosophy.

The open advocacy of atheism effectively began during the middle of the eighteenth century in France. Diderot, Holbach, La Mettrie, and d'Alembert were the most famous defenders of atheism in opposition not only to Christianity but also to deists like Voltaire and Rousseau. All these atheists were also materialists, but atheism is not necessarily connected with any metaphysical system. Fichte and Schopenhauer, for example, were atheists who subscribed to metaphysical idealism. Hegel's views cannot be easily classified, chiefly because they are so obscure. He believed in something called the 'Absolute Idea', and some of his conservative followers, known as the 'Right Hegelians', had no difficulty identifying the Absolute Idea with a personal God. However, almost all his most famous students, known as 'Left Hegelians', were outspoken atheists. They included Marx, Engels, Feuerbach, Bruno Bauer, and D. F. Strauss, the author of the extremely influential *Life of Jesus*. It might be noted that Fichte lost his academic position when his atheism was discovered, and the same was true of Bauer and Strauss. None of the others just mentioned ever had a chance. Even David Hume never obtained an academic appointment.

The most interesting late nineteenth-century atheist was unquestionably Friedrich Nietzsche, whose full influence was not felt until the early decades of the twentieth

century. Nietzsche's rejection of God and immortality is combined with a subtle analysis of the emotions which inspire life-denying religions like Christianity. The notion of God, according to Nietzsche, is extremely harmful because it is employed, especially by Christian moralists, to denigrate earthly happiness and other secular values. 'The concept "God"', he wrote, 'was invented as the opposite of the concept "life"—everything detrimental, poisonous and slanderous, and all deadly hostility to life, was bound together in one horrible unit!' Unfortunately, Nietzsche's works, especially those written near the end of his sane period, also contain tirades against compassion and vaguely worded recommendations to exterminate 'the bungled and the botched'.

Nietzsche denied that he was a Social Darwinist, but many passages in his writing show that this is precisely what he was. Along with other Social Darwinists and power-worshippers, Nietzsche was denounced by Bertrand Russell, who was probably the most influential atheist in the Anglo-Saxon world during the present century. Although he disagreed with Nietzsche on certain ethical and political issues, Russell's views were in every other respect quite similar. Like Nietzsche he attacked not only traditional views about God and the soul, but also the harmful influence of Christian moral teachings, especially those relating to sexual morality. Russell also made important contributions of a purely theoretical nature. Following Cantor, he showed that there is nothing contradictory in the notion of an infinite series, an insight that undermines the cosmological argument. Following Frege, he showed that the word 'exists' is a logical constant comparable to such words as 'all' and 'not', and not the name of a characteristic. This insight complements Kant's refutation of the ontological argument.

The two leading French \*existentialists, Jean-Paul Sartre and Albert Camus, were outspoken atheists, and in a programmatic essay Sartre also counts Heidegger as an atheist. It is, however, very misleading to describe Heidegger so. He did indeed reject Christian and Jewish theism, but he believed in an ultimate reality called 'Being' which has striking similarities to the traditional deity. Being is in everything and is the source of everything. It is always referred to as 'the Holy' and as something 'transcendent' which cannot be adequately described in language taken from ordinary experience. It can be reached by various mystical techniques, especially one which Heidegger calls *Gelassenheit* and which has been facetiously described as a form of 'creative waiting'. It should be noted that Heidegger felt an affinity with medieval mystics, whom he frequently quoted with approval, and that he was unequivocally opposed to any form of naturalism.

Sartre really was an atheist. He rejected theism because it is incompatible with \*free will in the somewhat peculiar sense in which he takes it to be a basic fact about human beings. If there were a God, he would create human beings with a 'nature' or 'essence', and this is incompatible with Sartre's view that in man existence precedes essence. This seems to mean that human beings do not have an

essence until they have chosen their initial 'fundamental projects', Sartre's term for character traits. The trouble with such a view is that, regardless of the extent and power of our volitions, *ultimately* we are the result of our heredity and early environment. Like many other philosophers, Sartre manages not to see this disturbing but inescapable fact, which may be compatible with free will in *some* sense, but is incompatible with Sartre's view that our character is self-chosen.

As for free will as an argument against God's existence, it should be observed that even if Sartre's argument is otherwise valid, it would not show that there is no God, but only that God cannot have given human beings their 'essences'.

The twentieth century witnessed perhaps the most lethal of all attacks on traditional belief in God. We may call this the 'semantic' challenge. It consists of questioning the very intelligibility of statements about God. It began in the 1930s with the verificationism of the Logical Positivists, according to which statements about God are meaningless since they are not even in principle verifiable. More recently it has centred on difficulties arising from the view of most sophisticated believers that God does not possess a body. Words like 'good', 'kind', 'compassionate', 'caring', and also of course 'intelligent' and 'powerful', are initially introduced in connection with human beings who possess bodies. Can they retain any meaning when applied to a pure mind?

There is also the problem of how a purely spiritual being could be contacted, and how he (or she or it) could interfere in the universe. Suppose I suffer from an inoperable brain tumour and pray to God for a cure. If God is physical he might hear my prayer and send healing rays, unavailable to earthly physicians, that would break up the tumour. But how could a disembodied mind hear me in the first place, and, if he could, how could he, not being physical, apply the force that would send the rays into my brain? More basically, how could a pure mind create the physical universe, or for that matter how could he create anything at all?

**Gödel, Kurt** (1906–78). The greatest mathematical logician and a bold, heterodox philosopher of mathematics. Among his mathematical discoveries are: the completeness of first-order logic, i.e. there is a sound formal system in which every first-order logical truth is deducible; the incompleteness of arithmetic, i.e. there is no sound formal system in which every first-order arithmetical truth is deducible (known as \*Gödel's theorem); the internal unprovability of the consistency of any system containing computable arithmetic; the consistency of classical arithmetic relative to intuitionistic arithmetic; the relative consistency of the axiom of \*choice and of Cantor's

continuum conjecture. (\*Continuum problem.) Along the way he invented an arithmetical method of reasoning *about* formal systems and he discovered the hierarchy of constructible sets. As a sideline he showed that general relativity, the theory of his close friend Einstein, allowed the possibility of what may be loosely described as circular time.

Crowning this phenomenal output was a striking view of mathematics, a twentieth-century philosophy akin to Plato's. Its main elements are as follows: the objects of mathematical study, e.g. the structures of numbers and sets, exist independently of thought and language; all clear mathematical statements are true or false, even those which are currently undecidable such as Cantor's continuum conjecture; mathematical concepts such as recursiveness and differentiability exist independently of our formulations; and finally, our mathematical knowledge consists in deductions from axioms which are known by intuition—all against the tide of his time. Though he allowed the possibility of coming to know axioms by the fruitfulness of their consequences, he gave no quarter to the empiricist view that the basis of mathematical knowledge is the evidence of the senses. Aside from Brouwer's view that much of established mathematics is false or nonsense, the only serious alternatives to the empiricist view and Gödel's own were logicism, i.e. the view that mathematics is a body of tautologies deducible from a system of purely logical axioms, and formalism, i.e. the view that mathematics is a purely formal extension of finitary reasoning, an extension which could never lead us into falsehood; but these views, logicism and formalism, had been effectively destroyed by Gödel's mathematical work.

Opinion is sharply divided about the plausibility of Gödel's bold philosophy of mathematics, but its value is unquestionable. It is the product of a deep knowledge of mathematics, a master craftsman's knowledge, combined with great carefulness and clarity of thought. M.D.G.

**Gödel's theorem.** A formal system is a computable list of axioms stated in a precise language with precise inference rules. The theorem states that for any consistent formal system *M* containing a certain part of arithmetic, a sentence in the language of *M* can be constructed which is neither provable nor refutable in *M*. Its discovery amazed those who saw its significance. Assuming that every mathematical proposition is true or false, it entails that there is no consistent formal system in which every mathematical truth is provable, contrary to the view of Frege and Russell. Paired with Gödel's discovery that the consistency of formal systems containing arithmetic is not internally provable, this effectively destroyed attempts to justify classical mathematics by means of formal systems. M.D.G.

S. Shanker (ed.), *Gödel's Theorem in Focus* (London, 1988).

**God is dead.** A formula employed by Nietzsche to signify the demise—both cultural and intellectual—of the 'God-hypothesis', the associated 'Christian-moral interpretation' of the world and ourselves, and all kindred notions and interpretations involving the postulation of some sort of ultimate reality and source of meaning and value transcending 'this life' and 'this world'. Nietzsche associated this disillusionment with the advent of nihilism, which while unavoidable must be overcome through the creation of 'new values' in a manner 'faithful to the earth'. (See e.g. *The Gay Science*, sects. 108–9, 125, 343.) R.S.

Walter Kaufmann, *Nietzsche*, 4th edn. (Princeton, NJ, 1974), ch. 3.

**Godmanhood.** A theologico-philosophical notion deriving from the Christian doctrine of the Incarnation. According to the latter, Christ was both truly human and truly divine, and thus could be described as a 'God-man'. In scriptural, patristic, and medieval writings a related notion emerges according to which Christ (usually in the resurrected state) represents the perfection of \*human nature. Accordingly, human beings possess natures the full and sustained realization of which would bring them to the condition of the transfigured Christ. The term 'Godmanhood' usually refers to a version of this general idea as it was developed in the religious anthropology of the Russian religious philosopher Vladimir Solovyov (1853–1900). J.HAL.

F. Copleston, *Russian Religious Philosophy* (Tunbridge Wells, 1988).

**Godwin, William** (1756–1836). British moral and political philosopher, author of numerous political novels, including *Caleb Williams* (1794); husband of Mary Wollstonecraft. *An Enquiry Concerning Political Justice* (1793) was notorious for its extreme \*anarchism and \*utilitarianism, though Godwin somehow escaped prosecution. His view was grounded in the claim that human beings are naturally equal. Government corrupts governors and people, creating and aggravating inequalities. Only a non-political society will permit unconstrained impartial benevolence. His optimistic faith in reason led him into an equally sanguine view of human moral capacity. Godwin speaks also of rights and natural rights, some of which are in tension with his utilitarianism: we have rights over our present property even if the distribution is not utility-maximizing. His utopian radicalism attracted Romantics such as the young Wordsworth and Shelley, later his son-in-law. R.CRI.

— *Caleb Williams*, ed. D. McCracken (Oxford, 1977).

**Goethe, Johann Wolfgang** (1749–1832). German poet and thinker who influenced and was influenced by post-Kantian \*idealism. 'For philosophy in the strict sense I had no organ': he had no taste for traditional logic and epistemology, but he had a lively appreciation of the works of

Kant and other philosophers, and from his study of Plato, \*Neoplatonism, and above all Spinoza he derived an exuberant pantheism that pervades his poetry as well as his prose. Nature is a living unity, in which mind and matter are inextricably linked: 'Where object and subject meet, there is life; when Hegel places himself between subject and object by means of his philosophy of identity, we must do him honour.' Nature reveals her secrets to the discerning eye, but it resists quantitative, mechanistic treatment. Thus Goethe's biological researches, especially on the metamorphosis of plants, were guided by the belief that organisms are constructed on a uniform plan, and he defended the purity of white light against Newton's theory that it consists of the seven prismatic colours.

He had little sympathy for democracy, industrialization, or revolution: 'I see a time coming when God will no longer have any pleasure in mankind; he will once more have to destroy everything to make room for a renewed creation.'

M.J.I.

T. J. Reed, *Goethe* (Oxford, 1984).

**Goldbach's conjecture** (1742). Christian Goldbach (1690–1764) was born in Königsberg. His conjecture states that every even integer greater than 3 is the sum of two prime numbers; thus  $4 = 2 + 2$ ,  $16 = 5 + 11$ , etc. The truth of Goldbach's conjecture is still an open question. But curiously, any proof that the conjecture is not refutable would imply that there are no counter-examples, and hence would prove the conjecture!

Richard K. Guy, *Unsolved Problems in Number Theory* (New York, 1981).

**golden mean:** see mean, doctrine of.

**golden mountain:** see Meinong.

**golden rule.** This rule designates a guide to conduct which has been thought fundamental in most major religious and moral traditions. It has been formulated either positively as an injunction to 'do unto others as you would have them do unto you' (Matthew 7: 12); or negatively, urging that you not do to others what you would not wish them to do to you, as in the sayings of Confucius or Hillel. The rule's all-encompassing simplicity has invited countless trivializing counter-examples: Should devotees of fried mosquitoes serve them as a special delicacy to their guests? Or masochists inflict their favourite torments on unsuspecting acquaintances? Such questions, however, miss the point of the rule. It was never intended as a guide to practical choice independently of all other principles of conduct. It has nothing to say about specific choices, nor does it endorse particular moral principles, virtues, or ideals.

The golden rule concerns, rather, a perspective thought necessary to the exercise of even the most rudimentary morality: that of trying to put oneself in the place of those affected by one's actions, so as to counter the natural

tendency to moral myopia. It enjoins listeners to treat others with the understanding and respect they would themselves wish to encounter, and above all not to inflict misfortunes on others that they would abhor to have inflicted upon themselves.

Precisely because the golden rule has so long been thought fundamental, many moral philosophers have compared it to their own principles concerning moral choice and conduct. Thus Immanuel Kant famously dismissed the rule as trivial and too limited to be a universal law, in a footnote to his *Foundations of the Metaphysics of Morals*, whereas John Stuart Mill claimed, in *Utilitarianism*, that 'In the golden rule of Jesus of Nazareth, we read the complete spirit of the ethics of utility.'

**Goldman, Alvin I.** (1938– ). Professor of Philosophy, University of Arizona, best known for a thoroughgoing 'naturalized' approach to epistemology, metaphysics, and the philosophy of mind, an approach that takes philosophical theses to be constrained by our best empirical theories. Goldman envisages 'liaisons' between philosophical domains and their counterparts in the social and behavioural sciences. His theory of \*knowledge centres on the notion of a 'reliable belief-forming process', and accords psychology the task of identifying such processes. Goldman's account of mental concepts and ascriptions, including 'simulation theory' (according to which your understanding of my states of mind reflects an ability to put yourself in my shoes), gives a central role to cognitive psychology, and his work on social power and social epistemology exploits findings in political science, social psychology, economics, and the law.

**good.** G. E. Moore, in *Principia Ethica* (Cambridge, 1903), declared that the term 'good' stood for a simple, non-natural, indefinable quality, known by intuition, and that attempts to define it were inevitably fallacious. (\*Naturalistic fallacy.) This somewhat obscure view has not generally prevailed, and philosophical inquiry into good continues. Philosophical concern with good can roughly be subdivided into four sorts. (1) What does the term or word 'good' signify? (2) What things are good, and how do we know them to be so? (3) What is the highest good, the complete good? (4) What sorts of goodness are there, and how, in particular, is moral goodness related to other varieties of goodness? These concerns are plainly interrelated.

With respect to the first, it is natural to think that since 'good' most commonly functions as an adjective it designates some distinctive quality possessed in common by everything that is good. This is implausible. It is doubtful that a good novel possesses any property of significance in common with a good semiconductor, at least no intrinsic property. But the property may not be intrinsic. For something to be good may be for it to meet some human interest, directly or indirectly. This could be a common relational property. Others have argued that the term does not ascribe a property at all. Rather it is used to express approval or commendation of the item dubbed good. Such views are associated with the emotive theory of ethics and with prescriptivism.

Clearly, the issue of how we know what items are good will be much influenced by the view one has of what it is for something to be good. If to hold something to be good is to approve of it, or otherwise feel favourably disposed towards it, then one must consult one's own feelings and dispositions to determine whether some event, object, or outcome is good. If, on the other hand, goodness is a relational property of something concerned with its meeting human interests, then what things are good will be something fairly readily settled by informal inquiry. The rather widespread idea that goodness is 'subjective' usually results from the first of these views, or from a confusion of the question what is good with the question whether some good is preferable to another. The latter can be subjective even when it is a plain matter of fact what is or is not good.

Things that are good may also be viewed from the point of view of how they will contribute to a well-spent or happy human life. The idea of a complete good is that of what will wholly satisfy the complete need and destiny of humans, the *summum bonum*. This may be one thing (e.g. contemplating the face of God); or a combination of many things, as envisaged in Aristotle's account of the 'political' life in the *Nicomachean Ethics*. The notion of the highest good is often obscure. It may signify that one good which is better than any other good; or that one good better than all other goods taken together.

Goods may be taxonomized in other ways also, such as hedonic (goods of or dependent on pleasure); utilitarian (goods derived from usefulness); and so on. Goods may also be distinguished as intrinsic (in and of themselves) or extrinsic (good as a means to an end). Whether the moral goodness of a person, their character, and actions is a distinctive type, or is derived from their goodness in other ways (e.g. in producing happiness for others, as envisaged in utilitarian moral theory) is a vexed matter. The relations between what it is good to do and what it is right to do are also intricate and obscure.

**Good, Form of the.** In virtue of what, are all beautiful things beautiful? What makes all chairs chairs? For Plato, the answer is their real essence, a Form, in which they somehow partake. There is one Form, it seems, to which every thing that falls under a particular concept is related in this way. Forms, although sometimes called Ideas, are real, rather than being ideas in the ordinary sense. They are unchanging, somehow not in the lower world we know, and, so to speak, are the very perfection of the things in question. The Form of Beauty is ideally beautiful. The supreme Form is the Form of the Good, or just the Good. Its grandeur is beyond description, but it includes its being the foundation and source of all knowledge and all reality, of truth and of all things. It can be no surprise that the Good was identified with God by later philosophers. For Plato, knowledge of it is the ultimate purpose of philosophy in a wide sense, and we are to be ruled only by those who have come to know it. Whatever else, the Form of the Good is an idea of elusive beauty that has endured.

**good, greatest.** Goal of human life or \**eudaemonia*. The correct conception must include all goods. The view that *eudaemonia* consists in pleasure alone is false, since pleasure fails to include goods such as knowledge. Aristotle held that *eudaemonia* consisted in exercise of the virtues, which itself instantiates all human goods. Cicero and the Stoics spoke of the *summum bonum*. The notion was also used for the collective good of all in \*utilitarianism.

**good-in-itself.** A good-in-itself is otherwise referred to as an intrinsic good. Aristotle in the *Nicomachean Ethics* made use of the idea, in attempting to define the \*good for man. He distinguished between things pursued for their own sake (such as health) and things pursued for the sake of their consequences (such as money). He concluded that there was a number of different things that were goods-in-themselves. To his list of health, sight, and intelligence, we might now add such values as the continuing existence of diverse species of animals.

David Wiggins, *Needs, Values, Truth* (Oxford, 1987).

**Goodman, Nelson** (1906–98). One of the most influential American philosophers of the twentieth century, trained at Harvard and Professor there for thirty years. Goodman's first published book was *The Structure of Appearance* (1951), an attempt to apply techniques of formal logic to 'the analysis of phenomena'. Certain entities are characterized as 'basic individuals'; the objects of ordinary experience are in some sense 'constructions' out of these. Goodman has a partiality (though not a commitment) to \*phenomenalism, the view that basic individuals are

sensory items rather than physical things. He describes himself as a nominalist and *The Structure of Appearance* as formulated in nominalistic terms. Goodman's \*nominalism is sometimes described as a rejection of classes, but may best be summed up in his words: 'the nominalist recognizes no distinction of entities without a distinction of content'. According to Goodman, then, the class whose members are the counties of Utah is not to be distinguished from the class of acres of Utah or from the single individual, the state of Utah. This view has been described as a 'simple materialism' based on the 'crude principle' that the entities supposed unintelligible (classes as distinct from their members) are those things we cannot point at or hold in our hands.

In *Fact, Fiction, and Forecast* Goodman proposed his 'new riddle of induction'. Hume had seen that we make predictions based on regularities in experience, while arguing that there was no rational basis for this. But not all observed regularities form the basis for predictions: though all examined emeralds are \*grue we do not imagine that all emeralds are.

Goodman was an art collector, and this interest was also reflected in his philosophical writings. In *Languages of Art* (1968) he discusses such topics as representation, expression, and authenticity from the perspective of what he calls 'a general theory of symbols'. M.C.

**good will.** Moral agents, on a Kantian view, can be held accountable for the orientation of their will, as they can not for their physical and psychological make-up. The will has to be seen as free—initiating action because duty calls for it, or else assenting—also freely—to action out of inclination. Thus, distinctive or 'genuine' moral worth lies not simply in the mere performance of right acts, but in doing them from a motive of duty—that is, from a good will, steadily aligned to whatever duty requires. Such a view is of course compatible with a concern about the consequences of action—but only so long as the supreme value of the good will itself is not lost from sight. Moral theorists dispute whether this account warps and narrows the range of moral appraisal, by undervaluing spontaneous goodness and goodness of character. But it is hard not to agree that my good will is morally appraisable in a distinctive and strong sense. It monitors, endorses, rejects, and modifies the components of my temperament and character for whose existence I am not in the same thoroughgoing way responsible. What I choose to make of these components or do with them is indeed morally appraisable, and is a matter of attention and will. R. W. H.

\*consequentialism.

**Gorgias** (5th century BC). The most celebrated rhetorician of the century. From Leontini in Sicily, he was a prominent figure in the sophistic movement in Athens in the last quarter of the century. (\*Sophists.) He also had philosophical interests, and was reputedly a pupil of Empedocles. The surviving portions of his works not only attest his florid rhetorical style, but also touch on some substantial issues, including responsibility (in his *Defence of Helen*). The curious essay *On What Is Not* is an application (of dubious seriousness) of Eleatic argumentative techniques to establish a variety of sceptical and nihilistic conclusions. He figures prominently in Plato's *Gorgias*. c.c.w.t.

W. K. C. Guthrie, *A History of Greek Philosophy*, iii (Cambridge, 1969), ch. 11.2.

**grace.** That which is granted by the will of God. Divine assistance, especially that conducive to sanctification and salvation. It is argued, for example by Augustine, Luther, and Calvin (following Romans 9: 11–26), that the grace of God does not depend on merit. Augustine distinguishes grace necessary for action (*adiutorium sine quo non fit*) from grace sufficient for action (*adiutorium quo fit*). Aquinas calls the inspiring presence of God in the soul 'habitual grace' or 'sanctifying grace', and divine intervention causing a good human act 'actual' grace. The ability to not act sinfully since the Fall, the salvation of the soul, and the possession of Christian faith itself are arguably by the grace of God. The sacraments are symbols or instruments for the reception of grace, but grace may be bestowed without them. s.p.

**grammar.** A formal system for describing the structure of natural languages. The term is used, in one sense, to mean traditional grammar, and in another, more theoretical sense, to mean generative grammar. Traditional grammar at best describes ideals of practice offering prescriptive rules that tell us how others would like us to use our language. It is alleged that it can provide philosophical insight into the presuppositions harboured in ordinary language, and that correct attention to it resolves philosophical misunderstanding.

Grammar in the more technical sense, given precision by Chomsky's notion of a generative grammar, is a system of rules or principles from which can be derived all and only the grammatical \*sentences of a language. The task in constructing grammars for particular languages is to design a formal system that will account for most of the facts with the fewest number of independent principles and posits. Such a grammar is generative in the formal sense that it makes it explicit how all of the permissible sequences of words follow from a finite set of principles and a finite stock of vocabulary (lexical) items.

The theory of grammar studies linguistic competence, not performance; i.e. it accounts for what speakers know

about their language, not all the uses they make of it. This is because performance may be full of slips of the tongue, inattention, false starts, mistakes speakers would like to correct on reflection, etc. A theory of performance would have to include not just a theory of linguistic mastery but also psychological theories of memory, perception, attention, and motor functioning which all contribute to actual language use. This means that the data for theories of grammar will always be indirect. In addition to verbal behaviour, linguists elicit judgements from speakers (misleadingly called intuitions) about which strings of words are grammatical, or belong to their language. For example, 'George drank the wine' and even the semantically anomalous 'The wine drank George' are grammatical; whereas 'George wine drank the' is not. To use it to say what the first sentence says is not to be speaking English. Judgements about what is grammatical, however, are not always reliable; they simply provide the best available evidence of which sentences are well formed (i.e. grammatical) in the speaker's language.

Speakers may find some sentences ungrammatical at first due to parsing problems. Well-known examples are centre-embedded constructions such as 'The girl the cat the dog bit scratched cried' (cf. 'The boy the dog bit cried'), and garden-path sentences such as 'The horse raced past the barn fell'. Difficulties with these are due to processing and memory limitations. Hence even the mentalist hypothesis that grammar is a cognitive state has to distinguish *grammars* as bodies of knowledge, from *parsers* as systems of processing rules for producing and comprehending strings.

A grammar that generates all and only the grammatical sentences of a speaker's language is said to be *observationally adequate*. A grammar is said to be *descriptively adequate* when it also assigns structural descriptions to those strings. Grammar is really the theory of syntactic structures rather than word strings, since it must account for grammatical relations between sentences and explain why certain structures are ruled out. To do this it must postulate real, though hidden, levels of syntactic representation. (\*Structure, deep and surface.) For example, the sentences 'John is easy to please' and 'John is eager to please' look on the surface like similar arrangements of words of the same grammatical category. But the first can be transformed into the sentence 'It is easy to please John', whereas the second has no related form 'It is eager to please John'. This is because 'John' is the object of 'to please' in the first structure, but the subject in the second. (Chomsky argues that these subject and object positions should be marked in the syntax by empty categories.) Sentences are hierarchical, not linear, arrangements of constituents, where constituent structures are units of syntax larger than the word and smaller than the sentence. All sentences contain groupings like noun phrase and verb phrase which mark major constituent boundaries. These phrase structures can be represented by tree diagrams, or labelled and bracketed strings; e.g. [<sub>S</sub> [<sub>NP</sub> The horse raced past the barn] [<sub>VP</sub> fell]]. A theory of grammar is said to be *explanatorily adequate* if it is the descriptive grammar

which records the knowledge of language speakers have actually acquired and the structural descriptions they assign to their sentences, i.e. if it is psychologically real.

N. Chomsky, *Aspects of the Theory of Syntax* (Cambridge, Mass., 1965).

J. Katz (ed.), *The Philosophy of Linguistics* (Oxford, 1985).

P. Sells, *Lectures on Contemporary Syntactic Theories* (Stanford, Calif., 1985).

**grammar, autonomy of.** In his *Tractatus*, Wittgenstein argued that language is answerable to the essential nature of reality. The logical syntax of simple names (their combinatorial possibilities) must mirror the metaphysical combinatorial possibilities of the simple objects that are their meanings. Names are *connected* with the objects in reality which are their meanings by word-world correlations. Similarly, the use of the negation sign must reflect the essence of the operation of negation, etc.

In *Philosophical Grammar*, chapters II and X, he repudiated this view. He ceased to employ the term 'logical syntax', no longer believing that there is a philosophically significant distinction between syntactical (formation) rules and semantical rules 'connecting language with reality' (e.g. by means of ostensive definitions). Ostensive definitions appear to connect words with objects and properties in reality, but this appearance is deceptive. The object pointed at in an ostensive definition of a colour-word, for example, is being used as a sample, and a sample is part of the means of representation, not an object represented (described) by the ostensive definition. This is evident from the fact that instead of the description 'A is red' one may say 'A is this ↑ colour [pointing at a sample]', substituting a sample, deictic gesture and indexical for the word 'red'. Here the \*ostensive definition is visibly functioning as a substitution rule. So ostensive definition remains within language and does not connect language and reality.

\*Grammar, he now suggested, is constituted by *all* the linguistic rules that *determine the sense of an expression*. Here he diverged from the customary use of 'grammar' (which excludes explanations of word-meaning, and admits as grammatical sequences of words that lack sense). But he denied that there are two different kinds of grammar, ordinary grammar and philosophical grammar. Rather there are two different kinds of interest in the rules of language, the grammarian's and the philosopher's. The latter's interest is guided by the purpose of resolving philosophical problems.

Wittgenstein now argued, contrary to his earlier view, that grammar is 'arbitrary' or autonomous, i.e. that it is not answerable to the nature of things. The idea that grammar can be justified by reference to reality in the sense in which an empirical proposition is justified by reference to what makes it true is incoherent. The rules for the use of names, e.g. 'red', do not mirror the metaphysical nature of the colour, but constitute it. Similarly, the rules for the use of the negation sign do not reflect the

nature of negation, but determine it. 'Grammatical propositions', e.g. 'Nothing can be red and green all over', are in effect rules, not descriptions of reality. What appear to be metaphysical necessities are in effect no more than the shadows cast upon the world by our methods of representation, our rules for the use of expressions. Concepts are not 'correct', let alone justifiable as true, but only more or less useful for our purposes. Alternative grammars are conceivable. They are constrained, but not made more or less correct, by our nature (e.g. by our perceptual and intellectual capacities) and by the contingencies of the world.

P.M.S.H.

P. M. S. Hacker, *Insight and Illusion: Themes in the Philosophy of Wittgenstein*, rev. edn. (Oxford, 1986), 179–92.

**grammatical proposition.** Term of art used by the later Wittgenstein to signify a proposition which appears to state truths about the nature of things, but whose actual role is to give a rule for the use of its constituent expressions. 'Red is a colour', 'Nothing can be red and green all over simultaneously', 'Red is darker than pink' look as if they state necessary truths about the nature of colours. Actually they specify rules for the use of colour words, namely that if something is red, it can also be said to be coloured; if something is red all over, it cannot also be said to be green all over; if *A* is red and *B* pink, then the inference that *A* is darker than *B* is licit. Wittgenstein argued that what appear to be necessary metaphysical truths are at best grammatical propositions.

**Gramsci, Antonio** (1891–1937). Born in Sardinia, Gramsci was a founder-member and the principal ideologist of the Italian Communist Party, which he briefly led prior to his imprisonment by Mussolini. Whilst in jail, where he remained until his death, he wrote the *Prison Notebooks*. These are generally regarded as amongst the founding documents of Western Marxism. Drawing on the writings of Croce, Gramsci modified orthodox historical materialism so as to give an independent role to human consciousness and hence to the superstructure relative to the economic base. He used this insight to develop the concept of hegemony, or ideological power, to explain the resilience of liberal democracy in the advanced industrial nations of the West. He argued that in order to overthrow the state in such countries, revolutionary parties must first overcome the sources of hegemonic power within civil society, such as churches, schools, and the media. R.P.B.

\*dialectical materialism.

Richard Bellamy and Darrow Schecter, *Gramsci and the Italian State* (Manchester, 1993).

**greatest happiness principle.** This is one name for the leading principle of \*utilitarianism, and one which Bentham specifically gave to his central principle towards the

end of his life. The main reason for the change was that he thought that 'happiness' was a clearer designation than \*'utility' for the right end of action; the happiness to be considered was of everyone affected by a proposed action or state of affairs.

R.H.

Jeremy Bentham, *Introduction to the Principles of Morals and Legislation*, 2nd edn. (1823), ch. 1, sect. 1, n.

**great man theory of history.** An expression used to refer to the claim that the course of the historical process is basically governed by the actions of outstanding individuals, a contention encapsulated in Carlyle's famous dictum that history is 'the biography of great men'. Its nineteenth-century opponents, who included Engels, Tolstoy, and Herbert Spencer, argued instead that history was ultimately determined by such general factors as economic or social relations, the individuals wielding power being themselves the products or instruments of society. Despite the intrinsic interest of problems concerning the role of the individual in history, debates on this score have tended to be vitiated by uncritically monistic conceptions of historical causation, failures to distinguish between the necessary and sufficient conditions of events, and divergences in the criteria employed for estimating the nature and extent of social influence or importance.

P.L.G.

\*superman.

S. Hook, *The Hero in History* (New York, 1943).

**great-souled man.** Greatness of soul (Greek *megalopsukhia*, rendered into Latin as *magnanimitas*) is a self-referential evaluative disposition characteristic of Aristotle's virtuous agent, consisting in a proper sense of his own worth, manifesting itself in the desire to be honoured for his virtues by his equals (coupled with indifference to the opinion of inferiors) and in self-conscious dignity of demeanour (verging on pomposity to the modern eye). Despite the etymological connection, it is nearer to pride than to magnanimity; while the great-souled man appears magnanimous, e.g. in forgiving injuries, he does so not from generosity of spirit, but because nursing grudges is beneath him.

C.C.W.T.

\*superman.

W. F. R. Hardie, "'Magnanimity" in Aristotle's Ethics', *Phronesis* (1978).

**Greek philosophy:** see ancient philosophy; Greek philosophy, modern.

**Greek philosophy, modern.** What point of origin one selects for modern Greek philosophy is to a certain extent an arbitrary matter. For, on the one hand, intellectual phenomena never fall neatly into line with the facts of history, while, on the other, modern Greek philosophy has its roots deep in antiquity, being the prolongation of the classical and Christian spirit during Byzantine rule and the Turkish occupation.

With this caveat, one can usefully think of 'early modern Greek philosophy' as lasting from the year 1453 (the Fall of Constantinople) to the year 1821 (the start of the struggle for national independence). This whole period has certain distinctive features: its attachment to ideals, its Graeco-Christian values, and its unremitting efforts to inform and awaken Hellenic consciousness. 'Later modern Greek philosophy' (and it is with this that the present article is chiefly concerned) emerges from the revolution of 1821. Greece breaks free from the Ottoman Empire, and organizes herself into a nation state. Decisively influenced by the new freedom of thought and action, modern Greek philosophy manifests a number of tendencies.

1. Ancient authors are published, annotated, translated, and interpreted. Thinkers turn to the great philosophers of the past—in particular Plato and Aristotle—for inspiration. A halt is called to the conflict between Platonists and Aristotelians that had prevailed in Byzantium and throughout early modern Greek philosophy. Though a majority of intellectuals opt for \*Platonism, they take proper account of Aristotle, a large number of whose doctrines win acceptance. Simultaneously there develops a sort of \*scholasticism: the idea that faithfully copying the language of the ancient Greeks is the means whereby to advance spiritual culture.

2. Christian authors are published, and commentaries on them are written. This is because those engaged in philosophy are also theologians, with a lively faith in the power of Christianity to mould the individual, especially from the perspective of the Greek Orthodox religion. (The second tendency is not seldom at loggerheads with the first; but both are in agreement as regards the need for a 'learned' language.)

3. A majority of philosophers attempt a synthesis of Greek and Christian values in the light of the applied sciences now under cultivation in western Europe. The major figure in the nineteenth century is Peter Vrailas-Armenis (1812–84). Vrailas-Armenis accepts Plato's theory of \*innate ideas. His ontology is based on Aristotle's method in the *Categories*, whereas his argument for a provident deity is derived from the Christian creed. Parallel with this, he endeavours to assimilate the scientific findings of his time and to synthesize them into a unified theory of the cosmos and humankind.

This trend towards synthesis had a new lease of life in the twentieth century, in response to various stimuli: \*Kantian ethics, the work of the Baden and Marburg Schools, Hegel's system, and Herbart and Wundt's philosophy. No one school is dominant: instead, an eclectic spirit makes itself felt. The specificity of the cultural sciences is recognized. In the search for a more convincing theory of values, new methodological criteria are adopted. Outstanding figures in this movement include Constantine Tsatsos (1899–1987), President of the Greek Republic, the politician and Prime Minister Panayotis Kanellopoulos (1902–86), Theophilos Voreas (1873–1954), John Theodorakopoulos

(1900–81), Christos Androutos (1869–1935), and Alexander Tsirintanis (1903–77).

4. From the beginning of the twentieth century onwards, there is a radically different philosophical movement which questions traditional solutions and looks for alternatives in \*positivism and in a mechanistic account of life and the universe. A considerable number of its adherents embrace \*materialism and follow the \*Marxist view of man and society. Three very representative figures in this movement are George Skliros (1877–1919), Demetrios Glinos (1882–1943), and Avrotelis Eleftheropoulos (1869–1964).

5. After the Second World War, a dialogue develops between modern Greek philosophy and contemporary modes of thought such as \*analytic philosophy, \*existentialism, \*philosophy of language, \*phenomenology, the \*Frankfurt School, \*Thomism, personalism. Though the description and analysis of present currents of European thought is carried out by university lecturers and teachers in institutes of philosophy, one cannot make great claims for the existence of any philosophical school. Today's Greek philosopher continues to be an eclectic cherishing a belief in the regenerative powers of humanism. G.B.

G. E. Voumvlinopoulos, *Bibliographie critique de la philosophie grecque* (Athens, 1966).

**Green, Thomas Hill** (1836–82). English idealist philosopher and liberal political theorist. His \*idealism logically entails that something's being what it is essentially consists in its being related to other things. According to Green, no relations can be detected empirically, but they may be known by the rational self-conscious minds that construct them. Green emphasizes that this idealism is anti-empiricist because it includes the denial that what something is may be known by sense experience. Indeed, Green's contributions to the edition of Hume's works he helped to compile are critical of Hume's empiricism and his naturalism.

Green's \*liberalism is the doctrine that a minimal state is justified in so far as it maximizes the freedom of the individual. Hence the state may intervene to prevent the freedom of some citizens being curtailed by others. Green's holistic view of the state owes more to Hegel than to classical English liberalism, despite Green's endorsement of the principle that each individual's freedom should be maximized in so far as this is consistent with a similar freedom for every other individual. S.P.

T. H. Green, *Prolegomena to Ethics* (Oxford, 1883; new edn. with introduction by D. Brink, Oxford, 2003).

**Gregory of Rimini** (c.1300–58). A member of the Eremite Order of St Augustine, he taught at Paris, Bologna, Padua, and Perugia, and was Prior General of his order from 1357 till his death. He wrote an influential commentary on the *Sentences* of Peter of Lombard, in which he has a good deal

to say about our knowledge of the external world. He accepts the common view that perception of the outer world requires species which emanate from outer objects and strike our receptors, and argues that in the absence of those objects we still know them, though 'abstractively', because we have intuitive, that is, immediate knowledge of the species which have lodged in our minds. In the case of our knowledge of outer objects, it is immediate in that though we cannot see such an object without the aid of the species emanating from it, we do not see the species themselves; the causal role they play does not involve their being perceived. To say otherwise would be to deny that we can have intuitive knowledge of external things.

G. Leff, *Gregory of Rimini: Tradition and Innovation in Fourteenth Century Thought* (Manchester, 1961).

**Grelling's paradox.** Due to Kurt Grelling (1886–1941), who was killed by the Nazis while trying to escape across the Pyrenees. Grelling defined the adjective 'heterological' to mean the same as 'not self-applicable'. This seems to entail that 'heterological' is heterological if and only if it is not heterological, which is impossible. Now whether 'not self-applicable' is self-applicable depends entirely on what that phrase means in application to itself. If it means 'expresses in itself a property it does not instantiate' then it is not self-applicable (and 'heterological' is heterological) because the phrase (the word), in itself, does not express any property. It expresses different properties depending on its application. If it means 'yields a true sentence when grammatically self-applied', then "'Not self-applicable" is not self-applicable' is a version of the \*liar paradox, and similarly with 'heterological'.

Kurt Grelling, 'The Logical Paradoxes', *Mind* (1936).

— and L. Nelson, 'Bemerkungen zu den Paradoxien von Russell und Burali-Forti', *Abhandlungen der Fries'schen Schule* (1907–8).

**Grice, H. Paul** (1913–88). English philosopher best known for his work on meaning, especially the relation between speaker meaning and linguistic meaning. Grice, who was at Oxford until 1967 and at Berkeley thereafter, introduced several notions commonly employed by philosophers today. These include *conversational implicature*, what a speaker implies as opposed to what he says or what his words imply, and *reflexive intention*, a notion central to the idea of speaker meaning (or \*communication). Grice maintained that speaker meaning is prior to linguistic meaning, i.e. that \*semantics reduces to \*propositional attitude psychology. Taken together, his notions have helped linguists as well as philosophers draw the line between semantics and pragmatics. The distinction between meaning and use has squelched such formerly popular philosophical claims as that looking red precludes being red or that believing something precludes knowing it, claims which were based on the fact that it is misleading to make a weaker statement when a stronger one is justified.

K.B.

Paul Grice, *Studies in the Ways of Words* (Cambridge, Mass., 1989).

— *Aspects of Reason* (Oxford, 2001).

**Griffin, James** (1933– ). Moral philosopher best known for work on \*well-being, interpersonal comparison of well-being, and consequentialism. His first book was *Wittgenstein's Logical Atomism* (Oxford, 1964). In *Well-Being* (Oxford, 1986), Griffin argues for an 'informed-desire theory': well-being consists in the possession of those objects one would desire if rational and informed. These are accomplishment, the components of human existence (autonomy, basic capabilities to act, etc.), understanding, enjoyment, and deep personal relations. The good-making property of these objects is not their fulfilling desires, so Griffin is best interpreted as moving beyond a preference-based theory of well-being to an objective account in the tradition of Aristotle, G. E. Moore, and Rashdall. Though Griffin sees promotion of well-being as the animating aim of morality, he is not clearly utilitarian. He stresses the many levels of moral thinking—personal, political, etc.—and each level has its own characteristic principles.

R.CRI.

\*consequentialism.

**Grossmann, Reinhardt** (1931– ). Born in Berlin; professor at Indiana University, Bloomington, since 1962. Grossmann's work is notable for its openness to both contemporary 'analytical' philosophy and 'modern continental philosophy'. For example, he is the author of not only *Reflections on Frege's Philosophy* (1969) but also *Meinong* (1974) and *Phenomenology and Existentialism* (1984). In his own thinking, Grossmann has developed a neo-Kantian epistemology according to which what passes for reality is determined by an intellectual categorical framework. This is apparent in *The Structure of Mind* (1965) and *The Categorical Structure of the World* (1983).

S.P.

\*Meinong.

**Grosseteste, Robert** (c.1170–1253). A Suffolk man, he became Chancellor of Oxford University c.1221, Archdeacon of Leicester in 1229, and was Bishop of Lincoln from 1235 till his death in 1253. He wrote on a wide range of topics in philosophy and theology from an essentially Augustinian perspective. In line with that perspective, which itself is strongly influenced by Platonic and biblical ideas, he placed the concept of light at the centre of his metaphysics, and also at the centre of his epistemology, where he gives an account of human understanding in terms of natural, and ultimately divine, illumination. Grosseteste also composed numerous scientific treatises, being one of a small but growing band who recognized the

importance of experiment in the establishment of scientific truth. He was a pioneer in the Christian West as a translator of Aristotle from Greek into Latin. A.BRO.

J. McEvoy, *Robert Grosseteste* (Oxford, 2002).

**Grotius, Hugo** (1583–1645). Lawyer, poet, and theologian, he mediated classical and medieval political and legal theory to the Enlightenment. While Descartes meditated in army winter quarters, Grotius was a political prisoner planning his masterwork, *De Iure Belli ac Pacis* (On the Law [and Rights and Wrongs] of War and Peace, 1625).

The philosophical concepts he elaborated with juridical learning and creative statesmanship were transposed from late medieval theology. Moral requirements would be valid even if one granted (*etiamsi daremus*) God's non-existence. Natural moral law identifies acts as morally necessary or base (and divinely commanded or forbidden) because 'conformable (or disconformable) with rational and social nature'. \*Rights are powers or liberties; political society is for safeguarding individual moral rights. Hume's celebrated 'is-ought' paragraph targets his evasive natural law theory, Rousseau's *Social Contract* his social contract theory. J.M.F.

— *Philosophy and Government 1572–1651* (Cambridge, 1993).

**grue**. Imagine a time  $t$ —say midnight on 1 January 2020. Define 'x is grue' to mean 'x is examined before  $t$  and is green or x is examined after  $t$  and is blue'. If generalizations are confirmed by their instances, then the fact that all emeralds so far examined are green confirms the generalization that all emeralds are grue as well as the generalization that all emeralds are green: but the consequences of the two generalizations are different and the former seems quite bizarre. This is Goodman's 'new riddle of \*induction'. Goodman introduced the idea of the entrenchment of a predicate (or more properly its extension) in an attempt to distinguish those generalizations which are genuinely confirmed by their instances. M.C.

N. Goodman, *Fact, Fiction, and Forecast*, 4th edn. (Cambridge, Mass., 1983).

**Grünbaum, Adolf** (1923–). A prolific philosopher of science, he has made many contributions to both philosophy of physics and philosophy of psychiatry. Perhaps the most striking claim argued for in his *Philosophical Problems of Space and Time* (1963; expanded edn. 1973) is the thesis that physical geometry and chronometry are, in part, matters of convention because continuous physical space and time are metrically amorphous. His influential *The Foundations of Psychoanalysis* (1984) contains a critique of the scientific credentials of Freudian psychoanalytic theory; it argues that there are methodological and epistemological reasons to think that some central Freudian doctrines are not well supported by empirical evidence. Grünbaum's more recent studies in the philosophy of psychoanalysis treat in detail such topics as the psychoanalytic theory of transference,

the viability of the single-subject case-study method, the placebo concept, and the dream theory. P.L.Q.

\*psychoanalysis, philosophical problems of.

A. Grünbaum, *Validation in the Clinical Theory of Psychoanalysis* (Madison, Conn., 1993).

**guilt**. The state imputed to a person who has done moral or legal wrong. It is distinguishable from having a sense, or feelings, of guilt, since a guilty person may not experience such feelings, and an innocent person may be burdened by unwarranted feelings of guilt. The crux is the question: Was avoidable wrong done by this responsible moral agent?

Full acceptance and realization of guilt involves remorse and desire to expiate the wrong done. Ill-managed or excessive guilt can be morally crippling; but equally damaging to moral seriousness is the attempt to disown real guilt—as pathological or as never more than the effect of external conditioning. Mature commitment to moral obligations deeply affects a person's conception of his own identity, and entails a strong sense of guilty failure on being disloyal to them. Yet guilt is not simply self-reproach: it is inseparable from awareness of the harm, or neglect, brought about to the others affected by one's action or inaction.

The neighbouring concept of shame both overlaps and diverges interestingly from the logical behaviour of guilt. A sense of shame is a sensitivity to the moral criticism of others—especially when one is tempted to fall short of basic standards of decency or integrity. To be ashamed is not only to acknowledge one's objective guilt, but also to be painfully and depressedly aware of moral failure, of lost esteem and self-esteem, prompting withdrawal from others' gaze. To be shameless (compare guiltless!) is to lack such sensitivity: when I am guilty, I ought to be ashamed of myself. R.W.H.

\*forgiveness.

R. Spaemann, *Basic Moral Concepts* (London, 1989), chs. 6 and 7.

**guru**. The Sanskrit word means 'weighty'. A guru is a preceptor who had the weighty role of preserving the oral wisdom called Veda. Veda is supposed to have been taught originally by God, who is the primordial guru. In ancient times pupils staying at a guru's home for twelve years had to learn Vedic hymns and rituals, along with phonetics, grammar, astronomy, metrics, rhetoric, logic, and metaphysics. A worshipful attitude towards a guru is inherent in Indian culture—whence the perverted Western use of the term for a cult-leader. In the tradition of \*Tantra, the word is broken up into *gu* meaning 'darkness' and *ru* meaning 'light', signifying the role of a spiritual eye-opener. Buddhism, which denies the knowledge-yielding capacity of testimony, recommends reliance on one's own reason rather than on a guru. A.C.

\*Vedānta; Indian philosophy.

# H

**Habermas, Jürgen** (1929– ). A second-generation member of the \*Frankfurt School whose work has ranged widely over issues in epistemology, philosophy of language, political and constitutional theory, ethics, and aesthetics. In the late twentieth century the most eminent (as well as controversial) figure in German socio-cultural debate, chiefly because he engaged with these issues not only at a specialist or academic level but also through regular interventions in the broader public sphere. Indeed, it is among his leading claims that this kind of two-way flow between ‘expert’ discourses and matters of shared communal concern is vital to preserving the values of an open participant democracy. Hence Habermas’s many journalistic writings about the post-war West German constitution, about developments in the wake of unification, about asylum-seekers, global justice, and the issue of national identity *vis-à-vis* the prospects for a federal Europe conceived in terms of a ‘cosmopolitical’ (post-nationalist) agenda. His earlier contribution to the so-called *Historikerstreit*—the debate about right-wing revisionist accounts of the Holocaust—is one striking instance of Habermas’s role as a public intellectual in the wider context of ethico-political discussion. Most recently he has carried this thinking forward to take account of the drastically changed world situation since the events of 11 September 2001 and the emergence of a US foreign policy with thinly veiled global geo-strategic aims.

Perhaps the most impressive feature of Habermas’s work is the way that these interests link up with his other, more ‘purely’ philosophical concerns. Influenced by, but also taking issue with, his teacher, Adorno, Habermas has devoted great energy to defending and reclaiming the values of Enlightenment critique, or what he calls the ‘philosophical discourse of modernity’. In early texts, such as *Knowledge and Human Interests* (1968), he adopts a broadly Kantian but also Marxist-inflected approach, one that seeks to reconstruct the genealogy of the modern natural and human sciences by inquiring back into their social, historical, and epistemological conditions of emergence. What this reveals is a process of increasing specialization in the various spheres of knowledge-constitutive interest, leading to a point where there seems little hope of an informed critical dialogue between them. Thus thought gives way to a naïve or unreflecting (positivist) conception

of scientific method, on the one hand, and on the other—in philosophy and the humanistic disciplines—to various forms of subjectivist, relativist, or downright irrationalist belief. Habermas’s aim is to offer an alternative account of this history that draws out *both* its symptomatic blind spots of prejudice, ideological investment, etc., *and* those critical or emancipatory resources which can yet be recovered through a reading alert to their presence in the texts of that same tradition. Hence his departure from Adorno’s mode of ‘negative dialectics’, a thinking that implacably refused the assurances of system or method, and which held out remorselessly against all ideas of achieved rational consensus. For Habermas, as likewise for Kant, such ideas have an indispensable role in orientating thought toward a regulative notion of truth at the end of inquiry.

In his later (post-1970) work Habermas adopts a very different perspective, an account of ‘communicative action’ derived largely from speech-act theory, sociolinguistics, and ideas about conversational implicature developed by thinkers like Paul Grice. One reason for this turn toward language (or \*discourse) is no doubt the currently widespread rejection of ‘foundationalist’ arguments in whatever shape or form. Another is Habermas’s growing conviction that Enlightenment thinking—or the ‘unfinished project’ of modernity—had run into precisely such criticism through its over-reliance on a subject-centred epistemological paradigm. His aim is therefore to reformulate that project in terms of a ‘transcendental pragmatics’, a theory that retains the basic commitment to values of truth, critique, and rational consensus, but which pins its faith on the regulative precept of an ‘ideal speech situation’, a public sphere of uncoerced participant debate wherein those values might yet achieve their fullest, least impeded, or distorted expression. Only thus can Enlightenment thinking make good its emancipatory claims without falling prey to the objections mounted by wholesale pragmatists (such as Richard Rorty) who carry this linguistic turn to the point of equating truth with whatever is currently and contingently ‘good in the way of belief’. During the past decade Habermas has shown a heightened awareness of developments in Anglo-American philosophy. Of particular interest is his lengthy exchange with Robert Brandom with regard to the latter’s

inferentialist account of epistemic commitment, an account which (as both parties agree) exhibits certain striking points of similarity and contrast with Habermas's theory of communicative action. He has also—in works like *Justification and Application*—explored the consequences of that theory for debates in ethics, jurisprudence, and other normative discourses.

Commentators differ sharply in their views as to how far this project stands up to the objections brought against it from various quarters, e.g. by post-modernists and hermeneutic thinkers in the line of descent from Heidegger and Gadamer. On one point at least there is general agreement: that Habermas has always sought to combine these philosophical interests with an active commitment to promoting informed discussion on issues of urgent socio-political concern. It is an example all the more impressive when compared with the stance adopted by those in the post-modern (counter-Enlightenment) camp who have no time for such old-fashioned ideas as 'the political responsibility of the intellectuals'. c.n.

**habit memory:** see memory.

**Hacking, Ian** (1936– ). Canadian philosopher, long based at the University of Toronto. Insisting upon the importance of the empirical, Hacking argues that philosophers too often over-value theory, and hence he would like to promote a 'back to Bacon' movement. Consistently, he accepts a doctrine of \*natural kinds, argues for epistemological differences between the natural and social sciences, and views realism–anti-realism debates which fail to take account of actual scientific practices (both in cosmology and in the microcosm) as empty. He is a noted Leibniz scholar. In *The Emergence of Probability* (1975) and *The Taming of Chance* (1990) he has given us ground-breaking accounts of two important periods in the history of \*probability. In philosophy of language he has mustered empirical evidence against claimed radical mistranslation, and similarly has contrasted actual languages without particulars (Wakashan languages such as Nootka and Kwakiutl) to Strawson's theoretical views. J.J.M.

Ian Hacking, *Representing and Intervening* (Cambridge, 1983).

— *The Social Construction of What?* (Cambridge, Mass., 1999).

**haecceity.** A \*property is something such that some things have or exemplify it; for example, red objects exemplify the property *being red*. A haecceity or individual essence is a property such that exactly one individual thing can have it. Thus, Socrates has the individual property of *being Socrates*. Some philosophers (e.g. Chisholm) argue, however, that there are no individual essences, only the

property of *being self-identical* and concrete individuals such as Socrates. M.B.

\*qualities; individual property; essence.

A. Plantinga, *The Nature of Necessity* (Oxford, 1974). Cf. R. M. Chisholm, *On Metaphysics* (Minneapolis, 1989).

**Halevi, Judah** (before 1075–c.1141). Hebrew poet and philosopher. Of a cultured family in the early Reconquista, Halevi travelled widely in Muslim and Christian Spain, winning fame for his poems, the finest in Hebrew since the Bible. As the Almoravid invasion devastated his world, Halevi practised medicine and wrote songs of love, wine, friendship, faith, and witness to the destruction around him.

Halevi's philosophic dialogue the *Kuzari* pictures the conversations that led the Khazar king to his historic conversion to Judaism. Having dreamed that his intentions but not his actions are pleasing to God, the king summons advisers. The intellectualism of the philosopher, he finds, critically needs fleshing out by ethical culture. Christian and Muslim doctrines clearly depend on Jewish lore. When a rabbi is finally summoned, he rests his case not on abstract reasoning but on historical experience, urging the primacy of the land, language, and peoplehood of Israel and addressing pure theology only after the Khazar is committed to the historic faith of Israel.

Although widely cited as an anti-philosophical thinker, Halevi is a serious *internal* critic of philosophy. His strikingly modern rejection of the baroque ontology of disembodied intellects between God and nature aids his philosophical task of showing how God's word enspirits the people of Israel, empowering them to achieve their mission to the nations. Like his literary persona, Halevi could not remain exiled in 'the farthest West'. He left Spain for the Land of Israel, where, according to legend, he was ridden down by an Arab and slain. L.E.G.

Judah Halevi, *The Kuzari*, tr. H. Hirschfeld (New York, 1964). The original title is preserved in *The Book of Vindication and Evidence in Behalf of the Despised Faith*. Critical edn. by David Baneth (Jerusalem, 1977).

**hallucination.** Seeing and hearing things when there is nothing of the sort to be seen or heard. What we observe is usually explained by our surroundings, so theorists readily assume that hallucinations are similarly explained by something image-like and introspectible in our heads. Philosophers who reject this as armchair psychology suggest that hallucinators just form false \*beliefs about what they perceive, whatever produces them being unavailable to the victim (if not to brain scientists). This 'belief' description, however, looks too intellectual if interpreted as entertaining thoughts about what you perceive, and too thin if interpreted as a disposition to act as if you perceive it; it is still hard to resist the idea that any false beliefs formed by hallucinators are *based on* what is happening to them, which is something *like* seeing or hearing. So what is the resemblance? J.E.R.S.

\*dreams.

P. Smith and O. R. Jones, *The Philosophy of Mind* (Cambridge, 1986), chs. 7 and 8.

**Hamilton, William** (1788–1856). Educated at Glasgow, Edinburgh, and Oxford, Hamilton first professed civil history at Edinburgh in 1821. He later transferred to logic and metaphysics, achieving eminence as a teacher and editor. His invaluable editions of Dugald Stewart and Reid are scholarly but patronizing. He criticizes Reid effectively, yet misrepresents him as saying that sensation is a subjective feeling of pleasure or pain. He deliberately set out to counterbalance the materialism of natural science which ignores God, freedom, and immortality. Believing \*knowledge to be perceptual, he called himself a 'natural or intuitive realist', although he admitted unconscious modifications of mind not accessible to consciousness but revealed through associations of ideas. Mill pointed out his inconsistency in holding that the primary qualities of objects are known while objects in themselves are not.

V.H.

William Hamilton, *Lectures of Metaphysics and Logic*, ed. H. L. Mansell and J. Veitch (Edinburgh, 1869).

**Hamlyn, David W.** (1924– ). Professor of Philosophy at Birkbeck College, London (1964–88), and editor of *Mind* (1972–84). Interests in Aristotle (translation of *De anima* with commentary (Oxford, 1968)) and in Wittgenstein have influenced Hamlyn's approach to questions in epistemology and philosophy of psychology. His central thesis (developed in *Experience and the Growth of Understanding* (London, 1978), *Perception, Learning and the Self* (London, 1983), and *In and Out of the Black Box* (Oxford, 1990)) is that in order to be a knower a being must be active and seek to regulate its beliefs in accord with a norm of truth; this requires membership of a community, interaction with which involves emotional responses. In short, knowers are social, affective agents. The other main area of Hamlyn's writing is history of philosophy.

J.HAL.

\*epistemology, history of; epistemology, problems of.

**Hampshire, Stuart Newton** (1914–2004). English philosopher with special interests in the philosophical theory of freedom and the philosophy of mind.

In the course of a long career in which he was Grote Professor of Philosophy at University College London, a professor at several American universities, and Warden of Wadham College, Oxford, Stuart Hampshire developed a distinctive and influential position. The key to his position is perhaps to be found in his early book *Spinoza* (1951) in which he explores Spinoza's conception of mind and will. These ideas were developed in much more detail in his major work *Thought and Action* (1959). In this book he examines a set of contrasts between that which is unavoidable in human thought and that which is contingent; between knowledge and decision; criticism and

practice; philosophy and experience. These contrasts continued to occupy his thinking in several later works. He was married to Nancy Cartwright.

R.S.D.

\*London philosophy.

**Hannay, Alastair** (1932– ). Professor emeritus at the University of Oslo, educated in Edinburgh and London, he continues the Scottish tradition of subjective idealism. In *Mental Images* (1971, reprinted 2003) he argues that visual images, like physical portraits, resemble visible objects. As a kind of sensation a mental image has material properties of its own which allow it to picture. He thus contradicts Ryle and Dennett. Hannay has translated Kierkegaard, and written an intellectual biography and a monograph about his philosophy. Under Hannay's direction (managing editor 1962–71, editor 1971–2002), *Inquiry* grew into a widely read philosophical journal. *Human Consciousness* (1990) reviews contemporary theories of human consciousness while maintaining a characteristic conservatism. Hannay argues that consciousness and the first-person point of view cannot be analysed or displaced by scientific materialism, nor can they be explained functionally, a view close to that of Reid, Hamilton, and Ferrier.

**Hao Wang:** see Wang, Hao.

**happiness.** Philosophical discussion of the concept of 'happiness' has tended to be found mainly within moral philosophy. It is associated especially with the classical \*utilitarianism of Jeremy Bentham and John Stuart Mill. The utilitarians assert that happiness is *as a matter of fact* the ultimate aim at which all human actions are directed and that it is therefore the ultimate standard by which to judge the *rightness or wrongness* of actions. 'Actions are right', says Mill, 'in proportion as they tend to promote happiness'—that is to say, 'the general happiness', the happiness of all concerned.

Still following Bentham, Mill goes on to equate happiness with 'pleasure and the absence of pain'. For Bentham the identity of 'happiness' and 'pleasure' is quite straightforward. An action's tendency to promote happiness is determined simply by adding up the amounts of pleasure, and subtracting the amounts of pain, which it will produce. It is a matter solely of quantitative factors such as the intensity and the duration of the pleasurable and painful feelings.

Mill is aware that this is altogether too crude. Happiness, he acknowledges, depends not only on the *quantity* but also on the *quality* of pleasures. Human beings, because of the distinctively human capacities they possess, require more to make them happy than the accumulation of pleasurable sensations. They are made happy not by the

'lower pleasures' but by the 'higher pleasures'—'the pleasures of the intellect, of the feelings and imagination, and of the moral sentiments'.

Mill departs still further from the purely quantitative notion of happiness when he recognizes that it is not just a sum of unrelated experiences but an ordered whole. To say that human beings aim at happiness is not to deny that they pursue more specific goals such as knowledge or artistic and cultural activity or moral goodness, and that they pursue these things for their own sake. These are some of the 'ingredients' which go to make up a life of happiness.

Mill is here attempting, perhaps unsuccessfully, to combine two traditions of thought about 'happiness'. The identification of 'happiness' with 'pleasure' we may call the 'hedonistic' conception of happiness. This we may contrast with what has been called the 'eudaimonistic' conception of happiness. The term comes from the Greek word *\*eudaimonia*, which is usually translated as 'happiness'. Although one of the Greek philosophical schools, *\*Epicureanism*, did identify *eudaimonia* with pleasure, the Greek concept lends itself less easily than the English term to this identification. In English one can speak of 'feeling happy', and although the relation between such states of feeling and a life of happiness is not entirely clear, they are undoubtedly connected—one could not be said to have a happy life if one never felt happy. The term *eudaimonia* refers not so much to a psychological state as to the objective character of a person's life.

The classic account of *eudaimonia* is given by Aristotle. He emphasizes that it has to do with the quality of one's life as a whole; indeed, he sees some plausibility in the traditional aphorism 'Call no man happy until he is dead' (though he also recognizes that there is little plausibility in calling someone happy *after* he is dead). For Aristotle happiness is to be identified above all with the fulfilment of one's distinctively human potentialities. These are located in the exercise of reason, in both its practical and its theoretical form. Aristotle is thus the ancestor of one strand in Mill, and of that general conception of 'happiness' which links it with ideas of 'fulfilment' and 'self-realization'.

**hard determinism:** see freedom and determinism.

**Hare, Richard M.** (1919–2002). Probably the most influential moral philosopher of his generation, Hare's ideas very largely shaped Anglo-American moral theory for upwards of twenty years, from the mid-1950s. His best-known works are *The Language of Morals* (Oxford, 1952) and *Freedom and Reason* (Oxford, 1963), in which he explores fun-

damental questions regarding the meaning of value and moral words such as *\*good* and *\*ought*, and regarding the foundations of moral reasoning. Hare argues that moral judgements have 'prescriptive' meaning, and imply universal imperatives. For instance, to declare something wrong is not (or is not principally) to indicate that it has some property of 'wrongness', but is to prescribe or direct its avoidance by anyone relevantly circumstanced. Because prescribing the doing or avoidance of something is logically distinct from giving a factual, descriptive account of the nature of the situation, Hare holds that there is no logical relationship between the facts of any case and the moral judgement we may make about it. But because of the universal (or 'universalizable') side of moral prescriptions, a person may be given cause to change his moral position by pointing out that it will also apply to himself in like circumstances. He will then realize that he is inconsistent if he does not wish to accept the prescription as applied to himself but still wishes to judge others in these terms. He must in consistency withdraw and revise his initial judgement. Hare's full statement of his developed theory of moral judgement and reasoning is in *Moral Thinking* (Oxford, 1981).

In later years, Hare made extensive application of his theoretical principles to practical questions of morality, the environment, education, and so on. Several collections of his essays in these areas have appeared, including *Essays on Political Morality* (Oxford, 1989) and *Essays on Religion and Education* (Oxford, 1992). Hare also wrote a short book on Plato (Oxford, 1982). He was White's Professor of Moral Philosophy at Oxford from 1966 until 1983, and he held many visiting professorships particularly in America and in Australia. A collection of essays debating his work was published in 1988, *Hare and Critics* (ed. D. Seanor and N. Fotion, Oxford). N.J.H.D.

\*prescriptivism; universalizability.

**harm.** Important to ethics and political philosophy, the concept is difficult to pin down. One view concentrates on consequences. A person is harmed by another if the actions of the 'harmer' negatively affect the interests of her victim. However, this must be specified further. If my health, say, was going to improve enormously relative to now, and you intervene (lightly poisoning me) so that it improves, but not as much as it would have, you have nevertheless harmed me in spite of my positive increase in health. One could instead say that harm is making me worse off than I would have been. This still faces a problem of overdetermination: what if Jane shoots me a millisecond before a boulder falls on me? She can argue that I am no worse off than I would have been had she not shot me; either way I am dead. But it still seems that she harmed me, even if it made me no worse off. Further, not all negative effects on my interests count as harm. Being fined thousands of pounds for fraud, whilst negatively affecting my interests, or losing my house because of another's contract enforcement, may not count as being

harmed. Problems for the view are especially salient in the ethics of creation. Imagine an embryologist who can choose which embryos to implant in women seeking to have children. She knows which embryos would be born with a painful genetic condition and which without. Does choosing embryos with the condition harm the resultant offspring? On the above view, it does not. For the choice with respect to each potential individual is existence with pain versus non-existence. The net gain of existing minus some pain must in most cases be more than not existing. Even if one concedes that comparing existence with non-existence is not to compare like with like, the problem remains. For, then, against what should we compare the offspring's medical state? The offspring's suffering is, nevertheless, due to the embryologist's choice. This perhaps points to some non-consequentialist features of harm, focusing, perhaps, on harmers' intentions, or some other characteristics of their actions.

A further problem is avoiding a collapse of the notion of harm into the related notion of wrong, or being wronged. If harming me is simply the commission of a morally wrongful act against me, then there will be as many notions of harm as there are moral principles of rightful action towards others which can be breached. A key question here is whether there can be a harmful but not wrongful act. Examples of accidental, or unavoidable, harms might bear out this distinction. There are also cases where we can place a person at a (morally) wrongful disadvantage, yet would decline to call this a harm. S.M.-G.

**Harman, Gilbert** (1938– ). Professor of Philosophy at Princeton University, best known for contributions in the philosophy of mind, epistemology, and ethics. Although it is common to equate 'being rational' with 'being logical', Harman distinguishes these sharply. Logic provides a theory of implication relations among sentences. 'If A then B', coupled with 'A', logically implies 'B'. An agent's accepting the first two statements, however, does not thereby rationally oblige him to infer or accept the third. At most, reason demands acceptance of 'B' or the rejection of either 'If A then B' or 'A'. In ethics, Harman advances a robust \*moral relativism according to which what agents 'ought' to do depends on socially reinforced principles they come to acquire. Agents imbued with different principles will be differently motivated, hence morally judge and act in different ways. J.HEIL

**harmony, logical.** In a \*natural deduction formalization of logic, harmony is a relation between the introduction

and elimination rules governing a logical constant which renders them in accord with one another: it is not possible to infer from a statement of a given form more than is warranted by the way in which that statement was arrived at in the first instance. The condition for this to hold good is precisely the condition that the basic step of normalization can be carried out with respect to a given logical constant, namely that, whenever in a deduction a statement is derived by an introduction rule, only to be used immediately as the major premiss of an elimination rule, a short cut is always possible that makes no use of that statement. This condition is plausible independently of Prawitz's idea for a proof-theoretic justification of the elimination rules: namely as a formulation of the requirement of *harmony* between introduction and elimination rules. For if, with respect to a given logical constant, such harmony does not obtain, the addition of that constant to the language is a non-conservative extension, in that we can derive conclusions not containing that constant from premisses not containing it that we could not have derived in the language lacking the constant.

Disharmony occurs when the elimination rules are stronger than is warranted by the introduction rules, taken collectively. It can also occur that they are weaker. This may also be seen as a defect, though its effects are less serious: the condition that the elimination rules be no weaker than they need be may be termed *stability*.

If we distinguish what justifies the assertion of a form of statement and the consequences that follow from accepting it as two aspects of the linguistic practice governing it, these notions of harmony and of stability may be generalized from logic to the whole of language. They then become conditions, stronger than the requirement of consistency, for the proper functioning of a language, ones not guaranteed satisfaction by the mere existence and use of that language. **harmony, pre-established.** A theory associated with the philosophy of G. W. Leibniz. It is a basic thesis of Leibniz's philosophy that there are no causal interactions between created \*substances, although there appear to be. According to Leibniz the states of a created substance are causal consequences of its own preceding states, except for its initial state, which is brought about by God at its creation. Leibniz held that God so created substances that, although they do not causally interact, they behave just as we would expect them to behave were they to causally interact. Leibniz utilized this theory in order to provide an explanation for the relation of the mind to the body, although that is not its basic motivation. R.C.SLE.

\*occasionalism.

**Hart, H. L. A.** (1907–92). Philosopher and lawyer who with J. L. Austin was central to late 1940s Oxford analytical philosophy. His work while Oxford's Professor of Jurisprudence (1952–68) transformed philosophy of law (particularly analytical jurisprudence and \*legal positivism) by opening it to social theory mindful of the 'internal point of view' of social actors, and so to normative political and moral theory (conceived by Hart in liberal and Humean fashion). For Hart, our language is a reminder of the complexity and inner dimension of human affairs; philosophically sophisticated attention to it undermines simplifying and sceptical reductivisms, whether about causation (*Causation in the Law* (1959)), punishment and the mental element in crime (*Punishment and Responsibility* (1968)), or the general structure and functions of law (*The Concept of Law* (1961); *Essays on Bentham* (1982)). **Hartley, David** (1705–57). Hartley's interest was in the body's role in the production and association of ideas; he found the key in Newton's theory of vibrations. Hartley's major writing in English appeared in 1749. Here he develops the view that vibratory motions in the brain are set up by the nerves receiving impressions of external objects, acting through the ether, and these vibrations typically continue in the brain, as sensations, a short time after the removal of the external objects. Hartley's is a physiological explanation of the short persistence of a feeling after the removal of the stimulus. He also undertakes a 'deduction' of the character of each type of sensation from the theory of vibrations. Ideas of heat, cold, sight, etc. and sexual desires result from the vibratory effect in the 'medullary Particles', specifically from the kind and locality of the vibrations in the brain, and the line of direction of influences from nerves to the brain.

His writings contain a 'natural Assent' argument for a first cause and an account of moral-political matters and their dependence upon 'the Christian Revelation'. D.G.

\*associationism.

**Hartmann, Eduard von** (1842–1906). German philosopher who tried to reconcile Schopenhauer with Hegel, Schelling, and Leibniz. In *The Philosophy of the Unconscious* (1869; tr. London, 1931) he argued that the unconscious \*Absolute is both will and idea, which respectively

account for the existence of the world and its orderly nature. Will appears in suffering, idea in order and consciousness. Thus there are grounds for both \*pessimism and optimism, and, since the Absolute is one, these must be reconciled. As the cosmic process advances, idea prevails over will, making possible aesthetic and intellectual pleasures. But intellectual development increases our capacity for pain, and material progress suppresses spiritual values. Hence ultimate happiness is not attainable in this world, in heaven, or by endless progress towards an earthly paradise. These illusions are ruses employed by the absolute to induce mankind to propagate itself. We will eventually shed illusions and commit collective suicide—the final, redeeming triumph of idea over will. M.J.I.

D. N. K. Darnoi, *The Unconscious and Eduard von Hartmann* (The Hague, 1967).

**Hartmann, Nicolai** (1882–1950). German philosopher who abandoned his original neo-Kantian belief that objective reality is a mental construct and, in, for example, *New Ways of Ontology* (1942; tr. Chicago, 1953), developed a realist \*ontology. There are various levels of being: inorganic, organic, spiritual, etc. A higher level is rooted in a lower, but not wholly determined by it. Some categories are involved at all levels of being: e.g. unity and multiplicity, persistence and change. But each level has its own complex of categories (e.g. matter and causality at the inorganic level) which apply to a higher level (e.g. organic life) only with modifications. As well as general ontology, Hartmann produced a series of 'regional ontologies', exploring the categories of, for example, the human spirit and its objectifications and those of inorganic and organic nature. In *Ethics* (1926; tr. London, from 1932) he developed a non-formal theory of values which, though objective, have only ideal being and affect the world only in so far as men act on them. He denies the existence of a providential God, since it is incompatible with human \*freedom. Unlike Heidegger, he was concerned with beings, not \*being. M.J.I.

W. Stegmüller, *Main Currents in German, British, American Philosophy* (Bloomington, Ind., 1969).

**Hartshorne, Charles** (1897–2000). American process philosopher and theologian at the University of Chicago and the University of Texas who continued to the end of the twentieth century the 'process' tradition in which \*becoming is the primary reality. Although strongly influenced by his teacher Alfred North Whitehead, some of his ideas antedate his encounter with Whitehead and others are improvements on him. Like Whitehead, he holds a panexperientialism in which the basic units of reality are creative, experiential events. This doctrine does not imply that the reality of an electron is very similar to the reality of human consciousness, only that both are on a continuous spectrum of processive reality. Hartshorne's chief improvements are in the theory of compound individuals.

Hartshorne and Whitehead, as pantheists, hold that God transcends the world while including it. But, whereas for

Whitehead God is a single, everlasting entity, for Hartshorne God is a temporal society of experiential occasions.

Also an ornithologist, he published notable studies of birdsong. P.H.H.

**Harvard philosophy.** Harvard was founded in 1635, a century and a half before the achievement of independence by the United States. There were two distinguished philosophers during the colonial period, but they were both Yale men: Jonathan Edwards, the most rigid of determinists, and the American Samuel Johnson, a follower of Berkeley. The first capable Harvard philosopher was Francis Bowen, an adherent of the Scottish common-sense philosophy of Reid and Dugald Stewart, which dominated American universities from soon after its introduction to the country at the beginning of the nineteenth century. At Harvard it was expounded by Levi Hedge from 1795 to 1832 and then by Bowen from 1835 to 1889. The practical attraction of Scottish common-sense philosophy was that it offered a rational alternative to the fanatical excesses of Calvinist orthodoxy while resisting, on another front, the speculative nebulosities of the amateur philosophers of the Transcendentalist movement. C. S. Peirce, William James, and their early associate Chauncey Wright were all Bowen's pupils.

In the 1870s these three and others, including John Fiske, disciple of Herbert Spencer, formed a Metaphysical Society in which, under the influence of the prevailing Darwinian evolutionism, the ideas were worked out that were to constitute pragmatism, a Harvard invention. Peirce, like Wright, the most positivistic of the group, and Fiske, was associated only informally with Harvard after graduation. But his close relation to the much more immediately influential James gave his ideas, much more sophisticated than those of James, some currency. James was soon joined at Harvard by Josiah Royce, who combined an up-to-date interest in logic with the kind of idealism which holds that only mind is real and that all finite minds are included in an absolute mind.

James's most gifted student, George Santayana, was also his intellectually most disobedient one. Both were naturalists who wanted to find some place for religion in the scheme of things, but they went about the project in very different ways. James adjusted his concepts of truth and reality so as to accommodate his spiritual yearnings; Santayana affirmed the materiality of the real and saw mind as at once its product and decorator. He contributed in 1920 to the collective volume *\*Critical Realism*. The organizer of the earlier collection *\*The New Realism* (1912) had been Ralph Barton Perry, another Harvard teacher, loyal to the memory, if not the doctrine, of William James. He went on to write large, soft-centred books about ethics and the theory of value.

James died in 1910, Peirce in 1914, Royce in 1916, and Santayana had departed for Europe in 1912. It seemed that the golden age of Harvard philosophy, and of philosophy in America in general, had come to an end. Whitehead arrived in the mid-1920s to begin, in his sixties, a productive and obscurely brilliant new career as a speculative cosmologist, but he had little effect outside a small circle of devotees and a distantly admiring element in the general reading public. Harvard philosophy turned from James's conversational breeziness, Royce's pulpit eloquence, and Santayana's civilized belletrism to an altogether more rigorous and professional mode of philosophizing. The emblem of this change was C. I. Lewis, intensional logician, analytic theorist of knowledge, and combatively naturalist theorist of value, the best philosopher of the inter-war years in the United States. His abler associates were unproductive, his productive colleagues were not all that able. He was, therefore, somewhat solitary. But his main doctrines had a considerable overlap with those of the analytic philosophers of Britain and the Logical Positivists of Europe.

W. V. Quine arrived for graduate study in Lewis's time. From the start his interest in formal logic was accompanied by a concern for its philosophical underpinnings. He visited the Vienna Circle and was soon discarding some of their most treasured substantive beliefs, although not their methods and aims. As aspects of a comprehensive suspicion of the clarity and usefulness of the idea of \*meaning, he rejected the distinction between analytic truths (true in virtue of the meaning of their terms) and synthetic truths, reinstated ontology (condemned by the positivists as meaningless metaphysics), and denied the reducibility of all significant discourse to individually meaningful reports of immediate experience.

Something like a new golden age was clearly under way by the time of his *Word and Object* (1960). Harvard now established itself as the most important philosophical centre in the English-speaking world, reversing a cultural dependence on British philosophy which had been interrupted, but not overturned, by the episode of \*pragmatism. Quine's early ally Nelson Goodman joined him there, as, later, did Hilary Putnam and Robert Nozick.

**Hayek, Friedrich August von** (1899–1992). Although often regarded primarily as an economist (for which he won the Nobel Prize in 1974), Hayek's philosophical work was fundamental to his thinking. His basic insight is epistemological. Human knowledge is limited and reason constrained in many ways. These limitations become

particularly acute when attempting to survey and predict the workings of a large society, not just because of its complexity, but also because of general difficulties in knowing human social and economic behaviour in advance of the decision of agents, and because any predicting agency will itself become a player in the game. But the knowledge dispersed among millions of individual agents can be amplified and captured through the workings of the free market, and condenses in spontaneously developing traditions and customs. Hayek's epistemology thus leads to a defence of moral and institutional \*conservatism, as against rationalistic reformers, and of the free market, as against command economics (which interfere inefficiently with the flow of economic information within a society). The neglect of Hayek's ideas by philosophers is unfortunate because, though at times unclear and incomplete, they are both suggestive and influential. A.O.H.

F. A. von Hayek, *The Fatal Conceit* (London, 1988).

J. Gray, *Hayek on Liberty* (Oxford, 1986).

**heap, paradox of the.** Paradox due to vagueness. With a single grain of sand, you cannot make a heap. If you cannot make a heap with the grains you have, you cannot make one with just one more. So even with 10 million grains you cannot make a heap. Despite its antiquity, 'heap' may be badly chosen: arguably, you can make a heap of sand with just four or more grains (enough to make a stable heaping-up without adhesive). But the paradox can be recast, e.g.: 1 is a small number, and any number bigger by 1 than a small number is small; so all numbers are small. Responses include: denying the major premiss, that is, affirming that there is a sharp cut-off (even if we don't know where); and (alternatively) avoiding the conclusion by revamping classical logic and semantics. Mark Sainsbury, *Paradoxes* (New York, 1988), ch. 2.

**heaven.** The abode of God and the angels. Celestial paradise. The ultimate destination of the redeemed (e.g. in Job 3, Hebrews 12, and Luke 16). Once wholly free of sin, souls or resurrected persons in heaven enjoy the Beatific Vision, the intuition of God's essence. According to Job 3, the wicked no longer trouble those in heaven, the weary are at rest, both 'small' and 'great' are there, and the slave is free from the master. There are graphic descriptions of heaven in Revelation and in Dante's *Divine Comedy*.

Although spatial, heaven is not spatially related to ordinary space-time. Travel to heaven is only by dying and redemption, not by \*motion, so the existence of heaven is inconsistent with the Kant's thesis that there is only one space, because putatively distinct spaces will turn out to be spatially related. Heaven exists now (Romans 10: 6, 1 Thessalonians 1: 10, 4: 16) but is concealed by ordinary space-time events and sin. At death, the presence of God is revealed. S.P.

**hedonic calculus.** If the ultimate object of moral endeavour is to maximize pleasure, satisfaction, happiness; and if pleasures, miseries, and pains can be meaningfully represented on a single scale, and summed, then it may be thought possible to quantify the overall value or disvalue of particular acts or policies, and the desirability of introducing, or rescinding, laws. Jeremy Bentham (1748–1832) proposed a 'felicific calculus' which would take account of such factors as intensity, duration, the likelihood of an action producing further pleasure or unwanted pain . . . But the project of such a calculus must fail: human good and evil cannot be reduced to homogeneous sensation, positive and negative. Such a scale cannot display the moral urgency of remedying great evils, nor acknowledge that some pleasurable sensations (those of the sadist and rapist, for example) count wholly for the bad. R.W.H.

\*utilitarianism.

J. Bentham, *An Introduction to the Principles of Morals and Legislation* (1789).

**hedonism.** The doctrine that \*pleasure is the \*good. It falls into three main types not always distinguished by their proponents:

1. Psychological hedonism: pleasure is the only possible object of desire or pursuit. This may be held on observational grounds, or be thought to be necessitated by what we mean by 'desire'.
2. Evaluative hedonism: pleasure is what we ought to desire or pursue.
3. Rationalizing hedonism: pleasure is the only object that makes a pursuit rational.

(2) and (3), when made explicit, seem to suppose the falsity of (1) in that they suppose it possible, wickedly or irrationally, to pursue something other than pleasure.

Usually the pleasure in question has been thought to be the subject's own pleasure, and so the view has been a form of egoism; but there is no reason in theory why it should not be the pleasure of humans, or even of sentient beings generally. Where psychological hedonism is in question, this has not proved a popular line, but utilitarians have developed altruistic versions of (2).

Utilitarians are committed to comprehensive and long-term calculations of pleasure. Egoists may also consider the subject's long-term pleasure; or they may consider that the immediate option which in itself yields or is thought to yield greater pleasure ought to be or is pursued. Some hedonists seem only or mainly to have so-called physical pleasures in mind; others, like John Stuart Mill, have a penchant for the pleasures of civilized discourse. There are clearly, then, many versions of hedonism, and two apparently identical views may, further,

turn out to be very different when one considers the proponents' views of the nature of pleasure.

Arguments for hedonism will vary according to type. Psychological hedonists ought to show either that all pursuits are in fact aimed at what the subject takes to yield pleasure; or that we only count as really wanted what the subject either believes will produce pleasure, or is pleased at the prospect of. There is a risk of retreating into the second kind of position whenever the arguments for the first begin to look a little shaky. There is a further risk of moving without notice from points about what the subject thinks will yield most pleasure to points about what they view with most pleasure in prospect, and in general to do the rounds of a variety of explanations in the pleasure family without inquiring whether there is a legitimate route from one to the other.

Evaluative hedonists may be content to describe their end to us in the hope of winning converts. Sometimes it seems that a supposedly familiar morality is taken as given and desirable, and hedonism is propounded, and so defended, as the rationale of our moral thought and practice. This is particularly likely to happen with utilitarianism, which might, it is hoped, be seen both as making sense of what we do and as enabling us to see how to sort out the muddles we get into morally. Most forms of hedonism are egoistic in form and are seen by opponents, and sometimes by proponents, as hostile to traditional morality and Victorian values.

Rationalizing hedonists will tend to invite us, by consideration of examples, to recognize that our criterion of rationality is the presence of a bedrock justification in terms of pleasure. This is usually a version of psychological hedonism applied not to all our pursuits or desires, but to our practice of reflective evaluation.

All long-term versions of hedonism have to face the problem of how pleasure is to be measured. These problems are aggravated if there have to be cross-personal comparisons, as in utilitarianism.

In classical Greece and Rome (\*hedonism, ancient), the doctrine was in various forms popular and much discussed. It underwent a revival in post-Cartesian philosophy, especially among the British Empiricists, although the most unequivocal hedonist, Helvétius, was produced by the continent of Europe. In Britain it tended either to take a utilitarian form, or to be made the basis of a utilitarian development. A combination of partial truth, general cynicism about human motivation, and confusion of a variety of different familiar explanations of behaviour will probably ensure the recurrent attractiveness of some form of the doctrine.

John Skorupski, *John Stuart Mill* (London, 1989).

T. Sprigge, *The Rational Foundations of Ethics* (London, 1987).

**hedonism, ancient.** The central questions of ancient ethical theory concerned the nature of the good life (i.e. the life most worth living) and the conditions of its achievement. (\**Eudaimonia*.) Given that focus, the role of \*pleasure in the good life was a topic which, throughout antiquity, was rarely far from the central area of debate. In particular, the thesis that pleasure is the good was urged on different grounds by various individuals and schools, and as vigorously disputed by their opponents.

*The Pre-Platonic Period.* The pre-philosophical beginnings of Greek ethical thought, represented by the didactic poetry of the seventh to the fifth centuries BC, show an ambivalent attitude to pleasure. While a few passages advocate the cultivation of the pleasures of the moment, the prevailing attitude is cautious, stressing the dangers of excessive indulgence. Yet the latter attitude too can tend towards a more enlightened hedonism, as in the \*Sophist Prodicus' fable of the choice of Heracles between virtue and vice, in which the hero chooses virtue on the ground that, while vice offers more immediate pleasure, virtue offers a pleasanter life in the long run, taking into account the pleasures of good reputation and friendship, which are forfeited by a life of vice. This contrast between immediate pleasure and the pleasure of one's life, viewed as a whole, comes to the fore in Democritus, who is reported to have held that the supreme good is a state of tranquillity of mind (thereby anticipating Epicurus' doctrine of \*ataraxia. But tranquillity must be conceived, not merely negatively, as the absence of disturbance, but as a pleasant state. Democritus seems, then, to have maintained that the choice of particular pleasures and pains must be made on the basis of their contribution to the good life, i.e. to the pleasant life of tranquillity (for which his own term was *euthumia*, whose ordinary sense is cheerfulness). This 'enlightened' hedonism may be contrasted with the view of Aristippus, that the supreme good is the pleasure of the moment.

*Plato.* Traces of both kinds of hedonism may be discerned in the dialogues. In the *Protagoras* Socrates presents (whether as his own position or as the best available basis for popular morality is disputed) a version of Democritean enlightened hedonism, incorporating the idea of a calculus of pleasures and pains. Callicles in the *Gorgias*, on the other hand, advocates the Aristippean ideal of a life devoted to the satisfaction of short-term bodily appetite, supporting this evaluation by the claim that the goal to which nature prompts every agent (indeed every animal) is the satisfaction of its desires, and by the identification of pleasure with the satisfaction of desire, a conception which is not distinguished from that of the making good of a physiological deficiency. The conception of pleasure as a natural goal is central to most ancient discussions of hedonism. The modern distinction between psychological hedonism (a theory of motivation) and evaluative hedonism (a theory of value) was not drawn. Rather, both proponents and opponents of hedonism agreed that the natural direction of motivation, for humans as well as for

other animals, either determined or served as evidence for the good of the organism thus motivated, but differed on whether that direction was towards pleasure. Socrates' response to Callicles is therefore to argue that every agent is naturally motivated to seek his own good, not his immediate pleasure, and that the pursuit of one's good requires that one differentiate good (i.e. good-promoting) pleasures from bad (i.e. harmful) ones. Plato's own views on the topic seem to have undergone some development. While he may at an early stage have espoused Democritean hedonism (if the hedonism of the *Protagoras* represents his own view), the position defended in the middle and later dialogues is that, while the good life is indeed pleasant (and in the *Republic* the pleasantest of all lives) its pleasantness is merely an adjunct to its goodness, which consists, not in pleasantness, but in rationality.

*Aristotle.* Like Plato, Aristotle both provides evidence of ongoing debate on the value of pleasure and contributes to that debate himself. The *Nicomachean Ethics* contains two substantial and independent treatments of pleasure (that in book vii probably belonging originally to the *Eudemean Ethics*), each of which starts from a confrontation of various opposed views, the extreme positions being on the one hand the view of the contemporary philosopher and mathematician Eudoxus that pleasure is the \*good, and on the other the thesis, usually attributed to Plato's nephew Speusippus, that pleasure is an evil. Of those two, Aristotle's own position is closer to the former, but it is dubious whether he endorses Eudoxus' view without qualification. He rebuts the attacks on pleasure by arguing that they rely on a mistaken account of its nature, namely the view (see above) that pleasure consists in the process of remedying a natural deficiency in the organism. For Aristotle, pleasure is not any kind of process. Rather it occurs when a natural potentiality (e.g. for thought or perception) is realized in perfect conditions (when, for instance, the mind is working well, free from distractions, thinking about worthwhile objects, etc.). Every kind of actualization has its own specific pleasure, e.g. the pleasures of thought, and the bodily pleasures of sex, food, and drink. Since *eudaimonia* itself consists in excellent realization of the capacities for thought and for rational choice, it follows that the good life is characterized by the greatest degree of pleasure. It is, however, disputed whether Aristotle goes so far as to identify the perfection of perfect realization with its pleasantness. While he appears to endorse that identification in *Nicomachean Ethics* vii, in book x he appears to say (obscurely) that pleasure is not perfection itself, but a feature supervenient on it 'like the bloom on the cheek of youth' (1174<sup>b</sup>33). He gives no hint, however, of what that feature might be, and some commentators argue that it is nothing other than perfection itself, and that what it supervenes upon is not (as normally assumed) perfection, but the simple activity.

*The Post-Aristotelian Period.* Some of the positions mentioned above continued to have their adherents in this period. Among proponents of hedonism a major dispute

was that between on the one hand the \*Cyrenaics, who developed the Calliclean position by maintaining that the supreme good is the pleasure of the moment and that bodily pleasures are of higher value than mental, and on the other Epicurus and his school, who developed the Democritean ideal of the life of pleasant tranquility as the supreme good. Epicurus took over Eudoxus' argument that the natural impulse of all animals to seek pleasure shows it to be good, and distinguished two types of pleasure, that experienced when the organism is making good a deficiency and that experienced when the organism is in a stable state, free from all pain or disturbance; the latter type was assigned supreme value. His identification of the latter with the absence of pain has been criticized as confused, but seems in fact to have been the unexceptionable doctrine that a painless, trouble-free life is *ipso facto* pleasant. **Hegel, Georg Wilhelm Friedrich** (1770–1831). Of all the major Western philosophers, Hegel has gained the reputation of being the most impenetrable. He was a formidable critic of his predecessor Immanuel Kant and a formative influence on Karl Marx. Through his influence on Marx, Hegel's thought has changed the course of nineteenth- and twentieth-century history.

Hegel lived and worked in what we now know as Germany, although in his time the many independent states of the region had not been united into one nation. He came of age at the time of the French Revolution, sharing what he later called 'the jubilation of this epoch'. His career included periods as a private tutor, and nine years as the headmaster of a secondary school, before his growing reputation gained him a university chair. He ended his days as Professor of Philosophy at the University of Berlin, which under the reformed Prussian monarchy was becoming the intellectual centre of the German states.

Hegel wrote several long and dense books, of which the most important are *The Phenomenology of Mind*, *The Science of Logic*, and *The Philosophy of Right*. His *Encyclopedia of the Philosophical Sciences* is a summary version of his philosophical system. A number of other works were delivered as lectures, and in some cases published after his death from his lecture notes. These include his *Lectures on the Philosophy of History*, *Lectures on Aesthetics*, *Lectures on the Philosophy of Religion*, and *Lectures on the History of Philosophy*.

Hegel is a difficult thinker because all his work reflects a systematic view of the world, and he makes few concessions to those not familiar with his way of thinking. In addition his style is anything but 'user-friendly'; at first

## CONTINENTAL EUROPEAN PHILOSOPHY: THE INFLUENCE OF HEGEL

**G. W. F. HEGEL:** the lasting hostility of most Anglophone philosophers to his difficult and ambitious system failed to prevent the diffusion of his influence into most streams of philosophy.

**KARL MARX** adopted Hegel's theory of the process of historical development, but gave matter rather than spirit the central role in the process. So it was that his philosophy came to be described as dialectical, historical, or scientific materialism; for him, production is the determining material function of humans.

**GEORG LUKACS,** Hungary's most famous philosopher. The life of a prominent public intellectual was not a tranquil one in the Communist world. Twice briefly a government minister, twice exiled, Lukacs was endlessly attacked by rival ideologues but managed to survive Stalin's Russia and grow old in his native city of Budapest.

**BENEDETTO CROCE** developed a Hegelian philosophy of spirit, of which his aesthetics was most notable, and put forward a view of philosophy as history. The second great Neapolitan philosopher, 650 years after Aquinas.

glance most readers will find his sentences simply incomprehensible. This has led some to denounce him as a charlatan, hiding an emptiness of thought behind a deliberate obscurity of expression in order to give an air of profundity. Yet the meaning of Hegel's writing does, eventually, become apparent after careful study. Though his philosophical system as a whole finds few adherents today, his writings yield original insights and arguments that illuminate many philosophical, social, and political issues.

The easiest point of entry to Hegel's thought is his *Lectures on the Philosophy of History*. One of Hegel's greatest contributions to our intellectual heritage is—as Marx appreciated—his grasp of the historically conditioned nature of our thinking. One might ask why a philosopher should write a work that is, in one sense, a brief outline of the history of the world, from ancient times to his own day. The answer is that for Hegel the facts of history are raw material to which the philosopher must give some sense. For Hegel thought that history displays a rational process of development, and, by studying it, we can understand our own nature and place in the world. This idea of history having meaning can be interpreted as a reworking of the religious idea that the world was created by a being with some purpose in mind; but it may also be understood in a more limited way, as a claim that history has a direction that we can discern, and is heading to a goal that we can welcome.

Hegel presents his view of the direction of history in a famous sentence from the introduction to *The Philosophy of History*: 'The history of the world is none other than the progress of the consciousness of freedom.' The remainder of the work is a long illustration of this thought. Hegel begins with the ancient empires of China, India, and Persia. Here, he says, only one individual—the ruler—is free. The subjects of these oriental despots, Hegel thought, lacked not merely political freedom, but even the very awareness that they are capable of forming their own judgements about right or wrong. It was only in ancient Greece that the principle of free individual thinking developed, and even then Hegel saw the Greeks as so closely identified with their city-state, and so much ruled by its habits and customs, that they did not see themselves as independent individuals in the modern sense. Though the spark of individuality was lit by the critical thinking of Socrates, individuality did not triumph until the Protestant Reformation recognized that each individual can find his or her own salvation, and gave the right of individual conscience its proper place.

For Hegel the course of history since the Reformation has been governed by the need to transform the world so as to reflect the newly recognized principle of individual freedom. The era of the \*Enlightenment, culminating in the French Revolution, was an attempt to abolish every institution that depended on mere custom, and instead ensure that the light of reason, to which every individual can freely assent, guides every aspect of our political and social lives. To Hegel this attempt was based on a 'glorious mental dawn': the understanding that thought ought to

govern reality, instead of the other way around. Yet the French revolutionaries misunderstood reason, taking it in too abstract a way, without considering the nature of existing communities and the way in which these communities have formed their inhabitants. Thus the abstract universalism of the Enlightenment led to the excesses of the guillotine. Yet now that we understand what is needed, Hegel concluded, a fully rational organization of the world—and hence a truly free community—is ready to unfold.

Hegel's conception of freedom is central to his thought, but it often misleads modern readers brought up on a conception of freedom made popular through the writings of such classical liberal thinkers as John Stuart Mill. According to the standard liberal conception, I am free when I am left alone, not interfered with, and able to choose as I please. (\*Freedom and determinism; \*liberty; political freedom.) This is, for example, the sense of freedom used by economists who picture consumers as free when there are no restrictions on the goods and services they can choose to buy in a free market. Hegel thought this an utterly superficial notion of freedom, because it does not probe beneath the surface and ask *why* individuals make the choices they do. Hegel saw these choices as often determined by external forces which effectively control us. He even anticipates, by more than a century, the modern critique of the consumer society as creating needs in order to satisfy them: he points out that the need for greater 'comfort' does not arise within us, but 'is suggested to you by those who hope to make a profit from its creation'.

Behind such insights lies Hegel's grasp of history as a process that shapes our choices and our very nature. So to be left alone to make our own choices without interference by others is not to be free; it is merely to be subjected to the historical forces of our own times. Real freedom begins with the realization that instead of allowing these forces to control us, we can take control of them. But how can this happen? As long as we see ourselves as independent beings with conflicting wills, we will always regard the existence of other human beings as something alien to ourselves, placing limits on our own freedom. In the classical liberal tradition, that is simply the way the world is, and there is nothing that can be done about it. For Hegel, however, the problem is overcome when we recognize that all human beings share a common ability to reason. Hence if a community can be built on a rational basis, every human being can accept it, not as something alien, but as an expression of his or her own rational will. Our duty and our self-interest will then coincide, for our duty will be rationally based, and our true interest is to realize our nature as a rational being.

In his belief that we are free only when we act in accordance with our reason, Hegel is in agreement with Kant; and so too when he sees our duty as based on our reason; but Hegel criticized Kant's notion of morality, based as it is on a \*categorical imperative derived from pure reason, as too abstract, a bare formal framework lacking all

content. Moreover, on Kant's view human beings are destined for perpetual conflict between duty and interest. They will always be subject to desires that they must suppress if they are to act as the categorical imperative commands. A purely rational morality like Kant's, Hegel thought, needs to be combined in some way with the ethical customs that are part of our nature as beings of a particular time and place. Thus Hegel sought a synthesis between our concrete ethical nature, formed in a specific community, and the rational aspect of our being. When this synthesis was achieved, we would have a community in which each of us would find our own fulfillment, while contributing to the well-being of the whole. We would be free both in the subjective sense, in that we could do as we wished to do, and in the objective sense, in that we would rationally determine the course of our history, instead of being determined by it. This would then be a truly rational state, reconciling individual freedom with the values of community.

In *The Philosophy of Right*, Hegel describes this rational community in a manner that parallels—though is not identical with—the Prussian monarchy of his own day. For this he was accused by Schopenhauer of selling himself to his employer. After Hegel's death, the Young Hegelians, a group of young radicals that for a time included Marx among its members, thought that in *The Philosophy of Right* Hegel had betrayed the essence of his own philosophy. They determined to develop his ideas in a way that was truer to the core of his thought than Hegel himself had been. From this group arose the criticism of religion developed by Bruno Bauer and Ludwig Feuerbach, Max Stirner's individual anarchism, developed in his *The Ego and its Own*, and such early writings of Marx as *The Economic and Philosophical Manuscripts of 1844* and *The German Ideology*.

More recently Karl Popper has seen Hegel as a precursor of the modern totalitarian state. Popper argues that by exalting the rational state and using the concept of freedom in a way that denies that irrational choices are truly free, Hegel made it possible for later authoritarian rulers to justify their tyranny by saying that they must force their citizens to be free. It may be true that Hegel's philosophy is open to this misreading, but it is a misreading. The real Hegel supported constitutional monarchy, the rule of law, trial by jury, and (by the standards of his day) considerable freedom of expression. He would never have regarded the kind of state set up by Hitler or Stalin as a rational state with free citizens.

Yet Popper has touched on a real problem in Hegel's philosophy. Hegel was driven by an extraordinary optimism about the prospects of overcoming conflict between human beings, and hence of bringing about a rational and harmonious community. The roots of this optimistic view lie in his metaphysics, and especially in his concept of *Geist*. This German word can be rendered in English, according to the context, either as \*'spirit' or as \*'mind'. In the former sense it can have religious connotations; in the second it is the normal word used to describe

the mental or intellectual side of our being, as distinct from the physical. Because the German term covers both these meanings, Hegel is able to use it in a way that suggests an overarching collective Mind that is an active force throughout history, and of which all individual minds—that is, all human beings, considered in their mental aspect—are a part. Thus Hegel sees the study of history as a way of getting to know the nature of *Geist*, and sees the rational state as *Geist* objectified. Since there is no ideal English translation, I shall henceforth use the capitalized term 'Mind' to express Hegel's concept of *Geist*.

Hegel's greatest work is his *The Phenomenology of Mind* (sometimes referred to in English as *The Phenomenology of Spirit*), described by Marx as 'the true birthplace and secret of Hegel's philosophy'. In it Hegel seeks to show that all human intellectual development up to now is the logically necessary working out of Mind's coming to know itself. The logic of this process is, however, not the traditional logic of the \*syllogism, but rather Hegel's own dialectical logic. In dialectical logic, we start from a given position—as an example, we might take the customary ethics of ancient Greece. Then we find that this position contains within itself the seeds of its own destruction, in the form of an internal contradiction. The questioning of a Socrates leads eventually to the downfall of customary ethics, for example, and its replacement during the Reformation by a morality based on individual conscience alone. Yet this too is one-sided and unstable, and so we must move to a third position, the rational community. This third position combines the positive aspects of its two predecessors.

This \*dialectic is sometimes referred to as a movement from *thesis* to *antithesis* to *synthesis*. In the example given, the customary morality of ancient Greece is the thesis, the Reformation morality of individual conscience its antithesis, and the rational community is the synthesis of the two. This last is, in Hegel's philosophy of history, the final synthesis, but in other instances, the synthesis of one stage of the dialectic can serve as the thesis for a new dialectical movement. In *The Science of Logic*, Hegel applies the same method to the abstract categories with which we think. Here Hegel starts with the bare notion of existence, or being, and argues that since this bare notion of being has no content at all, it cannot be anything. Thus it must be nothing, the antithesis of being. Being and nothing, however, are opposites, constantly moving in and apart from each other; they require to be brought together under the synthesis, becoming. Then the dialectic moves on, through many more obscure stages, until in the end Hegel claims to be able to demonstrate the necessity of absolute \*idealism: that is, that the only thing that is ultimately real is the absolute idea, which is Mind, knowing itself as all reality.

Absolute idealism seems a strange doctrine, but it was by no means unique to Hegel. Kant had already argued that the mind constitutes the known universe because we can only know things within a framework of our own creation, namely the categories of time, space, and substance.

Yet Kant thought that beyond these categories there must be the \*‘thing-in-itself’, forever unknowable. In doing away with the ‘thing-in-itself’, and saying that all we know is also all that there is, Hegel was following the line of Kantian criticism developed earlier by Johann Fichte.

Both *The Phenomenology of Mind* and *The Science of Logic*, then, have the same process as their subject, the process of Mind coming to know itself as ultimate reality. In the *Phenomenology* this process is presented by an attempt to show the logical necessity inherent in the historical development of human consciousness. In the *Logic* it is shown as a pure dialectical necessity, as (Hegel tells us) showing ‘God as he is in his eternal essence, before the creation of nature and of a finite mind’. The *Logic* is, therefore, by far the more abstract and difficult work. The *Phenomenology* is, by comparison (but only by comparison), a gripping account of how the finite minds of human beings progress to a point at which they can see that the world beyond them is not alien or hostile to them, but a part of themselves. This is so, because Mind alone is all that is real, and each finite mind is a part of Mind.

One curious aspect of the enterprise of the *Phenomenology* is that it seeks to understand a process that is completed by the fact that it is understood. The goal of all history is that mind should come to understand itself as the only ultimate reality. When is that understanding first achieved? By Hegel himself in the *Phenomenology*! If Hegel is to be believed, the closing pages of his masterpiece are no mere description of the culmination of everything that has happened since finite minds were first created: they are that culmination.

In the light of Hegel’s belief that all finite minds share in a greater underlying reality, we can appreciate why he should have believed in the possibility of a form of society that transcended all conflicts between the individual and the collective, and was truly free while at the same time in no sense anarchic. We can also see why this belief should have made it possible for Hegel’s ideas to lead some of his successors, Marx among them, to a similarly misplaced optimism about the possibility of avoiding such conflicts. For while Marx claimed to have rejected the ‘mysticism’ in which Hegel enveloped his system, Marx never freed himself from the conviction that history is tending toward a final destination in which there will be complete harmony between the interests of the individual and the common interests of the community. That is why he believed that \*communism would be a condition in which everyone freely advanced the common interests of all. p.s.

**Hegelianism.** ‘Hegelianism’ refers not only to the doctrines and methods of Hegel himself, but to those of his followers, especially, but not only, in Germany.

Even in Hegel’s lifetime, the obscurity and ambiguity of his teaching gave rise to disagreement over its significance. Does his claim that ‘what is rational is actual and what is actual is rational’ imply that everything that exists, including for example the Prussian state, is as it should be, or rather that whatever is not as it should be, even though it exists, is not genuinely ‘actual’? Do his resounding tributes to the \*freedom and self-consciousness attained in the modern world imply that significant history, including the history of philosophy, has come to an end? Does his belief that \*God is not *distinct* from the world mean that God does exist or that he does not? Does his claim that religion and philosophy have the same ‘content’ but present it in different ‘forms’ (imagination and thought, respectively) imply that religion and the Church are now dispensable? Does his assertion that the spirit is eternal amount to an endorsement of the orthodox belief in immortality?

Hegel himself does not supply unequivocal answers to these questions, and this omission is connected with several important features of his thought:

1. Hegel believed his own philosophy to be not ‘one-sided’, like most philosophies of the past, but the ‘universal’ philosophy, embracing and ‘sublating’ (or cannibalizing) all significant past philosophies, doing justice to realism or materialism as well as idealism, to atheism as well as theism, and so on. (But Hegel is not a dualist, or a monist, or a pluralist. The best numerical account of him is that he is a Three-in-One-ist.)

2. Another reason why Hegel’s system refuses to yield ‘straight’ answers to ‘straight’ questions is that he attempts to examine the terms in which questions are framed, often pre-empting them for purposes of his own, or assigning them a developing series of interconnected meanings. Does Hegel believe that God exists? It depends on what we mean by ‘God’, ‘believe’, and ‘exist’.

3. He believes that at their extreme points opposites veer into each other. For example, if we take theism seriously and say that a truly infinite God cannot be distinct from the world, but must be in some sense identical with it, this takes us to the brink of saying that the world is everything and God nothing.

4. In the past, humanity has advanced owing in part to its tendency to reflect on its own condition. In reflecting on a philosophy, we develop new thoughts or categories that are at most implicit in the philosophy on which we reflect, and in reflecting on historical events we acquire new thoughts that were not available to the participants in those events. We cannot learn from history, since in

thinking about past events we change ourselves, so that our situation and the problems it presents are now importantly different from those of the past. It is not the philosopher's or the historian's business to predict, or plan for, the future, in part because significant future events will involve new thoughts or categories which are not yet available to him. But Hegel's reluctance to discuss the future, together with his insistence on the universality and completeness of his own system, left it unclear whether there is any possibility of significant future developments in philosophy or in history. Is his own system 'infinite' in the sense that reflection on it, unlike past philosophies, generates no categories not already contained in it? If so, he seems to exclude the possibility of further interesting philosophical or historical developments. If it is not so, he still gives his followers no firm guidance on what to do in the changed historical circumstances following his death.

5. As a philosopher, Hegel inclined to aloof objectivity, to detached observation of the conflicts of the past and the fates of the opposing, but interdependent, parties—factions, states, religions, philosophies, and so on. He also believed, however, that such conflicts and the spiritual advances which they generated would not have been possible if men had not passionately and resolutely championed a one-sided cause, if they had for the most part abstained from a decision in stoical or ironical detachment or dithered in the middle ground. (Conflict, as well as reflection, is required if humanity is to remain alive and awake.) Thus as a *philosopher* he favoured impassioned engagement on the part of the *citizen* in the conflicts of his age. But as a philosopher he can give no clear guidance to the Hegelian citizen as to which side he should choose.

Hence Hegel's followers gave different answers to the above questions, answers which characteristically reflected their *own* prior beliefs, religious and political as well as philosophical, and which tended to fall into coherent clusters. \*Right Hegelians', such as Karl Göschel (1784–1862), interpreted Hegel as a supporter of clerical orthodoxy and of political restorationism, the attempt, under way from 1815, to restore the old order undermined by the French Revolution. By contrast, \*Left Hegelians', such as Feuerbach, Stirner, Bruno Bauer, and David Strauss (1808–74), were religious and political radicals. In the centre stood moderate reformists, such as Karl Rosenkranz (1805–79). (Left and Right Hegelians were also referred to, respectively, as 'Young' and 'Old' Hegelians; but this nomenclature has the defect that it provides no term for the centre and also implies that ideology depends on age.) The Left Hegelians are of more intrinsic interest than the Right or centre. They made significant contributions to theology and biblical criticism (Feuerbach, Strauss) and heavily influenced Marx.

The Hegelian movement disintegrated in Germany in the early 1840s. It remained strong in Denmark long enough to provoke Kierkegaard's continuous polemic against 'the [Hegelian] system'. Hegelianism was established in Britain by James Hutchinson Stirling's *The Secret*

*of Hegel* (1865), and the British idealists (Green, Bradley, Bosanquet, McTaggart) found in Hegel an antidote to empiricism, utilitarianism, and *laissez-faire* economics. (But McTaggart, unlike Hegel, was a staunch individualist and free-trader. This coheres with his intense belief in individual immortality—which he erroneously attributed to Hegel.) In the USA Hegelianism was represented by William Torrey Harris and Josiah Royce, and left its mark on pragmatism. Hegelianism flourished in Italy from the first half of the nineteenth century (Gioberti, Rosmini) until well into the twentieth (Croce, Gentile). In France it was established by Victor Cousin and influenced, among others, Taine and Renan; Hegel was revived in the 1930s by the lectures of Alexandre Kojève, who read him through Marxist and existentialist lenses. (In France in particular, the *Phenomenology of Spirit*, rather than the later system, has been especially influential, along with Marx's early philosophical writings.) In the English-speaking world, Hegel survived the attacks of Russell, Moore, and Popper, and remains popular and influential.

Hegel's influence has outlasted anything resembling a Hegelian 'movement'. It has certain noteworthy features:

1. No one of consequence, with the possible exception of Hegel himself, has been an undiluted Hegelian. The reason for this is not simply that much of his thought is superseded (especially by advances in the natural sciences), but that Hegel's thought is too rich, complex, and ambivalent for any single individual to swallow it whole. But many philosophers, such as Sartre and Derrida, digest parts of his thought and assimilate them to their own constitution. Even Hegel's immediate followers did this, since no single one of them, however Hegelian by profession, could encompass the whole of his thought; his thought is refracted, so that different elements in it are represented by different Hegelians.

2. Hegel's influence has often weighed as heavily on his opponents as on his avowed followers. This influence takes different forms. \*Existentialism, for example, arose in conscious antagonism to Hegel: its rejection of systems, its insistence on human finitude, its stress on crucial decisions which cannot be determined by philosophical reason or by historical learning, essentially depend on a contrast with Hegel (or some similar figure, such as Aquinas, who supposedly believed the contrary. But the anti-Hegelian often absorbs Hegel's ideas in the process of combating them. Heidegger, for example, consciously set his own thought in opposition to Hegel's. His view was that Hegel's system deepens our 'forgetfulness of being'. It perpetuates Aristotle's misconception of time. It is a part of the 'tradition' which distorts our view of the genuine philosophers of Greece and which must be 'destroyed' or deconstructed if we are to appropriate the past. For Hegel, the history of philosophy is (circuitously) progressive, later philosophies, especially his own, preserving all that is true in past philosophies. For Heidegger, by contrast, philosophy has declined: crucial questions have been obscured and forgotten, crucial concepts distorted and enfeebled.

The truth can only be recovered by a line-by-line examination of ancient texts (such as Plato's *Sophist*, Hegel's own favourite Platonic dialogue), and also by exploring the history of philosophy in reverse, starting with Kant, for example, and progressively peeling away the accumulated layers of distortion until we arrive at the unblinkered vision of, for example, Parmenides. But the result of Heidegger's quest is a view remarkably similar to Hegel's own: his 'history of being', in which being achieves illumination through man, owes far more to Hegel's 'history of spirit', in which the \*Absolute attains self-consciousness in the development of the human spirit, than to Parmenides. (It also owes much to Schelling, whom Heidegger studied intensively in the 1930s and whose portrait, as legend has it, he put up in place of Kant's.)

3. If Hegel saw his own philosophy as complete and definitive, to propose a significant philosophical idea which Hegel did not consider and which he cannot accommodate or sublimate is sufficient to refute him. It is, however, less easy than one might suppose to devise a view that Hegel has not already considered. This is due in part to the power of his intelligence and imagination, but in part also to the fact that his work concludes and synthesizes an immensely rich period in the history of human thought, in which he encountered viewpoints similar to those later revived by his critics. Hegel knew of, and rejected, something like Russell's theory of definite descriptions: he, like Russell, found it in Leibniz. He knew of someone rather like Kierkegaard, and described him, under the title of the 'unhappy consciousness', in his *Phenomenology of Spirit*: he found him, perhaps, in Johann Georg Hamann (1730–88) or among the Romantics, for example in Novalis (Friedrich von Hardenberg, 1772–1801). He found a precursor of Sartre's studiously unsystematic Genet, whom Derrida counterposes to Hegel, again among the Romantics or in Diderot's portrayal of *Rameau's Nephew* (which Hegel read in Goethe's translation of 1805).

Because of this richness Hegel can accommodate a diversity of 'one-sided' interpretations: he has, for example, been variously seen as an existentialist, a Marxist, and a Wittgensteinian. But if the one-sided positions of his successors become tiresome or obsolete, one can always return to Hegel and find in him a new one-sided position or, alternatively, a comprehensive, many-sided objectivity with regard to the multifarious conflicts of the past and the present. **hegemony.** From the Greek verb meaning 'to lead', hegemony has sometimes been used as a synonym for

domination. In its subtler sense, however, it implies some notion of consent and is particularly associated with the writings of the Italian Marxist Antonio Gramsci. Drawing on writers such as Machiavelli and Pareto, Gramsci argues that a politically dominant class maintains its position not simply by force, or the threat of force, but also by \*consent. That is achieved by making compromises with various other social and political forces which are welded together and consent to a certain social order under the intellectual and moral leadership of the dominant class. This hegemony is produced and reproduced through a network of institutions, social relations, and ideas which are outside the directly political sphere. Gramsci especially emphasized the role of intellectuals in the creation of hegemony. The result is one of the most important, if elusive, concepts in contemporary social theory. D.M.L.

**Heidegger, Martin** (1889–1976). German philosopher usually seen as a founder of Existentialism. He prepared the ground for his major work, *Sein und Zeit* (Being and Time (1927; tr. Oxford, 1962; New York, 1996)), with some lucid and solid, if unremarkable, writings, which anticipated several themes of his mature work. 'The Problem of Reality in Modern Philosophy' (1912) argued against various versions of \*idealism, including Kant's critical idealism, and in favour of critical \*realism. It criticizes the stress on epistemology characteristic of philosophy since Descartes. 'New Investigations of Logic' (1912) assessed recent work on logic, including that of Frege, Russell, and Whitehead, from the standpoint of Husserl's critique of psychologism. (In conformity with his doctrine of truth as 'unconcealment', the mature Heidegger had little sympathy for the traditional 'logic of assertion'; like the later Wittgenstein, he would be more inclined to found arithmetic on everyday activities such as counting and measurement than on the principles of logic.) *The Doctrine of the Judgement in Psychologism* (1914), his doctoral dissertation, opposed the reduction of logic to psychological facts and processes. His habilitation thesis, *Duns Scotus's Doctrine of Categories and of Meaning* (1916), shows the respect for metaphysics, history, and subjectivity which marks his later work; it examines a treatise, *Grammatica Speculativa*, which has since been attributed to Thomas of Erfurt, but Heidegger's thought has often been seen as akin to Duns Scotus', even as 'secularized Scotism'. His habilitation lecture, 'The Concept of Time in the Discipline of History' (1916), argued that time as seen by historians differs from the quantitative time of physics: it is not uniform, but articulated into qualitatively distinct periods, such as the Victorian era, whose significance depends on more than their temporal duration.

From 1916 to 1927 he published nothing, but studied widely, especially Husserl's 'phenomenology', Scheler's philosophical \*anthropology, Dilthey's \*hermeneutics,

and the texts of St Paul, Augustine, and Luther. Christianity supplied examples of momentous, historic decisions, important in his later work, but also an ‘ontology’ distinct from that of the Greeks. At the same time he lectured, with enthralling brilliance, on these and other themes. (Most of his publications were based on lectures.) He taught at Marburg, 1923–8, and Freiburg, 1928–44. He was elected Rector of Freiburg in 1933, but resigned in 1934. In 1945 he was forbidden to teach, owing to his links with Nazism, until 1951. His initial support for Nazism was rooted not in anti-Semitism, but in distaste for technology and industrialized mass society, which he associated with the USA and the USSR; later he regarded Nazism as an aspect of technological modernity and its ‘forgetfulness of being’ rather than as an abnormal excrescence. His conduct as Rector, his private beliefs, and the relationship of his thought to Nazi ideology are still matters of controversy.

*Being and Time* (*Sein und Zeit*, 1927) crystallized his study of virtually the whole of past and contemporary philosophy. Its central concern is the ‘question of being’. Since the beginnings of philosophy in Greece, being (*Sein*) has been ill at ease with time. It has been insulated from change by being seen as *presence*, to the exclusion of past and future—not necessarily temporal presence, but also the atemporal, eternal presence of, for example, Plato’s Forms. This affects our conception of the world, including man himself. Heidegger proposes to revive the long-forgotten question of the ‘sense of being’, and to practise ‘fundamental ontology’, an ontology underpinning the ‘regional’ ontologies dealing with the being of particular realms of entity, such as nature and history. To examine being as such, we need to consider a particular type of entity: namely, the entity that asks the question ‘What is \*being?’ and whose ‘understanding of being’ is an essential feature of its own being, i.e. man or \**Dasein*. *Dasein*’s being is *Existenz*: it has no fixed nature, but ‘its essence lies in its always having its being to be, and having it as its own’. (*Existenz* is used in its root sense of ‘stepping forth’, as in Walter Bagehot’s description of ‘those who live during their life, whose essence is existence, whose being is animation’. Heidegger disclaims any similarity to Sartre’s doctrine that ‘existence precedes essence’.) Why does this mean that being must be approached by way of *Dasein*? In conducting such a large, amorphous inquiry as the question of being, we no doubt need to take our bearings from our ordinary implicit understanding of being, and this will involve a preliminary examination of *Dasein*. But Heidegger also says that ‘there is being, only as long as *Dasein* is’, suggesting that being, if not entities, depends on our understanding of it. This perhaps gives a stronger reason for approaching being by way of *Dasein*: Heidegger agrees with Kant and Husserl that how things are depends in large measure on what we contribute to them, with the difference that ‘we’ are concrete, ‘existing’ human beings, rather than pure consciousness.

Although *Dasein* is essentially ‘ontological’, that is, has an understanding of being, the philosopher cannot simply adopt *Dasein*’s own understanding of itself and other

entities. For *Dasein* tends systematically to misinterpret itself and its world, regarding itself, for example, as a thing on a par with other things. Much of the vocabulary of traditional philosophy—‘consciousness’, ‘subject’, ‘object’, etc.—is infected with such misinterpretation. Thus Heidegger (like ‘analytical’ philosophers such as Wittgenstein, Ryle, and J. L. Austin) avoids such terminology, preferring non-committal terms such as ‘*Dasein*’ or down-to-earth words (such as *Sorge*, ‘care’) which carry no burden of philosophical assumptions. (In accordance with Heidegger’s view that silence is an ‘essential possibility of discourse’, his readers need to bear in mind the words he purposely avoids, as well as those he uses.) Like Husserl, he attempts to describe ‘the things themselves’, without the help of theories and preconceptions; unlike Husserl, he holds that this requires a determined recasting of philosophical language. He uses old words in unusual ways, often appealing (like Austin) to etymology, and sometimes coins new words; but his coinages are invariably in the spirit of the German language. His terminology is marked by an aversion to the static ontology of substance, stemming from Aristotle, and a preference for a more dynamic, verbal ontology: *Dasein*, for example, is not primarily a solid, biological substance that occasionally acts; it is essentially and primarily activity. (*Being and Time* is strangely silent about sleep.) In giving the correct or ‘authentic’ term for, or account of, a phenomenon (such as man, time, or truth) he does not simply counterpose this to the degenerate term or account; he attempts to explain why the degeneration occurred. It is not enough to show, for example, that Descartes was mistaken to regard man as a \**res cogitans*. One must also show, in terms of the correct account of man, how the mistake arose. Misinterpretation is not sheer, unaccountable error, but a ‘possibility’ to which *Dasein* is essentially prone.

For Heidegger, unlike Descartes, *Dasein* is essentially ‘in-the-world’ and is inseparable from the world: ‘In understanding the world, Being-in is always understood along with it, while understanding of existence as such is always an understanding of the world.’ The world is not primarily the world of the sciences, but the everyday world, the \*‘life-world’ (Husserl). It is disclosed to us not by scientific knowledge, but by pre-scientific experiences, by ‘care’ and by moods. Entities in the world are not primarily objects of theoretical cognition, but tools that are ‘ready to hand’ (*zuhanden*), such as a hammer, to be used rather than studied and observed. Theoretical cognition, as when I observe a hammer (or a beetle) disinterestedly, is a secondary phenomenon, which occurs especially when a tool fails to give satisfaction, when, for example, the hammer breaks. Tools are not independent of each other, but belong to a ‘context of significance’, in which items such as hammers, nails, and work-bench ‘refer’ to each other and ultimately to *Dasein* and its purposes. Tools or equipment form a coherent world, radiating out from *Dasein*, in a way that objects of theoretical cognition (such as Descartes’s *res extensae*) do not. This world is correlative to, even ‘projected’ by, the *Dasein* that ‘steps forth’ into it.

Just as *Dasein* is in the world, so it is essentially 'with' others of its kind. It does not first exist as an isolated subject and then subsequently acquire knowledge of and relations to others; it is with others from the start. But others threaten its integrity: 'as being together with others, *Dasein* stands in thrall to others. It itself is not; the others have usurped its being'. 'The self of everyday *Dasein* is the they-self, which we distinguish from the authentic self, the self that has itself in its own grip.' 'They' is the German *man*, 'one': the they-self does and believes what *one* does and believes, rather than what it has independently and authentically decided on. Heidegger's theory of the They or One (*das Man*), is influenced by Tolstoy's *The Death of Ivan Ilyich*: Ivan's carefully redecorated house seems quite exceptional to him, but in fact contains 'all the things people of a certain class have in order to resemble other people of that class'; when Ivan's family discuss Sarah Bernhardt's acting, it is 'the sort of conversation that is always repeated and always the same'. The account of everyday life, which Heidegger initially presents as a neutral account of man's bedrock condition, becomes an account of man's 'fallenness' and inauthenticity.

Inauthenticity and the They are not, however, unmitigated evils. Scheler accused Heidegger of a 'solipsism of *Dasein*': each of us inhabits our own world together with our own others. Descartes may be vulnerable to such a charge, but Heidegger is not. For him, the shared, public world is the world as *one* sees it, not the world as *I* see it. Without such a public world, and therefore a dose of inauthenticity, even the most authentic of us would be unable to engage in coherent, purposeful action. Heidegger believed, for example, that to do philosophy properly we must be authentic, somewhat detached, that is, from 'everydayness' and also from the concerns of run-of-the-mill philosophy. We need to rethink the tradition by returning to early philosophers, such as Plato. But Heidegger believes that Plato is an early philosopher because that is what *they* say; he goes to a library to read him because that is where *one* goes to read a book; he is not naked, since *one* wears clothes in a library. If Heidegger had decided all such matters from his own, individual resources, he would hardly have got around to philosophy. On the other hand, we would not expect Heidegger to say about Plato only what *one* says about Plato. Coherent thought and action require a discriminating blend of authenticity and inauthenticity.

The primary form of 'talk' (*Rede*), for Heidegger, is not explicit assertion, such as "This hammer is heavy", but such utterances as "Too heavy! Give me a lighter one" made in a context of significance. Explicit assertion arises only with *Gerede*, 'idle talk', which retails talk beyond its original context, and thus gives rise to language. Truth too is not primarily the correspondence between an assertion or proposition and a state of the world, but the disclosure of the world to and by *Dasein*, unmediated by concepts, propositions, or inner mental states; at bottom, truth is '*Dasein*'s disclosedness', a necessary condition for both truth and falsity in the ordinary sense. (He supported this

by appeal to the Greek word for truth, *alētheia*, which, he claimed, means 'unconcealment'.) Meaning, like truth, is extruded from the mind:

Mill's allegedly verbal propositions cannot be completely severed from the beings they intend. Names, words in the broadest sense, have no a priori fixed measure of their significative content. Names, or again their meanings, change with transformations in our knowledge of things, and the meanings of names and words always change according to the predominance of a specific line of vision toward the thing somehow named by the name. All significations, including those that are apparently mere verbal meanings, arise from reference to things. (*The Basic Problems of Phenomenology*, lectures given in 1927 (published 1975; tr. Bloomington, Ind., 1982), 197)

The \*representative theory of perception is rejected along with the \*correspondence theory of truth: 'What we "first" hear is never noises or complexes of sounds, but the creaking wagon, the motor-cycle . . . It requires a very artificial and complicated state of mind to "hear" a "pure noise".' *Dasein* interprets things all the way down, so that a *Dasein*-independent account of them can hardly be given. Hence the problem of the reality of the \*external world, like that of the existence of other minds, is a pseudo-problem: for Kant, the 'scandal of philosophy' is that no proof has yet been given of the 'existence of things outside of us', but for Heidegger the scandal is 'not that this proof has yet to be given, but that *such proofs are expected and attempted again and again*'.

*Dasein* must be considered as a whole, and this requires an account of \*death. *Dasein* can be genuinely authentic only in its 'being towards death', since here it accepts its finitude. *Dasein* is individualized by death: it dies alone, and no one else can die in its place. Death is a criterion of authenticity: I must recognize that *I* will die, not simply that *one* dies. There is a pervasive tendency to conceal the inevitability of one's own death. (Like Kierkegaard and Tolstoy, Heidegger cites the old syllogism 'All men are mortal. Caius is a man, so Caius is mortal': "That Caius, man in the abstract, was mortal", mused Tolstoy's Ivan, 'was perfectly correct, but he was not Caius, not an abstract man, but a creature quite, quite separate from all the others.'). Authentic being towards death is related to 'resoluteness' (*Entschlossenheit*): only if I am aware of my finitude do I have reason to act now, rather than to procrastinate, and it is the crucial decision made with a view to the whole course of my life that gives my life its unity and shape.

Authentic *Dasein*, and even inauthentic *Dasein*, is essentially 'temporal', unfolding in the 'ecstases' of future, past, and present. The future, running ahead to death, is the primary 'ecstasis'. (The root meaning of 'ecstasis', like that of 'existence', is 'stepping forth'.) A decision is also constrained by a situation inherited from the past and the more important it is, the more it will be taken in view of the past. The authentic present is the 'moment' of decision:

To the anticipation which goes with resoluteness, there belongs a present in accordance with which a resolution discloses the situation. In resoluteness, the present is not only brought back from

distraction with the objects of one's closest concern, but it gets held in the future and in having been. That present which is held in authentic temporality and which thus is authentic itself, we call the 'moment of vision' [*Augenblick*; 'instant, moment', but literally 'eye-glance'].

Several features of time have been ignored by the Aristotelian tradition. (An Aristotelian view of time inspired Russell's claim that it would make little difference if our present position were reversed, that is, if we barely remembered the past, but foresaw much of the future. This applies to the time of physics, but not to the time of action and decision: in deciding whether to do this or that, I characteristically do not yet know which I shall do.) Time is significant: it is time to do such-and-such. Time is datable by events: it is the time *when*, for example, I first went to Marburg. Time is spanned: now is not a durationless instant, but now, *during*, say, the lecture. Time is public: we can all indicate the same time by 'now' or 'then', even if we date it by different events. Time is finite: (my) time does not run on for ever, but is running out. History is to be understood in terms of this account of time and of *Dasein*'s 'historicality'. *Dasein*'s understanding of itself and the world depends on an interpretation inherited from the past. This interpretation regulates and discloses the possibilities open to it. Inauthentic *Dasein* accepts tradition unthinkingly and fulfils the possibilities shaped by it; authentic *Dasein* probes tradition and thereby opens up new and weightier possibilities. Heidegger, for example, does not simply contribute to contemporary philosophical controversy, but by 'repeating' and 'de(con)structing' crucial episodes in the development of our philosophical tradition hopes to change the whole course of philosophical inquiry. It is only because *Dasein* is historical that history in the usual sense is possible: 'Our going back to "the past" does not first get its start from the acquisition, sifting and securing of such material [namely, remains, monuments, and records]; these activities presuppose *historical Being towards the Dasein* that has-been-there—that is to say, they presuppose the historicality of the historian's existence.'

*Being and Time* remained unfinished: the third section of part 1, which was to explicate being in terms of time, and the whole of part 2, which was to examine Kant, Descartes, and Aristotle, never appeared. But shorter works of the same period fill some of the gaps. His Freiburg inaugural lecture, 'What is Metaphysics?' (1929), expands on 'the nothing', which made a brief appearance in *Being and Time*, and which is disclosed in the 'Angst that reveals to *Dasein*, in its freedom and finitude, the ultimate groundlessness of itself, its world, and its projects. *Kant and the Problem of Metaphysics* (1929; tr. Bloomington, Ind., 1962) argues that the first *Critique* is not a theory of knowledge or of the sciences (as such neo-Kantians as Hermann Cohen, Paul Natorp, and Ernst Cassirer held), but lays the foundation for metaphysics. Kant saw that reason, knowledge, and man in general are finite, and thus made the transcendental imagination the basis of the possibility of synthetic a priori knowledge. But since this threatens the

primacy of reason and the foundations of 'Western metaphysics', Kant recoiled from the 'abyss' in the second edition of the *Critique* and made the imagination a 'function of the understanding'. Heidegger's interpretation was attacked by most Kant scholars, including Cassirer; he implicitly retracts some of his views in later essays on Kant.

Heidegger published little in the 1930s, but lectures delivered then and published later suggest that at that time he abandoned many of his earlier views, especially on the centrality of *Dasein*. In 'On the Essence of Truth' (1943), 'truth, and by implication being, is no longer located primarily in *Dasein*, but is the 'open region' to which man is exposed. 'Plato's Doctrine of Truth' (1942) argued that in Plato's allegory of the cave truth ceased to be 'unhiddenness' and became, 'under the yoke of the *idea*', mere 'correctness', i.e. *our* ideas' correspondence to things. This initiated the degeneration of thought about being into 'metaphysics': man moved to the centre of things. The history of Western philosophy is a history of decline. This view reached its more or less final form in his 1935 lectures, *An Introduction to Metaphysics* (1953; tr. New York, 1961). The term 'metaphysics' alters its significance. For the early Heidegger it was a favourable term, approximating to '(fundamental) ontology'. In the late 1930s it became unfavourable, implying, among other things, an anthropocentrism of which *Being and Time* is not wholly innocent. However, since the missing third division of *Being and Time* was to examine being independently of *Dasein*, it may be that Heidegger's later works develop ideas he had formed earlier.

Heidegger's late philosophy emerges for the most part in 'conversations' with past thinkers, especially poets such as Hölderlin who offer a way out of 'forgetfulness of being'; and the Pre-Socratic thinkers (Anaximander, Parmenides, and Heraclitus) who preceded it, and the 'most unbridled Platonist in the history of Western metaphysics', Nietzsche (*Nietzsche* (1961; tr. New York, 1979–87). ('Truth', Nietzsche said, 'is the sort of error without which a definite type of living entity could not live. Ultimately, the value for life decides.' This is 'metaphysical', because it locates truth in man's thought; it is 'Platonist', because it assumes a realm of values distinct from the world.) Being becomes ever more elusive in his writings, barely describable except in such tautological terms as 'It gives itself'. The 'ontological difference', the crucial distinction between being and beings, is differently described at different times. Heidegger sometimes supplements this 'twofold' with a 'fourfold' inspired by Plato and Hölderlin: earth, world (or sky), gods, and men. Despite his denials, being resembles God. It is not at man's disposal; it disposes of man. Whatever happens comes from being. Man, the 'shepherd of being', must respond to its directions. It is above history, but since the time of Plato it has been hidden, and the 'history of being' can be reconstructed from the texts of philosophers and poets. Forgetfulness of being, 'nihilism', has culminated in the domination of the world by technology, which is not

primarily machines but an event in the history of being, 'the completion of metaphysics': everything, including eventually human beings, is regarded as a disposable resource. Whether or not we can return to genuine thinking of being will determine the future of the planet. He was not wholly pessimistic: 'But where there is danger, the remedy grows too' (Hölderlin). The effects of technology, as Heidegger describes them—homelessness, rootlessness, the flattening out of worldly significance—are similar to the effects he had earlier attributed to *Angst* and boredom, moods especially conducive to philosophy. (Such moods are the counterpart, in Heidegger, of Husserl's \*epochē, supplying what Husserl neglected: a motivation within everydayness for philosophical reflection.) Technology is double-edged. If we succumb to it, it threatens to turn us into the calculating functionaries that Heidegger found in the dystopian works of his friend Ernst Jünger. If we think about it in the right way, it offers an unprecedented prospect of philosophical illumination. How else can Heidegger explain how he, in this benighted age, succeeded in recovering the vision of the early Greeks?

The appropriate response to being is thinking. Thinking is our obedient answer to the call of being: the early Greeks did it, but we have forgotten it. Thinking contrasts with assertion, logic, science ('science does not think'), metaphysics, philosophy itself, and especially technology, which is merely an instrument for the calculation and domination of entities. Language, like thinking, played a subordinate part in *Being and Time*: meaning and language grow out of worldly significance and our understanding of it. Now language becomes central, not language as an instrument of manipulation—into which it has degenerated under the auspices of metaphysics—but language as the 'abode of being': 'Language speaks, not man. Man only speaks, when he fatefully responds to language.' Language no longer emerges from a pre-existing significant world; it opens up a significant world and thus creates speakers and hearers for itself. Art, especially poetry, is critically important for thinking and language. Poetry is not a secondary phenomenon: it has a special relation to being and truth. Poetry is 'founding of truth': it discloses the (or 'a') world and creates a language for its adequate expression. When a painting, such as Van Gogh's peasant shoes, 'opens up' a world, the world of the peasant, when a Greek temple 'sets up' a world, they are essentially 'poetry' (*Dichtung*). Unpoetic thought and language are parasitic on poetry and its vision. Poetry is close to the sacred: 'The thinker says being. The poet names the holy.'

The change from *Being and Time* to Heidegger's later thought is often called 'the turn' (*die Kehre*). Heidegger used this expression (influenced perhaps by the 'turn' of the prisoners in Plato's cave) in his *Letter on Humanism* (1947) for the change of direction involved in his intended, but unfulfilled, continuation of *Being and Time*. (He also used it for the hoped-for change, in the history of being, from forgetfulness of being to thinking.) But he regularly denied any significant difference between his early and his

later thought and any similarity of either to Sartre's existentialism. Heidegger's interpretation of his own work, as of much else, is of continuing interest, but open to question.

The ultimate worth of Heidegger's thought is still *sub judice*. Like his great rival Hegel (who also made life difficult for his non-German readers by trying to 'teach philosophy to speak German'), he is alternately worshipped, reviled, or sympathetically assimilated to other, more accessible philosophers, especially Wittgenstein. (Heidegger's relation to Husserl is comparable to the relation of the late to the early Wittgenstein.) But his immense learning, his profound and innovative intelligence, his commitment to philosophical inquiry, and, above all, his intense influence on modern thought, are not in doubt. Philosophers such as Sartre, Gadamer, and Derrida derive many of their basic concepts from him, and his philosophical influence extends to Japan and China. Theologians, Catholic (Karl Rahner) as well as Protestant (Rudolf Bultmann), are in his debt, as are psychologists (Ludwig Binswanger) and literary critics (Emil Staiger). The difficulty of his writings stems partly from the profundity of his questions. Other philosophers asked what it is about a statement or a belief that makes it true rather than false; Heidegger asks what it is that enables us to make any statements or have any beliefs at all, how we get the 'elbow-room' (*Spielraum*) to step back from the world and freely assess it from a distance rather than to remain engrossed in the stimulus of the present moment. Others, such as Husserl, assumed that philosophy was a feasible and respected enterprise; Heidegger tried to explain *Dasein's* transition from everydayness to philosophical reflection, locating it (in division 2 of *Being and Time*) in authenticity, *Angst*, and resoluteness. Others sought the foundations of the sciences; Heidegger asked how the sciences emerge from undifferentiated everydayness. Whether or not Heidegger's answers to such questions are true in the traditional sense, he has disclosed something of the world, and of the possibilities for our 'comportment' to it, that was previously concealed.

**Heisenberg, Werner** (1901–76). German physicist best known for discovering and articulating the \*uncertainty principle in \*quantum mechanics. With Schrödinger, he

co-founded modern quantum mechanics, improving on the older semi-classical theory of Planck, Einstein, and Bohr. Heisenberg's approach ('matrix mechanics') highlighted the structural features of the physical magnitudes that can be measured on quantum systems, while Schrödinger's ('wave mechanics') focused on their allowed states. But the two approaches were soon shown to be mathematically equivalent ways of expressing the same physical theory. In later years, against the grain of the strict \*operationalism that permeated much of his work in physics, Heisenberg regarded the irreducibly statistical predictions of quantum mechanics as representing a system's inherent tendency to react one way or another in response to a measurement (resurrecting Aristotle's idea of intrinsic 'potentiality'): 'In the experiments of atomic physics we have to do with things and facts, with phenomena that are just as real as any phenomena in daily life. But the atoms or the elementary particles themselves are not as real; they form a world of potentialities or possibilities rather than one of things or facts.'

**hell.** Traditionally, Christianity has taught that those who have no faith in Christ (faith typically being manifested by seeking baptism), or, having that faith, commit mortal sin (i.e. obviously bad sin) of which they have not repented, go after death to Hell. There they are punished both with *poena damni* (the punishment of the loss of the vision of God in Heaven) and *poena sensus* (sensory pain) forever. (Islam teaches a similar doctrine.) Not all elements of this doctrine are evident in the New Testament, some later theologians put various qualifications on it, and most modern theologians would deny most aspects of it. Why would a good \*God allow anyone to be deprived of him, let alone to suffer forever? Part of the answer may be that it is a generous act to give to humans the ultimate choice of rejecting the \*good forever.

**Hellenistic philosophy.** A rubric invented by scholars to cover the period of Greek philosophy between the death of Alexander the Great in 323 BC and the end of the Roman Republic in 31 BC. More broadly, it applies to the principal philosophical movements of this period—\*Stoicism, \*Epicureanism, and \*scepticism—as well as to their further developments in Imperial Rome and elsewhere. It should be noted that it is wrong simply to identify Hellenistic philosophy with a period of *Greek* philosophy. For there are members of the Hellenistic philosophical schools, e.g. Seneca, and important sources for our knowledge of the schools, e.g. Cicero, who wrote in Latin, not Greek. Further, although the three schools mentioned above certainly dominated during this period, not all the philosophy that was done was under their sponsorship. The successors of Aristotle, especially Theophrastus, should be mentioned in this regard.

Hellenistic philosophy is rooted in the two great philosophical schools of the fourth century BC, Plato's \*Academy and Aristotle's Lyceum. A convenient means of orientating oneself to the corpus of Hellenistic philosophical writings is according to the division of philosophy laid down by Xenocrates, the head of Plato's Academy between 339 and 314 BC. Xenocrates divided all philosophy into three wide categories: logic (the study of reasoning and rational discourse); physics (the study of external nature in all its manifestations); and ethics (the study of human nature and how life ought to be lived). This division became standard throughout the Hellenistic period both in the philosophers' own works and in their treatment of their predecessors. For example, the Aristotelian corpus was arranged in the first century BC by Andronicus of Rhodes according to the Xenocratean system.

In physics, Stoics and Epicureans rejected the immaterial entities of Platonism and Aristotelianism—Plato's Forms and the soul and Aristotle's God or unmoved mover. They rejected the claim that the postulation of such entities was required to explain various features of the world. Forms or immaterial gods were unnecessary for explaining the intelligibility of sensible reality or the existence of motion. This view led both Hellenistic schools to new accounts of what things there really are and what they are like. They were inspired by some provocative speculative conclusions of the Pre-Socratic philosophers that Plato and Aristotle had themselves rejected. The Stoics were inspired by Heraclitus. They took Aristotle at his word when he said that if an immaterial god does not exist, then metaphysics is just physics. For the Stoics, theology then becomes a branch of physics, investigating the fundamental immanent materialistic principle of the organic universe. Epicurus recurred to the \*atomism of Democritus and Leucippus as a basis for his scientific investigations. Atomism's strength was supposed to lie in its suitability as a framework for unified explanation in areas thought to be widely separate, such as ethics, theology, and epistemology.

The \*materialism of both the Stoics and the Epicureans is joined to an empiricist methodology. Careful attention to methodology is a hallmark of the Hellenistic schools. Logic, as understood by these schools, encompasses whatever matters pertain to the methodology of empiricism, including semantics and epistemology as well as formal reasoning. The members of the Old Stoa have left a great deal of impressive work in these areas. Epicurus was particularly conscious of the need to develop a logic suitable to scientific investigation. He gave it the name 'canonic', indicating a study of the proper rules governing the pursuit of knowledge. Sceptics were moved to refine their anti-dogmatic arguments in response to both Stoic and Epicurean innovations. They claimed that \*empiricism can provide no basis for claims to knowledge. Within Plato's Academy, however, a sceptical movement arose which was rather more hospitable to empiricism in practice. These Sceptics were prepared to countenance criteria of rational belief, if not of knowledge. The association of

scepticism with empiricism is one of the more remarkable developments in the Hellenistic period.

In ethics, Stoics and Epicureans adhered to the \*rationalism of Socrates as it is found in the early dialogues of Plato. They believed that the entire human soul was rational and that the road to happiness consisted in using reason correctly. Moral flaws were actually flaws in the functioning of reason. Moral improvement consisted in replacing erroneous beliefs with true beliefs. They rejected Plato's major qualifications of Socrates' position mainly because that involved a dualistic account of the person that conflicted with materialism. They also rejected Aristotle's less extreme approach wherein the affective side of human life and external circumstances contributed to happiness. Stoicism and Epicureanism represent two conflicting types of rationalism in ethics. It is difficult to arrive at a clear idea of what ethics would mean for a Sceptic. No doubt, they would argue that it is not possible to obtain knowledge of universal rules of human behaviour. This would seem to drive them to some form of subjectivism, although the Sceptic would wish to refrain from the dogmatic defence of such a view.

While insisting on the opposition of the Hellenistic philosophical schools to \*Platonism and \*Aristotelianism, it is well to bear in mind that there is nevertheless a profound continuity of underlying assumptions among them. For instance, apart from the Sceptics, they all believe that philosophy is a serious activity capable of attaining life-enhancing wisdom. In an odd way, this is even true of the Sceptics who believed that destructive argument was after all the key to happiness. There is also a shared assumption about the centrality of the concept of nature in philosophy. The naturalism of the Stoics and Epicureans can be traced back to the Pre-Socratic idea that human nature is illuminated by the study of external nature. This assumption resonates throughout the history of philosophy.

The main Hellenistic schools continued to dominate philosophical work into the period of Imperial Rome. Both Epicureanism and Stoicism appealed to those who were not particularly interested in theoretical issues, but who were eager for guidance on how best to live. Impartial observers of the time looked upon Christianity as just another philosophical school with a relatively new approach to old questions. As Christianity rose in influence, the Hellenistic philosophical schools declined. Important elements of Stoicism and Epicureanism found their way into the writings of Christian theologians. L.P.G.

**Héloïse complex.** Diagnosed by Michèle Le Dœuff, this is the tendency of women in philosophy to idolize either a male colleague or teacher (as did Héloïse and de Beauvoir), or a 'great' living or dead philosopher whose banner they carry (as do contemporary women seeking the best

male exponent of feminism, and becoming 'Lacanian', 'Foucauldian', even 'Nietzschean' feminists). This situation benefits the man, destroys the woman—removing her intellectual independence and need to create philosophy herself. De Beauvoir, however, escaped the Héloïse complex sufficiently to produce philosophy 'unawares'.

Michèle Le Dœuff, *Hipparchia's Choice* (Oxford, 1991).

**Helvétius, Claude Adrien** (1715–71). In *De l'esprit* (1758), Helvétius claimed that all normal humans share the same intellectual potential at birth, so that differences in character and intellectual achievement should be explained as products of environmental difference. To explain differences in intellectual achievement, Helvétius stressed the far-reaching consequences that lucky observations could have for an individual's thinking. He also argued that intellectual development depended on an individual's being motivated to inquiry by stimulation of his passions. Helvétius' doctrine led him to place importance on public education. The goal of social policy was to maximize pleasure and minimize pain. Human action was motivated by a desire for pleasure and this fact should be exploited to encourage virtuous, i.e. socially beneficial, action. Virtue should be encouraged not by moralizing but by reward, including—as Helvétius suggested—sexual gratification. T.P.

\*utilitarianism.

**Hempel, Carl Gustav** (1905–97). One of the leaders of the logical empiricist movement in the philosophy of science, which flourished for about three decades after the Second World War, Hempel saw the task of science as that of showing phenomena to be the consequence of unbroken \*laws. A major implication was the so-called \*covering-law model of scientific understanding, stressing that there is a symmetry between explanation and prediction, where the only difference is temporal—in the case of explanation, that which you are explaining has already occurred, whereas in the case of prediction, that which you are predicting has yet to occur.

With today's move from prescriptive philosophy of science to a more descriptive stance, not to mention the switch from an exclusive concern with the physical sciences to a more general interest in such areas as biology and psychology. Hempel's views now are often contemptuously described as the 'received view' meaning the 'not received by anyone who has read my latest article view'. Whether this will prove to be the end of such an approach to science will presumably be the topic of many future Ph.D. theses. M.R.

**Henry of Ghent** (?–1293). He taught in the faculties of arts and theology at the University of Paris, and was also in turn Archdeacon of Bruges and principal Archdeacon of Tournai. His philosophical reputation rests largely upon his *Summa Theologiae* (Summation of Theology) and upon a set of *Quodlibeta*, reports of his response to questions on a wide range of issues, put to him in the context of disputations. His writing is a synthesis of \*Aristotelianism and Augustinianism, though important parts of his metaphysical thinking, concerning the nature of being *qua* being, owe a good deal to Avicenna. As regards his Augustinianism, Henry held that knowledge of natural things depends in part upon divine illumination, so that there is no purely natural way of knowing about the natural order.

J. Paulus, *Henri de Gand: Essai sur les tendances de sa métaphysique* (Paris, 1938).

**Heraclitus of Ephesus** (fl. c.500 BC). Pre-Socratic philosopher. Nothing is known of his life (the ancient 'biographies' are fiction). There is no sign that he ever left his native city, which at that time was part of the empire of the Achaemenid dynasty of Persia. (Iranian influences on his thinking have sometimes been suggested.)

The book of Heraclitus was famous in antiquity for its aphoristic obscurity. About 100 sentences survive. Interpretation of Heraclitus has been a controversial matter since at least the late fifth century BC. Both Plato and Aristotle accepted the view of Cratylus, who attributed to Heraclitus his own version of 'universal \*flux'; in consequence they underrated Heraclitus. Later ancient interpreters, e.g. Theophrastus and Cleanthes, also influenced and clouded the later testimony.

Heraclitus' obscurity is a calculated consequence of his style, which is usually compact and often deliberately cryptic. He believed that what he has to say goes beyond the limits of ordinary language. Combined with the fragmentary state of the surviving evidence, his obscurity is a formidable obstacle to understanding. It is clear, though, that Heraclitus' thinking was meant as a comprehensive and systematic whole, covering every aspect of human experience, of which every part was connected with every other. It is clear too that his statements are often intended to be self-applicable: their linguistic form exemplifies the very structure of which they speak.

This observation can serve as the starting-point of an interpretation with some prospect of making sense of the fragments in their totality.

1. The abstract notion of 'structure' is omnipresent, explicitly in the word *harmonia*, but mostly implicitly.
2. There is a parallelism or identity of structure between the operations of the mind, as expressed in

thought and language, and those of the reality which it grasps.

3. In general the structure is that of 'unity-in-opposites'. This appears in many examples, static or dynamic, drawn from everyday life: 'People step into the same rivers, and different waters flow on to them'; 'A road, uphill and downhill, one and the same'; 'Sea is water most pure and most polluted: for fish drinkable and life-giving, for human beings undrinkable and deadly'. These remarks and their generalizations are not meant to infringe the law of non-contradiction; rather they trade on it to point out a systematic ambivalence (between polar opposites) in the essential nature of things.

4. The parallelism of structure implies that understanding the world is like grasping the meaning of a statement. The 'meaning of the world', like that of a statement in words, is not obvious, but yet is present in the statement, and can be worked out provided one 'knows the language'. Human reason has the power to know the language, precisely because its own operations are conducted in the very same or an analogous one. The word *logos* (basically 'story', 'account'; then 'calculation, proportion, reason') expresses this analogy or identity.

5. Hence the key to understanding the nature of the world is *\*introspection*: 'I went looking for myself.' The human self ('soul', *psukhē*) is variously occupied: it is combatively active, physically, emotionally, and intellectually; it is reflectively self-discovering and self-extending; and it is constantly self-reversing in the swings of circumstances or passion or thought. Yet it needs firm frameworks (objective truths, fixed rules of conduct) to be at all, or to make sense of its own existence. All this is true of the world too; here also there is no sharp line between what it is and what it means. Behaviour and structure of the world and of the soul run parallel; both are particular cases of the general 'unity-in-opposites'. The image of a child playing both sides of a board game presents the fundamental coexistences: of conflict and law, of freedom and regularity, of intelligence and its lapses, of opposition and unity.

Since he was 'rediscovered' at the end of the eighteenth century, and rescued from crude misunderstandings, Heraclitus' appeal has grown, in spite of his obscurity. Hegel explicitly acknowledged his indebtedness; Heidegger has given lengthy exegesis. Wittgenstein's *Tractatus* is rather similar to Heraclitus in style and perhaps partly in method.

**Herder, Johann Gottfried** (1744–1803). German philosopher who held that thought and \*language are inseparable, and that a people's thought and culture are accessible

only through its language. All languages descend from a common source, which he mistakenly sought within the short span of recorded history. He studied folk-song, and criticized Kant for neglecting language. His *Understanding and Reason: A Metacritique of the Critique of Pure Reason* (1799) argued that language, which is both sensuous and intellectual, forbids Kant's dissection of the mind into sensibility and understanding, and other ensuing dualisms. History, like language, develops out of nature; it does not begin with a contract or divine intervention. Cultures vary according to a people's natural endowments and circumstances, but they form an organic series which progressively realizes the idea of 'humanity'. In Herder enlightenment became historical.

**heredity and environment.** The development of human intellect and personality results from a complex interplay of biological and environmental factors. The mind is not wholly the product of nature or nurture. Any 'nurturist' must concede that a creature cannot learn unless it has innate abilities to interact with its environment, process and retain information. Any 'nativist' must admit that the relation between genes and behaviour is so intricate and probabilistic that talk of 'genetic determinism' is rarely appropriate. The exact nature of the interplay between biology and environment remains, however, a matter of profound controversy.

Those who favour nativist explanations argue that findings in cognitive science, behavioural genetics, evolutionary theory, and developmental psychology favour the view that the human mind has significant innate structure, and that the parameters of intellect and personality are genetically defined. We are urged to see the mind as a system of modules each with its own internal developmental trajectory. Chomsky argued half a century ago that we must posit an innate 'language acquisition device' if we are to explain how children acquire natural languages. We now know that children are innately equipped with considerable mental capacities. Immediately after birth, babies are attuned to their mother's voice and can imitate certain facial expressions. In time, they deploy 'folk' theories of the behaviour of physical objects and other people. The emergence of these abilities may require environmental triggers, but they are not learnt. All this makes sound evolutionary sense. In addition, our rapidly expanding knowledge of the human genome suggests that significant genetic factors influence sexual orientation, mental health, moral sensibility, and intelligence.

In response, some critics of nativism have argued that 'connectionist' models of neural architecture are able to explain learning without positing innate structures. But the most compelling arguments are those that invoke culture. Tomasello has argued that natural selection proceeds too slowly to explain the rapid evolution of human

cognitive capacities. The latter depends on a process of 'cumulative cultural evolution' whereby each individual inherits the collective achievement of past generations. This distinguishes us from other intelligent primates which lack the means to preserve innovations and transmit them to future generations. Cumulative cultural evolution is a natural process, but one which cannot be understood exclusively in natural-scientific terms.

A more purely philosophical defence of culturalism is found in John McDowell's recent writings. McDowell argues that children become rational agents through enculturation, which equips them with the conceptual capacities that enable them to respond to reasons. But the terms in which we explain the behaviour of rational agents are fundamentally incommensurable with the causal-explanatory framework of the natural sciences. Hence, in so far as we appeal to genetic or neurological factors to explain some action, we do not represent it as the purposive activity of a rational, autonomous being. It follows that our genetic endowment and brain functioning enable, but do not constitute, our mental lives.

The supposed moral and political implications of these various positions often stand as an obstacle to their clear-headed assessment. Hostility to nativism has traditionally inspired egalitarian and democratic political theories, and nativism has been associated with repugnant views of the innate intellectual and/or moral inferiority of women, non-whites, and the labouring masses, and with eugenics. In response, contemporary nativists reply that it is one thing to know the facts about human nature, another to draw moral conclusions from them. They point out that nurturism is itself associated with disastrous visions of social engineering (e.g. the creation of the New Soviet Man) and deplorable environmental explanations of conditions now known to be indifferent to nurture (e.g. the attribution of autism to 'cold' mothering; attempts to condition people out of homosexuality).

The old nature–nurture debate may be dead, but intense controversy about the foundations of human nature promises to continue *ad infinitum*.

**hermeneutic circle.** Term often used by philosophers in the (mainly continental) tradition running from Schleiermacher and Dilthey to Heidegger, Gadamer, and Ricœur. Has to do with the inherent circularity of all understanding, or the fact that comprehension can only come about through a tacit foreknowledge that alerts us to salient features of the text which would otherwise escape notice. Yet it is also the case that every text (and every reading of it) in some way manages to pass beyond the 'horizon of intelligibility' that makes up this background of foregone interpretative assumptions. The debate is joined between

those (like Gadamer) who think of understanding in terms of a dialogue or ongoing cultural conversation, and those—Habermas among them—who wish to maintain a more independent role for the exercise of critical thought.

C.N.

\*hermeneutics.

D. C. Hoy, *The Critical Circle: Literature and History in Contemporary Hermeneutics* (Berkeley, Calif., 1978).

**hermeneutics.** The name of Hermes, the messenger of the Greek gods, gave rise to *hermēneuein*, 'to interpret', and *hermēneutike* (*technē*) is the 'art of interpretation'. It became important after the Reformation, when Protestants needed to interpret the Bible accurately. Medieval hermeneutics ascribed to the Bible four levels of meaning: literal, allegorical, tropological (moral), and anagogical (eschatological). But the Reformation insisted on literal or 'grammatical' exegesis and on the study of Hebrew and Greek. Modern hermeneutics falls into three phases.

1. Friedrich Schleiermacher (1768–1834), the great Protestant theologian and Plato scholar, gave in lectures, from 1819 on, a systematic theory of the interpretation of texts and speech. (Another Plato scholar, Friedrich Ast (1778–1841), had in 1808 published *Elements of Grammar, Hermeneutics and Criticism*.) The interpreter's aim is to 'understand the text at first as well as and then even better than its author': 'Since we have no direct knowledge of what was in the author's mind, we must try to become aware of many things of which he himself may have been unconscious, except in so far as he reflects on his own work and becomes his own reader.' A text is interpreted from two points of view: 'grammatical', in relation to the language in which it is written, and 'psychological', in relation to the mentality and development of the author. We cannot gain complete understanding of either of these aspects, since we cannot have complete knowledge of a language or a person: we 'move back and forth between the grammatical and the psychological sides, and no rules can stipulate exactly how to do this'. We cannot fully understand a \*language, a person, or a text, unless we understand its parts, but we cannot fully understand the parts unless we understand the whole. Thus at each level we are involved in a \*hermeneutical circle, a continual reciprocity between whole and parts; a significant 'text can never be understood right away . . . every reading puts us in a better position to understand since it increases our knowledge'. (It is the range of relevant knowledge, not circularity alone, that precludes definitive interpretation. Our understanding of 'Hand me my clubs!' on a golf-course is circular, since only the whole utterance disambiguates 'hand' and 'clubs', but it is definitive and complete.)

2. Schleiermacher's biographer, Dilthey, extended hermeneutics to the understanding of all human behaviour and products. Our understanding of an author, artist, or historical agent is not direct, but by way of analogies to our own experience. We relive past decisions, etc. in imaginative sympathy.

3. Heidegger learned of hermeneutics from his theological training and from Dilthey. Theological hermeneutics considers the interpretation of ancient texts; Dilthey is concerned with understanding in the cultural, in contrast to the natural, sciences, and again mainly, if not exclusively, with the interpretation of the products of past societies. In Heidegger's *Being and Time*, hermeneutics acquires a deeper and wider sense. It is concerned with the interpretation of the being who interprets texts and other artefacts, who may become, but is not essentially, either a natural or a cultural scientist: the human being or \**Dasein*. Heidegger's \*phenomenology is hermeneutical, rather than, like Husserl's, transcendental. Our approach to *Dasein* must be hermeneutical since the fundamental traits of *Dasein* and its 'world' are not, as Husserl supposed, on open display, but hidden, owing in part to their very familiarity, in part to *Dasein*'s tendency to misinterpret and obscure its own nature and such features of itself as mortality. Understanding *Dasein* is more like interpreting a text overlaid by past misinterpretations (or penetrating the self-rationalizations of a neurotic) than studying mathematics or planetary motions. Hermeneutics no longer presents rules for, or a theory of, interpretation; it is the interpretation of *Dasein*. But hermeneutic phenomenology gives an account of understanding, since a central feature of *Dasein* is to understand itself and its environment, not in the sense of disinterested interpretation or of explicit assertion, but of seeing the 'possibilities' available to it, seeing a hammer, for example, as something with which to mend a chair: 'All pre-predicative simple seeing of the invisible world of the ready-to-hand is in itself already an "understanding-interpreting" seeing.' It is only because *Dasein* has such 'pre-understanding' that it can interpret alien texts and understand itself in an explicit philosophical way. Heidegger's later works rarely mention hermeneutics, but interpret poetic and philosophical texts in a more traditional sense. His hermeneutics differs from Derrida's: for Heidegger, words 'show' something beyond themselves, namely being, and we need to think about this, not simply about the text, in order to understand what is said. *Being and Time* influenced Gadamer, and Rudolf Bultmann's (1884–1976) demythologizing interpretation of the Bible.

**Hermetic corpus.** A body of texts composed between AD 100 and 300, but supposed, together with a text advertising ceremonial magic called *Asclepius*, to contain the ancient 'Egyptian' wisdom, from which both Moses and

\*Plato borrowed. Translated by \*Marsilio Ficino in 1463, they strengthened a growing conviction that human beings could be as gods: through Reason, the child of God, we could be cleansed of 'the twelve madresses', and come to see the ordered beauty of nature; people have forgotten that they exist to understand and tend the works of God, who is himself beyond our intellectual grasp. Later scholars, beginning with Casaubon in 1614, have discredited the claim to represent an original, pre-Greek theology, but its historical importance is obvious, and its doctrines, however poetically expressed, deserve close consideration.

**Herzen, Alexandr Ivanovich** (1812–70). A leading figure in Russian political thought, Herzen lived according to a youthful vow of hostility to Russian despotism. After periods in exile, he became an influential member of the 'Westernizers' in the 1840s. Though initially influenced by Hegel, whose dialectic he described as 'the algebra of revolution', Herzen developed a 'philosophy of contingency' that stressed the role of chance in history. Though he passionately defended individual \*liberty, Herzen saw the peasant commune as a model of an agrarian socialism that might flourish without the prior development of capitalism, a system he abhorred. He emigrated in 1847, settling in London where he published *Kolokol* (The Bell). Smuggled into Russia, the journal became a powerful forum of political debate. Herzen's memoirs, *My Past and Thoughts*, are an outstanding contribution to literature and an engaging chronicle of Russian life.

— *My Past and Thoughts*, tr. C. Garnett, 4 vols. (London, 1968).

**heterological and homological.** A homological (or autological) word is one that applies to itself, e.g. the word 'polysyllabic', which is polysyllabic. A heterological word is one that does not apply to itself, e.g. the word 'Spanish', which is not Spanish. The heterological, or \*Grelling's, paradox, related to the \*liar paradox, is an \*antinomy: the word 'heterological' is heterological if and only if it is not heterological.

C.A.K.

**heteronomy:** see autonomy and heteronomy.

**heuristic.** Conducive to \*understanding, explanation, or discovery; an item, especially a thesis, that is heuristic. Especially, a heuristic investigation is one conducted by trial and error. In pedagogy, the heuristic method is a type of education through self-learning. In logic, a heuristic is a problem-solving procedure that may fall short of providing a proof.

S.P.

**higher-order logic.** In each interpretation of a standard logical system, variables range over a single domain of discourse. These are sometimes called 'first-order variables'. In second-order systems, there is also a type of variable

that ranges over sets, properties, functions, or propositional functions on the range of the first-order variables, the domain of discourse. For example, a statement like 'There is a property that holds of all and only the prime numbers' would naturally be interpreted in a second-order system. In third-order systems, there is a type of variable that ranges over properties of properties, or sets of sets, or functions of properties, etc. of whatever is in the range of the first-order variables. For example, according to some philosophical accounts, the number 4 is the property of all properties that apply to exactly four objects. This is a third-order statement. Extensions to fourth-order logic and beyond, even into the transfinite, follow the same pattern. A logical system is higher-order if it is at least second-order.

\*types, theory of.

Stewart Shapiro, *Foundations without Foundationalism: A Case for Second-Order Logic*, Oxford Logic Guides, xvii (Oxford, 1991).

**Hilbert, David** (1862–1943). German mathematician of encyclopaedic range. He and his followers pioneered the use of formal \*axioms both for logical reasoning and to define classes of mathematical structures. With Ackermann in 1928 he wrote the first textbook to include first-order logic. His work of 1899 on the foundations of geometry was the first to describe a systematic method for proving non-deducibility in logic. 'Hilbert's programme' (sometimes misleadingly called 'formalism', though not by Hilbert himself) aimed to justify the use of infinity in mathematics by producing a finitary (i.e. purely syntactic) \*consistency proof for an axiom system of arithmetic. Gödel showed that no such proof can be given. Though Hilbert was philosophically naïve, his controversies with Frege on the foundations of geometry and with Brouwer on formal versus contentful mathematics raised questions worth studying.

W.A.H.

Constance Reid, *Hilbert*, with an appreciation of Hilbert's mathematical work by Hermann Weyl (London, 1970).

**Hindu philosophy.** The word 'Hindu' comes from a Greek mispronunciation of the name of the River Sindhu, which also gave its name to the 'Indus' Valley civilization that flourished in north-west India between 2500 and 1500 BC. Assimilation of this pre-existent culture by the later Indo-Aryan immigrants resulted in the body of orally preserved literature called \*'Veda', divided into hymns, sacrificial texts, and philosophical and mystical musings about ultimate reality and the goal of life. 'Hinduism' is the Western name given to the loosely knit family of diverse religious beliefs and practices which call themselves 'Vaidika' ('Vedic' in English) after these sacred texts.

Unlike Christianity or Islam, Hinduism is a non-proselytizing religion based on the Vedic principle that 'Reality is one, but different religious teachers speak of it differently'. The Vedic belief in universal determinism, coupled with belief in reincarnation of individual souls which are as

eternal as God, translates into the law of \*karma, which is the principle that no suffering or enjoyment can be undeserved. Unlike fatalism, which takes life as largely accidental and beyond our control, karma-determinism takes it to be nomologically controlled by our own past actions which even God does not condone. \**Bhagavadgītā*, the Hindu equivalent of the New Testament, says 'The Lord does not create human agency or actions.' Although he has divided society into four castes, God cannot, therefore, be held responsible for a man's birth in a family of priests, soldier-rulers, merchants, or workers. Under the general Vedic tolerance of diversity, Hindu philosophy, as distinguished from \*Buddhism, \*Jainism, and Indian materialism, divided into the Six Systems called Sāṃkhya, Yoga, Nyāya, Vaiśeṣika, \*Vedānta, and Mīmāṃsā.

Sāṃkhya, perhaps the oldest school of independent metaphysical reasoning, is based on a fundamental dualism of many *selves*, which are eternal inactive centres of pure consciousness, and one *nature*, which is a constantly changing fusion of three material principles of illumination, kinesis, and inertia. These three strands of nature are affectively experienced as pleasure, pain, and torpor. The intellect, egoism, sense-organs, and bodies of living beings who suffer in this world are all evolutes of this objective nature with which subjective consciousness mistakenly confuses itself.

Accepting Sāṃkhya ontology for the most part, Yoga suggests an eight-step method of arresting the object-directed modifications of the mind—through which method a self can get back to its pure essence and hence stop suffering. This is the method of liberation through meditative discrimination between the self and nature. Sāṃkhya is atheistic whereas Yoga makes room for a God who does not create the world but is the most perfect self who can elevate others by teaching.

Differing mostly in their epistemologies, Nyāya and Vaiśeṣika share their atomistic metaphysics of matter, belief in eternal souls, and a general realism in all spheres. The Vaiśeṣika ontology posits seven categories, classifying all knowable and nameable existents into substances, unrepeatable qualities, events, natural universals, the relation of inherence or *being inseparably in*, ultimate individualators of simples, and absences. The Nyāya school is responsible for developing a rigorous theory of sound inference and rules of constructive as well as destructive debate, whence the wider usage of 'Nyāya' to mean logic.

Vedānta, which is exegesis of the original philosophy of the \*Upanishad portions of the Veda, branched out into many subschools. Of these, the non-dualism of Saṃkara, which argues for the falsehood of the world of plurality and the identity between the individual and the Absolute Self, is the most well-known.

Mīmāṃsā arose out of the systematic interpretation of apparently conflicting Vedic injunctions. In spite of its obsession with rituals and their karma-theoretic causal powers, Mīmāṃsā developed a sophisticated semantics for 'ought' sentences and a fine-grained taxonomy of hermeneutic devices. Mīmāṃsā authors like Kumarila

(AD 650) offered extremely sophisticated arguments to resist Buddhist anti-realism about the self, the external world, and universals.

David Zilberman, *The Birth of Meaning in Hindu Thought* (Dordrecht, 1988).

**Hintikka, Jaakko** (1929– ). A leading philosophical logician, Hintikka is known for his development of model set-theoretic \*semantics for knowledge and belief. Subsequently Hintikka developed a semantics for perception with two sets of quantifiers, a standard pair which ranges over physically individuated objects, and a second pair which ranges over objects perceptually individuated over model sets (in effect, intensional objects). Later formulations of his epistemic and doxastic systems are similarly equipped with a second set of quantifiers. Through this work Hintikka was able to shed light upon what it means to know who someone is. His work also clarifies what it means to know that one knows. In addition, Hintikka has contributed to the history of philosophy with his original writings on Aristotle, Kant, and Wittgenstein.

**Hippocrates** (c.430 BC). A famous physician, head of a medical group or school at Cos. (To be distinguished from his contemporary Hippocrates of Chios, author of the first known geometry textbook.)

The name of Hippocrates became attached to a collection of medical writings (the Hippocratic corpus) of the fifth and fourth centuries BC, a few of which may in fact be by Hippocrates. The more theoretical works in this collection are connected with Ionian cosmology (\*Pre-Socratics); some show traces of the philosophical thinking of Xenophanes, Heraclitus, the \*Eleatics, or Protagoras; or of the argumentative techniques of the \*Sophists. They are evidence for the history of philosophy but not themselves original philosophical works, apart perhaps from the essay entitled 'On Ancient Medicine'. This contains thoughts on the relation between theory and practice which were developed by Plato and influenced Aristotle's discussion of the 'mean' in action.

**historical determinism:** see determinism, historical.

**historical materialism.** The programme of historical research formulated in the writings of Karl Marx and Friedrich Engels. According to the materialist conception, the fundamental thing in human history is the productive powers of society and their tendency to grow. Productive powers at a given stage of development determine the nature of human labouring activity because labour consists in the exercise of precisely those powers. A given set of productive powers also thereby favours certain

'material relations of production', forms of human co-operation or division of labour which are not directly part of them, but facilitate their employment to a greater degree than rival forms would do. They thereby also favour certain 'social relations of production', systems of social roles relating to the control of the production process and the disposition of its fruits. It is this system of social relations of production which Marx calls the 'economic structure of society', which forms the 'real basis' of social life on the materialist theory, conditioning \*'superstructures' such as the political state and the 'ideological' forms of consciousness found in religion, philosophy, morality, and art.

Within the framework of any system of social relations of production, society's productive powers expand at a greater or lesser rate, depending on the historical circumstances, including the social relations themselves. Eventually, however, a given set of social relations of production are outgrown or rendered obsolete by the productive powers. The prevailing relations either make it difficult to employ the existing powers or else fetter the further development of these powers. Powers and relations of production thus come into conflict or 'contradiction'; an 'epoch of social revolution' begins. The outcome of the conflict is the transformation of the relations of production to bring them into line with the productive powers so as to facilitate the further expansion of these powers. Changes in the superstructure of society, including its political and legal institutions, are to be explained by the required changes in the social relations of production. The mechanism by which these adjustments are to be carried out is the \*class struggle. At a given stage of history, that class is victorious whose class interests consist in the establishment of that set of production relations which best suits the productive powers at that stage.

The materialist conception of history is a general programme of historical research, an explanatory sketch which is supposed to prove fruitful when applied not only to past changes but also to the historical future. Although Marx occasionally applies it to pre-modern societies, it was obviously suggested to him by the rise of capitalism; Marx envisions the overthrow of capitalism and the rise of socialism as following the same pattern of historical development.

In Marxian theory, historical materialism was closely associated with the thesis that the class rule of the bourgeoisie is incompatible with the continued growth of productive forces, and that capitalism is therefore doomed to be overthrown by the revolutionary proletariat. At the present time, when most people are apt to conclude that this has not happened and is not going to happen, it may be worth pointing out that while Marx may have associated historical materialism with his thesis about the inevitable overthrow of capitalism, the materialist theory of history is quite independent of that thesis, and what are in fact historical materialist explanations are sometimes invoked by people who do not consider themselves Marxists. For example, it is sometimes claimed that Leninist

socialism in Eastern Europe survived as long as it did because a command system is compatible with an economy based on heavy industry but incompatible with one based on the high tech of the information age. Whatever may be said for or against such explanations, they should be easily recognized as based on the explanatory framework of Marx's historical materialism. A.W.W.

**historicism.** A label which has been confusingly applied to distinguishable positions in \*social philosophy. It was originally used to refer to a particular conception of the aims of history which emphasized the need to recognize the essential individuality of historical phenomena; these phenomena, being expressive of human thought and feeling, required for their proper understanding an empathetic grasp of the conditions that gave them life and meaning in a social context. A wider interpretation of the term, often held to have relativist implications, involves the claim that the nature of any phenomenon can only be adequately comprehended by considering its place within a process of historical development. Thirdly, it has been employed to designate doctrines which attribute to the social sciences the role of predicting future developments on the basis of discoverable laws of historical change. P.L.G.

Friedrich Meinecke, *Historism: The Rise of a New Historical Outlook*, tr. J. E. Anderson, foreword by Isaiah Berlin (London, 1972).

**histories of moral philosophy.** Modern histories of Western moral philosophy generally share a familiar periodic structure: first, the inquiries of the major ancient Greek thinkers and schools and their later Roman followers, whose focus is upon the nature of the human good and the consequent relationships between virtue and knowledge and between virtue and pleasure; next, the writings of medieval Christian, Islamic, and Jewish philosophers, whose moral inquiries have a theological setting; then the moral philosophies of the Renaissance, in which a variety of Greek and scholastic themes are revived, followed by those of the eighteenth and nineteenth centuries, in which the epistemological preoccupations of moral rationalists and moral sense theorists are a prologue to the major constructions of the Utilitarians and of Kant; and finally the range of recent and contemporary standpoints. But what kind of attention is given to each, and how the relationships between them are envisaged, has varied first with whether and if so how far the history of moral philosophy has been embedded within some larger history, and what kind of history that is, secondly with the extent to which views of the present state of the argument in moral philosophy have dictated the perspective in which its history has been understood, and thirdly with how the task of the historian has been defined.

In the eighteenth and early nineteenth centuries episodes in the history of moral philosophy are sometimes treated not primarily in terms of this division into periods, but rather in terms dictated by some philosophical scheme informed by its author's own larger purpose. So it was with Vico, who understood his own account of the morality of natural law as a correction of the errors of his ancient and seventeenth-century predecessors, an achievement which would not have been possible before what he took to be the third and then present stage of a history, through which, on his view, all nations characteristically passed, the stage in which the authority of human reason temporarily displaced older allegiances first to divine authority and later to aristocratic, heroic authority. So too in many of the entries of the *Encyclopédie* of Diderot and d'Alembert a narrative of human progress is presupposed in which various moral philosophers are taken to have succeeded or failed in so far as they contributed to the emergence of the true and rational account of morality now finally advanced in the *Encyclopédie* and to the defeat of a range of earlier theological superstitions. And so also at various points in the unfolding narrative of Hegel's *Phänomenologie des Geistes* what are recognizably portraits of particular moral philosophies, including utilitarianism and Kantianism, are presented under descriptions which represent them as partial and inadequate moments in the rational development of Spirit, a development of which Hegel's own philosophy is so far the most adequate rational articulation. Thus Vico, the Encyclopaedists, and Hegel each made the history of moral philosophy part of a larger philosophical history.

By contrast Adam Smith in part VII of *The Theory of the Moral Sentiments* wrote the history of moral philosophy as a distinct and independent form of inquiry. Having already advanced his own answers to what he had identified as the central questions of moral philosophy, Smith surveyed what he took to be the major systems of the past, testing his conclusions against those of their authors, and arguing that where theirs differ from his, there is good reason to think theirs erroneous. Plato, Aristotle, Stoics, Epicureans, and Eclectics are the ancient authors considered and criticized. Among the moderns most attention is paid to Mandeville and Hutcheson. Medieval moral philosophy merits only two passing references to 'the schoolmen'. As with Vico, the Encyclopaedists, and Hegel, it is the perspective afforded by Smith's own moral philosophy which dictates in key part his treatment of the past. So it was too with Carl Friedrich Staudlin, whose *Geschichte der Moralphilosophie* of 1821, the first history of moral philosophy as such, was written from his own Kantian standpoint.

In the nineteenth and twentieth centuries those who embed the history of moral philosophy or parts of it in some other, larger history include those who understand it as an integral part of the history of philosophy, such as Ueberweg and Windelband in nineteenth-century Germany, and Abbagnano in twentieth-century Italy, those who treat it as one aspect of the history of moral thought

and practice, such as Lecky and Westermarck, and those successors of Vico, the Encyclopaedists, and Hegel for whom it is some overall theory of human history which provides the categories in terms of which the history of moral philosophy is to be understood, the most distinguished of whom were Marx and Nietzsche. Sainte-Beuve as a literary historian contributed to the history of French moral philosophy in some of his essays and in his study of Port Royal. The history of specifically English moral philosophy was presented as an integral part of the history of English literature by such Cambridge teachers as Basil Willey in *The English Moralists* and Dorothea Krook in *Three Traditions of Moral Thought*. Of those who followed Smith in writing the history of moral philosophy as an independent inquiry the single most outstanding figure was Henry Sidgwick, but there were also important histories, of ancient moral philosophy by Jacques Francis Denis in nineteenth-century France, and of the whole history of Western ethics by James Martineau in nineteenth-century England and by Ottmar Dittrich in twentieth-century Germany. From the late nineteenth century onwards the history of moral philosophy has been hospitable to two distinct and contrasting genres: on the one hand large interpretative treatments in which the theses and arguments of particular moral philosophers are construed in terms of their place in some philosophical scheme of progress or regress or both, and on the other scholarly monographs establishing in historical detail what one or more particular moral philosophers said and meant. The ideal history of moral philosophy would therefore have been one which both exhibited the rational superiority of its narrative structure to that of all rival interpretation and also integrated into itself the findings of all the best scholarly monographs. All twentieth-century histories, including my own *A Short History of Ethics*, fall notably short of the standard set by this ideal, but they are to be measured by how far, if at all, they have had a higher degree of success than did Sidgwick's, whose *Outlines of the History of Ethics for English Readers* (1886) remains the major classic in this area of philosophical writing.

On Sidgwick's account ancient Greek ethics was distinctive in aiming at a knowledge of the human good, the achievement of which in a life ordered by reason both required virtue and served the interests of each individual. Christianity by contrast understood morality as founded upon the knowledge of a divinely authorized code of law and emphasized practical beneficence by exalting love as the root of all the virtues. Medieval scholastic philosophers attempted the impossible task of synthesizing Christianity and Aristotle. Modern moral philosophy differs from its predecessors in two ways. After the Reformation reflective persons began to search for a method in ethics, acceptable independently of one's religious allegiance, appealing only to reason and to common moral experience. And in the early eighteenth century a number of philosophers, but especially Butler, recognized that, while ancient moral philosophers had taken reason to be our practical governing faculty, a reason which treats what is

virtuous and what is to our interest as coincident, in fact there are in human beings two independent governing faculties, universal reason, which prescribes impartial benevolence, and egoistic reason, which prescribes the pursuit by each individual of what is to his or her interest. The subsequent history of modern moral philosophy records a number of failures to reconcile these two as well as the achievement of a better understanding of both.

Sidgwick's history is thus a prologue to his own statement of what he took to be the present condition of moral philosophy in *The Methods of Ethics* (1874). Sidgwick's philosophical and historical claims both stand in the sharpest contrast to the claims of Marx and Nietzsche, for both of whom not only the moral beliefs of the past, but also the philosophical theories which provided ostensible justification for those beliefs, were discredited by historical investigation. But on what such investigation has to teach us Marx and Nietzsche were of course at odds.

Marx assigned both past conceptions of what is right and good and past philosophical theorizing about the right and the good to the realm of ideology. Morality and moral philosophy are secondary phenomena, to be explained by class structure and class conflict. Engels in *Anti-Dühring* wrote a history of the idea of equality in what he took to be Marx's terms, showing how it was initially generated and then transformed by the changing relationships between social classes. Lukács, who imputed to Marx a more Hegelian view of things, suggested a more complex way of relating ideas to social and economic development. What \*Marxism achieved for the history of moral philosophy was twofold. It made it evident that neglect of the relationships between philosophy and social structure will always be in danger of producing an idealized and distorted history. And it focused attention on the extent to which the history of moral philosophy is a history of conflicts.

Nietzsche's starting-point for his contrasting diagnosis of the failures of moral philosophy was his claim that the teachings of Socrates and Plato were a symptom of the decline of Greek culture. In *Zur Genealogie der Moral* (1887) and elsewhere Nietzsche attempted to explain morality itself as an unrecognized device of the cowardly herd, a self-crippling defence against those who are strong and self-assertive, whose protagonists portray as virtues qualities useful to the weak, while they denigrate the virtues of the strong. Moral philosophy from Socrates onwards is nothing but a series of apologetic rationalizations for morality, and is, like morality and religion, an unacknowledged expression of the will to power. Those modern philosophers who suppose themselves to be emancipated from religious morality are merely victims of a new set of delusions, among them not only those of the moral philosophies of Kant and the Utilitarians, but also belief in the ideal of objectivity prized by academic historians. Nietzsche's perspectivism is designed to undermine appeals to standards of impersonal truth both in understanding morality and in narrating its history.

The issues dividing Sidgwick from Marx and from Nietzsche are of course philosophical as well as historical.

Any attempt to judge which of them is in the right about the history of moral philosophy may be inescapably question-begging, since it seems that whatever methods of evaluation are employed will already presuppose prior commitment on just those philosophical issues on which they are divided. But at least we can inquire how far particular episodes in the history of moral philosophy can be illuminatingly described and explained in Nietzschean or post-Nietzschean terms. Parts of Michel Foucault's history of sexuality and some of the discussions of Greek philosophers in his last lecture series are exemplary post-Nietzschean treatments of the relationship between forms of power and types of moral theorizing. But they do not afford decisive grounds for accepting or rejecting the fundamental Nietzschean claims.

Against both Sidgwick and Nietzsche moral philosophers influenced by the Thomist revival of the late nineteenth and twentieth centuries, most notably Jacques Maritain, have proposed an interpretation of the history of moral philosophy according to which it is the moral philosophy of the high Middle Ages, especially that of Aquinas, which alone provides a standpoint from which ancient and modern moral philosophy can be adequately understood. Their defence of Aquinas's integration of Aristotelian virtue ethics with a biblical conception of a divine law apprehended by natural reason challenged Sidgwick's view of the relationship of ancient to medieval moral philosophy. Their account of the failures of modern moral philosophies to find a due place for both the right and the good is on some matters in agreement with Nietzsche's negative criticisms. But their Aristotelian rejection both of Nietzsche's perspectivism and of his psychology of the will to power puts them fundamentally at odds with Nietzsche. Once again philosophical disagreements are inseparable from disagreements over historical interpretation.

Recent work on the history of moral philosophy has raised more sharply than ever before the question whether it can be adequately narrated in independence of the history of philosophy in general and there is strong evidence to be cited on both sides of the question. T. H. Irwin in *Aristotle's First Principles* (Oxford, 1988) has presented an account of Aristotle's arguments and theses about the good, the virtues, and political association, according to which those arguments and theses are underpinned by and need to be made intelligible in terms of Aristotle's metaphysical and psychological conclusions. Annette Baier in *A Progress of Sentiments* (Cambridge, Mass., 1991) has interpreted the third book of Hume's *A Treatise of Human Nature* on his moral philosophy as related so intimately to the first two books on his epistemology and his philosophical psychology that it cannot be rightly understood in detachment from them. What work such as Irwin's and Baier's strongly suggests is that any attempt to abstract and isolate an account of the moral philosophy from an extended treatment of the larger philosophical intentions and commitments of the greatest moral philosophers is bound to distort and to falsify.

Yet at the same time there have been some equally remarkable achievements in constructing histories specifically devoted to moral philosophy. J. B. Schneewind provided what is for the foreseeable future a definitive account of nineteenth-century British moral philosophy in *Sidgwick's Ethics and Victorian Moral Philosophy*. And on a larger scale it has become clear that what no single author can any longer hope to achieve, because of the large body of scholarly material that needs to be mastered, may none the less be achieved by the co-operative work of a number of authors.

The most impressive co-operative work to date of this kind is the indispensable series of monographs included in the three-volume *Historia de la ética* edited by Victoria Camps. The first volume divides moral philosophy from the Homeric age to Machiavelli between eleven authors. The sixteen contributions to the second volume, including the editor's essay on Locke, and essays both on other individual thinkers and on movements of thought, is to end with Nietzsche. The third volume's fourteen essays on contemporary ethics (Barcelona, 1989) culminate in accounts of Habermas, Rawls, and socio-biology.

Much shorter, but an extraordinary achievement for its length, is *A History of Western Ethics*, edited by Lawrence C. Becker and Charlotte B. Becker (New York, 1992), in which thirteen authors survey the history of Western moral philosophy from the Pre-Socratics to the present. What these two collections jointly ensure is that the need for overall accounts of Western moral philosophy which meet the requisite scholarly standards but avoid any large interpretative commitments has been met for the time being. Indeed they prompt the question whether anything more ambitious is feasible. Is there indeed any possibility, on the basis provided by these and other scholarly monographs, of constructing some narrative of the history of Western moral philosophy, unified by some single, if complex, overall interpretation, superior to those already advanced by Sidgwick, by the Marxists, by Nietzsche's heirs, and by modern Thomists? Or do such books as those by Irwin and Baier warrant the conclusion that we ought not even to attempt to write the history of moral philosophy as a separate history? Should we write the history of moral philosophy only as one strand in the history of philosophy?

Some of the difficulties in answering these particular questions arise from our failure to provide satisfactory answers to another set of questions. Can we write the history of moral philosophy except in the context of writing the history of moral practice? Moral philosophy is after all in significant part theoretical reflection upon certain aspects of a variety of modes of social practice, and Marxists and others have made us aware that changes in those modes have at different times transformed the subject-matter upon which moral philosophers reflect. Moreover, in certain periods moral philosophies have been influential in changing the terms of moral debate and in providing new ways of understanding social practice. Abstract the theories of moral philosophers from the contexts of social

practice in which they were at home and you distort the character of those theories. Omit from the histories of social practices those episodes of philosophical reflection in which morality was from time to time reconceived and you distort the history of those practices. But any extended history of moral theory which systematically understands it as embedded in moral practice has yet to be attempted.

There is another limitation on even the best work to date which it is crucial to note. Historians of Western moral philosophy very rarely exhibit any awareness of the history of moral thought in non-Western cultures, so depriving their own narratives of any comparative dimension, and so preventing us from understanding how the history of Western moral philosophy is to be viewed from various non-Western standpoints. Consider, for example, the rival Chinese moral traditions of \*Buddhism, \*Confucianism, and \*Taoism, each with its own modes of philosophizing. In the debates between such traditions, as well as in the discussions internal to each of them, issues and problems instructively similar to those within Western moral philosophy, but with their own distinctive characteristics, continually recur. It is not that the history of these various traditions has yet to be written. Admirable studies by Chinese, Japanese, and Western scholars already exist. But Western comparative historical work remains rare. One seminal inquiry is Lee H. Yearley's *Mencius and Aquinas: Theories of Virtue and Conceptions of Courage* (Albany, NY, 1990). The need for more writing of the same kind about the history of a wide range of non-European moral philosophies is evident. A. MacI.

\*Buddhist philosophy; moral philosophy, history of.

**history, history of the philosophy of.** Philosophy of history is generally understood as covering two distinct types of inquiry. The first of these—commonly referred to as 'speculative' or 'substantive' philosophy of history—is broadly taken to have as its subject-matter the actual human past, the latter being viewed from a universal or synoptic standpoint and studied with the aim of disclosing the overall workings and significance of the historical process considered as a whole. The second branch of inquiry—usually entitled 'critical' or 'analytical' philosophy of history—is primarily directed towards investigating the manner in which practising historians proceed in the course of eliciting and interpreting the particular events, developments, and so forth of which the human past is composed. Here the focus of attention is upon history regarded as a specific form of knowledge, the philosopher's concern being with such matters as the fundamental concepts or categories historical thinking involves and the presuppositions underlying the historian's cognitive claims and typical modes of inference. Philosophy of history in the speculative sense has enjoyed a long if somewhat variegated career. Critical philosophy of history, on the other hand, is of far more recent origin, only rising to prominence in the twentieth century. As

will be seen, however, the two disciplines have not evolved altogether independently of one another, there being discernible points of connection as well as major differences between the two.

*Speculative theories.* The belief that the course followed by human history ultimately amounts to more than a purposeless sequence or fortuitous flux of happenings and that it should be possible to descry within it some overarching pattern or design which would endow it with a rationally or morally acceptable meaning is very old. So far as Western thought is concerned, a pre-eminent source of speculation along these lines lay in religious conceptions of the destiny of humanity and its place in a divinely governed universe. Thus early in the Christian era certain Church fathers were already to be found reacting against Graeco-Roman cyclical theories of historical development and seeking instead to portray it as conforming to a linear course that reflected the intentions of a supernatural providence. The most influential view of this kind was given sophisticated expression in the fifth century by St Augustine. Augustine's ideas, as presented in the *City of God* and elsewhere, diverged considerably from the cruder notions espoused by some of his predecessors; he drew a crucial distinction between sacred and secular history and displayed a cautious reticence regarding the feasibility of trying to interpret the details of the latter in a providential fashion. It cannot, however, be said that a comparable subtlety and reserve characterized the works of subsequent Christian theorists, who for more than a thousand years after he wrote still looked to him for inspiration in their approach to the past. This was particularly evident in the case of the seventeenth-century French historian and religious thinker J. B. Bossuet, who exhibited a striking confidence in the possibility of plumbing the designs of the 'everlasting mind' as these impinged upon human affairs. In his best-known book, the *Discourse on Universal History* (1681), Bossuet makes no attempt to disguise the theological concerns underlying his enterprise: the interpretation the author provides mirrors his conviction that the direction taken by the historical process was 'contrived by a higher wisdom' and that the fortunes of empires and creeds could be seen to manifest God's purposes in a manner that was as reassuring to the devout as it was—or at least should have been—disturbing to sceptics and infidels.

Although philosophical speculation about history may have been originally prompted and shaped by such pre-occupations, this was no longer true of its development in the more secular climate of the eighteenth-century \*Enlightenment. The shift in outlook largely derived from the momentous advances that had been achieved in the sphere of the physical sciences, above all from those associated with Newton. For it now appeared that, rather than through relying on the postulates of religious or metaphysical dogma, the search for a meaningful pattern or order in the historical sphere might be more effectively pursued by adopting empirically based methods of

inquiry analogous to those that had proved so successful in the scientific investigation of nature. If natural phenomena had been thus shown to be subject to universal laws of immense scope and explanatory power, why should it not be accepted that similarly discoverable uniformities governed the realm of social and historical phenomena?

The project of utilizing past experience in order to construct a universally valid science of man and society found adherents amongst a number of the French \*philosophes and was passionately endorsed by Condorcet in his *Sketch for a Historical Picture of the Progress of the Human Mind* (1795). Condorcet held that the principles of such a science would not only serve to explain the course history had so far followed; they would also provide the means of forecasting the outlines of future developments and of facilitating the promotion of social and cultural advances. In so connecting the predictive potential of a 'science of social phenomena' with practical ideals and long-term goals, Condorcet emerges as the forerunner of a line of nineteenth-century theorists who treated knowledge of the fundamental factors governing historical change as lending essential support to radical programmes of institutional reorganization and political or economic reform. Men like Henri de Saint Simon, Auguste Comte, and H. T. Buckle may have differed significantly in what they considered to be the prime determinants of historical progress. Nevertheless, they shared a common commitment to the existence of comprehensive laws, whose operation was invoked in both explanatory and predictive contexts and which tended to be regularly cited as bearing upon the feasibility of reformist policies and aims. Since no serious doubts were entertained regarding the desirability of the ends towards which history was ultimately leading, it seemed clear to such thinkers that the realization of these should be hastened rather than merely awaited, confidence in their eventual fulfilment in the future functioning as a spur to anticipatory exhortation and active planning in the present.

How far, though, was that confidence justified? Those who entertained it were for the most part content to argue that it was warranted on purely inductive grounds. There were contemporary critics, however, who remained unimpressed by current appeals to allegedly scientific modes of reasoning and who questioned both the formal status and the evidential backing of some of the so-called 'laws' to which reference was made; the latter appeared to savour more of what the Swiss historian Jakob Burckhardt termed an 'astrological impatience' to preempt the course of things to come than of an open-minded readiness to formulate and assess empirically testable hypotheses. Furthermore, behind such doubts there often lay a more general uncertainty concerning the theoretical adequacy of the scientific paradigm itself as an appropriate model for the interpretation of the historical process. From the circumstance that the apparently well-regulated realm of natural objects had proved amenable to a particular type of inquiry, it by no means automatically followed that the behaviour of people in societies was comprehensively

intelligible along the same lines. On the contrary: the notion that such behaviour could be profitably studied or explained in terms of a methodology approximating that of the physical sciences remained a mere assumption which—at least to some critics—seemed a highly implausible one.

The assumption in question had in fact already been challenged in the previous century by two major speculative theorists who, occupying independent standpoints, shared the conviction that profound differences separate the cognitive resources available to us in our dealings with the world of physical nature from the forms of understanding that are appropriate to the sphere of human beings and their activities. Giambattista Vico's *Scienza nuova* (New Science, 3rd edn. 1744) was a strange and difficult work that attracted little notice on its initial appearance and certainly achieved no immediate recognition for its obscure Neapolitan author. In retrospect, however, it has come to be regarded as a product of genius, introducing conceptions of historical thought and knowledge that were of striking originality and prescience. At the centre of the book is the idea that human societies ('nations') pass through distinct stages of development, each of which manifests a particular type of mentality or outlook that pervades the various institutions, rituals, styles of art, etc. of the time. In the light of this it was a mistake to suppose that human nature and consciousness remained constant and uniform throughout the course of the past, and Vico repeatedly criticized contemporary writers for interpreting the actions or creations of previous generations in inapposite terms that derived from the cultural ethos of their own age. Instead of imposing such 'falsifying pseudo-myths' on what had been produced in other periods, the historian should seek to enter imaginatively into the different beliefs and attitudes that informed it. Vico laid special stress upon the various kinds of evidence—linguistic, archaeological, mythological—which could help him to do so. The task involved might require 'incredible effort' but even so it was in principle practicable. For, as Vico consistently maintained, in order truly to know something it was necessary to have made it. Unlike the world of natural objects, which 'since God made it, he alone knows', the 'world of nations' had been created by human beings and was therefore something they could 'hope to know' in a fashion other than, and superior to, any available mode of comprehending the workings of the material universe.

While there appears to have been no question of direct influence, some of Vico's cardinal themes re-emerged in the writings of the German philosopher J. G. Herder, and especially in the latter's massive panoramic survey of the past, *Ideas for the Philosophy of the History of Mankind* (1784–91). In common with his Italian predecessor, Herder laid stress upon the 'plasticity' of human nature. The human spirit did not conform to the tidy models or formulae within which scientifically minded theorists sought to contain it, but was on the contrary distinguished by the great diversity of forms it manifested in the context of

different societies and cultures. Particular human undertakings and achievements must always be interpreted in relation to the cultural milieu to which they essentially belonged, not prized out of these and assessed from some generalizing or abstract standpoint that transcended the limits of time, place, and circumstance. And for Herder, as for Vico, this meant underlining the importance of imaginative understanding as representing an indispensable condition of historical knowledge. What was required was *Einfühlung*, a 'feeling into' the individual significance of actions, characters, periods, each being considered for itself 'without foisting any set pattern upon it'.

A comparable, and perhaps partly derivative, conviction that it was fundamentally misconceived to interpret the historical process in 'naturalistic' or putatively scientific terms underlay what amounted to the most complex and ambitious contribution to speculative philosophy of history in the nineteenth century. G. W. F. Hegel's aims in his famous *Lectures* (1837) on the subject may have been rivalled in scope by those of such near-contemporaries as Comte and Buckle; his own account, however, was rooted in a wholly different tradition of thought. For Hegel combined a rejection of uniformitarian views of human nature with an explicitly teleological approach to the past according to which this involved the unfolding in reality of a certain paramount conception or idea. Thus he maintained that history was essentially concerned with the development of what he termed 'spirit' (*Geist*); the essence of spirit—here contrasted with physical nature or 'matter'—was freedom, and the historical process should consequently be seen as comprising a stage-by-stage realization of that rational notion within a social setting. Hegel did not deny that the societies in which these stages were successively embodied displayed contrasting modes of life, the behaviour of their members being only fully intelligible in the light of whatever distinctive outlook prevailed at a particular epoch; in this sense what he wrote echoed the Herderian contention that human nature was subject to radical variations that set definite limits to the types of interpretation appropriate to distinguishable periods or cultures. He was insistent, on the other hand, that the variations in question occurred in a progressive temporal order; spirit was engaged in an 'ascent to an ever higher concept of itself', overcoming its previous manifestations in a continual process of self-transformation and self-transcendence. In practice this meant that historical advance did not take the form of a smooth or uninterrupted series of changes. Rather, Hegel pictures such transitions in dramatic terms, each new phase involving the 'negation' of a state of society which has lost its original historical role and contains the seeds of its own destruction. History, in other words, is a 'dialectical' process, its forward movement generated by the creative opposition of spiritual principles and its final outcome attributable to a rational purpose 'higher and broader' than any conceived by the innumerable human individuals whose multifarious aims and activities are none the less actually instrumental in bringing it about.

In view of the uncompromisingly anti-naturalistic tenor of Hegel's philosophy of history it may appear somewhat paradoxical that it should have exercised a decisive influence on Karl Marx, the scientific character of whose own theory of social development has been tirelessly emphasized by its proponents. Marx certainly repudiated the idealist or 'mystical' aspects of the Hegelian doctrine, substituting for it one in which the fundamental agents of change were not spiritual but material, the direction of history being ultimately governed by the evolving methods whereby men sought to exploit their natural environment in the course of satisfying their needs. The result was an account that stressed both the role in history played by conflicts between economically determined classes and the extent to which the shape taken by the ideological 'superstructure' of a society was causally dependent on the forces and relations of material production that lay at its foundation. Even so, Marx himself implied that if the basic priorities of Hegel's system were suitably transposed in the manner suggested, the latter's conception of history as proceeding dialectically towards the realization of a rationally ordered community could be seen to yield profound insights into its true meaning. From this point of view the complex origins of Marx's own historical theory may be said to have owed as much to aspects of German post-Kantian metaphysics as they did to the postulates and scientific aspirations of French and British radicalism.

*Critical approaches.* By contrast with its predecessor the twentieth century witnessed a significant reduction in the popularity and prestige of speculative philosophy of history. Admittedly, it saw the publication of two major contributions to the genre: Oswald Spengler's *The Decline of the West* (1918–22) and Arnold Toynbee's ten-volume comparative study of civilizations, *A Study of History* (1934–54). By the time these works appeared, however, the project of producing general theories which purported to transcend the perspective of ordinary historiography in the name of what Toynbee called 'a scientific approach to human affairs' had been subjected to a variety of wide-ranging critiques. As we have seen, opposition to such an approach had already found expression in the influential methodological contentions which earlier thinkers like Herder and Hegel had advanced within a predominantly speculative setting. But it was only towards the close of the nineteenth century that a systematic reappraisal was initiated by philosophers who were distrustful of the speculative enterprise in any of the protean forms it might assume and who felt that its extravagant ambitions should be eschewed in favour of undertaking a more narrowly focused examination of history's epistemological status. This seemed especially called for in view of the considerable strides historical scholarship and research had made in the previous decades. It was time for philosophy to come to terms with the apparent autonomy of history, investigating the conditions of its possibility and its claims to qualify as an accredited branch of inquiry or discipline.

Foremost amongst the writers who broached these issues were Heinrich Rickert and Wilhelm Dilthey in Germany and Benedetto Croce in Italy. All three underlined features of historical thinking which seemed to them to set it apart from that of natural science. Thus the historian, unlike the scientist, was not concerned with the discovery of laws or theories from which predictions could be derived, his attention being directed instead to delineating things and events in their unique and unrepeatable particularity. And this was connected with further points upon which both Dilthey and Croce laid great emphasis and which were taken up and eloquently developed by their British admirer R. G. Collingwood. Collingwood wrote approvingly of Dilthey's doctrine of *Verstehen* (hermeneutic understanding) and of Croce's characterization of historical thought as the recreation of past experience, going on to elaborate his own conception of what it involved in his posthumously published *The Idea of History* (1946). In that book he claimed that the historian's essential task was to 'rethink' or inwardly re-enact the deliberations of past agents, thereby rendering their behaviour intelligible in a fashion that had no counterpart in the sphere of scientific explanation. Understanding a given occurrence in history was not a matter of subsuming it beneath empirical laws or generalizations but of eliciting its 'inner side', this comprising (for example) considerations that showed what had been done to have constituted a rational, or at least motivationally comprehensible, response to a practical issue or dilemma.

The rapid growth of critical philosophy of history in the English-speaking world after the Second World War owed much to the stimulus provided by the work of these writers. This is not to say that their specific contentions met with general acceptance; a number of analytical philosophers objected to what they felt to be an inappropriately psychological construal of conceptual or epistemic questions, while others maintained that historical and social explanations ultimately conformed to the same logical model as those characteristic of other domains of empirical inquiry. None the less, the original claims made on behalf of the autonomy of the historical studies proved to be a fertile source of subsequent controversies, their traces still being discernible in the fundamental problems that continue to haunt the subject. **history, problems of the philosophy of.** The distinction that has been drawn between speculative and critical

approaches to the philosophy of history may be illustrated by considering the different sorts of problem to which they respectively give rise. Thus speculative theorists have sought to answer substantive questions dealing with such matters as the significance or possible purpose of the historical process and the factors fundamentally responsible for historical development and change. In doing so, they have been inspired by the conviction that history raises issues which transcend the mostly limited concerns of the ordinary working historian and which pertain to perennial demands for an intellectually or morally satisfying overall perspective on the human past. By contrast, the questions that preoccupy critically orientated thinkers are of a radically dissimilar type, these tending instead to be directed to such subjects as the nature of historical understanding, the possibility of objectivity in historical writing, and the kind of truth ascribable to historical interpretations or accounts. So conceived, the problems involved invite comparison with those investigated by contributors to other branches of contemporary philosophy—e.g. philosophy of science—in being essentially second-order ones that here have to do with the distinctive features of history as a particular discipline. It is accordingly to outstanding issues of the latter sort that this article is chiefly addressed. At the same time, however, we should remember that work in this domain has often been influenced—even if only indirectly—by developments in epistemological \*hermeneutics that are more readily associated with continental writers than with analytical philosophers representative of the English-speaking world. It is therefore not surprising that tensions due to the impact of divergent traditions of thought should from time to time find expression in some of the discussions which problems in the critical philosophy of history have provoked.

*Historical explanation.* One topic which has proved to be a persistent source of argument and disagreement concerns the underlying character or structure of explanation in history. Amongst other things, this has thrown into relief the wide gulf separating those philosophers who regard a certain account of scientific \*explanation as providing a paradigm to which all explanation should ideally conform and those who on the contrary maintain that the distinctive subject-matter of history is susceptible to, or even requires, a wholly different mode of understanding. We shall begin with the first.

In what has come to be known as the \*‘covering-law’ model or ‘deductive-nomological’ account, it is implied that any acceptable explanation of events involves showing them to instantiate certain general laws or uniformities. More specifically, an occurrence can only be said to be adequately explained when it is shown to be deducible from premisses consisting, on the one hand, of assertions descriptive of given initial or boundary conditions and, on the other, of statements expressive of empirically well-confirmed universal hypotheses. On such a view, the historian who offers a causal explanation of an event is seemingly committed thereby to accepting the existence

of whatever laws or regularities its validity presupposes; for, in the words of a prominent early proponent of the covering-law theory (Carl Hempel), ‘to speak of empirical determination independently of any reference to general laws means to use a metaphor without cognitive content’. It might be objected that historical inquiry is primarily directed towards the particular and singular, not to the general or universal. But it is argued that this, though true, does not affect the present issue; the above-mentioned implicit commitment to generality is in no way incompatible with the claim that the historian is occupationally concerned with the detailed delineation and analysis of individual occurrences or states of affairs. It is not even incompatible with the contention that there are respects in which complex historical events may properly be termed ‘unique’. All that is requisite for explanatory purposes is that the explananda should be classifiable with other events under *certain* aspects, namely, those relevant to the application of appropriate generalizations or laws to the particular cases in question.

Despite its attractions as apparently combining conceptual economy with a respect for the distinguishing character of the historian’s interests and concerns, the covering-law model has encountered various criticisms, of which two may briefly be mentioned. The first relates to the nature of the ‘general laws’ allegedly presupposed in historical explanation. It has been argued that any attempt to specify them is apt to issue either in formulations too vague and porous to be of use in practice or else in ones so highly particularized as not to qualify as genuine statements of law at all; thus the model has been held at best to require major qualifications or amendments if it is to serve as a plausible representation of how historians actually proceed. Secondly, it has been urged that the proposed analysis fails to do justice to a crucial aspect of the historian’s approach to his or her material. History has to do with the activities of human beings, and understanding the latter standardly involves notions like those of desire, belief, and purpose whose explanatory role cannot (it is claimed) be adequately comprehended within the framework of the covering-law theory. Hence it has been maintained by a number of philosophers, of whom William Dray has been one of the most influential, that an alternative model of ‘rational explanation’ often provides a better guide to the ways in which historians typically seek to render the past intelligible. The happenings of which they treat commonly comprise deliberate actions and their intended consequences, and satisfactorily accounting for these is a matter of reconstructing the reasons that made them appear appropriate or justified in the eyes of the agents concerned rather than of presenting them merely as occurrences that supposedly exemplify inductively attested uniformities. Such a rational model may be regarded as implicitly endorsing the ‘re-enactment’ account of historical thinking propounded earlier by R. G. Collingwood, but without carrying the dubious epistemological implications for which theories embodying appeals to empathetic insight have sometimes been

criticized. The question remains, on the other hand, whether it can be validly employed in a manner that altogether dispenses with underlying generalizations concerning the determinants of human behaviour—a question that impinges on some notoriously controversial issues in the philosophy of mind.

Whatever the merits or otherwise of the covering-law and rational models of explanation, it seems clear that neither can be said to do more than offer partial and highly schematic perspectives on a topic which can take a variety of diverse forms and which has tended to prove in consequence resistant to different attempts to encapsulate its essence in a tidy formula or unitary interpretative scheme. Thus explanations in history may range from being ones that purport to demonstrate the inevitability of a particular event to others that are confined to indicating how an unexpected occurrence was possible in a given set of circumstances, and from being ones that focus on the individual motivation attributable to certain historical figures to others whose chief concern is with the influence exerted by such impersonal factors as environmental conditions or advances in technology. Nor is it obvious that explaining something in a historical context is invariably a matter of showing it to be in some sense the causal outcome of other events or states of affairs. Descriptions of an occurrence as being of a certain kind (e.g. as constituting a revolution), or again as being symptomatic of a particular tendency or trend, may perceptibly increase or illuminate our understanding of what took place. They do not, however, appear to do so by providing anything straightforwardly analogous to a causal explanation, whether in the natural sciences or elsewhere.

*Objectivity and valuation.* What is often referred to as the problem of historical objectivity has been the source of further disputes about the status of history in relation to other branches of study or investigation. Admittedly, it has sometimes been argued that the question whether history is or can be objective is not one that can legitimately be raised in a general or unrestricted way: within the discipline itself there certainly exist accepted criteria according to which the objectivity or otherwise of particular historical accounts may be appraised and relevant comparisons or contrasts drawn; but seeking to identify and critically examine such internal standards is a very different matter from asking whether history as such constitutes an objective form of inquiry. Different it may be; nevertheless, this has not prevented philosophers and historians alike from giving serious consideration to the latter question or from seeing it as touching upon a number of complex and troublesome issues. The notion of objectivity is renowned for being a slippery one. What specific difficulties has it been thought to present here?

One point frequently stressed concerns the fact that history is necessarily selective; a historian whose account aimed to include every conceivable constituent of a particular stretch of the past would be comparable in some respects to Lewis Carroll's imaginary cartographer, whose

ideal map was one that exactly reproduced, both in scale and detail, the piece of country it was meant to chart. Instead it must be recognized that the employment of selective judgements of relevance, together with ones of comparative importance or interest, represents a central and ineliminable feature of historical procedure. And this is held to have significant implications. For such judgements can be said to presuppose a range of preconceptions and attitudes which are in principle contestable and which are liable to vary from person to person, culture to culture, period to period. Individual preferences or contemporary preoccupations, metaphysical or religious beliefs, moral or political convictions—these may all, if at times only unconsciously, influence such things as the presentation of historical findings, the choice of what to put in or omit, the relative weight assigned to different factors or causal conditions, and even the critical assessment of evidence and sources. In consequence, the conclusion has often been drawn that history is infected with a radical 'subjectivity' which casts doubt on its claims to be an indisputably factual discipline with impeccable cognitive credentials.

As with many arguments of a purportedly sceptical character, there is a danger in the present instance of various distinctions being blurred or overlooked. For example, it is an error to suppose that a historian's presentation of material and judgements of inclusion or exclusion must invariably be determined by allegedly subjective or arbitrary considerations. On the contrary, they may be dictated in a quite unexceptionable fashion by the specific nature and parameters of the particular problem that is under discussion. Again, it is one thing to say that a historian's own choice of subject is due to temperamental preference or to matters of current interest, but quite another to suggest that factors of the latter kind will necessarily affect the manner in which the topic is investigated or conclusions about it reached; nor, incidentally, does there seem to be any justification on this score for distinguishing history from other accredited types of inquiry where similar points apply. Furthermore, so far as criteria of historical importance are concerned, it may be contended that these are commonly susceptible to an interpretation involving what has been called 'causal fertility'. Thus the decision over whether some given occurrence was of greater importance than another event may be made on the strength of its having been causally productive of more far-reaching effects or more lasting repercussions. But it is arguable that questions of this type are purely empirical and as such responsive to impartial or detached investigation; they have nothing essentially to do with subjective beliefs or attitudes attributable to the historian and are answerable without any reference to those.

However, the concept of importance cannot invariably be interpreted along such narrowly causal or instrumental lines. It is also frequently used—in history as well as elsewhere—to characterize what is regarded as intrinsically significant or worthy of note on its own account. And it is far from clear that ascriptions of importance, so construed, can be treated as straightforwardly objective in the

sense in which scientific statements are often assumed to merit this encomium. For they appear to reflect distinctively evaluative positions or points of view that may be allowed to exercise a definite, though by no means exclusive, influence on the ways in which historians sift and organize the material at their disposal. To maintain that history can to this extent be considered to have an irreducibly evaluative dimension is not, of course, equivalent to suggesting that it is subjective in the pejorative sense of implying personal idiosyncrasy or prejudice. Evaluative outlooks or standpoints can be widely shared and are capable of being understood in a fashion that permits of critical discussion and rational debate; moreover, the logical status of moral judgements in particular continues to be a matter of philosophical dispute. None the less, it cannot be denied that it is on the specific issue of the role and relevance of evaluative considerations that much of the argument about historical objectivity has in fact tended to turn. There are certainly modern historians and philosophers who have felt that moral judgement should be as far as possible excluded from history as strictly conceived, its being—in the words of one of the former—‘alien’ to history’s ‘intellectual realm’, and similar views have been expressed on other aspects of value. But the problem has also met with quite different types of response, not least on the part of recent analytical writers who have argued that many of the fundamental terms and categories which the historical studies presuppose cannot be fully understood or properly applied without reference to the element of evaluation that pervades the sphere of human life and action. In the eyes of such objectors the conception of a wholly *wertfrei* history is at best unrealizable in practice and at worst perhaps incoherent in principle. Generally, however, they have not seen this as in any way committing them to the opinion that history is not a valid form of inquiry or that there is no such thing as historical truth; despite what has at times been supposed, a suitably circumspect appreciation of the role of value-judgement in historical thinking entails no consequences of a radically sceptical kind.

*Narrative and interpretation.* The same cannot be said of an aspect of historiography which has increasingly attracted the attention of philosophers and which has undoubtedly come to be viewed by some of them as having revisionary implications for the cognitive status of the subject. This concerns the nature and uses of narrative in the portrayal of the past. In opposition to certain accounts according to which story-telling essentially functions as little more than a convenient device for conveying or writing up the results of independent research, it has been contended that narrative in fact constitutes an autonomous mode of understanding which is distinctive of historical thought. Amongst other things, it involves apprehending historical occurrences in what has been termed a ‘synoptic’ or ‘configurational’ fashion that makes it possible to see them as forming part of an intelligible pattern and as contributing to an interrelated whole. When regarded in this light

narrative can be said to transcend the presentation of a merely chronological sequence of events; at the same time the kind of interpretation it provides is more comprehensive than what is usually understood by explanation in history, although it may be allowed to overlap with the latter in some of its forms.

Philosophers who have addressed themselves to this topic have often shown insight and subtlety, both in articulating and illustrating the crucial part played in narrative by factors like coherence and followability and in drawing interesting parallels between its uses in history and literature. In invoking such parallels they have been especially concerned to emphasize the role of imagination in historical writing and the extent to which the ‘stories’ historians tell are actively constructed rather than ‘read off’ from the factual or evidential data in a passive or uncritical manner; they should not be thought of as retailing a set of happenings already neatly organized and waiting to be reproduced in linguistic form. But whatever the force of such contentions, it is another thing to suggest—as is sometimes done—that narratives in history must be conceived as artificially ‘imposed’ or freely ‘projected’ upon a past which itself lacks a discoverable narrative structure and which may be ‘emplotted’ (to use a favoured term) in any one of a number of different ways. While it may be salutary to challenge a naïvely mimetic view of their character, it does not follow that historical narratives are not answerable to criteria of truth in a fashion which sharply distinguishes them from works of literary fiction and which practising historians regard as setting recognizable limits to their acceptability. Hence, despite the contributions that writers like Louis Mink and Hayden White have made towards enlarging philosophical perspectives on the place of narrative in history, it is hardly surprising that the strain of epistemological scepticism running through much of their work has provoked lively criticism and is the subject of continuing controversy. Here, as elsewhere in the rich field of philosophy of history, may be found a host of contentious issues with roots often stretching out into adjoining areas of thought and inquiry: it has been possible in this article to touch on only a representative selection of these.

**Hobbes, Thomas** (1588–1679). Generally regarded as the founder of English moral and political philosophy. He

wrote several versions of his moral and political theory, but although he improved many important details, the overall theory remains the same. *Leviathan* (English edition 1651, Latin edition 1668) is generally considered to be his masterpiece, but *De Cive* (1642, new notes and a new preface to the reader added in 1647, English translation 1651) may be the most careful presentation of his moral and political theory. In so far as Hobbes expresses the same view in both *De Cive* and *Leviathan*, this view should be taken as his considered position. *De Cive* was part of a philosophical trilogy in Latin: *De Corpore* (1655), *De Homine* (1658), and *De Cive*. *De Cive*, which was concerned with 'the rights of dominion and the obedience due from subjects', was supposed to be the final book of the trilogy, but Hobbes published it first, saying that the approaching Civil War 'plucked from me this third part'.

Hobbes wrote on a wide variety of philosophical topics: aesthetics, free will and determinism, epistemology, human nature, law, logic, language, and metaphysics, as well as moral and political theory. He also wrote on optics, science, and religion, and is considered by some to be a founder of modern biblical interpretation. He also published translations of Thucydides (1628) and Homer (1674–6) and authored a somewhat biased history of the period of the Civil War. He entered into some unfortunate mathematical controversies by claiming that he had squared the circle. He was a secretary to Francis Bacon, visited Galileo, and engaged in disputes with Descartes.

Hobbes claims that he was born prematurely (5 April 1588) because of his mother's fright over the coming of the Spanish Armada. He seems to have been proud of being fearful, proclaiming that he was the first of all who fled the Civil War; and he did leave England for France in 1640 and remained in Paris for eleven years. However, his writings are very bold. He published views that he knew would be strongly disliked by both parties to the English Civil War. He supported the king over Parliament, which earned him the enmity of those supporting Parliament, but he not only denied the divine right of the king, he said that democracy was an equally legitimate form of government, which earned him the enmity of many royalists, though not of the king. He also put forward views concerning God and religion that he knew would cause those who held traditional religious views to regard him as dangerous. The Roman Catholic Church put his books on the Index, and Oxford University dismissed faculty for being Hobbits. Some people recommended burning not only his books but Hobbes himself. Although he had gained great fame on the continent as well as in England, he remained a controversial person even after his death on 4 December 1679 at the age of 91.

Hobbes not only wanted to discover the truth, he wanted to persuade others that he had discovered it. He believed that if his discoveries were universally accepted, there would be no more civil wars and people would live together in peace and harmony. After praising the work of the geometers, he says:

If the moral philosophers had as happily discharged their duty, I know not what could have been added by human industry to the completion of that happiness, which is consistent with human life. For were the nature of human actions as distinctly known as the nature of *quantity* in geometrical figures, the strength of *avarice* and *ambition*, which is sustained by the erroneous opinions of the vulgar as touching the nature of *right* and *wrong*, would presently faint and languish; and mankind should enjoy such an immortal peace, that unless it were for habitation, on supposition that the earth should grow too narrow for her inhabitants, there would hardly be left any pretence for war.

Although Hobbes knew that it was extremely unlikely that his moral and political discoveries would be accepted by any significant number of people, let alone universally accepted, he continued to improve his moral and political theory and to present it more forcefully. His interest in other philosophical topics was also practical, although not always quite so directly. He used his philosophical views to argue against and discredit standard religious views. For Hobbes it was a practical necessity to discredit those religious views that were incompatible with his moral and political philosophy. Failure to appreciate how important Hobbes thought it was to make religion compatible with civil peace would make it unintelligible that he explicitly devotes about a third of *De Cive* and about a half of *Leviathan* to the interpretation of Christian scriptures. He knew that belief in some form or another of Christianity was going to be a dominant factor in the political life of England (and of the other European countries). Thus he attempted to provide an interpretation of Christianity that removed it as a threat to civil peace.

Although Hobbes's major interest is in moral and political theory, he is a systematic thinker, and his views about language, reasoning, and science had a significant impact on the presentation of his moral and political theory. His epistemological and metaphysical views were less developed, and he used them primarily as a foundation for his anti-religious views. Although Hobbes explicitly claims to be a materialist, he vacillates between epiphenomenalism and what would now be called 'reductive materialism'. After defining the theoretical concept of endeavour as the invisible beginnings of voluntary motion, he uses endeavour to define the more common psychological terms that are part of his analyses of particular passions. 'This endeavour, when it is toward something that causes it, is called APPETITE OF DESIRE . . . And when the endeavour is fromward something, it is generally called AVERSION.' He sometimes regards pleasure and pain as epiphenomena, i.e. as appearances of the motions of desire and aversion; but in other places he puts forward a reductive materialist account of pleasure and pain, i.e. pleasure simply is a desire for what one already has. On this account, to take pleasure in something is to desire for it to continue.

All that Hobbes wanted to show was that there is a plausible materialist explanation of all the features of human psychology, e.g. sense, imagination, dreams, appetites, and aversions, in terms of the motions in the body. He did not claim to show how the motions of sense

and imagination actually interact with the vital motion, e.g. breathing and blood flow. He simply uses the concept of endeavour to show that his philosophy of motion is compatible with an ordinary understanding of psychological concepts.

Once Hobbes has the concepts of appetite and aversion, pleasure and pain, his account of the individual passions completely ignores the relation between human psychology and his materialist philosophy. He simply proceeds by way of introspection and experience, along with liberal borrowings from Aristotle's account of the passions. Hobbes explicitly maintains that introspection and experience, not a materialist philosophy, provide the key to understanding human psychology. In the introduction to *Leviathan*, he says, 'whosoever looketh into himself, and considereth what he doth, when he does *think, opine, reason, hope, fear, &c.* and upon what grounds, he shall thereby read and know, what are the thoughts and passions of all other men upon the like occasions.' He closes his introduction with the claim that he has provided an account of mankind, and that all that anyone else has to do is 'to consider, if he also find not the same in himself. For this kind of doctrine admitteth no other demonstration.'

Just as Hobbes finds no incompatibility between materialism and human psychology, so he finds no incompatibility between determinism (or God's omniscience and omnipotence) and human freedom. On his view, all that is required for a person to be free is that his action proceeds from his will. Since Hobbes defines the 'will' as 'the last appetite (either of doing or omitting), the one that leads immediately to action or omission', all that is necessary for a person to be free is that he act as he wants. This kind of freedom is compatible with both materialistic determinism and God's omniscience and omnipotence. However, at least since Freud, doing what one wants has not been taken by many philosophers as sufficient for free will. Unlike Hobbes, they do not take free will to mean 'the liberty of the man [to do] what he has the will, desire, or inclination to do'. Rather, they take free will to refer to some power within the person with regard to his desires, e.g. the ability to change one's desires in response to changes in the circumstances. Hobbes thought that people did have that power, which he called reason, and although he does not explicitly relate reason to free will, he may be regarded as the forerunner of contemporary compatibilist views that do so.

Hobbes has a somewhat pessimistic view of human nature, but he did not hold the view that the only motive for human action was self-interest, a view known as 'psychological egoism'. He did hold that children are born concerned only with themselves, but he thought that with appropriate education and training they might come to be concerned with others and with acting in a morally acceptable way. He thought that, unfortunately, most children are not provided with such training. He holds that most people care primarily for themselves and their families, and that very few are strongly motivated by a more general concern for other people. He does not deny

that some people are concerned with others, and in *Leviathan* he includes in his list of the passions the following definitions: '*Desire of good to another, BENEVOLENCE, GOOD WILL, CHARITY. If to man generally, GOOD NATURE*' and '*Love of persons for society, KINDNESS.*' But he does not think that such passions are widespread enough to count on them when constructing a civil society.

Given Hobbes's definition of the will as the appetite that leads to action, it follows that we always act on our desires. Since Hobbes further holds that 'The common name for all things that are desired, in so far as they are desired, is good', it follows that every man seeks what is good to him. This view, which might be called 'tautological egoism', does not provide any limits on the motives of human action. However, it has been confused with psychological egoism, and this confusion has resulted in the claim that Hobbes holds that no one is ever benevolent or desires to act justly. The definitions quoted in the previous paragraph show that Hobbes acknowledges the existence of benevolence and kindness. Similarly, he does not deny that a few are strongly motivated by a desire to act justly. This is shown by the following definitions that he offers: e.g. a just person is one who is 'delighted in just dealings', studies 'how to do righteousness', and endeavours 'in all things to do that which is just'. He also acknowledges that we can be strongly affected by injustice or injury, as is shown by his definition of INDIGNATION as 'Anger for great hurt done to another, when we consider the same to be done by injury'.

Since Hobbes claims that false moral views were one of the main causes of the Civil War, it would be absurd for him to deny that people are motivated by their moral views. As the quote comparing geometers to moral philosophers shows, he thought that the correct account of morality could have significant practical benefits. Further, Hobbes grounds the citizens' obligation to obey the law on their promise of obedience. He explicitly says that a person 'is obliged by his contracts, that is, that he ought to perform for his promise sake'. This is not a claim that would be made by someone who did not think that people were ever motivated by moral concerns. Finally, Hobbes knew that the danger to the stability of the state did not arise from the self-interest of each of its ordinary citizens, but rather from the self-interest of a few powerful persons, who would exploit false moral views. He regarded it as one of the most important duties of the sovereign to combat these false views, and to put forward true views about morality.

Hobbes's account of the relationship between \*reason and the \*passions is more complex and subtle than it is usually taken to be. Not only is reason not the slave of the passions, as Hume maintains, but the passions do not necessarily oppose reason, as Kant seems to hold. Rather, reason has lifelong, long-term goals, viz. the avoidance of avoidable death, pain, and disability, whereas some passions lead people to act in ways that conflict with reason obtaining its goals, while other passions lead people to act in ways that support the goals of reason. Reason differs

from the passions in that its goals are the same for all, whereas the objects of the passions differ from person to person. Reason also differs from the passions in that, since it is concerned with lifelong, long-term goals, it considers not merely immediate consequences but also the long-term consequences of an action. It is also concerned with determining the most effective means of obtaining these goals. By contrast, the passions react to the immediate desirable consequences, without considering the long-term undesirable consequences.

Hobbes's account of rationality and the emotions is a fairly accurate account of the ordinary view. We hold that though people have different passions, rationality is the same in all. Many of us also acknowledge, with Hobbes, that in a conflict between reason and passion, people ought to follow reason, but we realize that they often follow their passions; e.g. many people act on their passions when doing so threatens their life, and this is acting irrationally. That Hobbes's account of reason is so different from the current philosophically dominant Humean view of reason as purely instrumental may explain why it has been so widely misinterpreted.

Hobbes's views about the universality of reason make it possible for him to formulate general rules of reason, the Laws of Nature, that apply to all people. Throughout all of his works Hobbes is completely consistent on the point that the Laws of Nature are the dictates of reason and that, as such, they are concerned with self-preservation. But the dictates of reason that Hobbes discusses as the Laws of Nature are not concerned with the preservation of particular persons, but, as Hobbes puts it, with 'the conservation of men in multitudes'. These are the dictates of reason that concern the threats to life and limb that come from war and civil discord. The goal of these dictates is peace. It is these Laws of Nature that, Hobbes holds, provide an objective basis for morality. 'Reason declaring peace to be good, it follows by the same reason, that all the necessary means to peace be good also; and therefore that modesty, equity, trust, humanity, mercy (which we have demonstrated to be necessary to peace), are good manners or habits, that is, virtues.' Hobbes, following Aristotle, considers morality as applying primarily to manners or traits of character. He regards courage, prudence, and temperance as personal virtues, because they lead to the preservation of the individual person who has them, but he distinguishes them from the moral virtues, which by leading to peace, lead to the preservation of everyone. His account of reason as having the goal of self-preservation provides a justification of both the personal and the moral virtues. The personal virtues directly aid individual self-preservation, and the moral virtues are necessary means to peace and a stable society that are essential for lasting preservation for all. This simple and elegant attempt to reconcile rational self-interest and morality is as successful as it is because of the limited view Hobbes takes of the goal of reason. It may be controversial to maintain that it is always in one's self-interest, widely conceived, to have all of the moral virtues. It is extremely

plausible to maintain this, when the goal of reason is limited to self-preservation.

The importance of reason for Hobbes can be seen from the fact that both the Laws of Nature and the Right of Nature are derived from reason. In the State of Nature reason dictates to everyone that they seek peace when they can do so safely, which yields the Laws of Nature; but when they believe themselves to be in danger, even in the distant future, reason allows them to use any means they see fit to best achieve lasting preservation, which yields the Right of Nature. But if each person retains the Right of Nature, the result would be what Hobbes calls the State of Nature, in which the life of man is 'solitary, poor, nasty, brutish, and short'. In order to gain lasting preservation, the goal of reason, people must create a stable society; and this requires them to give up their Right of Nature. This only means giving up the right to decide what is best for your own long-term preservation; it does not mean giving up your right to respond to what is immediately threatening. It would be irrational for a person not to respond to an immediate threat. If he seems to give up the right to respond to such threats, that indicates that either he does not mean what he seems to mean, or that he is irrational and hence not competent to engage in any kind of transfer of rights. That is why Hobbes regards self-defence as an inalienable right; nothing counts as giving it up.

Hobbes provides a powerful argument to show that giving up your right to decide what is best for your long term preservation, and letting that be decided by a designated person or group of persons, called a sovereign, is actually the best way to guarantee your long term preservation, provided that other people also give up their Right of Nature to the sovereign. Since the sovereign makes the laws, this powerful but paradoxical-sounding argument is equivalent to an argument for obeying the law as long as it is generally obeyed; failing to obey the law increases the chances of unrest and civil war, and hence goes against the dictate of reason which commands people to seek self-preservation through peace. By allowing for the exception of self-defence, Hobbes has a strong case for saying that reason always supports obeying the civil law.

Although Hobbes is called a \*social contract theorist, he regards the foundation of the state, not as a mutual contract or covenant, but as what he calls a free gift. This free gift may be viewed as the result of people contracting among themselves to make a free gift of their Right of Nature to some sovereign because of their fear of living with each other without a sovereign, i.e. in the State of Nature. However, Hobbes thought that states were naturally formed when people, because of their fear of a person or group who had the power to kill them, made a free gift of their Right of Nature directly to that sovereign. Giving up their Right of Nature to the sovereign was necessary to avoid being killed immediately. In whatever way a state is formed, the subject does not contract with the sovereign, but rather makes a free gift of obedience in the hope of living longer and in greater security.

Making a free gift of one's right to the sovereign obliges the subject to obey the sovereign. It is unjust if he disobeys, for injustice is doing what a person has given up the right to do. Since the sovereign has not conveyed any right to the subjects, he cannot be unjust; however, in accepting the free gift of the subject, he comes under the law of nature prohibiting ingratitude. Thus, he is required to act so 'that the giver shall have no just occasion to repent him of his gift', which is why Hobbes says, 'Now all the duties of the rulers are contained in this one sentence, the safety of the people is the supreme law.' This explains why Hobbes lists the Law of Nature requiring gratitude immediately after the Laws of Nature concerning justice. The former applies to the citizens, the latter to the sovereign.

It is important for Hobbes to show that the sovereign cannot commit injustice, because he regards injustice as the only kind of immorality that can be legitimately punished. He never claims that the sovereign cannot be immoral or that there cannot be immoral or bad laws. However, if immoral behaviour by sovereigns were unjust, any immoral act by the sovereign would serve as a pretext for punishing the sovereign, that is, for civil war. It is to avoid this possibility that Hobbes argues that the sovereign can never be unjust and that there can be no unjust laws. What is moral and immoral is determined by what leads to lasting peace or is contrary to it; what is just and unjust is determined by the laws of the state. Morality exists, even in the State of Nature; justice does not. It is immoral to claim that the sovereign can act unjustly, for to claim this is contrary to the stability of the state and hence incompatible with a lasting peace.

Hobbes took religion very seriously. He believed that if one were forced to choose between what God commands and what the sovereign commands, most people would follow God. Thus, he spends much effort trying to show that Scripture supports his moral and political views. He also tries hard to discredit those religious views that can lead to disobeying the law. Hobbes, like Aquinas, held that God was completely unknowable by human beings. He holds that all rational persons, including atheists and deists, are subject to the laws of nature and to the laws of the civil state, but he explicitly denies that atheists and deists are subject to the commands of God. For Hobbes, reason by itself provides a guide to conduct to be followed by all people, so that even if he regarded God as the source of reason, God plays no independent role in his moral and political theory.

For Hobbes, moral and political philosophy were not merely academic exercises; he believed that they could be of tremendous practical importance. He held that 'questions concerning the rights of dominion, and the obedience due from subjects [were] the true forerunners of an approaching war'. And he explains his writing of *De Cive* prior to the works that should have preceded it as an attempt to forestall that war. Hobbes's moral and political philosophy is informed by a purpose, the attainment of peace and the avoidance of war, especially civil war. When he errs, it is generally in his attempt to state the

cause of peace in the strongest possible form. In this day of nuclear weapons, when whole nations can be destroyed almost as easily as a single person in Hobbes's day, we would do well to pay increased attention to the philosopher for whom the attaining of peace was the primary goal of moral and political philosophy. **Hobhouse, Leonard Trelawney** (1864–1929). English social philosopher, sociologist, and political journalist. Hobhouse began his career as a Philosophy Fellow of Corpus Christi College, Oxford. The prevailing outlook in Oxford of British \*idealism was uncongenial to him (although his writings on social philosophy reveal its influence), and he joined the staff of the *Manchester Guardian* in 1897. His many newspaper articles express an outlook which might be described as 'liberal or democratic socialist'. For the contemporary philosopher he is instructive for the manner in which he combined interests in animal psychology, sociology, ethics, social philosophy, logic, epistemology, and metaphysics without drawing the contentious demarcation lines between empirical, conceptual, and normative studies which have impoverished philosophy this century. His major contribution to sociology and \*social philosophy is in *Principles of Sociology* (1921–4), and the fullest exposition of his philosophical outlook is in *Development and Purpose* (2nd edn. 1927).

R.S.D.

\*liberalism.

**Hocking, William Ernest** (1873–1966). American idealist at Harvard University who continued the work of his teacher Royce in revising \*idealism to incorporate insights of \*empiricism, \*naturalism, and \*pragmatism. Metaphysics must, he held, make inductions from experience. In his 'negative pragmatism', 'That which does not work is not true'. For example, he enjoined us to 'try to get along without God and see what happens', and concluded that we cannot do without God as our associate in facing evil. Liberalism must be superseded by a new form of individualism in which the principle of the state is: 'every man shall be a whole man.' There is only one natural right, the right that 'an individual should develop the powers that are in him'. Consequently, the 'most important freedom' is 'the

freedom to perfect one's freedom'. Hocking extensively applied his principles to international problems. Christianity, he urged, should be reconceived to become a powerful agent in the making of world civilization. P.H.H.

Leroy S. Rouner, *Within Human Experience: The Philosophy of William Ernest Hocking* (Cambridge, 1969).

**Hodgson, Shadworth Holloway** (1832–1912). British epistemologist and metaphysician who anticipated and/or influenced \*phenomenology, \*pragmatism, and \*process philosophy. He was the founding President of the now well-known Aristotelian Society but taught at no university. His doctrine that things are what they are 'known as' influenced James's radical empiricism and anticipated Husserl's phenomenological reduction. His insistence that the test of truth 'depends upon the future' foreshadowed later forms of empiricism, especially pragmatism. He attached much importance to the relationship between empirical distinguishability and inseparability, a doctrine akin to Husserl's reduction to essences. Before James or Bergson, Hodgson developed a temporalist theory of consciousness as a stream or field, and broadly anticipated process philosophy by treating 'process-contents' as basic to the analysis of experience. P.H.H.

Andrew J. Reck, 'Hodgson's Metaphysics of Experience', in John Sallis (ed.), *Philosophy and Archaic Experience* (Pittsburgh, 1982).

**Høffding, Harald** (1843–1931). Danish philosopher who, having first obtained a degree in divinity, was caused by the study of Kierkegaard to break with Christianity. Høffding's positivist and non-metaphysical *Outline of Psychology* (1882; Eng. edn. 1893) and his *History of Modern Philosophy* (1894–5; Eng. edn. 1900) were widely read. In the latter he anticipated Cassirer by stressing the importance of mathematics and the natural sciences for the development of philosophy.

In Høffding's epistemology the fundamental category is that of synthesis, which he considered to be a psychological concept. According to Høffding, synthesis is an act of consciousness studied empirically by psychology, in direct opposition to Kant's critical philosophy in which synthesis is conceived as an epistemological condition for the possibility of human knowledge. Høffding argued in *Den menneskelige Tanke* (Human Thought, 1910 (German and French edns. 1911)) in favour of a theory of \*categories in which, in contradistinction to Kant, he maintained that the categories change as human knowledge increases. This implies that it is impossible to provide absolute proofs of their validity. Høffding did not in general differentiate between philosophy and psychology, and his epistemology is in this respect psychological. C.H.K.

**Holbach, Paul-Henri Thiry, Baron d'** (1723–89). A leading Encyclopedist, Holbach was the author of the *Système de la nature* (1770), a systematic defence of an atheistic

\*materialism. According to Holbach, the universe is a deterministic system, consisting of an eternal and constant totality of matter and motion. Man is an organic machine whose mental life, including the higher faculties, consists in sensation in various forms. The goal of any individual's life is to promote his happiness which, in society, will require the co-operation of others. Ethics is the science of how, through social co-operation, to promote the well-being of the individual. Holbach argued that the function of government is to foster social co-operation, its legitimacy depending on the happiness of its subjects. Holbach opposed absolute monarchy, hereditary privilege, and Christianity as obstacles to happiness. T.P.

\*determinism.

P.-H. d'Holbach, *The System of Nature* (New York, 1970).

**holism.** Any view according to which properties of individual elements in a complex are taken to be determined by relations they bear to other elements. Holism is less a doctrine than a class of doctrines. One can be a holist about \*meaning (the meaning of a sentence turns on its relations to other sentences in the language), without being a holist about justification (a belief's warrant depends on relations it bears to an agent's other beliefs). A holist about theory confirmation (empirical claims face experience, not individually, but all together) need not be a holist about \*belief (the content of a belief is fixed by its relations to an agent's other beliefs). It must be admitted, however, that holism tends to induce a frame of mind that finds holistic phenomena widespread.

In this century holism has been particularly associated with the biological and social sciences, and with conceptions of mind and language. Biological holists (e.g. C. Lloyd Morgan) oppose 'mechanists', those who hold biological phenomena to be explicable ultimately in terms of properties of their inorganic constituents. In the social sciences, 'methodological holists' (e.g. Ernest Gellner) deny the contention of 'individualists' that social phenomena are reducible to psychological characteristics of individual agents. In each case, the question is whether 'emergent' properties of a whole can affect the behaviour of its individual constituents in ways that cannot be accounted for solely by reference to properties those constituents possess independently of their membership in the whole.

It is easy to make holism appear trivial. Any collection of individuals exhibits properties its constituents lack. A group of three pebbles could constitute a triangle, though none of the pebbles is triangular. If my attention is attracted by triangles, then the whole has a causal property, the power to attract my attention, not reducible to properties of individuals making it up. An appropriate holist response might focus on particular cases, the putatively holistic character of linguistic meaning, for instance. The meaning of a sentence, it has been argued (e.g. by W. V. Quine and Donald Davidson), depends on its relations with other sentences in a language; thus, understanding a sentence involves understanding a language—

either the language in which the sentence is expressed or one into which it is translatable.

In an attempt to clarify holism about meaning, Jerry Fodor and Ernest Lepore appeal to ‘anatomic properties’, those possessed by a thing only if they are possessed by at least one other thing. Holistic properties are ‘very anatomic’, they are ‘such that, if anything has them, then lots of other things must have them’. This characterization has the virtue of making more precise something notoriously difficult to make precise, though it is not obvious that it captures what holists have in mind. It is consistent with holism that there be a language, *L*, with ‘very few’ sentences. What is crucial, so far as holism is concerned, is that the meanings of these sentences depend on their place in *L*.

The example brings out an apparently remarkable consequence of holism, however. An element in a holistic system cannot exist apart from that system. Thus, no sentence of *L* is translatable into English, because no sentence of *L* bears relations to other sentences of *L* comparable to those any English sentence bears to every other English sentence. Although it is open to holists to appeal to some principle restricting the scope of the holistic requirement, it is not easy to see how such a restriction could be motivated without tacitly abandoning holism. A further question is whether ‘molecular’ or ‘atomistic’ alternatives to holism fare better. J. HEIL

**holy, numinous, and sacred.** A spectrum of historical development stretches from the earliest concepts of the holy and sacred as terms marking off the fearful domain of divine power—supernatural, unpredictable, not-to-be-touched, weird. Corresponding to the gradual emergence of concepts of deity as *morally* perfect, the holy also becomes profoundly moralized. Yet it retains also the note of awesome otherness: \*God remains the *mysterium tremendum et fascinans*—the One who inspires both dread and exhilaration beyond reason’s grasp. That, in phenomenological terms, hints at the felt quality of ‘numinous’ experience, as Rudolf Otto wrote of it: the distinctive experience of God, at once ineffably transcendent, remote, yet stirring a recognition that here is the primary source of beauty and love.

Although appeal to such experience, by no means uncommon, will hardly amount (on its own) to a ‘proof’ of the existence of God, philosophy of religion must take heed of it in inquiring how values, moral and non-moral, are related to God’s nature, and in attempts to rework cosmological (‘contingency’) arguments for God’s existence as the world’s incessantly sustaining uncaused cause. It cannot ignore a striking experiential correlate. Relevant to

aesthetics, also, is the striking parallel between the duality (dread and fascination) of numinous experience and the fearful delight of many accounts of the \*sublime. R. W. H.

**homeland, right to a.** The claim that a particular territory belongs to a particular people. The usual basis of the claim is a long history of residence and sentimental attachment, and its usual occasion is some interruption in that history: foreign conquest or colonization of the territory, and/or the exile of the people. Hence the right to a homeland is sometimes asserted from outside the land itself, as in the classic case of early Zionism. More often, though exiles play a part in elaborating the sentimental attachment, the effective political claim is made by a native population, like the Palestinians, describing itself as oppressed, ruled by foreigners, deprived not so much of a home as of the right to rule in its own home—a localized claim for self-determination.

In principle, self-determination can be claimed by any collective self and enacted anywhere in the world. It is possible to leave one’s homeland for its sake—especially when the ‘self’ is religiously or ideologically constituted and focused by its doctrine on a new place, like English Puritans dreaming of America as a ‘promised land’. The claim to a homeland, by contrast, is specific with reference to place and people. The place is old and familiar, and the people, as befits men and women at home, commonly think of themselves in familial terms. So homelands are also motherlands and fatherlands, and the people are children of the place, brothers and sisters. Behind the legal or moral right—so they often say—is a bond of blood. (It helps in establishing this bond if blood has actually been spilled in defence of the land—which can then be described as ‘sanctified by the blood of our ancestors’.)

It follows from this set of associations that men and women from minority groups, who are not members of the family, are not at home in the land, however many years they or their ancestors have lived there. They are called aliens and may well be persecuted or deported—as if to vindicate the claim that the land belongs to *this* people and no other. So one people’s claim to a homeland leads, sometimes, to the homelessness of other people.

Sometimes, again, two groups of people (‘nations’, usually) claim the same homeland. A serial history in which first one, then the other, was the majority in the land, developed the requisite attachments, governed themselves or aspired to do so, generates two claims of exactly the same sort. It is radically unclear how to adjudicate disputes of this kind. Current possession and dominance do not seem sufficient in themselves to determine the issue, especially not if they were achieved by force. Length of time in residence seems also insufficient so long as both groups include people born in the land (and so not

themselves conquerors or colonists). Partition of the land is a solution commonly recommended, but this is more easily justified in principle than it is made effective (or just) on the ground. A 'neutral' regime, with cultural or regional autonomy for the rival groups (\*pluralism), is another possible solution, which has worked best, however, where the groups are immigrant communities—that is, where they cannot claim homeland rights.

In recent years, the claims of indigenous peoples have received both moral and political attention. These peoples, originally hunters and gatherers, are currently living in a small part of what was once their homeland, having been 'constrained', as Hobbes wrote in *Leviathan*, 'to inhabit closer together and not range a great deal of ground to snatch what they find'. They now claim territorial rights and some limited version of sovereignty on the land they occupy (including the right to bar 'foreigners' from coming in or from voting in local elections once they are in). And sometimes they also claim reparations for the larger homeland they have lost. States with significant indigenous populations have shown a (perhaps surprising) readiness to grant some portion of these claims, though the extent of the grant is still contested.

**homological:** see heterological and homological.

**homosexuality.** This phenomenon, erotic interaction between people of the same sex, was condemned by both Christianity and ancient Greek philosophy. Although, supposedly, Plato was himself homosexual, in the *Laws* he argued that since neither animals or birds do it, nor should we humans. Aquinas combined both traditions, concluding that homosexual activity is worse than rape, since the former violates natural law and therefore God, whereas the latter only violates another human being. Uniquely among philosophers, Bentham argued (on utilitarian grounds) for its permissibility, although (as with much that he penned) he left his reflections unpublished.

In the teeth of religion and philosophy, attitudes have changed. In part, this is a function of sex surveys (particularly Kinsey) suggesting that homosexuality is no bizarre minority phenomenon, but a widespread aspect of \*human nature. In part, this is a function of advances in biology and psychology (particularly Freud) strongly implying that homosexuality is no freely chosen sin, but an imposed state of nature, whether innately or environmentally caused. Philosophical emphasis today has therefore switched from the moral issue to other questions, primarily the thesis of the French historian-philosopher Michel

Foucault that homosexuality is a 'social construction', invented and forced upon a minority by those seeking power, particularly those in the medical profession who label homosexuality a sickness and thus in need of cure. But while agreeing to the potentially healthy state of the mature homosexual, one suspects that Foucault's thesis might itself be something of a construction, made plausible by a very selective reading of the historical record, and backed by a confusion between the undoubted existence of people whose inclinations are exclusively homosexual and the fact that society picks out such people, labelling them and treating them in distinctive ways.

**homunculus.** Literally, 'little man'. The term 'homunculus fallacy' has been applied to theories of mental states and processes that explain the phenomenon in question implicitly in terms of that very phenomenon. For example, suppose seeing objects is explained by postulating a device that 'scans' or 'views' images on an 'inner screen'. This explanation is vacuous, it is claimed, since it appeals to the notion of 'scanning' or 'viewing'—which is precisely what we wanted to explain in the first place. It is as if we said that we see by having a little man in our heads who sees: hence 'homunculus'. However, Daniel Dennett has argued (controversially) that there is nothing wrong with appealing to a hierarchy of homunculi in psychological explanation, as long as they become progressively more 'stupid': that is, the tasks they perform are simpler than the task explained by postulating them.

T.C.

Daniel C. Dennett, *Brainstorms* (Hassocks, 1979).

**Honderich, Ted** (1933– ). British philosopher, Canadian-born. Emeritus Grote Professor of the Philosophy of Mind and Logic, University College London. Advocate of the near-physicalist doctrine of Consciousness as Existence: what it is for you to be perceptually aware of the room you are now in is for an extra-cranial state of affairs to exist in a certain defined way. Thus perceptual consciousness is close to what is identified in other theories with its content. With respect to freedom, Honderich is a determinist opposed to both compatibilism and incompatibilism. In political philosophy, he is a socialist who has authored radical reflections on inhumanity, terrorism, conservatism, and the supposed justifications of punishment. In moral philosophy he is a consequentialist: if we were presented with the power to remove either all the bad consequences or all the bad intentions in the world, we would rightly choose to remove the bad consequences. Honderich has written controversially about the significance of the 11 September 2001 attack on the United States. His autobiography provides a view of philosophy as a profession

**Hook, Sidney** (1902–89). American exponent of \*pragmatism, \*naturalism, and \*socialism; a student of Morris R. Cohen and John Dewey. When he was on the faculty of New York University, Hook's writings, often in publications of broad circulation and on social, political, moral, and educational issues, made him widely known to the general public. Early and famously a Marxist activist, he soon became even more celebrated as a critic of communism from the standpoint of democratic socialism, with commitment to freedom and to the method of pragmatic naturalism as the foundation of his thought. Recognizing both the glory and the tragedy of human life, Hook saw 'in men something which is at once . . . more wonderful and more terrible than anything else in the universe—the power to make themselves and the world around them better or worse'.

P.H.H.

Paul Kurtz (ed.), *Sidney Hook and the Contemporary World: Essays on the Pragmatic Intelligence* (New York, 1968).

**horizon.** The unthematized field of perception or background of understanding accompanying the subject's experience of objects and meaning. The metaphor of the horizon has first proved useful in phenomenological theory of perception (Husserl, Merleau-Ponty). Accordingly, every awareness of a perceptual object is attended by a frame of not directly represented features. While perceiving merely the front of a house, for example, we nevertheless 'see' a complete three-dimensional object. Spatiality, temporality, and a \*background of indirectly represented objects thus form the horizon within which we always experience an object as such. In philosophical hermeneutics, the cultural tradition provides the horizon within which the interpreter is capable of making sense of other meaning. Successful \*interpretation is conceived as a dialogue between interpreter and text, reaching a new understanding of the subject-matter in a 'fusion of horizons' (Gadamer).

H.H.K.

H. G. Gadamer, *Truth and Method* (New York, 1989), 242–54 and 302–7.

**Hornsby, Jennifer** (1951– ). Professor at Birkbeck College, London, who, in her philosophy of \*action, denies that 'actions are bodily movements' and maintains that they all 'occur inside the body'. After distinguishing between causally basic and teleologically basic action, she argues that causally basic actions, like moving an arm, are not bodily movements, but are the 'tryings' which are the inner causes of such movements. Granted, trying to move one's paralysed arm is not an action since it fails to produce movement; but if the trying successfully causes the arm to move in the normal way, via appropriate muscular contractions, then it—the trying—is an action. Thus

bodily movements are necessary if the trying is to be an action, but the action itself is to be identified with the trying, which is 'inside the body'.

O.R.J.

\*agent; sexism.

Jennifer Hornsby, *Actions* (London, 1980).

— *Simple Mindedness: In Defence of Naïve Naturalism in the Philosophy of Mind* (Cambridge, Mass., 1996).

**horseshoe.** The symbol '⊃', used in symbolic logic, signifying \*material implication, which is a relation holding between two propositions. Let  $p$  and  $q$  be symbols for propositions, then ' $p \supset q$ ' is short for 'If  $p$  then  $q$ ', and this is true if and only if (i) both  $p$  and  $q$  are true, (ii)  $p$  is false and  $q$  is true, or (iii) both  $p$  and  $q$  are false. Ruled out is:  $p$  true and  $q$  false. An alternative symbol for material implication is the arrow, '→'.

Material implication thus defined is different from \*implication as informally understood in everyday communication; e.g. one would not normally agree that 'If it's raining then it's blowing' is true just because it isn't raining, though normal intuition would agree with the formal definition that the statement is false if in fact it is raining but isn't blowing.

**Horwich, Paul** (1947– ). Professor of Philosophy at City University, New York, having previously taught at University College London and at the Massachusetts Institute of Technology. Born in England, he studied physics at Oxford before going to Yale for a year and then to Cornell, from which he received a doctorate in philosophy.

His principal contributions to this subject are in books on scientific methodology, time asymmetry, and the concept of truth. He presented the first broad treatment of the scientific method from a Bayesian point of view, offered a unified theory of the 'directional' aspects of causation, entropy, 'the now', deliberation, explanation, and knowledge, and has recently advanced a deflationary account of truth, examining its implications for debates over realism, vagueness, and the nature of meaning.

His work manifests a strong sense of the interconnectedness of the different areas of philosophy, a belief in the clear distinction between philosophical and scientific problems, and a Wittgensteinian penchant for dissolving questions rather than straightforwardly answering them.

**Hsün Tzū** (3rd century BC). Master Hsün was a Chinese Confucian thinker, probably best known for his view that human nature is evil. His full name was Hsün K'uang, and his teachings are recorded in the text *Hsün Tzū*. Like Confucius and Mencius, he sought to defend traditional values and norms associated with established social distinctions. In opposition to Mencius, he held that human nature is evil in the sense that human beings in the natural state are

moved primarily by self-regarding desires, and that unregulated pursuit of satisfaction of such desires will lead to strife and disorder. General observance of norms associated with traditional social distinctions serves to transform as well as regulate the pursuit of satisfaction of such desires, thereby making possible order in society and maximal satisfaction of human desires. **human, all too human:** see Nietzsche.

**human beings.** We humans are animals, classified in the Linnaean system into the genus *Homo* (in which there are now no other living representatives), but with our own distinct species (interbreeding group), *Homo sapiens*. There is some doubt about when we first appeared, and indeed it is all really a matter of definition—certainly not much more than a million years ago and probably not much less than a half million years ago, depending on how much variation you are prepared to allow within a group before you insist on dividing it into two. We fall into various subgroups ('races') which would probably be called 'sub-species' in other organisms; but they are all fully interbreeding and today (thanks to such things as easy travel) there is very considerable breakdown of sharp divisions.

The Greeks, especially that first-class biologist Aristotle, recognized our resemblances with the animals, and traditionally we were always put with them on the same Chain of Being: humans coming at the head of the organic world, but below God and the angels. However, it was not until the coming of evolutionism at the end of the eighteenth century that humans were firmly linked through descent with other organisms. Much time was spent on speculation about who was our immediate ancestor. Many agreed with Lamarck that the orang-utan was the most likely candidate.

It was Darwin, notably in his *Descent of Man*, who moved debate to the modern phase, raising questions about how we evolved and what implication this all has, if any, for \*human nature. Yet it was not until the present day that some of the most pressing queries were adequately answered. Thanks to molecular techniques, we now know that, although our ancestors are now extinct, biologically speaking our relationship with today's great apes is very close. Indeed, appearances notwithstanding, we may be more closely related to chimpanzees than they are to gorillas. We know also, thanks to fossil discoveries, that of the two really distinctive human characteristics, the large brain and the upright walk, the second definitely appeared before the former.

However, some of the questions with most obviously philosophical implications remain still unanswered. Notwithstanding massive amounts of individual variation within our species, there are clearly some biological differences between members of different races, as there are clearly some biological differences (and not just those bearing directly on reproduction) between males and

females. But what exactly these may be and what implications these might have for fields from education to politics still remain essentially unanswered, despite confident assertions of significance from people of the right and of insignificance from people of the left. Whether it is sensible to inquire into these possible differences is also a question not readily answered.

One biological finding of major philosophical interest is that what really makes us humans successful as a species is our ability to interact socially with our fellows. Notwithstanding the horrendous wars and other human-caused catastrophes of this century, the rate of violence between humans is still significantly below that to be found in the average pride of lions. This is not to deny the reality of evil, but it is to warn against absurd arguments about us and the brutes, claiming that we alone are the killer apes, marked for ever for our misdeeds, as was Cain. This should serve as a cautionary warning for those who would draw instant moral conclusions from our evolved nature.

**humanism.** The tendency to emphasize man and his status, importance, powers, achievements, interests, or authority. Humanism has many different connotations, which depend largely on what it is being contrasted with. As well as denoting particular claims about man it can also denote the tendency to study man at all. Early Greek thought began by studying the cosmos as a whole and particular phenomena in it, such as the weather, earthquakes, etc., and then turned to questions of logic and metaphysics, but the so-called humanist movement arose in the fifth century BC when the Sophists and Socrates 'called philosophy down from heaven to earth', as Cicero later put it, by introducing social, political, and moral questions.

Humanism is also associated with the \*Renaissance, when it denoted a move away from God to man as the centre of interest. God still remained as creator and supreme authority—the Renaissance humanists were far from being atheists—but his activity was seen as less immediate, more as general control than as day-to-day interference, and this enabled a scientific outlook to arise which saw the universe as governed by general laws, albeit these were laid down by God. (A rather similar development had occurred earlier when the Stoics relied on the notion of an impersonal fate to provide the stability needed for a coherent description of the world.) One feature which made this specifically a humanist development was the emphasis it both presupposed and, by its successes, encouraged on the ability of man to find out about the universe by his own efforts, and more and more to control it.

It was when the conflict between science and religion arose in the nineteenth century, largely because of

Darwinism's inconsistency with a fundamentalist reading of the Bible, that humanism acquired its modern association with atheism or agnosticism. Humanism, often called scientific humanism, then becomes associated with \*rationalism, not in its main philosophical senses but in that of an appeal to reason in contrast to revelation or religious authority as a means of finding out about the natural world and the nature and destiny of man, and also as giving a grounding for morality; the term 'ethical humanism' is sometimes used in this last context, though the outlook can also be called scientific humanism in so far as it claims that science can provide a basis for morality. However, this appeal to reason in ethics should be distinguished from that common in the seventeenth and eighteenth centuries, and not without echoes in the twentieth, where reason was opposed not to religious authority but to feelings or emotions.

Some humanists in fact demur at the title 'rationalist' or 'scientific humanist' because, though they are quite willing to follow reason rather than authority or revelation (and for that reason are willing to call themselves humanists at all), they do not accept that reason can provide the basis for morality, but may appeal to feelings or emotions instead; in fact throughout their histories the British Humanist Association and the Rationalist Press Association have been independent entities, though allied on most issues. Humanists may also reject the implication in the title 'scientific humanist' that science can at least ultimately answer all questions. (\*Naturalism; positivism.) Humanist ethics is also distinguished by placing the end of moral action in the welfare of humanity rather than in fulfilling the will of God.

**human nature.** The explication of the notion of human nature, what it is essentially to be a human, is as difficult as it is important to philosophy. A major problem is that it is not immediately obvious what kind of answer would satisfy. Must human nature be defined with respect to the new-born infant, in which case it would seem to be a bundle of potentialities, or is it to be defined with respect to the full-grown adult, in which case does one consider training something crucial to the development of human nature or is it rather something which takes our nature from its true state?

However one answers these questions, or rather in part according to the way in which one answers these questions, there are a number of key issues which have dominated philosophical discussion of human nature: Is there some qualitative difference between humans and other animals, or is it all a question of quantities and balance? Is there one key thing that all humans have, or is there a range of qualities, irregularly dispensed? And, most crucially, is human nature inherently good, bad, or indifferent?

Plato, with his three-part division of the soul, had answers to all of these questions: We are undoubtedly different from other beings in our rational ability to perceive the Forms; all and only humans may have the three key elements, but by nature some have one part more developed and dominant than do others; and as such human nature is neither good nor bad but with appropriate training (or its lack) this nature can be turned to good or ill. In this last claim, Plato differed strongly from the Judaeo-Christian conception of human nature, which through the story of the Fall saw humans as being essentially in a state of sin, from which we can be rescued only by God's grace.

Deeply influential was the thinking of Aquinas, who drew on Aristotelian roots in formulating his doctrine of natural law, thus emphasizing that any adequate account of human nature must not emphasize our spiritual side to the exclusion of the body, although his particular conclusions—for instance, that \*homosexuality involves an unnatural and therefore sinful use of bodily parts—remain controversial. As a Christian, nevertheless, he remained committed to our essential uniqueness, a belief which was not really challenged until the eighteenth century, when such writers as David Hume started to stress the continuity between human powers of reason and sentiment and those of animals. Obviously this was a challenge continued by the rise of evolutionary speculations.

Paralleling such developments as these was an increasing turn from the Christian belief in our inherent wickedness. Rousseau and Romanticism pushed the pendulum to the other extreme, suggesting that only the young and undeveloped is the truly good. Based on a totally inadequate grasp of the facts, the belief grew that it is in the 'noble savage' that we find the pure and untainted human nature. Not that all felt this way. John Stuart Mill, and early evolutionists like Thomas Henry Huxley, were convinced of the ape within and of the need to conquer our brute nature. More balanced was Freud, who emphasized both the innate element in human nature and the crucial effects of family environment on its development. In respects, his major contribution lay less in his specific theories and more in his presumption that, inasmuch as we are a product of our past, it is inappropriate to assign guilt or blame to those who do not fit usual patterns.

Extremely influential today, albeit more outside professional philosophy than within, is the view of the 'constructivists' which denies that there is any essential human nature, arguing rather that all such conceptions are merely cultural artefacts, often invented by one part of society to suppress another part. But a spectrum of more traditional positions continues to exist, from those like the sociobiologists, who see human nature as completely determined and thus not appropriately subject to moral evaluation, to those like the existentialists and their successors, who see human nature as entirely a product of human free choice and thus essentially and inherently moral. **human rights** is a more politically correct alternative to the more eloquent 'Rights of Man', designed to stress their possession by Woman (and, for that matter, Boy). They are much the same as the older 'natural rights' which would, however, embrace the rights sometimes claimed for animals. It also serves to detach natural rights from the much criticized doctrine of natural law. The latter is at the centre of the political thought of the Stoics and Cicero and of Christian political theory in the Middle Ages, and so seems antiquated and theological. But it is not obvious that the detachment of right from law is an advantage. Rights without law seem as questionable as law without a lawgiver. Human rights are rights which human beings possess simply in virtue of being human, however widely they differ. Human rights are perhaps more satisfactorily defined as rights which humans possess independently of positive law (\*legal positivism). Such rights came into their own through the religious individualism of the Protestant Reformation. That led, in Protestant communities, to a multiplicity of mutually hostile sects, elsewhere to the existence of Protestant subjects under a Catholic sovereign, and vice versa. Protracted wars of religion in France and Germany somewhat muted religious ferocity. The first fully formed, essentially secular theory of human rights was that of Locke's second *Treatise of Government* (1690). His prime instances of life, liberty, and estate (i.e. property) are closely followed by the American Declaration of Independence (1776), in which the pursuit of happiness piously replaces property. In that document Jefferson followed Locke in holding these principles to be self-evident. Such rationally obvious limits to the just sphere of government action were unrecognized by the prevailing absolutism of the early modern period, but were upheld, somewhat patchily, by the medieval Church.

Objections were soon raised, notably by Hume, Burke, and Bentham. The first is that rights, like law, presuppose a sovereign legislator and organized sanctions to enforce them. A second focuses on the variety and continuing proliferation of the rights claimed, including rights to such things as employment, education, and an adequate standard of living. Rights for all to be provided with something are less plausible than rights to non-interference. A third, Burkean, line of criticism takes exception to the universalism of a theory which insists on the same rights for all and ignores historically rooted differences between societies. Part of an answer to the first objection is the emergence of quasi-sovereigns like the United Nations and the European Union which legislate freely enough although their sanctions are ineffective. Despite these objections, it is hard to resist a minimal theory of human rights which maintains that the actions of governments are fit subjects for moral criticism by individuals meditating morally principled disobedience or resistance, most plausibly in matters about which there is some approximation to moral consensus.

Maurice Cranston, *What Are Human Rights?* (London, 1973).

**Humboldt, Wilhelm von** (1767–1835). German philosopher, linguist, and statesman who was a pioneer of historical-comparative linguistics. He helped to found the University of Berlin in 1811. In *The Limits of State Action* (1791; pub. 1851; tr. Cambridge, 1969), he argued that the sole purpose of the state is to protect the lives and property of its citizens. He supplied an epigraph for J. S. Mill's *On Liberty*: 'The grand, leading principle, towards which every argument unfolded in these pages directly converges, is the absolute and essential importance of human development in its richest diversity.'

His last years were devoted to philology. In *On the Dual* (1828) he argued that older languages, such as Sanskrit, are syntactically more complex than later ones; this ended attempts to find the origin of \*language within recorded history. His *magnum opus* on the language of the Kawis of Java remained unfinished. The introduction (1830–5; pub. 1836) argues that the 'inner structure' of a language reflects the 'spirit' of its speakers. Morphology and syntax reveal differences in the 'inner form' of languages and enable us to classify and relate them.

**Hume, David** (1711–76). Scottish philosopher, essayist, and historian. Perhaps the greatest of British philosophers since Locke, Hume aimed to place 'Logic, Morals, Criticism, and Politics' on a new foundation—the 'science of man' and the theory of human nature. Famous for his \*scepticism in metaphysics, Hume also emphasized the limits that human nature places on our capacity for scepticism. In morals, he insisted on the reality of moral distinctions, though our judgements are ultimately founded only in human sentiment. In these and other areas, his concern was to expose the limitations of reason, and to explain how we none the less make the judgements we do, careless of the absence of rational support.

*Life.* Hume was the second son in a strict Presbyterian family that was a minor branch of the line of the Earls of Home. After two or three years at the University of Edinburgh, Hume began to study for a legal career, but discovered that his interests lay elsewhere. Immersing himself in the classics (with a particular love of Cicero's philosophical works), Hume decided that the existing philosophy contained 'little more than endless disputes', and set out to find 'some medium by which truth might be established'. About the age of 18, there finally seemed to open up to him 'a new scene of thought', which made him 'throw up every other pleasure or business to apply entirely to it'. He decided on the life of 'a scholar and a philosopher'.

After four years of intense study overshadowed by something like a nervous breakdown, Hume left Scotland in 1734. He settled in France, at La Flèche, a town in Angjou at whose Jesuit school Descartes had studied a century before. He conceived his general plan of life: 'to make a

very rigid frugality supply my deficiency of fortune, to maintain unimpaired my independency, and to regard every object as contemptible, except the improvement of my talents in literature.'

It was mostly at La Flèche that Hume wrote *A Treatise of Human Nature*, the most widely studied of his works today. He returned to London in 1737, at the age of 26, and the work appeared in 1739 and 1740. It was soon a disappointment to the author. 'Never literary attempt was more unfortunate than my *Treatise of Human Nature*. It fell *dead-born from the press*, without reaching such distinction, as even to excite a murmur among the zealots.' Hume had hopes for a second edition, but the work was not reprinted in England until 1817.

Hume had some success with two volumes of *Essays: Moral and Political* (1741, 1742). But he failed in an attempt at the Chair of Ethics and Pneumatical Philosophy in Edinburgh, and turned in his mid-thirties to less literary activities. He was tutor for a year to a mad nobleman, and secretary to General St Clair on an abortive attempt to invade France. Hume seems to have appreciated these activities mainly for the contribution they made to his precarious finances.

The neglect of the *Treatise*, Hume believed, arose from going to press too early, 'carried away by the heat of youth and invention'. He reworked book I, and restored a discussion of miracles that he had cut from the earlier work. The result was a slim volume of *Philosophical Essays Concerning Human Understanding* (1748)—known after 1758 as *An Enquiry Concerning Human Understanding*. He developed book III of the *Treatise* into a parallel volume, *An Enquiry Concerning the Principles of Morals* (1751). Hume later asked that his philosophical views should be judged on the basis of the *Enquiries*, rather than the *Treatise*. They are the works that spread his philosophy most widely—and in due course roused Kant from his 'dogmatic slumber'.

A draft of the *Dialogues Concerning Natural Religion* existed by 1751, though for reasons of expediency Hume kept this dangerously sceptical work unpublished. In his forties, Hume's main energies turned from philosophy to politics and history. The *Political Discourses* (1752) contain important essays on money and interest. Having failed again to get an academic post (this time at Glasgow), in 1752 Hume became Librarian to the Faculty of Advocates in Edinburgh. With his own library, he worked fast on a *History of England*, publishing volumes on the Stuarts (1754, 1756), the Tudors (1759), and the period from Julius Caesar to Henry VII (1762). Persuaded at first that he was of 'no party' and 'no bias', he found himself a determined opponent of the Whig interpretation of history. The *History* earned Hume a great following and royalties far larger, he said, than 'anything formerly known in England'.

Hume wrote little of note in his fifties. He lived in Paris for a while (1763–6), where he became the darling of the philosophical salons. He returned to England accompanied by Rousseau, who promptly quarrelled with him, imagining that Hume was plotting to ruin his reputation.

Hume served for two years in London as under-secretary in the Northern Department—a position which, ironically, gave him responsibility for ecclesiastical preferment in Scotland. He returned to Edinburgh finally in 1769.

The death of Hume earned him something of the status of a secular saint. Knowing that his disease of the bowel was incurable, he faced death with equanimity, cheerfulness, and resignation. His persistence in irreligion shook the conviction of Boswell, and provoked some strikingly unpleasant comments from Dr Johnson.

Hume died on 25 August 1776. Some months before, he had written a few pages of autobiography under the title 'My Own Life'. Besides his frugality and need for independence, he stresses the 'great moderation' in his passions. 'Even my love of literary fame, my ruling passion, never soured my temper, notwithstanding my frequent disappointments.' Adam Smith commented: 'Upon the whole, I have always considered him, both in his lifetime and since his death, as approaching as nearly to the idea of a perfectly wise and virtuous man, as perhaps the nature of human frailty will permit.'

*Logic and Metaphysics.* Hume divides the contents of the mind into *\*impressions* and *\*ideas*. Impressions are our 'sensations, passions and emotions'; ideas are 'the faint images of these' in thought, reflection, and imagination. Complex ideas may be formed out of simpler ideas; but simple ideas can enter the mind in only one way, as 'copies of our impressions'.

*Causal reasoning.* How do we acquire beliefs about things we are not currently experiencing? We see a flame, for example, and conclude that it is hot. Hume notes that we start from a present impression—the sight of the flame—and suppose a causal relation—between flames and heat. But how do we come to believe in that causal relation?

Hume's great claim is that it is not because of reason. *Reason alone* cannot tell us that flames are hot: it is conceivable that a fire might be cold, and therefore possible. *Reason and experience together* cannot produce the belief either. Our experience has been confined to certain tracts of space and time. Within those reaches, we have found flames to be hot. But there is a gap between 'Observed flames have been hot' and 'All flames are hot'. To reach the second, we would need to add the principle that nature is uniform, that the future resembles the past. But how could we ever establish the uniformity principle?

Hume claims that there are only two kinds of reasoning, 'demonstrative' and 'probable' (see *\*fork Hume's*), and neither can do the job. Demonstrative reasoning (such as deduction) cannot establish the uniformity of nature—for non-uniformity is conceivable, and therefore possible. 'Probable' reasoning—or causal reasoning from the observed to the unobserved—cannot establish the uniformity either. Probable reasoning itself presupposes the uniformity of nature, so to employ it in support of that principle would be circular. As Russell later explained, even if experience has told us that past futures resembled

past pasts, we cannot conclude that future futures will resemble future pasts—unless we already assume that the future resembles the past.

If reason does not give us our beliefs about the unobserved, what does? Simply ‘custom or habit’, trading on two fundamentally non-rational processes. Repeated experience of the conjunction of flames and heat creates an *association of ideas*—so when we see a flame, by sheer habit an idea of heat will come to mind. A belief differs from a mere conception by being ‘lively or vivid’; so when *vivacity* from the impression of the flame is *transferred* to the associated idea of heat, the idea becomes a belief in the presence of heat. Our beliefs are the product not of reason but of these mechanisms of ‘the Imagination’.

Does this make Hume a sceptic about \*induction? He says that we have ‘no reason’ to believe that the sun will rise tomorrow. On the other hand, he believes that our inductive reasoning processes are genuinely ‘correspondent’ to the natural processes in the world; he describes induction as ‘essential to the subsistence of human creatures’; and he even says that causal conclusions have their own kind of certainty, ‘as satisfactory to the mind . . . as the demonstrative kind’. Perhaps the way to reconcile these claims is to remember that ‘reason’ is for Hume ‘nothing but the comparing of ideas and the discovery of their relations’; so discovering that ‘reason’, in this sense, is not the source of our inductive beliefs is very different from claiming that induction is, in a more general sense, unreasonable.

Hume’s account of causal power builds on his account of causal inference. In accord with the empiricist principle that ideas are derived from impressions, Hume explains that to clarify our idea of necessity we must find and examine the impression that has given rise to it. This proves surprisingly hard. Necessity cannot be found in our experience of *individual* cases of causation. ‘We are never able, in a single instance, to discover any power or necessary connexion’; we simply see one event follow another. The idea must therefore come from our experience of a *multiplicity* of similar cases. The *\*constant conjunction* (say, of flames and heat) produces, as we have seen, an association of ideas. Hume now adds that ‘this connexion . . . which we feel in the mind’ is the true source of our idea of necessity, and therefore all we can be talking about when we talk about power, connection, or necessity.

Hume’s view here is not entirely clear. He in fact indicates not one source for the idea of necessity, but a chain of three—conjunction in the objects, association in the mind, and a feeling of connection—and each of these is a candidate referent for our idea of necessity, i.e., a candidate for what necessity is. Of the three, the first and the second tend to weigh most with Hume, and we find them at the heart of his definitions of cause.

Hume gives two definitions. The notion of cause is made up of the notions of *priority* and *necessary connection*. (The *Treatise* treats *contiguity* as a third constituent.) Taking necessity as constant conjunction, therefore, we may define a cause as ‘an object, followed by another, and where all the objects similar to the first are followed by objects similar to the

*second*’—the famous account of causation as regular succession. Taking necessity as connection in the mind, we may define a cause as ‘an object followed by another, and whose appearance always conveys the thought to that other’—a rather different account, and one less influential upon Hume’s followers.

Does Hume deny the existence of power and necessity? Certainly not—any more than Berkeley denies the existence of tables and trees. ‘Necessity, according to the sense in which it is here taken, has never yet been rejected, nor can ever, I think, be rejected by any philosopher.’ Far from rejecting necessity, Hume is attempting a reductive explanation of it. There is something, however, that Hume does deny, namely, necessity as misconceived. The mind has a ‘propensity to spread itself on external objects’: we are apt to treat the feeling of connection, which is really only in the mind, instead as a feature of external objects. This is a mistake—the mistake made by rationalists who believe in an intelligible connection between cause and effect.

*External world.* The final part of book I of the *Treatise* purports to be a study of ‘the sceptical and other systems of philosophy’—as if scepticism were a malady to be studied in other people. In the course of discussion, however, it becomes clear that the malady is one that Hume himself has caught, and only the strongest instincts can save him from succumbing to it. Hume discusses two versions of the belief in external objects, the ‘vulgar’ and the ‘philosophical’, and finds both of them unjustified. The vulgar or common-sense belief is, as Hume presents it, a belief in the ‘continued and distinct existence’ of the ‘interrupted images’ of sense. (This attributes to common sense a view like that which Berkeley held—and also, surely implausibly, attributed to common sense.) This ‘vulgar’ view is false. ‘Tis a gross illusion to suppose, that our resembling perceptions are numerically the same’ after a gap—an illusion due to the *constancy* and *coherence* of our perceptions.

The ‘philosophical’ or Lockean view does no better, in holding that our impressions are only *representations* of external objects, resembling and caused by them. For ‘as no beings are ever present to the mind but perceptions’, we can never observe a causal relation (or indeed a similarity) between perceptions and external objects thus conceived.

Hume implies that the ‘necessary consequence’ is, strictly, that we should altogether reject ‘the opinion of a continued existence’—and believe in nothing but interrupted and dependent ideas and impressions. Nature, however, saves us from this fate: ‘The sceptic must assent to the principle concerning the existence of body, tho’ he cannot pretend by any arguments of philosophy to maintain its veracity. Nature has not left this to his choice.’ Hume’s arguments may have produced in the reader a moment of philosophical doubt, but an hour hence he will again be ‘persuaded there is both an external and internal world’.

*Personal identity.* Hume rejects the view, apparently shared by philosophers and the vulgar, that we are conscious of a self, simple in itself, and identical from one

time to another. We have no impression of a simple, identical \*self; so we can have no idea of any such thing. Hume's own view is that mankind 'is nothing but a bundle or collection of different perceptions, which succeed each other with an inconceivable rapidity, and are in a perpetual flux and movement'. The common mistake arises, he thinks, from a tendency to confuse related perceptions with identical.

Hume maintains a more steady scepticism about personal identity than about the external world. In the latter case nature saves us from the hard conclusions of 'intense reflection'; with personal identity, on the other hand, Hume thinks he can live with his own deflationary conclusions. This later proved to be an exaggeration. In an appendix, he admits to feeling confused about his the account of personal identity, though for reasons that few readers find clear.

*Scepticism.* The concluding section of the *Treatise*, book I, depicts a battle between reason and nature. Hume has exposed the weakness of the human mind—where what passed for reason turns out to be 'imagination', and even the strongest inference can be made to seem uncertain. In the face of this weakness Hume is 'ready to reject all belief and reasoning, and can look upon no opinion even as more probable or likely than another'.

Human nature saves him. 'Most fortunately it happens, that since reason is incapable of dispelling these clouds, nature herself suffices to that purpose.' A few hours of good company and \*backgammon make his melancholy and sceptical conclusions seem ridiculous. What is more, 'amusement and company' lead Hume to a third phase—of curiosity and constructive philosophical ambition. Following his own nature, Hume finds a place after all for philosophy and the modest pursuit of science.

Hume here reconciles scepticism and \*naturalism. It is not merely that scepticism is a natural attitude. Rather, the best expression of scepticism is one where we follow our nature without pretending we have an independent justification; in doing so we may even contribute to the 'advancement of knowledge'.

*Theory of the Passions, Moral Philosophy.* Like \*Hutcheson before him, Hume models his theory of morality on a theory of aesthetic judgement, linked with an account of the \*passions. The picture is roughly this. Finding something beautiful is deriving a certain sort of pleasure from it; and that pleasure is a 'calm passion'. Similarly, approving of someone's character, or finding it virtuous, is simply 'feeling that it pleases' in a certain way; and that feeling is a calm passion, though it is liable to be confused with a 'determination of reason'. Like beauty, morality 'is more properly felt than judged of'.

Hume seems himself to have become less confident of the details of his theory of the passions after the *Treatise*, and he never reworked book II as he did books I and III. He is both acute in analysing the conditions necessary for the various passions and resolute in tracing them to associative mechanisms in the mind.

Hume starts with pride and humility. 'Every thing related to us, which produces pleasure or pain, produces likewise pride or humility.' A beautiful house produces pleasure in anyone who looks at it; but it produces pride only in someone *related* to it, for example, as designer or owner. Hume explains this by two mechanisms. The house is related to the owner, so—by an association of ideas—the idea of the house produces in him the idea of himself. (This contributes to pride, because the self is 'the object of pride'.) At the same time, the house produces pleasure, and—by an association of impressions—pleasure produces pride. By two associative processes, the house produces the feeling of pride.

Hume treats love and hatred in a similar fashion, except that whereas the 'object' of pride and humility is oneself, the object of love and hate is another person. Book II also contains an important argument that determinism is compatible with a form of liberty.

*Moral theory.* Book III of the *Treatise* begins with a spirited rejection of the view that moral distinctions are derived from reason. 'Morals excite passions, and produce or prevent actions.' By contrast, 'Reason is perfectly inert,' and can never produce or prevent an action. (\*Reason as slave of the passions.) The rules of morality are therefore 'not conclusions of our reason'—and the rationalist theories of Clarke and Wollaston must be rejected. Moral distinctions are derived instead from a 'moral sense', not from reason.

Since approval and blame are, respectively, 'agreeable' and 'uneasy', they may be described as varieties of pleasure and pain. By producing pleasure, therefore, a \*virtue will tend (in accordance with the theory of the passions) to produce pride in the possessor, and love in other people. (Pride of this kind, therefore, is no sin.) Hume's remaining task is to explain exactly which characteristics produce that variety of love which is the discerning of virtue.

The answer is easy in the case of 'natural' virtues—characteristics which we approve of because of natural instinct. Hume places in this category those features of a person's character that are '*useful or agreeable to the person himself or to others*'; and he invokes *sympathy*, probably the central notion of his whole moral theory, to explain their operation. Qualities that are useful or agreeable to others will directly elicit pleasure and approval in them. Qualities that are useful or agreeable primarily to the possessor—like good sense or a cheerful character—are approved of because of *sympathy*. We have a natural propensity 'to sympathize with others, and to receive by communication their inclinations and sentiments, however different from, or even contrary to our own'. This process—given a complex mechanistic explanation in the *Treatise*, but treated as an ultimate principle in the second *Enquiry*—explains how qualities that give pleasure to one person can inspire pleasure (and hence approval) in others.

The 'artificial' virtues pose a greater problem. An individual act of justice may be approved of, though it benefits no one. Why do we approve of paying back a debt to 'a profligate debauchee, [who] would rather receive harm

than benefit from large possessions? The answer is that we have a conventional or 'artificial' system of rules of property, which as a whole provides security, in an environment where goods are scarce and people are greedy. Even if 'single acts of justice may be contrary, either to public or private interest', the whole scheme is 'absolutely requisite, both to the support of society, and the well-being of every individual'.

Hume's moral theory is in many ways parallel to his general epistemology: he shows the limits of reason, and then explains, in the naturalistic spirit of an empirical student of the mind, how we reach the judgements—or rather, feelings—that we do. But the consequences are less sceptical in the case of morals. To discover that morality is only a matter of feeling, informed by instincts of sympathy, modulated in accord with conventions of justice, and regulated by general rules, is not, it seems, to discover that moral judgement is any less than it could properly be expected to be. On the other hand, to learn that causal judgements are only the effects of habit, to learn that our beliefs in external objects and in the self are false, even if inescapable—all this, Hume seems to think, exposes a tear in the fabric of belief. We may continue to do philosophy, with a kind of confidence that consists in following human nature and being diffident even of our doubts. But Hume does not pretend that to philosophize in that 'careless manner' is to philosophize with no sense of loss.

*Philosophy of Religion.* The *Dialogues Concerning Natural Religion* appeared in 1779, three years after Hume's death. They present fundamental objections to the ontological and, above all, the cosmological arguments for the existence of God.

It is absurd, Hume suggests, to attempt to demonstrate the existence of God a priori; since the issue is a matter of fact. An a posteriori argument from order in the world to the existence of a designer, however, is also unpersuasive. We can infer only those characteristics which are precisely necessary to produce the features we find in the world; and the only licence we can use in our inference comes from regularities which we have observed. If we agree that order in the world has a cause, the question remains whether 'the cause or causes of order in the universe probably bear some remote analogy to human intelligence'. Even the answer is Yes, the analogy with human intelligence may still be quite remote; and in any case this gives us no licence to attribute to the cause any particular moral qualities.

The first *Enquiry* brought Hume notoriety for its argument against believing in 'miracles. On all topics, 'A wise man . . . proportions his belief to the evidence.' Hence: 'No testimony its sufficient to establish a miracle, unless the testimony be of such a kind, that its falsehood would be more miraculous, than the fact, which it endeavours to establish.' Hume adds reasons to suppose that the latter condition has never been met: witnesses have never been of 'unquestioned good-sense' and learning; human nature takes a misleading delight in things that amaze; moreover,

the miracles that supposedly support one religion must in the same way undermine other religions. 'Upon the whole,' Hume concludes, 'the *Christian Religion* not only was at first attended with miracles, but even at this day cannot be believed by any reasonable person without one.'

Having concluded that the source of religion can hardly be reason, Hume gives his own anthropological account of it—in the irreverent essay *The Natural History of Religion*, which appeared in the *Four Dissertations* of 1757.

**humour.** Although \*laughter, like language, is often cited as one of the distinguishing features of human beings, philosophers have spent only a small proportion of their time on it, and on the related topics of amusement and humour. Of the two most widely held theories, the first, that humour expresses a superiority of the individual who is amused over the object of amusement, is the most venerable. The second is that amusement is a response to incongruity. Amongst the topics that have surfaced in recent discussion, three catch the attention. We talk of a sense of humour, and this seems to assume that some are equipped to see what is funny about a situation whilst others cannot. Does it follow that the situation is itself funny antecedent to anybody finding it so? Are we then committed to realism about humour? Secondly, is humour a virtue? How does a sense of humour connect with other virtues, and is its absence a defect in an otherwise good man? Connected with both these issues is the general relevance of moral considerations to humour. Does the fact that a joke is racist or sexist mean that it is not really funny, or that it is merely a fault in us if we laugh at it? R.A.S.

**Hungarian philosophy.** In the seventeenth century there were Hungarian Cartesians, mostly Protestant divines in Transylvania. Then at the beginning of the nineteenth

century counter-Reformation Jesuit philosophers and Hungarian Kantians created a theoretical vocabulary and so contributed to the inauguration of a national culture without giving the world any great innovation. The 'synthetic philosophy' of the mid-nineteenth century tried to fuse all metaphysical tendencies in a specifically Hungarian world-view. Later, the objectivist theory of values under the influence of Hermann Lotze and Immanuel Hermann Fichte played an important role, along with Hegelian aesthetics.

The first really original Hungarian contribution to philosophy was the *fin-de-siècle* anti-psychologism or \*Platonism represented by such thinkers as Akos Pauler (1876–1933), a gifted follower of Bolzano and Brentano, and Georg Lukács (1885–1971). Pauler was a Catholic who tried to reconcile the Aristotelian inclination of the then vigorous \*neo-scholasticism with his own strong views on validity. Validity for him is a combination of truth and existence. True assertions and existent objects are both valid, so that the gap between \*fact and value is filled; validity is also divine.

Lukács, the best-known Hungarian philosopher, influenced a host of theorists. His work before the First World War was extremely \*conservative and romantic. He sought to demonstrate that individual psychic life is nothing but an aberration: any utterance can be meaningful only if it partakes of the objectivity of \*forms, created culturally. \*Culture, therefore, is more than the sum of individual or group endeavours, it is the primary reality that speaks through people, especially seers, mystics, and poets. The tragedy of life consists in our desire to be ourselves, whereby we demote ourselves from the highest level of objectivity (cultural forms), particularly while experiencing erotic love. The inescapable abdication inherent in every individual life necessitates history, through which second-rate individuality can merge progressively in the impersonality of the meaningful form: civilization. Form is divine: but love turns us away from it, condemning us to superficiality and meaninglessness; love of the 'objective' (religion) seems hopeless. The Sunday Circle, the first Lukácsian group in Hungarian philosophy—of whom only Karl Mannheim (1893–1947) is internationally renowned—took up his views enthusiastically, combining Platonism with Dostoevsky and Kierkegaard, and prophesying a conservative revolution against \*individualism and liberal \*capitalism.

It is perhaps interesting to note that it was this group rather than the uninspired socialists who were the messianic ideologues of the Hungarian Soviet Republic in 1919, where one young philosopher read excerpts from *The Brothers Karamazov* to capture the minds of right-wing officers.

Between the two world wars Hungarian philosophy was part of the so-called neo-baroque official culture, continuing the Platonist tradition with an added (corporatist) social dimension along the lines of the 'universalism' of Othmar Spann, the theorist of the *Ständestaat*, a sort of modern caste society.

After 1945 the erstwhile messianic revolutionaries returned from Moscow as wizened and dogmatic Marxist-Leninists and built the imposing edifice of institutional philosophy, a vast network of research institutes, university departments, indoctrination schools, periodicals, and popularization courses. For the first time, classic works (particularly, of course, of Spinoza and Hegel) became available in cheap editions. Every dogmatism is beset with heresies and the ritual and public ideological debates were only the visible expression of the fissures within the system: they played a political role rarely associated with philosophy in liberal democracies. The Lukács debates in 1949, 1956, 1957, and the late 1960s gave shape to the so-called revisionism that rejected crude materialist determinism, class theory, and positivist beliefs in progress and science, reconnecting Marxian tradition with its romantic sources in theories of alienation and reification where the ideas of the young, non-Marxist Lukács about objective meaningful forms make a spectacular come-back. Revisionists, through their abstruse disagreements with official doctrine, were the first agents of a *de facto* \*pluralism. The condemnation of the revisionists, and their joining forces with other dissidents, quickened the pace of the disintegration of the system. The demand for freedom to philosophize preceded in time-honoured fashion ideological scepticism, which then prompted liberal development. Today in Hungary you can find Heideggerians and Rawlsians, Oakeshottians and Straussians, analytical Marxists and post-moderns, just like everywhere else. G.M.T.

Béla Tankó, *Hungarian Philosophy* (Szeged, 1934).

**Husserl, Edmund** (1859–1938). German philosopher who was the founder, and a skilful practitioner, of \*phenomenology. His early works, *On the Concept of Number* (1887) and *Philosophy of Arithmetic* (1891), were marked by psychologism, the attempt to base logic and arithmetic on psychology. The concept of plurality, for example, was explained in terms of our mental act of combining different contents of consciousness into one representation, of, for example, seeing distinct people as a single group. Influenced in part by Frege's criticism, Husserl abandoned this view, and in his *Logical Investigations* (1900–1; tr. London, 1970) argued that logic is not reducible to psychology. For example, the statement:

- (1) If all men are mortal and all Greeks are men, then all Greeks are mortal

neither entails nor is entailed by:

- (2) Anyone who believes that all men are mortal and that all Greeks are men also believes that all Greeks are mortal

or:

- (3) No one who believes that all men are mortal and that all Greeks are men believes that not all Greeks are mortal.

(Nor is (1) equivalent to a rule of correct thinking:

- (4) Anyone who believes that all men are mortal and that all Greeks are men ought to believe that all Greeks are mortal.

We could argue, with equal justification, that an empirical statement, e.g. 'The earth is not flat', amounts to a rule, 'No one ought to believe that the earth is flat'. If (1) were equivalent to (2) or (3), (1) would be at most probable and would presuppose the existence of mental phenomena. The claim is also viciously circular in that any attempt to derive (1) from (2) or (3), or, more generally, to derive logic from psychology, must presuppose some rule of logic. (Parallel objections can be raised to the claim that the truth of (1) depends on the meanings of the words used to express it or on 'rules of language', if these are interpreted as empirical generalizations about natural languages.)

We need to distinguish between, on the one hand, what is meant or intended, the objects of \*consciousness, and, on the other, our psychical acts or experiences, our consciousness of such objects. (The idea of an 'intended' object stems from medieval philosophy by way of Brentano.) Logic deals with what is meant, not with our acts of meaning it. The objects of consciousness appear to us, are 'phenomena', while our psychical acts are merely experienced. (We may in turn reflect on psychical acts and thus convert them into phenomena. They are then no longer real, experienced acts, but the objects of further acts.) Psychical acts, like any other real entity, must be individual entities; but what is meant is an ideal entity and may be universal. If, for example, I am thinking about love, my thinking is a particular act distinct from other acts of thinking; but the love that I think about may be no particular love, simply love in general. Intended objects are thus 'essences', and it is essences and their interrelations that logic describes. Heidegger (like Adorno) was puzzled by the apparent revival of psychologism in the second volume of the *Logical Investigations*: 'But if such a gross error cannot be attributed to Husserl's work, then what is the phenomenological description of the acts of consciousness? Wherein does what is peculiar to phenomenology consist if it is neither logic nor psychology?'

Husserl published little for some years after the *Logical Investigations*, but continued to develop his ideas in lectures. For example, in his 1905 *Lectures on the Phenomenology of Internal Time-Consciousness* (edited for publication by Heidegger in 1928; tr. The Hague, 1964), he wrestled with a problem that had exercised St Augustine and William James: How can I experience a temporally extended object *as such*? Suppose that I am listening to a tune consisting of a succession of notes, 1, 2, 3, 4, ..., each of which occurs at a certain time,  $t_1, t_2, t_3, t_4, \dots$ . If at any given time,  $t_n$ , I hear only the note that occurs at that time,  $n$ , and have no awareness of the notes that occur before and after  $t_n$ , then at no time am I conscious of a temporally extended tune, but only of the note that is occurring *now*. (I am not strictly aware even of the occurrence of the note *now*, since the awareness of the present *as such* implies some

awareness of before and after.) If, on the other hand, at  $t_n$  I hear with equal force all the earlier notes, then again I hear not an enduring tune, but a deafening cacophony. The basis of Husserl's solution is this: At any given time, say  $t_n$ , I have a 'primal impression' of the note that is occurring *now*, note 9. I do not now have a primal impression of note 8, but I 'retain' it, that is I am aware of it as just past. When note 10 occurs, I am aware of 9 as just past and of 8 as further past. As the tune proceeds, note 8 recedes further into the past and 'appears' in ever-changing 'retentional modifications'. Thus I retain not only the individual notes of the tune, but the order in which they occurred. Similarly, at any given point in the tune I 'protrain' its future course. If I have not heard the tune before, my protention is less determinate than my retention, but following a tune involves an expectation that its future course will lie within certain limits. (If I were to end this article with the words 'And that concludes my account of the Pyramids', the reader's surprise would indicate *both* that on reading this sentence, he retained (his reading of) earlier sentences *and* that while reading earlier sentences he protained, more or less roughly, the future course of the article.) Ordinary, or 'secondary', memory presupposes, but is distinct from, retention, or 'primary' memory. If I am trying to remember an earlier phase of a tune, this impairs my appreciation of its present phase; retention of earlier phases is, by contrast, essential to my appreciation of the present phase. Expectation similarly presupposes, but is distinct from, protention. Husserl does not (as the example of a tune consisting of notes may suggest) regard time as atomized into a series of discrete instants, or periods: our time-consciousness is a 'continuous flux'.

In his next major work, *Ideas: General Introduction to Pure Phenomenology* (1913; tr. London, 1931), Husserl introduces a range of technical vocabulary. The act of consciousness, for example, is *noēsis*, while its intended object is the *noēma*. Logic and pure mathematics rests on the intuition of \*essences (*Wesensschau*) or *eidē*, and 'phenomenology' is the descriptive analysis of essences in general. Not only objects, such as an object of sense-perception, can be analysed in this way, but also acts of consciousness. But the acts must then be 'reduced' to an essence or *eidōs* (the 'eidetic reduction'). The phenomenologist is not concerned, for example, with particular acts of sense-perception, but with the essential features common to all such acts. Moral and aesthetic values, and desires and emotions, are also open to phenomenological investigation.

The phenomenologist must, on Husserl's view, perform an \**epochē*, that is, suspend judgement, with regard to the existence of objects of consciousness. In analysing, for example, the essence of perceived objects, we must not assume that such objects as trees and tables exist and causally engage with our sense-organs, but focus exclusively on the essential structure of perceptual consciousness. We must suspend, or 'bracket', the 'natural attitude' to the world. The reason for this is that Husserl, like Descartes, advocated 'philosophy as rigorous science' (the title of an article of 1911), philosophy as the indubitable

basis of our dubitable, if for the most part correct, beliefs about the empirical world.

But Husserl disagreed with Descartes in one crucial respect. Descartes moved swiftly from the proposition that 'I think' to the conclusion that I am a 'thinking thing'. The belief that I am a thinking thing is itself, Husserl claims, to be bracketed. I, who am conscious of objects, am neither a thinking substance, nor an embodied person, nor even the stream of my experiences—for I am conscious of, and in that sense distinct from, my experiences; I am the pure or transcendental ego, what Kant called the 'I think' which 'must be able to accompany all my representations'. The transcendental ego or 'transcendental subjectivity' cannot itself be bracketed, any more than Cartesian doubt can extend to the existence of the doubter. Thus only transcendental subjectivity is 'non-relative . . . while the real world indeed exists, but in respect of essence is relative to transcendental subjectivity, in such a way that it can have its meaning as existing reality only as the intentional meaning-product of transcendental subjectivity'. Husserl here infers an idealist conclusion, namely that objects are constituted by consciousness and could not exist without it, from the true premiss that nothing can be conceived without being an object of consciousness. The error depends on either or both of two confusions: (1) between an intentional and a real object—in conceiving an object, I make it an object of my consciousness, but I do not thereby make it a real object, e.g. a tree; (2) between making something my intentional object by conceiving it and conceiving it as my intentional object—I cannot think of a possible lifeless universe without making it the object of my thought, but I do not thereby think of it as an object of my thought and thus suppose myself to be one of its inhabitants. (It is a mistake to suppose that Husserl's \*idealism can only be avoided if we reject the methodological use of *epochē*.) In his *Cartesian Meditations* (1931; tr. The Hague, 1960) Husserl tried to relieve phenomenology of the charge that it entails solipsism by explaining how one transcendental ego can experience another transcendental ego on a par with itself.

From the *Ideas* to the *Cartesian Meditations*, Husserl's enterprise is avowedly akin to Descartes's *Meditations* and, unavowedly, to Fichte's \**Wissenschaftslehre*. But his last great (unfinished) work, *The Crisis of European Sciences and Transcendental Phenomenology* (1936; tr. 1954) is closer to Hegel's *Phenomenology of Spirit*. For it purports to show, 'by way of a teleological–historical reflection on the origins of our critical scientific and philosophical situation, the inescapable necessity of a transcendental–phenomenological reorientation of philosophy'. This is at odds with his earlier approach in at least two respects: (1) a historical or causal account of the genesis of our consciousness was excluded or \*'bracketed' in his earlier works; (2) in so far as Husserl is now concerned not so much with particular past events, as with the *eidōs* of history, with the essential historicity of consciousness, its burden of preconceptions derived from the traditions of its social milieu, this casts doubt on his own attempt to found a rigorous science, free

of all preconceptions, that goes directly 'to the things themselves'. In part 3 of the *Crisis*, and in other papers intended for incorporation in it (such as 'The Origin of Geometry') he develops the concept of the 'life-world' (*Lebenswelt*), the intersubjective world of our natural, pre-theoretical experience and activity, which, he believes, was neglected by philosophers such as Kant in favour of the world of theoretical science. But the 'theoretical attitude' (exemplified, for Husserl, by Galileo) arose historically, in ancient Greece, against the background of the life-world, and the life-world *essentially* persists even after the development of the theoretical 'spirit'. Even the physicist thinks of the sun as rising and setting, and as marking the phases of his practical life. Husserl's account of the life-world, of its essential priority to theory, and of the emergence of theory from it, owes something to the eidetic method and to *epochē*: to describe the *essential* structures of the life-world involves suspending our scientific presuppositions and our practical engagement with the life-world. Nevertheless, some philosophers, notably Merleau-Ponty, see the *Crisis* as a distinct departure from Husserl's earlier work.

Husserl has had an immense influence in continental Europe. Phenomenological analysis has been applied to psychology (Pfander), law (Reinach), values, aesthetics, and religion (Scheler). Even philosophers who reject Husserl's theoretical doctrines have benefited from his meticulous analyses of particular phenomena. But thinkers such as Heidegger, Sartre, and Merleau-Ponty have used phenomenology in the service of philosophical positions quite different from Husserl's own, and his hope that his rigorous science would put an end to radical philosophical disagreements has remained unfulfilled. **Hutcheson, Francis** (1694–1746/7). An academic philosopher of Irish origin who taught (and was criticized by) Adam Smith at Glasgow University and strongly influenced Hume, he was the main representative of the \*'moral sense' doctrine in ethics, which he inherited from Shaftesbury. The main thrust of his philosophy was to emphasize feeling rather than reason or intuition as the source of what we think of as moral knowledge, though it is unclear whether this feeling detects special moral qualities in actions or situations, as we feel the warmth of fire, or whether we simply have feelings of approval or disapproval towards their non-moral properties. This latter interpretation would place Hutcheson as an ancestor of the twentieth-century \*emotive theory of ethics, and similar theories, but the eighteenth century was less

sensitive than the twentieth to precise semantic analyses of the meanings of words and phrases. A.R.L.

M. P. Strasser, *Francis Hutcheson's Moral Theory* (Wakefield, NH, 1990).

**hylomorphism.** The doctrine that sensible things are composites of matter (Greek *hylē*) and form (*morphē*). Against atomists, who explained big things in terms of varying arrangements of small things, Aristotle found his model in sculptures 'formed' from matter by the artist. Once reified into metaphysical constituents, forms are treated as primitive explanatory entities accounting for both static and dynamic structure of things (e.g. the substantial form of bovinity explains both the organic differentiation of cow bodies and their distinctive digestive processes). **hylozoism:** see panpsychism.

**hypothesis.** A hunch, speculation, or conjecture proposed as a possible solution to a problem, and requiring further investigation of its acceptability by argument or observation and \*experiment. Hypotheses are indispensable to human thinking, and used by everyone from detectives (Sherlock Holmes) to metaphysicians. They form the basis of an influential account of scientific method

(\*hypothetico-deductive method), which is closely related to the claim, associated with Popper, that scientific \*theories are empirical hypotheses and remain so, however successful they are at withstanding repeated attempts to falsify them. A.BEL.

\*evidence.

Larry Laudan, *Science and Hypothesis* (Dordrecht, 1981).

**hypothetical imperative:** see categorical imperative.

**hypothetico-deductive method.** A theory in science is a general statement (or \*hypothesis) from which particular inferences may be deduced. Thus, from the theory 'All planets have elliptical orbits', given the information that Mars is a planet, we can deduce that Mars has an elliptical orbit. Observations (here, of Mars's orbit) can then be seen as confirming or falsifying the hypothesis.

In the twentieth century Karl Popper and many other philosophers of science before him saw the core of science as the deployment of what is called the hypothetico-deductive method. An unfortunate consequence of this view has been a concentration on the formal relationships between theories and the statements which follow from them. There has been consequent lack of interest in the relationship of theories to the actual practices, evidential and experimental, from which they emerge, despite the fact that even testing a theory is in practice more complex than the hypothetico-deductive model suggests. A.O'H.

\*Bacon.

E. Nagel, *The Structure of Science* (London, 1961).

# I

**I and thou.** The relation of subject to subject celebrated in Buber's ethical and religious philosophy: I may contemplate a tree 'as a picture: a rigid pillar in a flood of light . . . overcome its uniqueness and form so rigorously that I recognize it only as an expression of the law . . . dissolve it into a number . . . But it can also happen, if will and grace are joined . . . that I am drawn into a relation, and the tree ceases to be an It. The power of exclusiveness has seized me.' Placing relationality (and so, intersubjectivity) ahead of both subject and object, Buber's approach springs from Kant's foregrounding of the subject morally and in constituting experience and from Hegel and Feuerbach's insistence that dialectic constitutes the self. Similar thoughts unfold in Mead, Peirce, and Dewey; they take flight as fully fledged metaphysical themes in Cohen, Rosenzweig, and Buber.

Martin Buber, *I and Thou* (1922), tr. Walter Kaufmann (New York, 1970).

**Ibn Gabirol, Solomon** (c.1022–c.1058). Philosopher and poet, author of the *Fons Vitae*, an intricate, highly abstract dialogue on Neoplatonic metaphysics. Since the Arabic original is lost, it was not known until Salomon Munk (1845) recognized Shem Tov ibn Falaquera's Hebrew quotations from it that the Avecebrolo of the Latin manuscripts was the well-known Hebrew poet Ibn Gabirol. Born in Malaga and raised in Saragossa, Ibn Gabirol relied on the idea of intellectual or 'universal' matter to explain the emergence of multiplicity from God's unity. Matter here is the passive or receptive aspect of every being but God. Ibn Gabirol's *On the Improvement of the Moral Qualities* (tr. Steven Wise (1902)) offers a physiological treatment of ethics based on the theory of the four humours. 'The Kingly Crown', his Neoplatonic poem on the descent and destiny of the soul, is included in the Sephardic liturgy of the Day of Atonement.

**Ibn Khaldūn** (1332–1406). Born in Tunis, he was one of the

most creative of Muslim statesmen and political thinkers, widely acclaimed by modern historians as the greatest philosopher-historian. In his major theoretical work, *The Prolegomena*, he introduced the notion of natural causality in history, in contrast to Islamic theology, and called for the definition and study of sociological and political processes (considered to be the principles of historical methodology) with the express investigative intention of recovering historical accuracy. He defined and claimed to be the originator of a 'science of culture' (*'umrān*) that would study cultures in multiple stages in their natural human, social, and political development. His methodology emphasizes the study of environmental impact on social organizations and economic processes that define value, prosperity, and culture.

**idealism, British.** Movement in nineteenth- and twentieth-century British philosophy according to which ultimate reality is mental or spiritual, or at least not physical. Bradley, Green, and Bosanquet think matter is not real. Physical objects and the subjective points of view of conscious individuals stand in a system of \*internal relations called 'the absolute' or 'absolute mind', so British idealism is mostly a kind of quasi-Hegelian \*absolute idealism, and \*truth is ultimately construed as \*coherence. McTaggart, although denying the existence of God and the reality of time and matter, holds that we are essentially immortal souls. His influential argument that time is not real putatively shows that tense is incoherent. Change depends on tense, time depends on change, so time depends on tense, so there is no time. Tense is incoherent because it entails a contradiction to say, for example, that the same (token) event happened last week and will happen the day after tomorrow.

Newton might be an early if unwitting exponent of absolute idealism, depending on the meaning of his claim that absolute space and time are 'the sensoria of God'. Physical objects and events logically depend upon space

and time. Space and time logically depend upon the presence of God, so physical objects and events logically depend upon the presence of God.

More recently in Britain, \*Timothy Sprigge has argued for a kind of absolute idealism. Non-absolute or individualistic versions of idealism have been defended by John Foster and Howard Robinson. They argue that it is incoherent to maintain that ultimate reality is physical. Foster argues for a quasi-phenomenalist idealism on which physical facts are wholly constituted by experiential facts, even though physical concepts are not analytically reducible to experiential concepts. Foster therefore rejects physical realism and any naïve realist view on which we are directly acquainted with physical objects in sense perception.

Although late twentieth-century British philosophy was dominated by the materialist and positivist ideas common to English language philosophy, it is not impossible that idealism will have a new role once non-reductivist explanations of consciousness come to be taken more seriously. It is now clear, if it was not clear then, that materialism, naturalism, and positivistic science have wholly failed to provide any kind of explanation of the existence and reality of one's own subjective mind. s.p.

**idealism, German.** Movement in late eighteenth- and early nineteenth-century German philosophy according to which ultimate reality is mental or spiritual, or at least not physical. Kant, Hegel, Fichte, and Schelling are usually classed as German idealists, and Leibniz and Schopenhauer are sometimes included.

Arguably, Kant is not any kind of idealist. He called his critical philosophy 'transcendental idealism', but realized his mistake when readers understood this as a kind of idealism. In the second (B) edition of the *Critique of Pure Reason* he expressly included a new chapter called 'The Refutation of Idealism' (B 274–9). 'Idealism' in 'transcendental idealism' is in fact correctly understood as 'anti-realism'. Kant thinks there are no metaphysical propositions, so transcendental idealism is metaphysical anti-realism. Kant makes many claims consistent with idealism, but they are misunderstood as entailing idealism. Famously, he insists that we have knowledge only of appearances, not of things-in-themselves. This means we can only know things as they appear to us, not as they could not appear to us. There is nothing to suggest that

appearances are mental ('A motor car appeared around the street corner'). 'We can only know possible objects of experience' means: We can only know things as they would appear to us if we were experiencing them. This does not entail that those things are mind-dependent, only that our knowledge has a perspectival nature. Kant makes it clear that the notion of a noumenon is a 'limiting' concept, and 'existence' is a category, so whatever interpretation we give to 'noumena', it had better not imply that there are any. Kant thinks we can know objects only if they are spatio-temporal, Euclidian, Newtonian, countable, could interact causally, and are substances. If this epistemological conservatism carries any ontological implication, it is materialism, not idealism.

There is a huge secondary literature on Kant, most of it, from Hegel to contemporary British, German, and American commentators, mistakenly construing Kant as some sort of idealist. In the hands of Fichte, transcendental idealism does become a kind of idealism. Fichte rejects things-in-themselves, which he misunderstands as in hidden ontological duplication of appearances. Although Kant insists that there is no substantial subject or ego (for example in the \*paralogisms), and depicts the transcendental unity of apperception as the purely formal possibility that any thought of mine may be prefaced by 'I think [that]...' (in the Transcendental Deduction), Fichte nevertheless postulates an inner ego as owner of one's thoughts and experiences, a self-consciousness that 'posits' the external world and, with dubious coherence, itself. Self-consciousness presupposes an 'I-not I' distinction, it arguably making little sense to postulate a portion of what is that I am without positing a distinct portion that I am not.

In the *System of Transcendental Idealism* (1800) Schelling construes consciousness and the unconscious as reciprocally constituting. In the *Exposition of my System of Philosophy* (1801) Schelling advocates an 'identity' or 'indifference' between nature and spirit, object and subject; but 'identity' should not be understood here as 'numerical identity' or 'qualitative identity'. In a partial anticipation of Hegelian dialectic, *a* and *b* are identical if and only if, if not *a* then not *b*, and if not *b* then not *a*, so it is legitimate to regard *a* and *b* as parts or 'moments' of a larger whole. What *a* is a part of is nothing other than what *b* is a part of. Ultimately, nature and mind are aspects of the Absolute. Because nature and spirit are mutually dependent in Schelling's philosophy, it is better construed as \*neutral monism than idealism. In *Bruno* (1802) the Absolute is identified with God. In *Of Human Freedom* (1809) God is identified with the source of the universe as pure, infinite free will.

Hegel's philosophy may be understood as the application of Kant's critical philosophy to the totality of what is. The triadic arrangement of Kant's table of categories and the synthetic resolution of the Third Antinomy in which thesis and antithesis are both true, albeit at different levels of explanation, provide Hegel with the immediate model for his dialectic: the exhibiting of philosophical problems as prima-facie contradictions which, on closer inspection,

turn out to be mutually consistent depictions of a larger whole. By 'logic' Hegel does not mean logic but, roughly, the exhibiting of semantic, psychological, and ontological relations between universals.

Hegel made two attempts at writing his system: the *Phenomenology of Spirit* (1807) and the *Science of Logic* (1812–14), and, secondly, the so-called *Encyclopaedia of the Philosophical Sciences* (1815–31), including the *Lesser Logic* and *Philosophy of Mind*. In writing two fundamentally different kinds of philosophy book, phenomenology books and dialectic books, Hegel, the greatest synthesizing philosopher, failed to 'overcome' the greatest antithesis of Western philosophy: between empiricism and rationalism. Kant, in his own view, had done this. s.p.

**idealism, philosophical.** Philosophical idealism is not the same as idealism considered as an attitude to be observed in life; it is not the pursuit of an ideal. It is, rather, a metaphysical theory about the nature of reality, and thus presupposes a distinction between \*appearance and reality, drawn in an other than common-sense way. It maintains in general that what is real is in some way confined to or at least related to the contents of our own minds. Plato's theory of Forms is sometimes said to be a species of idealism on the grounds that his Forms are also called Ideas. But those so-called Ideas were not merely contents of our minds; indeed Plato explicitly rejects that supposition in his *Parmenides*. It has been argued by Myles Burnyeat that idealism proper could not appear before Descartes had argued for the epistemological priority of access to our own minds. Although this has been disputed, there is much to be said for the thesis. At all events, whether or not there are to be found any indications of belief in philosophical idealism before Descartes's time, it certainly needed his argument to provide it with any basis. Yet Descartes was not himself an idealist.

What are the reasons, therefore, for thinking that reality is confined to the contents of our minds—\*ideas, as they were called by Descartes and others at his time? Berkeley, who was the first idealist proper, generalized Locke's arguments to the effect that where the perception of qualities of things, such as colour, taste, and warmth, is circumstance-dependent (i.e. relative to the context in which perception takes place, e.g. the illumination, the condition of our tongue, or the temperature of our hands) those qualities cannot be real properties of things. Berkeley argued that this applied to all \*perception. Since perception is, he thought, a matter of having sensations or ideas, and since to be is to be perceived (Berkeley's cardinal thesis), only sensations or ideas can properly be said to be or to be real. He summed this up towards the end of his *Three Dialogues* by a twofold thesis maintained, he said, both by philosophers and by the 'vulgar': those things they

immediately perceive are the real things, and the things immediately perceived are ideas which exist only in the mind. There are many points to question about this thesis, including the whole idea of immediate perception and the claim that, whatever immediate perception is, it is confined to sensations or ideas.

The theory of perception involved, the so-called representative theory of perception, according to which what we perceive is at best mere representations of things, remained part of the apparatus of empiricist thought, and is implicit in Hume's doctrine that what we are given is impressions, of which ideas are in some way copies. In the eighteenth century only Reid challenged the theory, because he thought it led Hume to absurdity. But the theory is still there in the thought of Kant, who held that perception provides us only with representations (*Vorstellungen*), however mediated by concepts. Kant held, however, that a mere subjective, Berkeleian idealism would not do in that it did not make it possible to distinguish properly what is objective from what is subjective in the sense in which flights of fancy are subjective. Kant, followed to this extent by Schopenhauer, thought that idealism must be transcendental, which he tried to define by saying that 'appearances are to be regarded as being, one and all, representations only, not things-in-themselves, and that time and space are therefore only sensible forms of our intuition, not determinations given as existing by themselves, nor conditions of objects viewed as things-in-themselves' (*Critique of Pure Reason*, A 369). The main point is that Kant thought that he could distinguish between appearances or representations of perception and \*things-in-themselves, but that the conditions for a further distinction within appearances between what is objective and what is merely subjective could also be set out. The spatial-temporal features of objects as given in experience are thus, he said, empirically real but transcendently ideal. Kant thought that he could, in these terms, show the unacceptability of Berkeleian idealism.

We have, so far, a distinction between two forms of idealism. Post-Kantian philosophy supplied a third, which became known as absolute idealism. Fichte began it (although he called his form of idealism 'critical idealism') by rejecting what Kant had had to say about things-in-themselves, seeking to make the distinction between self and non-self purely within what is due to the activities of the self. Hegel took it much further, thinking that he could demonstrate, first, the identity of consciousness with its object and, second, the identity of consciousness with self-consciousness. This led, to simplify his argument grossly, to the idea of a universal self-consciousness, a universal 'notion' (*Begriff*), which is what reality is. This is the \*Absolute (a term introduced by Fichte), the one unconditional entity. While both Berkeleian, subjective idealism and Kantian, transcendental idealism, in effect construe reality in terms of the contents of an individual mind, absolute idealism tends to construe it in terms of some interpersonal consciousness. Indeed, in it the distinction between one self and another tends to lapse, leading, as is

explicit in F. H. Bradley's *Appearance and Reality*, to a form of \*monism, according to which there is only one thing, distinctions within which are simply appearance. This is clearly heady stuff.

All these forms of idealism have in common the view that there is no access to reality apart from what the mind provides us with, and further that the mind can provide and reveal to us only its own contents. This second consideration is supposed to follow from the first, but it does not do so unless one invokes additional considerations, such as those adduced by Berkeley when he claims that the circumstance-dependence of judgements of perception show that the objects of perception are mind-dependent. The effect of the latter is to assimilate perception to \*sensation. Something like pain is taken as the paradigm of sensation, and it is then argued that the feeling of warmth can be assimilated to pain, and that other forms of perception can be assimilated to that, in that, perhaps, they are all subject to bodily and other, contextual conditions. Reid reasonably defined sensation in terms of the idea that it has no object other than itself. He did not think that this was true of perception, despite what Hume and other empiricists had said; he thought that perception involves concepts and beliefs, but that these are of objects distinct from what takes place in the mind. But, in fact, however correct this last point is, one can *show* that it is so only by meeting the arguments which try to assimilate perception to sensation. G. E. Moore thought that he could refute idealism by drawing attention to the distinction within experience between the experience itself and its object. But one needs to show in addition that that object can be extra-mental.

Recent arguments for what has been called \*anti-realism raise difficulties over the idea that there can be forms of understanding reality which are verification-transcendent, so that there are problems about our attaching content to something if there is no way of verifying whether it does or does not hold good. Transcendental idealism can be construed similarly as a form of anti-realism in that Kant argues for limits on what can be understood if it cannot be brought under the conditions of objective judgement. However, anti-realism does not quite entail idealism. Kant depends also, for his transcendental idealism, on a representationalist view of perception, holding that sensible intuitions (i.e. what is given in perception) which are brought under concepts in judgement about the experienced world take the form of representations. Kant inherited that view from his predecessors, and accepted it because it seemed obvious. But it is not obvious (though something approaching it has become the vogue today, particularly among cognitive scientists, who hold that the mind's workings have to do with mental representations). It is not obvious because it is assumed that the stimulation of our sense-organs produces not merely sensations in the ordinary sense, but something that performs the role of representing whatever produces the stimulation, so that it is this which we are directly aware of (or which the mind is directly

concerned with), rather than the object itself. At the same time, without that misconceived view of perception (or something like it) idealism cannot get off the ground.

Idealism has been very pervasive in the history of philosophy since at any rate the eighteenth century. It has been less prevalent in recent times, but tendencies towards representationalism are liable to push adherents of that view in its direction. Consequently, defenders of idealism in some form are still to be found. Indeed, many beginners in philosophy seem to think that it is the most obvious philosophical theory, although nobody before Descartes would have thought just that. It is also noteworthy that Berkeley thought that his idealism amounted to a defence of common sense and that, as indicated earlier, it was what philosophers and the 'vulgar' had in common. Later forms of idealism have been less 'obvious' because they are more sophisticated and more complex. Schopenhauer characterized his form of transcendental idealism by saying that it amounted to the doctrine of 'no object without a subject', and he defended that, partly by appealing to Berkeley and partly by arguing that if we try to imagine a world without a knowing subject, we are bound to realize that we are involved in a contradiction. For what we shall be imagining is something that is indeed dependent on a knowing consciousness—our own. But while it is clear that it is impossible for us to imagine anything without an imaginer existing, namely ourselves, it does not follow that we cannot imagine a scene in which no conscious beings exist. It does not follow, that is, that there cannot be objects the existence of which does not depend on their being *for* a subject. As Hegel might have put it, and despite his arguments to the contrary, what is 'in-itself' need not be 'for another'. In the end, the only positive argument for idealism of any form is to be found in the representative theory of perception, and that theory is false.

**ideal observer theory.** A theory of justification in ethics. The theory is that moral judgements can be justified by appeal to what an ideal observer or 'impartial spectator' would do or say in a given situation. The theory has been developed from its origins in the British moralists of the eighteenth century, but it still has a problem in providing a non-circular account of an ideal observer.

R.S.D.

Roderick Firth, 'Ethical Absolutism and the Ideal Observer', *Philosophy and Phenomenological Research* (1952).

**ideals, moral.** Two levels of moral standards have been distinguished in ethical theory: ordinary moral standards and extraordinary moral standards. The first level is

confined to standards in the common morality that apply to everyone—the moral minimum. The second level is a morality of aspiration; here individuals adopt moral standards that do not hold for everyone. These ideals transcend what we appropriately expect of others and thus are aspirational ideals of individual excellence. In so far as a person aspires to *moral* goals that surpass the conventional moral point of view, the person accepts moral ideals. Those who fulfil these ideals can be praised and admired, whereas those who fall short of ideals cannot be rightly blamed or condemned by others.

\*Supererogation is a category of moral ideals pertaining principally to *actions*, rather than to *virtues* or *motives*. The etymological root of *supererogation* means paying or performing in addition to what is owed. It has several defining conditions. Supererogatory ideals and acts are those which exceed what is expected or demanded by the common morality; they are intentionally undertaken for the welfare of others (although the actor need not intend to act from an ideal). A supererogatory ideal is optional—neither required nor forbidden by the common morality. Omission of a supererogatory act is not morally wrong and not condemnable by common-morality standards.

Nevertheless, individuals who act from ideals often do not consider their actions to be morally optional. Many heroes and saints describe their actions in the language of *obligation* and even *necessity*: ‘I had to do it’, ‘It was my duty.’ The point of this language is to express a *personal* sense of obligation. Some philosophical accounts deny the literal appropriateness of this language, interpreting it as a form of moral modesty designed to deflect merit or praise that might be showered on the person. But a broader and more sympathetic interpretation is that a personal norm is accepted by the person as establishing what ought to be done from a pledge or assignment of personal responsibility.

Supererogatory acts done from moral ideals typically would be required were it not for an abnormal deprivation or risk present in the particular circumstances, but the individual elects not to invoke an exemption from acting based on the abnormal situation. The individual therefore does not make a mistake in regarding the action as personally required and can view failure as grounds for guilt, even though no one else is free to view the act as obligatory.

Not all ideals are exceptionally arduous, costly, or risky. Examples of less demanding ideals include generous gift-giving, volunteering for public service, forgiving another’s costly error, devoted and extended kindness, and complying with requests made by other persons when these exceed the requirements of the common morality. Many everyday actions exceed obligation without being at the highest level of ideals.

Aristotelians have held that the ideal of an admirable life of moral achievement is central to the very nature of ethics, not merely a second level beyond ordinary morality. Each individual should aspire to a level as elevated as his or her abilities permit. Some persons are more able

than others, and for this reason they merit more praise, acknowledgement, and admiration. The Aristotelian model does not expect perfection, but rather that one strives toward perfection. Ideals are thus *central* in this model, not merely ornaments to an already commendable life.

**ideals.** These are entities that exist only as contents of some mind. Ideas in this sense should be distinguished from Plato’s Ideas or \*Forms, which are non-physical but exist apart from any conscious beings. The image of a Platonic Form that occurs in a person’s mind would be an idea in our sense. Beginning in the seventeenth century all objects of consciousness were held to be ideas. For example, we are conscious of ideas when we imagine, remember, dream, or think about some concept or proposition. Ideas are subjective in that individuals can be aware only of their own ideas. If two individuals are imagining Pegasus or thinking about the Pythagorean theorem each is directly aware of a distinct idea, although these ideas may share many features. This is analogous to the sense in which two reproductions of the Mona Lisa are distinct objects even though most of their properties are identical, but it is impossible for one individual to inspect another’s ideas.

Reflection on the nature of our perceptual experience led Descartes and Locke, among others, to argue that even when we are perceiving we are directly aware of ideas, not physical objects. For example, touching a hot object or walking into a wall may cause someone to feel pain. The pain is caused by a physical interaction between the object and the perceiver’s body, but the pain exists only as long as the individual is conscious of it. Moreover, pain is subjective: if two people walk into the same wall each experiences a distinct pain that exists only in that individual’s experience. Thus to experience pain is to experience an idea. But all perceptual experience arises in the same way as does pain. We feel warmth or solidity, see colour or shape, and so forth, because an object acts causally on our sense-organs. The item we become directly aware of as a result of this interaction is an idea. This thesis receives further support when we consider the way in which the apparent size, shape, and colour of a physical object, such as a distant tower, changes as our distance from the tower and our angle of observation changes. Since the tower presumably remains unchanged it is concluded that we do not directly perceive the tower, but rather ideas that are caused to exist in our minds by the interaction between the tower and our sense-organs.

Once the doctrine that we experience only ideas was accepted, three major philosophical problems immediately arose. First, are the ideas we experience adequate copies of items that exist apart from our experience? In the case of perception it is generally agreed that pain does not exist apart from experience and philosophers argued that other ideas which physical objects cause us to experience may not actually characterize those objects. Thus philosophers sought criteria for assessing which of our perceptual ideas characterize items in the physical world. Second, ideas are mental entities which, according to Descartes's analysis, have nothing in common with physical objects. Thus it is unclear how interactions between a physical object and a human body (also a physical object) can generate ideas. This question is one aspect of the \*mind-body problem. Third, if we are directly aware only of our own ideas, it becomes problematic how we know that anything exists other than these ideas. This question also arises for ideas of non-physical objects such as God. After Descartes the doctrine that we are aware only of our own ideas became widely accepted and the three problems just noted became central problems of epistemology and metaphysics. H.I.B.

\*phenomenalism; concepts; content; innate ideas.

D. W. Hamlyn, *Sensation and Perception* (London, 1961).

**ideas, innate:** see innate ideas.

**ideas of reason.** This is Kant's expression for the products of \*reason. In the *Critique of Pure Reason* Kant argued that there are three such ideas corresponding to the self, the world, and God; and that human reason is subject to an unavoidable 'transcendental illusion' through which it assumes the existence of non-empirical objects corresponding to these ideas, but that they nevertheless have an important regulative function in the systematic unification of experience. H.E.A.

Norman Kemp Smith, *A Commentary to Kant's Critique of Pure Reason*, 2nd edn. rev. and enlarged (New York, 1962).

**identity.** The word 'same' is used sometimes to indicate similarity (*qualitative* sameness), as in 'Rachel is the same age as Tony, and the same height as last year', sometimes to indicate that what is named twice should be counted once (*numerical* sameness), as in 'The morning star and the evening star are the same planet'. The word 'identical' can also have the former sense (identical twins, identical dresses) as well as the latter; hence philosophers are liable to discuss both kinds of sameness under the label 'identity'.

Similarity comes in degrees and ways. Jane may be *exactly* the same *in looks* as she was, or as her sister, but only *roughly* the same *in weight*. Leibniz's thesis of the

identity (i.e. numerical identity) of indiscernibles (i.e. qualitative identicals) states that no two things can be exactly the same in every way, sharing all their qualities. This is disputable, but becomes a tautology if numerical-identity-with-*a* is allowed to count among the qualities of *a*. The converse thesis (often called Leibniz's law), that things differing in quality must be two, is harder to doubt. But it must not be interpreted in such a way as to banish change, since *a* can have some quality that *b* used to lack, and still be numerically the same as *b*: many things persist through change. Hume thought that in the 'proper' sense identity over time requires changelessness. That would be true if the proper sense of identity were exact qualitative identity; but in fact the numerical sense is no less proper, merely different.

Different kinds of thing have different *criteria* of numerical identity. For example, mathematical classes are the same if and only if they have the same members; contrast regiments, clubs, etc., which can survive the addition or withdrawal of members. The criterion of identity of many things is vague, especially over time. For example, even though the plural 'clouds' shows that we sometimes count clouds, as we do not at a single time count fog, nevertheless the question 'How many clouds are there in the sky?' will rarely have even an approximate answer, unless it is 'none'. Sometimes the criterion is purely conventional (one road runs all the way from Edinburgh to London) or stipulated for a particular purpose (you are to count books by titles, not volumes or copies of titles or copies of volumes). Conflicting criteria are even allowed to coexist. For example, someone might count St Mark's and the Palazzo Ducale as different buildings and also as parts of the same building.

Numerical identity is an \*equivalence relation, i.e. transitive, symmetric, and strongly reflexive. But philosophers have sometimes proposed criteria, e.g. of personal identity, that fail to respect these properties. For example, it is logically (if not physically) possible that two different persons should both be linked by memory chains with a given later person. But it is not logically possible that two different persons should be numerically the same person as a given person. For the same reason 'is a clone of' lacks the formal properties of numerical identity; and although 'lies on the same, non-branching line of clone-descent with' puts things right formally, it would be odd if, for example, the identity of last year's bulb with its current clone depended on there happening to be no current rivals. Some philosophers have concluded that a criterion of identity need not be logically equivalent to identity, i.e. equivalent in all logically possible situations, whether or not within our experience. Others infer that the search for a precise and helpful criterion cannot always succeed.

Geach and others have used Locke's myth of the prince whose soul comes to 'inform the Body of a Coblent' to argue that numerical identity is relative to sorts, so that it is logically possible, for example, that the prince of today should be the same *person* but not the same *man* as the prince of yesterday, even though both are persons and

both are men. (Locke's own conclusion was different, though just as odd.) If this is right, the number you get depends on what sort of things you are counting things *as*. In any case it depends on what sort of things you are counting, as Frege saw: e.g. one atlas is many maps. C.A.K.

\*identity of indiscernibles; of identity criterion.

D. Hume, *A Treatise of Human Nature* (1739), ed. L. A. Selby-Bigge, 3rd edn. (Oxford, 1978), i. iv. 6.

J. Locke, *An Essay Concerning Human Understanding*, 2nd edn. (1694), ed. P. H. Nidditch (Oxford, 1975), ii. xxvii.

M. K. Munitz (ed.), *Identity and Individuation* (New York, 1971).

D. R. P. Wiggins, *Sameness and Substance* (Oxford, 1980).

**identity, criterion of.** A criterion of \*identity is a principle specifying, in a non-circular way, the identity-conditions of objects of a given kind. Objects of different kinds can have different identity-conditions. Thus, a criterion of identity for rivers might specify that if *x* is a river and *y* is a river, then *x* and *y* are the *same* river if and only if *x* and *y* have the same source and the same mouth.

So, one common form for a criterion of identity to take is this: if *x* is a *K* and *y* is a *K*, then *x* and *y* are the same *K* if and only if *x* and *y* stand in relation *R*. But there is another form of identity criterion, commonly associated with Frege, and exemplified by his criterion of identity for the directions of lines: the direction of line *x* is the same as the direction of line *y* if and only if line *x* is parallel with line *y*.

E.J.L.

E. J. Lowe, 'What is a Criterion of Identity?', *Philosophical Quarterly* (1989).

**identity, the paradox of.** Wittgenstein says (*Tractatus Logico-Philosophicus*, 5.5303): 'Roughly speaking, to say of two things that they are identical is nonsense, and to say of one thing that it is identical with itself is to say nothing at all.' If identity is a relation it must hold either between two distinct things or between a thing and itself. To say that *A* is the same as *B*, when *A* and *B* are distinct, is bound to be false; but to say that *A* is the same as *A* is to utter a tautology. Different solutions have been found by different philosophers for this paradox, which is discussed by Plato, Hume, and Frege, amongst others. Frege dealt with the paradox by making a distinction between the \*sense and reference of an expression. Wittgenstein's solution is to deny that identity is a relation. Anything useful that is said by means of 'is the same as' can be said by a sentence containing a repeated expression. Thus instead of saying 'The author of the *Iliad* was the same as the author of the *Odyssey*' we can say, repeating the '*x*', 'For some person, *x*, both *x* wrote the *Iliad* and *x* wrote the *Odyssey*', and for 'Florence is the same as Firenze' 'For some city, *x*, both *x* is called Florence and *x* is called Firenze'.

C. J. F. Williams, *What is Identity?* (Oxford, 1989).

**identity of indiscernibles.** The doctrine of the \*identity of indiscernibles has various formulations, ranging from a trivially true version to the metaphysically weighty version employed by Leibniz. Here is a trivially true version:

for any individuals *x* and *y*, if, for any property *f*, *x* has *f* if and only if *y* has *f*, then *x* is identical with *y*. Let the property *f* be the property of being identical with *y*. Surely *y* has it. But, then, if *x* has every property *y* has, then *x* has it also. Hence, *x* is identical with *y*. Here is Leibniz's version: for any individuals *x* and *y*, if for any intrinsic, non-relational property *f*, *x* has *f* if and only if *y* has *f*, then *x* is identical with *y*. Thus, according to Leibniz's version, if *x* and *y* are distinct individuals, they can not differ simply with respect to extrinsic, relational properties; they must differ with respect to some intrinsic, non-relational property as well.

Clearly, the exact content of Leibniz's version of the identity of indiscernibles turns on how we understand the notion of an intrinsic, non-relational property. Subsequent to Leibniz, philosophers have formulated versions of the identity of indiscernibles intermediate in strength between his strong version and the trivial version first mentioned. Others have offered alleged counter-examples to various of the intermediate versions, many having their origin in Kant's examples of \*incongruent counterparts. Consider an exactly matching pair of gloves, suppose the entire universe consists in the left glove facing the right glove. There are two distinct gloves. But what is the difference between the two? Consideration of such alleged counter-examples has yielded insights concerning the notion of an intrinsic, non-relational property, as well as the nature of space.

\*identity, criterion of.

I. Kant, *Prolegomena to Any Future Metaphysics*, tr. Peter G. Lucas (Manchester, 1953), sect. 13.

G. W. Leibniz, 'On the Principle of Indiscernibles', in *Leibniz: Philosophical Writings*, ed. and tr. G. H. R. Parkinson and M. Morris (London, 1973).

**identity theory of mind, the.** The contemporary mind-body identity theory, developed in the late 1950s, is that mental events are (that is, are identical with) physical-biological processes in the brain. Pain, for example, is nothing over and above a neural state in the central nervous system, presumably the excitation of certain neurons ('nociceptive neurons') in the brain. Although minds as substantial entities (e.g. Cartesian mental substances) have largely disappeared from philosophy, we can formulate an identity theory for minds as well: minds are brains (of appropriate complexity)—or to have a mind is to have a brain.

The identity theory in this form identifies psychological types (properties, kinds) with physical types (properties, kinds). This is why the theory is sometimes called 'type \*physicalism'. When pain is identified with, say, the excitation of c-fibres, it is pain as a *type of event* that is being claimed to be a neural event. The identity can also be put in terms of *properties of events*, as follows: the property of being a pain event is identical with the property of being a c-fibre stimulation event. Of course, if pain is identical with a neural event type, individual occurrences of pain will also be identical with individual events falling under that neural type.

Proponents of the identity theory often invoke considerations of \*simplicity (\*Ockham's razor) in its support. We observe a regular correlation between pain and a certain neural state, *N*. Such correlations cry out for an explanation: Why is it that pain is experienced just when *N* occurs? Why don't we experience, say, an itch when *N* occurs? But there seems no way to give a more basic explanation of why the pain-*N* correlation holds, and we seem forced to accept it as a brute, unexplainable relationship whereby a mental state 'dangles' from a physical process. However, by identifying pain with *N*, and other mental states with their neural substrates, we can, it is argued, be rid of these 'nomological danglers', and simplify both our ontology and our theory.

Mind-body identity is often likened by its advocates to certain identities discovered by empirical science such as 'The temperature of a gas is the mean kinetic energy of its molecules', 'Light is electromagnetic radiation', and 'The gene is the DNA molecule'. Just as scientific research has uncovered these 'theoretical identities', research in neurophysiology has shown, goes the argument, that pain is the excitation of certain neurons, and similarly for other mental states.

Another major argument for the identity theory centres on considerations of mental causation. That mental events are sometimes causes and effects of bodily events is part of deeply entrenched common sense, and it is also a widely shared assumption of philosophers and working psychologists. It has been notoriously difficult, however, to explain how \*mental causation is possible, as long as mental phenomena are thought to lie outside the physical domain. On the identity theory, however, the problem simply vanishes: there no longer is a special problem about how one's desire for a drink of water can cause one's limbs to move, since to have a desire for water *is* for the brain to be in a certain neural state. On this approach, then, mental causation turns out to be merely a special case of physical causation.

An important objection against the identity theory exploits the \*variable realizability (or multiple realizability) of mental states. Consider pain: the neural substrate of pain in humans may be the excitation of c-fibres, but there is ample reason to doubt that the same neural state subserves pain in all pain-capable organisms (think of octopuses). Moreover, there seems no a priori reason to exclude non-biological systems as psychological systems. It appears then that pain as a type cannot be identified with any single physical kind. The best we can do, the objection goes, is the token-identity theory (or 'token physicalism'), which only identifies each instance (or 'token') of pain with an instance of some physical kind, without identifying kinds with kinds. Another major objection to the identity theory is based on the observation that the phenomenological features of the mental (e.g. the hurtfulness of pain, the visual qualities of an after-image), with their characteristic subjectivity and privacy, could not be identical with the neural properties of the brain which are entirely objective and publicly accessible.

**ideology.** In its original use, ideology was to be a general 'science of ideas', of their elements and relations (Destutt de Tracy, 1754–1836). Although interest in ideology in this broad sense has persisted—sometimes with a more a priori character, sometimes more sociological—perhaps the most important usage in contemporary philosophy and politics is narrower and more normative, standing for a collection of beliefs and values held by an individual or group for other than purely epistemic reasons, e.g. bourgeois ideology, nationalist ideology, or gender ideology.

The normative use of the term typically involves two elements.

First, a particular style of *explanation* in which the prevalence of certain beliefs and values is attributed (to some significant degree) to a non-epistemic role that they serve for the individuals who hold them or for society at large. This role can be specified in terms of the satisfaction of the non-epistemic interests of certain groups, or in terms of social-symbolic functions such as stabilization or legitimization of the status quo.

Second, a particular style of *criticism* in which beliefs and values are called into question precisely by giving this sort of interest-based or social-symbolic explanation of their prevalence—an explanation characteristically not known by the believers themselves.

Thus, Karl Marx and Friedrich Engels argued that the dominant ideas in any epoch not only reflect the experience of the dominant class, but also serve its interests. Dominant ideas do this in part by 'inverting' various features of social reality—reifying the historically contingent and class-bound as necessary and universal, or reversing the role of cause and effect in thinking about economic activity or 'human nature'—in ways that make the social order seem natural, inevitable, or just. More recently, members of the \*Frankfurt School have developed a conception of ideology as a communicative structure systematically distorted by power relations; Jürgen Habermas in particular developed a notion of 'ideological critique' that stresses the failure of certain beliefs and values to withstand open, uncoerced, but none the less interest-involving, intersubjective discussion. (In more orthodox sociology, Karl Mannheim and others have emphasized the social function of ideologies in opposing change or lessening apparent value conflicts.)

A number of important questions arise. What is the critical force of calling a belief ideological? Perhaps it is an epistemic defect to hold a belief in part for reasons 'hidden' from oneself and that involve interest rather than evidence, but perhaps all belief-forming processes involve unacknowledged causes and (at least some) non-epistemic interests. Moreover, such

belief-forming processes might also possess various epistemic virtues, such as reliability. It is an open question whether a given belief, produced by such a process, is true, or reflects available evidence. Would mere failure of a belief to withstand self-awareness about its origins or open social discussion of its content constitute a genuinely epistemic defect?

What is the structure of ideological explanations of beliefs and values? Is there a credible theory of the social psychological mechanisms by which social interests or symbolic needs shape individuals' beliefs and values in the unacknowledged ways that are presupposed when ideologies are claimed to have a functional role?

Finally, what does normative use of the concept of ideology presuppose about the existence of contrasting, epistemically respectable ways of knowing? In particular, does the normative notion of ideology presuppose the availability of notions of objective inquiry or objective interests of the very sort that attention to the social character of knowledge and valuation renders suspect? P.R.

**idiolect.** The term 'idiolect' is intended to mark the notion of a \*language which is not the language of a community (sociolect) but rather of an individual. Idiolects more than sociolects have been the focus of much philosophical interest in recent years because of the close connection between the language or meanings of an individual and his intentional states. Idiolects are the place where philosophy of language and philosophy of mind meet.

It is possible that one should have a highly social conception of idiolects, but that would still not spoil the idea that when one studies idiolects one's object of study is the individual's linguistic competence and performance rather than the language of a community. There is, in other words, no contradiction in the idea that one should think of idiolects as being socially constituted. In fact Tyler Burge holds precisely such a view of idiolects. This is an important point because it puts us on guard against the widespread and careless use of the term 'idiolect' to talk of a non-social or individualistic conception of the language of an individual. So care must be taken to distinguish between objects of study such as sociolects and idiolects on the one hand (such as Oxford English and Peter Strawson's English respectively) and on the other hand an individualist or social conception of these objects of study (such as those of Chomsky and of Tyler Burge respectively). The term 'idiolect' strictly applies only to a certain object of study (i.e. to an individual's language), not to an individualist conception of an individual's language. A.B.

**idols.** The danger of allegiance to false gods is a premiss of all orthodoxies which acknowledge nevertheless their powerful appeal to the common people and seek to persuade them that idol-worship is not only futile but also dangerous. For the Christian philosophers Boyle, Malebranche, and Berkeley, idolatry is implied by such common-sense beliefs as the self-sustaining power of nature, the causal efficacy of created things, and the mind-independent existence of the sun, moon, stars, and other objects. The theory of idols is transformed into a general theory of \*ideology in the first book of Bacon's *Novum Organum*, which describes the epistemologically pernicious effects of human attachment to the fictions created by language, tradition, custom, and imagination. The accusation of idolatry continues to have philosophical importance in Nietzsche's attacks on Socrates and Kant in his *Twilight of the Idols*, and in the attempts of Marx, Freud, and other social critics to demystify social and economic structures and to assist people in relinquishing their devotion to things which don't actually exist but which have power over them anyway. CATH.W.

F. Bacon, *Novum Organum*, in *Works*, ed. J. Spedding, R. L. Ellis, and P. D. Heath, 14 vols. (Cambridge, 1857–61; repr. Stuttgart, 1961–3), viii.

**if:** see conditionals.

**iff.** Abbreviation for the \*biconditional connective 'if and only if'. 'P if and only if Q' abbreviates 'P if Q, and P only if Q'. On the \*truth-functional treatment of 'iff', 'P iff Q' is true just when P and Q are both true or both false; so 'P iff Q' and 'Q iff P' are equivalent. In ordinary contexts, however, reversing the order in a biconditional can make a difference. 'Alicia comes down for lunch if and only if we serve alligator stew', for example, differs in meaning from 'We serve alligator stew if and only if Alicia comes down for lunch'. D.H.S.

David H. Sanford, *If P, Then Q: Conditionals and the Foundations of Reasoning*, 2nd edn. (London, 2003).

**ignoratio elenchi.** Literally, ignorance of refutation. A \*fallacy of traditional logic, where it was usually taken to mean 'ignorance of what is to be refuted' or, more inclusively, 'of what is to be proved'. *Ignoratio elenchi* is arguing for one thing as if it proved another thing. For example, it is *ignoratio elenchi* to use an argument against euthanasia as if it proved that you shouldn't eat the dead. The 'ignorance' is in the mind of the would-be refuter or prover, and often arises from confusion of similar-seeming conclusions. The rhetorical trick of deliberately infecting an audience with such confusion is not really this fallacy. C.A.K.  
C. L. Hamblin, *Fallacies* (London, 1970).

**illocutions:** see linguistic acts.

**illusion, arguments from.** The classic example of such an argument appears in the epistemology of \*perception; modern versions focus on cases of total hallucination, where one seems to see something when there is nothing there at all, rather than on illusions such as the famous bent-stick case in which there is *something* there (the stick) which looks one way and is another. The argument, which is still called the argument from illusion, starts from the seemingly undeniable fact that it is impossible to distinguish (from the inside, as it were) a hallucination of being faced with an elephant from the state of actually being faced with an elephant. What conclusion can we draw from this?

Suppose we hold that there are two states at issue here, a veridical one which is a relation between perceiver and (external) object, and a hallucinatory one which is a non-relational state of the perceiver. The argument from illusion then maintains that since there is no distinguishable difference between the two states, we must give a broadly similar account of them both. This suggests that the veridical state consists of two elements, one (the common element) which obtains even in hallucination, and the other (the presence of the outer object) which obtains only if we are lucky.

The argument is sometimes supposed to take us beyond this, and to support a particular account of the common element, the 'act-object' theory. The idea here is that since the deluded are not aware of outer things but are still aware of something, they must be aware of an inner thing (an appearance). We then appeal to the indistinguishability of hallucination and genuine perception to argue that in success too we are (primarily) aware of an appearance, sometimes called a \*'percept', 'sensus', or \*'sense-datum', and only secondarily aware of the outer object. But this move amounts more to an assertion of the act-object theory than an independent argument for it. For it assumes without argument that the content or nature of the hallucination is an inner object, when this was exactly what was in question. The adverbial theory, which denies that assumption, is equally compatible with the argument from illusion.

There is a different, sceptical form of argument from illusion. This is just a special case of Cartesian \*scepticism. Descartes argued that we do not know that we are fully clothed, because we cannot distinguish the state of being clothed from that of being naked while dreaming that we are clothed. This is an argument from the general possibility of error; it argues from perceptual error to the conclusion that we never know that things are the way they look.

If that conclusion is intended to be entirely general, the premiss must be that there is no case at all in which we can distinguish our being right from our being wrong; all seemingly veridical states may for all we know be hallucinatory ones. This is a strong claim, and it is one which the first argument from illusion had no need to make. In attempting to support the 'common element' theory, one need only suppose that in a reasonable range of cases we

are unable to distinguish hallucination from genuine perception.

Both of the arguments from illusion that we have considered so far concern perception. But their starting-point is one about indistinguishability. Considered in very general form, the argument from illusion argues from the indistinguishability of two states, one of which is a success and the other a failure, to what we might call the 'conjunctive thesis' that what one gets in success is a conjunction of two independent elements: (1) something which success and failure have in common and (2) something only present in successful cases.

If this is the general nature of arguments from illusion, there will be other examples to be found wherever there is indistinguishability. One such tries to persuade us that knowledge is some form of belief. You cannot tell (from the inside) whether your cognitive state is one of knowing or merely one of believing (truly or falsely, it doesn't matter which). Therefore, knowledge must be defined as belief *plus* something—e.g. as belief *plus* truth and justification, as in the tripartite definition. (\*Gettier.) This is a 'conjunctive' theory of knowledge.

In these ways arguments from illusion have been a potent weapon in establishing a broadly Cartesian view of the mind. J.D.

**image.** The nature of mental imagery and its relation to thought and imagination (as creative thought) are long-standing issues. Aristotle called attention to the mind's ability to present objects for itself (*phantasia*). 'Imagists' take picture-like entities to form the elements of all representational states, and some include here perception. Others claim that no such entities occur even in memory and imagining. The role of imagery in memory and problem-solving is contested in \*cognitive science, where Frege's contrast between image as psychological incident and thought is echoed in the view that images are simply arrays on the brain's 'visual buffer', their content fully accountable in general or syntactical terms. 'Pictorialists' argue plausibly that the content has an irreducibly spatial aspect. Some claim that the whole issue, as much in philosophy besides, rests on unexamined imagery in another sense, that is on analogy and figure of speech. A.H.

\*imagination; eidetic imagery.

Michael Tye, *The Imagery Debate* (Cambridge, Mass., 1991).

Alan R. White, *The Language of Imagination* (Oxford, 1990).

**imagery, eidetic:** see eidetic imagery.

**imagination.** Imagination is the power of the mind to consider things which are not present to the senses, and to

consider that which is not taken to be real. Just as the imaginary contrasts with the real, so imagination contrasts with both \*perception and \*cognition. Certain philosophers have nevertheless assigned it to a central role in explaining the mind's ability to represent any reality: thus Hume, despairing of the powers of both the senses and reason, explained the genesis of our idea of body by reference to the imagination; and Kant appealed to the imagination in his explanation of how thought or experience of an objective order was possible. The resources of the imagination have often been thought to be bound by the deliverances of the senses—the power of imagination being the recombination of simple elements presented to the mind through the senses. On accounts of thinking in the tradition of \*empiricism, imagination has been implicated through the role of imagery in all thought, the limits of imagination becoming the limits of thought. Berkeley notoriously argued for \*idealism by claiming that it was impossible to imagine a tree unperceived, and hence that it was impossible to conceive of objects existing independently of us.

Most heat has been expended debating the nature of mental \*images, those exercises of the imagination which correspond to our perceptual modalities. Certain acts of imagination have a distinctive phenomenology which others do not. In complying with the request to imagine that Scotland should be an independent country, one need not perform an act of the former sort, while one would do so in visualizing the destruction of the Houses of Parliament. Correlative to visualizing are other acts of imagination corresponding to the other sense modalities: for example, people are capable of auditory, gustatory, and olfactory imagining. Questions arise concerning both the relation of mental imagery to the corresponding perceptions and the differences between them, for Hume the problem of distinguishing impressions from ideas.

According to the picture theory of imagery, having a mental image consists of being aware of some mental entity before the mind which represents the external scene imagined. Inasmuch as this provides an inner surrogate for the outer object of a mental state, this account parallels the \*sense-datum theory of perception. There is now almost universal hostility to both views, not least because of the model of the mind they present: that of the subject surveying the mind's contents as the sole audience within a private theatre.

Those with leanings towards \*behaviourism often show the most hostility to the idea of mental imagery. The denial that there is any imagery is likely to be taken as evidence of the sceptic's own lack of imaginative powers while attempts to explain imagination purely in terms of outer performance lack plausibility: for example, Ryle's attempt to explain imagination in terms of pretence.

Mental imagery has become the focus of a debate within psychology since research has suggested that imagery is involved in certain kinds of reasoning. Subjects often report employing imagery in solving certain tasks, such as answering the query 'Do frogs have lips?' Imagery

also seems to be exploited in certain forms of spatial reasoning. This has led to a debate in both psychology and philosophy over the nature of the imagery involved in these cases, in particular whether there are distinct forms of representation within the brain, although it is not clear whether this new debate is continuous with the more traditional debates about imagery and imagination. B. Williams, 'Imagination and the Self', in *Problems of the Self* (Cambridge, 1973).

**imagination, aesthetic.** The \*imagination has often been put forward as the mental capacity most essential to the production and appreciation of \*art. Fictional representation is an obvious case in point. Instead of believing that we are seeing or reading about real persons and actions, we imagine them. Even if we see a real actor, it is the imagination that converts what we see into the character we are interested in. This form of imagination, which is continuous with a form of childhood play, may also be termed 'make-believe'.

The value of such activity no doubt lies in its broadening of our understanding beyond what we encounter in our own lives. It is a familiar fact—which some philosophers, including Plato, have found disconcerting—that emotional identification is to some extent indifferent to the barrier between reality and make-believe: while insulated from the imaginary scene, we can nevertheless 'feel for' the characters. Imaginative involvement with fiction seems to be of value because it allows us to experience vulnerability to a wide range of feelings, whilst not threatening us with the real-life predicament of actually having to do something.

It is arguable that all aesthetic experience brings the imagination into play. To hear a piece of music as expressive of a mood or feeling is not merely to hear sounds of a certain pitch and duration: the mind appears to be active in grouping together what it literally perceives into a form with added significance. Wittgenstein's \*duck-rabbit drawing provides a kind of analogy, where what is literally present is neither duck nor rabbit, but where the imagination has freedom to see the drawing as one or the other. Kant's idea that aesthetic experience involves a 'free play of the imagination and the understanding' has been prominent among the influences on this line of thinking.

\*aesthetic attitude.

R. Scruton, *Art and Imagination* (London, 1974).

K. Walton, *Mimesis as Make-Believe* (Cambridge, Mass., 1990).

**immediate inference:** *see* inference, immediate.

**immortality.** According to Christian and other Western theology, God is immortal in the strictest sense that he can

never die, either because he is essentially everlasting (i.e. his nature is such that if he exists at one time, he exists at all times) or because he is eternal or timeless (i.e. he exists outside time). Other things—e.g. angels and human souls—have also often been supposed to be immortal in the less strict sense that their nature is such that they will exist everlastingly unless God were to choose to eliminate them.

Plato (*Phaedo* 78b–80c) argued that the \*soul, being immaterial and not occupying space, has no parts; that the destruction of a thing consists in separating from each other its parts; and so that the soul can not be destroyed. Many subsequent philosophers—e.g. Berkeley—have repeated Plato's argument. However, it does seem that things can be destroyed (e.g. atoms reduced to energy) without their parts being separated.

Kant argued that the immortality of the soul was a 'postulate of pure practical reason'—that acting morally only made sense if thereby the agent made progress towards being totally holy, something he could attain only in unending life. Others have argued that acting morally only makes sense if there is a life after \*death in which the good are rewarded. An obvious response is that acting morally makes no sense unless there is some point in so acting at the time in question. The traditional Christian and Islamic doctrine of an unending life—in heaven or hell—does not, however, require that living for ever is natural for humans. It requires only that they live for ever, and that may happen because God intervenes in the natural order to resurrect the dead—either souls alone or embodied humans. Many modern Christian theologians have held that resurrection rather than natural immortality is what the New Testament and the early Christian Fathers taught; and that revelation, not a priori reasoning, is what provides the grounds for belief in life after death. (A few very radical theologians have interpreted talk of 'immortality' or 'resurrection' in terms of the eternal significance of our present-life choices and attitudes.)

Indian religions teach that the dead are often reincarnated in new bodies, human or animal, on earth, in accordance with the law of karma—i.e. those who have led good lives are reincarnated as superior beings, those who have led bad lives as inferior beings. Those who continue to live good lives eventually reach 'liberation' and escape the round of rebirth. For Hindus \*reincarnation is reincarnation of a soul; for Buddhists, some sort of continuity of experience. 'Liberation' is variously interpreted as merging into the one infinite consciousness, or as mere nothingness.

Those who hold that \*personal identity is constituted by sameness of body (or brain) can believe it coherent to suppose that humans survive death only if human bodies are reformed with largely the same matter (e.g. around the original bones in the cemetery). That cannot always happen, for bodies may be destroyed beyond the possibility of reassembly. Those who believe in life after death for all (on earth or elsewhere) must hold a non-bodily criterion of personal identity—as consisting in the continued existence of an immaterial soul, or perhaps in mere con-

tinuity of psychological states; even if resurrected persons have bodies (old or new), sameness of body cannot be what constitutes sameness of persons. R.G.S.

\*atheism and agnosticism.

J. Hick, *Death and Eternal Life* (London, 1976).

**imperialism.** The concept of imperialism is very general, involving the oppression or \*exploitation of weak and impoverished countries by powerful ones, though for most of its intellectual career 'imperialism' was a term of approbation. The word goes back to the Roman Empire, recent examples being the British Empire, which saw its heyday at the end of the nineteenth century, the recently deceased Russian Empire, and the contemporary American Empire, known as the New World Order. This latter involves a net transfer of resources from the underdeveloped countries to the developed ones, a process orchestrated by such American-dominated institutions as the International Monetary Fund.

Modern ideas of imperialism owe much to Lenin, who characterized the phenomenon as comprising emphasis on the export of capital, increasingly centralized production and distribution, merging of banking and industrial capital, and division of the world into spheres of influence between capitalist powers who then fight each other over their share of the spoils as, for example, in the First World War. In more recent decades, Lenin's ideas tend to have been replaced by views, going back to Kautsky, which look at imperialism as the relation between developed and underdeveloped countries and argue that conflict between developed countries is disappearing. These views are best exemplified in the trend known as dependency theory, which maintains that exploitation occurs through trade between the centre and the periphery of the world economy which embodies an unequal exchange with a long-run tendency for the terms of trade for Third World countries to worsen.

Explanations of imperialism are as varied as theories of human nature; and several versions of imperialism, including Lenin's and dependency theory, found it difficult to incorporate recent phenomena such as the newly industrializing countries. But it remained the concept around which thinking about international relations in the twentieth century revolved. D.McL.

\*international relations, philosophy of.

George Lichtheim, *Imperialism* (London, 1971).

**implication.** Ordinary uses of 'implication' are varied and often equivocal. Two important uses for logic are:

1. Implication understood as a relation between a set of premisses and a conclusion deducible from or a logical consequence of those premisses.
2. Implication understood as the relation between antecedent and consequent of a true \*conditional proposition.

On use (2) the truth of ' $(P \supset Q)$ ' of the propositional calculus is read as ' $P$  materially implies  $Q$ ' or ' $P$  implies  $Q$ '. Given the weak conditions for the truth of  $(P \supset Q)$  and the attendant 'paradoxes of material implication', alternative systems have been devised with stronger conditionals. C. I. Lewis's systems of \*strict implication introduce the symbol ' $\supset$ ', where the truth of ' $(P \supset Q)$ ' is read as ' $P$  strictly implies  $Q$ '.  $(P \supset Q)$  is equivalent to  $\Box (P \supset Q)$ , where ' $\Box$ ' is a necessity operator. Other systems with stronger conditionals are those of Carnap's system of L-implication, and more recent formal systems of entailment. A motivation for such efforts is to bring the conditional more into line either with (1) or with those uses in (2) which suppose further connections in meaning between antecedent and consequent.

\*truth-function.

A. Anderson and N. Belnap, *Entailment*, i (Princeton, NJ, 1975).  
C. Lewis and C. Langford, *Symbolic Logic* (New York, 1959).

**implicature.** Meaning that is supplementary or contrary to that logically entailed by a sentence. For example, in 'What did you think of his argument?', 'Impeccable scholarship'. The discovery of conversational and conventional implicature by Paul Grice in the 1960s cast doubt on the solution or dissolution of philosophical problems by \*linguistic philosophy, because it suggests meaning cannot be wholly and appropriately displayed by \*conceptual analysis. If you ask someone, 'Could you direct me to the library?', and they smugly answer only 'Yes', it is appropriate to ask them if they have heard of conversational implicature.

s.p.

Paul Grice, *Studies in the Ways of Words* (Cambridge, Mass., 1989).

**impredicative definition.** A definition is impredicative if it refers to a collection which contains the object to be defined. For example, the 'least upper bound' of a set is defined to be 'the smallest among the upper bounds' of the set; and the 'Russell set' is the set of all sets that don't contain themselves. The former is a common definition, usually uncontested. The latter leads to Russell's paradox. If one thinks of definitions as somehow creating or constructing the defined objects, then impredicative definitions are circular.

s.s.

\*vicious circle; types, theory of; reducibility, axiom of; mathematics, history of the philosophy of.

Allen Hazen, 'Predicative Logics', in D. Gabbay and F. Guenther (eds.), *Handbook of Philosophical Logic*, i, (Dordrecht, 1983).

**incommensurability.** Within philosophy of science, theories which, in a radical sense, cannot be compared are often said to be incommensurable, a term first given wide currency by Kuhn. Scientific revolutions, which involve wholesale discarding of one set of theories in favour of another, are thought typically to produce such radical shifts of meaning that the concepts employed in the theories propounded after revolution simply cannot be expressed in terms of the concepts of pre-revolutionary

theory. Commitment to such an incommensurability thesis is liable to lead on to a strong \*relativism or anti-rationalism. But the very intelligibility of this thesis is questionable. Genuinely incommensurable theories cannot be judged incompatible; but then why, and how, do scientific revolutions result in discarding theories—why not just preserve both the earlier theories and the later theories incommensurable with them?

J.L.

T. S. Kuhn, *The Structure of Scientific Revolutions*, 2nd edn. (Chicago, 1970).

**incommensurability, moral.** The idea of the incommensurability of scientific paradigms has been borrowed by moral philosophers to express the idea that, because there is a plurality of values, moral dilemmas may sometimes be irresolvable. The idea is best illuminated by its converse; \*utilitarianism is the classic example of a moral theory which supposes all values to be ultimately reducible to the one value of 'happiness', so that in any situation the various possible courses of action can all be weighed against one another by considering how much happiness each will produce. If, however, there is not just one ultimate value, then in some cases it may be impossible to weigh the competing claims of, say, \*'justice' against those of \*'friendship', or the claims of 'honesty' against those of \*'utility'. If these values are incommensurable, it may then be an illusion to suppose that there is always such a thing as 'the right thing to do'. Indeed, there may be situations of 'moral tragedy' where there is no action open to us which would not be morally wrong.

**incompatibilism:** see compatibilism.

**incompleteness.** A logical system is complete just in case there is no truth of the system that it is incapable of proving. By a theorem of Kurt Gödel in 1931, no formalization of ordinary arithmetic is complete. Either arithmetic is inconsistent or there is at least one of its truths which arithmetic cannot prove. More technically, Gödel demonstrated that any consistent first-order theory of arithmetic, if equipped with an effective procedure for recognizing its own proofs, is incomplete. Alternatively, let  $T$  be a first-order formalization of arithmetic and  $P$  be the predicate 'is a proof of  $T$ '. If the class of objects satisfying  $P$  is a decidable class, then  $T$  is incomplete.

The incompleteness theorem came as a nasty shock to mathematicians influenced by Hilbert's programme, for whom mathematical truth consisted in demonstrability.

J.W.

\*completeness; Gödel's theorem.

Ernest Nagel and James R. Newman, *Gödel's Proof* (New York, 1958).

**incomplete symbol.** A symbol that is a constituent of meaningful sentences but that has no meaning in

isolation. An incomplete symbol is amenable only to a contextual definition, not an explicit one. The idea of incomplete symbol gained prominence primarily through Russell, who used it to express distinctive views in logic and metaphysics. Thus Russell held that the theoretical terms of physics (e.g. 'particle') are incomplete symbols, meaning thereby that these terms do not mean or refer to anything in isolation, but sentences containing theoretical terms can be analysed using only non-theoretical vocabulary. Observe that the notion of incomplete symbol is quite different from Frege's notion of \*unsaturated expression. An extended discussion of incomplete symbols and their applications in logic is contained in chapter 3 of A. N. Whitehead and B. Russell, *Principia Mathematica*, i (Cambridge, 1927). A.G.U.P.

\*descriptions.

**incongruent counterparts.** Two hands may be identical except that one is left, the other right. An object capable of having an incongruent counterpart (whether or not one actually exists) is called an *enantiomorph*. This phenomenon was thought by Kant to show that space exists independently and is not merely a matter of relations between things. In terms of the spatial relations—distances and angles—between their parts, the two hands are indistinguishable. Since God might have created nothing but a single hand, which would still have been left or right, the spatial relations of the hands to each other or to other things is irrelevant. The difference between the hands must then consist, Kant argued, in a relation to \*space itself, though it is not clear how space is supposed to turn the explanatory trick. M.C.

G. Nerlich, *The Shape of Space* (Cambridge, 1976).

**inconsistent triad.** A set of three propositions that cannot all be true together. For example, 'She was an orphan; Tim outlived her; Tim was her father'. Often it will be implied that all the subsets of the triad—the units and pairs within it—are consistent. Inconsistent sets can be of any size, and the triads do not deserve special attention. C.A.K.

**incontinenence:** see weakness of will.

**incorrigibility.** The property of not being open to correction. One philosophical response to epistemological \*scepticism is to argue for the existence of a class of propositions which have the property. They would be propositions about which we could not be mistaken. Such incorrigible statements are taken by some philosophers to be a sure basis for our entire knowledge of the world. They are said to include assertions of present sensations and appearances, such as 'I am in pain' and 'It looks green to me'. It can be argued, however, that such statements may be false even if the speaker is sincere, through an error of misidentification or expression. W.E.A.

\*certainty; given, the.

William Alston, *Epistemic Justification* (Ithaca, NY, 1989).

**independence, logical.** Let  $s$  be a sentence and let  $T$  be a set of sentences in a formal language. Informally,  $s$  is *independent* of  $T$  if  $T$  does not determine the truth-value of  $s$ . In other words,  $s$  is independent of  $T$  if  $s$  is not a logical consequence of  $T$  and the negation of  $s$  is not a logical consequence of  $T$  (some authors omit the last clause). In particular,  $s$  is *deductively independent* of  $T$  if neither  $s$  nor the negation of  $s$  can be deduced from  $T$ , and  $s$  is *semantically independent* of  $T$  if there is an interpretation of the language in which every member of  $T$  is true and  $s$  is true, and also there is an interpretation of the language in which every member of  $T$  is true and  $s$  is false. In a logical system consisting of axioms and rules of inference, an axiom is 'independent' if neither it nor its negation can be deduced from the other axioms by the rules. s.s.

**indeterminacy in law.** It is a view widely held among legal philosophers that, when competent lawyers dispute about the answer to some difficult question of \*law, there is generally no single right answer—the law does not in fact resolve the issue either way, but leaves it open until it is resolved either by new legislation or by the decision of a judge exercising a discretion to make new law.

Such was the view of the advocates of \*legal positivism, including John Austin and H. L. A. Hart, who said that there is no right answer in controversial cases because law is only what past authoritative statements or conventions have declared it to be, and in such cases convention or past decisions have not settled the issue either way. It is also the view of more radical legal philosophers, such as the American legal realists and critical legal scholars, who argue that there is never a right answer to a legal question because past legal doctrine is not sufficiently consistent to yield a single result. But judges, at least in Anglo-American law, never refuse to decide a legal dispute on the ground that the law is indeterminate, and rarely claim to be exercising a discretion to create new law and apply it retroactively. Even in very controversial cases they give answers to the questions of law in dispute which they claim to be, at least in their opinion, the right ones. Either the judges are lying to the public, or they are themselves under an illusion, or the no-right-answer thesis, in spite of its popularity, is wrong.

Arguments for the no-right-answer thesis are often corrupted by a failure to distinguish it from other, more plausible, claims. Suppose it is controversial among lawyers, for example, whether someone injured in a particular kind of accident has a legal right to be compensated for his emotional as well as his physical injuries. We must take care to distinguish among the following propositions: (1) The legal case for such a right is, in these circumstances, and all things considered, stronger than the case against it. (2) The case against it is, all things considered, stronger. (3) Competent lawyers disagree about which case is stronger. (4) There are strong arguments on both sides of the issue, and neither view is unreasonable. (5) It is

uncertain which is stronger. (6) It is indeterminate which is stronger: the only 'right' answer is that there is no right answer.

Proposition 6—the no-right-answer claim—must of course be distinguished from proposition 3: it does not follow from the fact that lawyers disagree about a controversial case that neither side has the stronger arguments. Nor, obviously, is 6 the same as either 4 or 5: it does not follow from anyone's uncertainty about which case is stronger that neither is. Once these distinctions are made, it is unclear what kind of legal argument could show that proposition 6, rather than one or some combination of the other five choices, is the most accurate description of the law governing recovery for emotional damage. If we define law as the legal positivists did, of course, then proposition 6 might be true in virtue of that definition. But that would be circular reasoning: we should define law to match the practices of lawyers and judges, not redescribe those practices to suit some invented definition of law.

Legal philosophers sometimes make the mistake of thinking that in such a case proposition 6 is true by default: that is, when neither the case for the plaintiff nor for the case for the defendant is obviously much stronger than the other, and reasonable arguments can be made on both sides, it just follows that there is no right answer in the case. But that assumption neglects the difference between 6 on the one hand and 3, 4, and 5 on the other. Proposition 6 makes a very strong legal claim. It claims not just that we have no decisive reason to take one side or the other, and may never have one, but that, no matter how hard we look and think, we will not find any consideration or argument that would make the case on one side even marginally stronger than the case on the other. That is obviously a very ambitious claim, and, given the very wide range of considerations that lawyers regard as pertinent to legal argument, it would seem foolhardy to make it, at least in advance of the most painstaking research and reflection, about any particular legal controversy, let alone about all controversial cases taken together.

In fact, any lawyer or judge or law teacher or law student is likely to form an opinion about which side has the stronger legal argument in any particular case he or she studies, even though in difficult cases that opinion may be hesitant or unstable, and is very likely to be controversial. In practice, that is, almost no one accepts the no-right-answer thesis, even legal philosophers who are most vigorous in its theoretical support. The theoretical popularity of the thesis can be traced, I suggest, to two widespread assumptions. The first is the sound assumption that moral considerations are among the considerations that properly figure in controversies about what the law is. The second is the dubious view that there are often no right answers to moral disputes.

**indeterminacy of meaning.** A thesis advanced by W. V. Quine on the basis of his famous argument for the indeterminacy of translation. Meaning is what we aim to preserve in translating between languages, and if there is no fact of the matter as to which of two or more incompatible translations of a speaker's words is correct, there is no fact of the matter as to what precisely the words mean. The indeterminacy of meaning is taken to be a consequence of the indeterminacy of translation. Quine's argument for the latter assumes that the only facts that could settle which of two rival translations is correct are facts about the speaker's behaviour and circumstances: facts on show to other speakers. When a speaker of an unknown language utters the word 'gavagai' in the presence of a rabbit, there is nothing to indicate whether his utterance is to be translated as 'rabbit', or perhaps as 'undetached rabbit part'. Since there is no other evidence to decide the issue, there is nothing to choose between the two translations. Quine concludes that translation is indeterminate, and therefore meaning is indeterminate.

Chomsky has criticized Quine's argument for assuming that only behaviourist evidence can settle questions about the nature of linguistic reality. Others have pointed out that while we can deploy Quine's argument from the third-person perspective to a group of speakers we observe, the conclusion makes no sense from the first-person perspective. For how can we understand the two rival hypothesis about the meaning of the word 'rabbit' unless we can mean one thing by 'rabbit' when considering one hypothesis and another thing by 'rabbit' when considering the other hypothesis. And if we can understand each of these hypotheses, how can we accept a conclusion that is supposed to show that we cannot succeed in determinately meaning one thing or another by 'rabbit'?

**indeterminacy of translation:** see translation, indeterminacy of.

**indeterminism.** A view incompatible with \*determinism. Since there are several versions of determinism and many kinds of incompatibility, there are many varieties of indeterminism. This article uses a definition of determinism cast in terms of causal sufficiency. (\*Causality; \*necessary and sufficient conditions.)

When one state or event is causally sufficient for the occurrence or obtaining of another, it determines it. It is causally impossible, when one state of affairs determines another, for the first but not the second to obtain. The thesis of determinism includes the view that everything that happens or obtains is determined by something earlier. By itself, this does not ensure that any particular event is determined by a state of affairs that obtained a week (or day, or hour) earlier. As Łukasiewicz points out, an

infinite series of intervals, ordered by temporal priority, may have a finite total temporal extent. Consider, for example, an infinite series of intervals in which the final interval is twenty minutes long, and each interval is twice as long as its predecessor. The thesis of determinism requires some further specification such as that everything is determined by something not merely earlier, but earlier by a certain time increment, such as one second. This does support what determinists generally assume, namely that for any event  $e$  at time  $t$  and any earlier time  $t-1$ , some conditions obtaining earlier than time  $t-1$  determine the event  $e$ . Support for the simpler principle that the conditions determining  $e$  are not just earlier than but exactly at time  $t-1$  requires principles beyond the scope of this article. According to determinism, the state of the world long before you were born, a world you never made, determines everything that happens.

In one very weak version of indeterminism, its incompatibility with determinism is simple \*contradiction. Determinism is false; its negation is true. This view is true so long as somewhere in the universe some occurrence violates the thesis of determinism.

By way of maximum contrast, an extremely strong version of indeterminism is strongly \*contrary rather than merely contradictory to determinism. The world at any time and in all its aspects is totally independent of its state at any earlier time. Successive events are never causally related in any way. This form of indeterminism appears to be incompatible with the existence of successive events.

Between these extremely strong and weak versions of indeterminism, views of intermediate strength hold that there are many events, widely scattered in space and time, that violate determinism. These events need not be totally independent of earlier states of the world. Determination and indetermination admit of degrees. The state of the world ten minutes ago may, for example, be causally sufficient for your now being somewhere in the general vicinity without exactly determining your current location. If something determines that a person acts in a certain general way (which thereby precludes acting in many other ways), such as either to walk home on Divinity Avenue or to walk home on Oxford Street, it need not thereby determine which route the person chooses. Intermediate varieties of indeterminism do not imply that our behaviour is 'of an erratic and jerking phantom, without any rhyme or reason at all'. A person with good reason for walking home may have neither good reason nor prior determination for choosing one route over another.

Current science has no deterministic explanations for the emission of alpha particles by radio-active isotopes and some other very small-scale phenomena. One of the philosophical problems of \*physics is to examine the claim that deterministic explanations of these phenomena are impossible without a radical revision of physics.

It is hard to know, if the world does manifest a degree of indeterminism, how much actions and occurrences that matter to us are affected by undetermined micro-events that seem insignificant in themselves. It is possible that

they are affected a great deal. When sensors, switches, and amplifiers are hooked up in the right way, for example, indeterministic emissions of a few alpha particles can decide the location of the 2008 Olympic Games. Within our brains, perhaps there is often a similar amplification of indeterminacy.

**indexicals.** The pronouns 'I', 'here', 'now', 'this', and related expressions like 'today', 'my grandmother', 'your house', etc. are known by philosophers of language as 'indexicals'. The term derives from C. S. Peirce; indexicals are sometimes called 'demonstratives' or 'token-reflexives'. (\*Logically proper names.) These expressions seem to fall into the semantic category of *singular terms* or *referring expressions*—i.e. terms whose function in a language is to pick out a particular thing. But where indexicals seem to differ from other apparent singular terms, like names and descriptions, is that they pick out different objects or places or times in different contexts of utterance. So your utterance of 'I'm hungry' picks out you, while my utterance of the same sentence picks out me.

One way of appreciating the philosophical interest of indexicals is to look at them in the light of Frege's influential theory of \*sense and reference. For Frege, the sense of a word determines its reference. If two words have the same sense, they have the same reference; if 'oculist' and 'eye-doctor' have the same sense, they have the same reference—they refer to the same entity. Similarly, if two words have different references, they have different senses; if 'the Pope in Rome' and 'the Pope in Avignon' refer to different things, they must have different senses.

How can this theory apply to indexicals? The trouble is that if the sense of 'I' determines its reference, then my utterance of 'I' has a different sense from yours. But surely our uses of these terms have *something* semantic in common, something it is natural to call their common meaning? Likewise with 'here' and 'now'; the common meaning of all tokens of these types is something like 'the place of this utterance' and 'the time of this utterance'. But the common meaning cannot be the sense of these terms, since the meaning determines different references in different contexts.

Non-Fregeans (e.g. David Kaplan and John Perry) have therefore distinguished two components of the meaning of a sentence containing an indexical: (i) The first is the \*'proposition' expressed by the sentence. This is thought of in the 'Russellian' style as being composed out of objects and properties. Thus my utterance of 'I'm hungry'

expresses a different proposition from yours, but expresses the same proposition as your utterance of 'You're hungry', addressed to me. (ii) The second component is the common meaning of the indexical type-expression, which Perry calls the 'role' of the indexical and Kaplan calls its 'character'. The role of an indexical sentence is standardly thought of as a function taking the context of utterance into the proposition expressed by the utterance. Thus my utterance of 'I'm hungry' has the same role or character as your utterance of that sentence, but has a different role from that of utterances of 'You're hungry'. Neither proposition expressed nor role or character corresponds to Frege's notion of sense, so these philosophers conclude that Frege's theory breaks down at this point.

Fregeans (e.g. Gareth Evans) have responded by claiming that senses can be, as it were, context-sensitive: indexicals express 'ways of thinking' that are tied to particular objects, times, and places (e.g. my uses of 'I' all express the particular way I have of thinking about myself). Essential to Evans's claim is the idea that, in order for an indexical to have sense, this sense does not have to be expressible by a definite description uniquely true of the reference of the indexical.

The issue is important because many philosophers have plausibly argued that indexical thought is essential to our thinking about time, space, the self, and material objects. In particular, indexical thought seems essential to agency: my getting off the bus at Trafalgar Square can only be fully explained by attributing to me the belief that *Trafalgar Square is here*, which is not equivalent in explanatory power to any merely descriptive belief. r.c.

**Indian philosophy.** The beginnings of philosophical speculation in India can be traced back to the ancient body of oral literature called Veda. This was compiled and divided into Ṛg-Veda, Sāma-Veda, Yajur-Veda, and Atharva-Veda. Apart from hymns to nature-gods and recipes for rituals each Veda contained cosmological, moral, and mystical reflections which were later collected into \*Upanishads.

The eternally existent Vedic wisdom was believed to have been revealed to clear-minded sages who saw the truth from different points of view. Hence, the Sanskrit term for philosophy also stands for *seeing*. 'Seers' of the Ṛg-Vedic hymns, at least as early as 1500 BC, raise the question 'What did the universe come from?' and record an intellectual tussle between 'the existent' and 'the non-existent' as answers to it, with the agnostic hint that even gods, being part of the universe, would not know the right answer. Notice, also, the self-referring reflections on

thought, life, and language in the opening verse of an ancient Upanishad: 'Propelled by what does a directed mind fall upon its objects? By whom was life first set in motion? Urged by whom are *these* words being spoken? Which God harnesses the eyes and the ears?' The answer given shows that the enterprise was not theology but a phenomenological \*ontology of ubiquitous consciousness; no object 'that is worshipped as a *this*' could be the subjective spring of action, thought, and speech, according to these Vedic proponents of transcendental subjectivity.

Systematic philosophies grew up gradually through attempts to understand, rationalize, and react against the Vedic tenets. In spite of mystics and sceptics trying to prove the futility of metaphysical argumentation and the question-begging nature of all 'proofs', many major schools of philosophy—each with its own metaphysics, epistemology, and life-ideal—flourished in India, not in successive waves but side by side until their growth was arrested by colonial education which, however, did promote their preservation as intellectual antiques.

The schools are traditionally classified according to a dichotomy between those who accept the authority of the revealed wisdom of the Vedas and those who do not. Into the class of those who *affirm* the Vedas fall the following six systems: (1) Sāṃkhya (distinctionists), (2) Yoga (mind-stilling theorists), (3) Nyāya (logicians), (4) Vaiśeṣika (atomists), (5) Mīmāṃsā (ritualists), and (6) Vedānta (hermeneutists). Vedānta, in turn, divides into several schools, including (a) pure monists, (b) qualified monists, and (c) dualists. Another Vedic school, the 'panlinguistic monists', was developed by the philosophers of grammar, who identified ultimate reality with the eternal *Verbum* manifesting itself as both words and the world.

Into the class of those who *deny* the Vedas fall (1) the Cārvāka materialists, (2) the \*Jaina alternativists, and the four schools of \*Buddhist philosophy, namely (3) Vaibhāṣika direct realism, (4) Sautrāntika representative realism, (5) Yogācāra subjective idealism, and (6) Mādhyamika voidism. Besides these there are the earthy but subtle broadly monistic power-and-process philosophies of (7) \*Tantrā, and finally (8) Shaivism. The last-named tradition perhaps had pre-Vedic roots in the conception of Shiva as the Lord of fettered animals, that is, *us*. According to Shaivism, we can only be freed and saved by worshipping Lord Shiva with the utmost love.

In ontology these schools came up with competing definitions of reality. In Sautrāntika Buddhism to be real is to be causally efficacious. In non-dualistic Vedānta to be real is never to be negated, spatially, temporally, or otherwise. For the Nyāya–Vaiśeṣika, reality consists in having a determinate nature unique to oneself and hence is being knowable and nameable. These assumptions result in diverse metaphysics. Reality must be changeful and impermanent for the Buddhist, whereas for the non-dualist Vedānta only the changeless and eternal is real. Since all the anti-Vedic schools, and Sāṃkhya and Mīmāṃsā among the Vedic schools, were openly atheistic, the existence of God was a standard topic of rational disputation.

## EASTERN PHILOSOPHY

CONFUCIUS was a contemporary of the early Greek philosophers, but the school of philosophy he inspired is still prominent in Chinese thought today.

NISHIDA KITARŌ, the leading figure in twentieth-century Japanese philosophy, developed a systematic philosophy of 'pure experience', drawing together Zen Buddhism and Western thought.

RABINDRANATH TAGORE: poet and philosopher, champion of Bengali culture, humanist and internationalist.

SARVEPALLI RADHAKRISHNAN was a rare example of a philosopher-ruler. President of India and interpreter of the Indian and European philosophical traditions to each other.

Udayana (eleventh century) wrote *Flower-Offerings of Arguments*, detailing five ways of proving the existence of a God. Atheist objectors offered excellent refutations of his cosmological arguments, like this rejoinder: 'If the universe requires a maker because it undergoes change, even God needs a maker because he sometimes creates, sometimes destroys.'

Almost all classical schools had a fully developed account of change and causality. Four major stands here were:

1. The flux theory of the Buddhists: the cause perishes before the effect arises.
2. The emergence theory of Vaiśeṣika: the effect is a new entity emerging as inhering in the material cause even if the cause survives as the stuff.
3. The transformation theory of Sāṃkhya: the effect slumbers in the material cause, with which it is substantially identical.
4. The illusionism of monistic Vedānta: the cause alone is real; the effect is an illusory projection of variety which cannot be unreal or real; change is illusory like magic (*māyā*).

There was fierce discussion over these rival accounts of causation. For example, arguments for commonsensical emergence theory are:

- (E1) The perceptibly different lump of clay never does the same work as the pot made out of it.
- (E2) If the pot was already there in the clay, the potter's effort must have been in vain, unless it is said to produce something non-pre-existent, namely the pot's structure. If a structure can be added to reality, why not the pot?

Against this, the transformation theorists argue:

- (T1) What is unreal, like a rabbit's horn, cannot be made to exist.
- (T2) If *a* and *b* are distinct it makes sense to ask 'Bring *a* along with *b*', but 'Bring the coat along with the wool with which it was made' is nonsense. So the coat and the wool must be the same in substance.

To T1 the emergence theorist retorts, 'You are confusing absence with non-being. The future sculpture is absent—and not hidden somewhere in the hunk of marble—but it is not a non-entity.' A mere nothing does not qualify as a genuine absentee in the Vaiśeṣika category system. Specifically, this system classifies existents into substances, particular qualities, events, universals, inherence-relation, basic individuator, and absence. The first three have *realness*, which is a universal. Hence, on pain of a vicious regress, universals do not have the universal of realness inhering in them. The first seven classes of existents have positive *being*. But all seven, including absences, are knowable as well as *existent*. Thus, the absence of the effect before its emergence should not be looked upon as a mere nothing.

In epistemology, knowledge is understood by most systems as a doubt-free awareness-episode matching reality and causing pragmatic success. To meet an ancient tradition of tightly argued \*scepticism which, by the eleventh century, anticipated Gettier-type counter-examples where truth and justification fell apart, detailed theories of truth and causal routes of knowledge were constructed. Cārvāka materialists had attacked inferential knowledge by asking, 'How do you establish the universal generalization "Whatever has *g* has *f*"', without which any inference from *g* to *f* cannot take off? Perception cannot guarantee such a generalization and to base it on inference again would be circular or lead to regress.' In response to this attack Buddhists resorted to admitting an analytically or causally necessary relation between being an elm and being a tree, or between smoke and fire, and Nyāya spoke of intuitive knowledge of the entire class of *g/f* through the perceived universals. Apart from questions about perception, inference, and verbal testimony, issues about knowing that one has known, knowing other minds, the knowledge-object relationship, the mechanism of perceptual error, and doubt and ignorance as cognitive states were hotly debated. The seeing of a snake in a rope was understood by some as an unordinary recollective perception of a past real snake; by others as the seeing of a non-existent object; by yet others as mere failure to see the presented rope's distinction from the remembered snake. A fine-grained epistemology of illusion, of course, could well be used by friends and foes of the non-dualists' doctrine that the world is an illusion.

In ethics the \**Bhagavadgītā*, a central Hindu religious text, synthesized the life of work and the life of wisdom through its ethics of desireless performance of social duties. Buddhism generally prescribed an ethics of selflessness and universal compassion for fellow sufferers in a sorry world. The Mīmāṃsā ritualists developed an elaborate taxonomy of hypothetical and categorical imperatives, sometimes claiming that it is only in the context of an action-prescribing sentence that a word has meaning.

Out of an ancient tradition of defining drama and poetry, a rich philosophical aesthetics of music, poetic enjoyment, and the emotions developed. Disputes about grades of suggestive meaning and analysis of metaphors exercised generations of aesthetes. Except for the Cārvāka naturalists, every classical school believed in \**karma* and rebirth. Liberation from rebirth was set up as life's highest ideal, but alternative goals of life like pleasure, prosperity, moral rectitude, or piety were also realistically accepted. A methodologically sophisticated philosophy of bodily health was set out by the medical scriptures called *Ayurveda*.

Though we have focused only on ancient and medieval Indian philosophies, rejuvenated Sanskrit learning, especially of neo-Nyāya, with Kantian, Marxian, Wittgensteinian, or Heideggerian reinterpretations of the classical theories, along with original philosophical thinking, keep contemporary Indian philosophy as vibrant as it was a thousand years ago when Nyāya metaphysicians fought

with Buddhists about the existence of eternal cowness on top of bovine particulars, and Jaina philosophers tried to reconcile realists and anti-realists with their pluralistic perspective on alternative ways of world-making. A.C.

**indifference:** see spontaneity and indifference; freedom.

**indifference, principle of:** see probability.

**indirect discourse.** One paradigm of indirect discourse is reported speech: for example, 'Lambert said that Hume was a great Scottish historian.' Frege argued that in cases like this the term 'Hume' refers to its customary \*sense, rather than to Hume: the words after 'said that' do not denote a truth-value, but rather convey the thought (proposition) expressed by Lambert. Frege's account captures the insight that in indirect discourse the sense of a speaker's remarks can be captured in many different ways. Lambert could have said what is reported without using the name 'Hume' at all. A.BRE.

E. Lepore and H. Cappelen, 'On an Alleged Connection between Indirect Speech and Theory of Meaning', *Mind and Language* (1997).

**individualism, moral and political.** In ethical theory and political philosophy individualism is a view that gives primary moral value to individual human beings. Different interpretations are possible concerning what it is about individual human beings that justifies their being given primary value, and also concerning how it is that individuals thus valued are to be treated.

In political philosophy, certain forms of libertarian and liberal individualism, for example, are influenced by the Kantian view that individual human beings are \*ends in themselves', and thus agree that persons are owed respect for their \*autonomy, which is protected by inviolable rights; but while both these views may be anti-paternalistic, they notoriously differ in other recommendations for the political order; for example, \*liberalism will endorse certain welfare practices but \*libertarianism will not. Even regarding the shared anti-\*paternalism, these forms of individualism may dispute whether the prized feature of the given individual human being is an idealized 'rational nature' or his or her actual capacity for choice, marked as this may be by neurosis, character defects, and self-deception.

Another form of individualism is influenced by classical \*utilitarianism, and so prizes the capacity of the individual human being for pleasure and pain; it may also be anti-paternalistic regarding the activities of the state, but tend

to regard social practices and institutions generally as instruments for the achievement of the greatest aggregate happiness possible in the society's circumstances, rather than as expressions of or protections for rights, except as the latter might be conducive to the aggregate \*well-being.

Within ethics, the valuing of the person characteristic of individualism is especially problematic for the development of a normative theory of individual responsibility. One is oneself an individual, and thus to be prized; but others are individuals, and they too are to be prized. How does one reconcile a principled regard for one's own \*rights, self-realization, meaningful relationships, and material well-being with moral respect for these features of the lives and persons of others? The issue may become personally distressing as well as theoretically challenging when the fact is that many millions of people in the world are destitute in one way or other. Does individualism allow one to put oneself first in a world so filled with misery and oppression, or require self-sacrifice in the devotion of time, energy, and talent to the needs of others? Individualism prizes individual human beings, and different forms of individualism offer different accounts of what, morally, is prizable about individual human beings; but what this suggests for the conduct of the responsible agent in a world flawed by destitution and gross disparity in levels of life is not yet settled.

A further issue for individualism in both ethical theory and political philosophy is the question how the basic individual is to be construed. Is the person to be understood as an independent atomic particular whose connections with others are consensual or coerced but not constitutive of the identity of the particular? Or is it instead a being whose make-up includes essentially its relationships, and, indeed, other differentiating factors, such as deep interests, temperament, distinctive activities, or even ethnic or cultural heritage? Construing individuals in these different ways suggests differences in normative content for ethical theory and for political philosophy. 'Respect for persons' may differ among liberal, libertarian, or communitarian philosophies resting on different views of the essential make-up of the person. Similarly, these different views can alter an ethical theory's prescriptions for balancing one's responsibilities regarding others and oneself. An important element in assessing an ethical theory or political philosophy is the adequacy of its basic conception of the individual. N.S.C.

Charles Taylor, *Sources of the Self* (Cambridge, Mass., 1989).

Bernard Williams, 'Persons, Character, and Morality', in *Moral Luck* (Cambridge, 1981).

**individualism and anti-individualism.** Theses in philosophy of mind advocating opposed conceptions of the psychological subject.

The individualist conceives the psychological facts about a person as facts which hold independently of her relation to her physical and social environment. Pressure

is put on this conception by the claims (i) that some mental states are world-involving, (ii) that some mental states are linguistic-community-involving. \*Twin earth thought experiments are used to argue for (i); thought experiments originating from Burge, in which it is shown that communal standards of correctness prevail where terms are used in ascribing mental states to individuals, are used to argue for (ii). A philosopher who subscribes to a strong anti-individualism takes demonstrations of (i) and (ii) to be symptomatic of the fact that the physical and social environment permeates psychological investigation even where an individual's psychology is in question.

J.HORN.

\*externalism.

Tyler Burge, 'Individualism and the Mental', in *Midwest Studies in Philosophy*, iv (1979).

**individuation.** The determining of what constitutes an individual: that is, *one* of something. Principles of individuation are the principles by which things, normally of a kind, are distinguished into single individuals, most often at some given time. The single principle of \*counting which a \*sortal term 'F' supplies is commonly the principle used for distinguishing one F (say one table, tree, or person) from another at one time as opposed to doing so over periods of time. Principles of individuation are correspondingly sometimes contrasted to principles of \*identity, which concern counting and being the same F over periods of time.

Where there is no single principle for determining how many Xs there are somewhere at some time, it may be said that Xs cannot be individuated. Thus 'objects' cannot be individuated as such. And while *dodos* or *aardvaarks* could be, the same is not true for their negative counterparts introduced in some contexts. Supposing there to be not-*dodos* wherever there are no *dodos*, not-*dodos* cannot be individuated, which helps show why these are not entities on a footing with *dodos*.

**indoctrination:** *see* teaching and indoctrinating.

**induction.** Induction has traditionally been defined as the \*inference from particular to general. More generally an inductive inference can be characterized as one whose conclusion, while not following deductively from its premisses, is in some way supported by them or rendered plausible in the light of them. Scientific reasoning from observations to theories is often held to be a paradigm of inductive reasoning.

Most philosophers hold that there is a problem about induction: its classic statement is found in Hume's *Enquiry Concerning Human Understanding*. Having observed that all arguments to unobserved matters of fact depend upon the relation of cause and effect, Hume remarks that our

knowledge of this relation depends on experience: but, he goes on to argue:

all inferences from experience suppose, as their foundation, that the future will resemble the past . . . If there be any suspicion that the course of nature may change, and that the past may be no rule for the future, all experience becomes useless, and can give rise to no inference or conclusion. It is impossible, therefore, that any arguments from experience can prove this resemblance of the past to the future; since all these arguments are founded on the supposition of that resemblance. (iv. ii. 32)

Hume does not try to counter these arguments by presenting a justification of inductive reasoning; but neither does he suggest that we might eschew inductive reasoning. If we have observed that flame and heat 'have always been conjoined together', our expectation of heat is, he says, 'the necessary result' of seeing the flame. This expectation is 'a species of natural instincts, which no reasoning or process of the thought and understanding is able either to produce or to prevent' (ibid. v. i. 38).

Many philosophers have rejected this disbelief in the rationality of induction. Some have said that, taking deduction as the paradigm of reasoning, Hume has merely noticed that induction is not deduction, arguing against him that it is part of what we mean by rationality to operate in accordance with inductive procedures. Some have suggested that induction is justified inductively by its past successes, and that the circularity here is only apparently vicious. Some have proposed what is known as a pragmatic justification: not that inductive procedures will lead to the truth, but that if there is a truth to be known, inductive procedures are the best way of getting to it. None of these supposed justifications is universally accepted, and some philosophers—notably Popper—argue that scientists proceed not by cheerfully inferring the course of the future from past regularities, but by proposing bold generalizations and then seeking to falsify them.

Some philosophers have assumed the task not of justifying induction, but of setting out principles of inductive inference in a way analogous to that in which the principles of deductive inference have been codified. But there is a major difficulty in any account which seeks to characterize sound inductive argument in an abstract way. The deductive logician tells us that if all As are Bs and all Bs are Cs then all As are Cs: A, B, and C here might be anything. The trouble with the idea of inductive logic is that whether the fact that all observed As are Bs gives any support at all to the claim that all As are Bs depends on what A and B are. We swallow Hume's examples—like flame and heat—without noticing that we observe all kinds of regularities that we should not dream of expecting to persist. This is the point of Goodman's new riddle of induction. M.C.

R. Swinburne (ed.), *The Justification of Induction* (Oxford, 1974).

**inequality.** In political and social theory, inequality consists in the differences between individuals or groups in the possession of what is desirable or undesirable. The main categories of inequality embodied in a society are political, legal, social, and economic. The clearest forms of political inequality are aristocracy and the exclusion of certain groups—women, racial or religious minorities, or those without property—from voting or political office. Legal inequality is exemplified by differences in liability to criminal prosecution or civil action, or in freedom of contract. Social inequality involves differences in status, deference, and subordination—systems of racial caste being an extreme example. Class inequalities are both social and economic, marking children with the wealth and professional status of their parents.

Some inequalities are politically enforced; others merely arise unless they are prevented. While most modern political theories are opposed to the enforcement of inequalities between groups, they must all face the question how much should be done to prevent inequalities from developing, between either groups or individuals.

Two factors make it impossible to eliminate inequality entirely: first, the need for hierarchies of power in any political and legal system, and in any economic system except the most primitive; second, the fact that there are natural inequalities—of ability, enterprise, and luck—which affect people's success in life. Left to themselves, some people will accumulate more wealth than others and use it to benefit their children, who will do the same, thus giving rise to a class system. The upper classes will also tend to acquire more legal and political power and a higher social status, even if the system is formally democratic and no groups are legally excluded from these advantages.

The moral question is whether a society should be concerned to narrow gaps of this sort, on the ground that the losers, and more especially their children, do not deserve their disadvantages. The welfare state—provision of social benefits paid for by taxes—is one way of doing this. Moral radical methods, designed to abolish class hierarchy entirely by legal restrictions on the private accumulation of wealth, seem to entail unacceptable general interference by the state with personal as well as economic liberty, and also tend to undermine economic efficiency. Some people believe that so long as there is legal equality of opportunity—so that no one is prohibited from becoming rich and powerful if they can—inequality of results is unobjectionable. But even if it is morally unfortunate, some significant inequality of results probably has to be accepted as a permanent feature of the social world.

**inference.** Understood as the upgrading or adjustment of belief in the light of the play of new information upon

current beliefs, it is customary to recognize at least three modes of inference: deductive, inductive, and abductive, although abduction is often treated as a special case of induction.

In deductive theories, an inference is justified if it conforms to a principle of logic or to an argument validated by the principles of logic. In some treatments it is also required that the argument be sound. Most deductive theorists since Frege agree that although inference is a psychological process, the principles which make it deductively correct are valid independently of any psychological fact. This raises the question what justifies the laws of logic. The once dominant view that they are true in virtue of the meanings of (certain of) their constituent terms is discouraged by present-day scepticism about meaning as a theoretically fruitful notion in philosophy.

Some critics doubt whether, even if justified, the rules of logic are good rules of deductive *inference*. \**Modus ponens* is a case in point. Asserting that it is always permissible to infer *B* from *A* and 'If *A* then *B*', Harman points out that although *B* is here *implied*, it would not be correct to accept *B* for any reasoner who came to notice that *B* was false.

Inductive inferences are those that project beyond the known data, as in the paradigm of generalizing that all emeralds are green. Since Francis Bacon's day, efforts have been made to formulate an inductive logic which would specify conditions under which such projections are justified. Difficulties lie in wait, chiefly Hume's problem (\*induction) or Goodman's variation. That all the emeralds we have so far come upon are green is a fact which no more licenses the proposition that they are all green than it licenses the proposition that they are all green if observed before 1 January 2050, and are blue otherwise. What, then, justifies our making the former projection rather than the latter? A further projection problem arises from a puzzle invented by Hempel. If known instances of emeralds sustain the projection that they are all green, they likewise sustain the *equivalent* proposition that all non-green things are non-emeralds. But any non-green non-emerald will help sustain that generalization and any proposition equivalent to *it*. It would appear, then, that red sunsets, black cats, and all the other non-green non-emeralds sustain the generalization that all emeralds are green, which is strikingly implausible.

Inductive reasoning is also thought to include probabilistic reasoning. It is said that an inference is justified if it conforms to the theorems of the \*probability calculus. Against this, it is objected that, if true, a 'computational explosion' would ensue. Even cases of modest evidential complexity are 'too complicated for mere finite beings to make extensive use of probabilities' (Gilbert Harman, *Change in View*). Even so, Harman does seem to concede that the rules of the probability calculus might be thought of as normatively correct, that is, as rules which a human inferrer should use to the extent that he satisfies appropriate assumptions on computationally *ideal* reasons.

\*Abduction is recognized in two varieties. In one sense, it is \*'inference to the best explanation', which is a means of justifying the postulation of unobservable phenomena on the strength of explanations they afford of observable phenomena. In its other variety, abduction is the process of forming *generic* beliefs from known data. Observations incline us to think that tigers are four-legged, a proposition we hold true even upon discovery of a three-legged tiger. Generic sentences differ from general (i.e. universally quantified) sentences by their accommodation of negative instances, that is, of instances which would falsify general sentences.

Attractive though it is, the idea of inference to the best explanation awaits an adequate generalized specification of what 'best' consists of. And the idea of generic inference requires a satisfactory account of when negative instances do and do not falsify generic claims. J.W.

\*deduction; induction; implication.

Nelson Goodman, *Fact, Fiction, and Forecast*, 4th edn. (Cambridge, Mass., 1983).

**inference, immediate.** The name in traditional logic for drawing a conclusion from a single premiss, as opposed to the two premisses of the \*syllogism. Thus the move from 'Everything human is corrupt' ('All *S* are *P*') to 'Nothing human is not corrupt' ('No *S* are not *P*') is a valid immediate inference, while that from the regretful 'Only good Indians are dead Indians' ('All *S* are *P*') to the genocidal 'The only good Indian is a dead Indian' ('All *P* are *S*') is an invalid immediate inference. C.W.

\*logic, traditional.

L. S. Stebbing, *A Modern Introduction to Logic* (London, 1930), ch. 5.

**inference to the best explanation.** Accepting a statement because it is the best available \*explanation of one's evidence; deriving the conclusion that best explains one's premisses. According to Gilbert Harman, who uses the phrase in many publications, acceptable inductive inferences are all inferences to the best explanation. One can also use this notion in a response to \*scepticism. Do you know you are looking at a reference book right now rather than, say, having your brain intricately stimulated by a mad scientist? The sceptic carefully describes this alternative so that no experiment can refute it. The conclusion that you really are looking at a book, however, explains the aggregate of your experiences better than the mad scientist hypothesis or any other competing view. A sceptic who disagrees with this, instead of telling still more stories in which we cannot distinguish radically different situations, needs to address fresh issues about explanation.

D.H.S.

\*explanationism.

P. Lipton, *Inference to the Best Explanation*, 2nd edn. (London, 2003).

**infima species.** Literally, lowest form (sort, species). According to traditional Aristotelianism each individual can be pictured as lying permanently within a finite set of circles of genus, subgenera, and species, whose circumferences do not cross; the outermost circle is the individual's *summum genus*, the innermost its *infima species*. The idea makes some sense in biology, but less obviously elsewhere (e.g. what is the *infima species* of Mount Kenya, or Alpha Centauri, or the Vienna Philharmonic Orchestra?). On the other hand certain scholastics thought that individual angels must each *be* an *infima species*, and some have found the same thing implied in Aristotle's souls and Leibniz's monads. C.A.K.

\*genus and species.

**infinite, traversal of the:** *see* traversal of the infinite.

**infinite regress.** Suppose we define a voluntary act as one caused by an act of will: if acts of will are themselves voluntary then the definition requires that they themselves be caused by prior acts of will. But there is no limit to the number of times this train of reasoning can be reiterated: so either the definition is wrong or acts of will are not voluntary. The argument—deployed by Ryle in *The Concept of Mind*—shows that the proposed analysis of what it is for acts to be voluntary involves an infinite regress. M.C.

**infinitesimals.** \*Numbers greater than 0 but less than  $\frac{1}{2}$ ,  $\frac{1}{3}$ , etc. In mainstream mathematics infinitesimals do not exist, though Leibniz suggested inventing infinitesimals, written *dx*, *dy*, etc. as fictions to help in the differential and integral calculus. In 1960 Abraham Robinson used mathematical logic to introduce and justify non-standard analysis, an approach to calculus which allows us to use infinitesimals systematically in proofs and thus recapture Leibniz's intuitions. W.A.H.

Abraham Robinson, 'The Metaphysics of the Calculus', in Jaakko Hintikka (ed.), *The Philosophy of Mathematics* (Oxford, 1969).

**infinity.** \*Zeno's paradoxes were the first problems of infinity to vex philosophers, provoking Anaxagoras to hold that there was no smallest quantity of anything, and the Greek atomists to the opposite opinion. But the atomists showed no fear of the infinitely large, as they posited an infinite universe with innumerable worlds in it. Aristotle, however, held that there was nothing 'actually' infinite, either infinitely small or infinitely large or infinitely numerous; for him, all infinity was merely 'potential'. Many philosophers since have been wary of infinity. Most famously, Kant argued that it was beyond the reach of reason, and the source of insoluble \*antinomies.

In practice the infinitely large (in space or time) has not been troublesome. The change from Aristotle's finite universe to the infinite space of Newton's cosmology, though unsettling in other ways, did not tax the mathematician's understanding. (The real numbers are very naturally

correlated with the points of an infinite line, and hence triples of real numbers are naturally correlated with the points of an infinite three-dimensional space.)

The infinitely small proved more difficult. The Greek mathematicians had avoided it, by their elegant method of exhaustion, but when the differential calculus was introduced in the seventeenth century, it did seem to need the puzzling notion of an \*infinitesimal, i.e. a quantity smaller than any finite quantity but greater than zero. This puzzle persisted for nearly two centuries, until Cauchy (1789–1857) and then Weierstrass (1815–97) showed how the awkward notion could be eliminated.

The infinitely numerous was first seriously studied by Cantor, whose work led directly to the \*paradoxes of logic, and thence to modern \*set theory. It is easily seen that two finite sets have the same number of members if and only if there is a relation which correlates their members one to one. Cantor's basic idea was to extend this criterion to infinite sets, introducing infinite cardinal numbers to number their members. It follows from this criterion that an infinite set is not increased by adding to it any finite number of new members, nor decreased by subtracting from it any finite number of members. (For example, we can correlate all the positive integers with integers greater than 100 just by correlating  $x$  with  $x + 100$ .) Thus, where  $\kappa$  is an infinite cardinal and  $n$  a finite cardinal, we have  $\kappa + n = \kappa - n = \kappa$ . Similarly  $\kappa \cdot n = \kappa$  and  $\kappa^n = \kappa$ . But Cantor was able to prove the inequality  $2^\kappa > \kappa$ , for any cardinal  $\kappa$  whatever, from which it follows that the series of infinite cardinal numbers is itself an infinite series. The set of all finite cardinals is said to have the cardinal number  $\aleph_0$  (aleph null), which is the smallest infinite cardinal. The next is  $\aleph_1$  (aleph one), and so on. Cantor's \*continuum hypothesis states that  $\aleph_1$  is the number of the real numbers. It is now known that the hypothesis can be neither proved nor disproved from the currently accepted axioms of set theory.

Cantor also introduced infinite ordinal numbers, which are in fact more important to modern set theory than the infinite cardinals. But there is no space to describe them here. D.B.

**infinity, axiom of.** An axiom of standard set theories. It is required to ensure the existence of a \*set which has infinitely many members. A set has infinitely many members just in case there is no natural number  $n$  such that the set has exactly  $n$  members. An example of such a set is the set  $S$  containing the empty set (the set with no members) and the unit sets (sets with just one member) of any sets which  $S$  contains;  $S$  contains the empty set, the unit set of the empty set, the unit set of the unit set of the empty set, and so on. The axiom of infinity is required for set-theoretical

constructions such as the definition of the real numbers as infinite sequences of rational numbers. A.D.O.

**in-itself:** *see* for-itself and in-itself.

**innate ideas.** These are \*ideas that exist in the mind without having been derived from previous experience. Plato held that all of our ideas are innate, although we do not clearly grasp them; learning consists of remembering these ideas and we develop a clearer understanding of them through the process of Socratic questioning and dialectic. There is a close relation between a philosopher's views on innate ideas, \*a priori knowledge, and \*necessary truths. Rationalists typically hold that the mind has a set of innate ideas that provide the source of a priori knowledge of a wide variety of necessary truths. Empiricists deny that there are any innate ideas and limit a priori knowledge and our grasp of necessary truths to \*tautologies and propositions derived from arbitrary \*definitions of words.

There has been little agreement about the exact nature of innate ideas among either their defenders or their detractors. Descartes allows for a wide variety of innate ideas and principles; sometimes he suggests that virtually all our ideas are innate, at least potentially. He also describes our thinking faculty as an innate idea, and considers the idea of God to be innate, although he also argues that this idea must have been put into our minds by God. Locke held that the mind of an infant is like a blank paper and that all of our ideas are imprinted on the mind by experience. He treated the mind as having a number of inherent powers, such as remembering and imagining,

but held that our ideas of these powers are not innate. Locke also denied that there are any innate principles in the mind because (among other reasons) such principles would require innate ideas. Leibniz replied that the mind is more like a block of marble with veins which limit what can be sculpted from the block, rather than like a blank paper. On this view, innate ideas are natural tendencies of the mind and we need not be explicitly conscious of them or of the necessary truths that are based on them; we require experience and thought to determine which of our ideas are innate. Thus Leibniz accepted Locke's claim that much of our learning is from experience, but denied that this shows that the ideas and propositions we learn are not innate. Ultimately Leibniz agreed with Plato that all of our ideas are innate and that all learning is actually the exfoliation of ideas that were always present in our minds.

It can be argued that Kant's \*categories are innate ideas on a Leibnizian model. The categories are concepts that are internal to the nature of reason and that provide an a priori framework for all of our experience. Because the categories are imposed on experience by our minds, those aspects of experience that derive from the categories are necessary features of experience and we can know a priori that they will characterize all our experience.

Since innate ideas would provide universal features of human thought and experience, the debate over whether such ideas exist continued to rage in twentieth-century anthropology. Defenders of innate ideas also include Chomsky, who postulates a universal innate \*grammar in human beings to account for our ability to learn language and our ability to distinguish an unlimited number of grammatical from ungrammatical expressions in a language we have mastered. The debate over the existence of innate ideas has been superseded by the debate over which aspects of human knowledge (if any) are innate and which are learned; there is no clear resolution of this question at the present time.

**inner sense.** Regarded by Locke and Kant as a faculty of the mind whereby it is introspectively aware of its own contents in a manner which is analogous to the perception of external objects. More recent supporters of this notion have argued that the best model for inner sense is bodily perception, that is, one's awareness 'from the inside' of the position and movement of one's own body. One difficulty with this proposal, from a Kantian perspective, is that bodily perception is of something spatial, whereas the objects of Kantian inner sense are supposed to be temporally but not spatially ordered.

S. Shoemaker, *The First-Person Perspective and Other Essays* (Cambridge, 1996).

**instrumentalism.** The doctrine that scientific theories are not true descriptions of an unobservable reality, but merely useful instruments which enable us to order and anticipate the observable world. Traditional versions of instrumentalism were influenced by verificationist theories of meaning, and held that theoretical claims about unobservables cannot be regarded as literally meaningful. More recent versions of instrumentalism are motivated by sceptical rather than semantic arguments: they allow that scientists can make meaningful claims about an unobservable world, but deny that we should believe those claims. One motivation for this kind of sceptical instrumentalism is the 'underdetermination of theory by evidence'. However, realist opponents of instrumentalism can respond that the *compatibility* of different theories with the observational evidence does not mean those theories are all equally *well supported* by that evidence. A better argument for sceptical instrumentalism is probably the 'pessimistic meta-induction', which argues that, since past scientific theories have all proved false, we can expect present and future theories to prove false too.

B. van Fraassen, *The Scientific Image* (Oxford, 1980).

**instrumental value.** Some item has instrumental \*value just to the extent that it lends itself (fortuitously or by design) effectively to the achievement of some desired or valued purpose. It is that which is 'good as a means to . . .'. Hammers, chisels, and tools of all kinds are palmary instances of instrumentally valued items. Aristotle described slaves as living tools. In contrast, we think all humans have intrinsic value (or inherent value). Kant's dictum that one should treat all persons 'as ends' expresses this thought. Instrumental and other forms of value are discussed in G. H. von Wright, *The Varieties of Goodness* (London, 1963).

N.J.H.D.

\*ends and means.

**insufficient reason, principle of.** The principle of insufficient reason states that equal probabilities must be assigned to each of competing assertions if there is no positive reason for assigning them different probabilities. Keynes is the chief figure in discussion of this principle, which he preferred to call the principle of indifference. His own definition is 'if there is no known reason for predicating of our subject one rather than another of several alternatives, then relatively to such knowledge the assertions of each of these alternatives have an *equal probability*'. He devoted an entire chapter of his

book on \*probability to a vehement refutation of the principle.

The principle is of interest in the theory of rational choice. It has been shown to generate paradoxes (e.g. \*Bertrand's paradox) and to create difficulties for inductivist theories such as Carnap's, where its employment has to be sharply constrained to prevent the problem that if all a priori probabilities are equal, as Wittgenstein claimed in the *Tractatus*, the possibility of learning from experience is excluded.

A.C.G.

J. M. Keynes, *A Treatise of Probability* (1921), ch. 9.

**integrity.** The quality of a person who can be counted upon to give precedence to moral considerations, even when there is strong inducement to let self-interest or some clamant desire override them, or where the betrayal of moral principle might pass undetected. To have integrity is to have unconditional and steady commitment to moral values and obligations. For such a person, the fundamental question whether to conduct life on the plane of self-concern or of moral seriousness has been decisively resolved, though particular life situations will doubtless continue to put that commitment to strenuous test. This moral commitment becomes a crucial component in his or her sense of identity as a person: it confers a unity (integration) of \*character, and even a simplicity upon the man or woman of integrity. What integrity cannot guarantee is the soundness of the value-judgements themselves, which form the core of that person's commitment.

**intellectual virtues:** see virtues; virtues, doxastic.

**intelligence.** A family of intellectual traits, virtues, and abilities occurring in varying degrees and concentrations. An intelligent creature is one capable of coping with the unexpected. An intelligent person is one in whom memory and the capacity to grasp relations and to solve problems with speed and originality are especially pronounced. Despite much study, psychologists have yet to settle on a precise characterization of intelligence. This has not dampened enthusiasm for the design and application of tests purporting to measure intelligence, however, and E. G. Boring's remark that 'intelligence is what the tests test' is apposite. In recent years, debates have raged between those who regard intelligence as genetically fixed, and those who take it to be a product of social, cultural, and educational factors. Undoubtedly, heredity and environment contribute in ways difficult to untangle.

J.HEIL

\*rationality; reason.

R. J. Sternberg, *Metaphors of Mind: Conceptions of the Nature of Intelligence* (Cambridge, 1990).

**intension:** see extension and intension.

**intensionality.** A context or form of words is intensional if its truth is dependent on the \*meanings, and not just the \*reference, of its component words, or on the meanings, and not just the truth-value, of any of its subclauses. So, 'He coughed because he smoked' is intensional, since there is no guarantee that truth is preserved if 'he smoked' is replaced by some other true sentence. More problematic are such contexts as 'The sales assistant thought that the customer was wrong', which supposedly may not be true if 'the customer' is replaced by the person's name, or by some other mode of reference, as 'The sales assistant thought that your cousin was wrong'. On the one hand, it has been maintained that we may enlist only referential terms which could have been used by the person whose thought is being *reported*, so that if the sales assistant was unaware that the customer was cousin to the person addressed, this second variant would be false. On the other hand, our ordinary practice would suggest that choice of referential terms is dictated more by what secures reference for those currently *addressed*, a correct mode of reference giving rise at worst to an inapposite form of words, not to a falsehood.

\*opacity.

B. Rundle, *Grammar in Philosophy* (Oxford, 1979).

**intention.** Phenomenon, of intending to do something, treated in philosophy of mind and action, and in jurisprudence, and of importance in moral philosophy, e.g. in connection with \*akrasia.

Some notion of intention has seemed to be a crucial ingredient in an account of \*action: the adverb 'intentionally' may be put to work in marking out a class of actions; and the verb 'intend' introduces a state of mind of a person's intending to do something, which may be present even where the person does not actually do the thing, but which is directed towards action even so. (Whether someone can do something intentionally without having intended to do it is controversial.)

Some philosophers have distinguished between intentions directed at particular pieces of present behaviour, and intentions directed at future action. The former sort, called 'act-related', may be thought to be present wherever something is done intentionally; these are sometimes said to be the things of which we have an experience in acting, so that they may be used to account for the distinctive phenomenology of agency. (\*Agent.) It is the latter sort, the 'future-directed', with which accounts of intention are usually primarily concerned.

One aim of an account of intention is to connect the concept with related ones, so as to see how a person's intending to do something features in her practical deliberation and in action. An account may start from the question whether intention can be reduced to desire and belief. (Since the idea of *having a reason for action* can be explicated in terms of desire and belief, these two are often thought

of as the two primary psychological attitudes, so that, if a reduction were possible, intentions would not need to be recognized as mental states *sui generis*.) One suggested reduction says that a person intends to do something if and only if she desires to do it and believes that she will do it. But the recent literature contains many arguments against any such reduction. It also contains arguments against the assimilation of intending to either desiring or believing. Like desire, intention moves people to action; but whereas you may desire what you think you cannot achieve, you cannot intend what you think is impossible of attainment. Like belief, intention sets constraints on what is done; but intentions, unlike beliefs, are not straightforwardly evaluable as true or false, and an account of what it is for one intention to be consistent with another is different from an account of what it is for one belief to be consistent with another. Intention, it seems, must be treated neither as an affective state (like desire) nor as a cognitive one (like belief), but as a distinctively practical state, subject to its own 'rationality requirements'.

Michael E. Bratman has developed a planning theory of intention. His approach is initially a functional one: given believing, desiring creatures, who have limited time for deliberation, whose lives are coherent and co-ordinated with others', what would be the features of states of mind that would assist in making them effective agents? Well, those states must carry commitments to practice, and in doing so be such as to control conduct and be available to new episodes of practical reason. Being in such states is what it is for agents to have plans. And plans are typically decomposable into elements, which are intentions.

The idea of 'oblique' intention is sometimes introduced in jurisprudence, following Bentham: roughly, foreseen consequences of actions, although not directly intended, are obliquely so. Recognizing oblique intention introduces a class of things which people may be answerable for doing which is wider than the class of intended things.

Donald Davidson, 'Intending', in *Essays on Actions and Events* (Oxford, 1980).

J. R. Searle, *Intentionality* (Cambridge, 1983), ch. 3.

**intentional fallacy.** The alleged mistake of interpreting or evaluating a work of art on the basis of the artist's intentions (or other states of mind), instead of properties 'intrinsic' to the work itself. The idea was favoured by proponents of the post-war 'new criticism', but succumbs to two main objections: historical features of a work's production commonly do affect interpretation, and intentions may be manifest in the work, rather than wholly external to it.

C.J.

W. Wimsatt and M. Beardsley, 'The Intentional Fallacy', in D. Newton de Molina (ed.), *On Literary Intention* (Edinburgh, 1976).

**intentionality.** Technical term for a distinguishing feature of states of mind: the fact that they are 'about' or represent things. The term derives from the medieval Latin *intentio*, a scholastic term for the ideas or representations of things formed by the mind. The term was revived in 1874 by Franz Brentano for 'the direction of the mind on an object'. Brentano's idea was that intentionality is the mark of the mental: all and only mental states are intentional. This idea, often known as Brentano's thesis, can be expressed by saying that one cannot believe, wish, or hope without believing or wishing something. Beliefs, wishes, desires, hopes, and the like are therefore often called 'intentional states'. (\*Propositional attitudes.) Contemporary philosophers sometimes describe the intentionality of mental states as their 'aboutness'.

Used in this way, 'intentionality' does not necessarily involve the idea of intention—in the sense that actions are intentional (though somewhat confusingly, intentions are intentional states in the sense under discussion). The term should also be distinguished from the logical notion of \*intensionality. Intensionality is a feature of certain logical and linguistic contexts which exhibit the following features: (i) they are referentially opaque—substitution of co-referring expressions in a sentence may change the truth-value of the sentence; (ii) they do not license existential generalization—from 'Fa' we cannot infer 'There exists an x such that Fx'.

Ascriptions of intentional states certainly can exhibit intensionality in this sense. If I believe that Aristotle wrote the *Posterior Analytics*, it doesn't follow that I believe that Alexander's teacher wrote the *Posterior Analytics*, since I might not believe that Aristotle was Alexander's teacher. So ascriptions of intentionality can be opaque. Also, if I want to visit the lost city of Atlantis, it does not follow that something exists which I want to visit. So ascriptions of intentionality do not license existential generalization. But other non-psychological contexts exhibit intensionality too—notably, those contexts involving the ideas of necessity and possibility. (\*Modality.) Thus while 'Necessarily Aristotle is Aristotle' is true, 'Necessarily, Aristotle was the teacher of Alexander' is (on the face of it) false.

So treating intensionality as the mark of intentionality will not yield intentionality as the mark of the mental. (In fact, most contemporary philosophers deny that all mental phenomena are intentional in any case, on the grounds that sensations like pains are not 'directed' on anything.) Moreover, it is arguable that there are ascriptions of intentionality (in the sense of 'aboutness') which do not exhibit intensionality. If I see the Pope, and the Pope is a Polish man, then it plausibly follows that I see a Polish man. There is also a sense in which if I see something, there is something that I see. So there seem to be cases of ascriptions of intentionality which are not intensional.

Most contemporary philosophers therefore treat intensional contexts as a general phenomenon of which some of those attributing intentionality are a special case. However, those like Quine who are suspicious of intensionality will use this suspicion as grounds for attacking

the psychological notion of intentionality, in the course of attacking intentionality generally.

The intensionality of psychological ascriptions does, however, indicate a number of troublesome features of the idea of intentionality. Intentional states can be about objects that do not exist and they seem to be individuated in many cases not merely by the objects thought about but by the way they are thought about. (\*Representation; \*sense and reference.) How can such a peculiar phenomenon as intentionality be part of the natural order of the world? Contemporary answers to this question—the problem of intentionality—have thus been concerned with ‘naturalizing’ intentionality. This usually takes the form of giving some account of how intentional states are causally related to the things they are about. T.C.

\*belief and desire; mind, syntax, and semantics; intentional relation.

John Searle, *Intentionality* (Cambridge, 1983).

**intentional relation.** Brentano’s thesis of \*intentionality, that every mental phenomenon has a direction toward an object, creates the most difficult problem for the philosophy of mind. It leads immediately to the following dilemma. Either a mind is somehow related to what is before it—to what it perceives, desires, fears, asserts, imagines, etc.—or it is not. If one chooses the second horn, then one must give a non-relational account of intentionality. But there is at the present time no plausible non-relational account. If one embraces the first horn, then one is immediately faced with a second dilemma. Since a mind can perceive what does not exist, desire what shall never come to pass, assert what is not the case, etc., either an intentional relation must hold in such cases between a mind that exists and something that does not exist, or else these objects of the mind do exist, contrary to our firm conviction. If we accept the first alternative, then we are forced to hold that there is a relation, totally different from ‘ordinary’ ones, which connects with what does not exist. If we embrace the second alternative, then we must assume that, say, the golden mountain and the round square do after all exist. We are forced, in other words, to accept either the existence of a ‘weird’ relation or the existence of non-existent objects. It will not do, one must realize, to try to escape from this dilemma by claiming that the golden mountain and the round square, though they do not exist, have some sort of lesser being, and that the intentional relation can hold between a mind and things with this kind of ‘watered-down’ being. For, in this case, the fact remains that one has acknowledged the existence of what I just called a ‘weird’ relation. The intentional relation is still weird in that it is now believed to hold on occasion between an existent mind and

something that does not exist, but has some sort of being. In addition, of course, this attempt to escape from the dilemma has to make sense of the notion of ‘watered-down’ being.

If the thesis of intentionality in this fashion leads to a dilemma piled on top of a dilemma, it is to be expected that philosophers, in order to avoid the resulting difficulties, will adopt a materialistic (or physicalistic or behaviouristic) attitude. Intentionality disappears, if there are no minds (mental acts). Therefore, the dilemmas disappear, if there are no minds. Perhaps materialistic treatments of philosophical problems are so popular at the present time, because they promise escape from the dilemmas. R.G.

\*behaviourism; materialism; physicalism.

F. Brentano, *Psychology from an Empirical Standpoint* (London, 1973).

**intentional stance:** see Dennett.

**interactionism.** The view that some mental events cause some physical events and some physical events cause mental events, closely related to the commonsense idea that thoughts and desires cause various physical events, such as limb movements, and some physical events cause visual experiences and the like. The view is therefore different from epiphenomenalism, which regards all mental events as causally inefficacious themselves and as effects of physical events. It is also different from and does not entail a philosophically commoner view which takes each mental event to be nomically connected with a neural event. It is also different from identity theories. It is necessarily dualistic in character, but need not involve the view held by many pre-twentieth-century philosophers, most famously Descartes, and wisely regarded as a crucial tenet of theism, that mind and matter are two distinct substances. N.L.

**internal and external relations:** see relations, internal and external.

**international law.** Term coined in Latin (*ius inter gentes*) in the sixteenth-century renovation of natural law theory after the breakdown of unitary secular-ecclesiastical Christendom, and Englished perhaps by \*Bentham. But what it denotes was understood until the mid or late twentieth century as law governing relations between states, rather than nations or peoples. In the absence of standing legislative and judicial institutions, its sources remain largely agreement between states (treaties) and those elements of state practice (custom) that manifest a judgement that, in the relevant domain, general adherence to a common rule of action is desirable (*opinio iuris*).

Plainly a non-central and precarious kind of law and legal system, there seems no reason to doubt either its positivity, as something added by human decision to natural morality, or its obligatoriness in some measure, in a world where no state can plausibly claim to be a fully complete community entitled to constitute the ultimate and unconditional horizon of a just person's allegiance.

Developments in international law in recent decades have responded to a set of interrelated questions: Has an individual person, or a non-state group, the right to move international organs, as a subject of international law with substantive and procedural rights derived from international law? Has an organization such as the United Nations an international personality comparable to that of a state, and are its rights in international law limited to those conceded by the states party to its establishment? Can the same be said of a non-governmental organization such as the International Red Cross? If 'persons' other than states can be subjects of international law rights, can they also be creators of international law rules, as states can? When can individuals, including rulers of states, be tried by internationally authorized tribunals for offences against international law? These questions, like the tentative affirmative answers being given to them, arise from a widespread understanding that new interdependencies, economic, environmental, and cultural, are bringing into being a world-wide human community which might in principle become a fully complete community governmentally equipped to supervise, coercively, the doing of justice everywhere, but that no governmental authority can yet be envisaged such as could be relied upon to act with an effective justice sufficient to merit a general transfer or subordination of state jurisdiction to it. This last proposition, reasonable though it doubtless is, has the practical implication that international law will remain for the foreseeable future a system largely bereft of sanctions and, for that and other reasons, one that is peculiarly open to violation and to change by *fait accompli*, not least by states prominent in shaping and appealing to its rules, principles, and institutions.

Wilhelm G. Grewe, *The Epochs of International Law* (Berlin, 2000).

Hersch Lauterpacht, 'The Definition and Nature of International Law and its Place in Jurisprudence', in his *Collected Works*, i (Cambridge, 1970).

**international relations, the philosophy of.** The set of doctrines, ideas, justifications, and excuses that guides the study and, perhaps, the practice of sovereign states in their dealings with one another. Two broadly opposed positions have been articulated, the first mostly by students of politics (and also by politicians), the second mostly by students of law (and by lawyers). Only in very recent years has either one attracted much philosophical attention.

The first position is commonly called 'realist' because its advocates claim to see states as they really are (in the tradition of Thucydides and Machiavelli). On this view, sovereignty is taken as a kind of exemption from the moral

restraints that apply to individual men and women. The rulers of states are driven by the 'necessities' of international anarchy, standardly conceived as a Hobbesian \*state of nature, to defend the interests of their own people without regard to the rights of anyone else. Thus the Greek generals in Thucydides' Melian dialogue: 'they that have odds of power exact as much as they can, and the weak yield to such conditions as they can get.' Strategic and security studies are the political expression of this realist view.

The second position is best called 'legalist' because it views international society, on analogy with domestic society, as a rule-governed world. In the absence of a global authority that might serve as the source of the required rules, they are derived instead from the tacit or explicit consent of existing states—hence from customs, treaties, and conventions—or from some version of \*natural law. \*Just war theory is the first moral offspring of this legalist view, though many of its protagonists believe that what the domestic analogy requires is that war should be conceptually, as well as practically, repressed. Unjust wars must be understood as criminal acts, and just wars simply as police actions, aimed at law enforcement.

What is at issue between realists and legalists, above all, is the responsibility of rulers. The realist view is only putatively amoral; its central claim is that rulers are morally bound to their subjects or fellow citizens and must be permitted to do, or be excused for doing, whatever they have to do in order to guarantee the physical security and advance the well-being of those people. The legalist view is that nothing can be done for those people that they could not, as individuals, do for themselves. Since they could not kill innocent people to save their own lives, innocent people cannot be killed on their behalf. As this example suggests, arguments about responsibility have focused mostly on the conduct of war, with realists insisting that *inter arma silent leges* and legalists refusing to be silent even then. But the disagreement extends also to questions of diplomacy and commerce. Here too rulers of states commonly act as if ordinary moral standards were relaxed or lifted entirely in their case: gentlemen do not open each other's mail, but statesmen authorize (and pay for) espionage and think themselves morally justified.

The same issue also arises in discussions of distributive \*justice, which is commonly taken to deal with domestic, but not with international, transactions. Of course, trade across borders is governed by the same prohibitions (against fraud, say) as trade within borders. \*Markets are international; the old *jus gentium* was first of all market law. Governments, however, are not international, and whatever obligations government officials have to promote justice—to redistribute resources, establish a welfare 'floor', ban discriminatory practices, and so on—are owed to their fellow citizens and not to foreigners. But this view, standard for a very long time, has come increasingly under criticism by writers seeking some way of addressing the radical \*inequalities of international society. Perhaps

foreign aid is as obligatory as domestic welfare. Perhaps the \*difference principle should be applied globally. Legalists are likely to be more sympathetic than realists to such proposals, but even for them these are extensions of law and morality beyond their current reach.

It might be said that international distributive justice would not require the reform of international relations so much as its abolition—in favour of a new global domesticity. The society of sovereign states would be replaced by a new political entity, encompassing all the men and women in the world and treating them with equal respect and concern, as rights-possessing individuals. But it is also possible to imagine states of the world that fall between international anarchy and global rule. Organizations like the United Nations, the International Monetary Fund, and the World Trade Organization have something less than governmental power, but they could still act, if the leading states in the global economy wanted them to do so, in the interests of international distributive justice.

**internet, philosophy on the.** The Internet is awash with philosophy. Type 'philosophy' into an Internet search engine, and it returns millions of entries; and EpistemeLinks.com, the leading portal website for philosophy, currently features some 13,000 categorized links to philosophy resources on the Internet. Inevitably, with this quantity of material available, much of it is not of professional standard. In part, this is because the Internet facilitates publication without editorial control or peer review (which itself leads to difficult questions about the reliability of information found on the Internet). Nevertheless, professional philosophers and philosophy publishers are increasingly making use of the opportunities presented by the Internet.

Most significantly, the worldwide web is beginning to change the face of philosophy publishing. Partly, it is doing so because it offers a number of advantages over traditional, non-electronic publishing. (1) A single web publication has a potential audience of millions of people, many of whom, in the case of philosophy, would not otherwise have ready access to such material. (2) The web is a dynamic medium, allowing for published material to be updated frequently. For example, online reference works, such as the *Stanford Encyclopedia of Philosophy* (<http://plato.stanford.edu>), are kept up to date in a way that their paper-based counterparts cannot be. (3) By utilizing embedded hypertext links, web publications allow for sophisticated cross-referencing and facilitate non-linear research strategies. (4) The worldwide web makes it

relatively easy for individuals to embark on their own publishing ventures, something which philosophers such as David Chalmers (at Arizona/ANU), Peter Suber (Earlham), Ted Honderich (UCL), and Stephen Clark (Liverpool) have exploited to excellent effect. (5) It is relatively inexpensive to publish on the worldwide web. Therefore, the option of an exclusively online journal or collection is an attractive one for publishers. Good examples of these are *The Philosophers' Imprint* ([www.philosophersimprint.org](http://www.philosophersimprint.org)), an online journal with an editorial board the equal of any traditional philosophy journal, and the *Marxists Internet Archive* ([www.marxists.org](http://www.marxists.org)), a digital library of works by authors sympathetic to Marxism.

The Internet is also transforming the way that philosophers interact with each other. In particular, email and mailing lists such as Philos-L ([www.liv.ac.uk/Philosophy/philos.html](http://www.liv.ac.uk/Philosophy/philos.html)) mean that philosophers around the globe are in constant communication. J.S.

**interpretation.** Theoretical or narrative account of facts, texts, persons, or events that renders the subject-matter intelligible. As a genuinely philosophical problem, interpretation became recognized first as a specific feature of the human sciences. Historical interpretation based on lived experience, understanding, and ordinary language is contrasted with scientific explanation based on alien construction, observation, and theoretical concepts. In existential and hermeneutic philosophy, interpretation becomes the most essential moment of human life: The human being is characterized by having an understanding of itself, the world, and others. This understanding, to be sure, does not consist—as in classical ontology or epistemology—in universal features of universe or mind, but in subjective-relative and historically situated interpretations of the social \*life-world. Recent trends like \*post-modernism or \*neo-pragmatism have emphasized the universality of interpretation, arguing that even natural sciences are nothing but interpretations. H.H.K.

\*hermeneutics.

C. Taylor, 'Interpretation and the Sciences of Man', in *Philosophy and the Human Sciences*, ii (Cambridge, 1985).

**intersubjective.** This term refers to the status of being somehow accessible to at least two (usually all, in principle) minds or 'subjectivities'. It thus implies that there is some sort of communication between those minds; which in turn implies that each communicating mind is aware not only of the existence of the other but also of its intention to convey information to the other. The idea, for theorists, is that if subjective processes can be brought into *agreement*, then perhaps that is as good as the (unattainable?) status of being *objective*—completely independent of subjectivity. The question facing such theorists is whether intersubjectivity is definable without presupposing an objective environment in which communication takes place (the 'wiring' from Subject A to Subject B). At a less fundamental level, however, the need for

intersubjective verification of scientific hypotheses has been long recognized. J.N.

\*subjectivism.

D. Davidson, *Subjective, Intersubjective, Objective* (Oxford, 2001).

**intrinsic good:** see good in itself.

**introspection.** The nature of introspection and sometimes even its existence are a subject of controversy, and so it is difficult to provide a neutral account of it. It is not just the awareness that accompanies some mental states. It is rather a person's internal way of ascertaining what mental state he or she is currently in.

Sometimes introspection is taken to be a type of perception and there is talk of a 'mental eye', or, if minds are thought to be material, brain-scanning. Others deny any similarity with sense-perception and view such talk as misleading. They think it is acceptable to talk of introspection as perception only if a very minimal understanding of perception is brought to bear, in which case it is uninformative. Another alternative is to take introspection to be a form of recollection, or retrospection, in which case we would have to characterize it as a person's internal way of ascertaining his or her mental states just past. The motivation for this approach is that it is thought implausible for one to have a thought simultaneously with having another thought the content of which is the first thought.

Much philosophical discussion has centred around the status of the beliefs we obtain through introspection. 'Are they justified?' and 'How likely are they to be false?' are questions often asked. P.J.P.N.

\*apperception; inner sense.

W. Lyons, *The Disappearance of Introspection* (Cambridge, Mass., 1986).

**intuition.** Originally an alleged direct relation, analogous to visual seeing, between the mind and something abstract and so not accessible to the senses. What are intuited (which can be derivatively called 'intuitions') may be abstract objects, like numbers or properties, or certain truths regarded as not accessible to investigation through the senses or calculation; the mere short-circuiting of such processes in 'bank manager's intuition' would not count as intuition for philosophy. Kant talks of our intuiting space and time, in a way which is direct and entirely free from any mediation by the intellect—but this must be distinguished from an alleged pure reception of 'raw data' from the senses; the intuiting is presupposed by, and so cannot depend upon, sensory experience.

Intuitions or alleged intuitions have been important in logic, metaphysics, and ethics, as well as in epistemology. Recently, however, the term 'intuition' has been used for pre-philosophical thoughts or feelings, e.g. on morality, which emerge in thought experiments and are then used philosophically. A.R.L.

\*empirical.

D. Pole, *Conditions of Rational Inquiry* (London, 1961), ch. 1.

**intuitionism, ethical.** Ethical intuitionism is mainly associated with British philosophers; it is sometimes called British intuitionism. But the term 'intuitionist' is used for more than one position. In one sense, intuitionism is the view that basic moral truths are known by intuition—that is, directly, rather than by inference. In this sense, Sidgwick was an intuitionist. More recently, intuitionism has been taken to be a form of pluralism, pluralism in the theory of the right. Monists in the theory of the right say that there is only one way in which an action can get to be right. Kant was a monist, and so was G. E. Moore, who held at one time that for an action to be right is for it to have the best consequences. Against Moore, Ross argued that actions can be made right in any of a number of ways. J.D.

W. D. Ross, *The Right and the Good* (Oxford, 1930).

**intuitionism, mathematical.** A school founded by L. E. J. Brouwer (1881–1966) which construes mathematics as mental constructions, opposing the view that mathematical reality is independent of our thought. (Intuitionism is thus a species of \*constructivism about mathematics.) The intuitionist criticizes classical mathematics for its unrestricted use of the law of excluded middle, the claim that 'A or not-A' is always true. Classically, one may prove A by refuting not-A, or by showing that A follows both from B and from not-B. But for the intuitionist, if a statement is neither provable nor refutable, we cannot assume that either it or its negation is true: there is no mathematical reality, independent of our thought, to settle the truth-value of all mathematical statements. See \*intuitionist logic for the framework in terms of which intuitionists investigate how much of mathematics survives their critique. The applicability of intuitionist thought outside mathematics has been explored by Dummett. D.E.

M. A. Dummett, *Elements of Intuitionism*, 2nd edn. (Oxford, 2000).  
A. Heyting, *Intuitionism: An Introduction* (Amsterdam, 1956).

**intuitionist logic.** A logic in which truth is equated with provability, or warranted assertibility, or something of the kind. Let us use '□' to abbreviate 'We have grounds for asserting' or 'We have a proof' or 'We have a method which, if applied, would yield a proof', and so on. Then the intuitionist connectives answering to 'and', 'or', 'if', and 'not', are explained thus:

□(P & Q)	if and only if	□P and □Q.
□(P ∨ Q)	if and only if	□P or □Q.
□(P → Q)	if and only if	□(If □P then □Q).
□¬P	if and only if	□ not □P.

In words, the explanation of '→' would often be given thus: 'We have grounds for asserting that  $P \rightarrow Q$  if and only if we have a method of transforming any grounds for asserting that P into grounds for asserting that Q'. And the explanation of '¬' would be: 'We have grounds for asserting that  $\neg P$  if and only if we have grounds for asserting that we could never have grounds for asserting that P'. (An equivalent account defines '¬P' as abbreviating ' $P \rightarrow \perp$ ',

where ‘ $\rightarrow$ ’ is understood as above and ‘ $\perp$ ’ represents an arbitrary contradiction.) As for the quantifiers, where D is the domain of quantification, the explanation is

- $\exists xFx$  if and only if for some object  $a$ ,  $\Box(a$  is in D) and  $\Box Fa$ .
- $\forall xFx$  if and only if  $\Box$ (for every object  $a$ , if  $\Box(a$  is in D) then  $\Box Fa$ ).

The logic that results from these explanations differs from classical logic primarily where negation is concerned. Notoriously, it lacks the law of \*excluded middle ‘ $P \vee \neg P$ ’, for on the intuitionist account we should have grounds for asserting that  $P \vee \neg P$  only if we have grounds either for asserting that  $P$  or for asserting that we could never have grounds for asserting that  $P$ . But of course it may be that we do not have grounds for either. Similarly, this logic lacks the law ‘ $\neg \neg P \rightarrow P$ ’, and many other classical laws for negation. This has some unexpected consequences. For example, none of the connectives and quantifiers listed above can be defined in terms of any combination of the others.

The simplest way of formulating intuitionist logic is in a style suitable for \*natural deduction, with one introduction rule and one elimination rule for each sign. The rules are just the same as the classical rules in all cases except for negation, where the introduction rule is *reductio ad absurdum* and the elimination rule is *ex falso quodlibet*. There are several ways of giving a formal semantics for this logic, the most popular being that based on ‘Kripke trees’, but this topic is too complex to be explained here.

There are also several ways of ‘translating’ some or all of intuitionist logic into classical logic. The most interesting one, because it seems to be most in accordance with the intended meaning of the intuitionist connectives and quantifiers, is this. In the explanations given earlier, assume that the English expressions used on the right are the classical connectives and quantifiers. Then where  $\phi$  is any formula of intuitionist logic, the formula  $\Box \phi$  will translate, via these explanations, into a formula  $\phi^*$  containing only classical connectives and quantifiers, interspersed with occurrences of  $\Box$ . It turns out that  $\phi$  is valid intuitionistically if and only if  $\phi^*$  is valid in the modal logic S4.

Intuitionist arithmetic is obtained by adding to this logic the same axioms as for classical arithmetic. The two arithmetics differ only on formulae involving quantifiers. The intuitionist theory of the real numbers is a \*predicative theory. D.B.

**inversion.** A term introduced by J. N. Keynes to signify inferences in which from a given proposition another proposition is inferred having for its subject the negation of the original subject. One such inference is interesting because it violates a rule of \*distribution. A series of

\*immediate inferences permits us to infer ‘Some non-S are not P’ from ‘All S are P’, but P is undistributed in the premiss, distributed in the conclusion. C.W.

J. N. Keynes, *Formal Logic*, 4th edn. (London, 1906), 137–40.

**inverted spectrum.** That two people outwardly indistinguishable in their colour discriminating may nevertheless systematically differ in their colour experiences was a possibility raised by Locke (*Essay*, bk. II, ch. xxxii). Under the title ‘spectrum inversion’ it has entered modern debate via objections to \*behaviourist accounts of the mind that at least some conscious mental states have no clear relations to behaviour. Similarly, the causal relations that \*functionalists appeal to in accounting for colour discrimination are dogged by the possibility of subjective differences which, being systematic, escape the functional net. Some functionalists argue that spectrum inversion is a metaphysical possibility, but scarcely credible, while, being epiphenomenalists, they may not care anyway. Those who take colour experiences to be states of the brain rely on the possibility of inversion being discounted explanatorily by future neurobiological advances. It is nevertheless difficult to say what precise discoveries would enable science to explain what Locke himself could only describe as God ‘annexing’ ideas in our minds to certain objects.

**invisible hand.** Although in a free transaction the butcher sells me meat to profit himself, and I buy his meat as cheaply as possible, we each benefit the other as well as ourselves. Adam Smith regarded the \*market as a whole as a universally beneficent order which comes about spontaneously (as by an invisible hand) from countless such acts, whose agents have no thought of their systemic effects. Any order which arises spontaneously without intention or design can be regarded as an instance of the invisible hand, but Smithian economics was the first study of the phenomenon. A.O’H.

\*conservatism.

Adam Smith, *The Wealth of Nations* (1776).

**inwardness.** The inner form or quality of a person’s outward-looking engagement, rather than self-scrutiny or silent pondering. A concept associated with existentialism and central in Kierkegaard (*Underlighed*—drawing on the senses of ‘fervent’, ‘intimate’, ‘tender’, ‘sincere’, ‘with longing’, but not of ‘directed inward’). Inwardness is measured not by external criteria but by the mental pitch, as it were, of a person’s engagement. Kierkegaard’s concept is well captured in his ironical reference to ‘town criers of inwardness’. It is only when matters of moment are grasped with appropriate inwardness that they can be properly addressed. Noise and show rob human activity of all of the positive characteristics of inwardness. Kierkegaard was especially occupied with those cases in

which the noise and show were marketed as expressions of the very matters that call for inwardness. A.H.

**Iqbāl, Allāmeḥ Muḥammad** (1877–1938). Born in Sialkot (now in Pakistan), Iqbāl was a Muslim thinker and poet. Educated in Berlin, his goal was to revitalize Islamic thought and re-establish its creative role in philosophy. His prose work, *The Development of Metaphysics in Persia*, is one of the first modern non-polemical Muslim texts reflecting Western scholarly methodology. Most of his works are in Persian and Urdu poetry, inspired by classical Persian mystical poetry, especially that of the great Persian mystic Jalāl al-Dīn Rūmī (1207–73). Iqbāl's most accomplished poem, the Persian *The Secrets of the Self*, is a modern reaffirmation of Islamic philosophy's widely held epistemological principle of the primacy of intuition and experience by the self-cognizant 'I', or 'knowledge by presence'. **Irigaray, Luce** (1932–). French feminist philosopher, linguist, and practising analyst. Her early work focused on psycholinguistics, analysing speech patterns in senile dementia and schizophrenia. She studied with Lacan but was expelled from his Vincennes school for dissenting from his views on women's sexuality. *Speculum of the Other Women* (1974) is a large-scale critical reading of the history of Western philosophy as 'the master discourse', which exposes an exclusion or suppression of the feminine and the maternal and an undue bias towards masculinity, written in her characteristically allusive style. Many of her texts attempt to construct a version of feminine subjectivity ('speaking (as) woman') in the light of the above exclusion, using the strategic and symbolic positioning of Woman as \*Other (e.g. *This Sex which is not One* (1979)). Some of her recent work is more explicitly political, some more lyrically poetic. A.C.A.

\*feminism.

**Irish philosophy.** There has been only one period of continuous, creative philosophy in Ireland—from the 1690s to the 1750s. Before that the only prominent figure is John Scotus Eriugena, whose work has some points of contact with that in the eighteenth century, particularly in its tendency towards \*pantheism, negative theology, \*idealism, and heterodoxy; although Irish philosophy has been traced back to the so-called Irish Augustine, c.sixth century. After the 1750s, the most noteworthy philosophical activity—at least until now—has been derivative and scholarly, either within Catholic scholasticism, or in elucidating and editing the work of Berkeley (A. A. Luce), Kant (T. K. Abbott), and Hegel (H. S. Macran).

The outstanding figure in Ireland's one creative period was George Berkeley, whose principal writings indicate the main concerns of Irish philosophy, i.e. epistemology, theory of perception and language, and philosophy of religion. Also important, however, is the contribution in aesthetics by Francis Hutcheson—who was born and died in Ireland and produced most of his important books while teaching in Dublin in the 1720s—and Edmund Burke, whose chief philosophical work, *Philosophical Enquiry into the Ideas of the Beautiful and the Sublime* (1757), was largely written while he was a student at Trinity College in the late 1740s. While Berkeley, Hutcheson, and Burke are probably the best-known names, there were other able philosophers—among them, John Toland, William Molyneux, William King, Peter Browne, Robert Clayton, and Edward Synge. There were also popular writers, most notably Jonathan Swift, some of whose writings reflect key theories and arguments in Irish philosophy.

The seminal work is Toland's *Christianity not Mysterious* (1696), which, drawing chiefly on Locke's theories of meaning and essence, argues that Christianity either asserts meaningless doctrines—'Blictri'—or is a non-mysterious religion. Toland's rationalist challenge was answered by Browne, then a Fellow of Trinity College, first in his *Letter* (1697) and, more weightily, in his *Procedure, Extents and Limits of the Human Understanding* (1728), which argues for the old negative theology by developing a radical sensationalist account of mind. Browne, like Toland, was influenced by Locke, whose *Essay* is the most important external influence on Irish philosophy.

There are two principal tendencies in Irish philosophy—the left- and right-wing Lockean. Toland is a left-winger, drawing on Locke's rationalism and enlightened attitude to religion. Browne is in the right-wing, which uses Locke's empiricism and the sceptical and quietistic trends in the *Essay*. Yet neither those on the left nor those on the right were slavish adherents of Locke; instead, they were often his most astute critics, boldly drawing out conclusions from his work which he was either unable or unwilling to accept. Molyneux comes closest to being a follower; yet he is more a collaborator than a disciple. Indeed, the final form of the *Essay* owes more to him than anyone (apart from Locke), as their correspondence, published in 1708, clearly shows. Another creative response to Toland from the right was by Archbishop King, whose *Sermon on Predestination* (1709) defends religious mystery by applying \*representationalism and the \*primary-secondary quality distinction to theology. King is also remembered for his influential *De Origine Mali* (1702), which is appreciatively discussed by Leibniz in his *Théodicée*.

Toland's challenge also gave rise to Berkeley's precocious emotive theory of meaning, which Berkeley uses in *Alciphron* (1732), dialogue vii, to explain religious mystery. Yet Berkeley was not a clear adherent of the right wing. Thus in *Alciphron*, dialogue iv, he forcefully attacks the Browne-King theological position and in ways remarkably similar to those he had earlier used against matter.

Browne counter-attacked in his *Divine Analogy* (1733), whose scornful and incredulous comments on Berkeley's emotive theory of mystery shows the revolutionary character of the theory, a theory which Burke uses in his *Philosophical Enquiry* along with sensationalism, which he probably derived from Browne. Another topic which shows the inner unity and interest of Irish philosophy is the \*Molyneux problem. Not only was it devised by an Irishman, but some of the most interesting responses to it were made by Irishmen—Berkeley, Hutcheson, Synge, as well as (less directly) Swift and Burke. D.BER.

**iron block universe:** see determinism.

**irony, Romantic.** Notion of irony as an attitude or ethos that calls everything into doubt, from utterer's intentions to our knowledge of the world as given (supposedly) through sensory acquaintance or the concepts and categories of reason. Such 'infinite' irony—as distinct from its 'stable' or unproblematic varieties—aroused great interest among poet-philosophers in the early-to-mid-nineteenth century, notably Novalis, Hölderlin, and Friedrich Schlegel. These thinkers pursued the various problems bequeathed (as they saw it) by Kant's critical philosophy, e.g. the \*antinomies of subject and object, of \*freedom and \*determinism, and of thought as a perpetual striving for truth in the face of human finitude. Hence their fascination with the giddy depths of uncertainty—the interpretative *mise-en-abîme*—opened up by reflection on this topic. Such thinking was attacked by Hegel and Kierkegaard on account of its sceptical or nihilist implications. C.N.

David Simpson (ed.), *The Origins of Modern Critical Thought: German Aesthetic and Literary Criticism from Lessing to Hegel* (Cambridge, 1988).

**irony, Socratic.** Socrates, in the early dialogues of Plato, is depicted as claiming to know nothing, as having no superior doctrine to offer even as he confounds and defeats his interlocutors by his pointed questions. This famous Socratic 'profession of ignorance' is also regarded as an instance of Socratic irony, of his saying less than he thinks or means (as the root of the term in the Greek *eirōn*, a dissembler, suggests). He adopts this affectation, it is said,

simply to avoid being subjected to the same critical treatment himself. It would seem, however that there was no dissembling involved.

N.J.H.D.

S. Kierkegaard, *The Concept of Irony* (1841) is a classic treatment.

G. Vlastos, *Socrates* (Cambridge, 1991) contains a recent discussion.

**irrationalism** is the opposition to reason on principle as distinct from the mere tendency to lapse into *ad hoc* illogicality or unreason. What this outlook amounts to more specifically depends on the answers to the following questions. What is the *reason* thus opposed? What is counterposed to it? And what is the extent of the opposition?

To start with the last: irrationalism has never involved a total disavowal of \*reason. For example, an irrationalist falsely accused of murder can be expected to marshal evidence and argument in proof of his innocence as best he can. Nor is he likely to ignore well-established algorithms in the solution of a computational problem. What he would insist upon is that principles such as those of probable and demonstrative reasoning that are used in the mental activities mentioned are, though appropriate and effective in their own spheres, inapplicable to issues of superior importance like the spiritual self-realization of the ego, the ultimate destiny of humankind, and the transcendent ground of the existence of the world. Within the domain to which these issues belong, he would contend, knowledge can only be attained through some non-logical and non-empirical modes of direct cognition such as are encountered (in purest form) in mystical intuition or in faith induced by some transcendental source.

Faith and \*intuition, then, on this reckoning, are and ought to be recognized as the superiors of reason in matters that matter. Although the concept of reason has been variously interpreted, it has an uncontroversial core of reference which includes deductive and inductive inference, to which allusion has already been made, and the logical and semantical analysis of concepts and statements based on clearly ascertainable rules. Given that these procedures of thought are supposed to be incapacitated in the areas of cognition reserved by the irrationalist, it is apparent that any inquiries by the unconverted into the intelligibility, not to talk of the validity, of the deliverances of faith and intuition are irremediably handicapped. And this is, possibly, the most striking thing about irrationalism: it is apt to become a constraint on dialogue.

It is a remarkable fact that some of the greatest thinkers in the history of Western philosophy have had some irrationalist leanings, however peripheral in some cases. Thus so ingenious a dialectician as Plato seems to have credited knowledge of the profoundest truths exclusively to some superior mode of unmediated cognition, exempt from all possibility of error and therefore of debate; and St Thomas Aquinas, for all his demonstrated powers of reasoning, conceded some truths to the sole competence of faith. Even Kant, giant of the Enlightenment, confessedly found it necessary to 'deny *knowledge* in order to make room for *faith*'.

But, of course, reason has not lacked its philosophical celebrants. It is not for nothing, for example, that the seventeenth and eighteenth centuries in European history have been called the Age of Reason. The rational foundations laid in the teachings of seventeenth-century thinkers like Bacon, Locke, Leibniz, Spinoza, reached their denouement in the optimistic rationalism (using this word in the broad sense) of the stalwarts of eighteenth-century Enlightenment such as, to mention only a few, Bentham and Godwin in England and Voltaire, Diderot, and Montesquieu in France. Their shared conviction, which may not at times have been without a touch of hyperbole, was that it was entirely possible to improve the human condition out of all recognition through the expansion of the role of reason in human affairs.

It was in reaction to this enthusiastic trust in reason that Romanticism emerged in art, literature, and philosophy in the nineteenth century as perhaps the most self-consciously irrationalist movement in Western thought. In contemporary culture there are not a few currents of irrationalism—witness, for instance, the ‘new age’ movement and the even grosser tendencies to demonism in sectarian life—but in serious philosophy familiar animadversions against *Reason*, when duly analysed, are frequently revealed to be in reality more against certain conceits about reason than against reason itself. **Irwin, Terence H.** (1947– ). A noted classical philosopher at Cornell University, Irwin has written books on Plato’s ethical ideas (*Plato’s Moral Theory* (Oxford, 1977)) and on Aristotle’s metaphysical and epistemological theses (*Aristotle’s First Principles* (Oxford, 1988)). His work is marked by a strong current of active philosophical questioning. Irwin’s task has been not only scholarly, but one of understanding and evaluating the theses under examination as significant and living ideas. He has done the bulk of his mature work in America, where he stands alongside a number of other North American classical philosophers in demonstrating the continued power of the intellectual inheritance of Plato and Aristotle. N.J.H.D.

**‘is’:** see ‘to be’; being; real; subject and predicate.

**‘is’ and ‘ought’.** Moral philosophy has to give an account of how, if at all, we can legitimately move from *is* to *ought*, from describing how things do in fact stand, to expressing an urgent concern either that they be changed or that they be respected, preserved as they are. If the *is–ought* gap is over-dramatized, value is detached altogether from the world and becomes a function of sheer decision. But moral deliberation does not and cannot work in a factual

vacuum. To *underplay* the gap is to suggest, no less implausibly, that an *ought* can be simply read off from an *is*.

A satisfactory account must start from the idea that *ought* and *is* interpenetrate. We may grasp a situation as demanding action: conversely, reflection on values and obligations powerfully affects our understanding of human nature and its potentialities.

The classical formulation of the ‘is’–‘ought’ issue is David Hume’s, in *A Treatise of Human Nature*, III. i. 1.

R.W.H.

\*fact–value distinction.

W. D. Hudson (ed.), *The Is/Ought Question* (London, 1969).

**Islamic aesthetics.** Much Islamic aesthetics, like Islamic philosophy as a whole, is thoroughly Neoplatonic. This replaced the earlier theories of thinkers like al-Kindī, for whom beauty is taken to be derived from perfection, and since God is the most perfect being in the universe, he is also the most beautiful. He is constantly aware of his beauty, while we are only occasionally able to come close to experiencing it, since it is an essential feature of the deity, but its perception is merely an accidental human attribute. This version of Pythagoreanism was replaced by the argument that we operate on the level of imagination, so our ideas of beauty are limited to what we can experience and abstract from those experiences. On the other hand, we can use our material ideas and experiences to construct more abstract and perfect concepts of beauty, and so come closer to the range of completely pure beauty which exists far from the material world.

The area of aesthetics which came in for much discussion was poetry, and the ways in which poetry works logically. Many of the Islamic philosophers such as al-Fārābī, Avicenna, and Ibn Rushd were convinced that poetry follows a syllogistic pattern of proof, albeit with far weaker premisses than most such reasoning processes, and with the conclusion that the audience should be moved to action or emotion. Imagination is again crucial here, blending our ability to be both spiritual and material. Our material ideas reflect our experiences, yet they can be made more abstract, and thereby extend those experiences in novel and exciting ways. Were we to be entirely rational, we would not need imagination, and could be spoken to entirely in terms of what we regard as logical; but since we are emotional creatures, we require to be addressed at least partially through our emotions, and this is where poetry and other art-forms come in. They appeal to us both intellectually and emotionally, and persuade us that we should adopt a certain attitude or share a particular feeling. O.L.

S. Kemal, ‘Aesthetics’, in S. Nasr and O. Leaman (eds.), *A History of Islamic Philosophy* (London, 1996).

**Islamic ethics.** Ethics in Islamic philosophy is a surprisingly uncontroversial area, since most thinkers agreed on the general principles of ethics. There was an early

theological dispute as to how objective the principles of ethics are, but this did not really become part of the debate in philosophy. The latter took off when the views of Plato and Aristotle became familiar to Islamic philosophers, especially the notion of the just society in the *Republic* of Plato and virtue as a mean in Aristotle's *Nicomachean Ethics*. One of the issues which the Islamic thinkers had to address was how to discuss happiness in such a way that it would be available to all who were prepared to behave well, as opposed to just those who were intelligent. The Aristotelian debate about how far the moral and social life is important, as compared to the life of the mind, was of particular interest, since the idea that salvation was restricted to those who are intellectually gifted is hardly compatible with Islam. Al-Fārābī and Ibn Sīnā (Avicenna) imply that the masses' route to salvation is through religion and morality, while the philosophers' route is through philosophy.

Ibn Miskawayh (d. 1030) and Naṣīr al-Dīn al-Ṭūsī (d. 1274) produced very elaborate discussions of ethics, and the philosophical psychology which accompanies them displays considerable acuity. God is taken to be the epitome of the religious law which incorporates both spiritual and physical goods. We should obey not only God, but also his representatives on earth, and all those who are superior to us morally. The view of human beings being the representatives of God is particularly attractive to Shī'ite thinkers, who can relate the imam or spiritual leader with the deity in this way.

A particular interesting debate arose in the work of al-Ghazālī (d. 1111) and is his response to an argument produced by Ibn Miskawayh. The latter argues that the religious and moral law is based on what is in our interest, and that we can see what the point of the law is by asking what its point is. Al-Ghazālī replies that the point of the moral and religious law is that it has no point; it is entirely arbitrary and rests on nothing but the will of God. Some people may follow the principles of morality out of some confused idea that they are the right principles, but unless they follow those principles because they believe they are commanded by God to do so, their action is without value. Here al-Ghazālī is using the ideas of an earlier theological debate between the Mu'tazila and the Ash'ariyya on the basis of morality. For the former, morality can be derived from reason, and that is why God establishes it, since he acts in accordance with reason. The Ash'arites argued, by contrast, that morality means nothing more than what God demands of us, and it has no basis apart from that.

It was the Ash'arite view that prevailed in Islamic philosophy. The objectivist account of ethics of the Mu'tazilites was held to suffer from a number of problems. It places huge reliance on the ability of human reason to determine our moral duty. It also implies that religion plays no significant role in determining morality, and that religious law is not an essential part of that morality. Yet the Qur'ān itself points frequently to the significance of guidance for human beings, and although reason

is clearly important in assessing what form of guidance is valid, it cannot replace the authority of God as revealed to his representatives on earth. This notion of human beings being divine representatives is often taken to be important morally, and has implications for how we can behave and what our relationships should be with each other and with our environment in general. It is worth pointing out that the starting-point for working out what our duties as God's representatives on earth are is Scripture, and without divine guidance we would have no idea how to behave. o.l.

O. Leaman, *Brief Introduction to Islamic Philosophy* (Oxford, 1999).

— *Introduction to Classical Islamic Philosophy* (Cambridge, 2002).

**Islamic philosophy.** Originally based on Arabic translations of Greek texts, developed as a syncretic yet systematic body of thought in the Islamic world, from Andalusia to India, from the ninth century to the present. Most works were originally written in Arabic, many in Persian. Though marked during its formative period by Mu'tazila theologians, who were influenced by issues of revelation and reason in Christian theology (e.g. Origen, John of Damascus), Islamic philosophy does not constitute a religion; nor was it the 'handmaiden of theology'. Most practitioners were Muslims of various cultural, social, and linguistic backgrounds; some were notable members of other religions.

*The Formative Period: The Late Eighth to Mid-Ninth Century.* Philosophical activity at this time centred in Baghdad's new Academy ('House of Wisdom'). Supported by the caliphs, notably al-Ma'mūn (reigned 813–33), the school was known for its academic tolerance and freedom of scientific inquiry. Learned representatives of all subject nations participated in the state-endowed centres where a universal world-view was sought to sustain the Empire. Some extremist groups questioned the caliphs' authority, introducing critical political issues (later addressed by theologians such as Bāqillānī and Baghdādī) and theoretical problems (later picked up by Fārābī and Avicenna). Others, drawing upon older traditions (materialist, Manichaean, Jewish, Christian, Zoroastrian, Arabian, and Indian), challenged Islamic philosophy's fundamental doctrine of revealed truths by identifying its supposed contradictions and inconsistencies. The Mu'tazila thus established a set of doctrines regarding anthropomorphism and God's knowledge, creation, prophecy, human free will, and immortality. Greek thought became the most attractive tool for the construction of a defined Islamic theology, providing a rational defence for revealed teachings.

One major thinker of this period was al-Kindī, who was interested in philosophical investigation *per se*. Although upholding the validity of revealed truth, he also proposed its recovery by demonstration. He did not attempt a systematic 'harmonization' of prophecy with philosophy, however, one of the primary goals of the

following period. His main contribution was identifying Greek texts and refining their Arabic translations, some of which he commissioned. They include extensive paraphrases of Pre-Socratic authors; Plato's *Laws*, *Timaeus*, and *Republic*, plus paraphrases of *Phaedo*, and other Platonic texts; most of the Aristotelian corpus except the *Politics*; selected Neoplatonic texts, some incorrectly identified (notably parts of Plotinus' *Enneads* iv–vi, thought to be 'Aristotle's theology'), as well as works by Porphyry (especially the *Isagoge*) and Proclus; plus many other texts and fragments, including elements of Stoic logic and physics associated with the late antiquity schools of Alexandria and Athens; and significant Aristotelian commentaries, notably those of Alexander of Aphrodisias, along with their Neoplatonist interpretations.

Al-Kindī's syncretic approach is based on Neoplatonist theories of emanation and the concept of the One, Aristotelian metaphysics of causality and intellectual knowledge, and Platonic doctrines of the soul and dialectic method. Aristotelian logic was used to investigate Hellenic-defined problems as well as the 'new' set of issues fundamental to Islamic revelation. Al-Kindī argued for creation *ex nihilo* as a type of emanation, but not natural causation where the First Being is created simply by God's eternal will. He also argued for immortality of the individual soul as the rational explanation for resurrection. His arguments as well as some of their corollaries were later rejected or revised, but his writings, especially in theoretical philosophy, represent the foundations of Islamic philosophy.

*The Creative Period: The Ninth to the Eleventh Century.* The rise of anti-rationalist sentiments proclaimed by al-'Ash'arī (912), along with political events and populist movements, curtailed Islam's spirit of scientific discovery, while radical advancements were taking place in areas such as computational mathematics and astronomy. Two notable philosophers of this period, al-Fārābī and Avicenna, met the challenge by harmonizing reason with revelation, introducing innovations, and refining philosophical technique and analysis. There are three seminal innovations of this period:

1. Al-Fārābī's commentaries on Aristotelian texts of the *Organon* define a standard Arabic logical terminology and improve formal techniques. His independent technical works, such as *Utterances Employed in Logic* and the *Book of Letters*, describe a new linguistic structure and examine 'how many ways a thing is said'.

2. Al-Fārābī creates the first works on Islamic political philosophy within the context of Islamic religion. His *Attainment of Happiness* and the *Political Regime* are novel in their technical discussions of prophecy and creation, and the roles of the lawgiver and divine law in the city. Redefined metaphysically as the 'science of politics', these philosophical domains are promoted as the means for attaining happiness and the establishment of just rule, stipulated to be the ultimate purpose of philosophy. Fārābī's most popular work, *The Ideas of the Inhabitants of the*

*Virtuous City*, furthered the doctrine of just rule by encouraging philosophical discourse on prophecy and law, which affected the beliefs and actions of the entire Muslim community. The text describes an epistemology based on Aristotelian theories of intellectual knowledge and active intellect wherein human prophetic knowledge is not restricted by God's will. Thus any person devoted to philosophical inquiry may gain access to unrestricted, objective knowledge, or union with the active intellect. This theory of knowledge, later refined and reformulated by Avicenna into a unified theory of prophecy, is one of the most significant components of Islamic philosophy. It informs the Shī'a political doctrine in the sixteenth century and its later refinements, where the 'Virtuous City' is invoked to describe divinely inspired just rule by the philosopher-ruler, then called 'jurist-guardian'.

3. Avicenna defines Islamic Peripatetic philosophy in the first independent, comprehensive corpus on the subject. Most of his texts were later translated into Latin, and their arguments used by scholastic authors from Bacon to Ockham. Avicenna is distinguished from previous thinkers by his recomposition of the entire range of philosophical subjects, adding fresh arguments and refining earlier ones. He incorporates political theory into a reconstructed metaphysics, describing prophecy as a generalized theory of intellectual knowledge capable of describing mystical experience. His ontological distinction between contingent and necessary being became accepted doctrine. He is the first thinker to state the psychological theory that an individual suspended with no spatial or temporal referents will necessarily affirm his soul as an act of self-identification and that the soul's active imagination is responsible for the feeling of pain or pleasure after separation from the body. These novel concepts were considered by Sohravardī, the founder of Illuminationist philosophy, as essential components in the chain of being. Avicenna's theories of prophetic knowledge, based on notions of 'holy intellect' as well as Koranic exegesis, were accepted by religious scholars, especially in the post-medieval period. Avicenna's students, including Gorgānī and Bahmanyār, become identified as Peripatetics, constituting Islam's first 'school' of philosophy, as such.

*The Period of Reconstruction and Reaction: The Twelfth to the Fifteenth Century.* Several political and intellectual currents run through this period, which is also marked by the rise of al-Ghazālī's 'Ash'arite theology. After the Abbāsīd caliphate was overthrown by Mongol conquests (thirteenth century), Islamic philosophy subsisted in multiple intellectual centres, which had also spread to the West. In the fourteenth century, fundamentalist traditionalism was promulgated through the eclectic polemics of Ibn Taymiyya, who called for believers to rid Islam of all forms of innovation.

Two main types of philosophical writing emerged in Andalusian centres such as Cordoba and Seville in the twelfth century: the philosophical writings of Ibn Bājja (d. 1138), Ibn Ṭufayl (d. 1185), and others extend al-Fārābī's

political doctrine; and the Aristotelian commentaries of Averroës, called 'the Commentator' in Latin texts.

Ibn Bājja interprets al-Fārābī's political doctrine in a pessimistic light. Although upholding the virtues of the ideal city, he considers it non-existent, emphasizing the dark aspect of actual cities in which the populace lives in the cave (after Plato) but perceives only shadows. Unlike al-Fārābī, he considers the city incompatible with the philosopher's need for solitude. He supports Avicenna's idea of experiential knowledge, or 'enlightenment', through conjunction with the active intellect (*Directives and Remarks*, ix, x), but considers the value of 'prophetic' knowledge to be individual not collective.

Ibn Tūfayl also extends al-Fārābī's political doctrine in a pessimistic direction. Inspired by Avicenna's philosophical allegories and mention of an 'Eastern Philosophy' with non-Peripatetic 'wisdom', he created an allegory in which a wise hermit from a deserted island comes to civilization with the gift of theoretical knowledge but fails to save the multitudes (translated in English as *The Improvement of Reason* (London, 1708)).

In the East, the philosophy of illumination, constructed by Sohrawardī, represents Islamic philosophy's most successful response to this period's reactionary stance. Commentaries by Mollā Ṣadrā and others extend its political doctrine to other areas. Sohrawardī offered a clear and accessible system, calling for the enlightened rule of the divinely inspired, appearing in every age, who manifest signs indicating knowledge and power, and thus become authorities who serve as rulers or 'hidden' guardians of justice. The sixteenth-century Shī'a scholars readily identified with the philosophy of illumination and used it in the formulation of Shī'ite political doctrine. It remains one of the three accepted schools of Islamic philosophy to date.

The philosophy of illumination includes many technical innovations. In logic these include definition of an independent modal operator 'necessarily/it is necessary that' in defining a superiterated modal proposition as the form to which all other propositions are reduced; the impossibility of the 'necessary and always true' validity of the universal proposition because of the necessity of future contingency; and reduction of the figures of syllogism. The principal epistemological innovation was a unified theory of knowledge capable of explaining all types of knowledge—prophetic, inspired, and sensory. In a highly innovative manner, Sohrawardī posits a reformulated proposition of the sameness of knowing and being as the foundation for a unified epistemological theory. A most general concept of 'knowing' is assumed, for which the verb 'apprehension' (*idrāk*) is used. It is then stated that any type of 'knowing' is that the 'knower' and the 'known', as the apprehender (*mudrīk*) and the apprehended (*mudrak*), the sensing and the sensed, the intellect and intellect, and so on, form a sameness relation. Such a relation is identity preserving one-to-one correspondence among each and every member of the set of all 'knowers' and the set of all 'knowns' in any type of 'know-

ing'. New ideas in ontology and cosmology involved cosmological light essences and time-space continuum, where measured time and Euclidean space apply to the corporeal realm, and time without measure and non-Euclidean space define a separate realm called *mundus imaginalis*. The notion of an intermediary realm of imagination, the *mundus imaginalis*, was a crucial development, especially as elaborated by illuminationist commentators Shahraz'ī (thirteenth century), Ibn Kamm'na (thirteenth century), Davvānī (d. 1501), Dashtakī (d. 1542), and others, whose work contributed to the origins of Islamic religious philosophy.

During the second half of the twelfth century, a new genre of philosophical works by theologians emerged which continue to be taught today. The most significant impetus for these were al-Ghazālī's demands on theologians to defend the faith against rational philosophy by use of philosophical technique and language. Two texts by Athīr al-Dīn Abharī (d. 1264), *Guide on Philosophy and Commentary on the Isagoge*, established the range of subjects and language, and elucidated the forbidden aspects of philosophy. These include Avicenna's cosmic motion and Sohrawardī's time-space 'will-less' continuum theories of the propagation of lights. The *Guide on Philosophy* is divided into three parts—logic, physics, and metaphysics—consisting of *metaphysica generalis* and *metaphysica specialis*. The most popular commentary on this work, written in 1475 by Mir Husayn Maybudi, is customarily read along with the text. *Commentary on the Isagoge*, a primer in logic, is also read with commentaries, such as that by al-Fanārī (d. 1470), often along with glosses, superglosses, and versifications.

While numerous works of this genre continue today, most tend to lack the philosophical depth and creativity revived in the sixteenth century by Mollā Ṣadrā and extended by Mollā Hadī Sabzevārī (d. 1878). Exceptions include the treatise *Sun-Radiance (Shamsiyya)* by Dabīrān Qazvīnī (d. 1276), presented in Nicholas Rescher's *Temporal Modalities in Arabic Logic* (Dordrecht, 1967), which includes one of the most precise pre-modern definitions and comprehensive listing and discussion of simple and compound modal propositions and modalities, their contradictions, rules for their conversions, as well as an intricate analysis of validating modal syllogisms. Qazvīnī's text, together with its commentary by medieval theologian-philosopher Taftāzānī (d. 1389), author of *Refinements on Logic and Theology*, became a textbook.

*The Period of Revival: The Sixteenth to Early Seventeenth Century.* This period coincides with Safavid rule in Iran, which established Shī'ism as the state religion, primarily as a defensive measure against conquests by the Ottoman Sunnī Empire. A new world-view with rational but wider appeal was sought to re-establish the ruling Safavid's legitimacy and to defend his position against the better-established theology and judicial doctrine of the Sunnī. Similar to the academies of the formative period, the Safavid's well-endowed centres supported scholarship

and scholastic freedom. The results were complex and far-reaching. Major outcomes were the creation of Shī'ite thought based on multiple sources, possessing reason and defining a political-philosophical place for al-Fārābī's 'learned' reformers of law and for the role of a supreme informed source, whose authority was established by unified epistemological theories combining Peripatetic and Illuminationist concepts; and a parallel judicial tradition based on revealed authority. This period of revival led not only to the recovery of nearly the entire range of earlier philosophical works, but also to the third major synthesis and recomposition of philosophy, which proved consistent with theories of revelation and was accepted by most contemporaneous religious scholars. While most problems in earlier syncretic works continued to be debated, many were also added, refined, and redefined to reflect this period's preoccupation with uniform theories.

Foremost thinkers of this period included Mīr Dāmād; his acclaimed pupil Mollā Ṣadrā, and other members of the School of Isfahan; and Mīr Fendereskī and Shaykh Bahā'ī, who excelled in scientific and mathematical discoveries. All contributed to what became a systematic reconstruction defined by Mollā Ṣadrā as 'metaphysical philosophy', which continues to this day as the third independent school of Islamic philosophy. Structurally distinguished from both the Peripatetic and the Illuminationist systems, metaphysical philosophy is principally characterized by a singular emphasis on the question of being. Logic is separated and discussed in independent works which include the subject-matter of the traditional *Isagoge*, exclude the *Categories* and the *Poetics*, and are divided into three parts: semantics, formal techniques, and material logic. Mollā Ṣadrā's own independent *magnum opus* on metaphysical philosophy is the voluminous work *The Four Intellectual Journeys*. This text begins with the study of being, and reduces the traditional subject of physics primarily to the study of time, modality, and motion. A modified theory of five categories is introduced through a unified theory named 'motion-in-category substance' (also called substantial motion).

This further serves to explain a uniform theory of being, further employed to define a unified theory of knowledge, finally explaining creation as a non-natural, non-causal 'substantial motion' away from the One in durationless time, a concept taught by Mīr Dāmād, who is widely known for the theory of creation defined as 'eternal becoming' (*ḥudūth dahrī*). Among the philosophical problems extensively discussed, and reformulated and refined by Mollā Ṣadrā, the following stands out: the reformulated Illuminationist unified epistemological theory of knowledge by presence, where the foundation proposition is stated as the unity of the intellect and the intellect.

The initial creative and innovative phase of this period soon deteriorated, particularly in the areas of science and technology. Philosophical activity, however, continued to take place, mostly among members of the now-defined clergy groups.

*The Post-medieval Period: The Early Seventeenth Century to the late Twentieth Century.* The final period in Islamic philosophy may be distinguished by a scholastic tradition that continues to the present. One of its main characteristic components is the acceptance of works by religious scholars, especially those of Mollā Ṣadrā. Although a large number of philosophers from this period have not been studied completely, a recent biographical compilation lists some 400 individuals, each with several works on specific philosophical and logical subjects. Most of the authors are identified as members of the clergy class, some of whom also assumed juridical duties. This scholastic tradition marks the final acceptance of philosophy by religion. Mollā Ṣadrā incorporated Fārābī's idea of learned reformers with Sohrawardī's 'inspired sources of authority' into a unified theory. Thus, the select religious scholars, possessing knowledge and inspiration, were confirmed as the legitimate 'guardians' of just rule. This unified theory also became the final channel for the continuity of philosophy. Although the study of higher levels of philosophy is still restricted, the scholastic tradition incorporated aspects of philosophy into the school curricula. One of the first 'primers' studied by beginning students includes a section on logic. Some of the Shī'a doctrines that accept the role of independent reason (*ijtihād*) in principles of jurisprudence have been central in the scholastic tradition of Islamic philosophy in Iran from the sixteenth century—which marks the final harmonization of philosophy with religion—to the present. This is exemplified by many prominent contemporary clergy known and revered for their philosophical teachings, such as Abol-Hasan Qazvīnī, Allāmeḥ Husayn Tabātabā'ī, Mehdi Ashtiyānī, Jalāl Ashtiyānī, and Mehdi Ha'iri Yazdī. The latter also turned to the systematic study of contemporary analytic philosophy, receiving his doctorate in philosophy in Toronto in 1979. His book *The Principles of Epistemology in Islamic Philosophy: Knowledge by Presence* (Albany, NY, 1992) is the first serious work that describes certain key problems of Islamic philosophy within a contemporary analytic frame. This type of scholarship marks the beginning of a new trend in which some Islamic philosophers are studying various Western philosophical systems and methods and making attempts to explain them within the frameworks of one or more of the three Islamic schools of thought. These scholars are also attempting to open a dialogue with Western practitioners, thus reaching beyond the limits of previous historical descriptions and generalizations by Muslims and Orientalists. **Islamic philosophy today.** Within modern times a number of themes in Islamic philosophy have become much discussed. One topic is how distinct that philosophy ought to be from other types of world philosophy, in particular systems of thought not based on religion. Another, related issue is what relationship Islamic philosophy should have with Western thought. Further, some thinkers in the Islamic world have taken general philosophical ideas and have applied them to what they see as the leading issues of the day within their cultural environment. Finally, traditional ways of doing philosophy have continued, albeit with some importation of wider theoretical machinery.

An issue which philosophers have dealt with at some length is the relationship that the Islamic world should have with the West. This issue is of course one that has existed for some time, but arose with particular force from the nineteenth century onwards with the success of colonialism, imperialism, and Zionism in apparently gaining supremacy over the Islamic world. In earlier periods the Islamic world had represented a superior cultural and material force in the world, but over the last few centuries it had radically declined, and the reasons for this apparent decadence were, and continue to be, much discussed by philosophers.

Of great significance was the *Nahda*, or Islamic renaissance, which started in the nineteenth century and really took root in Egypt. The idea behind it was to maintain a distinctive Islamic identity within the Islamic world, yet at the same time incorporate modern scientific and cultural values, where these are compatible with Islam. The two leading thinkers were Jamal al-Din al-Afghani and Muhammad 'Abduh, who both argued that Islam is perfectly rational and in no way opposed by Western scientific and cultural ideas. The Egyptian philosopher Mustafa 'Abd al-Raziq extended their ideas and suggested that all the main Islamic schools of thought, even the mystical schools of Sufism which were much suspected by the *Nahda* thinkers, are inherently rational and in no way opposed to the science and rationality which are such an important feature of Western culture. Some Arab thinkers have been more sceptical of this point. Muhammad 'Abd al-Jabri is critical of much traditional Islamic thought, arguing that we need to analyse clearly the reasons for the decline of the Arab world. He calls for a deconstruction of the clash between those who emphasize the glory of the Islamic past and those who praise Western modernity. What is required is a liberation of the Arab consciousness from its traditional ties with its Islamic heritage, yet also a cautious attitude to the ideas which have come from the West and are part and parcel of foreign domination.

Fu'ad Zakariyya agrees that Arab failure is linked with the failure to criticize tradition, while Fazlur Rahman stresses the links between Islam and social progress. Islamic traditionalism is opposed to Islam itself, since the religion is in favour of economic and social development and change. The attempt to fix a rigid, stultified version of Islam as the ideal is to fail to grasp the ways in which science and technology can improve the life-style and moral welfare of the mass of the community. Zaki Najib Mahmud is not convinced that philosophy has much to contribute to this debate. Hasan Hanafi is one of the many contemporary Arab philosophers who use a novel philosophical technique, in his case phenomenology, to develop a traditional Islamic concept, that of *tawhid*, or unity. He suggests that Islam is dynamic enough to broaden this notion so that it can provide a generally acceptable principle of unity and equality for everyone. He is also critical of the idea of Western progress, suggesting that the West itself is now entering a period of decadence that will require an infusion of ideas from elsewhere, and in particular the East. The idea that Islam is based on fixed rules he finds unacceptable; it is based on a revelation appropriate at its own time and place, but now other interpretations of the message should be adopted to fit present conditions and represent more accurately the dynamism of Islam.

It is often said that philosophy declined in the Islamic world after the death of Ibn Rushd in the twelfth century, but this is far from the truth. Today there is a lively philosophical presence in most of the Islamic world, often with the incorporation into Islamic philosophy of ideas like Logical Positivism, hermeneutics, pragmatism, Hegelianism, and so on. Philosophy continued very vigorously in the Persian cultural world, especially the philosophy of Ibn Sīnā and the Ishraqī (Illuminationist) thinkers developing and commenting on al-Sohravardī and Mollā Ṣadrā. In Iran philosophy has now moved away from the theological school, the *madrasa*, into the university, and a good example is provided by the thought of Mehdi Ha'iri Yazdī. He develops a complex theory of knowledge by presence, a form of knowledge which is incorrigible and which grounds our other knowledge claims using material from both Ishraqī thinkers like al-Sohravardī, and the modern philosopher Wittgenstein. 'Ali Shariati uses the ishraqī school's intermediary position between mysticism and Peripateticism to develop a view of the human being as having God at its essence while maintaining the scope to determine its own form of existence. The notion of unity (*tawhid*) is seen as therapeutic; it is designed to establish both personal and political justice and harmony. He interprets the main figures of Shi'ite Islam as models for us not only in a personal sense but also to bring about more progressive social ideals; he sees them as fulfilling archetypes which have always been regarded as desirable. Over time the archetypes themselves have not changed essentially, but they have changed in appearance, to make them more suitable to the local audiences for whom they are designed.

This link of the personal and the political is significant in modern Persian thought. It is well represented by Ayatollah Khomeini, who overthrew the Shah and became both the spiritual and the temporal ruler of the Islamic Republic of Iran. He argued that religion does not just apply to private morality but must also be applied to the state as a whole, and the religious authorities should be in charge of the state, since only then will the community be rightly guided. The school of Qom, of which he was a member, contained also Muhammad Hossein Tabataba'i, Murtaza Mutahheri, and Muhammad Taqi Misbah Yazdi, all important religious Shī'ite thinkers who none the less were far from suspicious of intellectual thought coming from the West. They argued that traditional Islamic philosophy can only gain by opening itself to some of the important philosophical achievements created outside the Islamic world. But they uniformly disapproved of the work of Abdul Soroush, who took a rather critical view of religion when he applied what he took to be the arguments of Popper, Moore, and Wittgenstein to them. Soroush was opposed by Sadiq Larijani, the chief representative of the school of Qom, who suggested that Soroush had misapplied the theories of Popper, Stalnaker, Watkins, and Hempel. It is interesting that the debate took the form not of religion as opposed to reason, but of what the correct philosophical view should be, and then how it should be applied to religion. Soroush upset not only the school of Qom, but also the supporters of Heidegger, so he was quite isolated intellectually in Iran.

Perhaps the best-known Iranian thinker outside the country is Seyyed Hossein Nasr. He is highly critical of Western science, praising some of its achievements but pointing to the ecological consequences of a world-view which does not acknowledge the presence of God at the centre of that view. Science without spirituality is without limits, since there is nothing which it holds sacred, and it bases itself entirely on measurements of quantities, not on the quality of existence. More spiritual philosophies are harmonious and integrative; they embed spiritual values in the technological agenda, and so make ecological disasters less likely. For him the question is not what the East should take from the West, but vice versa. Along with this view he has established in some detail the theoretical presuppositions of Sufism, the school of mysticism in Islamic thought, and his historical accounts of this doctrine have played a large role in its increasing domestication outside of the traditional Islamic world. **Italian philosophy.** A self-consciously Italian philosophical tradition only developed in the nineteenth century

with the growth of the movement for national unification. Since that time, Italian philosophy has been dominated by the rival schools of \*idealism and \*positivism, with the important Italian current of \*Marxism drawing on both. However, each of these camps has laid claim to a native inheritance going back to the Renaissance, and their selective interpretations of their intellectual forebears still find an echo in some of the standard histories of Italian philosophy. The idealists traced a lineage from the Platonist \*humanism of Ficino and Pico della Mirandola in the fifteenth century, through the rationalist \*pantheism of Bruno and the Baconian utopia of Tommaso Campanella (1568–1639), to Vico and Vincenzo Cuoco (1770–1823) in the eighteenth century, which they assimilated to their own reading and critical elaboration of Kant and Hegel. The positivists went back to the more scientifically orientated Paduan followers of Aristotle, such as Pietro Pompanazzi (1462–1525), and found a line of descent that included the mechanistic \*materialism and sensationalism of Bernardino Telesio (1509–88), Galileo, Machiavelli, and the social reformers of the Italian Enlightenment, such as Vico (who they also claimed), Antonio Genovesi (1712–69), and Gaetano Filangeri (1752–88) in the south, and the Milanese group of Cesare Beccaria (1738–94), Melchiorre Gioja (1767–1829), and Gian Domenico Romagnosi (1765–1835), who were profoundly influenced in their turn by the \*empiricism of Locke and Hume and the associationist and utilitarian doctrines of Helvétius, Condillac, and Bentham. One theme ran through both accounts that persists up to the present: the dialectical tension between the two Romes, between Pope and Emperor, the active and the contemplative life, social emancipation and heavenly contemplation.

The two main figures of the positivist school in the nineteenth century were Carlo Cattaneo (1801–69) and Roberto Ardigo (1828–1920). The first drew on the reformers of the Milanese Enlightenment, Vico and Comte, and urged the need for philosophy to adopt the methods of the natural sciences and develop into a social science. Ardigo, a former priest, became the apostle of a theistic Newtonianism, in which the same mechanistic 'forces' explained all physical and psychological phenomena. In the twentieth century, positivist thinking was continued by the Italian school of criminology, particularly Cesare Lombroso (1835–1909) and Enrico Ferri (1846–1929), historians and social scientists such as Pasquale Villari (1826–1917), some early Marxists, notably Achille Loria (1857–1943), and by the pioneering political sociologists Vilfredo Pareto (1848–1923) and Gaetano Mosca (1858–1941). There were also a number of important philosophers of science within the empiricist tradition, notably Giovanni Vailati (1863–1909) and Mario Calderoni (1879–1914).

Amongst the idealists, Antonio Rosmini-Serbati (1797–1855) and Vincenzo Gioberti (1801–52) mixed the Italian Neoplatonist tradition with \*neo-Kantianism, attributing in different ways the activity of the Kantian categories of the understanding to our intuition of the divine

being. During the revolutions of 1848 they placed their philosophies at the service of the Catholic-liberal supporters of Pius IX as a rival to the humanistic and democratic nationalism of Giuseppe Mazzini (1804–72), who identified God with the people, but were condemned by conservatives for heresy. Whilst their thinking was eclipsed in the north by the positivist tradition in the latter half of the nineteenth century, it was critically elaborated and secularized by the southern group of Hegelian scholars, particularly Augusto Vera (1813–85), Bertrando Spaventa (1817–82), and Francesco De Sanctis (1817–82). They also sought to integrate the main currents of contemporary European philosophy with the Italian tradition. Spaventa argued that there had been a ‘circulation of European thought’ in which Italian philosophers had either pre-empted or independently conceived all the main elements of modern European philosophy, with the Platonists representing the rationalists and the Aristotelians the empiricists, and Campanella and Vico anticipating the resolution of these two schools in Kant and Hegel respectively. This tradition was continued by Croce and Gentile, who both

evolved explicitly historicist doctrines and whose ideas dominated Italian philosophy in the early twentieth century. Gentile became the official philosopher of \*fascism, and the idealist school also had by far the greatest influence on Italian Marxism, Antonio Labriola (1843–1904) being a pupil of Spaventa’s and Gramsci a sympathetic critic of Croce, although an important positivist strand also existed, of which Galvano della Volpe (1895–1968) and Colletti were the main exponents.

Whilst some contemporary philosophers have carried on the positivist tradition, such as Bobbio in law and politics and Ludovico Geymonat (1908–91) in the philosophy of science, most Italian philosophers, such as the existentialists Niccola Abbagnano (1901–90) and Luigi Pareyson (1918– ) and the post-modernist Vattimo, remain original reworkers of the German philosophic tradition, although their attention has shifted from Kant and Hegel to Nietzsche, Husserl, Jaspers, and Heidegger. # J

**Jackson, Frank** (1943– ). Australian philosopher of mind, logic, and metaphysics who is noted for his adherence to a \*representative theory of perception and for his work on \*conditionals. Jackson is unusual amongst contemporary philosophers in defending the existence of \*sense-data, arguing that an adequate account of the truth-conditions of statements about how things 'look' or otherwise 'appear' to us phenomenally requires us to admit reference to such items. In his 1986 essay 'What Mary Didn't Know' he introduced a now-famous thought experiment about knowledge gained through phenomenal experience.

Jackson's work on conditionals builds upon Grice's theory of the indicative conditional as a statement whose truth-condition is that of the so-called material conditional, making 'If *p*, then *q*' true if and only if 'Not both *p* and not-*q*' is true. In order to defuse apparent counter-examples to this in natural language, Jackson gives an account of the assertibility-conditions of conditionals which explains why we do not always assert a conditional whose truth-condition we believe to be satisfied. E.J.L.

**Jacobi, Friedrich Heinrich** (1743–1819), German pietist philosopher of 'faith and feeling'. He was the sharpest of the critics of the intellectualistic German \*Enlightenment, represented chiefly by Wolff and Kant. His philosophy and character were important in moving German philosophy and literature to a somewhat mystical and Romantic *Weltanschauung*.

From Hume's scepticism Jacobi inferred the inadequacy of abstract systematic thought and the practical necessity of irrational belief (*David Hume über den Glauben* (1787)). The use of pure reason in philosophy, he held, leads inevitably to Spinozism (then almost universally condemned as pantheism and fatalism). By revealing that Lessing shortly before his death had confessed to being a Spinozist, Jacobi caused a great scandal in making such an injurious charge against the universally admired Lessing, and precipitated the so-called *Pantheismusstreit* between

himself and another anti-Spinozist who was Lessing's best friend, Moses Mendelssohn. The *Streit* was carried on in books, articles, and personal correspondence circulated and published without permission. Each participant was egged on by friends and disciples, and the ensuing quarrel was not an edifying spectacle. Mendelssohn's death in 1786 at the height of the dispute prompted allegations that Jacobi had caused it; these slanderous charges exacerbated the quarrel and gave it an emotional depth and a personal drama in which nothing less than the legitimacy of the entire Enlightenment was at stake. Hamann, Herder, Goethe, and Kant were soon involved in the battle.

Jacobi and Mendelssohn agreed that pure reason is not a sufficient instrument for metaphysics and that to avoid the abyss of Spinozism something else is needed: for Jacobi it was an act of faith (*salto mortale*, he called it), for Mendelssohn it was common sense. Each party appealed to the practical (i.e. the moral) aspect of Kant's philosophy. Seeing both participants in the controversy as enemies of reason, 'the touchstone of truth', Kant in *What is Orientation in Thinking?* (1786) rejected both of the opposing views. Jacobi was one of the most effective of Kant's critics, famous even in the twentieth century for his epigram 'Without the \*thing-in-itself I cannot enter the Kantian philosophy, and with it I cannot remain'. **Jainism.** Atheistic school of \*Indian philosophy much older than Buddhism (dating back to the eighth century BC) and still alive. The ethical principle of non-violence is taken by Jainism to an extreme in both practice and theory. To make peace among the endlessly disputing schools of Indian philosophy, Jaina philosophers made the metatheoretic move of non-exclusivism, which is spelt out as a seven-valued logic, illustrated as follows:

- (1) From one perspective, the self is permanent.
- (2) From another, it is not.

- (3) From a joint perspective, it is and is not so (successively).  
 (4) From a neutral one, it is indescribable.

Adding the combinations of each of 1, 2, and 3 with 4, you get seven theses, each of which is objectively correct in that it confesses its own conditionality. Jainism accepts the notion of eternal souls which assume the form of a human body and are repeatedly reborn until they are liberated from pleasurable and painful effects of egoistic actions called \*karma. Jaina logicians affirmed the existence of the external world, impugning Buddhist idealism. A.C.

\*Buddhist philosophy; atheism and agnosticism.

B. K. Matilal, *The Central Philosophy of Jainism* (Ahmedabad, 1981).

**James, William** (1842–1910). American philosopher and psychologist, son of Henry James the Swedenborgian religious thinker, brother of Henry James the novelist, and Professor of Psychology and Philosophy at Harvard. Only some of his many concerns can be considered.

1. *The Principles of Psychology* (1890) is officially committed to the scientific study of mind, conceived as the ascertainment of 'the empirical correlation of the various sorts of thought or feeling with definite conditions of the brain'. Although ostensibly avoiding metaphysics, much of it is as philosophical as psychological. Avoiding metaphysics means mainly assuming the existence of a physical world independent of mind, ignoring any philosophical case against this scientifically necessary presupposition. Four themes call for notice here.

(i) For James mind is identified with \*consciousness, known primarily through \*introspection; scientific psychology explores its physical basis and biological function. This is evidently to assist the organism to cope with its environment more flexibly than can inherited behavioural patterns. The criterion for the presence of mind is, therefore, the occurrence of behaviour which reaches the same goal, as circumstances alter, through differing means.

James thinks it unlikely that such behaviour could ever be explained mechanistically. While consciousness is too obviously a distinct reality in his eyes for anything like the brain–mind \*identity theories of today even to be considered, James carefully examines the automaton theory (\*epiphenomenalism) but dismisses it (with debatable logic) as failing to explain why consciousness has been picked out for development by natural selection. (James was strongly influenced by Darwinian ideas.) The old-fashioned idea of a distinct soul is better, but James's own view is rather that 'the stream of consciousness' is generated afresh each moment by the current state of the whole brain and reacts back on it, and hence on behaviour, with a modicum of free spontaneity (a view anticipative of the positions of both Whitehead and Roger Sperry).

(ii) This notion of the \*stream of consciousness (or thought) is the most famous theme in *The Principles of*

*Psychology*. Among its varied heirs are stream-of-consciousness literature (e.g. Gertrude Stein), aspects of Husserlian phenomenology, and Whiteheadian process thought. Consciousness comes in a continuous flow without sharp breaks or clearly distinguishable components. Thus experience is always of a specious present, a stretch of sensible duration in which the just-past still figures along with the dawning of the future. As against traditional \*empiricism, for which a state of consciousness is a complex of individually repeatable impressions and ideas, James contends that no item of consciousness is ever exactly repeated. I may perceive or think of the same thing twice but never by way of numerically or qualitatively identical representations.

(iii) James distinguishes between the I and the Me. The I is the ultimate thinker, the Me is the object of all those concerns we call selfish and which the I and its organism primarily seek to preserve. The Me divides into the material me, my body and my possessions; the social Me (or Mes), the image (or images) I present to the various communities to which I belong; and the spiritual Me, which covers both my mental capacities and achievements, and some supposed inner source thereof. As for the ultimate I, which does the thinking, James, having dismissed a permanent ego, decides that (if there is such a thing at all and not simply each total conscious state in turn) it is the momentary thinker of the total present thought. Personal identity through time consists in the fact that the I of one moment adopts the Mes and Is of earlier times by the peculiarly warm and intimate way in which it recollects them. (James pays particular attention to cases of multiple personality in developing his account.)

(iv) The subject of \*free will was of immense emotional significance to James. He was rescued from a phase of serious psychological depression in 1879 partly by discovering Charles Renouvier's defence of free will as 'the sustaining of a thought because I choose to when I might have other thoughts'. This is James's own view. Consciousness cannot determine what ideas are presented to it but, by effortful selective direction of attention, can decide which will affect behaviour. This power can neither be proved nor disproved scientifically, but belief in it is a legitimate exercise of 'the will to believe'.

James's naturalistic approach (and his role at Harvard) contributed significantly to the development of experimental psychology in America (though he had no love of experiment himself); his treatment of the various types of self has had an influence on social psychology; and his introspectionist investigations enormously influenced Husserlian \*phenomenology and its offshoots. It should be noted that though James rejects materialism, in any ordinary sense, he does take what might be called a phenomenological materialist view of many mental processes, seeing them as the consciousness of physical states, as in the \*James–Lange theory of the emotions or his replacement of the Kantian 'I think' as the constant in experience by the 'I breathe'.

2. The best known of James's purely philosophical works is *Pragmatism* (1908). James takes over from C. S. Peirce the idea that the meaning of a concept lies in its practical bearings but puts it to different (not necessarily worse) uses. Truth, for James's \*pragmatism, consists in useful ideas. Their utility may lie in either the power to predict experience they confer or their encouragement of valuable emotion and behaviour. Obvious objections to this appear less strong when it is realized that James's account incorporates what is currently called an externalist critique of inherent intentionality (sometimes expressed as the rejection of the very idea of consciousness as opposed to experience). Thus an idea (*qua* piece of 'flat' experience) is only about something to the extent that it produces behaviour fitted to deal with it if it exists, and is true only if it does so. (Thus my belief that God exists requires a God it helps me deal with to be true.) This was a response to his colleague Royce, who claimed that only through the mediation of a divine mind can thought be linked to definite external objects and thus enabled James to avoid the absolute idealism to which he had previously felt unwillingly forced. Actually James's pragmatic account of truth is the fulfilment of a variety of strands in his prior thought and takes somewhat different forms according to which is uppermost. Among these are Peirce's operationalism, Royce's account of intentionality, and his own doctrine of the will to believe.

3. James's other chief philosophical doctrine is radical empiricism, the view that the ultimate stuff of reality (or at least all knowable reality) is pure experience. When the natures or qualia which compose this occur in one kind of arrangement they constitute minds, when in another, physical things. (The clash with the earlier denial of repeatable components of consciousness is modified in his final pluralistic metaphysics.) This relates to pragmatism because knowledge is conceived as the way in which the experience composing a mind leads it to successful negotiation with experience beyond itself (whether in a physical or a mental arrangement). In *Essays in Radical Empiricism* (a posthumous collection of 1904–5 articles) James oscillates between various radical empiricist accounts of the physical world, a phenomenalist view for which the physical consists in possible experience, a 'new realist' position for which it consists in sensory vistas only some of them in minds, and the panpsychist view that the physical consists in its own inner experience of itself. Upon the whole he seems to have thought the last the final metaphysical truth and the second the best analysis of our ordinary conception of things.

4. An inherited concern with religious issues was central to James's thought throughout his life. *The Varieties of Religious Experience* (1902) studies the phenomena of mysticism and \*religious experience with a view to an eventual empirical assessment of their validity, a concern which also led to James's substantial involvement in psychological research, while later works, such as *A Pluralist Universe* (1909), after sharply attacking the metaphysical \*monism of absolute idealists like Royce and Bradley,

develop a mystical pluralistic metaphysics in which a 'finite God', or more interestingly a 'mother sea of consciousness', plays some of the roles of an infinite God or Absolute, while leaving us an independence we are refused by monism, and avoiding the apology for evil which it, along with orthodox \*theism, imposes. Death prevented the completion of a final working-out of his metaphysics, but *Some Problems of Philosophy* (1911), which particularly focuses on the nature of relations and continuity, taken with other works, sufficiently exhibits its main outlines.

5. In these later works James allied himself with Henri Bergson in arguing that conceptual thought cannot do proper justice to reality. This arises largely from the fact that concepts can only provide a static picture of a world which is essentially dynamic. (It was partly by exploiting this, he argued, that absolute idealists promoted their specious claim that the familiar world of contingency and change is somehow unreal, and that Reality proper consists in a static \*Absolute.) This is all right so long as that static picture is used to guide our dynamic dealings with things, but it leads to trouble when we expect it to provide a real grasp of the nature of its object. James's treatment of the limitations of conceptual thought is related to his pragmatic conception of truth in a somewhat curious manner. \*Truth, he argued, as a pragmatist, is no mere copy of reality in another conceptual or verbal medium. There would be little point in it if it were, and we should regard the conceptual symbols in which it consists rather as tools for dealing with (and perhaps sometimes as a worthwhile addition to) reality than as revelations of its essence. None the less, James did hanker for something which could provide a sense of the real essence of things and, since concepts and truth were precluded from this role, it had to be sought in a metaphysics which turns us towards reality in some more intimate way than they do. And here the standard logic by which we organize our concepts is more an obstacle than an aid. We should not look for a revelation of reality from what are merely tools for dealing with it but must do so by sinking ourselves perceptually in the flux and be prepared to give an account of a world in process which will capture something of its essence even if conceptually it contains some apparent contradictions. The specific upshot of these reflections is, in effect, a process philosophy, incorporating an 'epochal' view of time, not unlike that later developed by Whitehead and Hartshorne (who, however, aimed to put into satisfactory concepts what James thought could not be adequately conceptualized). **James–Lange theory of the emotions.** Independently advanced by Carl G. Lange in 1885 and by William James in 1884, it holds that an emotion is the experience of an appropriate physical response to external stimuli. Sadness and anger don't make us cry and strike, rather they are the feeling of doing so. Typical of a note of 'phenomenological materialism' in James, like his substitution of the 'I breathe', as the accompaniment of all consciousness, for the 'I think'.

T.L.S.S.

**Jansenism.** This movement in seventeenth-century French Catholic thought is named after the Fleming Cornelius Otto Jansen (1585–1638), whose treatise *Augustinus* inspired it. Jansenists held that it is impossible to do good works without God's grace and that this grace is irresistible. They adopted a rigoristic position in Christian ethics and criticized their Jesuit opponents for moral laxity. Pascal, who was influenced by and sympathetic to Jansenism, satirized the moral reasoning of its opponents in his *Lettres provinciales*.

**Japanese philosophy.** The first thing to be said about Japanese philosophy is that it does indeed exist. If philosophy is understood as 'thinking about the fundamental structures and meaning of human existence in the world', it has been practised in Japan for well over a thousand years. But the most striking feature of Japanese philosophy is its distinctly multiple heritage, drawing as it does from a variety of Indian, Chinese, indigenous, and—eventually—Western sources. Also, compared with most European philosophies, East Asian thinking tends to focus on particular, concrete issues, and is correspondingly uninterested in abstract speculation.

A few initial remarks—of necessity quite general—may help to orientate the reader to the very different kind of thinking that one finds in the Japanese tradition. Many of the philosophical categories that seem natural in the West are simply not found in East Asian thought. This is in part a function of the structures of the Chinese and Japanese languages, which are quite different from the subject–predicate structure of languages in the Indo-European family. In Chinese, words that would for us be substantives function more as verbs, corresponding to an experience of the world as dynamic process rather than as substance; and in Japanese, so much emphasis is placed on the predicate that the subject is usually omitted altogether, while there are two verbs for 'is–exists'—neither of which is used for the copula.

There are also considerable differences in philosophical rhetoric and style. In a culture that prizes allusive understatement and subtle indirectness in human intercourse, forcefully to advance arguments in terms of clear and

distinct ideas—let alone to attack or defend a philosophical position—would be considered boorish to the point of barbarism. In addition, the ways relative clauses function in Japanese make for even more indeterminacy. But what to the Western student of philosophy might seem impossibly vague may appear to the Japanese reader a pregnant play of multiple meanings that reflects the actual complexities of experience. In general, the line between philosophy and literature is less clearly drawn than in the West.

Most of the dualisms on which Western philosophy tends to be predicated—the intelligible as opposed to the sensible realm, the divine in contrast to the human, culture versus nature, mind (or spirit) in opposition to body (or matter), the logical and rational versus the aesthetic and intuitive—are not prominent in East Asian thinking. And since Japanese philosophy tends to be firmly grounded in *practice*, reading and reflection are best supplemented by engaging in (or at least observing) the relevant practices—going to Japanese theatre, studying Japanese literature, sitting or walking in \*Zen meditation, practising Japanese arts (whether martial or fine), watching Japanese films, visiting Japanese gardens, or even eating in traditional Japanese restaurants.

A major reason for the late start of philosophical thinking in Japan was that the indigenous language lacked a system of writing. When the Japanese began 'importing' Chinese culture around the fifth century, one of the first things they took over was the ideographic system of written Chinese. Three major philosophies were embodied in the texts that were brought from China over the next few hundred years: \*Confucian, \*Taoist, and \*Buddhist thought, all of which—together with the indigenous religious world-view of Shinto—shaped the subsequent development of Japanese thought. A major figure in the introduction of Chinese and Indian culture to Japan was Kūkai (774–835), founder of an esoteric school of Buddhism deriving from Indian tantrism. Like many great Japanese thinkers, Kūkai was a man of many talents and a paradigm of the religious thinker who is simultaneously beyond the everyday world and fully engaged in it. He thus exemplifies two general traits of Japanese philosophy: it has a strong religious component, while being inherently embodied in practice.

Several centuries later, two other philosophically fertile schools of Buddhism came to prominence, the first being the 'Pure Land' Buddhism founded by Hōnen (1133–1212) and his disciple Shinran (1173–1262). The other was Zen, which grew out of Chan Buddhism in China. The introducers into Japan of the two major Zen schools were Eisai (1141–1215) for the Rinzai school and Dōgen (1200–53) for the Sōtō school. Of all the philosophies developed in Japan, Zen has had the broadest cultural impact. During the medieval period it profoundly informed the evolution of such arts as poetry and Noh drama, architecture and landscape gardening, calligraphy and painting, the tea ceremony and flower arrangement, as well as swordsmanship, archery, and other martial arts.

Two figures from the Rinzai school deserve mention as exemplifying the fusion of Zen thought with practice. Takuan Sōhō (1573–1645) was a prolific author whose more speculative works attempted a synthesis of Zen thinking with neo-Confucian metaphysics, but who is best known for his writings on the art of the Zen sword. Takuan explicated the Zen doctrine of ‘no mind’ by showing how, in combat, focusing the mind on any one place, or letting it ‘stop’ anywhere, leads to disaster; one must rather let one’s awareness diffuse through the entire body and beyond, so as to allow immediate response from any part. This schema—in which rigorous psychophysical practice carried out over decades leads to an enlightened spontaneity that is even more rapid and attuned than instinctual responses—is typical of the Zen discipline that underlies practice in meditation and the arts. Two later Zen masters were responsible for a revitalization and efflorescence of the Rinzai school during the Tokugawa period, Bankei Yōtaku (1622–93) and Hakuin Ekaku (1685–1768). Like Takuan, Hakuin was a man of multiple talents and is highly regarded as a poet, a painter and calligrapher, and a thinker of the first rank. For the Rinzai school Zen practice is a matter of ‘seeing into one’s own true nature’, which is basically already enlightened. Hakuin emphasizes that genuine practice consists in ‘uninterrupted meditation in the midst of all activities’ rather than the ‘dead sitting and silent illumination’ advocated by the quietistic schools. (There is a remarkable similarity between Hakuin’s style of writing and Nietzsche’s, as well as between many of their ideas—especially about the role of the emotions in the best human life.)

Towards the end of the Tokugawa period a movement arose in reaction to the dominance of Buddhist and Confucian thinking in Japanese philosophy that came to be known as the Kokugaku (‘national learning’) school, the primary figures in which were Motoori Norinaga (1730–1801) and Hirata Atsune (1776–1843). While receptive to the neo-Confucian Kogaku thinkers’ emphasis on the earliest classical texts, these men called for a return to the study of Japanese antiquity. Through a philosophical reconstruction of Shinto and careful study of the early classics of Japanese myth and literature, they sought to recover the ‘true heart’ of ancient Japan as a basis for spiritual renewal in the present. While the Kokugaku philosophies are impressive in their philological sophistication, the exclusiveness of their concern with ‘pure Japanese-ness’—while understandable in view of the multiple heritage of Japanese culture—tends toward a vehement nationalism.

Upon the reopening of the country to the West with the Meiji Restoration of 1868, the Japanese embarked upon a comprehensive programme of ‘adopting and adapting’ Western philosophies. Around the turn of the century, thorough engagements with the full historical sweep of Western philosophy were complemented by special studies of British \*utilitarianism, American \*pragmatism, French \*positivism, and—above all \*German philosophy from Leibniz and Kant, through Hegel and Fichte and

Schelling, to Schopenhauer and Nietzsche. The first masterpiece to emerge from the ferment that resulted from this confluence of the Asian and Western philosophical traditions was *An Inquiry into the Good* (1911) by Nishida Kitarō (1870–1945), an epochal work that sought to articulate an original philosophy rooted in the tradition of East Asian thought by way of concepts derived from Western philosophy. Over the next thirty years Nishida went on to elaborate a vast and complex body of thought ranging over metaphysics and epistemology, ethics and aesthetics, and philosophy of politics and religion.

Nishida influenced a whole generation of younger philosophers, many of whom also taught at Kyoto University and came to be known collectively as the Kyoto School. The thought of these men was often influenced by religious existentialism and always informed by thorough study of the history of Western philosophy. Tanabe Hajime (1885–1962), much influenced by Hegel, wrote extensively in the fields of ethics and phenomenology and philosophy of religion from the perspective of Pure Land Buddhism, while his younger contemporary Nishitani Keiji (1900–90), more influenced by Nietzsche, wrote from a more existential standpoint conditioned by Zen. Watsuji Tetsurō (1889–1960) began his writing career with insightful studies of Schopenhauer, Kierkegaard, and Nietzsche, and went on to publish prolifically on Buddhism, Confucianism, the philosophy of the visual and theatrical arts, and especially ethics.

Several of the major figures in the Kyoto School came in for severe criticism from their Marxist colleagues—among whom the most impressive thinker was Tosaka Jun (1900–45)—for publishing material during the Second World War that was distinctly nationalistic and right-wing in tone. The political writings of these thinkers deserve close attention, since they open some fascinating perspectives on the difficult question concerning the relations between a thinker’s politics and his or her philosophy. Unfortunately, much of the recent commentary on these issues in the United States has come from post-Marxist Japanologists so ready to point the accusing finger from positions of ethical superiority that ideological complacency has tended to take the place of responsible scholarship in this area.

Three other thinkers of the period deserve mention. Hatano Seiichi (1877–1950) is distinguished by being a practising Christian and by his broad competence in the history of Western philosophy with special emphasis on the Greeks and philosophy of religion. Miki Kiyoshi (1897–1945) was an existential humanist, strongly influenced by Marxism for a time, who produced important works in the fields of social and political philosophy and philosophical anthropology. Kuki Shūzō (1888–1943) was a cosmopolitan aristocrat who spent the 1920s studying in Europe, where he made a great impression on both Heidegger and Sartre among others. While he is best known for his subtle work on the aesthetics of Japanese taste, *Iki no kōzō* (The Structure of ‘Iki’ (1930)), Kuki wrote with great sophistication in the fields of existential philosophy,

literary theory, and modern French thought. He was also an accomplished poet who wrote numerous belletristic essays.

At the close of the twentieth century, number of philosophers (such as Abe Masao, Takeuchi Yoshinori, Tsujimura Kōichi, and Ueda Shizuteru) were carrying on the work of the Kyoto School, while their counterparts in Tokyo (Nakamura Hajime and Yuasa Yasuo) were focusing more on historical issues, especially with regard to Buddhism. An exciting feature of current philosophy in Japan is the dialogue being initiated by syntheses of contemporary Western thought with the Japanese philosophical tradition by such thinkers as Sakabe Megumi in Tokyo and Ohashi Ryōsuke in Kyoto. **Jaspers, Karl** (1883–1969). German philosopher, who was one of the founders of \*existentialism. Originally a psychiatrist, his first book was *General Psychopathology* (1913). *Die Psychologie der Weltanschauungen* (1919) marked his transition to philosophy. It presented a typology of world-views, and also introduced his philosophy of *Existenz*, which he elaborated in *Philosophy* (1932; tr. Chicago, 1967–71) and other works. The great philosophical systems have collapsed, since men are essentially limited, conditioned and uncertain. We must learn from philosophers, such as Kierkegaard and Nietzsche, who accept and probe human finitude. Only three ways of philosophizing are now open to us: to explore (1) the limits of science (world-orientation), (2) the self, and (3) what transcends world and self. World, soul, and God are the three 'encompassers', within whose 'horizons' we know everything we know: we cannot ascend to the supreme encompasser of these horizons, e.g. to Heidegger's 'being'.

1. Science has only relative, not absolute, truth. It serves for the manipulation of measurable objects, but gives no answers to the crucial questions of life and death. Between the four spheres of reality—matter, life, soul, spirit—there are gaps which science will never succeed in filling.

2. The self is *Existenz*: it has no fixed nature, but is its possibilities, what it can become. It exists only in 'communication' with other existences. It acts not only within the routines and rituals of everyday life, but sometimes 'unconditionally', with a freedom amounting to the 'choice of

itself'. Its condition is starkly revealed in 'limit-situations', such as death, suffering, conflict, and guilt, requiring decisions perplexed by uncertainty and antinomy.

3. World and *Existenz* point to the transcendent. This is discernible in the 'ciphers' presented by experience and tradition. One such cipher is the law of the day and the passion of the night, the perennial conflict between orderly reason and destructive unreason. Another is the pervasive defeat of human aspirations. 'Failure is ultimate', but to philosophize is 'to learn to die' and 'to encounter being by means of failure'.

**jaundice.** Favourite philosophical example of how the state of observers can affect their \*perception; used from Lucretius and Sextus Empiricus, through Berkeley, and into the twentieth century. 'In the *jaundice*, every one knows that all things seem yellow' (Berkeley, *Three Dialogues*, 1). In sceptics' hands this was used to show that (since there was nothing to choose between the jaundiced eye and the unjaundiced eye) we cannot ascribe to an object a 'true colour'. For other philosophers, the example shows only that, while objects have colours (which in good circumstances are seen by people with good eyesight in good health), a white thing will in particular circumstances look yellow and a person may even mistakenly take it to be that colour.

The example may itself be an instance of mistake. It has been remarked that in jaundice it is the sufferer who looks yellow to the world, not the world that looks yellow to the sufferer.

**Jefferson, Thomas** (1743–1826). Statesman (third President of the United States) and political theorist, author of the Declaration of Independence and the (1779) Act for Establishing Religious Freedom (state of Virginia), among other political and philosophical documents. Jefferson's general philosophical outlook was empiricist and materialist, his religious convictions were deist, and his political opinions were grounded in Lockean social \*contract theory. His vision of representative \*democracy required an educated and self-sufficient populace, and he insisted that free public education, together with the recognition that no generation's political consent could bind another's, would promote in the new nation the 'natural aristocracy' of 'virtue and talents', eliminating the 'artificial aristocracy' of 'wealth and birth'.

K.H.

Morton White, *The Philosophy of the American Revolution* (New York, 1978).

**Jeffrey, Richard** (1926–2002). Princeton philosopher. Jeffrey helped develop the subjective interpretation of probability and Bayesian approaches to \*decision theory and \*confirmation. Using relatively simple mathematical and logical machinery, he developed materials from Thomas Bayes, Frank Ramsey, and others into what amounts to a version of the ancient Sceptic Sextus Empiricus' dream of solving practical and theoretical problems by appeal to one's own desires, preferences, and subjective impressions, without assuming any objective knowledge. Jeffrey's contributions to the epistemology of science include techniques for calculating the probability of a hypothesis from uncertain evidence, and investigations of problems raised for confirmation theories by photographs and other such non-propositional evidence. By popularizing the use of truth trees in teaching introductory logic he saved countless thousands of innocent students from incalculable hours of drudgery. J.B.B.

Richard Jeffrey, *The Logic of Decision*, 2nd edn. (Chicago, 1983).

**jen:** see Confucianism.

**Jevons, William Stanley** (1835–82). British economist and philosopher who taught in Manchester and London. Much of his work was pioneering and influential, such as his theory of utility in economics, and his inclusive interpretation of the logical connective 'either . . . or'. His logical theory was based on the principle of 'the substitution of similars', the idea that what is true of a thing is true of its like. He recognized that logical deduction is a mechanical process, and invented a machine that could perform inferences. However, his theory of \*scientific method, developed in *The Principles of Science* (1874), though more neglected, is equally deserving of respect. He opposed Mill's views on induction, arguing instead for a \*hypothetico-deductive account of science, in which theories are not conclusively verified but have a degree of \*probability, interpreted as a measure of reasonable belief. A.BEL.

Margaret Schabas, *A World Ruled by Number: William Stanley Jevons and the Rise of Mathematical Economics* (Princeton, NJ, 1990).

**Jewish philosophy.** Taking its origin and problematic from the biblical and rabbinic texts, Jewish philosophy, in its critical mode, reflects the rabbinic endeavour to reinterpret and reapply those texts in continually altered circumstances. Its synthetic mode is a creative reappropriation and rediscovery of their core spiritual and moral values.

Judaism is a culture, a nation and ethnicity, and a historical tradition as well as a religion. All these aspects are reflected in Jewish philosophy. They are not always successfully integrated. And not all of Judaism, even conceived intellectually, is philosophical. Mysticism, legal positivism, and certain romantic strains can be actively anti-philosophical, even when they take on philosophical colorations. Fideism and fundamentalism, the most prominent anti-philosophical trends within Christianity,

are notably absent in Judaism. Jewish orthodoxy is committed to practice. Piety takes the form of ritual observance rather than credal correctness. The faith of the Hebrew Bible is the moral virtue of faithfulness, conceived as loyalty, which like the biblical ideas of blessing, grace, joy, favour, and love, involves a mutuality between humanity and God, which is echoed in human fellowship. Faith is not in the first instance a cognitive notion. It has nothing to do with 'salvation'. The aim of Jewish life is not the hereafter but fulfilment for individuals and communities, through adherence to the 'laws of life', which reason apprehends in their bare outlines, but which Scripture and tradition richly elaborate in an ongoing historical process. Hence the alienness of fundamentalism. Karaism, the only scripturalist, back-to-basics movement in Judaism, was marginalized precisely because it sought (with notable lack of success) to undermine the intellectual and cultural authority that allowed the continuing thematic elaboration of Jewish law and practice.

The opening lines of the Torah, 'In the beginning God created heaven and earth', typify the oblique biblical method of broaching philosophical issues. God's existence is not 'proved' in the medieval manner, but God's act is offered as the explanation of all the world we know. Similarly, there is no direct polemic against pagan mythology, but the silence of the text about God's motives, ancestry, battles, lineaments, and plans complements its later, practical prohibitions of attempts to represent the divine—speaking volumes, by indirection, about God's sublimity and transcendence, without resort to abstract vocabulary.

The biblical word for transcendence is holiness. Those who would be ruled by God are called upon to share it (Leviticus 19: 2), symbolically and pragmatically, by ritual and moral purity, and by the hygienic purity that links the two. God's love and favour are reciprocated by human love of his creatures and creation. Thus the seeming *non sequitur* 'Thou shalt not hate an Egyptian, for thou wast a stranger in his land' (Deuteronomy 23: 8) generalized in the universal rule 'Love thy fellow as thyself' (Leviticus 19: 18) is transformed into sound reasoning only by the adoption of a Godlike, universal perspective, valuing all persons alike and so capable of adopting their perspectives and acknowledging them as the authors of their own ends. The absoluteness of the source of such moral objectivity, which is not the objectivity of disinterest but that is universal love, is clearly reflected in the biblical tagline 'I am the Lord', repeatedly offered as the reason for God's moral demands, as, for example, in the prohibition of cursing the deaf or putting a stumbling-block before the blind, or otherwise abusing the weak or helpless (Leviticus 19: 4). Thus the central interpersonal commandment to love one's fellows as oneself is a corollary of the commandment to love God. All God's commandments are rabbinically construed as interpretations, that is, applications, of these two.

The prophets, as the rabbis read them, successively refine, order, and sublimate the biblical laws: the barbarism of paganism is condemned, with all its trappings of

luxury and cruel pomp, but no merely ritual infraction is ever amongst the sins against which the prophets inveigh. The Talmud writes (*Makkot* 23b–24a): ‘Moses was given 613 commandments. David summed these up in eleven (Psalm 15), Isaiah in six (33: 16–17), Micah in three (6: 8), Isaiah in two (56: 1), and finally Habakkuk grounded them all in one principle, fidelity.’ The rabbis see themselves as continuing this process. But there is no \*reductionism in the reduction. That is, no minimalism. The part does not replace the whole but only voices its intention and thus fosters the interpretative practice that keeps the text alive. Through such continuous sifting the rabbis discover the thematics of Scripture long before Socratic method has taught them the conceptual mode of discourse. They rely on dialogical analysis, the logic of association—puns, hints, and allusions—as their nominal proofs, but never as their grounds. Treating Scripture as a portent, they find significance in the resolution of every seeming redundancy and verbal paradox. But the *misus* they uncover is never paradox itself, and the objects of their homilies (*midrashim*) are tangential only to the immediate intentions of the contexts that are their springboard, never irrelevant to the core moral and spiritual themes of the canon, which are the real grounds of the argument that is generally left unspoken.

The first explicit philosopher of Judaism is Philo, the learned, highly principled, and highly aesthetic Hellenistic Alexandrian, who reads Scripture through the eyes of Plato, and Plato through the eyes of Scripture, and who solves the problem of God’s governance of nature by introducing the Logos as, at once, an attribute and an act of God, transcendent in its wholeness but immanent in its immediacy. The most eloquent is Halevi, the poet and the advocate of the material aspects of the tradition—land, language, culture, and imagination—against a backdrop of intellectualism. Ibn Gabirol, the most abstract Neoplatonist of medieval Jewish philosophy, also spoke for materiality, in the intellectual matter of the divine realm. He too was a major Hebrew poet. The most spiritual of the Jewish philosophers was Bahya ibn Paquda, a profound and cosmopolitan pietist, who spoke compellingly of the need to supplement the ‘duties of the limbs’ so near to the practice of his contemporaries, with the corresponding Duties of the Heart, including in their number not only spiritual but intellectual and philosophical duties.

The first systematic Jewish philosopher was Saadiah Gaon, the exegete, translator, grammarian, liturgist, jurist, and inductive philologist of biblical thematics, who forged his method from the techniques of his Muslim counterparts, his Greek and rabbinic predecessors, and his Karaite contemporaries, in keeping with the rabbinic maxim that he is wise who learns from every human being. The greatest philosopher committed whole-heartedly to Judaism was the jurist and physician Maimonides, Rabbi Moses ben Maimon, affectionately known by the acronym Rambam, and admired by Muslim contemporaries and Christian successors, including Aquinas, for his brilliant exposition of the theology of transcendence.

The most radically creative Jewish philosopher was the excommunicate Spinoza, whose *Ethics* seems today to be the most popularly appreciated and most professionally misunderstood and neglected major work of philosophy. Too spirited to develop his thoughts in the manner of closet philosophy long practised, for example, in the \*Kabbalah, Spinoza was forced as a young man into an open break with the tradition that had nurtured him. That break was aggravated by his need to criticize biblicism systematically, turning the problematics of traditional rabbinic exegesis into a foundation of modern biblical criticism. His hope was to create the intellectual space needed for the philosophical work of the *Ethics* and for its open-minded reception, a reception it would win, but not in his lifetime. The major theses of the *Ethics* respond to the full repertoire of philosophical concerns in the Western tradition from Parmenides to Descartes and beyond. The intellectual resources Spinoza brings to his task are his own. But the detailed strategies he uses are critically informed by the achievements of such Jewish philosophers as Ibn Gabirol, Maimonides, Gersonides, Crescas, Leo Hebraeus, and Abraham Herrera, as Harry Wolfson, Richard Popkin, and others have shown. And the subtle monism of Spinoza’s metaphysics, like the perfectionism of his ethics and the calm intuitionism of his epistemology, uniting the correspondence theory of truth with the clear formalism of rationalist coherentism, is as much a fulfilment of the biblical project as it is a response to the problematics of Aristotle and Plato.

All of the thinkers mentioned here use the techniques of their time and place. The biblical writers forge myths and laws, answer authors like those of the epic of Gilgamesh and the code of Hammurabi. The prophets use oracle and symbolic parable. Philo speaks in allegories and homiletic glosses. Saadiah thematizes in the manner of the Arabic *kalām* Muslim dialectical theology. Maimonides devises a hybrid genre, part essay, part commentary, part thematic treatise, allowing philosophy to inform his reading of Scripture, even as Scripture affords him a critical standpoint for examining the underlying assumptions of the prevalent philosophical schools. Spinoza uses the geometrical method of Euclid and Proclus, and of his own reformed Descartes.

Current Jewish philosophy has adopted the mode of the journal article and treatise, although Levinas will revert to the midrashic, homiletic method, as Cohen and Rosenzweig adopted the tones of the lecture hall, and Fackenheim the questioning rhetoric of the synagogue, and as Buber used the Hasidic tale and the European novel as vehicles of exposition. Through all the change of style and structure, and all the seeming change of paradigms, the thematic content remains remarkably steady, anchored in tradition and in text: God offers love and demands justice and generosity. Life is a gift; truth, a sacred and unescapable responsibility.

**Johnson, Samuel** (1709–84). As far as his incursions into philosophy are concerned, Samuel Johnson is most often remembered for his choleric rejections of metaphysical claims. When taxed with the arguments of Berkeley he kicked a stone with the words 'I refute it thus'. But Johnson might have been a remarkable philosopher, as is shown by the brilliant and extremely funny review of Soames Jenyn's *Free Inquiry into the Origin and Nature of Evil*, in which Johnson destroys with lacerating logic a facile expression of eighteenth-century \*optimism. That Johnson realized this is shown by his proposal to reserve the teaching of logic and metaphysics for himself when he and Boswell, on their Scottish journey, were speculating on the creation of a separate University in St Andrews employing members of 'The Club'. He did, after all, declare metaphysics to be his favourite subject. R.A.S.

I do not know of any very recommendable account of Johnson on philosophy. As a stopgap, Charles H. Hinnault, *Samuel Johnson: An Analysis* (1988) may be consulted.

**Johnson, W. E.** (1858–1931). British philosopher who taught first mathematics and then philosophy at Cambridge. Author of *Logic*, and of 'Probability' (*Mind* (1932)), intended as a fourth part. Part I concentrates on informal logic; part II concerns syllogistic logic; and part III causality. In part I Johnson suggested the \*redundancy theory of truth, later attributed to Ramsey, adducing reasons why 'we may say strictly that the adjective *true* is redundant as applied to the proposition *p*' (I. iv. 2). He also explored \*determinables (e.g. 'colour') and determinates (e.g. 'red'), drawing contrasts between 'Red is a colour' and 'Plato is a man' and between ways of increasing the intension or \*connotation of a term. One can do so by passing from 'coloured' chair to 'red' chair or by adding 'foreign' attributes, like weight or shape, e.g. by going instead to 'coloured and straight-backed chair'. S.W.

**joint method:** see method, joint.

**Jørgensen, Jørgen** (1894–1969). Danish philosopher, originally a neo-Kantian, later influenced by Russell and Carnap, and a leading member of the group of philosophers called Logical Positivists. He wrote an encyclopaedic work on logic representing an anti-psychologistic point of view (*Treatise of Formal Logic* (1931)). Jørgensen was an ardent supporter of the idea of an encyclopaedia of unified science and became a member of the editorial board of the \*Vienna Circle monograph series called *Einheitswissenschaft* (Vienna, 1932–9). He returned later in his *Psykologi paa biologisk Grundlag* (Psychology based on

Biology (1941–5)) to a modified version of \*psychologism, and tried to reduce psychology to biology. But he was forced to conclude that this reduction was impossible and developed, instead of biologism, a kind of Spinozism in which consciousness was reduced to its phenomenological, physiological, and behavioural manifestations. According to Jørgensen it is meaningless to ask what consciousness is in contradistinction to its manifestations. C.H.K.

J. Witt-Hansen, 'Jørgen Jørgensen and the Grammar of Science', in *Danish Yearbook of Philosophy* (1964).

**journals of philosophy.** The journal is the most recently established of the major institutions of learning. The first, fully developed in ancient Greece, were the academy, or research institute, and the library. The ecclesiastical domination of learning in general, and of philosophy in particular, led to their being pursued in monastic schools and, from the twelfth century on, in universities, on a larger and more productive scale. From the Renaissance to the mid-eighteenth century it was carried on by private individuals or by like-minded groups of men of letters rather than by professors. Printing led to the multiplication of smaller and generally more ephemeral literary forms than the book. The first learned journals, in which a little philosophy was to be found, appeared in the mid-seventeenth century: the *Journal des savants* from 1655 and *Acta eruditorum* (inspired by Leibniz) in 1682. In the 1660s the Royal Society and the French Académie des Sciences were founded and soon began to publish their transactions.

The private individuals whose work made up the unprecedentedly vigorous philosophical life of the seventeenth century were not isolated and out of contact with each other. Their chief medium of communication was correspondence, notable instances being the objections to Descartes's *Meditations* and his replies to them, and the exchanges about the nature of space between Leibniz and Samuel Clarke. With the secularization of philosophy in the universities of Germany and Scotland in the eighteenth century a philosophical profession began to emerge and in Germany some short-lived periodicals were soon brought out.

But philosophical journals proper did not become important until 1876, the year in which both *Mind* and the *Revue philosophique* were started. They had been preceded by the *Archiv für Geschichte der Philosophie* in 1868 and a year before that by the interesting *Journal of Speculative Philosophy* in the USA, which, in its quarter-century of life, published important work by Peirce, James, and Royce. *Mind* has been the main philosophical publication in English from its foundation until comparatively recent times, particularly under the editorships of G. F. Stout (1892–1920) and G. E. Moore (1921–47). F. H. Bradley and William James wrote extensively in it during the early years; Russell and Moore after 1900. The *Revue philosophique*, also still being published, deliberately sought contributors from outside France. From a slightly later period there still survive the American *Monist* (1888)

and *Ethics* (1890), the French *Revue de métaphysique et morale* (1893), and the German *Kant-Studien* (1896).

The most interesting products of the 1890s and just afterwards not only still alive, but of the first importance, however, are the *Proceedings of the Aristotelian Society* (1891), more important than the meetings and symposia from which its contents came, the best barometer of the state of British philosophy since its first publication, and the American *Philosophical Review* (1892) and *Journal of Philosophy* (1904) emanating from Cornell and Columbia Universities. The two latter have much increased in distinction and influence since the 1940s with the increasing domination of English-speaking philosophy by the United States. With contributions from C. I. Lewis, Quine, Goodman, and Davidson they became and remain the leading philosophical journals in the English language.

The emergence of Logical Positivism was chronicled, and to a large extent took place, in the pages of *Erkenntnis* between 1930 and 1940, under the editorship of Carnap and Reichenbach, the leaders, respectively, of the Vienna Circle and its Berlin associate. Together with Schlick and Otto Neurath they published copiously in it until it became a casualty of war. It has recently been revived. The slim, pamphlet-like *Analysis* (since 1933) expressed the ideas of British sympathizers with positivism in the 1930s: Ayer, Waismann, Ryle, and Popper contributing in the first twenty years of its history.

The *Journal of Symbolic Logic* (since 1936) covered its subject at a high level of technical seriousness. Analytic philosophy outside Britain and America was catered for by the *Australasian Journal of Philosophy* (since 1923), admirably combative ever since its early years as the house organ of John Anderson's school, by *Theoria* (since 1935) from Sweden, by the fairly short-lived *Studia logica* and *Studia philosophica* from Poland, and by *Synthese* from Holland (since 1936), which has much improved in quality in recent years. Of more inclusive scope and less narrow doctrinal allegiance are the Belgian *Revue internationale de philosophie* (since 1938), which really is international, the British *Philosophy* (since 1926), and the Scottish *Philosophical Quarterly* (since 1950). Somewhat at odds with the prevailing fashions, but not exclusively so, are the American *Philosophy and Phenomenological Research* (since 1940) and *Review of Metaphysics* (since 1947).

The great age of philosophical journals ran from around 1890 to 1960. Since then they have increasingly come to serve as platforms for budding philosophers, in an expanding and competitive profession, from which to call attention to themselves, rather than as vehicles for the ideas of established leading figures. **Judaism:** see Jewish philosophy.

**judgement.** A term meaning \*belief or \*decision. The term has the so-called act-object ambiguity, denoting either the

judging that something is true, or that which is judged true. In the object sense, judgements are \*propositions: abstract objects that are true or false, stand in logical relationships, and are composed of concepts or other judgements. In the act sense, judgements are \*propositional attitudes: introspectible mental states or acts which have a variety of causes and effects, and vary from person to person and time to time. Judgements are commonly distinguished from the \*sentences expressing them. 'All men are animals' and 'Every man is an animal' are different English sentences, containing different numbers of words with different grammatical properties. The sentences, nevertheless, express the same judgement, which is not composed of words, and does not belong to any particular language. W.A.D.

N. Salmon and S. Soames (eds.), *Propositions and Attitudes* (Oxford, 1988).

**Jung, Carl** (1875–1961). Swiss psychiatrist and psychoanalyst, founder of 'analytical psychology'; from 1906 to 1913 one of Freud's main advocates. They ostensibly separated over Jung's generalization of the concept 'libido' beyond the carnal meaning on which Freud then insisted. Freud was later to adopt a view of libido which many have found impossible to distinguish from Jung's, and which has caused the dispute to be likened to that over transubstantiation in its empirical emptiness. Though Jung complained of Freud's intolerance of dissent, it is noteworthy that during the period of their association he was no less vituperative nor less forward in proposing expulsions and exclusions.

Jung introduced the now familiar notion 'complex' for a constellation of affect-laden ideas which secretly influence behaviour (a term with which he was so closely associated that, after his estrangement from Freud, Ernest Jones proposed its exclusion from the psychoanalytic vocabulary). Other concepts which were distinctive of Jung were those of individuation, the collective unconscious and its archetypes, and the introversion-extroversion typology which has entered into common use and been adapted and operationalized by Hans Eysenck. Jung, though he appears to have been as personally charismatic as Freud, did not have Freud's literary gifts and few of his works make the indelible impression of so many of Freud's. F.C.

**jurisprudence:** see philosophy of law.

**justice** in one sense is identical with the ethics of who should receive benefits and burdens, good or bad things of many sorts, given that others might receive these things. Although discourse about justice is often influenced by models of law, the ethics of justice is a subject in itself. To 'receive' a benefit or burden is to have any of a large number of more concrete relations to it: not only legal

ownership or other entitlement may be relevant, but also non-legal matters. Enjoyment of an experience, having access to many opportunities, getting protection from or exposure to a risk, and so on may be relevant. The 'others' relevant to justice may be those living in a person's community, those in other communities, or even those dead, those yet to live, or perhaps possible persons who will never live. Central cases of justice, however, usually involve persons living at the same time in the same community (although the community may be very narrowly or broadly defined). Here intuitions and arguments seem better grounded.

There are various contexts for talk about justice, including (at least) distributive, retributive, and 'corrective' justice (which apparently overlap to some extent). Distributive justice concerns the ethical appropriateness of which recipients get which benefits and burdens. Retributive justice concerns the ethical appropriateness of \*punishment for wrongdoing. Corrective justice concerns the ethical appropriateness of compensating with some good because of a loss or appropriating some good because of a gain. (From Aristotle onward, philosophers have sometimes taken an interest in this.)

A few in philosophy have doubted the rational basis or the desirability of any justice orientation. But many philosophers have advocated some conception of justice, often aligning themselves with some general political tendency: 'liberal democratic capitalism', '*laissez-faire* market-oriented capitalism', some variety of 'socialism', etc. Indeed, political and economic power are goods, and to worry about the justice of who has them is familiar, especially for those philosophers who have taken egalitarianism to be basic to justice.

There is indeed a presumption in favour of treating persons equally in distributive matters, unless some relevant difference can be specified to distinguish persons treated unequally. To treat persons unequally with respect to distribution of important benefits and burdens, in the absence of a justification, is a paradigm of injustice. The burden of justification should be regarded as very weighty, strong enough so that a reasonable case might be made (hypothetically, if not actually) to those less favoured by the distribution. Utilitarian arguments, notoriously, seem incapable of discharging this justificatory burden. For one thing, utilitarians arguably are not entitled to a sufficiently strong notion of a moral right to unpack many modern, rights-centred notions of justice. Although considerations of distributive justice might not always trump other sorts of ethical considerations (including utility) in a context, they do properly count a great deal.

Modern accounts of justice tend to be based on ideas about human rationality, human intuitions, human community, or the like (as opposed, say, to 'cosmic justice' or the will of God). John Rawls's very influential *A Theory of Justice*, and subsequent writings, are instructive in this connection. Rawls argues that his two principles of justice (the first requiring, roughly, an equal right to the most extensive system of equal basic liberties, taking priority

over the second, a principle that allows for certain \*inequalities subject to various constraints, including the requirement that the inequalities are to the greatest benefit of the least advantaged) would be chosen by autonomous judges behind a veil of ignorance designed to deny them knowledge of their own positions in a social system to which the principles will apply. Increasingly, in post-*Theory of Justice* writing especially, Rawls stresses the constructivism of his theory, and its roots in a particular community.

A large variety of criteria have been proposed for ethically just distributions. Some think just distributions should be in accordance with contribution, some with effort, some need, some \*desert, and so on. Some think that just distributions are a matter of the history of how a certain distribution came about. There seems no finite list of criteria, no definitive decision procedure here.

In light of this, one can see the attractions of 'pluralism' and 'complex equality', as presented by Michael Walzer. People collectively 'create' goods of innumerable sorts and distribute them in accordance with many criteria, the appropriateness of which changes historically and varies with the social sphere concerned, whether we are talking about money, medical care, schooling, political power, love, and so on.

**justice, international.** Theories of international relations propose explanatory models for studying relations between states. Theories of international justice, on the other hand, formulate moral principles for judging the legitimacy of non-domestic institutions and policies. Three main schools exist in this respect. First, 'cosmopolitans' hold that the ultimate subject of moral value is the individual person, and consequently institutions, including states, are only legitimate in so far as they advance equal moral treatment of persons, irrespective of their location and affiliation. Claiming a right over a significant resource solely on the basis of territorial ownership, for example, is illegitimate on this view. By contrast, another school identifies an independent value in national affiliation and self-determination which must be taken into account in principles of international justice. Finally, there is a view which, whilst not attributing value to nation-states, nevertheless sees their existence as relevant to questions of principle.

John Rawls explicitly develops principles for the just *foreign policy* of liberal states, rather than a conception of a just 'world order'. Liberal states should accept other states as legitimate which, whilst not fully liberal, protect basic human rights (not the full liberal complement), and have a well-ordered legal system dispensing a 'common good' conception of justice. No global principle of distributive

justice is offered by Rawls. It is not clear why Rawls should require liberal states to accept non-liberal states as legitimate. However, assuming no equivalent coercive structure to the state is present or desirable at a global level, he opts for addressing the external practices of liberal states in a way that maximizes stable external relations, whilst permitting intervention in case of extreme abuses. In doing so he continues the Kantian tradition of international justice as peace and security, rather than principles of justice for a world order.

Cosmopolitan critics of this approach claim that the distinction between just foreign policy and justice for a world order is not sustainable. But it is unclear to which entity standards for global justice could be applied. In circumstances where no global coercive institution exists, any redistributive account will face compliance assurance problems. Furthermore, a principle placing a duty on any state to enforce internationally anything more than a limited number of very important rights would incur such costs as to make it unviable. Consequently, cosmopolitans can either bite the bullet and develop principles which, if acted upon by individuals or states, will lead to a just institutional world order assuring global compliance, or they can simply modify Rawls's principles for foreign policy in a way that will plausibly produce more global justice. Some 'weak' cosmopolitans have adopted the latter course.

**justice and benevolence:** see benevolence.

**justification, epistemic.** The property ascribed to a belief in virtue of satisfying certain evaluative norms concerning what a person ought to believe. Such norms measure the

'goodness' of a belief in so far as we are interested in epistemic goals, such as attaining truth and avoiding error.

The classical view conceives of justification as necessary for \*knowledge, and sees it as a matter of the adequacy of the reasons or evidence one has for a given belief. This reasons-based view leads to two pressing questions: (1) Is every justified belief based upon other beliefs that act as reasons? Is there not some foundation of beliefs whose goodness is not transmitted to them from other beliefs? (2) Under what conditions are a person's reasons for some belief good enough that the belief is justified?

\*Foundationalism is a theory about the structure of justification that affirms that some beliefs are basic, i.e. justified without being based upon other beliefs. Justified non-basic beliefs are based upon these foundations through good inferences or reasoning. The theory of such reasoning is expected to yield the answer to question 2.

Coherentism denies that any beliefs are foundational, and claims that justification is always a matter of the degree to which a belief 'coheres' with one's other beliefs. Various coherence theories define coherence differently, e.g. as a matter of consistency, explanation, probability, or 'comparative reasonableness'. Some measure of the degree of a belief's coherence is necessary to answer the second question.

\*Reliabilism replaces the traditional reasons-based view with the idea that a belief is justified when it is the result of a permissible process or method, where permissibility is a function of that procedure's reliability, and reliability measures the likelihood that the produced belief is true. Delineating the processes or methods that are reliable (an issue to which psychology and cognitive science seem relevant) provides this theory's answer to question 2.

**Kabbalah.** Literally, tradition; specifically, Jewish mysticism as developed by such thinkers as Isaac the Blind, Abraham of Posquieres, Moses ben Naḥman of Gerona (Naḥmanides) (1194–1270), and Isaac Luria of Safed in Galilee (1535–72). Kabbalah invokes an elaborate cosmology based on the theurgic powers of the Hebrew alphabet, conceived in Neoplatonic and neo-Pythagorean terms as the instrument of creation. The letters, whose numerical values figure in esoteric glosses of Scripture, link creation with the supernal *sephiroth*, archetypal attributes of the Infinite, whose Self-confinement (*tsimtsum*) gives definition to creation and revelation, but also explains human freedom and the possibility of evil. With the ingathering of divine sparks, confined in shells of darkness since the primal explosion of creation, God will be reunited with his exiled *Shechinah* (Immanence), and the world resolved again into unity. Such repair (*tikkun*) of the broken universe is achieved through spiritual acts of a moral and ritual character, in which man aids in God's self-reconciliation. Kabbalah has been a force in Jewish spirituality since the late twelfth century. Its classic text, the *Zohar*, or Book of Splendour, was written by Moses de León (1240–1305). Modern Ḥasidim (Jewish pietists) and the Renaissance philosopher Pico della Mirandola bear its imprint, as did the tragic pseudo-messiah Shabtai Tzvi (1627–76). Spinoza was influenced by Kabbalah through the work of Abraham Herrera, but forcefully rejected its more fanciful elements.

**Kagan, Shelly** (1954– ). American philosopher, currently Professor at Yale University. An acute critic and leading consequentialist, Kagan's work offers sustained attacks on the view that morality includes either options or constraints. Options involve permissions to pursue personal goals and interests, even at the cost of maximizing the good; constraints involve prohibitions against performing certain actions, even if they would maximize the good. Kagan's arguments have far-reaching theoretical and practical implications, threatening two pillars of common-sense deontological morality. He challenges standard

methodological assumptions and forms of argument that underlie much of contemporary moral and political philosophy. He has also done work on the structure or geometry of desert, and published articles on the nature of value, addressing such topics as the value of a life, intrinsic value, infinite value, and finitely additive value theory.

**Kant, Immanuel** (1724–1804). Perhaps the most important European philosopher of modern times, Kant was born, spent his entire life, and died in Königsberg in East Prussia. After studying at the University of Königsberg from 1740 to 1746, he worked for a time as a private tutor. In 1755 he returned to the University, received his master's degree, and began lecturing. In 1770 he was appointed professor and he continued to lecture on a wide variety of subjects, including mathematics, physics, anthropology, pedagogy, and physical geography, as well as the central fields in philosophy, until his retirement in 1796. Although he never married or travelled outside of East Prussia and led a highly regimented existence, he was not reclusive. On the contrary, he was known as a brilliant lecturer and conversationalist, had a wide circle of friends, and was keenly interested in the intellectual and political issues of the day.

Kant's philosophical career is conventionally divided into three periods. The first, or 'pre-critical period', runs from 1747, the year of his first publication, 'On the True Estimate of Living Forces', to 1770, when he published his inaugural dissertation, *On the Form and Principles of the Sensible and the Intelligible Worlds*. In spite of significant shifting of views, the writings of this period are unified by Kant's abiding concerns with foundational questions in science and the search for the proper method in \*metaphysics. The middle period (1771–80) is often called the 'silent decade', because Kant published virtually nothing, devoting himself instead to the reflections that led eventually to the *Critique of Pure Reason*. The third, or 'critical period', dates from the publication of the first edition of the *Critique* in 1781. This was followed by the *Prolegomena to any Future Metaphysic* (1783), the *Groundwork to the*

*Metaphysic of Morals* (1785), the *Metaphysical Foundations of Natural Science* (1786), a second edition of the *Critique of Pure Reason* (1787), the *Critique of Practical Reason* (1788), the *Critique of Judgement* (1790), *Religion within the Boundaries of Mere Reason* (1793), and the *Metaphysic of Morals* (1797), as well as many important essays on topics in metaphysics, science, morals, legal and political theory, and the philosophy of history. In addition, he published compilations of his lectures on anthropology, logic, and pedagogy. In his last years he devoted himself to a major revision of some of his basic views on metaphysics and the foundations of science. The work remained uncompleted at his death, but has been edited and published under the title *Opus Postumum*. Although earlier dismissed as a product of senility, it has more recently been regarded as providing an important, albeit highly obscure, indication of Kant's late move towards something like a 'post-critical' philosophy.

The central concern of Kant's greatest masterpiece, the *Critique of Pure Reason*, is with the possibility of metaphysics, understood as philosophical knowledge that transcends the bounds of experience. For Kant, such knowledge claims to be both \*synthetic and \*a priori. In other words, metaphysics purports to provide necessary truths, which, as such, cannot be based on empirical evidence (their apriority), but which also claim more of their referents than can be derived from an analysis of their concepts (their syntheticity). The propositions 'God exists' and 'Every event has a cause' are examples of such claims. By contrast, propositions which merely explicate what is already thought in the concept of a subject, e.g. 'God is omnipotent', are termed \*analytic. Since the truth of the latter can be ascertained merely by appealing to accepted meanings and logical considerations, Kant thought that these were non-problematic. Accordingly, the fundamental philosophical task is to account for the possibility of synthetic a priori knowledge; and since Kant also believed that mathematical propositions are of this nature, accounting for their possibility likewise became an integral part of his project.

The second aspect of Kant's concern with metaphysics is with the problem of the \*antinomies. As a result of reflection on the concept of a world, he became convinced that reason inevitably falls into contradiction with itself when it endeavours to 'think the whole', that is, when it ventures beyond experience in order to answer such questions as whether the universe has a beginning in time, limit in space, or first cause, or is, rather, infinite in these respects. The contradiction or antinomy arises because it is possible to construct valid proofs for each of the two conflicting positions: the universe has a beginning in time; the universe has existed for an infinite period of time; etc. He also thought that, if unresolved, this problem would lead to a hopeless \*scepticism, which he termed 'the euthanasia of pure reason'. Consequently, Kant came to see the 'fate of metaphysics' as crucially dependent on a successful resolution of the antinomies as well as an account of the possibility of synthetic a priori knowledge.

Kant thought that he could deal with both problems at once by means of what is usually called his 'Copernican revolution in philosophy', since he compared his innovation to the 'first thoughts of Copernicus'. This involves reversing the usual way of viewing cognition and instead of thinking of our knowledge as conforming (or failing to conform) to a realm of pre-given objects, we think of objects as conforming to the conditions of our cognition of them. The latter include 'forms of sensibility', through which objects are given in sensory experience, and pure concepts or \*categories through which they are thought. Since objects can be cognized only in so far as they are given in accordance with these forms, it follows that we can know them only as they appear, not as they may be in themselves, that is as comprehended from some God's-eye perspective. Accordingly, for Kant human knowledge is limited to \*appearances or \*phenomena, whereas \*things-in-themselves or \*noumena are thinkable but not actually knowable. Kant termed this doctrine \*transcendental idealism; and juxtaposed it to transcendental realism, which identifies appearances with things-in-themselves. Thus, these two forms of \*transcendentalism are effectively viewed by Kant as two all-inclusive and mutually exclusive philosophical standpoints. His central claim is that the former is capable of both accounting for the possibility of synthetic a priori knowledge and avoiding the antinomy, while the latter is not.

This whole project assumes, however, that the human mind is, in fact, endowed with such conditions, and demonstrating this is the main task of the Transcendental Aesthetic and the \*Transcendental Analytic in the *Critique of Pure Reason*. In the former, Kant argued that space and time are subjective forms of human sensibility, through which the \*manifold of sense is given to the mind, rather than either self-subsisting realities (\*Newton) or relations between self-subsisting things (\*Leibniz). He also argued that only this conception of space is capable of accounting for the possibility of geometry, which he equated with Euclidean geometry. In the latter, he first tried to establish by means of a 'transcendental deduction' that certain pure concepts or categories, including substance and causality, are universally valid with respect to possible experience, since they are necessary conditions of such experience. On the basis of these results, he then argued for a set of synthetic a priori principles regarding nature, considered as the sum total of objects of possible experience. Prominent among these are the principles that substance remains permanent throughout all change and that every alteration has a cause. The latter is usually viewed as Kant's response to \*Hume's scepticism concerning causality.

The immediate consequence of Kant's limitation of knowledge is to rule out virtually all traditional metaphysics, which contains two parts: general metaphysics or \*ontology, which is concerned with the universal properties of things (\*Aristotle's science of being *qua* being), and special metaphysics, which encompasses the disciplines of rational psychology (the soul), rational cosmology (the

world), and rational theology (God). Although the limitation of knowledge to objects of possible experience suffices to rule out both branches of metaphysics, Kant devotes a large portion of the *Critique*, the Transcendental Dialectic, to exposing the 'transcendental illusion' which supposedly underlies the latter. Since this illusion is rooted in the very nature of human reason, it cannot be eliminated; though Kant contends that it is possible to avoid being deceived by it. In fact, the therapeutic function of the *Critique* is to provide the tool (transcendental idealism) for avoiding such deception.

This is best illustrated by Kant's treatment of the antinomies. In each case, the appearance of a contradiction arises from the assumption that there must be some fact of the matter to be determined. This is the illusion, and once it is exposed, it can be seen that the sensible (spatio-temporal) world is neither finite nor infinite in the relevant respects. Similarly, the apparent conflict between the causal determinism presupposed by science and the freedom presupposed by morality, which is the topic of the third antinomy, can be resolved by restricting the former to appearances, thereby leaving room for the latter with respect to things-in-themselves. In other words, though everything in the realm of appearance, including human actions, is causally determined, it remains conceivable that human beings, considered as noumena, are free. Obviously, this does not prove that we are in fact free, but it does supposedly liberate us from the illusion that we must be either one or the other. Thus, for the either/or underlying much of traditional thought regarding the \*free-will problem, it opens up the possibility of a both/and. As such, it is a form of \*compatibilism; but it differs from the usual forms of compatibilism because the conception of freedom it attempts to reconcile with causal determinism is an \*indeterminist one.

Kant's moral theory centres around the \*categorical imperative: 'Act only on that maxim which you can at the same time will to be a universal law'. Maxims are the general rules or principles on which rational agents act, and they reflect the end that an agent has in view in choosing actions of a certain type in given circumstances. Thus, maxims are principles of the form: When in an *S*-type situation, act in an *A*-type manner in order to attain end-*E*. For example, I might make it my maxim always to pay my debts as soon as possible so as to avoid incurring unnecessary obligations. The categorical imperative tests maxims by prescribing a thought experiment in which one asks oneself whether one could consistently will one's maxim as a universal law. The idea is to determine not simply whether the imagined universal law is consistent with itself, but whether its universal adoption is consistent with the agent's own ends and, therefore, something that the agent could consistently will. A maxim which passes this test is morally permissible, whereas one which does not is forbidden. Consider the maxim of borrowing money by falsely promising to repay it. This maxim, Kant argues, conflicts with itself when universalized because it assumes a state of affairs in which promises to repay would not be

believed and, therefore, the agent's project of profiting by false promising could not succeed. Consequently, policies such as false promising succeed only in so far as they are not universally adopted, so that in choosing them one makes an exception of oneself to a rule that one wills to hold for others.

The whole issue of the categorical imperative is extremely controversial, however, and there are a large number of interpretations and objections in the literature. The basic problem is that the test seems to yield both false positives such as 'I shall smother infants who keep me awake at night by crying', which is clearly immoral but does not seem to be ruled out by the test, and false negatives such as 'I shall play tennis on Sunday mornings when courts are available since everyone else is in church', which seems both to fail the test and to be morally permissible. Although there have been many attempts to deal with these problems, it is not clear that any has been entirely satisfactory.

A second key notion in Kant's moral theory is that of \*autonomy, understood as the capacity of the will to legislate to itself, that is, to choose maxims for itself independently of desires stemming from one's nature as a sensuous being. Since the categorical imperative demands that we select maxims on the basis of their conformity to universal law, which presupposes that we are able to disregard our inclinations and the thought of our own happiness in choosing a course of action, Kant claimed that morality presupposes autonomy. But since he also thought that autonomy, so conceived, itself presupposes freedom in the sense of independence from causal determination by anything in the phenomenal world, he concluded that the possibility of morality rests ultimately on the assumption of such freedom. Thus, the project of grounding or justifying morality for Kant (as opposed to merely analysing its presuppositions) turns crucially on the possibility of establishing our noumenal freedom. Although this poses a problem, since, as we have seen, Kant denies the possibility of any theoretical knowledge of this freedom, he thought that a way out was provided by the fact that its conceivability was assured by the resolution of the third antinomy. In the *Groundwork*, Kant appealed to this result and argued that we must assume the reality of freedom from a 'practical point of view', if we are to regard ourselves as rational agents capable of reasoned choice; and from this he inferred the validity of the categorical imperative or moral law as the 'law of freedom'. He appears to have changed his mind on this point, however, for in the *Critique of Practical Reason* he argues instead that the reality of the categorical imperative is immediately guaranteed as a 'fact of reason', from which the reality of freedom may be inferred.

But morality for Kant involves not only a law (the categorical imperative) and the autonomy of the will but also an object, that is, an ultimate end at which all action is directed. This object is defined as the 'Highest good' or \**Summum bonum*, understood as the just apportionment of happiness to virtue. This, in turn, provides the basis for moral arguments for God and immortality as 'postulates

of practical reason'. The basic idea is that, since such an apportionment is inconceivable according to the laws of nature, we are constrained to assume the reality of a noumenal ground, that is, God, as its guarantor. This is not an argument for the existence of such a being, however, but rather for the rational necessity of assuming its existence in order to make sense of the demands of morality. Although the latter requires us to strive to be 'worthy of happiness', rather than to be happy, Kant thought that such striving is impossible unless it is combined with the hope for happiness commensurate with one's worthiness of it. Interestingly enough, Kant does not argue for immortality on the grounds that we must assume an after-life in order to account for the reward of the virtuous and the punishment of the wicked, but claims instead that it is necessary in order to conceive of the possibility of the attainment of the moral perfection that is commanded by the categorical imperative yet unattainable in this life.

*The Metaphysics of Morals* contains the systematic presentation of Kant's practical philosophy broadly construed. It is divided into two parts: a doctrine of \*right and a doctrine of \*virtue, each of which is concerned with the first principles governing its domain. The universal principle of right is that 'Any action is *right* if it can coexist with everyone's freedom in accordance with a universal law, or if on its maxim the freedom of choice of each can coexist with everyone's freedom in accordance with a universal law'. This principle, which provides the foundation of Kant's political philosophy, concerns the legality of actions. It affirms that an action is right or legal (which is not to be confused with its being morally good), if and only if it does not infringe on the freedom of others to perform their rightful actions. Since anyone who hinders a person's rightful exercise of freedom does that person wrong, this gives rise to a set of negative duties (duties of justice), obedience to which may rightly be compelled. But since in a \*state of nature no one is in a position to enforce their rights, there is an obligation to enter into a civil condition in which these rights are protected by a governmental power with the authority to compel obedience to the law. Thus, Kant affirms a version of the \*social contract theory, albeit one which treats the latter normatively as an idea of reason rather than as a historical fact.

The second part of *The Metaphysics of Morals* is concerned with moral philosophy more narrowly construed. In it Kant endeavours to establish a set of duties (both to oneself and to others), which, since they must be thought of as self-imposed (through the autonomy of the agent's will), cannot be enforced by an external authority. These are termed 'duties of virtue' and are supposedly grounded in a pair of obligatory ends imposed on us by the categorical imperative: one's own perfection and the happiness of others. This yields both negative or perfect duties not to perform any actions that conflict with these ends, e.g. suicide, and positive or imperfect duties to work towards their furtherance, e.g. beneficence. As open-ended, the latter obligate one to adopt policies (maxims) that promote these ends rather than to specific actions.

The *Critique of Judgement*, or third *Critique*, is an extraordinarily complex work in which Kant attempts to complete his critical programme by finding an a priori principle for judgement. Traditionally, judgement was viewed, together with understanding and reason, as one of the three 'higher' cognitive faculties, and Kant consistently maintained this view. But in the first *Critique*, Kant had regarded judgement as essentially 'determinative', that is, as a capacity to subsume sensibly given particulars under the concepts and principles supplied by the understanding, and from this point of view there is no basis for attributing to judgement (unlike understanding and reason) any 'a priori' principle of its own. In the third *Critique*, however, Kant affirms a distinct function for judgement ('reflection') and argues that with respect to that function it does have a separate a priori principle: namely, the purposiveness of nature. The function of judgement in its reflective capacity is to find concepts and laws in terms of which nature can be cognized in a scientific manner. This requires concepts, such as those of \*natural kinds, through which it is possible to represent real connections and distinctions in things rather than merely accidental similarities and differences. Since the first *Critique* argued only that nature necessarily conforms to the universal principles of the understanding, it left open the possibility that the true order of nature might be so complex as to be incapable of discovery by the human mind. Thus, Kant now argues that it is necessary to assume, as a distinct principle, that nature is ordered in such a way as to be intelligible, which means that we are constrained to think of it as if it were designed by a supreme intelligence with our cognitive requirements in view. To think of nature in this way is to regard it as purposive. Naturally, Kant denies that this entitles us to assume that nature really is so designed, but he insists that the necessity of thinking of it in this manner suffices to give to the principle of purposiveness a regulative function.

After discussing this general principle of purposiveness in the introduction, Kant turns in the first part of the *Critique of Judgement* to judgements regarding the beautiful and the sublime, both of which are 'aesthetic' because they are based on feeling rather than concepts of their objects. Confining ourselves to judgements of beauty, with which Kant was primarily concerned, the problem is that, although based on feeling, such judgements claim to be universally valid. In other words, when I claim that an object is beautiful, I am saying not merely that it pleases me but also that it ought to please any other observer who views it in the appropriate manner. The main task, then, is to account for the possibility of such judgements, just as the central task of the first *Critique* was to account for the possibility of synthetic a priori judgements. Not surprisingly, Kant's solution to this problem bears a certain similarity to his solution of the earlier one. The claim is that the peculiar pleasure in the beautiful consists in a feeling of the 'subjective purposiveness' of an object, that is, the accord of its form, which is apprehended in an act of aesthetic reflection, with the general requirements of judgement.

Since these requirements hold for all subjects, the liking for the beautiful may be required of everyone.

The second part of the third *Critique* is concerned with teleological judgement, particularly its role in biology. It also includes a lengthy appendix, however, in which Kant articulates his views on the relationship between teleology, theology, and morality and sketches his philosophy of history, together with his views on culture and its relation to the moral development of the human race. Thus, taken as a whole, the *Critique of Judgement* is an extremely rich and important, if frequently perplexing, work, which exhibits virtually the full range of Kant's interests as a philosopher. **Kantian ethics.** Ethical theories which have their origins in, or are constructively influenced by, the moral philosophy of Kant.

Kant's outstanding contribution to moral philosophy was to develop with great complexity the thesis that moral judgements are expressions of practical as distinct from theoretical reason. For Kant \*practical reason, or the 'rational will', does not derive its principles of action by examples from the senses or from theoretical reason; it somehow finds its principles within its own rational nature. The ability to use practical reason to generate principles of conduct Kant calls 'the \*autonomy of the will', and Kant sees it as constituting the dignity of a person. It is this conception of the autonomous will which is the main source of the several sorts of theory which might reasonably be called 'Kantian ethics'.

One sort of Kantian ethics is developed by those who are influenced by Kant's view of the nature of the principles which are generated by the autonomous will. Kant argues that willing is truly autonomous if but only if the principles which we will are capable of being made universal laws. Such principles give rise to \*'categorical imperatives', or duties binding unconditionally, as distinct from hypothetical imperatives, or commands of reason binding in certain conditions, such as that we have desires for certain ends. Kant seems to hold that \*universalizability is both necessary and sufficient for moral rightness. This thesis has been much criticized, and those espousing Kantian ethics, as distinct from Kant's own position, generally argue more moderately that universalizability is necessary but not sufficient for moral rightness. This is the position of R. M. Hare and the theory of \*'prescriptivism' of which he has been the outstanding proponent. The

position is 'Kantian' in that it makes central one version of the universalizability thesis, but it departs from Kant in important ways, such as making room for utilitarian considerations.

Kant argues, as we have seen, that it is in virtue of their autonomous wills that persons have dignity or are 'ends in themselves'. Combining this aspect of the autonomous will with the idea of universalizability, Kant arrives at the ideal of the kingdom of ends in themselves, or of people respecting each other's universalizing wills. This has been an enormously influential idea, and its most distinguished recent exponent has been John Rawls, who accepts the core Kantian idea of mutually respecting autonomous rational wills, but adds to it ideas of his own to constitute the basis of his theory of justice.

It is a nice point in many given cases when a theory is simply influenced by Kantian ethics, as distinct from being an example of Kantian ethics. An Existentialist such as Jean-Paul Sartre would not be happy with the idea that he was offering a version of Kantian ethics, but there is no doubt that he is greatly influenced by Kant. In Sartre (as in Nietzsche before him) Kant's autonomous will, free but constrained by its essentially rational nature, becomes the totally unconstrained will creating its own values in arbitrarily free choice. This is clearly a Kantian idea in origin but developed in a way which Kant would have repudiated.

To stress that these are just a few of the many examples of Kant's influence on ethics is to acknowledge his greatness as a moral philosopher. R.S.D.

**Kantianism** covers any philosophical view which derives from, or echoes, the central tenets of Kant's critical philosophy. After the publication of the *Critique of Pure Reason* in 1781 that philosophy had an impact that was both immediate and enduring, and few Western philosophers have been able to escape its influence. There is evidently a direct line of descent among German philosophers from Kant through Fichte and Hegel, past Schelling, Schopenhauer, and neo-Kantians such as Hermann Cohen and Natorp, to Husserl and Heidegger. These philosophers mostly incorporated part of Kant's teaching into their own philosophies, though they rarely endorsed everything that Kant said and were often, like Hegel and Heidegger, deeply critical of Kant's own position. Nor, of course, did they all agree in their interpretations of Kant.

Kant's influence in the Anglo-Saxon world has been more variable. In the earliest days De Quincey, in *Blackwood's Magazine*, took the view that Kant's personal life was more interesting than his philosophy—a view that

would now be regarded as odd to the point of perversity. Bertrand Russell in his *History of Western Philosophy* quotes James Mill's patronizing judgement 'I see clearly enough what poor Kant would be at', and explicitly dissented from the view that Kant was the greatest of modern philosophers. The American Pragmatists acknowledged the influence that Kant had on them by linking their own term '\*Pragmatism' with what Kant had said in the *Transcendental Dialectic* of 'pragmatic belief' (*Critique of Pure Reason*, B 852). Charles Peirce adopted a strongly Kantian account of categories, but William James rejected what he understood of Kant's '\*transcendentalism', and urged that the right way to deal with Kant was to go round him rather than through him. And yet, despite this catalogue of hostility and incomprehension, Kant has constructively influenced many recent analytic philosophers from Wittgenstein to Strawson and Putnam. Nowadays few philosophers in this tradition resist a token reference to Kant, even though their views could not be regarded as Kantian. Davidson's '\*anomalous monism', for example, was constructed in part with a conscious reference to Kant's treatment of the conflict between free will and causality.

Two central features of Kant's critical philosophy serve to define Kantianism. First is the fundamental reference to what Kant calls 'transcendental apperception', and especially to that aspect of it which covers personal identity and self-consciousness. Second is the reference to a transcendental method which Kant conceived as a revolutionary way of resolving the endless conflicts in the philosophical tradition from the Greeks to David Hume.

Both aspects are complex, and ramify prolifically through Kant's own writing and that of his Kantian successors. Transcendental apperception, for example, covers for Kant not only the central datum of self-consciousness, but also the a priori network of \*categories through which an objective experience is made possible. In its purely personal aspect it defines various conceptions of transcendental idealism, from the extreme subjectivity of Fichte's notion of the 'ego' to Strawson's account of the concept of a 'person' as primitive. It has additionally a vital link through Kant's conception of transcendental freedom to the notions of personal agency, responsibility, and the moral law. Most of the German philosophers influenced by Kant, from Fichte to Husserl and Heidegger, recognized some notion of the self as the hinge about which the critical philosophy revolved. Many of them, like Fichte himself and Schopenhauer, regarded that notion as one with a primary moral significance. In more recent times, through a simple contrast between \*Utilitarianism and Kantianism in moral philosophy, this aspect of Kant's view has been associated with a non-consequentialist conception of the intrinsic moral character of acts.

The second feature, Kant's transcendentalism, is also complex and variously interpreted. It covers the ground from a tacit appeal to supernatural, or supersensible, entities which Kant called '\*noumena' or '\*things-in-themselves', to a purported new form of logic, a transcendental

logic, with a claimed revolutionary application to traditional philosophical issues. The former context might be further divided into a positive *acceptance* of such things in themselves, especially in relation to the transcendental self, and a negative *rejection* of any genuine knowledge of such supersensible entities. It was the negative aspect which led Schopenhauer to approve of Kant's rejection of transcendent metaphysics, and the positive aspect which led James to reject a Kantian transcendent self in favour of a modified Humean and empiricist account.

But Kant's transcendental method, and its alleged logic, are less mysterious in Kant than in some of his successors. Husserl's 'transcendental-phenomenological reduction', for example, sought to effect a transition from unreflective common sense to the recognition of a pure consciousness or transcendental ego which was not accessible to empirical observation. But it remains unclear how his phenomenological descriptions could yield a priori knowledge of such items. Peirce took seriously Kant's appeal to an architectonic structure for the critical system in his own account of categories and 'triadicty', but it has more often seemed dubious to attach so much significance to Kant's 'architectonic. Moreover, although Kant's references to a transcendental logic as part of his distinctive method may seem to indicate a non-standard version of formal logic, there seems no good reason to think of it in that way.

In fact Kant's transcendental method appeals essentially to two features: first to his novel classification of 'synthetic a priori' judgement, and second to the conception of a 'condition of a possible experience'. The two features coincide naturally with the thought that any proposition which expresses a condition of any possible experience will be bound to have a special status which may be described in terms of the synthetic a priori classification. On one side the conception of a condition of a possible experience places a restriction on what can count as knowledge and licenses it only when it can be brought to bear upon some possible experience. Although such a view is not the same as the Logical Positivists' appeal to verifiability, nevertheless it shares with them and with Hume a tough-minded criterion with which to evaluate speculative philosophy. On the other side the conception offers the prospect of a new and constructive approach to experience, in which the conditions of that experience are identified as a priori and treated as the background framework which makes it possible. It is this aspect which connects so naturally with recent philosophical accounts of \*language-games (Wittgenstein), or \*conceptual schemes (Strawson), categorial frameworks (Körner), or conceptual relativity (Putnam). It is associated also with Collingwood's account of 'absolute presuppositions' and above all with Strawson's project of 'descriptive metaphysics'.

Wittgenstein's *Tractatus Logico-Philosophicus* is often thought to echo Kantian themes in its account of the inexpressible limits to our experience, and especially in its references to a 'metaphysical' self which marks a limit to the world and is not therefore simply a part of it (5.641). But it

is in Wittgenstein's later works, such as *Philosophical Investigations* and *On Certainty*, that a more direct reference to Kantianism is to be found. For Wittgenstein's ideas of a form of life and of a language-game expressing such a form and governed by rules which make that experience possible echo Kant's notion of a condition of possible experience governed by his synthetic a priori principles. Wittgenstein did not classify his rules as synthetic a priori, but he recognized their special status by calling them 'grammatical' rules. Although the notion of a language-game captures the Kantian idea of a systematic experience governed by rules, Wittgenstein's conception, like Körner's account of a categorial framework, is not designed to cover the whole of our experience, but only some differentiable aspect of it. Strawson's account of a conceptual scheme, too, dispensed with the synthetic a priori classification, and so produced a Kantianism with more of an empiricist flavour than Kant would have accepted.

Of all these recent Kantian accounts, however, Strawson's has been the most committed and influential. It brings together the two aspects noted above of a fundamental and irreducible appeal to the notion of the self, and a transcendental method of justifying such fundamental notions. For in Strawson the appeal to conditions of possible experience has been seen as a distinctively Kantian response to traditional scepticism through the notion of a transcendental argument. In a similar way Putnam's 'internal realism' is also a conscious attempt to follow Kant's appeal to a justified objectivity in experience which does not rest on an absolutist 'God's-eye view' of an independent reality.

A doubt, for example, about the feasibility of providing an empiricist analysis of the \*self in terms of a closed sequence of sense-impressions might encourage an alternative non-empiricist and Kantian account. If the self, something to which such sequences of impressions belong, is a necessary, a priori, condition of any possible experience, then this may answer, or at least evade, such a traditional scepticism. Strawson's Kantian account of the self as a primitive notion, not to be itself analysed in terms of mental or physical features, echoes such a response. And in his account of a necessary reidentification of objects as a further condition for possible experience the same technique is explicitly used to rebut a traditional scepticism about \*identity. The central idea is that if reidentification is a necessary condition for any possible experience, then the sceptic's doubt will be either incoherent or else will embody a revisionary recommendation which is at best optional. The doubt will be incoherent on one side, since without a belief in identity there is no possible experience, and hence no way of making sense of the sceptic's query. It will be an optional revision, on the other side, if the sceptic uses his argument to recommend a change from the standard forms in which such reidentification is realized in our conceptual scheme.

Strawson's appeal to 'primitive' features of our experience such as the concept of a person or of reidentification

provides a modest Kantianism, but there are less modest ways of understanding Kant's own account. With regard to the self, for example, many Kantians have taken the view that for Kant such a reference is unavoidably to noumena or things-in-themselves. Such a view is encouraged by Kant's account of the resolution of the conflict between cause and \*freedom in the Third Antinomy, where it is easy to read him as accepting a 'two-worlds' picture of phenomenal causality and noumenal freedom. His remarks on the distinction between empirical and intelligible characters in human agents have sometimes associated Kantianism with an indeterminist doctrine, in which human freedom and responsibility are safeguarded by being exempted from natural causation. Although Kant himself rejects the strategy of exempting humans from causal influence, it remains unclear whether his own resolution of the traditional debate in this context is indeterminist or compatibilist.

**Kaplan, David B.** (1933– ). American philosopher at the University of California, known for his work in intensional logic, semantics, pragmatics, and philosophy of language. His initial stance was Fregean as in the influential 'Quantifying In', but his later work evolved into a theory of direct \*reference where, for example, expressions such as demonstratives, indexicals, and proper names are held to be unmediated by abstract senses.

In 'Opacity' he addresses problems of substitution, differences between naming and describing, quantifiers, and causal theories of reference. His views are further articulated in studies of demonstratives and \*indexicals, at the centre of which is the distinction between the content of an expression and its character. Content is the referent in a given context of use. Character (corresponding roughly to linguistic 'meaning') determines a content for any given context, as in the utterance 'I am here'.

Also influential are papers on \*descriptions, and on metaphysical questions raised by modal \*semantics.

**karma.** Literally action, whether bodily, linguistic, or mental. In most classical Indian traditions, 'karma' can also mean the unseen potentials for future pain and

pleasure which we accumulate as the result of good and bad action. Without exhausting these potentials there is no release from rebirth for the soul. Thus karma constitutes bondage in Jaina, Buddhist, and Vedic thought. The law of karma links up the moral quality of past actions with the hedonic quality of present and future life in a deterministic way. Ancient Indian medical and moral philosophers retrodict the birth, life-span, and well-being of an individual in terms of this theory. A slanderer, for example, is allegedly reborn with bad breath. Thanks to this doctrine, the Hindu theist's God is acquitted of responsibility for evil. Buddhists or Jaina atheists take it as a natural law needing no omniscient monitor. A.C.

**Kautsky, Karl** (1854–1938). The leading Marxist theoretician during the two decades before the First World War, Kautsky expressed the precarious orthodoxy of the time. He defended his view with vigour both against the revisionist tendencies of Bernstein and against the more revolutionary Marxism of Luxemburg and, later, of Lenin. As well as popularizing Marx's economic and philosophical ideas, Kautsky produced pioneering works on such diverse subjects as the agrarian question and the origins of Christianity. He was much influenced by the 'scientific' \*materialism of writers such as Haecker and Darwin, and this perspective marked all his writings. Even in his politics Kautsky remained evolutionary, materialist, and essentially passive. D.McL.

\*Marxist philosophy.

Massimo Salvadori, *Karl Kautsky and the Socialist Revolution 1880–1938* (London, 1979).

**Kelsen, Hans** (1881–1973). Austrian public lawyer and political theorist, his 'pure theory of law' was central to mid-twentieth-century philosophy of law. Rooted in nineteenth-century German \*legal positivism and, later, neo-Kantian concern with the conditions for knowing legal norms as norms (neither mere facts nor morally grounded), his sceptically positivist and ethically non-cognitivist work became more Humean after his emigration to America in 1940.

Every legal system's unity and validity derives, he argued, from its basic norm (*Grundnorm*): apply sanctions in accordance with the historically first (after the latest revolution) constitution and norms made thereunder. Juristic thought is possible only on the hypothesis, presupposition, or transcendental-logical postulate of the basic norm, which in late Kelsen is the content of a fictitious act of will and no longer has the role of resolving conflict between norms. J.M.F.

— *Introduction to the Problems of Legal Theory*, tr. and intro. B. L. and S. L. Paulson (Oxford, 1992).

**Kenny, Anthony John Patrick** (1931– ). British philosopher who has written on topics in the philosophy of mind, medieval philosophy, ancient philosophy, the philosophy of Wittgenstein, the philosophy of Descartes, moral philosophy, and the philosophy of religion. His output includes over thirty books, beginning with *Action, Emotion and Will*, published in 1963.

Kenny was ordained a Catholic priest in 1955 but returned to the lay state in 1963. He then held various university teaching posts. He has been Master of Balliol College, Oxford. The philosophy of religion has remained one of his major interests and he has produced several volumes in which he has examined arguments for the existence of God.

In the area of philosophy of mind, the greatest influence on him has been Wittgenstein, on whom Kenny has written two volumes, and his influence is also evident in his other writings on the philosophy of mind, on Descartes, and on Aquinas. H.W.N.

\*Frege.

A. J. P. Kenny, *The Metaphysics of Mind* (Oxford, 1992).

— *A Brief History of Western Philosophy* (Oxford, 1998).

**Keynes, John Maynard** (1883–1946). Keynes is primarily remembered for his economic works *Treatise on Money* (1930) and *The General Theory of Employment, Interest and Money* (1936), which argued that governments should raise taxes and lower spending during prosperity and lower taxes and increase spending during recessionary periods, and for his practical contributions to developing the international monetary system. Many believe that Keynesian economics was crucial to avoiding the escalating cycle of boom and bust that Marx believed would inevitably contribute to the destruction of capitalism.

Philosophically, Keynes is primarily remembered for his devotion to G. E. Moore's moral philosophy, and admired for his seminal *A Treatise on Probability* (1921), which is one of the most important expressions of the a priori or logical theory of \*probability: that probability consists fundamentally of an evidentiary relation between propositions. R.C.W.

**Khaldūn:** see Ibn Khaldūn.

**Kierkegaard, Søren Aabye** (1813–55). Danish writer and social critic widely credited with setting the stage and providing the conceptual tools for modern \*existentialism. Kierkegaard was also one of Hegel's most devastating critics. The formative years in Copenhagen were marked by personal dependence on an oppressively religious father and by the deaths, before he reached the age of 21, of his

mother and five of the family of seven of which he was the youngest. Kierkegaard spent ten years at the university before completing his dissertation *On the Concept of Irony with Constant Reference to Socrates* (1841) preliminary to a career in the Church. His second major work *Either/Or* (1843) marked a postponement of that career and was the outcome of the fateful decision to break off an engagement and disappointment at not finding in Schelling's Berlin lectures a philosophical alternative to established Hegelianism. The work portrays two life-views, one consciously hedonistic, the other ethical in a way which Hegelians would recognize except that the choice of the ethical is a personal one, not the outcome of a philosophical insight. The hedonistic or 'aesthetic' alternative is presented by a gifted essayist, and member of a society called 'companions of the deathbound', who applies it as a consistent principle in his own life, while the ethical perspective is conveyed in two extended admonitory letters addressed to the hedonist by a friend, a state functionary who urges him to admit that his situation is one of \*despair so that he can then 'choose himself' in ethical categories, these providing the true fulfilment of the aesthetic values he prizes. Kierkegaard's own intentions are concealed behind an elaborate barrage of *noms de plume* (the work is published by a pseudonymous 'editor' who tells how he has come upon the papers quite by accident).

The impression given by the title that the aesthetic and ethical life-views represent an exhaustive choice is disturbed by a concluding sermon passed on to the hedonist by the functionary on the theme that before God we are always in the wrong. Kierkegaard claimed later that at the time he himself had despaired of finding fulfilment in marriage but said that he had portrayed marriage as a form of fulfilment because it struck him as being 'the deepest form of revelation'. Unable to reveal himself in that way, Kierkegaard embarked on a series of 'edifying' works under his own name. These works, though on the surface in a conventionally religious vein, convey deep moral-psychological insight and it would not be improper to refer to them as philosophical.

The practice of concealment was continued, however, in a parallel series of pseudonymous works which include those more usually regarded as philosophical. These include, already in 1843, two works written largely in Berlin, *Repetition* and *Fear and Trembling*, followed in 1844 by *Philosophical Fragments* and *The Concept of Anxiety*, and in 1845 by *Stages on Life's Way*, in which a religious stage is distinguished from *Either/Or's* ethical alternative.

The pseudonymous authorship was to have ended with the publication of the *Concluding Unscientific Postscript to Philosophical Fragments* (1846), Kierkegaard having in mind to resume his intention to enter the priesthood. Instead, however, he wrote further non-pseudonymous works on specifically Christian themes motivated in part by the thought that he was better able to serve the truth as a writer. Among them are *Purity of Heart is to Will One Thing* (1847) with its account of \*double-mindedness and the

formidable *Works of Love* (1847). But at the same time, virtually ostracized by a feud he had himself provoked with a satiric weekly and which left him a figure of public ridicule, Kierkegaard's plans for at least partial self-revelatory absorption into society had given way to an urge to reveal to society its errors. The popular monarchy and people's Church, newly established in the aftermath of 1848, and which Kierkegaard saw as merely finite institutions catastrophically usurping the true role of religion, provided the political target. Deciding to announce that his intentions as an author had been religious all along, Kierkegaard now planned a second (unrevised) edition of *Either/Or* together with an explanation (*The Point of View of my Work as an Author*) of the relation of that and the subsequent pseudonymous works to the Christian themes of his non-pseudonymous production. For a variety of reasons detailed in his journals the explanation was withheld (but published posthumously by his brother in 1859), and instead Kierkegaard gave out two further works under a new pseudonym.

The first of these, *The Sickness unto Death* (1849), followed hard upon the second edition of *Either/Or*. It typologizes forms of despair as failures to sustain a 'synthesis' which expresses the structure of selfhood. The work introduces a non-substantial but normative concept of the self or 'spirit'. The most common and dangerous form of despair is one which people fail to recognize in themselves and even mistake for its opposite. In a spiritless society whose institutions have taken over spirit's functions also in name, no real basis for spirit, or true selfhood, remains in the established forms of life. Spiritual possibilities then tend to find their outlets outside such forms in madness, religious intoxication, the cult of the aesthetic, or in utopian politics. This, from the individual's perspective, is one way of failing to maintain the synthesis. The other is for the individual to duck below the level of its own spiritual possibilities and lead a spiritually emasculated life of worldliness. The solution which *The Sickness unto Death* prescribes for despair is faith, or willing acceptance of the task of becoming a self 'posited' not by itself but by a transcendent power.

In the final pseudonymous work, *Training in Christianity* (1850), Kierkegaard readdresses themes raised in the earlier *Philosophical Fragments*, in particular the individual's relation to Christ as one not of history but of contemporaneity and of shared human degradation. In the five years remaining until his early death at 42, Kierkegaard lived in increasingly straitened (though never degrading) circumstances, expending the remainder of a considerable inheritance on an explosive broadsheet (*The Instant*), in which, under his own name, he savagely satirized the State Church, its dignitaries, and minions.

According to the withheld explanation the pseudonymous ('aesthetic') works deliberately adopt an aesthetic point of view in order to loosen the grip on their readers of a falsely 'aesthetic' picture of religious fulfilment. They can also be read as mirroring their true author's own struggles as a social outsider playing with the thought that his

literary talents and situation might have marked him out for a specifically religious mission. In *Either/Or* human fulfilment, corresponding to the second, 'ethical' stage in the progression from the aesthetic to the religious, meant choice of a self wedded in a conventionally Hegelian way to shared social norms. The subsequent pseudonymous works, beginning with *Repetition* and *Fear and Trembling*, present the radically anti-Hegelian idea that the ethical component in the individual's life is established first in a psychologically unmasked and socially unmediated relation to God. The slim but elegantly crafted *Philosophical Fragments* contrasts an idealist view, identified with Plato's Socrates but clearly to be construed as a progenitor of Hegel, with one where the relationship to truth depends on faith. The massive *Postscript* is described by Kierkegaard as a turning-point in the 'aesthetic' works, since it clearly identifies the latter view with Christianity and raises explicitly the question of what it means to be a Christian. The Christian's proper relation to the 'absolute object of worship' is \*inwardness, or a 'passionate' interest in a transcendently grounded fulfilment, the more passionate because the individual is aware that no empirical or rational inquiry can support acceptance of an assurance based exclusively on the belief that some other existing individual has been the eternal in time (the God-man). This is literally unthinkable and therefore immune to argument or evidence one way or the other. The principal target is Hegel's 'System', which, by treating matters requiring personal choice as topics for a shared rational insight, turns living issues into matters for a generalized curiosity. In fact there are two opposed objections to a scientific approach to the question of personal fulfilment. In Hegelian science the matter is decided already by the truth of being which will emerge as the system of thought develops, but that abstracts from your own existence which 'keeps thought and being apart' and therefore fails to capture the forward movement of the individual's own life. And treating the issue as a scientific matter in a general sense to be decided collaboratively in the light of evidence not all of which is (or ever will be) in, ignores the urgency of the Christian message which stands there, as William James would say, as a 'forced' option that brooks no delay.

Some see in Kierkegaard's philosophical pseudonym (Johannes Climacus) an assassin hired to deal with the Hegelians, so that the absurdity and paradox of Christianity arise only for the misguided 'systematizer'. Wittgensteinians have interpreted the *Postscript* as a demonstration of what happens if you apply the rules of one language-game inappropriately to another, but this inner relativism fits ill with Kierkegaard's emphasis on the 'crucifixion' of reason in faith. In his journals Kierkegaard says that paradox and absurdity are the negative conditions of faith—guarantees, as it were, that the assurance sought in faith is not being treated as though it were achievable through the exercise of some human capacity. That capacity need not be cognitive; the distinction between \*Religiosity A and Religiosity B is between, on the one hand, a view which interprets what the pseudonymous author calls 'dying

from immediacy' procedurally, as if a relationship with the object of worship can be established simply by subordinating all 'relative' ends to an 'absolute' end, and on the other hand a non-immanentist view and the 'Christian' view in which human capacities as such extend no further than to history so that a historical event, the Incarnation, offers our only relation to the Absolute. From this point of view the Absolute lies beyond the reach of any kind of natural relationship.

What then is the positive content of faith? The pseudonymous works do not say; their 'dialectic' is, as some have said, merely 'negative'. But the final pseudonymous work, *Training in Christianity*, can be read together with parts of the non-pseudonymous 'religious' corpus as indicating that the saving truth can be grasped in a moral agent's sense, in imitating the example of Christ, of acting out this truth in the form of Christian love. The earlier *Works of Love* presents the Christian ideal of love of one's neighbour in the form of a generalized selflessness. Part of what emerges is that it is only by removing personal preferences that values inherent in other persons, but also in nature, can be truly acknowledged and allowed their fulfilment. This assumes that the value or worth of persons and things is neither, as Hobbes has it, their price nor any degree of natural attachment to them. Values, on this view, reside in possibilities inherent in the persons and things themselves independently of human interests, and indeed these interests stand in the way of those values both in the sense that they do not become visible and in the sense that they fail to be elicited. The inner consistency of the view as a generally applicable ethics depends at least in part on how far the sacrifice of human desires or interests is compatible with the sacrificer's own personal or human fulfilment.

Kierkegaard detects in social forms, and in patterns of human behaviour in general, a pervasive disinclination to face live issues in their appropriately living form. In this respect Hegelianism is not simply a failed attempt to capture the forward movement of life, but part of a general contempt for the individual, evident also in the conflation of the truism that human life is impossible without political groupings with the pernicious idea that the individual's fulfilment can come to expression only in the form of political association or religious community (see *Literary Review: The Two Ages* (1846)). Kierkegaard's writings are profitably grasped in the light of his sense of a prevailing flight from \*subjectivity and of society's need to divest itself of protective self-images. The more scandalous views attributed to Kierkegaard, such as the arbitrary defeasibility of shared norms, the subjectivity of truth, and the supposed foundational role assigned to criterionless choice, often vanish on a closer reading of the texts, which in context lend themselves to more readily acceptable readings. Thus the notorious teleological suspension of the ethical in *Fear and Trembling* can be seen as part of Kierkegaard's nowadays uncontroversial insistence that systems of shared social norms are purely historical phenomena set against his championing of the view

that a true system of values derives directly from an unconditioned transcendent source, unmediated by contingent and merely finite facts of preference. His target is the common assumption in his time that facts of preference are both historical and expressions of an unfolding Absolute. The claims in the *Postscript* for the subjectivity of truth can be read as the requirement that the relation to the unconditional source of value be one of inwardness and personal devotion both to the source itself and, through it, though distributively rather than collectively, to mankind. As for the rumour of a criterionless choice, in Kierkegaard there is little or no evidence for this idea as distinct from that of the notion of personal commitment and choice. At least the reader of *Either/Or*, the most widely cited source for the rumour, cannot fail to detect signs of dialogue in that work, objections to the ethical life-view implicit in the first part which are then made explicit and countered in the second part, which is also in itself a sustained argument in favour of the ethical alternative. Failure to choose the ethical alternative is presented as more in the nature of a motivated rejection of a form of human fulfilment that the hedonist is already in a position to acknowledge but refuses so to do, than a choice made in a vacuum between two quite independent and equally valid ways of life.

The tendency to ascribe extreme views to Kierkegaard may be due in part to the fanatical anti-humanism of his later rejection of all bourgeois forms of human association, including marriage and the family. Kierkegaard himself remarks on how the original either/or becomes radicalized so that in the end both ethics and institutional religion (castigated as the fraud of 'Christendom') end up on the aesthetic side as merely forms of self-indulgence, while self-abnegation, suffering, and devotion to God now form the saving option. This could be seen as a pattern set from the start; Lukács suggests it is the outcome of Kierkegaard's life-long tendency to spite reality. Or perhaps the extremity was one that Kierkegaard was driven to by circumstances. The radical stance might also, however, at a pinch be interpreted as prescribed by the *Postscript's* insistence that Religiousness A is a necessary prolegomenon to Religiousness B. The later Kierkegaard may be insisting that the institutions of a spiritless society must be comprehensively vacated before creative alternatives based on true selfhood can replace them. We note that Kierkegaard describes *The Sickness unto Death* as containing a polemic directed at that 'altogether un-Christian conception', Christendom. Regarding the establishment's scorn of sects, he said there was 'infinitely more Christian truth' in the errors of their ways than in 'the mawkishness, torpor, and sloth of the establishment'. The trick is to be rid of the errors of the pagans without losing, as in a spiritless society which shuns true selfhood, their 'primitive' spiritual impetus.

For obvious reasons rationalists and, because of his attitude to shared norms, Hegelians have dismissed Kierkegaard as an irrationalist; while what in Kierkegaard's writings repels rationalists and Hegelians alike has drawn

sympathy from circles later stigmatized as fascist. Equally, democrats are put off by Kierkegaard's contempt for public opinion, the crowd, and parliamentary institutions, and although Marcuse saw 'traits of a deep-rooted social theory' in Kierkegaard, the Christian framework and the focus on the individual make Kierkegaard an obvious target for the Marxist. Eagerly read in German academic circles at the beginning of the twentieth century, and heralded by theologians as the provider of a radical Christian apologetic, Kierkegaard also influenced agnostic and atheist thinkers of such divergent political sympathies as Heidegger and Lukács. The enormous extent of the former's debt to Kierkegaard is still to be appreciated. The latter in his pre-Marxist days admired what he saw as the tragic heroism with which Kierkegaard, by exalting the notion of choice, vainly defied the necessities of life by seeking, first in his own life, to impose on them a poetic form. The later Lukács blamed Kierkegaard for the 'bourgeois' philosophy of post-war existentialism and even saw in him a source of modern nihilism and decadence. As if in confirmation of this latter charge some post-modern writers, notably Jean Baudrillard, focus on Kierkegaard the 'aesthetic' author and see in this complex man a pre-incarnation of the modern existentialist. Adorno, sympathizing with Kierkegaard's campaign against the tyranny of the universal over the particular though not with the resort to religious concepts, found in Kierkegaard's experimental 'aesthetic' writings the makings of a new style of reasoning which elicits rather than buries the truth of the particular. Many modern philosophers have found in the religious framework of Kierkegaard's writings an impediment to any serious appreciation of his thought. Wittgenstein, however, once referred to Kierkegaard as 'by far the most profound thinker of the last century'.

**killing.** Presumably no society could survive unless it had some restrictions on its members killing each other. But the prohibitions that societies have on killing vary greatly. In Greek and Roman times to be a human—that is, a member of the species *Homo sapiens*—was not sufficient to

guarantee that one's life would be protected. Slaves or other 'barbarians' could be killed, under conditions that varied from time to time; and deformed infants were exposed to the elements on a hilltop. The coming of Christianity brought a new insistence on the wrongness of killing all born of human parents, in part because all humans were seen as having an immortal soul, and in part because to kill a human being is to usurp God's right to decide when we shall live and when we shall die. Non-human animals, on the other hand, remained unprotected because they were believed to have been placed by God under man's dominion. This doctrine of the sanctity of all (and only) human life remains the orthodox view on the morality of killing.

Some contemporary philosophers, among them Jonathan Glover, James Rachels, and Peter Singer, have challenged this orthodoxy, arguing that membership of a given species—for example, *Homo sapiens*—cannot in itself determine the value of a being's life, or the wrongness of killing that being. Rather, this wrongness must depend on some morally relevant characteristics that the being has. Sentience, or the capacity to feel pleasure or pain, seems to be a minimal characteristic, and so the killing of plants is not wrong in itself. In addition to sentience, however, Glover gives an important place to the being's capacity for \*autonomy, for making his or her own decisions (including a decision about whether or not to continue living). Killing an autonomous being against that being's will is the most drastic possible violation of autonomy, and this makes it more seriously wrong than the killing of a sentient being not capable of autonomy.

Rachels focuses on whether the being can live a *biographical*, rather than a merely *biological*, life, which is similar to the emphasis given by Singer to the ability to see oneself as having a past and a future. To kill such a being, unless at the being's request, thwarts the preferences for the future that the being may have, and this makes the killing wrong in a way that is additional to any wrong that may be incurred by the killing of a sentient being unable to form any preferences for the future.

The effect of these arguments is to distinguish a class of beings whom it is especially wrong to kill. The term 'person' is often used to distinguish this class from the class of human beings as a whole, for not all human beings are autonomous, or capable of seeing themselves as having a past and a future. Infants, and the profoundly intellectually disabled, for example, are not. Chimpanzees, on the other hand, appear to be persons in this sense. Hence it is an implication of this view that, other things being equal, it is worse to kill a normal chimpanzee than a profoundly intellectually disabled human being. Of course, to arrive at a final judgement about the wrongness of killing any being, we need to consider also the effect of the killing on relatives and friends, and on the community as a whole.

The \*slippery slope argument is often used as an objection to any change in our attitude to killing human beings. We should, however, be equally aware of the possible undesirable effects of, for example, allowing severely

disabled infants to die slowly from dehydration or infection because we believe it wrong to kill them. p.s.

\*euthanasia.

**Kim, Jaegwon** (1934– ). Author of numerous well-known papers on metaphysics and epistemology, best known for his pioneering work on \*events, \*supervenience concepts, and psychophysical relations. Kim takes events to be exemplifications of properties (or relations) by an object (or set of objects) at a time. On this view, Oedipus' marrying Jocasta and Oedipus' marrying his mother would be the same event, while Brutus' killing Caesar and Brutus' stabbing Caesar would be different events. Kim has argued for a form of materialism in which mental properties are 'locally reducible' to physical properties by way of species-specific correlating laws. Non-reductive materialism, he argues, collapses either into a position in which mental properties do no causal work (a form of eliminativism) or into one in which mental properties do not depend in any significant way on physical properties (a form of dualism). N.L.

\*mind, problems of the philosophy of.

J. Kim, *Supervenience and Mind: Selected Philosophical Essays* (Cambridge, 1993).

— *Mind in a Physical World* (Cambridge, Mass., 1998).

**kind, natural.** It is easier to say what a natural kind *term* is than to say what natural kinds themselves are, ontologically speaking. Natural kind terms constitute a class of general terms and include both mass terms, like 'gold' and 'water', and certain \*sortal terms, like 'tiger' and 'apple'. Loosely, they may be said to denote types of naturally occurring stuffs and things. Kripke has argued that natural kind terms are \*rigid designators. E.J.L.

S. P. Schwartz (ed.), *Naming, Necessity, and Natural Kinds* (Ithaca, NY, 1977).

**Kindī, Yaaqūb ibn Ishāq al-** (d. after 870). Widely known as the first Arab philosopher, he was instrumental in the spread of Greek philosophy in the state-endowed Academy in Baghdad. He commissioned translations of Greek philosophical texts that served as inspiration for his own Arabic works, which identify the formative, syncretic period of Islamic philosophy. He is the first Islamic philosopher to offer systematic explanations for some of the debated theological issues of his time, such as creation, immortality, God's knowledge, and prophecy. His *On First Philosophy* was the first Arabic work on syncretic metaphysics. Though some of the issues he defined, such as creation *ex nihilo*, were later rejected, many, such as immortality of the individual soul, and the distinction

between human and revealed knowledge, helped define lasting problems of Islamic philosophy. H.Z.

*Al-Kindī's Metaphysics*, tr. Alfred L. Ivry (Albany, NY, 1974).

**kinēsis.** Aristotle's distinction between *kinēsis* (motion, change), and *energeia* (activity, actualization) prefigures various contemporary distinctions in the philosophy of agency. Theologically the notion occurs in 'first mover' proofs of God's existence: things changed in a basic quality can only be changed by something which, at the time of change, has that quality. In such a series, argued Aquinas, \*infinite regress is impossible; hence there must be a first mover.

J.J.M.

\*prime mover.

T. Penner, 'Verbs and the Identity of Actions: A Philosophical Exercise in the Interpretation of Aristotle', in O. P. Wood and G. Pitcher (eds.), *Ryle: A Collection of Critical Essays* (London, 1970).

**Philip Kitcher** (1947– ). Contemporary philosopher of science, defender of *naturalism* in philosophy, British-born but US-based. Kitcher focused initially on philosophy of biology and mathematics, but is now expansive in his interests. *Vaulting Ambition* (1985) was a harsh critique of sociobiology. But Kitcher has also resisted various arguments alleging conceptual problems with mainstream evolutionary theory. In the 1980s he defended the view that explanation in science is a matter of *unification*. This view, developed partly in reaction to causal theories of explanation, exemplifies his metaphysical outlook—generally realist but attracted to Kantian options in the area of causation. Kitcher presented a total philosophy of science in his weighty *Advancement of Science* (1993). Here and elsewhere, he has engaged in detail with claims that science has been shown to be essentially non-rational when fundamental theoretical choices are made. He defends a moderate conception of scientific progress and rationality, and includes innovative mathematical modelling of science's social organization. Kitcher's recent work has extended into ethics and the political role of science. *The Lives to Come* (1996) was commissioned by the Library of Congress as a philosophical exploration of the human genome project. **klepsydra.** The klepsydra was typically a metal vessel with an aperture at its narrow neck and little holes which could be plugged at its wide end. It is sometimes thought that the ancient Greek philosopher Empedocles used it to prove the reality and substantiality of air, by pointing out that, when inverted in water with the little holes plugged, water was prevented from rising in it, but, with the holes unplugged, water rose unhindered by the air which it expelled. As air was in fact one of the four Greek elements, there was taken to be no need for any proof of its distinct

reality. What Empedocles sought to prove by his remarks was the independent reality of \*space, which had just been denied by the Eleatics. The air was expelled, but not its space, which was left behind for water to occupy. The Greeks needed the reality of space to prove the possibility of \*motion. W.E.A.

John Burnet, *Early Greek Philosophy* (London, 1892).

**Kneale, William Calvert** (1906–90). British philosopher and historian of logic, Fellow of Exeter College, Oxford (1932–60), and White's Professor of Moral Philosophy at Oxford (1960–6). Kneale published in many areas including metaphysics, philosophical logic, philosophy of mind, and moral philosophy. In *Probability and Induction* (1949), he surveys classical theories of induction, argues that probability theory cannot justify induction, and offers his own justification. Here and elsewhere he argues for the importance of natural necessity in understanding law, causation, and subjunctive conditionals. *The Development of Logic*, written with his wife, Martha, is both a history of logic and an introduction to logic and topics connected to it. This thick book devotes about half of its 761 pages to the nineteenth and twentieth centuries, with extended attention to Frege. D.H.S.

\*necessity, nomic.

William Kneale and Martha Hurst Kneale, *The Development of Logic* (Oxford, 1962).

**knowledge.** The principal intellectual attainment studied by \*epistemology. Virtually all theorists agree that true belief is a necessary condition for knowledge, and it was once thought that justification, when added to true belief, yields a necessary and sufficient condition for knowledge. Its sufficiency, however, was disproved by Gettier as follows. Suppose one justifiably believes *q* although it is false; then one reasonably infers *p*, which is true. The result is a justified true belief in *p*, yet one cannot be said to know that *p*. Can the problem be solved by requiring that no intermediate conclusions like *q* be false? No; other counter-examples remain. Sam believes, through visual appearance, that a lighted candle is before him. There is indeed a candle there but Sam sees only a hologram of a candle, not the real candle, which is blocked from view. Then Sam lacks knowledge, although he has justified true belief that rests on no false intermediate conclusions.

Other theories of knowledge put less weight on justification. According to the causal theory, knowledge consists in true belief that bears an appropriate causal connection to the fact in question. This handles the candle case because its presence is causally unconnected to Sam's belief. Reliability theories say that someone knows only if his true belief is acquired by a reliable process or method. This may be understood to entail the \*counterfactual requirement: *S* would not believe *p* if *p* were false.

Causal, reliability, and counterfactual theories are generally called 'externalist', because they make it possible to

satisfy the conditions for knowledge (e.g. causal-connection conditions) without being aware that one satisfies them. ‘Internalist’ theories emphasize conditions of which subjects are aware. The demarcation between these types of theory is problematic, however, because paradigmatic internalist theories, such as coherentism, may also make knowledge attainable through subjectively inaccessible conditions. Whether a belief coheres with the rest of one’s beliefs, for example, might not be readily accessible to the subject.

Epistemologists often look to theories of knowledge to settle the problem of \*scepticism, but how easily this problem can be settled is questionable. One theory says that a person knows *p* only if he ‘discriminates’ it from relevant alternatives. This ostensibly favours anti-scepticism because not all logically possible alternatives seem relevant. Suppose Jane sees a barn in the field. Although she cannot discriminate it from a papier-mâché facsimile, such a facsimile is not a relevant alternative (unless facsimiles abound in the neighbourhood). Scepticism might gain a foothold here, however, by claiming that every logically possible alternative is relevant. Who is right in this dispute, and is there a determinate answer?

This raises methodological issues about the theory of knowledge. Is it a theory of some evaluator-independent ‘stuff’, on the model of the chemical theory of water? Or is it a theory of human concepts and their deployment? On the former approach, there should always be a fact about whether someone knows, but why should our ordinary judgements be reliable guides to such facts? On the latter approach, knowledge may be a very fuzzy concept that has determinate applications only when certain parameters are set, and these parameters can legitimately be set either to the sceptic’s or to the anti-sceptic’s taste. A.I.G.

**knowledge, the limits of.** The issue of the extent and limits of human \*knowledge is a perplexing one. There is no way of establishing a proportion between what we know and what we do not. We clearly cannot estimate the amount of knowledge yet to be discovered (both because there is no real measure of what is known and because we have no reliable information regarding new knowledge yet to come). We realize that our knowledge contains errors of omission and commission but do not know just where they lie.

Is human knowledge completable? The incompletability of scientific progress is compatible with the view that every question that can be asked at any particular state of the art is going to be answered—or dissolved—at some future state: it does *not* commit one to the idea that there

are any unanswerable questions placed altogether beyond the limits of possible resolution. No recourse to insolubilia need be made to maintain the incompletability of our scientific knowledge. How could we possibly establish that a question *Q* will continue to be both *raisable and unanswerable* in every future state of science, seeing that we cannot now circumscribe the changes that science might undergo in the future? If a question belongs to science at all—if it reflects the sort of issue that science might possibly resolve in principle and in theory—then we shall never be in a position to put it beyond the reach of possible future states of science as such. N.R.

\*justification, epistemic.

E. McMullin, ‘Limits of Scientific Inquiry’, in J. C. Steinhardt (ed.), *Science and the Modern World* (New York, 1966).

N. Rescher, *The Limits of Science* (Berkeley, Calif., 1984).

**knowledge, theories of:** see epistemology, history of; epistemology, problems of.

**knowledge and science.** Science systematically corrects the errors of \*common sense. Thus, from science we learned that, contrary to first appearances, the sun does not go round the earth each day. But what happens when science seems to undermine not particular beliefs, but whole tracts of experience? Can science really tell us that, say, the world is not in itself coloured or that the famous solid, unmoving table of Eddington’s physicist is mostly empty space thinly populated with rapidly moving particles? Too radical a correction of common sense by science runs the danger of depriving scientific theories of the ultimately commonsensical evidential basis on which they depend. It would be safer to regard the theories of science as a whole as offering highly generalized and effective abstractions from the richness of what there is, rather than as the only or the whole truth. A.O.H.

**knowledge by presence.** Distinguished from acquired \*knowledge, this technical term is used in Islamic philosophy to designate a non-predicative mode of cognition required prior to the definition and construction of fundamental philosophical principles. Similar in sense to Plato’s ‘intellectual vision’, and in form to Aristotle’s ‘quick wit’ (*ankhinoia*), it was first fully formulated by Sohrawardī. This type of knowledge posits priority to the self-conscious subject’s immediate grasp of the real, manifest essence of objects. Tantamount to primary intuition, similar to Kant’s ‘immediate relation to objects’, but not reduced to Russell’s ‘knowledge by \*acquaintance’, it was given objective validity by later mystics and theologians, who emphasized its mystical and experiential implications, and made rhetorical use of it to ‘prove’ the primacy

and validity of prophetic, inspirational, as well as esoteric and fantastic knowledge. H.Z.

Mehdi Ha'iri Yazdi, *The Principles of Epistemology in Islamic Philosophy: Knowledge by Presence* (Albany, NY, 1992).

**Komenský (Comenius), Jan Amos** (1592–1670). Czech philosopher and pedagogue. Bishop and theologian of the Unitas Fratrum (Moravian Brethren), exiled in the period of Counter-Reformation. He found refuge in various parts of Europe, including London, where he wrote the mystically coloured *Via Lucis* (1641). His principal philosophical treatise *De Rerum Humanarum Emendatione Consultatio Catholica* is based on the traditional Neoplatonic scheme of emanations specifically modified and enriched by the humanistic idea of restoration of humans to the divine universal harmony by the way of universal reform (*panorthosia*) and universal education (*pampaedia*). So conceived, his philosophy aimed at a grandiose reform of pedagogy in the spirit of modern didactic realism. In place of scholastic verbalism it turned to demonstrative teaching, conceiving school as play (*schola ludus*) and as a workshop of humanity (*officina humanitatis*). The same principles gave birth to his philosophy of non-violence, peace, and ecumenicity. 'Omnia sponte fluant, absit violentia rebus' became his device. M.P.

**Korean philosophy.** The reigning theme of Korean philosophy is irenic fusionism, as evidenced by the way of the flow of wind (*poong-ryu-do*) that is the substratum of Korean philosophy. The flow of wind is invisible and yet all-pervasive. This is also man's vibrating, unceasing way of communing with nature and fellow beings, thus evincing an 'undifferentiated aesthetic continuum' (to adopt F. S. C. Northrop's phrase) or Nothingness (*mu*).

*Poong-ryu-do* is the way of overcoming alienation, countenancing solidarity with fellow beings, and helping to achieve harmony of polarities. When \*Confucianism, Buddhism, \*Taoism, and other 'foreign' strands of thought were introduced to Korea, it was *poong-ryu-do* that helped to bring about their fusion and synthesis. I will illustrate the theme with two notable examples.

Attuned to *poong-ryu-do* was the Buddhist monk Wonhyo (617–86). If Buddhism originated in India and was nurtured in China in Mahāyāna form, it was segmented into various sects when it reached Korea. Wonhyo succeeded in integrating the contentions of these sects by Harmonizing of Contentions (*hwajaeng*): just as all rivers are bound for the sea, so are various sects bound to return to the Buddha mind. For Wonhyo, to attain Nirvana was to attain one heart–mind–body (*ilshimdongchae*) with humanity.

Paradoxically, for Wonhyo, to be exclusively Buddhist was not to be Buddhist. He propounded an all-encompassing cosmic universalism by absorbing elements not only of Buddhism but also of Confucianism and

Taoism. Wonhyo was the embodiment of the fusion of the three teachings (*shilnaepohamsamkyo*) and the way of mysterious wondrousness (*hyunmyochido*). He endeavoured to overcome the dichotomies of being and non-being, the true and the false, and the sacred and the secular. For Wonhyo, Nothingness (*mu*) meant integration, fusion, and harmony, and getting away from dogma. His *mu* was the prototype of the Zen Buddhist notion of Absolute Negation and Nothingness.

The theme of harmony, fusion, and synthesis is again manifest in Korean \*neo-Confucianism. In dealing with the metaphysical (*i*) and the physical (*ki*), the Chinese philosopher Chu Hsi (1130–1200) was dualistic and said that the Four Beginnings (commiseration, shame, deference, and discernment) of the Four Virtues (humanity, righteousness, propriety, and wisdom) emanate from *i* and the Seven Emotions (joy, anger, sadness, fear, love, hatred, and desire) from *ki*. The Korean philosopher Hwadam (Suh Kyungduk, 1489–1546) moved to integrate *i* and *ki* and spoke of Great Harmony (*taehwa*).

In the Four–Seven Debate with Ki Daesung, Toegye (Yi Hwang, 1501–70), while being still dualistic, broke away from Chu Hsi by espousing the reciprocal emanation (*hobal*) of *i* and *ki*: with the Four, *ki* follows *i* when *i* becomes emanant; with the Seven, when *ki* becomes emanant, *i* 'rides' *ki*. Though he was critical of Toegye's idea that *ki* follows *i* as being dualistic, Yulgok (Yi I, 1536–84) nevertheless embraced his notion that *i* 'rides' *ki*: only *ki* is emanant and *i* moves its emanation; *i* and *ki* are 'neither two things nor one thing', as evidenced by 'wondrous fusion' (*myohap*). For Yulgok, original nature (*i*) and physical nature (*ki*) coalesce into one human nature. Toegye and Yulgok, whose thoughts culminated in an irenic fusionism, constituted the crowning phase of East Asian neo-Confucianism by exhibiting dialectical dexterity in articulating the concepts of *i* and *ki*, left unclarified by the Chinese.

Toegye also developed the neo-Confucianist concept of single-mindedness (*kyung*), which was a manifestation of his unequivocal humanism, as shown by his total rejection of the Mandate of Heaven (*chunmyung*), which still had a hold on the Chinese, including Chu Hsi. Toegye's *kyung* synthesized the primeval Korean sense of supreme-efforts-cum-earnest-devotion (*chisung*) with the Confucianist notion of holding fast to mind (*jik-yung*); he advocated self-efforts for creating a meaningful life. In particular, his concept of single-mindedness had a lasting influence on the Japanese neo-Confucianists of the Tokugawa period.

Every major Korean neo-Confucianist shared Toegye's preoccupation with single-mindedness, which signalled new stress on praxis in the development of Korean neo-Confucianism: the fusion of the metaphysical and the physical is better brought about through action than speculation, important as theory might be. That was the point of Yulgok's integration of sincerity (*sung*) with single-mindedness. In this respect Korean neo-Confucianism made a break with the Cheng-Chu school of Chinese neo-Confucianism, which was overly speculative.

It is small wonder that Yulgok's thought flowered into Practical Learning (*shilhak*) in eighteenth- and nineteenth-century Korea. Practical Learning, keener on social issues than idle speculation, once more evinced the way of the flow of wind in striving to achieve the synthesis of theory and praxis. Practical Learning also helped to create an intellectual ambience open and receptive to Western Learning (*suhak*). K.-S.L.

**Korn, Alejandro** (1860–1936). Latin American philosopher born in San Vicente, Argentina. Korn's reading of Kant and Schopenhauer led him to move away from \*positivism, the predominant philosophy of Latin America in the late nineteenth century. Like the positivists, however, he maintained that knowledge must be based on experience. But philosophy must not be reduced to a science of empirical facts; it is fundamentally concerned with values. In *La libertad creadora* (1920–2), he proposed a creative concept of \*freedom according to which the goal of human actions is to overcome the laws of necessity that govern the objective world. Creative impulse, as manifested in self-control and the technological conquest of nature, enable the subject to accomplish this. In *Axiologia* (1930), his most important work, Korn defends a subjectivist position, where value is understood as relative to human evaluation. E.M.

J.G.

Solomon Lipp, *Three Argentine Thinkers* (New York, 1969).

**Korsgaard, Christine** (1952– ). American philosopher, Professor at Harvard. Korsgaard is one of the leading interpreters of \*Kant's moral philosophy and exponents of contemporary Kantian ethics. In her book *The Sources of Normativity* she argues, first, that our reflective nature forces us to look for reasons for our actions, and second, that we find these reasons in our own autonomous nature. The theory is realist, but does not involve metaphysical commitments. Korsgaard argues that in order to act at all we must have a conception of our own practical identity, and that compatibility with this conception is what determines whether a consideration counts a reason. Though Korsgaard admits that we can have many overlapping identities (as a mother, as a philosopher, as a friend), she argues that there is one identity that we must all have—identity simply as a human being among other human beings, and this is the identity that gives rise to traditional Kantian moral reasons. E.J.M.

\*constructivism.

— *Creating the Kingdom of Ends* (Cambridge, 1996).

**Kotarbiński, Tadeusz** (1886–1981). Polish philosopher and logician, author of a radically nominalist epistemology.

Studied in Darmstadt and Lvov, taught classical languages in high schools, was professor at the Universities of Warsaw, Lodz, and then Warsaw again. He was President of the Polish Academy of Science from 1957 to 1962.

He published a widely used textbook, *Elements of the Theory of Knowledge, Formal Logic and Methodology of Science* (1929, in Polish), a number of works on ethics that are independent of religious and political premisses and of the laws of nature (*Meditations on Worthy Life* (1966), in Polish), various historical studies, and studies on praxiology or the general theory of efficient work (*Treatise on Efficient Work* (1955), in Polish). His own metaphysical standpoint he described as reism, a kind of \*materialism without matter; it implies that the proper use of the verb 'to exist' is reserved to individual things and that all meaningful propositions (including those related to mathematical objects, literary works, cognitive acts, etc.) can, in principle, be translated into reistic language; without being thus translatable they are meaningless. Both before and after the Second World War Kotarbiński was regarded in Poland as a moral authority, engaged in fighting for tolerance against clericalism and anti-Semitism. L.K.

H. Skolimowski, *Polish Analytical Philosophy* (London, 1967).

**Kraus, Karl** (1874–1936). Viennese playwright, poet, and satirist, best known as publisher of *Die Fackel* (The Torch), a fiercely independent journal of social, political, and cultural criticism that created a sensation when it first appeared in 1899. *Die Fackel* was admired by many, including Wittgenstein. An uncompromising opponent of anything he judged to be humbug, Kraus considered \*language an important source of truth in its own right, and vigorously attacked any individual or institution, most particularly the Press, that he regarded as corrupting language and thus contributing to the hypocrisy and moral decline of the age. Kraus's scathing satirical attacks on the political and cultural institutions which he took to be responsible for the First World War culminated in an epic drama, *The Last Days of Mankind*, composed largely of quotations he allowed, characteristically, to speak for themselves. J.HEIL

E. Timms, *Karl Kraus: Apocalyptic Satirist* (New Haven, Conn., 1986).

**Kreisel, Georg** (1923– ). Austrian and cosmopolitan logician. As a mathematician he has chiefly studied proof and computation. Though not the founder of a school, he has had a wide influence in philosophy of mathematics through his many commentaries. Recurring themes in his writings are that 'the data of foundations consist of the mathematical experience of the working mathematician'; that foundational slogans (particularly formalist ones) can usually be proved wrong by careful attention to straightforward facts; that classical and constructivist mathematics each use the appropriate methods to describe different parts of the same world (respectively, mathematical objects and mathematical evidence); that the proof of a theorem may give extra information which is important

for understanding the role of the theorem; and that in mathematics one should cultivate a sense of when to be surprised.

W.A.H.

\*constructivism; formalism.

Georg Kreisel, 'Mathematical Logic: What has it Done for the Philosophy of Mathematics?', in R. Schoenman (ed.), *Bertrand Russell: Philosopher of the Century* (London, 1967).

**Kripke, Saul** (1940– ). American logician and philosopher of language noted for his work in \*modal logic but also for his interpretation of Wittgenstein's views on meaning. Exploiting the terminology of \*possible worlds, Kripke argues against descriptivist theories of proper \*names, holding instead that proper names are \*rigid designators, that is, expressions which (unlike most definite descriptions) retain the same reference in every world in which they refer to anything at all. He repudiates Frege's theory that proper names possess senses determining which objects they refer to, arguing instead that names are initially assigned their references by procedures such as ostension and are then passed on from speaker to speaker in a causal chain, each speaker receiving the name with an intention to use it to refer to the same object as that to which the speaker from which he received it referred.

Kripke appeals to the rigidity of names to defend the metaphysical theses of the necessity of identity and of origin, the latter implying that a composite object could not have been originally composed of parts very different in identity or kind from those from which it was in fact made. His defence of these theses leads him to reject the traditional association between \*necessity and the \*a priori and to hold that some necessary truths can be a posteriori and some contingent ones a priori. For instance, that water is H<sub>2</sub>O is a true identity statement whose truth was discovered only empirically and yet one which is, if Kripke is right, necessary. As a putative example of a contingent a priori truth he cites the statement that the standard metre bar is one metre in length. Kripke's stance on such issues has far-reaching metaphysical implications, as is demonstrated by his appeal to the necessity of identity to challenge the coherence of mind-brain \*identity theories.

**Kristeva, Julia** (1941– ). French theorist, linguist, literary critic, and philosopher, currently a psychoanalyst. Born in Bulgaria but based in Paris since the mid-1960s, she brought Marxist theory and Russian formalism together with \*structuralism and \*psychoanalysis to produce an eclectic interdisciplinary approach to questions concerning subjectivity. This approach has distinguished all her subsequent work. Initially working with Derrida and others in the intellectual group *Tel Quel*, her theoretical exploration of literary texts, creativity, and language acquisition has broadened to include relevant political,

sexual, philosophical, and linguistic issues. Some of her work has been in \*feminist philosophy, some in aesthetics, cultural studies, and psychoanalysis.

A.C.A.

Toril Moi (ed.), *The Kristeva Reader* (Oxford, 1986).

**Kropotkin, Peter** (1842–1921). After Bakunin's death in 1876, Kropotkin was the most influential theorist of \*anarchism for several decades. Early in his life he rejected his aristocratic background and stubbornly maintained his confidence in the supreme goodness of human nature and attributed any evidence to the contrary to the insidious influence of state authority and exploitative capitalism. For Kropotkin, any external authority was corrupt by definition and thus he never attempted to describe the organizational principles of an anarchist movement or society, believing that it was up to the oppressed masses to arrange the system under which they lived. In his attempt to imbue the whole of society with ethical principles, Kropotkin did produce many practical plans for the improvement of agricultural and industrial communities. And his biting criticisms of the terrible power of the state to disrupt and destroy what he considered natural communities remain impressive.

C. Cahm, *Kropotkin and the Rise of Revolutionary Anarchism 1872–1886* (Cambridge, 1989).

M. Miller, *Kropotkin* (Chicago, 1976).

**Kuhn, Thomas** (1922–96). In *The Structure of Scientific Revolutions*, the most influential book in modern \*philosophy of science, Kuhn argues that scientists work within and against the background of an unquestioned theory or set of beliefs, something he characterizes as a 'paradigm'. Sometimes, however, a paradigm seems to come unstuck, and it is necessary that a new one be provided. What makes Kuhn's position stimulating and controversial is the central claim that there can be no strictly logical reason for the change of a paradigm. As in political revolutions, partisans argue in a circular fashion from within their own camps. Expectedly, this claim was anathema to old-fashioned rationalists like Karl Popper, for whom science is the apotheosis of sound and logical defensible thought. Paradoxically, however, Kuhn and Popper are both evolutionary epistemologists, seeing essential analogies between their (very different) views of scientific change and the evolution of organisms.

M.R.

G. Gutting, *Paradigms and Revolutions* (Notre Dame, Ind., 1980).

T. Kuhn, *The Structure of Scientific Revolutions* (Chicago, 1962).

**Kūkai** (774–835). Posthumous name, Kōbō Daishi. Founder of the Shingon school of esoteric \*Buddhism, Kūkai was Japan's first philosophical thinker. He was an accomplished poet and expert calligrapher, an ascetic saint, nature mystic, and influential cultural leader, as well as a prolific writer on religion, philosophy, literature,

## PHILOSOPHY AT THE END OF THE TWENTIETH CENTURY

THOMAS KUHN'S 1962 monograph on *The Structure of Scientific Revolutions* swiftly established itself as the most important work of the century in the philosophy of science. The influence of its new vision of how theories come and go was felt throughout the academic world.

RICHARD RORTY, who himself once worked in the mainstream of analytic philosophy, became its scourge, and the contemporary philosopher most admired in other disciplines, where his ironic turn seemed a fitting response to doubts about truth and progress.

BERNARD WILLIAMS, impatient with the restricted scope and imagination of academic philosophers, led them to broader conceptions of ethics and the self, and sought to bring philosophy into closer engagement with real life and with the history of Western intellectual culture. Meanwhile his work on government committees helped Britons to address some problems of the self, specifically in connection with sex, drugs, and gambling.

DAVID K. LEWIS granted existence to a plethora of possible worlds in order to answer a wide range of philosophical questions. His systematic worldview was as hard to refute as it was to believe in.

history, art, architecture, linguistics, and education. Kūkai argued that every human being is in principle capable of 'attaining enlightenment in this very existence', on the grounds of a sophisticated synthesis of ideas from the four major schools of Mahāyāna Buddhism that had been transmitted to Japan. He held that through practice of the 'three mysteries' of meditation, mantra (*shingon*, 'true

word'), and *mudra* (hand gesture), one can proceed through the 'ten stages' to the ultimate realization of one's identity with Mahāvairocana (Japanese, Dainichi Nyorai), primary embodiment of the cosmic Buddha. G.R.P.

*Kūkai: Major Works*, tr. with an account of his life and a study of his thought by Yoshito S. Hakeda (New York, 1972).

# L

**Lacan, Jacques** (1901–81). French psychoanalyst whose riddling style and heterodox (though, as he would have it, scrupulously faithful) reading of Freud have generated numerous controversies and splits within the analytic movement over the past thirty years. Lacan's chief claim—drawing on the linguistics of Saussure and Jakobson—is that the unconscious is literally 'structured like a language', so that Freud's somewhat vague terminology of (e.g.) psychic 'condensation' and 'displacement' can be rendered more precise by translation into the equivalent rhetorical terms, 'metaphor' and 'metonymy'. In which case reason is no longer master in its own house but subject to all the lures and slippages of a language caught up in the toils of desire, or the endless 'defiles of the signifier'. Thus for Descartes's formula *\*Cogito, ergo sum* Lacan substitutes his own rendition: '*cogito, ergo sum*' *ubi cogito, ibi non sum*, or 'Where I think "I think, therefore I am", that is where I am not'.  
C.N.

J. Lacan, *Écrits*, tr. A. Sheridan (London, 1977).

**Lakatos, Imre** (1922–74). Born in Hungary. His doctoral study in Cambridge produced *Proofs and Refutations*, a multilogue embodying a fallibilist epistemology for mathematics in which mathematical proofs—and what they prove—are negotiated. After appointment at the London School of Economics, debates with Popper, Feyerabend, and Kuhn helped to forge his Methodology of Scientific Research Programmes (MSRP). According to Lakatos, Popper's naïve falsificationism fails on two counts: the logical Duhem problem, and the mismatch between falsificationist prescription and the history of science. As the chief criterion of scientific success and the neutral judge among competing methodological principles, Lakatos substituted, in the place of truth or truth-likeness, a historically characterized notion of progress.

**Lamarck, Jean-Baptiste, chevalier de** (1744–1829). French biologist and evolutionary theorist, now

principally remembered for his belief that the organs and habits of animals can be altered or newly produced in lawlike ways by pressure from the environment, and that organs and habits thus acquired by individuals are then transmitted to their offspring by hereditary means. The contrary Darwinian belief, that characteristics acquired by environmental pressure cannot be genetically transmitted, is now generally accepted by biologists. Nevertheless, well before Darwin Lamarck had taken the step of seeing the evolution of species as being governed by lawlike processes, even if—again unlike Darwin—he saw the law of \*evolution as having a natural drive towards perfection. Nevertheless, human \*culture, opposed to biological development, can be seen in broadly Lamarckian terms, as involving the transmission through tradition and education of what has been learned in the experience of earlier generations.  
A.O'H.

\*determinism; perfectionism.

H. G. Cannon, *Lamarck and Modern Genetics* (New York, 1960).

**La Mettrie, Julien Offray de** (1709–51). French physician and materialist philosopher, reviled in his own time for his professed \*atheism, \*determinism, and \*hedonism, but an important figure in the history of \*materialism. He followed the mechanical approach to medicine of his teacher Boerhaave, and developed a purely naturalistic, empiricist approach to living organisms, including human beings. He regarded his position as an extension of the worthwhile mechanistic aspect of Descartes's philosophy, while abandoning Cartesian \*dualism and \*rationalism. He first suggested the physiological character of mental processes in *Histoire naturelle de l'âme* (1745) and developed the doctrine in an even more resolutely mechanistic-materialist framework in his most famous work, *L'Homme machine* (Machine Man (1747)). However, he saw matter as essentially active and sensitive, rather than inert. Once neglected, La Mettrie can now be seen as a pioneer of scientific psychology.

**language.** What do we share when we share a language? Just as we count species by asking whether two candidates for the same species can interbreed, so we count languages by asking whether bringing speakers of them together breeds communication. By such a measure the world contains at least 4,500 natural languages, or languages naturally learned and spoken. Africa contains between 700 and 3,000; New Guinea languages alone number around 1,100, divided into some sixty families (it is the task of anthropological linguistics to bring a theoretical taxonomy into the superficial chaos). The imprecision of counting reflects phonetic, grammatical, and semantic lapses from perfect identity.

It is not surprising that our ability to speak together breaks down when we think of exotic and alien ways of living, perhaps involving different categories and different understanding of what is salient and what is unimportant. But if your experience and your reactions to the world, and your system of beliefs, is different from mine, as it will be, to what extent does superficial sameness of language mask difference of meaning? Exposure to a different generation or gender can be enough to make me ask if you can read my words as I intend them. But is not the way I intend them itself a function of something I already share with you, namely an identical linguistic inheritance? It is not as though my intentions are fixed points for me, independently of the linguistic expression I find it natural to give them. We ought not to think of sharing a language as a kind of accidental coincidence of idiolects (privately owned and defined languages). But how many factors must we take into account before declaring that we know what someone else means—and, for that matter, is it any easier to know what we ourselves mean, or meant a little while ago?

Recoiling from linguistic solipsism we may hope for uniformities: a God's-eye point of view from which all languages are means to one end. It would be nice if one's home tongue—twenty-first-century English, say—contained the resources to say everything that can be said in any language; indeed, some philosophers have argued that if we cannot interpret or translate a candidate back into our own tongue, then we can dismiss its claims to be a language at all. This is best diagnosed as a quaint misuse of the \*verification principle (for there is after all the rather less colonial alternative of going out and learning the new language, rather than learning to translate it back into one's home terms).

The conceptual difficulties in thinking about language become vivid when we consider marginal and unusual candidates. Are the signalling systems of animals properly regarded as languages? If a chimpanzee can associate sounds with things, and put sounds together in simple ways, is this acquiring the essence of linguistic behaviour? Is a computer language a kind of language? Does it make sense to posit a \*'language of thought' or background language, like the machine code of a computer, whereby human beings process their first natural language? And is there a language of music, or art, or clothes? These

questions are not so much troublesome in themselves, since we might just posit a criterion that marginal cases do or do not meet. The problem is that we cannot discern a principle. We are not sure what status any definition or criterion of linguistic behaviour could deserve. And quite apart from difficult cases other problems make themselves felt. Is it an essential aspect of language that it is used to communicate? If so, how do we explain soliloquy and solitary verbal play, and can we rule out a priori the possibility of a Robinson Crusoe from birth, who yet manages to symbolize things to himself? But if not, what other explanation can there be for such a specialized adaptation as linguistic competence?

**language, history of the philosophy of.** The history of philosophical thinking about \*language is not easily separated from the history of logic, nor indeed from the entire history of philosophy. There is no division between thought about the major philosophical categories—knowledge, truth, meaning, reason—and thought about the language used to express those categories. Furthermore, many problems can be phrased either metaphysically (Are species real or conventional? Is the number five an object?) or as problems in the philosophy of language (Are words for species controlled by distinctions in nature or by conventions? Does the numeral 'five' function like a name?). There is therefore no major philosopher or school that has not had some doctrine about the relationship between mind and language, and language and the world. In surveying such a history it is possible to concentrate upon the detailed grain and textures separating the problems of one period from those of another, but only at the cost of staying blind to the permanence of the great problems, and the ways in which modern doctrines and approaches are anticipated indefinitely earlier. In this brief survey I concentrate on the continuities rather than the differences.

It is possible that Parmenides attached to his metaphysical \*monism the doctrine that nothing false can be said or thought, on the grounds that sentences serve as names of states of affairs; names with no bearers are meaningless; but a false sentence fails to name anything; hence no false sentence has meaning. If the argument raises more astonishment than conviction, it also suggests the problems that prove permanently difficult: What is the relationship between a sentence and the state of affairs that it reports or that would make it true? How is a sentence for which there is no such state of affairs different from a name without a bearer? Are these always meaningless? The \*Sophists, who began the process of grammatical

categorization, were centrally concerned with 'the correctness of words', or the relationship that words need to bear to things to become instruments of knowledge. They were also concerned with understanding: thus Gorgias is presented as having raised the sceptical trouble that when I give you a word that is *all* that I do: there is no transfer of one and the same idea from my mind to yours and, even if there were, there is a gap between my idea and the features and qualities of things it may seem to represent. Versions of this problem reappear in the twentieth century in concerns of the later work of Wittgenstein, in the problems with translation emphasized by W. V. Quine, and in the general scepticism about determinate \*meaning characteristic of \*post-modernism.

Plato's dialogue *Cratylus* (c.390 BC) is the first general discussion of the role of convention in language. Socrates sees clearly that even if it is arbitrary or conventional whether we use one word or another for horses (one society may call them 'hippos' and another 'equus' with equal propriety) there is something else that it would be possible to be right or wrong about. It is not arbitrary or conventional that this particular animal is a horse, or that it is correct to call it a horse, nor is it conventional that there exists a similarity or form that horses share but cows, for example, do not. The distinction here may be between a word, whose association with anything is a matter of human usage and convention, and a concept or kind, whose application to things is not conventional but a matter of truth or falsity. Plato embodies this in the concept of an 'ideal name', which in more modern terms may be thought of as a correctly framed concept, conforming to the nature of things in the way that classifying substances as liquid or solid does, whereas classifying a substance as phlogiston, or classifying a complex phenomenon as brotherly love or freedom may not. Plato is dealing here with the fact that only an 'adequate' or correctly formed and stocked language can be a vehicle for framing and communicating knowledge. The demand is for a *correspondence* whereby thought reflects the nature of its objects. The ideal this represents surfaces throughout the subsequent history of philosophy, for example in the goal of finding an ideal language, found in Leibniz, Russell, and \*Logical Positivism. In Indian philosophy the Mīmāṃsā school celebrates the sacred correctness of Sanskrit, as opposed to the Buddhist emphasis on the conventional and possibly misleading role of language in knowledge. Especially in the *Sophist* Plato also gave extended discussions of the possibility of intelligible talk about the non-existent, and showed some recognition of the difference between stating something and naming something, the crucial distinction overlooked (or perhaps mishandled) in the Parmenidean argument against falsity.

Among the many problems bequeathed by Plato was that of \*universals (forms), or unchanging abstractions which make up the proper objects of human knowledge: partly the forms are an answer to the problem that, according to Aristotle, reduced the Sophist Cratylus to wagging his finger, which was that capturing the

ever-changing flux in words seemed like attempting to map a cloud. Aristotle saw (as, in some passages, Plato did) that the Forms are at best a stopgap, for it must be a mistake to try to explain what different things have in common by postulating a further *thing* to which they bear some relation. His naturalistic response to Plato's other world of unchanging Forms was to locate the universal in things, or in other words to identify it with the shared common properties lying in particulars. However, the suggestion opens the road to a more thoroughgoing nominalism, according to which everything that exists is particular: the problem is to reconcile this sensible, hard-headed view with the need for general terms if thought is to take place at all. Aristotle's vast contribution to logic and grammar should not conceal another fundamental idea that he brought to the philosophy of language. This is that words work by being symptoms or signs of mental states of the user (he also thought that written words are similarly only symbols of spoken words: the earliest example of the 'phonocentric' tradition railed against in \*deconstructionism). Aristotle distinguished names from predicates, and he saw that only a complex sentence was capable of truth and falsity. However, his account of the way in which a sequence of terms comes to be true or false remains unclear, partly because the basis of the difference between names and predicates remains insecure. In the syllogistic logic that descends from Aristotle through medieval philosophy the terms are common nouns (man, horse) that are thought of as *referring* to men or horses, but the idea breaks down when we ask which men or horses are referred to in phrases such as 'some men', or 'no horses', or in sentences such as 'Henry is not a horse'.

It was left to the \*Stoics to distinguish clearly the necessary concept of a *lekton* or proposition, as well as that of the sentence (the Stoics also recognized different kinds of *lekta*, corresponding to questions, commands, promises, and so on, so they may be said to have anticipated the theory of \*illocutionary force). However, propositions or *lekta* enjoy an uneasy relationship with other things. They are distinguished from the sequences of words, or sentences, that express them, but also from the sensations or images that loom up in conscious life, and from the states of affairs whose existence makes them true and whose non-existence makes them false. Their shadowy nature made them easy targets for both \*Epicureans and ancient \*Sceptics. Sextus Empiricus, for example, uses the standard modern anti-Platonist argument that abstract entities are not capable of having causal consequences; in which case they can neither 'indicate nor make evident' things, for to do this entails having effects on the person apprehending them; hence they are theoretically useless and should play no part in a naturalistic science of the mind. The argument applies to both Platonic and Aristotelian universals. There are only words and things, or even perhaps only words and sensations. The main problem such sensationalism faces is that in such a world nothing seems to *represent* anything else: meaning is

demystified only by being removed altogether. Although both Epicureans and Stoics made moves to fend off the catastrophe, the dilemma that the philosophy of language either makes use of mysterious, abstract, universal objects of thought or descends to the natural and the empirical but loses meaning altogether continues to dominate contemporary approaches to language.

Platonism about universals has an other-worldly flavour congenial to Christian thinkers such as St Augustine, but medieval thought tended either to Aristotelianism (centrally in St Thomas Aquinas) or to the nominalism of fourteenth-century thinkers influenced by William of Ockham. In particular Aquinas's moderate suggestion that a thing might be singular or universal according to different ways of taking it is mercilessly attacked by Ockham: anything whatsoever is one, single thing. But the medieval emphasis on the links between grammar and logic on the one hand and logic and reason on the other make nominalism particularly hard to stomach: utterances considered as physical particulars are not the subject of reason or logic. However, the medieval period saw the first major work in logic since Aristotle, with close attention paid to such problems as those of intensionality and the semantic paradoxes.

The seventeenth-century turn away from scholastic logic saw a surprising unanimity, stretching from Francis Bacon, Thomas Hobbes, and above all John Locke in Britain to Arnauld and the Port Royal Logic in France, that Aristotle was right in supposing that words were the \*signs of ideas, and ideas the signs of things. Equally characteristic of the period was the belief that while language was a dangerous medium, apt to distort and obscure ideas as much as to transmit them, it could be refined or reinvented in a form free from these dangers. Partly this was the result of recognizing that the developing sciences needed to find languages and notations adequate to their different tasks. This concern is later echoed in the nineteenth-century recognition of the intimate connection between an apparently notational advance (e.g. finding arabic numerals or Leibniz's notation for the calculus) and a major conceptual advance (learning the importance of the number zero, being able to differentiate). Book III of Locke's *Essay Concerning Human Understanding* is the most thoroughgoing late seventeenth-century attack on the problem. Words become substitutes for ideas, and in order to avoid the danger of being taken in by empty sounds without meaning, we must form the habit of substituting ideas, the real substance of thought, for words whenever possible. Locke's immense influence halted serious philosophy of language, arguably until Kant, although a small rearguard action was fought by Berkeley. For while Berkeley often subscribes to the conventional view that words without ideas give us only 'the husk of science rather than the thing' he does acknowledge 'that there may be another use of words, besides that of marking and suggesting distinct ideas, to wit, the influencing our conduct and actions; which may be done either by forming rules for us to act by, or by raising certain

passions, dispositions, and emotions in our minds' (*Alciphron*, bk. vii). Berkeley had here the ingredients for the later 'use'-based or pragmatist account of meaning, but can scarcely be said to have freed himself from the Lockean or Aristotelian model. A similar struggle to retain the meaning of words whilst realizing that there are no ideas associated with them can be seen in Hume's explorations of causation, identity, and the self. Berkeley's other quarrel with Locke is his rejection of any abstraction in favour of particular ideas standing for other particular things. Here he is later echoed by Bentham, who considered all abstractions as fictions, with meaningful talk confined to reference to concrete situations (too concrete, however, and we end up back with Cratylus, reduced to silence).

It was left to Kant to make the substantial break with the empiricist equation between understanding and the passive possession of mental phantasms. Kant not only repudiated the Lockean theory of ideas, but reintroduced the needed concentration on the nature of judgement, with its own forms and categories, presuppositions, and claims to objectivity. He also provided the terms within which much later philosophy of language became framed: \*analytic versus synthetic, \*a priori versus a posteriori, \*rules versus descriptions. But above all it is Kant's sovereign concern with the question how judgement of such-and-such a sort is possible that marks a reconnection to pre-seventeenth-century priorities, and a heralding of later ones.

Nevertheless, the Kantian judgement might still serve as Aristotle's intermediary, represented by words and itself representing things. Indeed, the other elements in Kant that led to the triumph of German \*idealism also provided an historical matrix within which Kantian judgements functioned, rather like the Empiricists' ideas, as fairly self-standing elements of consciousness compared with which everything else was problematic. Nineteenth-century idealism severs any connection between language and the world, at least if the world is conceived of as distinct from thought. Language and thought became entirely self-contained in a kind of solipsistic unity (as they arguably do in the deconstructionist view that nothing lies outside the text, since any attempt to correlate a text with anything else merely produces more text). On such views the main apparent casualty is truth, which stops being a correspondence between language and the world, but becomes either the unity and completeness of the whole structure of judgements (the \*coherence theory of truth), or the use words have in directing effective action (the \*pragmatic theory of truth).

It was Frege who reconnected language with truth without an intermediary psychology. Frege's revolution in logic is not the issue here (\*logic; \*quantifier; \*variable) but the associated belief that nothing 'psychologistic' gives us anything essential to meaning, which resides rather in the way a term or more fundamentally a sentence is employed in the world: the way it presents things as being. The connection that electrifies sentences is not one between them and ideas or even judgements, but one

between them and their 'truth-conditions'. The task of a systematic theory of meaning of a language (a semantic theory) is that of categorizing the expressions it contains, and describing in a systematic fashion the way in which the truth-conditions of sentences are built from the contributions of their components. Frege's description of this goal, and his brilliant application of the ideas to the language of mathematics, was the dominating impulse behind modern analytical philosophy, and the concern with the syntax and semantics of the languages of science that characterized Logical Positivism. However, on the topic of the human user of the language Frege is less forthcoming. He puts in place the idea of sentences as having objective senses, expressing thoughts that are grasped by those using them. But the story is entirely schematic, reminiscent of the Stoic doctrine of *lekta*, and Frege tells us nothing of the nature of this grasp, nor how to answer the old objections to the use of such abstract entities in the theory of language.

It is usually said that twentieth-century philosophy of language began with the eclipse of Hegelian idealism, and the triumph of \*realism. This is a half-truth that ignores the large place that both idealism and \*pragmatism played throughout the period. Pragmatism in particular promises to circumvent the old opposition between the idealist stasis of ideas-staying-in-the-head and the unargued realist correspondence between elements of language and elements of the world. The ingredient it adds is that of words answering a purpose, or playing a role in a practice or technique (ideas present in Berkeley, as was seen above, and reintroduced in the later work of Wittgenstein). James saw the correspondence between true judgement and reality not in terms of an abstract correspondence but as a dynamic control: true judgements are those that work, truths are what we must take account of if we are to survive. One might see some of James's concern with practice as foreshadowed too by Nietzsche's understanding of the political dimension of language use: by naming and categorizing we do not do something practically neutral, but privilege social attitudes and structures. Dictating thought is also dictating action. In turn there is a connection back to Kant's emphasis on the primacy of practical judgement, and the political turn that this idea is given in Hegel and Marx.

In the twentieth century the political and other practical dimensions of meaning were frequently regarded as a slightly disreputable secondary element, outside the pure theory of representation. For, going entirely the other way, Russell and Wittgenstein looked for an abstract correspondence between language and the world, and developed the application of Frege's logic to problems of language in terms of a structural resemblance between a sentence and that of which it is a picture (the \*truth-condition). Their work culminated in Wittgenstein's *Tractatus Logico-Philosophicus*, in which the curiously disembodied atomic constituents of language stand in relations that mirror the structure of the facts that make up the world. Wittgenstein's rejection of any association between

psychology and the philosophy of language went beyond anything to which the more traditional Russell could subscribe. Russell's own version of \*logical atomism located the atoms to which basic terms corresponded in an uneasy space between the objective world and the subjective representation of it. Atomism was, however, always a fragile flower, and amongst the hostile winds blowing over it was the work on language done by Ferdinand de Saussure, showing that the phonemes out of which spoken language is made could not be considered as individual, physically definable pulses, but exist only in a system of 'differences'; the same point applied to semantics quickly suggests that no sentence maintains its own private relationship with reality, but that the system as a whole must take priority (as, indeed, the idealists had always maintained). Nevertheless, and in spite of the short-lived adherence of its author, the *Tractatus* in turn gave birth to the fundamental positivist belief that the logic or syntax of language dictates the solution to all other epistemological or metaphysical concerns with it. Either a philosophical problem was solved by essentially Fregean semantics, or it was shown to be a pseudo-problem. Problems in the philosophy of language thus collapse into internal problems about the syntax and semantics of language, thought of as a pre-existent structure. But the foundations of this optimism crumbled on three ancient rocks. Firstly, it went along with no coherent story connecting language with experience. Secondly, it had no description of the status of logic and reason itself: the Fregean advance within logic had not produced a parallel advance in the question of the status of logic. And thirdly, it could produce no theory of the proper domain of the use of reason and experience together, certifying even the simplest movements of scientific thought. The need to reintroduce the excluded issues of experience, understanding, and the place of language use in the context of a set of practical questions was constantly urged against the Frege-Russell tradition by writers such as R. G. Collingwood. Although the possibility of external theory of this kind has been doubted, the authority given to the criticism by the later Wittgenstein means that contemporary works in the philosophy of language may bear as much resemblance to the idealist H. H. Joachim's *The Nature of Truth* (1906) or to the pragmatist William James's *The Meaning of Truth* (1909) as they do to the founding works of analytical philosophy. s.w.b.

There is no single specialist work on the history of the philosophy of language. But as well as general histories of philosophy, readers may wish to consult:

**language, knowledge of.** Competent use of a language depends on knowing a language, and the nature of this knowledge has been the subject of dispute amongst philosophers. Some conceive knowledge of language as a practical skill, a matter of know-how, like riding a bicycle

or swimming. However, competent speakers are in receipt of a vast range of complex knowledge. They can understand indefinitely many sentences they have never heard before: sentences that conform to complex grammatical rules that speakers are unable to articulate. To account for these facts, Noam Chomsky proposes that speakers tacitly know the rules of grammar for their language. Furthermore, he argues that each child's acquisition of language depends on a body of innate knowledge that equips it to develop a language. On this view, each child has a dedicated language faculty configured in accordance with universal grammar, and the grammar of each language is a refinement of it. Knowledge of word meaning is less plausibly a matter of innate endowment, but it can be conceived as knowledge of rules for the correct use of words. Explaining our immediate and effortless knowledge of what our words mean and our ability to follow rules for their use remains a philosophical challenge. B. C. S.

**language, problems of the philosophy of.** The philosophy of language explores the relationships between ourselves and our \*language, and our language and the world. The first kind of exploration asks what it is for us to invest words and sentences with a certain meaning, whilst the second investigates the relationships between words and the things to which they refer, or the facts that they describe. The former topic is sometimes called \*pragmatics, and the latter \*semantics, although the lines between them can easily blur.

It is given by the nature of a language that some things may be inferred from others. If a shape is square then it is four-sided, and if a person is a bachelor then he is unmarried. It is evident that these relationships are intimately connected to the very meaning of the words involved (either being determined by that meaning, or perhaps themselves playing an important role in fixing it). Logic studies the nature of these inferences, and a common element in the philosophy of language at least since Aristotle has been the desire to codify and lay bare the structure, perhaps hidden on the surface, whereby one thing may be inferred from another. This develops into the formal programme of defining firstly the syntax of a language (the ways in which grammatical strings of elements are generated and separated from ungrammatical ones) and then the logical structures responsible for the inferences which we can and cannot make. One major philosophical problem such inquiries raise is the relationship between the

smooth surface recognition of grammar and of logical relationships, and the extremely complex rules that appear necessary to enable any system to compute the same results. Are we to think of some such system of rules as really implemented at some level of our cognitive systems? Or are they ways of describing what we do that make no claim on how we do it?

To investigate language we might start with a list of platitudes about it. Language consists of *words*, which come in sequences or *sentences*. With our words we express our *ideas*, and we *intend to communicate*. Because of our *conventions* the words of a language *refer* to things, or have \*meanings. Other languages may, however, have attached the same meanings to their terms, with the result that they can be *translated*. Some words are *synonymous* or mean the same; some are *vague*. Some ('red') seem somehow keyed closely to *experience*, others ('quark') are highly *theoretical*. A whole sentence often expresses a *proposition*, which may be *true* or *false* (although we also do other things with language, such as issue commands, ask questions, and make promises). The truth or falsity of a sentence will depend on whether the world satisfies some condition, known as the \**truth-condition* of the sentence. The philosophy of language is largely a matter of trying to understand these italicized terms, and the revolutions in the subject occur when what seems a satisfactory basis for such understanding to one school or generation seems a very bad place to start to another. To illustrate the scope for dispute it can be recorded that all the terms that have seemed useful starting-points to some (words, language, ideas, convention, meaning, translation, reference, experience, intention, proposition, truth) have not only been denied foundational status by others, but even been violently excommunicated as spurious and unscientific notions.

From the beginnings of philosophy it has been realized that problems of meaning and language are intertwined with those of other areas of inquiry. Our languages are things we understand, so a theory of language must match with a philosophical psychology, or story about the powers of the mind. Furthermore, a theory of what the world is like must conform to the demand that it is describable by language: if, therefore, a linguistically describable world must have some form or another we can infer the structure of the world, at least in so far as we can describe it, from the structure of our representations of the world. The earliest example of this form of reasoning is the argument for the Forms in Plato, where the need for a common feature or form in things is witnessed by the fact that we have a common name (dog, chair) for numbers of them. Again, it is common to deduce that otherwise mysterious entities, such as events or facts or numbers, exist because we have terms for them and these terms function in language in just the way that names of other less suspect entities function. We therefore have no option to deny existence to events or facts or numbers, unless we wish to propose changing or abandoning our language. This latter option indeed shows that we can only infer conclusions

about how we *take* the world to be, rather than how it actually is, from facts about the general features of our language, for in principle our language might reflect a misunderstanding and misrepresentation of the real features of things. But in so far as we see no error in our usage, or no prospect of a linguistic reform that would change the feature in question, we will find ourselves committed to the substantive conclusion. And if, as in the *Tractatus Logico-Philosophicus* of Wittgenstein, we can put conditions on the nature of any possible representation of facts, then we have a \*transcendental argument that if meaning is possible, then the world must be such as to be representable in those ways.

The philosophical understanding of language must therefore achieve a stable equilibrium with our best philosophy of mind and our best metaphysics. It has been characteristic of twentieth-century philosophy to suppose that it dominates these partners, dictating how we are to think about mind and metaphysics. Thus to analytic philosophers, such as Russell and Moore, and to the Logical Positivists, such as Carnap and Schlick, but above all to Wittgenstein, the best route to a theory of mind is through describing our linguistic powers, since these may claim to be the most characteristic product of our understandings. On most issues, we do not know what to think until we know what to say. And if we cannot mean something, then we cannot understand it either. This suggests that if an investigation into language delivers results about the limits of meaning, then our science and our conception of the world must also conform to those limits. Such a result was claimed by logical atomism, in which the nature of linguistic representation is held to determine the kind of fact that can ever be represented, and most famously by \*Logical Positivism with the doctrine that since the meaning of a sentence is its method of verification (the \*verification principle), we can attach no meaning to hypotheses that are incapable of verification, and must tailor our concept of the world, and our philosophy of science, accordingly. The same strategy (and, some believe, the same principle) is at work in the \*private language argument of Wittgenstein, in which the impossibility of meaningfully describing the recurrence of a private sensation whose nature is independent of any physical or public events, is held to undermine the Cartesian philosophy of mind according to which such sensations exist. 'Linguistic' philosophy or 'Oxford' philosophy of the middle years of the twentieth century, is widely thought to have shown an excessive reliance on the implications of ordinary speech for other matters. More recently deconstructionist emphasis on the fluid contrasts and contingencies that shape an overall linguistic 'field' (pattern of inferences) leads to despair over finding any fixed meaning in our terms, with lurid consequences for the possibility of any objective description of things, or eventually of truth as opposed to falsehood.

The legacy of seventeenth- and eighteenth-century \*empiricism was confidence that language would be understood by the way of ideas, or, in other words, by

seeing it as a vehicle for making public our ideas, conceived of as the self-standing mental elements whereby we think, but which would otherwise remain private. Ideas and their properties, especially their derivation from experience, were the central topic, with language a mere vehicle for their transmission (although Hobbes, Locke, and others were aware that infirmities or 'abuses' of language affected the task of thinking properly: but this could be remedied by paying closer attention to ideas).

Ideas, however, prove a broken reed, because any inner display of any kind seems inessential to identifying what is thought and understood, and because the power of ideas to represent things other than themselves is just as hard to conceive as the power of words to do so. Competence with a language is not simply competence in packaging already given ideas. This is obvious if we imagine mastering some new area, such as physics, where there is no distinction between mastering the language and mastering the subject. With the work of Frege emphasis came to be placed on objective and public aspects of understanding: when I tell you that the Gulf Stream crosses the Atlantic, I do not excite in you an idea which may or may not be like some subjective idea of my own, but give you a definite and objective piece of information. I transmit a thought or proposition. But Frege remained largely silent on the question what it was to grasp such a thought or proposition. Its content, evidently, concerns the Gulf Stream and the Atlantic, but how my mind is related to such things for me to understand the proposition is left moot.

If we put that question to one side it is possible to sketch further relations between psychological states and meaning. One suggestion is that a term means something if it causes persons hearing it to go into some state. But this fails to distinguish the common consequences of using a term from its meaning: talking about spiders may make most people think of being bitten, but that is no part of the meaning of the term, and indeed only occurs because of its meaning. A better suggestion, although still inadequate, would focus on the intended effect. The most influential development of this line has been that of H. P. Grice, which saw an utterance's meaning in terms of the complex structure of intentions with which it is used. A variant of this approach may locate a public convention of using a type of utterance only with a certain intention, such as intending to induce a certain belief, or intending to signal that one has oneself a certain belief.

Even if such accounts work (and the complexity necessary to protect them from objections has tended to rouse suspicion) they have still put aside the question how it is that my mental state is properly representational, or, in other words, what is involved in my grasping a proposition whose content concerns the Gulf Stream or the Atlantic. The suggestion taking us away from pragmatics and towards semantics would be that this is so if I incline to express the state by using words which refer to those geographical objects. This, of course, requires that we have a separate account of word reference. One suggestion was that of Russell's famous theory of \*descriptions,

according to which reference is normally accomplished by the subject having in mind (in some sense) a description which the thing referred to satisfies. This in turn raises the demand for an account of what it is to have a description in mind, which in Russell terminates rather disappointingly in an acquaintance with universals, or features that things can share.

But it was also objected by Strawson and others that the account distorts the way in which \*reference is normally accomplished and the role that referring terms play in a language. The development of this objection by Kripke and Putnam led to explorations of a causal account, according to which I refer to something when my words are in some favoured causal relationship with that object. This approach is still active. Its chief current competitor is associated with the work of Davidson. This denies that the relationship of reference is a good place to start. Instead we have to consider the overall project of interpreting someone. This will require the simultaneous attribution of beliefs and meanings, done in accordance with the methodological principle that we try to make them appear as rational or sensibly tuned to their environment as possible. The programme this engenders is one of systematically attributing truth-conditions simultaneously to each of the infinite (or indefinitely large) number of possible sentences that a language may contain. The upshot is an \*interpretation made not by the piecemeal association of individual words with individual things or features of things, but more 'holistically' or 'top down'. On this approach the reference of a term becomes a mere intervening variable, in the sense that it is simply an aspect of a sentence certified by a procedure that has looked at a quite different thing: the overall pattern of association of truth-conditions with sentences. The approach encounters a notorious problem of determinacy. Unless the constraints are made very severe (possibly incorporating causal requirements) it looks as though arbitrarily different assignments of meaning may be made in conformity with them.

This problem, first identified as the \*indeterminacy of radical translation by Quine, has led to scepticism about the very existence of determinate meaning, and to consequent rejection of the idea that sentences ever manage to express single propositions and thoughts. A similar result may be supported (probably not in accordance with its author's intentions) by the 'rule-following considerations' as they appear in the later work of Wittgenstein. These too leave the fact that someone follows a determinate rule in their usage of a term a mysterious 'superlative' fact, and one response is to fear that meaning has disappeared altogether. This nihilism is often thought to accord with a proper appreciation of the contextual and socially rooted nature of meaning, and the genuine difficulties of real-life translation. It is also realistic to remember that, however strict we try to be with words, new situations can easily be envisaged in which we would not know whether a particular term applies or not. But Quine's thesis and a sceptical conclusion to the rule-following considerations go

beyond these proper cautions, for they make no distinction between alien and stressful cases and normal thought and communication. But nihilism about this ultimately self-destructs, since it is only by relying on my own (determinate) understanding of my terms that I can think at all. A dogged resolution to see others just as producers of noise fit to be interpreted in any of a variety of different ways may just about succeed for a time. But a similar resolution with regard to myself is impossible. We may, in the study, be sufficiently baffled by the problem to believe that there is nothing outside the text, and to see linguistic behaviour as a self-contained game of producing and consuming noise and script. But such scepticism is unlivable, and will not survive long when we actually ask directions, give recipes, and tell the time.

There is, then, no agreed solution to the problem what it is determinately to take a term in my language to refer to a particular thing or feature of things. Two recent developments are the extensive links between the philosophy of language and the general field of cognitive science, and the equally promising links between the subject and the biological and evolutionary perspective on the emergence of language. The latter suggests that we can isolate determinate meaning by considering the role of a term in the life of an animal in a determinate environment. That is, if a signal has evolved in order to fulfil some need (which in turn can be analysed in terms of the differential fitness it confers on its users) then it seems a short step to assign to it a determinate semantic role. This is a plausible reconstruction of a meaning for the signalling systems of some animals, for example. Critics respond either that such systems are so simple that they are misleading models for fully fledged language, or more fundamentally that we should not reduce meaning, which is a fact, to evolutionary biological relations, which may remain speculative, or we would be handing ourselves a strange kind of proof that evolutionary theory is true. The computational approach has developed in a different direction. Initially it seems unpromising, since computers respond simply to the syntax of elements of computer languages, without regard to their interpretation. But further thought suggests that by putting a computer in an environment (either 'virtual' or real) with receptors responding to different features of that environment, we get a small-scale version of a causal semantics for the terms in which it computes.

As well as work on these broad and fundamental themes the philosophy of language contains detailed work on the particular forms—\*conditionals, \*counterfactuals, tensed statements, modal statements—that are indispensable to ordinary \*communication. Whilst the classic approach to these has been to try to show that they are disguised versions of the tractable, simple forms of statement dealt with in classical logic, more relaxed and elastic approaches are now equally respectable. Equally important are the discrimination of such things as emotive meaning, derogatory and other attitude-bearing discourse, and the general study of the relation between the

vocabulary of a period and the social habits and structures that help to shape it.

**language, religious:** *see* religious language.

**language, social nature of.** We learn language from others in a social setting. But is this enough to show that language is an essentially social phenomenon? Opinions among philosophers are divided. Famously, Wittgenstein argued that the only meanings that speakers could attach to their words were the meanings they had in language of the surrounding community. Meaning, for Wittgenstein, was a matter of publicly sustained patterns of use, not private associations in the minds of individuals. The distinction between using words correctly and incorrectly cannot, he thought, be settled by the judgements of an individual, but depends on agreement among the community of language-users. To use a word correctly is to use it in accordance with a rule, and whether an individual is following a rule on a given occasion is a matter independent of the opinions of that individual. For the sounds speakers utter to have linguistic significance must be independent of the opinions of the individual speaker.

The distinction between the use of a word that *seems* right and a use that *is* right, and something more than the opinion of an individual, is required to set a standard or rule for using a word correctly. For Wittgenstein this is the institution of a social practice, and individuals come to use a language by participating in those practices. Other philosophers have supposed that speakers can communicate successfully only if they attach the same meanings to their words as others do, and this presupposes a shared communal language. However, an objection is that one is only required to know what significance another speaker attaches to the words uttered, not to attach the same significance oneself. Hence, speakers can differ in their use of language, departing from communal practice, and still be understood, so long as they make their meaning publicly available. Those who favour the view that the way language is used by the individual is of primary importance take idiolects rather than communal languages to be primary. An idiolect, or language of an individual, need not be private, and can still be used in a social setting. A further aspect of the social nature of language is what Hilary Putnam has called 'the division of linguistic labour'. This social phenomenon is illustrated by words like 'gold' which have both an ordinary non-technical use and a more precise meaning and application given to them by experts. In this case we may not know everything about the meaning of such words, but we defer to the relevant experts.

**language-game.** Wittgensteinian term of art, introduced in *The Blue and Brown Books* when rejecting the calculus model of language which had dominated his *Tractatus*. It highlights the fact that language use is a form of human rule governed activity, integrated into human transactions and social behaviour, context-dependent and purpose relative. Analogies between games and language, playing games and speaking, justify it. Imaginary language-games are introduced as simplified, readily surveyable objects of comparison to illuminate actual language-games, either by way of contrast or similarity. A description of a language-game may include words and sentences, 'instruments' (gestures, patterns, word-sample correlations), context (which often brings to light the presuppositions of the existence of a language-game as well as the essential background of engaging in it), the characteristic activity of the language-game, the antecedent training and learning in which the rules are imparted, the *use* of components of the language-game, and its *point*. Wittgenstein held the cardinal error of modern philosophy to be the focus on forms of expression rather than on their use in the stream of life. P.M.S.H.

**language of thought.** Following Aristotle some have argued that the significance of spoken words derives from intrinsically meaningful interior 'speech'. According to Ockham the *propositio vocalis* is posterior to and dependent upon the *propositio mentalis*. More recently Fodor has argued that thought is a form of symbol manipulation, and that \*language-learning involves the correlation of conventional symbols with those of one's innate mental language. Two main considerations are regularly advanced in support of the language of thought hypothesis. First, parallels between the structures of thought and language are brought out in reports of each. Thus, for any proposition *p* one may equally well say 'He thought that *p*' as that 'He said that *p*'—each act seems to involve a relation to a sentence. Second, sounds and marks appear to express meanings without themselves being intrinsically meaningful; this suggests that public language may be a vehicle for the expression of prior mental 'utterances'. It is often argued against the language of thought hypothesis, however, that it is regressive, since if the possibility of linguistic \*meaning always requires an explanation, so must that of mental language; on the other hand if the latter is held to be intrinsically significant, then it is false that all linguistic meaning must be derived, in which case why not suppose, after all, that the meaning of speech-acts is non-derivative, i.e. that the significance of spoken words is intrinsic in their use. J.HAL.

J. Fodor, *The Language of Thought* (Cambridge, Mass., 1975).

**langue and parole.** Distinction drawn by the Swiss founder of linguistics, Ferdinand de Saussure (1857–1913), in his lecture series *Cours de linguistique générale* (1916), between language as a system of formal rules and mutually defining terms and language in its everyday use. (In French, *langue* means ‘language’, and *parole* means ‘speech’.) *Langue* includes linguistic \*types or \*universals, *parole* linguistic \*tokens or \*particular inscriptions and utterances. The distinction was influential on \*structuralism, in which *langue* is studied as making *parole* possible, in a quasi-Kantian or transcendental fashion. s.p.

**Lao Tzū** (dates uncertain). An individual whose existence is in doubt, but who is traditionally viewed as the author of the classic of \*Taoism *Lao Tzū* and as an older contemporary of Confucius (sixth to fifth century BC) in China. Many modern scholars doubt the existence of Lao Tzū as a historical figure, and regard the text, also known as the *Tao Te Ching*, as composite and datable to as late as the third century BC. The text highlights how the natural order operates by ‘reversion’ (anything that has gone far in one direction will inevitably move in the opposite direction), and how the state of ‘weakness’ enables an object to thrive. Modelling their way of life on the natural order, human beings should avoid striving after worldly goals, which inevitably leads to loss, and should instead be non-assertive and have few desires. *Lao Tzu (Tao Te Ching)*, tr. D. C. Lau (Harmondsworth, 1963).

**Laplace, Pierre-Simon, marquis de** (1749–1827). French physicist and mathematician who made major contributions to celestial mechanics and \*probability theory. In cosmology he was one of the two independent originators of the nebular hypothesis (the other was Kant), according to which the solar system was formed from rotating gas. He showed that Newton’s worry that perturbations in the planetary orbits would lead to the long-term instability of the solar system was unfounded. (Newton thought that divine intervention was necessary to ensure stability.) This is the origin of the story that in reply to Napoleon, who complained that he had left God out of his system, Laplace said: ‘I have no need of that hypothesis.’ Laplacian \*determinism is the claim that granted complete knowledge of the state of the universe and the laws of nature, every detail of the future is predictable. **Latin American philosophy.** Latin American philosophy begins with the Spanish and Portuguese discovery and colonization of the New World. Throughout its 500-year history, this philosophy has maintained strong human and social interests, has been consistently affected by

scholastic and Catholic thought, and has significantly influenced the social and political institutions in the region. Latin American philosophers tend to be active in the educational, political, and social affairs of their countries and deeply concerned with their own cultural identity.

The history of philosophy in Latin America may be divided into four periods of development: colonial, independentist, positivist, and contemporary. The colonial period (c.1550–1750) was dominated by the type of scholasticism officially practised in the Iberian peninsula. The texts studied were those of medieval scholastics and of their Iberian commentators. The philosophical concerns in the colonies were those prevalent in Spain and Portugal and centred on logical and metaphysical issues inherited from the Middle Ages and on political and legal questions raised by the discovery and colonization. The main philosophical centre during the early colonial period, Mexico, was joined in the seventeenth century by Peru. Antonio Rubio’s (1548–1615) *Logica mexicana* was the most celebrated scholastic book written in the New World.

Although working within the tradition of \*scholasticism, some authors of this period were influenced by \*humanism. The most important of these was Bartolomé de las Casas (1484–1566), who became the leading champion of the rights of native Americans at the time. He argued that wars of conquest in the New World were unjustified because they were based on false generalizations and misinformation. He defended the autonomy of native Americans, claiming that neither the Spaniards nor the Catholic Church had rightful authority over them and therefore should not impose European cultural and religious values upon them.

A more complete break with scholasticism was made during the independentist period (c.1750–1850). The period began with growing interest in early modern philosophers; among these Descartes was most influential. The intellectual leaders of this period were men of action who used ideas for practical ends. They made reason a measure of legitimacy in social and governmental matters, and found the justification for revolutionary ideas in \*natural law. Moreover, they criticized authority, and some of them regarded religion as superstitious and opposed ecclesiastical power. Their ideas paved the way for the later development of \*positivism.

Positivism (c.1850–1910) was, in part, a response to the social, financial, and political needs of the newly liberated countries of Latin America. Juan Bautista Alberdi (Argentina, 1812–84) and Andrés Bello (Venezuela, 1781–1865) stand out as important figures of the early part of the positivist period. Alberdi argued for the development of a philosophy adequate to the social and economic needs of Latin America, and Bello attempted to reduce metaphysics to psychology; both began trends others were to follow.

Positivists emphasized the explicative value of empirical science and rejected metaphysics. For them, all

knowledge is to be based on experience rather than theoretical speculation, and its value rests in its practical applications. The universe is explained mechanistically, leaving little room for freedom and values. Positivism became the official philosophy of some Latin American countries and exerted strong social influence. Testifying to this is the preservation of the positivist inscription 'Order and Progress' on the Brazilian national flag. The most original positivists were the Cuban Enrique José Varona (1849–1933) and the Argentinian José Ingenieros (1877–1925). Ingenieros made some room for metaphysics in his philosophy, claiming that it is concerned with what is 'yet-to-be-experienced'.

Contemporary Latin American philosophy (c.1910–present) begins with the decline of positivism. The first part of the period is taken up by the generation of thinkers who rebelled against positivist ideas. The principal members of this early generation, called 'the Founders' by Francisco Romero, are: Alejandro Korn (Argentina, 1860–1936), Alejandro Octavio Deústua (Peru, 1849–1945), José Vasconcelos (Mexico, 1882–1959), Antonio Caso (Mexico, 1883–1946), Enrique Molina (Chile, 1871–1964), Carlos Vaz Ferreira (Uruguay, 1872–1958), and Raimundo de Fariás Brito (Brazil, 1862–1917). Trained as positivists, they became dissatisfied with positivism's dogmatic intransigence, mechanistic determinism, and emphasis on pragmatic values. The arguments against positivism of Deústua, Caso and Vaz Ferreira are characteristic of the period. Deústua attempted to show that the ideas of order and freedom are basic to society but that the second has priority over the first, for order cannot be established without freedom. Caso defended a view of man as capable of altruism and love. And Vaz Ferreira opposed the abstract logic favoured by positivists, developing instead a logic of life based on experience.

Positivism was superseded by the Founders with the help of ideas imported first from France and later from Germany. The process began with the influence of Boutroux and Bergson and of French \*vitalism and intuitionism, but it was cemented when Ortega y Gasset introduced into Latin America the thought of Max Scheler, Nicolai Hartmann, and other German philosophers during his first visit to Argentina in 1916.

\*Philosophical anthropology developed in response to the desire to move further away from the scientific emphasis of positivism. Samuel Ramos (Mexico, 1897–1959) focused upon what was particular in Mexican culture, thereby inspiring interest in what is culturally unique to Latin American nations. He, like most philosophers of this period, tried to develop a philosophical anthropology based on a spiritual conception of human beings. Francisco Romero (Argentina, 1891–1962) was the most original thinker of the group. In *Teoría del hombre* (1952) he conceives human nature as involving both intentionality and spirituality.

During the late 1930s and 1940s Latin Americans were exposed to a variety of recent European ideas and

methodologies. As a consequence of the political upheaval created by the Spanish Civil War, a substantial group of peninsular philosophers, known as the *transterrados*, settled in Latin America. Among these, José Gaos (1900–69) had the greatest influence. In particular, he introduced rigorous techniques of textual analysis in Mexico.

With the generation born around 1910, Latin American philosophy reached what Romero later called a 'state of normalcy'. Philosophy established itself as a professional and reputable discipline, and philosophical organizations, research centres, and journals flourished. The core of this eclectic generation was composed of philosophers working in the German tradition who concerned themselves primarily with axiology. Most of them granted some objectivity to values, but a few argued that values were neither objective nor subjective. This position is most clearly presented in Risieri Frondizi's (Argentina, 1910–83) *Qué son los valores?* (1958), where he proposes a view of value as a *Gestalt* quality.

Other developments of this period included a renewed interest in scholasticism. There was also a growing interest in the study of the history of ideas and on the question of the identity and possibility of an authentic Latin American philosophy. The latter was raised in the 1940s by Leopoldo Zea (Mexico, 1912–2004) and continues to be a source of interest in the region today.

Until 1960 philosophers working outside the traditions mentioned had limited visibility. This has now changed. \*Marxist philosophy and \*philosophical analysis have found places in the academy. As a result there has been renewed interest in areas where these philosophical currents are strong, such as social and political philosophy, logic, and the philosophy of science. The theology of liberation prepared the way for the development of the philosophy of liberation, which began in Argentina in the 1970s and combines an emphasis on Latin American intellectual independence with Catholic and Marxist ideas.

**latitudinarianism.** 'Dr Wilkins, my friend, the bishop of Chester . . . is a mighty rising man, as being a Latitudinarian,' said Pepys in 1669, and the 'latitude men', who favoured tolerance in belief and doctrine, were certainly among the late seventeenth century's intellectual élite. Though there is some controversy among historians over the precise application of the term 'latitudinarian', Seth Ward, Ralph Cudworth, Henry More, John Locke, and Robert Boyle provide additional examples of thinkers

with latitudinarian tendencies. Of course the latitude was limited. It did not include what Boyle in his Will called 'notorious Infidels (*viz*<sup>t</sup>) Atheists, Theists [i.e. deists], Pagans, Jews and Mahometans'. None the less latitudinarianism was not without critics. 'There were no such Latitudinarian Principles among the Apostles,' said Thomas Comber, and others found the latitudinarians 'meer moral men, without the power of Godliness'. J.J.M.

**laughter.** Laughter is a psychophysical phenomenon against which a number of philosophical theories of mental and personal identity can be tested. If laughter is essential to the psychology of \*humour, then a creature endowed with humour must be embodied. But since the bodily postures and motions which are characteristic of laughter can occur in the absence of amusement, laughter cannot be a simply physical occurrence. Aristotle uses these considerations to support a theory of \*human nature according to which a person is not identical with a body, yet does not exist without a body. More recently John Wisdom has hinted at how humour and its objects can provide helpful pointers to the analysis of the relation between subjective and objective elements in the nature of value. The topic deserves more attention in the philosophy of mind. J.D.G.E.

For an analytic treatment of the subject, see the symposium 'Laughter' by R. Scruton and P. Jones, *Aristotelian Society Supplementary Volume* (1982).

**law, feminist philosophy of.** Since the resurgence of the women's movement in the 1960s, scholars have begun to identify and explore distinctively feminist questions of and about law and legal philosophy. The questions which have occupied feminist scholars' attention cover a wide range of jurisprudential questions, encompassing issues identified with analytical, normative, and sociological jurisprudence. Are laws, legal practices, and even the very concept of law implicitly gendered and, if so, is this inevitable? In what ways has woman been constructed within legal discourse and excluded from or incorporated within prevailing notions of legal subjecthood? What role have laws played in constituting or reinforcing ideologies (such as that which assumes and prescribes a division between public and private spheres) which feminist political theorists have identified as influential in maintaining and obscuring women's social and political subordination? At the core of most feminist legal scholarship is a critique of the purported objectivity or gender-neutrality of legal method and legal regulation. The argument is that the purported gender-neutrality of legal concepts and of most legal arrangements in liberal societies in fact disguises the implicit instantiation in laws of a partial viewpoint, and one which generally reflects male rather than female interests and experience of the world. Feminist legal scholars

are therefore much concerned with debates in feminist epistemology and feminist ethics, and particularly with the problem of 'essentialism'—that associated with identifying masculine or feminine viewpoints in a world where both male and female experience is relative not only to gender but also to class, ethnic, and other social structures and axes of subordination. Another feature typical of feminist legal philosophy is scepticism about the idea that law is autonomous in the sense of being both a distinctive and, in significant respects, a discrete practice, insulated from broader political and social influence.

Like all sophisticated intellectual discourses, feminist legal philosophy is characterized by a diversity of both substantive commitment and method. A significant strand of feminist legal scholarship draws on post-modernist ideas and sees the feminist project in this area as a basically critical or deconstructive one. Scholars sympathetic with this position express scepticism about the participation of feminist theory in the enterprise of constructing a 'grand', universal theory of law, which they argue would be likely to reproduce the same kinds of distortion and exclusion which characterize orthodox legal theories. Others envisage the possibility of a feminist jurisprudence which could escape the bias and obfuscation of orthodox legal theories such as positivist or natural law conceptions and which could hold out the promise of conceiving genuinely equal legal subjecthood and gender justice as opposed to gender-neutrality. Similar diversity characterizes feminist approaches to the role of normative or prescriptive thought in legal philosophy. Whilst most feminist scholars are critical of the idea that normative argument can be objectively grounded or proceed 'from nowhere', they vary in terms of what role they see in the feminist enterprise for legal reformism, the reconstruction of normative concepts such as justice, rights, or equality from a feminist perspective, or utopian argument about legal and social change. Thus some feminist legal scholars see immanent critique—the holding-up of legal practices to critical scrutiny in the light of their failure to meet their own professed ideals—as the central task of feminist legal theory, while others see external, more broadly politically or ethically based critique as of equal importance. Like most forms of feminist theory, feminist legal philosophy retains a strong sense of the importance of the link between theory and practice. Much feminist philosophical work in the area of law therefore concerns itself with philosophical critique of concrete legal institutions and practices, notably the regulation of the family, and the structure of constitutional rights and their impact on practices such as abortion and pornography; the regulation of sexuality by and the construction of images of women and men, femininity and masculinity, within a wide range of criminal and civil laws; legal anti-discrimination policies and the ideals of equality and justice which inform them. **law, history of the philosophy of.** The philosophical reflections recalled here are about \*positive law, in particular the rules and principles authoritatively declared by people who make themselves responsible for (what they claim to be) the good order of their community, an order they specify and promote by proposing obligatory and other authoritative guidance for the actions of their community's members.

Throughout its history, legal philosophy has sought to differentiate positive law (hereafter 'law' or 'the law') from other standards relevant to human deliberation towards choice and action, and from the governing principles and norms of other intelligible orders (the systems of the cosmos or nature, of logic, and arts such as grammar or boat-building). Such differentiation has aimed both to clarify terminology and conceptual boundaries and to inquire whether the analogies or other relations between law and these norms of other orders help explain what is most puzzling about law: that it can 'necessitate' (make obligatory, indeed morally obligatory) actions which, until its enactment, were not so necessitated; that its rules and other 'institutions' somehow 'exist' by virtue of but also long after their positing by enactment or other 'act in the law', or judicial precedent or custom; that many of its rules have a normative form, and a social function, distinct from its obligation imposing rules; that it resorts to punitive and rectificatory coercion to outlaw force (as well as dishonesty and carelessness) in interpersonal relations. (\*Law, problems of the philosophy of.)

The surviving fragments of the \*Pre-Socratics on these matters suggest a vigorous debate which cannot now be securely reconstructed. The conversation of legal philosophy begins for us with two brief dialogues reflecting the debates in Socratic circles: a witty conversation between Alcibiades and Pericles composed by Xenophon (*Memorabilia* i. 2), and a 'Socratic' dialogue insecurely ascribed to Plato (the *Minos* 314b–315a). Each portrays the embarrassments awaiting philosophers who define law as whatever is decreed by rulers, neglecting or declining to refer to issues of (moral) right such as whether its subjects have in any way consented (Xenophon) or whether what it decrees is good, true, and in conformity with 'what really is' (*Minos*). Both dialogues suggest that, while everyone understands the sense in which a law's (in)justice is irrelevant to its empirical reality as enforced, in a more adequate understanding of law unjust laws are 'more a matter of force than of law' and are 'not without qualification law' (*Minos*).

So by the early fourth century bc two positions emerge, each still defended in the late twentieth century. The

one—today called \*legal positivism—asserts that to be described with realism and clarity law must be considered without regard to any moral predicates which it attracts in discourse (e.g. moral–political evaluation) outside the philosophy of law. The other—usually if confusingly called \*natural law theory—asserts that such a description misses the point of law: legal systems get their sense and shape (which a good descriptive account of law will identify) from their point, and a rational evaluation of particular laws or legal systems (or political communities) will use that (perhaps complex) point as a criterion for measuring their conformity to or deviation from the very idea of law. Plato articulates this second position: 'Enactments, to the extent that they are not for the interest of the whole community, are not truly laws' (*Laws* 715b; also 712e–713a; *Statesman* 293d–e). Cicero sums up the philosophical mainstream: 'In the very definition of the term "law" there inheres the idea and principle of choosing what is just and true' (*De legibus* ii. 11).

On this issue of definition, Plato had warned that ordinary talk of 'law' is one thing, explanatory definition of law another (*Hippias Major* 284d). Aristotle (*Politics* iii. 1275a–b) worked out the appropriate account of definition in social, including legal, theory. In this account, pure description or reportage (these purport to be, and are commonly called, friendships, political communities, constitutions, . . . laws) can coexist with explanatory definition within a theory which treats justification (and, where appropriate, critical delegitimization) as the primary mode of explanation. Thus the humanly good type of friendship, community, constitution, . . . or law is the paradigm, central case picked out by the explanatory definition, and by a corresponding word ('friendship', . . . 'law') in its focal meaning; specimens of this good type are in this sense truly, properly, or unqualifiedly (Greek *haplōs*, Latin *simpliciter*) friendship, law, etc. But instances of a type that is humanly deficient remain within the discipline's philosophical account, precisely as analogous to the central case. The philosophy of human affairs, as it bears on law, reflects on decent laws and legal systems, with due attention to what makes laws bad and how bad laws matter.

Until Bentham (foreshadowed in the seventeenth century by Bacon, Hobbes, and Spinoza), there is little or no legal philosophy which could be called positivist. Yet from Plato to Bentham legal philosophy was substantially a philosophy of positive law, a subject-matter regarded as distinct from the other subjects of moral and political philosophy, but as adequately intelligible only on the basis of the moral principles and political purposes identified, explicated, and defended within moral and political philosophy. Still, legal philosophy's self-interpretation precisely as a philosophy of positive law awaits the *Summa Theologiae* of Thomas Aquinas (c.1270). The term 'positive law' emerged c.1135, and soon became popular among theoretically minded jurists. But the new terminology did not immediately modify the ancient accounts of the precise subject of philosophical reflection on law(s). Aristotle (*Nicomachean Ethics* v. 1134<sup>b</sup>) had divided

political right/just(ice) into the natural and the legal; the latter he also described as conventional and human. Late twelfth- and thirteenth-century jurists divided *jus* (law/right) into natural (the moral law) and positive, subdividing the latter into the Roman-law categories of *jus gentium* (laws common to all peoples) and civil law (peculiar to a given community). Eventually Aquinas (*Summa Theologiae*, 1–2, Q. 95, A. 2) treats the distinction between natural and civil law as a distinction within positive law (i.e. within law humanly laid down). Some parts of positive law are *conclusiones* (entailments) of the principles and norms of natural moral law; for these he appropriates the name *jus gentium*. The other parts are purely positive, though related to moral principles by an intelligible, non-deductive relationship which he names *determinatio* (concretization).

Thus human positive law in both its parts is at last differentiated as an integral object of philosophical reflection. It is by analogy with this central analogue that we understand as law (i) the eternal law of God's creative providence (including all the laws investigated by the natural sciences), (ii) the \*natural law, or rational principles of good and right human deliberation and action, and (iii) the 'divine law', Aquinas's name for norms of positive law specially promulgated by divine revelation and including, like human positive law (ecclesiastical or secular), elements both of natural law (e.g. most of the Ten Commandments) and of purely positive law (regulating Israel and then the Church).

Aquinas describes human positive law as made by *will* (i.e. by preferring one reasonable scheme to another), but when speaking precisely contends that law is a matter of *reason* rather than will; obligation is a matter of means required for serving and respecting practical reason's ends and principles; the *imperium* by which one directs oneself in executing one's choices belongs to reason rather than will. All this soon met with opposition, and for the next 500 years the philosophy of law is dominated by efforts to explain law's source and obligatoriness by reference to will, whether of superiors or of consenting parties to a social contract.

The polemics launched in 1323 between Pope John XXII (canon lawyer and Thomist) and William of Ockham, concerning the nature of legal (especially property) rights, gave wide currency to Ockham's conceptions: of positive human law as founded on commanding or contracting will and legitimate even when opposed to natural law; of supreme (divine) will as binding to even the most inherently unreasonable act (e.g. hating God); of right as primarily a power or liberty of acting. The second scholasticism of sixteenth- to seventeenth-century Spain sought a balance between Thomist and voluntarist theory. Its monument is Suarez's *De legibus* (On Laws (1612)). Reason's capacity to discern right from wrong is emphasized, but obligation is still a driving force from a superior's will, and Aquinas's conception of *imperium* as reason's directive grasp of an action's intelligent point is rejected as a fiction. Suarez underlines the variety of types of law (eternal,

natural, human, divine) but also the variety of normative types of human law, including laws binding to compliance, laws binding only to payment of the 'penalty' for non-compliance, laws giving juridical acts their form and validity, and laws creating privileges. The principle of Suarez's analyses remains the moralist's interest in issues of conscience (conceived in terms of obligation and liberty).

Grotius, though clearly influenced by Suarez and other philosophical theologians, shifts the focus of inquiry in legal philosophy: the foundations of morality (natural law) and obligation are but lightly and ambiguously sketched. The work of 'philosophy of law' (a term promoted if not invented by Grotius) is conceived as identification of the reasonable scheme of law which will secure justice and rights in a community constituted by social contract. The scheme's content is settled, in effect, by making such adjustments to Roman law's conceptual framework as are suggested to Grotius by an immensely learned survey of classical culture, medieval commentary, and some comparative jurisprudence. Grotian (over-)confidence in reason's ability to identify uniquely appropriate legal solutions to problems of social life persists in the rationalist theories of natural and human law which prevail until Bentham and Kant.

But the seventeenth- to eighteenth-century descendants of Grotian theory had to respond to the radical questioning of their foundations by Hobbes and Spinoza. Paradigmatic is the response of Samuel Pufendorf (c.1670). Laws are decrees by which superiors obligate us subjects to conform our acts to their commands. Every law contains both a definition of what we are to do or avoid, and a statement of the punishment awaiting our non-compliance. Obligation is a moral quality created by persons who have not only the power to harm us if we resist them but also just grounds for their claim to limit our freedom by their choice. These just grounds may be the benefits those persons have rendered us, their benevolent ability to provide for us better than we could for ourselves, and/or our agreement to subject ourselves to them. Hobbes's claim that the right to rule is warranted solely from irresistible power must be rejected as failing to account for obligation's significance for conscience. Like the Calvinist Grotius, the Lutheran Pufendorf and the whole mainstream retain the Catholic division of law into natural, divine, and human and the Thomist position that human law is, as such, all positive (though rightly constrained by the natural law, many of whose precepts it should also repromulgate to recalcitrants). Philosophy of law identifies for jurists many details of the law which should obtain within and between states, and for morally upright citizens their duties of conscience in face of legal obligations.

The notion of natural law both limiting and justifying positive law remains in Kant's *Rechtslehre* (Doctrine of Law/Right (1797)), but now the natural law abstracts from all human benefits and reasons for action, other than conformity with the universalizing *form* of reason. Right

(and right law) is the coexistence of my freedom (in accordance with universal laws) with everyone else's; wrong is the hindering of such rightful freedom, and is itself rightfully hindered by coercion; strict right or law is a state of universal reciprocal coercibility. Kant seeks to ground the law's primary institutions (property, contract, status, and punishment) in the logical requirements of a self-consistent freedom. The obligation of contracts, as of law, he thinks is entailed by the concept of a (simultaneously) united will. His account thus abstracts from human benefit and empirical realities alike, and rests on fictions (virtually admitted by him in retaining the 'idea of an original contract' of society).

Bentham had taken a very different course. His *A Fragment of Government* (1776), ridiculing late echoes of Pufendorf, proposed a radical distinction between the 'provinces' of expositors, who by attending to facts explain what the law is, and 'censors', who by attending to reasons consider what it ought to be. Bentham's expository jurisprudence included a treatise *Of Laws in General*, not published until 1945 but very like John Austin's less ingenious account, *The Province of Jurisprudence Determined* (1832): all laws properly and strictly so called are commands, expressions of wish (accompanied by threat of sanction) by the sovereign in an independent political community; however influential in courts, rules not made or adopted by sovereign command are not laws properly so called. Having a legal obligation is being the subject of a command and susceptible to its accompanying sanction. Legal rights including powers are all to be explained in terms of commands and more or less complex permissions or negations of obligation.

English-language philosophy of law remained largely within the orbit of Bentham and Austin for more than a hundred years (though historico-comparative jurisprudence ranged widely). American and other legal realists denied that the substance of the law is rules or any other standard posited by commands or any other past acts. But they retained and reinforced the conception of law as an instrument, in itself morally neutral, of 'social control' for the purposes of those in power (most directly courts and other officials).

Hans Kelsen, whose ideas became influential outside German-speaking lands in the 1930s, attempted a union of Kantian with neo-Hobbesian and neo-Humean themes which issued ultimately in a radically will-, indeed command-, centred account of law and legal system. Legal philosophy ('pure theory of legal science') must be free from every value, and from any reference to fact such as might suggest that law's normativity derives from or is reducible to its efficacy or other empirical reality. Kelsen sought in effect a 'third theory', sharing with natural law theory the attempt to reproduce and explain non-reductively law's normativity, and with legal positivism the rejection of every norm or value not posited and made effective by contingent human acts and facts. The quest's failure is manifested in Kelsen's many shifts to and fro between contradictory views about the source and coherence of

legal norms, the content of normativity, and the meaning of propositions of legal science, and in his final open reliance upon 'fictitious acts of will'.

That explanations of law and legal obligation must point to commanding or consenting acts of will was denied in H. L. A. Hart's *The Concept of Law* (1961) and *Essays on Bentham* (1982). Legal rules are, rather, content-independent peremptory reasons for actions. Their sources may be commands but may equally be any fact having the normative significance attributed to it by a rule of recognition accepted by judges and officials (for any reason other than fear of immediate sanction). Not all laws are obligation-imposing; many are power conferring and an account which reduces these to conditions or protases of obligation disguises the variety of law's normative functions by overlooking the variety of its social functions. A descriptive legal philosophy can and should be free from moral presuppositions; law is not 'necessarily or conceptually' connected to morality, Hart holds. But legal philosophy should understand and reproduce the viewpoint or 'internal attitude' of those participants in a legal system for whom law is a genuine reason for action and something of (not necessarily moral) value. It therefore cannot maintain that law may have just any content.

Hart's many-sided resistance to reductive accounts of legal realities, and his strategy of understanding law as a type of reason created, maintained, and recognized for distinctive reasons, have encouraged many lines of inquiry into the point and function-related structure not only of law and legal system as a general type of social reality, but also of legal reasoning or judicial deliberation, of the rule of law as a distinctive ideal for politico-legal order, and of the shaping moral point and justification(s) of particular legal institutions such as contract, tort (delict), property, and punishment. Attention to Hart's neo-Aristotelian method of explanation by central and secondary cases has suggested that, despite his insistence on the opposition between the legal positivism he defended and every natural law theory, such opposition is needless unless positivism is taken (like Kelsen's but not Hart's) to deny that valuation and moral judgement have any philosophical warrant or truth.

Many positivist theories before Hart had been modelled on the natural (including mathematical and psychological) sciences. *The Concept of Law* opened legal philosophy to issues of method in descriptive social theory earlier discussed by Dilthey, Weber, and Winch, and showed, as Hart more or less clearly intended, the fruitlessness of seeking a value-free general social science. Interest has since shifted towards integrating legal theory with ethics and/or modelling it on the interpretation of cultural forms such as literature. For example, Ronald Dworkin's critique of positivism seemed at first intended to establish that Hart had misdescribed the types of standard used in judicial deliberation. But Dworkin's real theses were not that legal principles differ from rules, but that there are standards which are *legally* authoritative not because they were created or validated by enactment or

usage, but because, given the relevant political community's history, they are morally true (while being irreducibly distinct from utilitarian or other collective-goal-based policies); and that legal theory, as adjudication's prologue, is a practical enterprise of 'creative interpretation', participating in developing a 'liberal' legal system which, without violating integrity by repudiating too many of its 'materials' (constitution, enactments, and precedents), will treat citizens with equality of concern and respect. The debate about these theses asks whether Dworkin's rather unarticulated moral theory is sound, whether the analogy with creative literary interpretation is not a new form of reductive explanation, and whether the claim that the law, even in hard cases, can always be identified by moral reasoning about the legal materials is not, likewise, a reductive oversight of law's dependence on authoritative choice (will) between reasonable alternatives still legally open.

Kelly, *A Short History of Western Legal Theory* (Oxford, 1992).Alfred Verdross, *Abendlaendische Rechtsphilosophie* (Vienna, 1958).Michel Villey, *Leçons d'histoire de la philosophie du droit* (Paris, 1957).

**law, indeterminacy in:** see indeterminacy in law.

**law, moral:** see moral law.

**law, natural:** see natural law; laws, natural or scientific.

**law, positive.** A term (*jus positivum*) launched in philosophical commentary (Thierry of Chartres, c.1135, then Abelard), and focusing legal theory on to law's sources (*positum*, Latin 'laid down'). As Aquinas noted, earlier terminology confused rules 'human' in use with rules human in origin, though Plato and Aristotle had in substance distinguished (positive) law from morality. (\*Natural law.)

Human positive law includes rules (e.g. against murder) and institutions (e.g. punishment) belonging also to natural law (i.e. morally required willy-nilly). Hart called these the 'minimum content of natural law', but meant the minimum content of positive law. Most laws are 'purely positive'; what they require was not morally required until their positing (though Aristotle, *Nicomachean Ethics* v. 1134<sup>b</sup>, exaggerates in saying that they are on 'matters [morally] indifferent in themselves').

\*law, history of the philosophy of; feminist philosophy of law; law and continental philosophy.

Karl Olivecrona, *Law as Fact*, 2nd edn. (London, 1971).

**law, problems of the philosophy of.** How can there be a philosophy of law distinct from ethics, political philosophy, or a general social theory building on social anthropology and comparative history?

If ethics inquires into standards of right judgement in deliberation towards choice and action, philosophy of law investigates the relation of those standards to the directives laid down, by usage or authoritative decision, to guide people's actions in political community and thereby, purportedly, protect basic interests or rights, distribute burdens and advantages fairly, and restore the position of persons wronged. Thus legal philosophy goes beyond but cannot elude the main problems in ethics: whether moral propositions can be known as true; whether moral truths include intrinsic goods and reasons for action richer than Kantian conformity with reason's universalizing abstractness; whether right judgement is by maximizing values consequent on choice; how far choice is free and intention morally decisive.

If political philosophy investigates the grounds on which persons may (and do) claim authority to shape a community's actions by directing individual conduct, legal philosophy investigates reasons for and ways of making such authority and its exercise conditional on criteria of form (source, scope or *vires*, procedure, promulgation and publicity, adjudicative integrity, etc.). Thus legal philosophy adds to but is enmeshed in political philosophy's main issues: e.g. whether authority is justified by consent or by intent to benefit; whether interests are rights and rights secure equality, liberty, or other benefits; whether political action is well understood on the model of decisions in economics or competitive games.

If social theory generalizes from knowledge of particular societies and events in their history, legal philosophy investigates how such societies can be implicit subjects or bearers of legal systems' elements. It thus confronts main problems of general social theory: how to identify a subject-matter which can subsist as regimes and constitutions change and disappear; how to select and justify descriptive and analytical concepts and terms, given the variety of social self-interpretations and competing vocabularies disclosed by ethnography and comparative historical and cross-cultural studies.

Legal philosophy is often (e.g. John Austin, H. L. A. Hart, Joseph Raz) divided into analytical and critical. Analytical jurisprudence is to consider the definition of law, the theory of legal system, the analysis of legal concepts such as duty, transaction, and intention, and the theory of legal reasoning, especially in adjudication. Critical philosophy of law is to evaluate law and legal obligation, the minimum substantive content of legal systems, the interlocking procedural virtues called the rule of law, etc. But against such a division, and the similar recent division between conceptual (or explanatory) and justificatory, it can be said that legal systems are created and maintained for reasons, and these like every reason for action presuppose and/or propose evaluation(s). Any general account of legal systems (or of the concept of law and legal system) must identify those shaping evaluations.

Still, cannot descriptive or conceptual analysis of law's character as means to end(s) proceed without evaluating—and *a fortiori*, or at least, without morally

evaluating—the diverse purposes and uses to which the instrument is put? It seems not. For law's characteristic purport as obligatory and authoritative, like its purport as stipulating appropriate procedures and requiring fair trials and judgments based on truth, itself proposes an evaluation and critique—mainly if not exclusively moral—of alternative social conditions (anarchy, arbitrary domination). How, then, could there be an adequately inward understanding or analysis of what characterizes diverse legal systems—an account showing why law deserves a place in any truly general account of human social life—without an understanding of the ways law's characteristic features themselves (even when being unjustly manipulated) manifest a critical evaluation of, and value-affirming constructive response to, the sorts of injustice or other lesion of human good which are inherent in lawlessness? (Analogously, one may understand, describe, and analyse an argument without accepting or approving it; but can one understand, describe, or analyse *argument* unless one accepts some arguments as good and adopts as normative for one's description the criteria by which their soundness is recognizable?)

Law is somehow an institution or product of human deliberative reasoning, and addressed to human deliberative reasoning. Laws and legal systems, like the human persons who are their makers and subjects, somehow belong to all the four sorts of order with which human reason is concerned—roughly, natural, logical, moral, and cultural/technical. Using the conventional symbols and syntax of an ordinary language, and supplementing them with new conventions and techniques, legal rules articulate conceptions of the natural order (which reason does not make but only considers), of logical consistency and implication, and above all of rightness and wrongness in official and unofficial deliberation and action. This articulation is highly reflexive: Kelsen's slogan 'the law regulates its own creation' captures some of this reflexivity. Indeed, even philosophical reflections on law (and nature, logic, morality, and non-legal techniques) are often found among the concepts and terms manipulated in making, interpreting, and using legal rules, institutions, and processes. Legal philosophy is always tempted to resolve the resulting complexity into the relative simplicity of just one paradigm of order, on the basis of just one paradigm of description, analysis, or explanation.

Take causation. Some legal-philosophical accounts, particularly German accounts since Kant, have proposed that causing is by physical movements, and is unaffected by acting persons' purposes or other states of mind (which are relevant only to imputing culpability or legal liability). Such accounts of human causality are modelled on natural-scientific accounts of causality as regularities, or probabilities, or some inherent property of objects or events. Some other legal theories of causation, particularly American theories, have reduced 'cause in fact' to the minimal *conditio sine qua non* ('But for C, E would not have occurred'), and contended that 'cause in law' is merely a construct of social (i.e. moral and/or cultural) policies

about who is now to take the blame and/or pay. Against these reductions stands an account such as Hart and Honoré's. It accepts that judicial findings that someone's act caused some event and/or loss are justified by considerations substantially independent of moral conclusions or other policies about liability (blame and recompense); it adds, however, that the same is true of judicial findings that the event or loss was caused by someone's omission. It accepts that all such findings are similar to scientific, historical, and common-sense conceptions in distinguishing the causally relevant as a subclass of conditions *sine qua non*. But, on Hart and Honoré's account, the central causal concept, of deviation from normal conditions, itself extends to include conditions culturally established as conventional expectations or legal duties; attributions of causal responsibility are nested in, but are not reducible to, conceptions of role- and liability-responsibility, distributions of burden of proof, criteria and methods of proof, and other, in themselves non-causal considerations. The complexity of such a non-reductive account mirrors the irreducible complexity of the life, deeds, and efficacy of beings who live in the natural world as reasoning and choosing agents, artificers and creators.

Again, take legal personality. Some say: only members of the natural species human being are properly the subject of legal relations; lawyers' talk of other juridical subjects (corporations, unincorporated associations, ships, idols, etc.) is of mere, albeit useful, fictions. Others (e.g. Kelsen) say: the status of legal person is simply a creation of the law, which freely bestows or withholds it; the logic of legal rules leaves no room for attributing to human beings a legally cognizable priority. Another approach denies that human associations are mere fictions, acknowledges the convenience of attributing to associations and even non-human entities the status of subject of legal rules and processes, accepts that in a logical analysis of legal rules and relationships the human subject has no priority, but maintains that since the very point of guiding deliberation by law is to protect and promote the good of human beings, and since, prior to any human decision, subjects of that kind are naturally constituted as persons, in their radical potentiality and/or actuality, laws are radically disordered precisely as laws when they deny to any human being (slaves, embryos, *et al.*) the 'equal protection of the law' (minimally, equality of fundamental legal status and immunity).

As the foregoing makes evident, the vexed problem of *defining* law cannot be resolved by any purely 'analytical' or conceptual technique aspiring to be neutral and conceptually prior to the taking of substantive positions on disputed questions about, for example, the natural and the moral orders. Of course, stipulative definitions and/or lexicographical clarifications assist inquiry and should avoid begging disputed questions. But explanatory definitions summarize the results of, not linguistic data or regulations for, philosophical reflection. In legal philosophy it is particularly easy to see the value of a long-neglected classical technique announced by Aristotle, practised by his

medieval followers, and revived, if not fully consistently deployed, by Hart: take as the subject of an explanatory definition the *central case* of the explanandum (and correspondingly the *focal meaning* of the term signifying that reality), and treat as secondary and relatively peripheral, but by no means unimportant or irrelevant, the many realities which instantiate the central case in only a watered-down, immature, or defective way (and correspondingly the secondary uses of the term). Then one can say that a legal system which denies the legal personality and/or fails to protect the fundamental rights of some members of the human community it regulates and serves is not merely unjust and immoral but also a poor specimen of a legal system.

But note: such a thesis depends on the further, widely disputed premiss that what counts as the central case or fine specimen of a subject-matter of social (e.g. legal) philosophy is settled by reference to the evaluative concerns not of 'bad citizens' concerned only to avoid sanctions (as American legal realists proposed), nor of morally unconcerned judges or other officials as such (as Hart proposed), but rather of people who understand, accept, and promote law as a morally motivated and justified response to the evils and injustices of legally unregulated human relationships. The premiss is most easily defended when law is being considered in the course of a philosophical reflection which is from beginning to end practical, that is, concerned with the question, What should I (the reflecting person, the philosopher) choose and do?—a question asked not in relation to some particular situation and objective, but in the open horizon of one's whole life. That is the question shaping the whole course of Aristotle's two-volume philosophical reflection on 'human affairs', his *Ethics* and *Politics*, and of philosophical work clear-headedly in the same broad tradition. When this is the question, unjust laws and morally unconcerned or immoral viewpoints, though instructive, are evidently as *non-central* as, analogously, fallacious forms of argument are non-central (though instructive) in a philosophy of argumentation, and doomed strategies, bad recipes, or quack remedies are non-central (though instructive) in the arts of war, cooking, or medicine. Still, the premiss can also be defended even when the legal- or social-philosophical question is not itself practical, but descriptive, seeking merely to understand law, contemplatively, as a kind of reality found in many times and places. The defence will be dialectical: only those who understand, accept, commend, and promote the rule of law as an indispensable means of avoiding the evils and injustices of legally unregulated communities and relationships have sufficient reason not only to maintain and uphold the rule of law when it is in place but also, when it is not in place, to (re)introduce it, with just that complex set of features which legal philosophers of every school agree are its characteristics.

Such issues of definition and explanatory methodology are issues within the order of logic, i.e. of the rational order we introduce into our own thinking. Some of the problems peculiar to legal philosophy arise primarily within this order. How does the propositional character of

legal rules differ from that of legal principles or other legal standards? What are the types of logical opposition between rules, and to what extent is contradiction between rules possible in a legal system? Are all rules of, or at least reducible to, one logical type, such as the imposing of obligation on pain of sanction or the hypothetical authorization of sanctions? If so, are the logical types correlated with the social functions or point of different sorts of rules? What are the irreducibly distinct types of right (perhaps claim, liberty, power, immunity)? Are rights mere logical constructs from, or shadows of, a logically or explanatorily prior concept of duty? Is a liberty (permission) the mere absence of a contrary duty, or does it entail a prohibition of some (or all) types of interference by *A* in the exercise of *B*'s liberty, and if so would it always or ever entail that *B* has a liberty-right to do what he ought not to?

These and similar issues have an irreducibly logical core. But progress in resolving them requires close attention to the special meaning and use of terms such as 'rule', 'obligation', 'right', and 'liberty' within the specific cultural and technical construct called the law. That construct, in turn, characteristically serves certain human purposes, and does so by guiding deliberation. A truly general account of it cannot be limited to recording the purposes, aims, and techniques of one people, or to reproducing in a 'detached' mode their 'committed' discourse. It must, therefore, engage to some extent in reflection on the moral order (which we bring by reason into our deliberations towards choice and action), by asking when action is intelligently related to basic human purposes and reasons for action. In short, all the questions listed in the preceding paragraph require the taking of some position on the *point* of law. Is law most illuminatingly regarded as an instrument of social control, whatever the controllers' purposes—an instrument which merely *happens* to have the inherent capacity to serve justice, rights, and the common good, as hammers merely happen to have the inherent capacity to serve as murder weapons, paperweights, or wall decorations? Or does such an interpretation render much of the law's vocabulary and logic unintelligible or, at least, radically unexplained? Is law to serve liberty above all, or is the liberty it serves (if it does) only one among many fundamental benefits? Such questions may seem remote from a strictly logical analysis, but answers to them have proved to be necessary (though not sufficient) for analysis of the structure of legal systems as interrelated propositions or quasi-propositional meaning contents.

Efforts to reduce problems of legal philosophy to the logical order have issued in striking failures: e.g. Hobbes's attempt to explain contractual obligation by equating breach with logical absurdity; or Kant's claim that since *B*'s wrong contradicts *A*'s rightful use of freedom, *A*'s (or *C*'s) use of coercion 'to hinder' *B*'s wrong must, 'by virtue of the law of non-contradiction', be compatible with rightful freedom. As such failures powerfully suggest, the normativity of practical reasoning and legal norms is not reducible to logic's normativity, but rests on the necessity of means to or respect for basic ends.

Some have handled law-related moral problems and concepts by declaring them foreign to legal philosophy, or redefining them as cultural/technical, not moral. Does the injustice of a law affect its authority, validity, or authoritativeness? Is equity a matter simply of interpretation, or can it correct the intentions of the law givers? Do laws (and contracts) creating obligations entail no more than an obligation to pay the penalty (or damages) for 'non-fulfilment'? (And if so, is the last-mentioned obligation reducible to an obligation not to assault the bailiffs? And so on . . .) Problems such as these have been said to be matter merely for individual conscience, morality, or ethics. But in the proper (conscientious) performance of their judicial office as such, judges cannot avoid such questions. And there are others even more essentially concerned with the adjudicative role. Is it right for a judge to change the law at the cost of defeating the legitimate expectations of the unsuccessful litigant? Or to override the deliberately adopted policies of a democratic majority? Can judges rely upon their own personal knowledge unsupported or even opposed by the evidence admissibly tendered in the case? And then there are the responsibilities summarized in the ideal of a rule of law (*Rechtsstaat*): to ensure that there is law and that it is clear, coherent, stable, public, practicable, non-retroactive, general, and above all respected in official (including judicial) action. Is this set of purposes and features of legal ordering morally neutral (like the sharpness of a knife for cutting)? Or must the set, taken as a whole, have the moral purpose of securing a relationship of reciprocity between rulers and ruled, in recognition of the dignity and rights of the ruled?

To conclude that such questions are properly part of legal philosophy is not to take sides in the perennial debate whether to define the law as whatever standards are cognizable from social-factual sources (legislation, custom, judicial precedent), or rather as whatever standards judges should take into account in giving judgment.

It remains that laws are manifestly in the cultural/technical order (order which, by reasoning, we bring into matter subject to our power); they are objects created by human decision as an instrument of social co-ordination. This aspect of law's *positivity* seems put in question both by theories (\*legal realism) which reduce the law to a prediction of judicial action, and by theories (e.g. Dworkin's 'law as integrity') which locate the law not in any existing rules and standards (considered to be merely 'legal materials') but only in the act of judgment by a judge who, in a 'creative interpretation' subjects the 'legal materials' to ultimately individual moral assessment.

Law's many and varied artefacts include first the rules of law themselves. Even those rules which give legal expression to a moral norm are truly positive laws and usually of an artificial form: the law does not formally forbid murder, but rather specifies that murder is an offence, attaches penalties, disqualifications, and other legal consequences to offences, and posits (usually by implication) that 'offences' are not to be committed. Still, most legal rules are no mere repromulgations of moral norms, but

products of an irreducibly creative social decision. Their authenticity is a matter not immediately of moral truth, but rather of the considerations of form, source, and procedure encapsulated in the characteristically legal concept of validity.

Most other legal artefacts can be classed under another characteristically legal term: institutions. Legal institutions include not only public bodies such as courts and legislatures, but also types of legal arrangement involving clusters of rules (contract, sale, property, corporations, crime, delict, etc.) and specific instances of such types, deliberately instituted for the sake of their legal effect (thus a particular delict or crime). And these artefacts are to be distinguished from any documents used to create or record them. Obviously, then, the description and explanation of such artefacts would be complex even if the cultural/technical order could be sealed off from the orders of nature, logic, and morality. But it cannot, and some of the most intense debates in contemporary legal philosophy concern the moral and other (e.g. causation) foundations of the legal institutions of crime, tort (delict), contract, and property.

Other legal artefacts include definitions, whose purpose is not, as in legal philosophy, to summarize an understanding of central (and non-central) cases and focal (and secondary) meanings, but rather to assign objects and topics of human social life to universal classes for the purposes of a given rule (e.g. taxing or registering 'ships'); and inference rules establishing presumptions for legal judgment on facts. Definitions and inference rules meet in the peculiarly legal practice of *deeming X to be an instance of Y*.

Many problems of legal philosophy are displayed in the problems associated with the *interpretation* of constitutions, statutes, judgments, and other legal instruments (documents) and arrangements. Should legal interpreters find and follow the commitments originally made in the morally significant choices and intentions of the makers? Or should they give the language used—a set of conventional objects deployed to make a new and free-standing cultural object (the constitution, the Act of . . ., etc.)—a new meaning and effect in accordance with new conventional understandings of the language? Are not both the act of legislation and the act of judicial interpretation (though immediately and directly exercises of a cultural technique) limited in their plasticity or malleability not only by other conventions but also by the natural givenness of certain necessary pre-conditions for human action, by the requirements of logical coherence, and by the moral significance of every human act?

Reflections on these and other ways in which legal philosophy is distinct from ethics, political philosophy, and general social theory are compatible with expecting (anticipating and requiring) that its concepts and theses be compatible and even harmonious with the concepts and theses of those other disciplines or modes of inquiry. For it is one and the same set of persons and communities of persons that is the subject (subject-matter and agent) of them all.

**law, rule of:** see rule of law.

**law, scepticism about.** Scepticism about law can be understood in at least two senses. In a weaker meaning it is most usually attached to criticisms of the legal profession and refers to scepticism about specific features of legal practice and procedure. In this sense it dates back at least to Plato's castigation of forensic oratory as narrow, constrained, manipulative, and untruthful in the *Gorgias* and *Theaetetus*. In subsequent history criticism of the venality and immorality of legal practice has tended to focus on the obscurity and illogicality of legal argument as well as upon the arbitrariness of legal judgment. From Rabelais to the modern schools of \*legal realism, sceptics have argued that legal decision-making is divorced from legal rules and that the power of law-making lies in the unfettered discretion of judges, tribunals, and law enforcement agencies. In contemporary Anglo-American jurisprudence the term 'rule scepticism' thus denotes a scepticism about the necessary relationship between legal rules or the 'law in books' and judicial practice, while 'fact scepticism' asserts that the indeterminacy of fact-finding procedures renders all reference to rules problematic.

In a stronger sense, scepticism about law extends the criticism of the arbitrariness or injustice of legal judgment into arguments for the abolition of law, or predictions of the end of law. In this meaning, criticism of the profession and practice of law are taken cumulatively to condemn the institution of law as an unethical and unnecessary form of human relation. In this sense the earliest radical scepticism about law is to be associated with Sir Thomas More's fictional *Utopia* and subsequently with the various strands of anarchist and socialist political theory. The broad argument of such theories has been that the ideal of human \*freedom and specifically of self-determination is antithetical to the demands of legal governance. To the extent that \*law is necessarily coercive and repressive of human autonomy it is an evil and can have no part to play in a free society. The authority of law is in this perspective an ideological manipulation and is predicated upon a domination or repression of the ultimate human good which resides in a society of free association. The practice of law was perceived to be violent, irrational, and necessary only for the preservation of private property or the good of an élite minority.

While early anarchistic and utopian-socialist arguments against law tended to be either nostalgic, recalling a

primitive age of innocence, or oneiric, specifying utopia in terms of an ideal but unmapped future territory, a more substantive scepticism about law emerged within the \*Marxist tradition of political theory. Where Marx had adverted somewhat incidentally and allusively to an end of history, a communist society in which freedom would displace law and in which the state would wither away, subsequent elaborations of a Marxist critique of law developed more specific analyses of legal domination. In its strongest form, Marxist scepticism about law proceeds from an analysis of economic exploitation and argues that the legal order and its substantive rules are a more or less complex reflection of the class relations which constitute the reality of social experience. Within this broadly deterministic view of legal relations scepticism about law takes the form of critique of the ideology of the rule of law. Far from treating all legal subjects as free and equal before the law, legal rules are ideological in the sense of masking the real (economic) conditions of \*inequality and constraint which predetermine the content and the effect of law.

In what is arguably its most sophisticated expression in the writings of the post-revolutionary Russian jurist Pashukanis, law was to be understood as a direct expression of the commodity form of production and the legal subject was no more than the fictively free and equal subject who would come to market and buy and sell. The legal relation was thus exemplified by contract and by the unequal economic conditions within which goods were exchanged. For Pashukanis, the legal form was thus a bourgeois species of human relation and law would come to an end with the demise of the economic system upon which it was based. While contemporary scepticism about law derives, both directly and indirectly, from Marxist and \*communitarian anarchist critiques of law, it tends to be more partial and less millenarian in its approaches. Contemporary critical legal scholarship is broadly reformist in its goals yet also argues that law exploits and dominates to the benefit of vested economic and political interests. In common with \*feminist analyses of law, critical jurisprudence thus proposes an ethical critique law. The doctrinal tradition and its various positivistic justifications are analysed as abstract mystifications of the substantive injustices of legal practice. While such criticisms of law do not predict a foreseeable end to the legal order they are sceptical of the ethical value of law and argue in favour of alternative forms of relation and of social regulation.

**law and continental philosophy.** In its contemporary usage within Anglo-American jurisprudence, continental philosophy refers most broadly to the non-analytic traditions of modern European thought. In this generic sense, \*continental philosophy refers initially to Hegelian, Marxian, and Husserlian theories of law and of meaning. In a more recent and particular sense it refers to theoretical and methodological positions associated with or developed from structural linguistics, literary theory, and psychoanalysis. The classic texts are read mainly through their contemporary expositors but the translation and use of continental thought bears an aura of radicalism. Continental philosophy has the connotation of a reaction against the dominant tradition and methodology of common law jurisprudence. Exponents of continental theory, who may generally be termed critical legal scholars, are critical of the \*positivism and \*empiricism of Anglo-American legal theory and specifically of the belief in the autonomy of law and the determinacy of legal rules. Drawing widely, and often rather loosely, upon a variety of different areas of continental thought, critical legal scholarship seeks to deconstruct the established tradition and legitimizing function of common-law jurisprudence and to elaborate in its place more democratic and ethically based theories of the plurality of laws and of the indeterminacy or socially constructed and contingent character of legal meanings.

The use of continental philosophy as a form or source of critique draws upon too wide a range of thinkers and disciplines for it to be possible to provide a synoptic account of such scholarship. It is possible, however, to point to certain common themes, which include a pronounced comparative dimension to legal study and a concern with the textual character of law and its cultural determinations, an interest which suggests a turn towards historicism. The more distinctive ethical and ontological themes of continental philosophy, the concerns with being and nothingness, identity and difference, similarity and otherness, find a translation and application in a variety of critical theories of legal textuality. While continental influence upon legal scholarship cannot be reduced to radical \*hermeneutics, it may not be inaccurate to point to a shared desire to provide political and ethical readings of the legal tradition and of its texts. In this sense the turn to continental philosophy has become synonymous with a pluralistic and interdisciplinary critique of the unity and insularity of the legal tradition. Drawing latterly upon disciplines or movements as distinct as \*phenomenology, \*feminism, psychoanalysis, literary criticism, and \*discourse theory, critical scholarship uses continental philosophy to attack the closure of law and to undermine the doctrinal belief in the law as a discrete system of rules.

**law and morals.** Legal philosophers have debated three views about the connection between legal and moral truth—between what the law is and what it should be.

One view—\*legal positivism—insists that legal reasoning is entirely factual: what the law is depends only upon what has been declared to be law by whichever officials the public treats as having that authority, or on similar historical facts, and on nothing else. On that view, though moral views that are popular within a community are very likely to influence the laws its legislators adopt, there is no necessary connection between law and moral truth, and abstract moral considerations play no role in deciding what the law is.

According to a second—apparently opposite—view, which is a version of so-called \*‘natural law’ theory, legal reasoning is identical with moral reasoning, so that, at least on fundamental matters, the only real law in force in any community is the moral law, and any laws a legislature might make contrary to that moral law are invalid. On that view, the alleged legal system of a tyranny like Nazi Germany is not law at all.

On the third view, legal reasoning interprets rather than simply describes or judges legal history: it aims to reformulate past legal decisions in the most coherent and morally attractive way consistent with the facts of legal history, that is, with the words past legislators used, the concrete orders past judges actually made, and the political and moral traditions of the community. Understood as interpretative in this sense, legal reasoning is not just historical investigation, nor abstract moral reasoning about what rules or principles would be appropriate to an ideally just world, but combines elements of both.

Neither of the first two positions fits the actual practice of lawyers and judges. Contrary to legal positivism, they often offer moral arguments to support their claims about what the law actually is when the law is controversial or unclear: when the question arises, for example, whether the right to ‘due process of law’ in the American Constitution includes the right to freedom of choice about abortion, or whether a particular string of past judicial decisions allowing people injured in accidents to recover damages for their pain and suffering does or does not ‘embody’ a more general principle allowing recovery for any kind of emotional damage. Lawyers and judges divide, in their opinions about such matters, in ways that plainly reflect their moral convictions. They all concede, however, contrary to the natural law theory I described, that there is often a gap between what the law is and what they believe it should be: even lawyers who believe that tax rates are unjustly high or low do not declare them invalid on that ground, and even lawyers who think that the laws of Nazi Germany were so unjust that they should

- D. Carlson et al. (eds.), *Deconstruction and the Possibility of Justice* (New York, 1992).

not have been enforced by Nazi judges hesitate to say that they were not law at all.

The third, interpretative, view of law fits the practices of lawyers, judges, and other legal officials naturally and convincingly, however. It explains why, in some cases, they recognize as law even what they believe to be unjust: no 'interpretation' of the tax code which substituted a different tax rate could count as a genuine interpretation of the text. It also explains why, in other kinds of cases, judges do treat moral considerations as relevant. In controversial cases, when a variety of different interpretations would each fit the abstract statutory language or the results of actual past decisions, judges must choose among them by deciding which interpretation—which understanding of the due process clause or of liability for emotional damages, for example—better reflects people's moral and political rights and obligations.

It may be objected that on the interpretative view law is inherently \*subjective: that there is no law except what the judge thinks it is. But that presupposes that the morality of rights and obligations is inherently subjective. If it is, then so is law, at least in controversial cases. But though many legal philosophers have endorsed the subjectivity of morals as a philosophical thesis, few actually respect it in practice, and arguments for it are implausible. R.D.

\*moral scepticism.

H. L. A. Hart, *The Concept of Law* (Oxford, 1961).

**laws, natural or scientific.** In normal discourse, the term 'law of nature' signifies some basic or fundamental principle of science, such as Newton's law of universal gravitation, or the second law of thermodynamics. Such truths as 'Water always boils at 100° C at standard pressure', or 'Air resistance is proportional to velocity' are normally considered to be too specific to qualify as laws of nature. Within the philosophy of science, however, all these generalizations are counted alike as laws of nature. This is because one of the central problems in the philosophy of science is to explain what distinguishes general truths of all these kinds from accidental patterns.

This problem arises as a corollary of David Hume's analysis of \*causality as \*constant conjunction. Philosophers prior to Hume assumed that causation involves some *power* by which causes produce their effects, some *cement*, so to speak, which binds cause and effect together. But Hume argued that there is no such cement. All we observe is first the occurrence of the cause, followed by the occurrence of the effect. There is nothing to bind them together, apart from the fact that they are constantly conjoined, in the sense that events like the causes are always, as it happens, followed by events like the effect.

But if causal laws involve nothing more than constant conjunction, an obvious problem arises. Suppose the following statement is true: 'Whenever I go to Paris, it rains'. Then my going to Paris is constantly conjoined with its

raining there. But we wouldn't on this account want to count this as a causal law. It doesn't rain *because* I go to Paris. It just so happens that my visits are invariably followed by rain. However, what then distinguishes real laws of nature from such accidentally true generalizations? For Hume tells us that there isn't anything more than constant conjunction involved in genuine laws either.

Note that genuine laws but not accidents support \*counterfactual conditionals. Compare 'If the water in that kettle had been at 100° C, it would have started boiling' (true) with 'If I had gone to Paris last week, it would have started raining' (false). Taken on its own, however, this contrast simply restates the problem. For however we understand counterfactual claims, we will still need some explanation of why laws but not accidents support them, if both are simply statements of constant conjunction.

There are two general lines of solution to the problem of distinguishing laws from accidents. The first remains faithful to the Humean view that law statements assert nothing more than constant conjunction, and then seeks to explain why some statements of constant conjunction—the laws—are more important than others—the accidents. The alternative, non-Humean strategy rejects the Humean presupposition that laws involve nothing more than constant conjunction, and instead postulates a relationship of 'necessitation' or \*nomic necessity which obtains between event-types which are related by law, but not between those which are only accidentally conjoined.

At first sight it might seem easy to develop the Humean strategy. Cannot we simply require that laws be truly *general*, and not restricted to such things as what happened to a particular person in a particular city at particular times? However, this does not get to the heart of the matter. For even if we formulate our example in general terms, not mentioning me or Paris, but specifying a certain *kind* of person and city, it may still be that the only instances of these kinds in the universe are still, by accident, constantly conjoined with rain. Conversely, there seem to be examples of laws which are restricted in space and time, such as Kepler's law that the planets move in ellipses, which is specific to our solar system.

A better suggestion is that accidents, unlike laws, are no good for predicting the future. This is not because accidental patterns cannot stretch into the future, but rather because, when they do, we cannot know that they are true. J. L. Mackie has argued that laws differ from accidents in that they are *inductively supported* by their instances, whereas accidents can only be known to be true after all their instances have been exhaustively checked.

However, even if Mackie's criterion is necessary for lawhood, it is not clear whether it is sufficient: couldn't some inductively anticipatable patterns still be accidents? Perhaps a better Humean solution is that proposed by F. P. Ramsey, and later revived by David Lewis: laws are those true generalizations that can be fitted into an ideal systematization of knowledge—or, as Ramsey put it, laws are a 'consequence of those propositions which we should take as axioms if we knew everything and organized it as

simply as possible in a deductive system'. Accidents are then those true generalizations which cannot be explained within such an ideal theory.

In recent years a number of philosophers have rejected the Humean tradition, arguing that no account, however sophisticated, which equates laws with constant conjunctions can do justice to the real content of laws. In the late 1970s D. M. Armstrong, Fred Dretske, and Michael Tooley independently developed the thesis that laws express a relationship of 'necessitation' between properties. This relationship holds between properties which are related by law, but not between those which are only accidentally conjoined. So laws involve something more than Humean regularity: necessitation implies constant conjunction, but not conversely. Defenders of this view do not wish to suggest that the relationship of necessitation can be known *a priori*; rather, which properties necessitate which others is an empirical matter to be settled by a posteriori investigation.

Critics of the non-Humean approach complain that merely postulating a relationship of necessitation leaves the philosophical issues unsolved. Hume himself rejected necessitation on the grounds that it is not observable. Contemporary critics do not object to unobservability *per se*, but they do object that the non-Humean view gives no real explanation of what necessitation adds to constant conjunction, and of exactly why this extra component should support counterfactual claims about what would happen if things were different.

Despite these objections, some version of the non-Humean approach to laws may prove necessary to deal with probabilistic laws, that is, laws which say that all *As* have a probability *p* of being *Bs*. The natural generalization of the Humean approach would take these laws to state, not that *A* is constantly conjoined with *B*, but rather that 100*p* per cent of *As* are conjoined with *Bs*. Humeans could then seek to explain why some such statements of proportionate conjunction are regarded seriously as laws, while others are merely accidents. The difficulty facing this Humean approach, however, is that the exact proportionate conjunction of 100*p* per cent of *As* with *Bs* is not even a necessary condition for the truth of the probabilistic law—for example, a unique type of coin may have a 0.5 probability of heads, and yet, by chance, come down heads six times in the only ten tosses that are ever made with it. For this reason, it is uncontroversial that probabilistic laws state something other than actual proportions. Non-Humeans conclude that they state quantitative relationships of necessitation—property *A* necessitates property *B* to degree *p*. Whether this is the only way to construe such laws, however, will remain an open question as long as the interpretation of *\*probability* is an area of active philosophical controversy. D.P.

**laws of thought.** Traditionally these are 'What is, is' (confusingly called the law of identity) and 'Nothing both is and is not' (the law of *\*non-contradiction*); and sometimes also the law of *\*excluded middle*. They are certainly not descriptive laws, telling how people think, but rather prescriptive, telling people how to think or, more precisely, to reason. (*\*Reasoning.*) So a better name is 'rules of logic'. There is no good reason to select these laws as special, although the first two of them are not often disputed. Even logicians with the meanest conception of the scope of deductive reasoning, such as the supporters of *\*Intuitionism*, need to add other laws to the first two (besides, non-deductive reasoning might have laws too). And even logicians with the most generous conception of that scope know that all three laws can be presented as 'theorems', derivable from some alternative basis. C.A.K.

I. M. Copi, *Introduction to Logic* (London, 1978), 306–8.

**learning.** The acquisition of a form of knowledge or ability through the use of experience. Not all modifications of behaviour as a result of experience involve learning, although behaviourist theories of learning tend to assume otherwise. It is far from clear that changes of behaviour brought about by conditioning should be thought of as involving learning; the same applies to the biological phenomenon of 'imprinting', whereby something that happens at a certain point of an animal's life determines a subsequent form of behaviour. For learning to take place experience has to be *used* in some way, so that what results is in a genuine sense knowledge or is dependent on knowledge. On the other hand, learning need not involve intellectual processes such as those involved in inference, although an inference may produce new knowledge and if it involves experience it may then be a process of learning. It is arguable that all learning itself presupposes knowledge in some way, and this raises problems for *\*genetic epistemology*. D.W.H.

D. W. Hamlyn, *Perception, Learning and the Self* (London, 1983).

**learning paradox.** Hegel held that whatever we learn is part of an infinite wealth of knowledge, thoughts, etc. contained in a completely indivisible ego. If we do not remember what is learned we do not possess it and yet it is none the less there within us. It is preserved in us in spite of the fact that it does not exist. This doctrine concerning learning might well be called a paradox.

Other candidates for paradox concerning learning might be found in Plato arising from arguments tending to show that certain things are unlearnable because they must be known before any process of learning could be undertaken. J.C.

**Lebenswelt:** see life and science.

**Le Dœuff, Michèle** (1948– ). French philosopher with a scholarly interest in the philosophy of Francis Bacon, and More's \*utopianism. She questions the boundaries of philosophy, while insisting upon philosophy's importance ('Ants and Women'). She is critical of professional philosophers' neglectful attitude to science, and argues that disputes within sciences are often epistemological (that is, properly philosophical). In *Hipparchia's Choice* she questions philosophy's pretensions to being a unique practice which achieves a pure clarity: philosophy is inevitably shaped by language, metaphor, and power relations. According to Le Dœuff feminists make a special contribution. Their critique of gender categories in philosophy, science, and the humanities is empirical, philosophical, political, and interdisciplinary. Feminists see clearly how discourses are elevated to the status of 'philosophical' by a process in which social power is involved. E.J.F.

\*feminism; Héloïse complex.

— *Hipparchia's Choice* (Oxford, 1991).

**Left, the.** Parties of egalitarian transformation, claiming to speak for the 'people', or the dispossessed and impoverished among them. The term supposedly derives from seating arrangements in the French revolutionary assemblies. But older connotations of left-sidedness, having to do with irregular, spontaneous, free-wheeling, suspicious, or dangerous (*gauche* or *sinister*) attitudes and behaviour, may also play a part. If the designation is attributable to right-minded and respectable people, it is presumably derogatory. But it may also have been willingly embraced as a sign of oppositionist commitments. M.WALZ.

\*equality; well-being.

Leszek Kolakowski and Stuart Hampshire (eds.), *The Socialist Idea* (New York, 1974).

**Left and Right Hegelians:** *see* Hegelianism.

**legal positivism**, intending to oppose \*natural law theory, denies any 'necessary connexion between law and morality'. Central theses among a loose cluster: (1) law is definable and explainable without evaluative predicates or presuppositions; (2) the law (e.g. of England now) is identifiable from exclusively factual sources (e.g. legislation, judicial precedents). Some versions deny that there is knowable moral truth. Most understand positive law as products of will, some as imperatives. J.M.F.

\*law, positive.

Gerald J. Postema, *Bentham and the Common Law Tradition* (Oxford, 1986).

**legal realism** maintains that positive law's normativity is reducible to social facts. American legal realists (e.g. Holmes, Llewellyn), influenced by \*pragmatism, suggested that law is not really rules as directives but official

(particularly judicial) behaviour which legal propositions predict. Scandinavian legal realists (e.g. Olivecrona, Ross), more anti-metaphysical and nearer Comte's \*positivism, typically hold that law's reality consists in experiences of being bound that are induced ('mystically' or 'psychologically') by legal directives. J.M.F.

\*law, positive.

Karl Olivecrona, *Law as Fact*, 2nd edn. (London, 1971).

**legitimacy.** Theories of legitimization attempt to offer reasons why a given state deserves the allegiance of its members. In a famous analysis, Max Weber identified three sources of legitimacy—traditions and customs, legal-rational procedures (e.g. voting), and individual charisma—some combination of which can be found in most political systems. Many philosophers have felt unhappy with this scheme, however, which leaves out substantive questions about the justice of the state and the protection it offers the individuals who belong to it. These theories have generally argued that a state's legitimacy depends upon its upholding certain human \*rights, a thesis that is often expressed in terms of its ability to meet the criteria one would expect to emerge from some form of social contract between autonomous agents. This position was classically expressed by Hobbes, Locke, and Rousseau, and in more recent times by Rawls, although with important differences. R.P.B.

D. Beetham, *The Legitimation of Power* (Basingstoke, 1991).

M. Weber, *Economy and Society*, ed. G. Roth and C. Wittich (Berkeley, Calif., 1978), pt. 1, ch. 3.

**Lehrer, Keith** (1936– ). Arizona-based philosopher, best known for work in epistemology and philosophy of mind. Lehrer has steadfastly defended 'coherence' theories of \*knowledge. The human mind, he argues, is essentially self-reflective: minds are 'metaminds'. Knowledge, justified belief, and freedom stem from the capacity to reflect on one's beliefs and desires and to evaluate these in the light of one's intellectual and practical values. A positive evaluation of a belief leads to its 'acceptance'; a positive evaluation of a desire to a preference for its satisfaction. When such evaluations are 'trustworthy' they yield, respectively, knowledge (providing the accepted belief is true) and freedom. In the social domain, one's positive evaluation of the beliefs and desires of others produces 'consensus'. J.HEIL

\*justification, epistemic.

K. Lehrer, *Metamind* (Oxford, 1990).

**Leibniz, Gottfried Wilhelm** (1646–1716), eminent rationalist philosopher who was born in Leipzig and died in Hanover. Leibniz was acquainted with all the major scientific developments of the second half of the seventeenth century. He made important contributions in geology, linguistics, historiography, mathematics, and physics, as well as philosophy. His professional training was in the law; he earned his living in the Court of Hanover by

combining the roles of councillor, diplomat, librarian, and historian. He did his philosophy (as well as his physics and mathematics) in his spare time. Although the vast bulk of Leibniz's writings remained unpublished at his death, and a considerable amount is still unpublished, his contributions in the law, mathematics, physics, and philosophy were known and appreciated by his educated European contemporaries in virtue of what he did publish and in virtue of his vast correspondence with intellectuals in a variety of fields. He was best known in his lifetime for his contributions to mathematics, especially to the development of the \*calculus. The debate concerning to whom priority of discovery should be assigned—Newton or Leibniz—captured the attention of their contemporaries. Current scholarly opinion seems to have reached the conclusion that each discovered the basic foundations of the calculus independently, that Newton's discovery preceded that of Leibniz's, but Leibniz's publication of the basic theory of the calculus preceded that of Newton.

Although Leibniz published only one book on philosophy in his lifetime—*The Theodicy* (1710)—he did publish considerable philosophical work in the leading learned European journals of the time; for example, 'Meditations on Knowledge, Truth, and Ideas' (1684), 'Brief Demonstration of a Notable Error of Descartes' (1686), 'Whether the Essence of Body Consists in Extension' (1691), 'New System of Nature' (1695), and 'On Nature Itself' (1698). He also wrote a book-length study of John Locke's \*empiricism, *New Essays on Human Understanding*, but decided not to publish it when he learned of Locke's death.

Leibniz's philosophical thinking underwent significant development; the mature metaphysics, presented in bare-bones form in the *Monadology* (1714), is strikingly different from his early work on the nature of bodies. None the less, certain themes persist—the requirement that the basic individuals of an acceptable \*ontology (the individual \*substances) satisfy the most rigorous standards of substantial unity, and the requirement that individual substances be endowed with causal powers and, hence, be centres of genuine activity. In the *Monadology* Leibniz presented the main outlines of his mature metaphysical system unaccompanied by much in the way of argumentation in favour of the conclusions therein presented. Consider, for example, the first two paragraphs of the *Monadology*:

1. The Monad, which we shall discuss here, is nothing but a simple substance that enters into composites—simple, i.e. without parts.

2. And there must be simple substances, since there are composites; for the composite is nothing more than a collection, or aggregate, of simples.

These are striking doctrines. If true, the consequence would seem to be that there are no spatially extended substances. But surely the argument of paragraph 2 is in need of considerable support. Perhaps the most complete formulation of the relevant doctrines, and Leibniz's reasons for accepting these doctrines, occurs in his

correspondence (1698–1706) with Burcher de Volder, a professor of philosophy at the University of Leiden. In this correspondence Leibniz formulated his basic ontological thesis in the following passage:

considering matters accurately, it must be said that there is nothing in things except simple substances, and, in them, nothing but perception and appetite. Moreover, matter and motion are not so much substances or things as they are the phenomena of percipient beings, the reality of which is located in the harmony of each percipient with itself (with respect to different times) and with other percipients.

In this passage Leibniz claimed that the basic individuals are immaterial entities lacking spatial parts whose properties are a function of their perceptions and appetites. In the correspondence with de Volder, as in the *Monadology*, Leibniz presented his major metaphysical theses concerning these simple immaterial substances. With respect to \*causality he held the following theses. God creates, conserves, and concurs in the actions of each created substance. Each state of a created monad is a causal consequence of its preceding state, except for its initial state at creation and any other states that result from miraculous divine intervention. While intrasubstantial causality is the rule among created substances, according to Leibniz, he denied the possibility of intersubstantial causal relations among created substances. In what he denied, he agreed with Malebranche, but in affirming spontaneity, i.e. that each individual substance is the cause of its own states, he separated himself from Malebranche's occasionalism. The doctrine of the spontaneity of substance ensured for Leibniz that created individual substances were centres of activity, a feature he took to be a necessary condition of genuine individuality.

Leibniz was sensitive to the idea that this scheme is at odds with common sense—that there appear to be material entities that are spatially extended, existing in space, causally interacting with each other and with us. More than some of his rationalist contemporaries, Leibniz took the claims of common-sense seriously. In the second sentence of the passage quoted above Leibniz outlined his way of 'saving the appearances' that are sufficiently well-founded to deserve saving. Two theses are at the heart of his effort: (1) the thesis that each created monad perceives every other monad with varying levels of distinctness; (2) the thesis that God so programmed the monads at creation that, although none causally interacts with any other, each has the perceptions we would expect it to have, were they to interact, and each has the perceptions we would expect it to have, were there extended material objects that are perceived. The first is the thesis of universal expression; the second, the thesis of the \*pre-established harmony. In the case of material objects, Leibniz formulated the rudiments of a version of phenomenalism, based on the pre-established harmony among the perceptions of the monads. In the case of apparent causal interactions among monads, Leibniz proposed an analysis according to which the underlying reality is an increase in

the clarity of the relevant perceptions of the apparent causal agent, accompanied by a corresponding decrease in the clarity of the relevant perceptions of the entity apparently acted upon.

Leibniz's mature metaphysics includes a threefold classification of entities that must be accorded some degree of reality: ideal entities, well-founded phenomena, and actual existents, i.e. monads with their perceptions and appetites. Material objects are examples of well-founded phenomena, according to Leibniz, while space and time are ideal entities. In the following passage from another letter to de Volder, Leibniz formulated the distinction between actual and ideal entities:

in actual entities there is nothing but discrete quantity, namely, the multitude of monads, i.e. simple substances . . . But continuous quantity is something ideal, which pertains to possibles, and to actuals, insofar as they are possible. Indeed, a continuum involves indeterminate parts, whereas, by contrast, there is nothing indefinite in actual entities, in which every division that can be made, is made. Actual things are composed in the manner that a number is composed of unities, ideal things are composed in the manner that a number is composed of fractions. The parts are actual in the real whole, but not in the ideal. By confusing ideal things with real substances when we seek actual parts in the order of possibles and indeterminate parts in the aggregate of actual things, we entangle ourselves in the labyrinth of the continuum and in inexplicable contradictions.

Leibniz's consideration of the labyrinth of the continuum was one source of his monadology. Ultimately, he reached the conclusion that whatever can be infinitely divided without reaching entities that can not be further divided is not a basic individual in an acceptable ontology. In part, Leibniz's reasoning here turns on his beliefs that divisible entities of the sort noted can not satisfy the standards for substantial unity required of basic individuals. The originality and complexity of Leibniz's reasoning concerning these topics is on display in his correspondence with de Volder, and in his correspondence with Arnauld. In the process of refining the metaphysical considerations that shaped the monadology, Leibniz formulated and defended the following doctrines: the \*identity of indiscernibles—the thesis that individual substances differ with respect to their intrinsic, non-relational properties; the theory of minute perceptions—that each created monad has some perceptions of which it lacks awareness; as well as the theses of universal expression, the pre-established harmony, and spontaneity, previously mentioned.

An important element in Leibniz's treatment of entities he regarded as ideal is his treatment of \*space and \*time, which is formulated in his correspondence with Samuel Clarke. Leibniz set out to explicate the notion of place and space in terms of the spatial relations among material objects, thereby avoiding commitment to space as an independent entity.

Another route to Leibniz's monadology may be traced beginning from some of his conclusions concerning certain of the well-founded phenomena, in particular, material objects. He argued that a correct application of Galileo's

discoveries concerning the acceleration of freely falling bodies to the phenomena of impact established that force is not to be identified with quantity of motion, i.e. mass times velocity, as Descartes had held, but is to be measured by mass times the velocity squared. From these physical results, Leibniz drew important metaphysical conclusions—that force, unlike quantity of motion, cannot be identified with some mode of extension and that, therefore, Descartes was mistaken in identifying matter with extension and its modifications. He concluded that each material substance must have an immaterial component, a substantial form, which accounts for its active force.

The labyrinth of the continuum, previously noted, is one of two labyrinths that, according to Leibniz, vex the human mind. The second concerns the possibility of free choice. The nub of this problem for Leibniz is to explain how things might have been otherwise than they are. Leibniz was committed to the concept-containment account of truth, i.e. that a proposition is true just in case the concept of its predicate is contained in the concept of its subject. But that seems to imply that all true propositions are conceptually true, and, hence, necessarily true, and that, therefore, things could not have been otherwise than they are. Leibniz denied that all conceptually true propositions are necessarily true, employing the doctrine of infinite analysis, affirming that in the case of contingent truths, the subject concept contains the predicate concept, but there is no finite analysis of the relevant concepts that establishes that fact. By contrast, Leibniz argued that in the case of necessary truths there is always a finite analysis of the relevant concepts that constitutes a proof of the proposition in question.

Leibniz made important contributions to philosophical theology. The *Theodicy* contains his solution to the problem of \*evil, i.e. to the question how the facts concerning evil in this world can be consistent with the conception of God as omnipotent, morally perfect, and creator—a conception to which Leibniz was committed. One basic element in his answer to this question is his thesis that this is the best possible world. In outline, Leibniz reached this conclusion in the following manner. He was totally committed to the \*principle of sufficient reason, i.e. the thesis that for every state of affairs that obtains there must be a sufficient reason why it obtains. Applied to God's choice of a possible world to create, the principle of sufficient reason implies that God must have a sufficient reason for creating just this world, according to Leibniz. But, given God's moral perfection, this reason must have to do with the value of the world selected. Hence, the world selected must be the best possible.

Leibniz also made what he took to be a significant contribution to the formulation of the \*ontological argument for the existence of God. He claimed that the ontological argument, as formulated by Descartes, for example, proved that a perfect being exists, with one crucial proviso, namely, the premiss that a perfect being is possible. Leibniz believed that none of his predecessors had shown this premiss to be true, and so he set out to do so. The basic

idea of his purported proofs is this. A perfect being is a being with every perfection. A perfection is a simple, positive property. Therefore, there can be no demonstration that there is a formal contradiction involved in supposing that one and the same entity has all the perfections. Since there can be no demonstration of a formal contradiction, it must be possible for one and the same being to have them all. Such a being would be a perfect being. Hence, a perfect being is possible.

Although Leibniz was not as taken with epistemological problems as Descartes or the British Empiricists, none the less he made significant contributions to the theory of knowledge. In his commentary on John Locke, the *New Essays on Human Understanding*, Leibniz argued forcefully for the thesis that the mind is furnished with innate ideas. Leibniz summarized his debate with Locke on this point as follows:

Our differences are on matters of some importance. It is a matter of knowing if the soul in itself is entirely empty like a writing tablet on which nothing has as yet been written (*tabula rasa*) . . . and if everything inscribed there comes solely from the senses and experience, or if the soul contains originally the sources of various concepts and doctrines that external objects merely reveal on occasion.

The claim that some concepts and doctrines are innate to the mind is important for Leibniz's metaphysics as well as his theory of knowledge, because he held that some of the central concepts of metaphysics, e.g. the concepts of self, substance, and causation, are innate.

Throughout his career, Leibniz developed various systems of formal logic, most based on the concept containment account of truth, previously mentioned. Some of those systems provide the elements of an approach to formal logic that is a genuine alternative to Aristotelian logic and contemporary quantification theory.

R.C.SLE.

The definitive edn. of Leibniz's work, still a long way from completion, will be G. W. Leibniz: *Sämtliche Schriften und Briefe* (Darmstadt, 1923–). Series 2 and 6 are, respectively, the philosophical correspondence and writings. Currently, the most useful edn. is G. W. Leibniz: *Die philosophischen Schriften*, ed. C. J. Gerhardt, 7 vols. (Berlin, 1875–90).

The best source of bibliographic information concerning Leibniz's work is Émile Ravier, *Bibliographie des Œuvres de Leibniz* (Paris, 1937), as supplemented by Paul Schrecker, 'Une bibliographie de Leibniz', *Revue philosophique de la France et de l'Étranger* (1938).

The best source of bibliographic information concerning the secondary literature on Leibniz's work is Kurt Muller and Albert Heinekamp (eds.), *Leibniz-Bibliographie: Die Literatur über Leibniz bis 1980* (Frankfurt am Main, 1984).

The most complete edn. of Leibniz's philosophical work in English is Leroy E. Loemker, *Gottfried Wilhelm Leibniz: Philosophical Papers and Letters* (Dordrecht, 1969). Also available are the *New Essays on Human Understanding*, tr. Peter Remnant and Jonathan Bennett (Cambridge, 1981), and the *Theodicy*, ed. Austin Farrer, tr. E. M. Huggard (New Haven, Conn., 1952). A useful selection with introduction and notes is *Leibniz: Philosophical Texts*, tr. and ed. R. Woolhouse and R. Francks (Oxford, 1998).

As a sample of the vast secondary literature on Leibniz, the following may be recommended: C. D. Broad, *Leibniz: An Introduction* (Cambridge, 1975); Benson Mates, *The Philosophy of Leibniz* (Oxford, 1986); Nicholas Rescher, *Leibniz: An Introduction to his Philosophy* (Totowa, NJ, 1979); Catherine Wilson, *Leibniz's Metaphysics* (Manchester, 1989); N. Jolley (ed.), *The Cambridge Companion to Leibniz* (Cambridge, 1994).

**Leibniz's law:** see identity of indiscernibles.

**lemma.** A lemma is a proposition put forward in the course of an \*argument, often accompanied by its own proof. It thus differs from a premiss in that it need not occur at the start of the argument. In discussions of knowledge, the 'No false lemmas' principle is sometimes mentioned: this is the principle that a belief will not count as knowledge if the chain of reasoning that leads to it contains a false lemma.

W. Hodges, *Logic*, sect. 11 (Harmondsworth, 1977).

**Lenin, Vladimir Ilyich Ulyanov** (1870–1924). Lenin was the leader of the Bolshevik faction in Russian politics and architect of the 1917 Revolution. Although thus not primarily interested in philosophy, his two major contributions in this field were of considerable influence.

The first of these, *Materialism and Empirio-Criticism* (1909) was an extended polemic against his fellow Bolshevik Bogdanov's espousal of Mach's view that the world consisted entirely of sensations. Lenin's account was largely a simplified version of the philosophy found in Engels's later writings. It consisted in a fairly crude materialism whose central themes were the two doctrines of the external reality of the world and the 'copy' theory of knowledge. Lenin was not so much interested here in the philosophical arguments as in maintaining his view that, under the circumstances, this was the only philosophy that would benefit the proletariat.

After the 1914 débâcle, however, Lenin took a much less instrumental view of philosophy. In order to reorientate his perspective in face of the catastrophe that had overtaken European socialism, Lenin spent an amazing amount of time studying Hegel in great detail. The contrast between \*materialism and \*idealism characteristic of his earlier work was now replaced by a contrast between dialectical and non-dialectical thinking. Lenin emphasized the influence of Hegel's *Logic* on Marx and even went so far as to claim that human consciousness not only reflected the objective world but created it. Although only published posthumously in 1929, the *Philosophical Notebooks* in which this study was recorded did much to renew interest in the Hegelian roots of Marxism.

**lesbian feminism.** Lesbian feminists are largely concerned with issues at the intersection of female identity and

sexual–affectional orientation. Issues which arise at this intersection are distinct from those that arise around sex–gender and sexual–affectional orientation in general. Most lesbian feminists hold that self-conscious lesbianism threatens dominant political and social systems in a way that other identities (e.g. as woman or as gay man) do not. The reasoning is this: Patriarchal systems are founded on valuing men above women. Both heterosexuality and male \*homosexuality preserves this valuing of men above women. Only lesbian \*feminism which explicitly values women and is largely unconcerned with men really challenges this valuing. For a woman to love another woman is thus a political and revolutionary act. Other philosophical issues associated with lesbian feminism include: whether lesbian identity is essential or socially constructed, whether there is a distinctly lesbian ethics, whether lesbian feminists should be separatists (withdraw as far as possible from patriarchal political and social systems). Adrienne Rich, *On Lies, Secrets and Silences* (New York, 1979).

**Leśniewski, Stanisław** (1886–1939). Polish logician. He reacted to the logical \*paradoxes by demanding extreme rigour in logic. For example, he maintained that a system of logic should involve no assumptions about the world, except what is involved in identifying a written formula. This led him to develop three unorthodox axiomatic systems of logic: protothetic, ontology, and mereology. Protothetic is a system of propositional logic based on the notion of equivalence, mereology axiomatizes the part–whole relation, and ontology involves a controversial attempt to interpret \*quantifiers without assuming that anything exists beyond written expressions. Leśniewski also proposed an unusually sophisticated theory of \*definitions. His influence has largely been indirect, through his students (notably Tarski, whose definition of truth owes much to him). This may change if his writings become available in English. W.A.H.

Peter M. Simons, 'Leśniewski's Logic and its Relation to Classical and Free Logics', in Georg Dorn and P. Weingartner (eds.), *Foundations of Logic and Linguistics: Problems and their Solutions* (New York, 1985).

**Lessing, Gotthold Ephraim** (1729–81). German philosopher and dramatist, who upheld the \*Enlightenment ideals of freedom and tolerance, but in aesthetics anticipated Romanticism. In *Laocoon: On the Limits of Painting and Poetry* (1766) he tried to distinguish the laws governing the literary and the pictorial arts, and opposed Winckelmann's classical aesthetics, in favour of expressive art free of formal constraints. In a series of papers, the *Hamburg Dramaturgy* (1767–9), he discussed the true nature of Aristotelian catharsis and the superiority of Shakespeare to French tragedy. His theological works, especially *The Education of the Human Race* (1780), attacked religious dogmatism in the name of true religion. 'What education is to the individual man, revelation is to the whole human race': an age in which men will fulfil their duty for its

own sake will follow the present age of pleasure and ambition. His avowal of Spinozism, just before his death, stimulated the revival of Spinoza, previously treated as a 'dead dog'.

A. Ugrinsky (ed.), *Lessing and the Enlightenment* (London, 1986).

**Leucippus** (5th century BC). The founder of \*atomism. Virtually nothing is known of his life, and his very existence was disputed in antiquity, but his role as the originator of atomism is firmly attested by Aristotle and Theophrastus, though the evidence does not allow any distinction between his doctrines and those of his more celebrated successor Democritus. He wrote a comprehensive account of the universe, the *Great World-System*. The single surviving quotation from his work (from a work entitled *On Mind*, which may have been a part of the *Great World-System*) asserts universal \*determinism: 'Nothing happens at random, but everything from a rational principle and of necessity.'

D. Furley, *The Greek Cosmologists* (Cambridge, 1987), ch. 9.

**Leviathan.** *LEVIATHAN or the Matter, Form, and Power of A COMMONWEALTH Ecclesiastical and Civil*, Hobbes's masterpiece on moral and political philosophy, was published in 1651 (Latin version 1668). The title comes from chapter 41 of the book of Job. The leviathan is a sea monster who 'is a king over all the children of pride' (verse 34). That Hobbes chose *Leviathan* as the title of his book shows that he regarded pride, in particular the view that the individual citizen knows enough to challenge the laws of the sovereign, as providing an explanation of why an artificial leviathan, the state, needs to have absolute power. The book is divided into four parts: the first provides an account of persons prior to the state; the second shows how the state must be constructed to serve its purpose, lasting peace; the third shows how this is compatible with Christian Scripture; and the fourth is an attack on Roman Catholicism. The importance of religion is shown by the fact that the third and fourth parts comprise half of the book. B.G.

**Levinas, Emmanuel** (1906–1995). French philosopher influenced by \*phenomenology and \*Jewish philosophy. Born in Lithuania, Levinas introduced phenomenology into France in the 1930s after studying with Husserl and Heidegger, thinkers to whom he owes a clear debt. His lectures (*Time and the Other* (1948)) introduced themes such as time, death, and relations with others which are expanded in his major work, *Totality and Infinity* (1961). His main concern is to delineate an ethical 'face-to-face' relation with the Other, which, while immediate and singular, is none the less transcendent. Seeking such a possibility takes him to the 'limits of phenomenology', and to criticize many previous philosophers for their preoccupations with ontology. In *Otherwise than Being* (1974) he seeks language forms which might circumvent such preoccupations, and enable an ethical exchange with the \*Other. Levinas also published religious Talmudic readings. A.C.A.

\*French philosophy, today.

Sean Hand (ed.), *The Levinas Reader* (Oxford, 1989).

**Lévi-Strauss, Claude** (1908–). Anthropologist and ethnographer; leading exponent of the method of \*structuralism as applied to myth, ritual, oral narrative, kinship systems, and modes of symbolic representation. His aim is not so much to interpret particular instances, but rather to reveal the underlying structure—the deep grammar of mythical thought—which unites the otherwise endless multiplicity of culture-specific meanings and forms. Thus an ancient Greek and a modern Amerindian or Eskimo myth may well turn out, despite all their surface differences, to derive from the same generative matrix of conflicts posed and resolved. For Lévi-Strauss, mythical thought is a kind of ‘bricolage’, a logic that makes do with all manner of found or improvised cultural material, but which cannot be regarded as in any sense more ‘primitive’ than our own. His work thus combines a rigorous formalism with an immense range of sources—drawing upon cultures past and present—and a style that on occasion seeks to orchestrate these themes in a quasi-Wagnerian polyphony of themes. c.n.

**Lévy-Bruhl, Lucien** (1857–1939). Largely remembered for his studies *Primitive Mentality* and *How Natives Think*. Lévy-Bruhl argued that the mentality of so-called primitive peoples was radically different from that of Western rationality. He characterized primitive experience as ‘mystical’ in the sense of being dominated by affectivity, whereas scientific experience is largely cognitive. Furthermore, the ‘pre-logical thought’ of primitive peoples is bound, not so much by the law of non-contradiction, as by participation, as when members of a totemic group understand themselves to be identical with their totem. However, in the *Notebooks* written during his last two years, Lévy-Bruhl conceded that the isolation of a general primitive mentality had misdirected him: mystical participation is more easily observable among primitive peoples, but is present in every mind. J. Cazeneuve, *Lucien Lévy-Bruhl* (New York, 1972).

**Lewis, Clarence Irving** (1883–1964). American philosopher whose early work focused on symbolic and modal logic and who then went on to work in epistemology, general value theory, social philosophy, and ethics. He argued that empirical knowledge depends upon both a sensuous or subjective \*‘given’ and an \*a priori set of principles and categories through which we interpret the given. According to his ‘conceptualistic pragmatism’, however, the a priori ‘has alternatives’; it is not a set of eternal or self-evident truths or necessary structures of the mind, but a set of conceptual schemes whose organization of our experience

is subject to modification on pragmatic grounds, subject to change, that is, when it does not conduce to the ‘long-run satisfaction’ of our human needs. K.H.

P. A. Schilpp, *The Philosophy of C. I. Lewis* (La Salle, Ill., 1966).

**Lewis, David K.** (1941–2001). One of the most important and influential figures in American philosophy in the late twentieth century. Lewis studied at Harvard with Quine, and spent four years at UCLA (in the company of Montague and Carnap) before moving to Princeton, where he taught for thirty years. He was also a regular visitor to Australia, where he found, and helped to shape, a lively philosophical scene. He contributed significantly to the philosophies of mind, language, and logic, but he is best known for his systematic metaphysical system dominated by two ideas. One is the thesis he calls ‘Humean supervenience’: the claim that the world entirely consists of local physical matters of fact, and all other facts supervene on these facts. (\*Supervenience.) This thesis is Humean in its denial of necessary connections between matters of fact. The other is his modal realism: other possible worlds and their inhabitants exist. (\*Possible worlds.) Lewis argues for his modal realism by appealing to its philosophical utility: real possible worlds are invoked to explain such diverse phenomena as causation, conditionals, the contents of propositional attitudes, and the nature of properties. As Lewis says, his modal realism has met with many ‘incredulous stares’ but few convincing counter-arguments. r.c.

\*modal realism.

**Lexicon, the Philosophical.** Originally compiled by Daniel Dennett and Joe Lambert, and later by Dennett alone, this collection of definitions converts proper names of (mostly twentieth-century) philosophers into common nouns, verbs, adverbs, and adjectives. Entry examples follow. *braithwaite*, n. The interval of time between two books. ‘His second book followed his first after a long braithwaite.’ *carnap*, n. A formally defined symbol, operator, special bit of notation. *grice*, n. Conceptual intricacy. ‘His examination of Hume is distinguished by erudition and grice.’ Hence, *griceful*, adj., and *griceless*, adj., ‘An obvious and griceless polemic.’ *hintikka*, n. A measure of belief, the smallest logically discernible difference between beliefs; ‘He argued with me all night, but did not alter my beliefs one hintikka.’ *quine*, v. To deny resolutely the existence or importance of something real or significant. ‘Some philosophers have quined classes, and some have even quined physical objects.’ Occasionally used intr., e.g., ‘You think I quine, sir. I assure you I do not!’ The eighth edition of the Lexicon is available from the American Philosophical Association. D.H.S.

**lex talionis.** The law of retaliation, according to which deserved \*punishment is neither more nor less than the harm done in a crime, and ideally mirrors the crime. It appears in the Code of Hammurabi (c.1700 BC) but is best

known in the biblical statement 'life for life, eye for eye, tooth for tooth . . . wound for wound . . .' (Exodus 21: 22–5). Commentators agree that the biblical *lex talionis* was introduced as a moral upper bound on permissible \*revenge, i.e. take in retaliation *no more than* an eye for an eye, etc.

*Lex talionis*, also referred to as *jus talionis* (the right of retaliation), e.g. by Kant, is most plausibly confined to crimes against the person. Yet even here adjustments must be made; thus, the Code of Hammurabi provided that the son who strikes his father is not to be struck in return; he is to lose his hand. As Blackstone pointed out in his *Commentaries on the Laws of England* (1765–70), 'there are very many crimes, that will in no shape admit of these penalties, without manifest absurdity and wickedness'.

Marvin Henberg, *Retribution: Evil for Evil in Ethics Law, and Literature* (Philadelphia, 1990).

**li** : see Confucianism.

**liar paradox.** Semantic paradox, known in antiquity, focus of much recent work. Jack says 'I am now speaking falsely', referring to the words he is then uttering. If Jack speaks truly when he says he is speaking falsely, he is speaking falsely. If he is speaking falsely when this is what he says is going on, he is speaking truly. So what he says is true if, and only if, it is false; which seems absurd. One response claims that Jack says nothing true and nothing false. But a variant makes trouble: Jill says 'I am now not speaking truly'. If Jill is not speaking truly when this is what she says she is up to, she is speaking truly. If she is speaking truly, then she must be doing what she says, that is, not speaking truly. So, it seems, what she says is true if, and only if, it is not true.

\*paradoxes.

Mark Sainsbury, *Paradoxes* (New York, 1988), ch. 5.

**liberalism.** One of the major political ideologies of the modern world, liberalism is distinguished by the importance it attaches to the civil and political \*rights of individuals. Liberals demand a substantial realm of personal \*freedom—including freedom of conscience, speech, association, occupation, and, more recently, sexuality—which the state should not intrude upon, except to protect others from harm. Major philosophical exponents of liberalism include Locke, Kant, Constant, Humboldt, J. S. Mill, Green, Hobhouse, and, in the post-war era, Berlin, Hart, Rawls, and Dworkin.

Liberalism first emerged as an important movement in Europe in the sixteenth century. Today, particularly after the decline of \*communism, it is the dominant ideology in many parts of the world. There are two familiar ways of explaining the rise of liberalism. On one view, liberalism grew out of the recognition that \*toleration was the only alternative to the Wars of Religion. After innumerable wars, both Protestants and Catholics accepted that the

state could not impose a common faith, and that the only stable basis for a political regime was to separate Church and State. Liberalism has simply extended this principle from the sphere of religion to other areas of social life where citizens have conflicting beliefs about the meaning of life. A liberal state does not seek to resolve these conflicts, but rather provides a 'neutral' framework within which citizens can pursue their diverse conceptions of the good life. Liberalism, on this view, is the only humane response to the inevitable pluralism and diversity of modern societies.

Liberalism's critics, however, argue that liberalism emerged as the ideological justification for the rise of \*capitalism, and that its image of the autonomous individual is simply a glorification of the pursuit of self-interest in the market. Liberalism replaced the web of mutual obligations which bound people together in ethnic, religious, or other communities with a society predicated on competition and atomistic \*individualism.

There is perhaps some truth in both of these explanations. Liberalism was historically associated with capitalism, although most liberals today accept that \*justice requires regulating the market to ensure equality of opportunity. Those who continue to defend free markets and absolute property rights, such as Hayek and Nozick, are now called classical liberals or \*libertarians, as opposed to welfare liberals or liberal egalitarians, such as Rawls and Dworkin. (In Europe, the term 'liberal' is more likely to refer to a defender of the free market; in North America, to a defender of the welfare state.)

A major challenge for liberal philosophers has been to explain why individual freedom should have priority over competing values such as community or \*perfectionism. Why should the state allow individuals to criticize and abandon the traditional customs of the community, or engage in degrading or worthless life styles?

It is often assumed that the defence of liberalism must ultimately rest on some form of \*subjectivism or \*scepticism about values. If people's values are merely subjective preferences, lacking any rational or objective basis, then there is no justification for the state to prefer some ways of life over others.

Few liberals have endorsed this subjectivist argument, although it is commonly attributed to them by critics. Subjectivism provides a weak defence of individual freedom. For one thing, it conflicts with the way most people understand the value of their own lives, since we typically assume that some ways of leading our lives are intrinsically better than others. Moreover, if subjectivism were true, it would leave liberal values equally without rational foundation. When liberals argue that a state which upholds individual rights and equality of opportunity is better than a totalitarian or caste society, they view this as a rationally defensible moral belief, not simply as their subjective preference. But if claims about rights and justice are rationally defensible, then so presumably are claims about the value of different conceptions of the good. As a result, most liberals have sought to defend freedom of choice without

denying that the worth of different conceptions of the good life can be rationally evaluated.

There are a variety of non-sceptical arguments for freedom of choice within the liberal tradition. \*Utilitarian and \*pragmatist liberals offer various reasons why state coercion and paternalism are counter-productive over the long-term. For example, they argue that truth emerges from free debate with falsehood, and that valuable ways of life emerge from initially unsuccessful experiments in living. Moreover, giving the state the power to decide which ways of life are valuable and which are not increases the potential for the abuse of state power, arbitrary discrimination, tyranny, and civil strife. The advocates of different ways of life will end up fighting over which conceptions of the good should be promoted by the state, and which should be discouraged. Given that the merits of different ways of life are controversial, liberalism's neutrality provides the only way for the proponents of conflicting ways of life to live together.

These considerations are not insignificant, but they provide only contingent and indirect support for freedom. They point to various undesirable social consequences that might accompany the restriction on individual liberty, but they do not yet provide any reason for thinking that individuals have an inherent *right* to a certain sphere of liberty, or that there is any intrinsic *injustice* in limiting people's freedom.

Many liberals have sought to find a more principled argument for individual freedom. Kantian liberals, for example, argue that the capacity for rational \*autonomy is the highest capacity humans possess, and so is worthy of inherent respect. To restrict someone's freedom of choice, on this Kantian view, is to treat them as less than a fully mature and responsible human being, and this is wrong regardless of the desirable or undesirable social consequences that might follow. To respect someone entails respecting her capacity to judge for herself which customs, practices and traditions are worth maintaining.

This Kantian view has been very influential in the liberal tradition. However, it rests on a controversial claim about the nature of moral value and moral respect. The Kantian view is disputed by many cultural and religious traditions that emphasize instead the value of piety, deference to authority, and respect for tradition. Indeed, many critics argue that using the state to promote the Kantian ideal of rational autonomy is as 'sectarian' as using the state to promote Protestantism, and as likely to lead to civil strife. Some groups, particularly conservative religious groups, will view the state promotion of Kantian autonomy as a direct attack on their own way of life.

Critics of the Kantian approach argue that liberals should therefore avoid appealing to the value of autonomy, and instead defend liberalism simply as the only viable basis for peaceful coexistence in culturally and religiously plural societies. These '*modus vivendi*' liberals argue that liberalism should be defended as guaranteeing tolerance between different ways of life, not as promoting the autonomy of individuals.

Kantian liberals respond, however, that without appealing to the value of individual autonomy, there is no reason why coexistence *between groups* should take the form of guaranteeing the rights of *individuals*. Why not just allow each group in society to organize itself as it sees fit, even if this involves restricting the rights of its individual members? Enforcing individual rights sometimes means interfering with, rather than tolerating, various group practices, and this can only be justified (or so Kantians claim) by invoking the value of individual autonomy.

This internecine disagreement between Kantian autonomy-based liberals and *modus vivendi*, tolerance-based liberals remains unresolved. (The two sides are also sometimes described as 'comprehensive' versus 'political' liberals, or as 'Enlightenment' versus 'Reformation' liberals.)

Even if one accepts the liberal commitment to individual freedom, there are questions about its social and cultural pre-conditions. The capacity to make choices in a rational and informed manner is not innate—it must be developed in the course of one's upbringing and education. Moreover, freedom of choice is only meaningful if individuals have an adequate range of options to choose from—that is, if diverse life-styles and customs exist in society. Some \*communitarian critics argue that liberalism has not attended to these wider social pre-conditions of \*liberty. Indeed, critics argue that the unfettered exercise of individual freedom of choice will undermine the forms of family and community life which help develop people's capacity for choice and provide people with meaningful options. On this view, liberalism is self-defeating—liberals privilege individual rights, even when this undermines the social conditions which make individual freedom valuable.

Liberals respond to this criticism by arguing that individual rights, far from dissolving valuable social groups and associations, provide the best protection for them. Those groups which are truly worthy of people's allegiance will survive through the free assent and voluntary participation of their members. Those groups which need state support to survive, because they cannot maintain or recruit members, are often not worthy of allegiance or support. The example of religious toleration suggests that there is some merit to this liberal response. Legal guarantees of individual freedom of conscience have provided ample protection for a wide range of religious groups, while preventing the dangers that often accompany state-sponsored religion. Whether this example can be generalized is open to debate.

A similar question has been raised about the long-term political stability of a liberal society. Non-liberal societies are typically held together by shared conceptions of the good, such as a common religion, or by common ethnicity. Members of these societies are willing to make sacrifices for each other because of their commonalities. But what holds a society together when its members come from different ethnic and racial backgrounds and do not share a common conception of the good life?

Some liberals suggest that the tie that binds the citizens of a liberal society is simply a shared commitment to

liberal principles of freedom and \*equality. It is debatable whether this is a 'thick' enough bond to keep a \*multicultural society together. After all, a liberal society makes many demands of its members: they must be willing to accept considerable sacrifices (e.g. military service), to take an interest in public affairs, and to exercise self-restraint in their personal actions and political demands. Liberals have tended to focus on the rights of \*citizenship, but a liberal society would stop functioning if its citizens did not also accept certain duties and exercise certain virtues. It seems likely that a sense of commonality is needed for individuals to accept these sorts of duties.

\*Conservative critics have argued that the stability of liberal societies is based on a pre-liberal sense of shared identity. Citizens of England, for example, do not see each other primarily as individual rights-holders, but as fellow members of the English \*nation, with a shared history and culture. This gives rise to a sense of solidarity which is prior to, and deeper than, a shared commitment to liberalism. It is this national solidarity which explains why the English work together, and make sacrifices for each other. Conservatives worry that this sense of being members of the same 'people' or culture or community is gradually being eroded by the individualism of liberal rights, which treats people in abstraction from their communal ties and responsibilities.

Interestingly, many nineteenth-century liberals, agreed that liberalism is viable only in countries with a sense of common nationhood, a new shared by some recent theorists of 'liberal nationalism'. Most post-war liberal theorists, however, have rejected the idea that liberalism should ally itself with nationalism, and have instead asserted that a common commitment to liberal principles is a sufficient basis for social unity even in multicultural countries. Habermas's idea of 'constitutional patriotism' is one example of this view, explicitly offered as an alternative to nationalist theories of social cohesion.

One difficulty with this view is that it provides no guidance on how the boundaries of distinct political communities should be drawn. Indeed, it provides no explanation for why there should be distinct political communities at all. Why shouldn't all societies that share liberal values merge into a single state, aiming ultimately to create a single world state? If we reject the nationalist belief that states have the right and responsibility to express particular national identities, languages, and cultures, why shouldn't liberals favour abolishing existing nation-states and replacing them with a thoroughgoing \*cosmopolitanism of open borders within a single global state?

Few liberal theorists are willing to take this step towards an unqualified liberal cosmopolitanism, and most believe that nation-states remain the only viable forum for the implementation of liberal-democratic values. Yet equally few liberals are willing to acknowledge that these liberal nation-states depend for their viability not only on adherence to liberal values, but also on the inculcation of deeper feelings of national identity.

Whether the cohesion of a liberal society depends on some prior sense of identity remains an important topic

for debate. Whatever the explanation, national liberal societies have in fact proven remarkably stable. Dire warnings about liberalism's inability to contain the centrifugal tendencies of individual freedom can be found in every generation for the last three centuries, yet it appears that liberal societies have managed to endure while various forms of monarchy, theocracy, authoritarianism, and communism have come and gone.

Despite these disagreements about its philosophical foundations and sociological feasibility, the basic language of liberalism—individual rights, liberty, equality of opportunity—has become the dominant language of public discourse in most modern democracies. w.k.

\*anti-communism; civil society; liberty and equality; utilitarianism; well-being.

**libertarianism.** The theory about freedom that despite what has happened in the past, and given the present state of affairs and ourselves just as they are, we can choose or decide differently than we do—act so as to make the future different. Libertarianism asserts the freedom of the \*will or \*origination, and is contrasted with \*determinism. Contemporary libertarians may cite quantum mechanics as evidence that determinism is false. Even if this is so, the random behaviour of atoms certainly does not by itself make for the freedom and moral responsibility asserted by libertarians. R.C.W.

\*freedom and determinism; determinism, scientific.

J. C. Eccles and K. R. Popper, *The Self and its Brain* (Berlin, 1977).

**libertarianism, left-** 'Left-libertarianism' is a new term for an old conception of \*justice, dating back to Grotius. It combines the \*libertarian assumption that each person possesses a natural right of self-ownership over his person with the \*egalitarian premiss that natural resources should be shared equally. Right-wing libertarians argue that the right of self-ownership entails the right to appropriate unequal parts of the external world, such as unequal amounts of land. According to left-libertarians, however, the world's natural resources were initially unowned, or belonged equally to all, and it is illegitimate for anyone to claim exclusive private ownership of these resources to the detriment of others. Such private appropriation is legitimate only if everyone can appropriate an equal amount, or if those who appropriate more are taxed to compensate those who are thereby excluded from what was once common property. Historic proponents of this view include Thomas Paine, Herbert Spencer, and Henry George. Recent exponents include Philippe Van Parijs and Hillel Steiner. w.k.

\*libertarianism, political.

P. Vallentyne and H. Steiner (eds.), *Left-Libertarianism and its Critics* (Basingstoke, 2000).

**libertarianism, political.** A theory grounded in the right of free choice. Libertarianism comes in at least two varieties, both with roots in the writings of John Locke. One variety starts from the stipulation of particular \*rights, often by direct intuition. The other grounds individual rights in causal assumptions about what leads to \*freedom and productivity. Some libertarians mix these elements, arguing from intuition but hedging their discussions with references to the effects of a system of rights. Two issues, one conceptual and one practical, drive much of the discussion of libertarianism. Conceptually, there is a conflict between individual interest and its collective provision—it is odd that libertarian rights may work against our interests. Practically, it seems virtually impossible that a state could arise and survive by strictly libertarian principles in a competitive world.

R. C. W.

\*libertarianism, left-.

Robert Nozick, *Anarchy, State, and Utopia* (New York, 1974).

**libertinism.** A sixteenth- and seventeenth-century, mainly French and Italian, current which rejected Christian revelation and set up reason and nature alone as the criteria of morality, law, and politics. The term *libertin* was first used by Calvin against religious dissenters who wanted freedom of conscience in matters of faith and morals. Libertinism was then applied more widely to the following positions: the rejection as invalid of theology and metaphysics anchored to 'divine' revelation (especially the immortality of the soul, punishments and rewards in the afterlife, teleology in nature, and a providential ordering of history); pluralism in matters of religion and ethics; a sceptical defence of doubt in philosophical and religious matters; assertion of the historical origin and consequent human fabrication of religions, creeds, and dogmas; \*atheism or at least \*deism; and Epicureanism. Major French figures include Pierre Charron, Montaigne, François de La Mothe le Vayer, and Pierre Gassendi. In Italy, libertine thinkers like Pietro Pomponazzi, Giulio Cesare Vanini, Bruno, and Campanella follow a naturalistic interpretation of Aristotelian psychology and physics. A popular image of the allegedly depraved libertine is preserved in the character of Don Juan—Don Giovanni: sexually promiscuous, atheist, mocker of human and divine law.

**liberty.** What is political liberty? In the ancient world, particularly among the Greeks, to be free was to be able to participate in the government of one's city. The laws were valid only if one had had the right to take part in making and unmaking them. To be free was not to be forced to

obey laws made by others *for* one but not *by* one. This kind of \*democracy entailed that government and laws could penetrate into every province of life. Man was not free, nor did he claim freedom, from such supervision. All democrats claimed was that every man was equally liable to criticism, investigation, and if need be arraignment before the laws, or other arrangements, in the establishing and maintaining of which all the citizens had the right to participate.

In the modern world, a new idea—most clearly formulated by Benjamin Constant—makes itself felt, namely that there is a province of life—private life—with which it is thought undesirable, save in exceptional circumstances, for public authority to interfere. The central question posed by the ancient world is 'Who shall govern me?' Some said a monarch, some said the best, or the richest, or the bravest, or the majority, or the law courts, or the unanimous vote of all. In the modern world, an equally important question is 'How much government should there be?' The ancient world assumed that life was one, and that laws and the government covered the whole of it—there was no reason to protect any corner of it from such supervision. In the modern world, whether historically because of struggles of the Churches against intervention by the secular State, or of the State against the Church, or as a result of the growth of private enterprise, industry, commerce, and its desire for protection against State interference, or for whatever reason, we proceed on the assumption that there is a frontier between public and private life; and that, however small the private sphere may be, within it I can do as I please—live as I like, believe what I want, say what I please—provided this does not interfere with the similar rights of others, or undermine the order which makes this kind of arrangement possible. This is the classical liberal view, in whole or part expressed in various declarations of the rights of man in America and France, and in the writings of men like Locke, Voltaire, Tom Paine, Constant, and John Stuart Mill. When we speak of civil liberties or civilized values, this is part of what is meant.

The assumption that men need protection against each other and against the government is something which has never been fully accepted in any part of the world, and what I have called the ancient Greek or classical point of view comes back in the form of arguments such as this: 'You say that an individual has the right to choose the kind of life he or she prefers. But does this apply to everyone? If the individual is ignorant, immature, uneducated, mentally crippled, denied adequate opportunities of health and development, he or she will not know how to choose. Such a person will never truly know what it is he or she really wants. If there are others who understand what human nature is and what it craves, and if they do for people, perhaps by some measure of control, what they would be doing for themselves if they were wiser, better informed, maturer, more developed, are they curtailing the freedom of these others? They are interfering with people as they are, but only in order to enable them to do what they would do if they knew enough, or were always

at their best, instead of yielding to irrational motives, or behaving childishly, or allowing the animal side of their nature the upper hand. Is this then interference at all? If parents or teachers compel unwilling children to go to school or to work hard, in the name of what those children must really want, even though they may not know it, since that is what all men and women as such must want because they are human, then are they curtailing the liberty of the children? Surely not. Teachers and parents are bringing out their submerged or real selves, and catering to their needs, as against the transient demands of the more superficial self which greater maturity will slough off like a skin.'

If you substitute for parents a church or a party or a state, you get a theory on which much modern authority is based. We are told that to obey these institutions is but to obey ourselves, and therefore no slavery, for these institutions embody ourselves at our best and wisest, and self-restraint is not restraint, self-control is not slavery.

The battle between these two views, in all kinds of versions, has been one of the cardinal political issues of modern times. One side says that to put the bottle beyond the dipsomaniac's reach is not to curtail his liberties; if he is prevented from drinking, even by force, he will be healthier and therefore better capable of playing his part as man and citizen, will be more himself, and therefore freer, than if he reaches the bottle and destroys his health and sanity. The fact that he does not know this is merely a symptom of his disease, or ignorance of his own true wishes. The other side denies not that anti-social behaviour must be restrained, or that there is a case for preventing men from harming themselves or from harming the welfare of their children or of others, but that such a restraint, though justified, is liberty. Liberty may have to be curtailed to make room for other good things, security or peace or health; or liberty today may have to be curtailed to make possible wider liberty tomorrow; but to curtail freedom is not to provide it, and compulsion, no matter how well justified, is compulsion and not liberty. Freedom, such people say, is only one value among many, and if it is an obstacle to the securing of other equally important ends, or interferes with other people's opportunities of reaching these ends, it must make way.

To this the other side replies that this presupposes a division of life into private and public—it assumes that men may wish in their private lives to do what others may not like, and therefore need protection from these others—but that this view of human nature rests on a fundamental mistake. The human being is one, and in the ideal society, when everyone's faculties are developed, nobody will ever want to do anything that others may resent or wish to stop. The proper purpose of reformers and revolutionaries is to knock down walls between men, bring everything into the open, make men and women live together without partitions, so that what one wants all want. The desire to be left alone, to be allowed to do what one wishes without needing to account for it to some tribunal—one's family, or one's employers, or one's party,

or one's government, or indeed the whole of one's society—this desire is a symptom of maladjustment. To ask for freedom from society is to ask for freedom from oneself. This must be cured by altering property relations as socialists desire to do, or by eliminating critical reason as some religious sects and, for that matter, communist and fascist regimes seek to do.

In one view—which might be called organic—all separateness is bad, and the notion of human rights which must not be trampled on is that of dams—walls demanded by human beings to separate them from one another, needed perhaps in a bad society, but with no place in a justly organized world in which all human streams flow into one undivided human river. On the second or liberal view, human rights, and the idea of a private sphere in which I am free from scrutiny, is indispensable to that minimum of independence which everyone needs if he is to develop, each on his own lines; for variety is of the essence of the human race, not a passing condition. Proponents of this view think that destruction of such rights in order to build one universal self-directing human society—of everyone marching towards the same rational ends—destroys that area for individual choice, however small, without which life does not seem worth living.

In a crude and, some have maintained, a distorted form, totalitarian and authoritarian regimes have stood for one of these views: while liberal democracies incline to the other. And, of course, varieties and combinations of these views, and compromises between them, are possible. They are the two cardinal ideas that have faced one another and dominated the world since, say, the Renaissance. I.B.

\*freedom through goodness and reason; political freedom.

**liberty and equality.** Some philosophers have argued that these two values are bound to conflict with one another. Given the differences in people's abilities, they say, there will be an inevitable tendency for some to be more successful than others. Inequalities can therefore be prevented only by the strict exercise of authority to limit the prosperity of the more successful. To this others have replied that all members of society need to share equally in the material wealth and political power which are the pre-conditions of effective freedom; liberty and equality are therefore not conflicting but complementary values. R.J.N.

\*liberty; equality; political freedom; well-being.

Richard Norman, *Free and Equal* (Oxford, 1987).

**Lichtenberg, Georg Christoph** (1742–99). German physicist whose fame rests, apart from an experiment in

electricity, on aphorisms. He was a man of the Enlightenment: 'All the mischief in the world may be put down to the general, indiscriminate veneration of old laws, old customs and old religion.' He straddles \*Kantianism and \*scepticism: 'If an angel were to tell us his philosophy, I think many of his statements might sound like " $2 \times 2 = 13$ ".' He doubted even Descartes's \**cogito*: 'It thinks, we really ought to say, just as we say, it thunders. To say *cogito* is too much, if we translate this as "I think" '; 'I and myself. I feel myself—these are two distinct things. Our false philosophy is incorporated in our whole language; we cannot reason without, so to speak, reasoning wrongly. We overlook the fact that speaking, no matter of what, is itself a philosophy.' Schopenhauer often quotes him, and Hegel, in his *Phenomenology of Spirit*, cites his satirical critique of Lavater's theory of physiognomy (*On Physiognomy* (1778)). What he said of others applies to himself: 'Earth has greater need of their kind than Heaven.' M.J.I.

**lie, noble:** see noble lie.

**Lieh Tzu.** Daoist philosopher (440?–360 bc?). The *Lieh Tzu* text (c. third century AD?) is polysemic in style: a collection of narratives having multiple application—cosmological, linguistic, personal, socio-political. Developing the philosophies of Lao Tzu and Chuang Tzu, it interprets the processes of life and death with a yin-yang cosmology. Investigation of the way (*tao*) is not a theoretical enterprise, but a psycho-physical discipline resulting in an embodied understanding of processes of transformation, and in an exceptional skill in negotiating our life activities.

S.C.

*The Book of Lieh-tzu: A Classic of Tao*, tr. A. C. Graham (New York, 1990).

**life.** This, the distinguishing feature of organisms, is best thought of as involving some kind of complex organization, giving an ability to use energy sources for self-maintenance and reproduction. Efforts to find some distinctive substance characterizing life have proven as futile as they have been heroic. The one thing which is clear is that any analysis of life must accept and appreciate that there will be many borderline instances, like viruses. Inconvenient as this may be for the lexicographer, this is precisely what \*evolution theory would lead us to expect. M.R.

\*vitalism.

**life, form of:** see form of life.

**life, the good.** Perhaps the most fundamental question in ethics is that posed by Socrates: How should one live? But this question covers not just the 'moral' aspects of our conduct, such as the observance of duties, or our contribution to the general welfare, but also those other more personal

and individual aspects of a life which may make it worthwhile, or give it meaning. Aristotle's theory of virtue aimed to lay down the ingredients of *eudaimonia* (or human fulfilment), and though this included many elements of what we would now call morality, it was also concerned with the good life for humans in the sense of a flourishing or successful life. Later \*Stoic and \*Christian systems of ethics continued this tradition, though often in a more 'inner-oriented' way: they gave particular prominence to what we might now call 'spiritual' practices, the cultivation of disciplines aimed at deepening our self-awareness, and enabling us to live harmonious and ordered lives.

Several modern philosophers have been interested in these more personal and individual aspects of what makes a life worthwhile, and have begun to reconsider notions that were prominent in the ethical writings of earlier ages—the importance of the character, self-reflection, the nature of the self, and the relationship between the intellect and the emotions. The stress on the 'interior' dimension connects up with the ancient theme of self-awareness as basic to the good life, as in the Delphic motto, 'Know thyself'; the 'descent into the inner self' was also a fundamental theme of St Augustine's famous ethical and religious work, the *Confessions*. More recently, psychoanalytic writers have underlined the importance of uncovering the hidden drives and projections that may distort our perceptions and choices, and this has influenced philosophical work on self-integration as fundamental to the good life. There are also important philosophical questions to be asked about the relationship between these broadly ethical concerns and other quite distinct ingredients of good human lives, such as creativity and artistic achievement, the pursuit of which may often appear to conflict with personal equilibrium or commitments to others. Finally, a good human life is often supposed to be one that has *meaning*; it may be asked whether this simply refers to the fact that a life contains various individually worthwhile ingredients, or whether it implies some overarching purpose or goal. **life, the meaning of.** 'What is the meaning of life?' is one of those Big Questions about Ultimate Things that recent philosophers have so often been accused of neglecting. It may invite the retort that the meaning of our lives is what we care to give them; we cannot expect meanings to be handed to us on a plate, and even if they were, what use would they be to us? God may have his purposes in creating me, but why should I adopt them? First I must be convinced that they are good purposes (we can ignore the effects of the threat of hell-fire on non-conformists), and if

they are, why should I not adopt them anyway, without bothering whether they are God's?

Another version of the question focuses not on our individual lives but on the whole scheme of things: what is the point of it all? An implication of this, in the spirit if not in the letter, seems to be that without some overall purpose in things all our own projects are somehow worthless or doomed to frustration. But why should that be so? Often the underlying thought seems to be that real values can only exist if they are permanent. But why should something in itself valueless acquire value by being permanent, or belonging to a set of things which is permanent? The value of my having just passed my exam and the disvalue of having painfully stubbed my toe are surely not affected if the sun will explode in eight billion years and I myself face annihilation somewhat sooner? Perhaps the thought is that our projects will fail unless ultimately 'God is on our side'. But our short-term projects often succeed. Sometimes events may later make us wish they had not done so, but this is relatively rare, and often success is definite and there are no hidden snags.

But now perhaps the question broadens into something else: what *are* the conditions for our lives to reach ultimate success? Many philosophers have held, with Sidgwick, that ultimately nothing can be of value but certain conscious states, for how could values exist without conscious beings to appreciate them? But recently this inference has been attacked. No doubt a lifeless desert would lack value (*pace* G. E. Moore, who thought that if it was beautiful it would not), but perhaps the value of at least many conscious states presupposes that their owners value other things; how, for instance, could one see any value in the state of mind consequent on fulfilling one's ambition to climb Everest if one saw no value in having climbed Everest (which is not itself a state of mind)? The question then becomes: how should we assess these further values? Can any rational grounds be given for pursuing some of them rather than others; or one life plan rather than another?

A further, and age-old, question which arises out of this concerns the value to us of things that happen after our \*deaths, so that we cannot know about them. 'Call no man happy until he is dead' said the Greek sage Solon; but how can he be happy then? Suppose someone dies after an apparently happy and successful life, but his achievements are then shown to be nugatory, for reasons he could not have anticipated, and his children all come to grief: would we still call him a happy man, who lived a happy life? If not, happiness cannot be a state of mind, and even if the meaning of life is to acquire happiness, it cannot be simply to acquire a state of mind.

**life, quality of:** *see* quality of life.

**life and death.** Biological life is best understood as a \*family resemblance concept, because there is no one property common to all and only animate things. To be alive is to have some of: an organic chemistry, a digestive and excretive system, a reproductive capacity, a genetic make-up. Being alive is a property distinct from being sentient, conscious, or intelligent. For example, grass is alive but lacks those three properties. If there is artificial intelligence, then some computer is intelligent but not alive. Death is at least the cessation of life, but it is philosophically controversial what death consists in. Biologically and medically, death is brain death, or brain-stem death.

Should we fear death? Parfit has suggested that it is not personal identity that should matter to us, and one's own death is not the destruction of a unique Cartesian self but the ending of a certain series of connected experiences and actions. Nagel has argued that there is a fundamental problem about *being someone*: the unique fact of someone's being oneself resists \*reductionism in psychological theories of personal identity. Should we fear death less if there is life after death? Bernard Williams argued that immortality is not desirable, because everlasting life would become tedious. Perhaps this is not right. Perhaps the afterlife would be infinitely interesting and fulfilling.

Immortality requires that the person who lives after death be numerically identical with the person who lives the earthly life. For example, any resurrected person has to be oneself rather than some being qualitatively similar but numerically distinct from oneself. Arguably, this requires that each of us is a soul that could remain unchanged by such profound physical and psychological changes. Arguably, Nagel's problem of being someone can be solved only if we are souls.

Why are the living the living? Why are the dead the dead? These are hard philosophical questions to answer once it is realized that *any* life has some duration ending in death. To be one of the living is to be living now, or to be actual. To be one of the dead is not to be actual but to have been actual. It is an unsolved philosophical problem what actuality is. We do not have an answer to 'Why is it now now?', which means, 'Why is this particular time the present?' S.P.

**life and science.** Science describes and explains the world in terms of causal regularities. Effects simply follow causes because that is the way the world is ordered, not because it is better that one thing happens rather than another. The theories of science are mathematically based abstractions, prescinding, as far as possible, from much that is important in the world as lived and experienced by human beings (the *Lebenswelt* of the phenomenologists). In the *Lebenswelt* descriptions and explanations are irreducibly normative, coloured by values, feelings, and emotions. To describe a person as temperate or handsome, or a landscape as beautiful, is to praise them, implying that they are better than if they had turned out some other way. Reconciling the value-free theories of science with what we say and think in the *Lebenswelt* has troubled philosophers since the time of Kant. The best hope seems to be to regard neither scientific nor everyday accounts as exhaustive of the whole of reality, but both as valid within their own spheres. A.O'H.

\*phenomenology; science, history of the philosophy of; science, problems of the philosophy of.

A. O'Hear, *The Element of Fire: Science, Art and the Human World* (London, 1988).

**life-world.** The universally structured realm of beliefs, assumptions, feelings, values, and cultural practices that constitute meaning in everyday life. In criticism of the classical theory of knowledge (Descartes to Kant), the concept of the life-world is first introduced as the insurmountable basis for scientific experience. Scientific theories are seen as 'idealized constructions' (Husserl), dependent on immediate sense-perception which itself, however, is part of the human everyday world that is taken for granted. Accordingly, the life-world as such is understood as the unproblematic and pre-scientific presupposition of any understanding and meaning, providing an implicit \*background of once explicitly held or intended and now 'sedimented' beliefs, assumptions, and practices. Whereas the life-world has first been conceptualized as the world of the subject (Husserl, Schütz), more recently its genuinely social character has been emphasized (Gadamer, Habermas). H.-H.K.

**light of nature.** In Cartesian philosophy, the faculty of the soul by which knowledge, especially a priori knowledge, is discerned. Descartes's 'principles of natural light' are put forward as fundamental metaphysical truths; for example; an (efficient) cause must contain as much reality as an effect; what can exist from its own power always exists; if I doubt, then I exist; deception is caused by some

defect; if something happens, it cannot then not have happened; nothing can cause nothing. If *p* is a principle of natural light, then *p* is self-evident, *p* is indubitable, and *p* is a necessary truth. According to Descartes, there is no faculty more authoritative than the light of nature which could be deployed to call its findings into question. s.p.

Anthony Kenny, *Descartes: A Study of his Philosophy* (New York, 1968).

**linguistic acts.** Things done with words, an account of which may cast light on human language and its use.

J. L. Austin believed that the study of \*language had been too much focused on words, and the study of action too much focused on 'ordinary physical actions'. His stated overall project in *How to Do Things with Words* was to characterize performatives—utterances on the occasion of which something is *done* rather than stated. He wanted to draw a line between performatives and another sort of utterance which he thought had received all the attention and at whose expense performatives had previously been ignored. (\*Constatives.) But Austin's attempt to draw the line undermined the assumption that there was a line to be drawn in the first place, and this made way for the idea that *all* utterances have a performative dimension. Thus Austin's work led to 'speech-act theory', a branch of language studies premissed originally in the thought that speech is a species of action.

In any use of language—any occasion of someone's speaking, that is—there are many things the speaker does—many linguistic acts she performs. (For example, an action might be someone's doing at least these four things: *uttering the words 'It's 10 o'clock'*, *saying what time it is*, *reminding Jane that it's time to go to the lecture*, *alarming Ted*.) Each linguistic act corresponds to a type of action; and a principled way of organizing linguistic acts provides a framework into which the particularities of occasions on which one or another is done can potentially be fitted so as to provide for illuminating accounts of speech-actions. The classification of linguistic acts which Austin got started may be thought of as a means of imposing system on to the actual data of linguistic communication.

Austin's own primary classification was into locutionary (which incorporates phonetic, phatic, and rhetoric), illocutionary, and perlocutionary. Each of these categories subsumes some range of acts; and an action of speaking is typically a speaker's performing some act within each range. Locutionary acts are of saying something; illocutionary acts are acts done in saying something; and perlocutionary acts are acts done by saying something. (In the example, *uttering the words . . .* is a phonetic act, *saying that . . .* a locutionary one, *reminding . . .* (arguably) an illocutionary one, and *alarming . . .* (arguably) a perlocutionary one ('arguably', because Austin in fact had difficulty in making the illocutionary–perlocutionary distinction clearly).

The idea that speaking a language is engaging in behaviour of a rule-governed kind was developed by John Searle

in *Speech Acts*. He attempted to account for a variety of phenomena in the setting of an institutional theory of communication, and to clarify particular speech-acts, e.g. referring (sometimes called a subsentential speech-act, because it is done using a word or two rather than a whole sentence) and promising.

Subsequent work in speech-act theory has been confined to the area that comes under Austin's illocutionary head, so that what is usually meant by 'a speech-act' is in the category that Austin called illocutionary. Speech-act theory may then be thought of as a branch of pragmatics. It can be divided into two types, depending on the attitude taken to that which determines a speech-action to be of the illocutionary act it is of. In the work of such linguists as John Ross and Jerrold Katz, illocutionary force is absorbed into a more or less formalized account of locution. In the work of Searle and others, illocutionary force is a function of unformalized circumstances. The latter kind of speech-act theory is more in keeping with its Austinian beginnings.

**linguistic philosophy.** Linguistic philosophy may be regarded either as a variant form, or as a competitor, of \*analytic philosophy. The latter arose from the early collaboration of Wittgenstein and Russell. Linguistic philosophy was more particularly Wittgenstein's creation, although it had some elements of affinity with the philosophical practice of G. E. Moore, and, in its later development at Oxford with Ryle and Austin, showed some dependence on the thought of their Oxford predecessors Cook Wilson and H. A. Prichard.

The central principle of linguistic philosophy is that the traditional problems of philosophy (or metaphysics) are not genuine problems at all but confusions generated by misunderstandings about language or by the misuse of it. The apparent problems cannot be solved; but they can be dissolved, confusion can be dispelled. A philosophical puzzle is created by an inclination to assert something absurdly at variance with common sense for what seem convincing reasons (that we have no knowledge of, or that there are, no material things, people other than ourselves, past events, laws of nature).

Moore's defence of \*common sense was direct and primitive. It rested on Thomas Reid's assumption that the beliefs of common sense 'are older and of more authority than the arguments of philosophy'. Holding out his hand, he said that he knew for certain that this was a hand and, since a hand is unquestionably a material thing, it followed that he knew for certain that there was at least one material thing. This was more a rhetorical device for showing that philosophers commonly do not mean what they say than a way of getting to grips with what it is that concerns them.

Wittgenstein's technique was much more elaborate. He himself compared it to psychotherapy, in which a kind

of intellectual neurosis is relieved by a long-drawn-out process of reminding the puzzled philosopher of the way in which the crucial terms in the expression of his puzzlement are ordinarily used. Wittgenstein's treatment resembled psychotherapy not only in its apparently interminable duration but also in its failure to bring about lasting cures. But some successes should be acknowledged. No one will ever now suppose that understanding is a matter of inward illumination. We tell whether someone has understood a lesson in long division or French pronunciation by his capacity to do some sums or make the correct sounds, and so does he, whatever flashes of inward illumination he may, or may not, have had.

Devotional commentators on Wittgenstein have argued that there are not two Wittgensteins, but one, developing a single line of thought. There are, indeed, common elements in the thinking of the earlier and the later Wittgenstein. Both are centrally concerned with language, both insist that philosophy is not only quite distinct from science, but that it is an activity rather than a theory of any kind whatever. But what was formerly seen as 'the logical clarification of thoughts', the revelation by analysis of the formal structure which is hidden by ordinary language, is explicitly rejected by the later Wittgenstein and replaced by an absolutely opposed conception of the matter.

\*Language, on this new view, has no logical essence. It is an accumulation of a great number of different \*'language-games', of which the reporting or description of facts is just one. Each of these has its own way of working and they are no more identical in essential form than ordinary games, being related to one another, as ordinary games are, only by 'family resemblance', an idea on which Wittgenstein laid much stress. Just as it is not the universal function of sentences to describe, so it is not the universal task of the words making up those sentences to name or refer to objects, concrete or abstract, or to ideas or images in the minds of their users. The meaning of a word or sentence lies in the rules for its actual use in real life, not philosophical reflection; these rules are best discerned in the activity of learning how to use the expressions involved; they are the result of decisions which can be altered; but these conventions must be public and shared, a \*private language is impossible. That last point is argued for with something very like a traditional philosophical argument, and has not been found universally convincing. In the same spirit, Wittgenstein argues that the elemental truths Moore thought he could prove in his blunt way are really background assumptions without whose acceptance nothing we could recognize as doubt or its settlement could take place.

It is impossible not to see Wittgenstein's loosely affirmed principle that 'inner processes stand in need of outward criteria', in which he claimed some kind of necessary connection between mental states and their behavioural manifestations, as lying behind the less cautious view of Ryle on the same topic. Ryle proposes something like a generally applicable pattern of analysis of categorical

statements about mental events and processes into collections of hypothetical statements about what those referred to would do if certain conditions were satisfied. Ryle held that the familiar dualist conception of \*mind and body as distinct worlds with proprietary kinds of event going on in them was a large-scale 'category mistake', in which the matters under discussion were treated as belonging to the wrong logical class, as happens more obviously in wondering what colour a number is or what is the weight of a shadow.

Ryle's preoccupation with thinking paralleled Wittgenstein's with meaning. To think what one is doing is not to carry out some sequence of bodily movements while consciously rehearsing some appropriate sequence of inner thoughts. It is to make the bodily movements in an intelligent way, reacting quickly and adequately to obstructions and difficulties.

The most exquisite of linguistic philosophers was J. L. Austin, who from 1945 until his death in 1960 exercised a powerful influence in Oxford, which rapidly faded away after that. Austin's acute sensitivity to nuances of meaning led him to stress that the language we actually use is the evolutionary by-product of its long and various application. Philosophers, he held, persistently over-simplify, running together words which, although similar, are by no means identical in meaning: 'look' with 'appear' and 'seem', 'inadvertently' with 'accidentally' and 'unintentionally'. Admiration for the refinement and, indeed, correctness of these distinctions is compatible with doubt about whether they cut any philosophical ice.

Large claims were made for his identification and naming of \*'performative' utterances, such as 'I promise to pay you back' and 'I name this ship *Gladys*', which rather constitute than describe the performance of promising or naming. His suggestion that 'I know that so-and-so' is also performative as a kind of guarantee of the speaker's claim did not survive inspection. Something of the flavour of this detection of performativeness is present in the account of truth given by Sir Peter Strawson, ironically enough in a powerful criticism of Austin's own attempt to attempt to rehabilitate the \*correspondence theory of truth. To say '*p* is true', Strawson held, is not to say something about '*p*', such as that it corresponds to the facts, but is at once to assert it and to confirm its assertion or suggestion by someone else. In his later work, from *Individuals* (1959), he moved on from linguistic philosophy to a sophisticated kind of Kantianism, reinforced by the analytic philosophy of the twentieth century, which aimed to set out the general presuppositions of the possibility of articulate discourse about our experience. In his earlier phase he had produced a powerful criticism of the account of reference embodied in Russell's theory of \*descriptions and he went on to point out the lavishly Procrustean distortions of the logical rules of ordinary, natural language made by modern, mathematically inspired formal logic. **linguistics, formal.** An empirical discipline which provides a mathematical framework for characterizing properties of possible human languages, with different branches characterizing phenomena at different though related levels in the speech chain from sound to meaning. Each branch of linguistics provides a theory that isolates a unit of linguistic significance, such as property of sound, form, or meaning, which it analyses and relates to notions analysed at the levels above and below. The minimal units of analysis are abstract notions used to segment the continuous sound signal of human speech into phonemes, then syllables, then words and morphemes, constituents and phrases, sentences and discourse structures. Corresponding to these levels we have the theories of phonetics, phonology, morphology, syntax, semantics, and discourse representation theory. The general theory of language comprising these subtheories will also contain a formal treatment of the learnability of languages. B. C. S.

M. Atkinson, D. Kilby, and I. Roca, *Foundations of General Linguistics*, 2nd edn. (London, 1988).

**linguistics, philosophical relevance of.** Linguistics bears on certain issues in \*epistemology and in \*philosophy of mind and, of course, is directly relevant to philosophy of language. For example, Chomsky has forcefully argued that the exigencies of language learning strongly favour \*rationalism over \*empiricism in the traditional debate on \*innate ideas. The facility with which children learn their native languages, despite the severely limited quantity and variety of data available to them, indicates that language acquisition is hardly a matter of stimulus generalization. Rather, Chomsky proposes, we possess a language faculty specially equipped for acquiring languages with just those features that distinguish natural human languages. Characterizing these features is the task of what he calls universal grammar. Also, he draws a distinction between competence and performance. Though applied to knowledge of language, it is relevant to philosophy of psychology in general, for it points to the distinction, crucial to \*cognitive science, between explaining abilities and explaining behaviour. Chomsky's account of knowledge of language suggests that Ryle's distinction between knowing-that and knowing-how is not exhaustive, and it provides an antidote to Wittgenstein's and Kripke's scepticism about \*rules and rule-following.

Underlying these issues is the question of how grammatical information is represented and utilized in language production and comprehension. The findings of psycholinguistics strongly support the claim that grammatical information is not an artefact of theory but is psychologically real. Although the categories and principles of modern linguistic theory generally do not correspond to those of school grammar, and are not otherwise

intuitively accessible to language-users, people's linguistic behaviour and grammatical judgements seem sensitive to such principles. Accordingly, it is plausible to suppose that knowledge of language is not conscious but tacit, and that this knowledge includes representations of sentential structure corresponding to the categories of linguistic theory (not that there is any consensus on the best such theory). Otherwise, there would seem to be no explanation for a multitude of linguistic regularities or for the robustness of people's linguistic intuitions.

Various branches of linguistic theory are relevant to the philosophy of language. Syntactic theory sheds light on such concepts as argument structure, binding, scope, and \*logical form. Also, because some semantic information is encoded structurally rather than lexically, the theory of meaning (\*semantics) in philosophy cannot ignore syntactic theory in linguistics. Linguistic semantics illuminates such concepts as \*ambiguity, \*vagueness, and \*synonymy, and offers a framework for explicating the distinction between \*analytic and synthetic statements. Linguistic \*pragmatics overlaps with the philosophical theory of \*speech acts, and, as Grice showed, the distinction between pragmatic and semantic questions has important consequences for a variety of philosophical issues.

From a linguistic standpoint, the logical form of a sentence is not the form of a logical formula used to represent the proposition expressed by the sentence, but a level of syntactic structure. It is often construed as the input to semantic interpretation, the stage of a grammar at which information about the semantic contents of lexical items is applied to yield, as a function of this level of syntactic structure, the semantic content of the entire sentence. Logical form helps explain scope relations among quantified noun phrases, connectives, and other operators, and binding and anaphoric relations between noun phrases and pronouns. Also, there is often reason to impute hidden variables to the logical forms of sentences containing expressions of certain sorts, such as relational terms like 'local' and 'alien', and temporal adverbs and connectives, like 'usually' and 'whenever'. These latter terms, as they occur in such sentences as 'Usually Abe drinks wine with dinner' and 'Whenever Bob is late for work, he skips breakfast', function as quantifiers, and, plausibly, these sentences contain event variables bound by those quantifiers.

Lexical semanticists distinguish polysemy from lexical ambiguity. The ambiguity of nouns such as 'club', 'joint', and 'trunk', each with several unrelated meanings, is a linguistic coincidence, evident from their translation into other languages. However, polysemous words, such as the verbs 'call', 'go', and 'play', have closely related meanings that need to be explained systematically. From a philosophical standpoint, the phenomenon of polysemy challenges the simplistic view that for a word to have several literal uses is just a matter of its having several senses. This is clear from the case of adjectival modification, as illustrated by the different relations between adjective and noun in 'fast runner', 'fast track', and 'fast race', or between the nouns in 'child abuse' and in 'drug abuse'. k.v.

**linguistic turn.** Collective designation for a range of otherwise quite disparate trends in twentieth-century thought. What they all have in common is an appeal to language, to \*discourse, or forms of linguistic representation as the furthest point that philosophy can reach in its quest for knowledge and truth. There are no 'facts' outside language, and no 'reality' other than that which presents itself under some linguistic description. Thus philosophers can only be deluded if they seek to render language more accurate or perspicuous by removing its various natural imperfections—ambiguity, metaphor, opaque reference, etc.—and achieving a crystalline transparency of logical form. Rather they should follow Wittgenstein's example and acknowledge the open multiplicity of \*'language-games' (or cultural \*'forms of life'), each with its own criteria for what counts as a valid or meaningful utterance. In short, the proper business of philosophy in this therapeutic mode is to cure language of its abstract cravings and (in the words of Stanley Cavell) to 'lead it back, via the community, home'.

The project thus described was pursued most zealously by J. L. Austin and the proponents of so-called 'ordinary language' philosophy. 'Our common stock of words', Austin wrote, 'embodies all the distinctions men have found worth drawing . . . in the lifetimes of many generations: these are surely likely to be more numerous, more sound, and more subtle . . . than any that you or I are likely to think up in our arm-chairs of an afternoon—the most favoured alternative method'. But the trouble with this approach, as many have felt, is its tendency to consecrate the nuances of received ('common-sense') wisdom while failing to address more substantive philosophical issues. Thus it can easily give rise to an outlook of *laissez-faire* relativism or an inert consensus based recommendation that philosophy should cease asking awkward questions and be content—in Wittgenstein's phrase—to 'leave everything as it is'. **literature and philosophy.** Some philosophical writing, though not very much, it has to be said, displays literary merit. Plato was a great writer and the British Empiricists

are admired for the vivacity of their prose. However, imaginative literature—poetry, drama, and the novel—has presented problems to philosophers. Plato's hostility to art in general is well known. For him, art was a rival in the pursuit of truth, and liable to corrupt. Plato's antagonism, though shared to an extent by Tolstoy, finds few modern supporters. But, as usual, Plato raises, albeit obliquely, profound questions about literature.

There are two major issues. Firstly, there is what is sometimes described as the problem of belief. If a work of literature asserts or assumes propositions which I know or believe to be false, what difference does that make? If I do not share Milton's metaphysics, am I debarred to that extent from an appreciation of *Paradise Lost*? If I do not share his beliefs, can I nevertheless empathize with the poet by 'suspending my disbelief' or 'making believe' that these beliefs are true? Certainly I can be moved by \*poetry or prose which proceeds on assumptions which I do not share. An atheist may find the poetry of George Herbert moving. Yet there are limits. I may bridle at the anti-Semitism in Pound's cantos. I do not suspend my disbelief in order to enter sympathetically into the world of a racist. And we certainly will resist literature which tries to suborn us. We cannot take seriously and may even resent fiction which, as we say, verges on propaganda. So although we can learn from literature we certainly do not commonly learn by absorbing maxims; it exemplifies and displays truths rather than argues for them. Indeed it is not part of a proper reaction to literature *qua* literature to assess the validity of the arguments it contains. Its 'truthfulness' is, *pari passu*, not a matter of the truth of the claims it makes. The famous generalizations about marriage and the family which begin *Pride and Prejudice* and *Anna Karenina* are not exceptionless; it would be easy to find counter-examples. The truth of literature is generally a matter of the convincingness of the characters it portrays. Seen in this context, Plato's reservations about the arts seem less strange. If we believe that philosophy can increase our knowledge by its criticism of superstition and speculation, then philosophy teaches in a way which literature does not.

What literature does do is to offer us imaginary scenes, concentrated and complex settings, in which imaginary beings act. It is sometimes described as inductive. From literature I may learn about individual human propensities and peculiarities. In order that it can do this in its own peculiar fashion, it is necessary that literature move and involve us, and this raises the second of the two problems to which I alluded at the beginning. Not only am I moved by Hamlet's conversation with the ghost of his father, even though I do not believe in ghosts, I can be deeply moved by the death of Anna Karenina, even though I know that she has no existence outside these pages. But how can I be moved by the fate of somebody who does not exist? Is it that she is 'really dead' but only in the 'possible world' of Tolstoy's novel? Am I being irrational? It cannot be that I am moved by the general truth that there are real women who escape from a boring life into an ultimately

unsatisfactory affair. I know there are such women but it is the fate of Anna which moves me and not theirs. \*Imagination is crucial here for I can be moved by what I can imagine and the fact that I can be so moved is an important factor in planning the course of my life. Literature, we could say, is important because it nurtures the imagination in ways which moral maxims or philosophical discourse cannot.

**Locke, John** (1632–1704). The foremost English philosopher of the early period of modern post-Cartesian philosophy was educated at Westminster School and Christ Church, Oxford. Besides studying, and then teaching, subjects such as logic, moral philosophy, rhetoric, and Greek, he had a deep and abiding interest in medicine. Through the Earl of Shaftesbury, he became involved in Protestant politics; this resulted in exile in Holland from 1683 to 1689, when, after the 'Glorious Revolution' which put William of Orange on the throne, he returned to England and a life of private study and public service.

He wrote widely—on various branches of philosophy, on education, economics, religion, and medicine. He is best known for his *Treatises of Government* (1690), *Letter Concerning Toleration* (1689), and his *Essay Concerning Human Understanding* (1690).

The *Treatises*, which contain Locke's political philosophy, were composed in the years of the Exclusion Crisis, during which Locke's patron, Shaftesbury, and others, sought to exclude James, then Duke of York, from the succession to the throne, and argued for government by consent and for the right to religious dissent.

The *First Treatise*, contains criticism of Robert Filmer's theory (*Patriarcha* (1680)) of absolute monarchy and the divine right of kings. Locke found this account of political \*authority, according to which God granted Adam absolute and total political authority, unworkable. It could not be used to justify any actual political authority; we cannot show of any particular ruler that he is one of Adam's heirs. In an alternative account the *Second Treatise* argues that though subjects do have a duty to God to obey their ruler, their ruler's power is not God given or absolute, and it goes along with duties to his subjects.

Locke's account begins with the idea of a \*state of nature, in which people live, free from external authority, in families and loose groups. In this state people have a duty to God not to 'harm another in his life . . . liberty, or . . . goods' (sect. 6), and so have a corresponding right to defend against such attack. But these rights and duties

may not actually be respected and obeyed; we may lack the power to defend our rights, or may go too far in our own defence. For such reasons people agree to 'enter into society to make . . . one body politic, under one supreme government' (sect. 89). Leaving the state of nature, they 'set up a judge . . . with authority to determine all . . . controversies and redress . . . injuries' (sect. 89). But this authority is not absolute; they are answerable to 'the will and determination of the majority' (sect. 96). Popular consent not only creates, but also produces, the continued existence of a Lockean political society.

A distinction between tacit and explicit \*consent provides Locke's answer to the objection that there is no historical evidence for his account of the creation of political authority, and that people are simply born into civil societies and come under their laws and authority without choice. By remaining in society, one gives one's tacit consent to it. Locke's suggestion that a person is always 'at liberty to . . . incorporate himself into any other community, or . . . to begin a new one' (sect. 121) is even less plausible now than then. But his account can be seen as a picturesque way of analysing the structure of legitimate political authority, and of revealing it to be essentially based on the consent of the governed. The notion of tacit consent is given further substance by Locke's allowing the possibility of legitimate resistance or \*revolution. 'The community perpetually retains a supreme power of saving themselves from . . . their legislators, whenever they shall be so foolish or so wicked, as to . . . carry on designs against the[ir] liberties and properties' (sect. 149).

Locke's *Letter Concerning Toleration*, written during exile in Holland, considers how far the state can legitimately concern itself with religious practices. Convinced that Christianity as such requires toleration, Locke is scathing about states which persecute religious dissidents 'with a pretence of care of the public weal', and of national churches which persecute their 'under pretence of religion' (17). He then argues further against religious intolerance by the state by differentiating 'the business of civil government from that of religion' (17). States are constituted 'only for the procuring, preserving, and advancing their [subjects] civil interests': 'life, liberty, health . . . money, land, houses' (17); so a ruler's duty is never 'to be extended to the salvation of souls' (18). This conclusion is based on three considerations. First, the 'civil magistrate' has no more duty than anyone else has to concern himself with 'the care of souls': God has given him no authority 'to compel any one to his religion' (18); nor have his subjects left it to him to 'prescribe . . . what faith or worship [they] shall embrace' (18). Second, the means used by a ruler cannot bring about convictions in his subjects' minds. Civil power consists in outward force and earthly penalties, and these are unable to bring about 'inward persuasion' (18): 'the understanding . . . cannot be compelled to the belief of any thing by outward force . . . [which has no] efficacy as to make men change the inward judgement that they have framed of things' (18). We cannot simply believe what we are told to believe. Thirdly, even if it were possible,

imposition of a religion by the state would in many cases not help to save souls. While there is, Locke believed, 'but one truth, one way to heaven', there nevertheless is a 'variety and contradiction of opinions in religion, wherein the princes of the world are . . . divided' (19); so state interference in religious matters would mean that 'men would owe their eternal happiness or misery to the places of their nativity' (19).

But though the state's sole concern is to protect the civil interests of its subjects, laws might still properly be enacted which have consequences for some sects or churches. Things prejudicial to the state and its members 'ought not to be permitted to the churches in their sacred rites' (37); nor are 'opinions contrary to human society, or to those moral rules which are necessary to the preservation of civil society' (45) to be tolerated. Equally, a church should not be tolerated by the state if membership involves allegiance to another earthly power. It is Roman Catholics whom Locke has in mind in this case, but they are not the only group to whom toleration is not to be extended: atheists are similarly untrustworthy. 'Those are not at all to be tolerated who deny the being of God. Promises, covenants, and oaths, which are the bonds of human society, can have no hold upon an atheist. The taking away of God . . . dissolves all' (47).

Locke resists the suggestion that toleration should be denied to certain dissenting, non-conformist sects, even though these had sometimes been 'nurseries of factions and seditious' (47). Their civil unruliness was not rooted in their very nature, he thought, but had developed precisely through lack of toleration. 'If men enter into seditious conspiracies, it is not religion inspires them to it . . . but their suffering and oppressions' (48–9).

Locke also concerned himself with interdenominational toleration. What he says turns on his account of the nature of a church as a society of people who have voluntarily come together 'in order to the public worshipping of God, in such manner as they judge acceptable to him, and effectual to the salvation of their souls' (20). Societies need rules and regulations, and in the case of a church the authority to make and apply them resides in members. Locke explicitly denied that a church requires 'a bishop, or presbyter with ruling authority derived from the very apostles' (20–1). Christ did not say that churches should have governments of these kinds; he promised to be present simply 'wheresoever two or three are gathered together in his name' (21).

In short, then, 'the care . . . of every man's soul . . . is to be left unto himself' (28). But Locke is not allowing that someone might enter into private and solitary communion with God: God should be publicly worshipped, and people should 'meet together . . . to own to the world that they worship God' (32). He is not allowing, either, that there are many, equally good ways to eternal happiness: there is 'one only narrow way which leads to heaven' (30). But it is not for the state or some national church to prescribe what it is. 'Those things . . . every man ought sincerely to inquire into himself' (29). Even though there is

only one narrow way to heaven I cannot be on it unless I am thoroughly persuaded in my own mind: 'I cannot be saved by a religion that I distrust, and by a worship that I abhor' (32).

Locke is best known for his *Essay Concerning Human Understanding*, which contains his theory of knowledge. Believing we have been put here by God with some expectation of an afterlife, Locke's aim is to discover what kind of things God has fitted us to know, and so how we should direct and use our intellect and understanding. His purpose is 'to enquire into the original, certainty, and extent of human knowledge' (II. i. 2).

He maintains from the outset that none of our ideas or knowledge (whether theoretical or ethical) is innate: the mind at birth is like 'white paper' (II. i. 2), and all our ideas are derived from experience. But such experience-based ideas are only 'the materials' of reason and knowledge (II. i. 2). Knowledge itself is *not* 'made out to us by our senses' (Draft A, 157). It is a product of reason working out the connections between those ideas. Locke's \*empiricism about ideas is combined with a \*rationalism about knowledge: without reason all we have is belief, not knowledge.

His claim that all our 'ideas, the materials of knowledge, come from experience is facilitated by a distinction between simple and complex ideas—the former being unanalysable and undefinable, the latter being mentally constructible out of simples. Complex ideas are of various sorts: substances (e.g. gold, lead, horses), which represent things in the material world; modes (e.g. triangle, gratitude), which are 'dependences on, or affections of substances' (II. xii. 4); and relations (e.g. parent, whiter). He defends his view that all our ideas derive from experience by consideration of such cases as 'space, time, and infinity, and some few others' (II. xii. 8) such as perception, solidity, memory, number, volition, pure substance in general, cause and effect, identity. Besides offering these as difficult test cases, Locke obviously finds them philosophically interesting too.

Locke's discussion of 'pure \*substance in general' (II. xxiii. 2) became notorious, and there are different accounts of what he means. Often he is taken to be rejecting the kind of view which was later held by Bertrand Russell, according to which a material thing is no more than 'a bundle of properties'. He is often, that is, supposed to hold that, in addition to properties, things have a 'substratum' which 'supports' their properties. According to another interpretation, Locke's 'substratum' should not be seen in the context of abstract logical questions about the difference between 'things' and 'properties'. It should be identified simply with matter as understood by the 'corpuscularians' of his century, who revived classical Greek atomism, or, more specifically, with particular arrangements of corpuscles of that matter, arrangements which Locke calls the real essences of material things.

His discussion of identity has been of lasting interest. There is, he points out, a relativity about identity. 'Is this what was here before?' It depends what kind of thing *this* is meant to be. If a mass of matter, it is the same if it consists

of the same particles; if a living body, this need not be so: 'a colt grown up to a horse . . . is all the while the same . . . though there may be a manifest change of the parts' (II. xxvii. 3). Identity consists here in matter's being continuously arranged in a similar way so that it 'partakes of the same life' (II. xxvii. 4). The point is important for his distinction, made in connection with \*personal identity, between the idea of 'man' and that of 'person'. A man's identity is basically no different from that of any other animal. But a person is not simply a living body. Identity here is that of 'a thinking intelligent being, that has reason, and reflection, and can consider itself as itself, the same thinking thing in different times and places' (II. xxvii. 9). Locke's description of a person as 'a thinking intelligent being' does not mean that the continuity of self-consciousness which constitutes personal identity is the continuity of some immaterial substance, which is self-conscious, for he is clearly unhappy with this view of Descartes's.

In fact the *Essay* contains a fair amount of criticism of Descartes: the identification of extension as the whole essence of material substance, and the claim that the mind is always thinking, are further things to which he objects. Nevertheless, it was that 'justly-admired gentleman' Descartes who rescued Locke from the obscurantism (as it seemed) of the then-prevailing Aristotelian scholasticism to which he had been exposed as a student (*Works*, iv. 48). From Descartes too Locke takes his central and hard-worked notion of an 'idea' ('whatsoever is the object of the understanding when a man thinks' (*Essay*, I. i. 8)) as an essentially mind-dependent thing, rather than a Platonic entity with a reality of its own quite independent of any relation it might have to our minds.

Locke refers to the 'vague and insignificant forms of speech' of the scholastics in his 'Epistle to the Reader'. They come in for criticism in book III, 'On Words', where he rejects the idea that classificatory words stand for 'real essences', understood, not as Locke prefers (as corpuscular constitutions), but as so-called substantial forms which, by being embodied in things, make them to be of one sort or another. Instead, he argues that classification is a matter of human interests and convenience, and that general words stand for 'nominal essences', abstract ideas which we ourselves construct. Generality and universality, he says, 'belong not to the real existence of things; but are the inventions and creatures of the understanding, made by it for its own use' (III. iii. 11).

In book IV, \*knowledge is defined as 'the perception of the connection and agreement, or disagreement . . . of any of our ideas' (IV. i. 2). Some propositions are true because the relevant ideas are connected and related in such a way as to make them true. Any number is even or odd by virtue of there being a connection between the idea of 'number' and those of 'evenness' and 'oddness'. It is by 'perceiving' these relations by the light of our reason that we come to have knowledge. Where either intellectual incapacity or lack of any actual connection, means we can perceive no connection, then, 'though we may fancy, guess, or believe, yet we always come short of knowledge' (IV. i. 2).

The definition of knowledge as the perception of connections *between ideas* is ill suited to a third degree of knowledge, our 'sensitive knowledge' of the existence of *things* 'without us' (iv. ii. 14) *which correspond to our ideas*. Moreover, though the certainty of sensitive knowledge is not so great as that of the other two degrees, it still, Locke says, deserves the name of knowledge; and he is dismissive of those who might be sceptical about the existence of an external world. Because of his talk of a correspondence between external things and our ideas, Locke has usually been taken to be a representational realist about perception; but in recent years, and despite his saying that the mind 'perceives nothing but its own ideas' (iv. iv. 3), some have interpreted him as a direct realist.

Locke's definition of knowledge seems perfect for our a priori knowledge in a subject such as geometry, which deals with modes such as 'triangle'. But what of our knowledge in the area of what was known as 'natural philosophy', for example, the knowledge that the substance gold is malleable and graphite not? This is surely based on observation and experience and not on intellectual perception of any connection between ideas. Locke recognizes such cases where, because there is 'a want of a discoverable connection between those ideas which we have . . . we are . . . left only to observation and experiment' (iv. iii. 28) and explicitly says that they do not constitute 'knowledge', but what he calls belief or opinion.

The contrast between knowledge proper and belief or opinion is inherited from the scholastics. But, unlike them, Locke does not think that 'opinion' or 'belief' about the properties and behaviour of substances in the material world is not worth having. He clearly supports the idea of a systematic observationally and experimentally based study of nature, a study of the kind being pursued by his colleague and friend, the chemist Robert Boyle, whom he refers to as one of the 'master builders' of the 'commonwealth of learning'.

The reason why 'natural philosophy is not capable of being made a science' (iv. xii. 10), i.e. into a systematic body of *knowledge* as Locke defines it, is that we do not know the real essences, the corpuscular constitutions, of the substances with which it is concerned. The fact that we can perceive no connection between being gold and being malleable does not mean that there is not one. The properties of gold depend on or result from its corpuscular constitution, and if we knew just how its corpuscles are structured and arranged, we would be able to see just why it has those properties. If, that is to say, our idea of gold were an idea of its real essence, we might see a connection between being gold and being malleable.

But this limitation on our knowledge is no cause for pessimistic concern. The 'belief' and 'opinion' we have about the properties of substances in the world are sufficient for daily practicalities. 'Men have reason to be well satisfied with what God hath thought fit for them, since he has given them . . . whatsoever is necessary for the conveniences of life' (i. i. 5).

Unlike 'natural philosophy', geometry is a science and

falls on this side of the horizon of our knowledge. This is because it deals not with substances (e.g. gold, lead) but with modes (e.g. the triangle), whose real essences we know. As with a substance such as gold, it is because a mode such as a triangle is what it is that it has the properties it has; but whereas in the first case we do not know the real essence, in the second, Locke says, we do. It is because it is a figure of three lines enclosing a space that a triangle's external angle equals its internal opposites; and because our idea of a triangle is an idea of that real essence we can see a connection between being a triangle and having angles like that.

Our knowledge is bounded by our ideas, and, in general, extends only so far as they are ideas of real essences. But geometrical figures are not the only things whose real essences we might know. The ideas of morality are modes too, and Locke thinks that, with proper application, a systematic science of ethics similar to that of geometry could be developed.

Yet though moral principles are neither innate nor easy to acquire by reason, no one need remain ignorant of his duties and obligations; for the Bible teaches us them too. This need not mean taking things on authority and abandoning all thought of moral knowledge. We can in hindsight find rationally justifying arguments for what the Bible first suggests. Nevertheless, some people, 'perplexed in the necessary affairs of life' (i. iii. 25) may have no time for this, and their morality must be a matter of 'faith' or 'belief'.

Locke's general conclusion concerning the extent of our knowledge is, then, that not only has God 'put within the reach of [our] discovery [beliefs sufficient for] the comfortable provision for [this] life' (i. i. 5), he has also put within our grasp knowledge of 'the way that leads to a better'. He has given us the means to acquire knowledge of 'whatsoever is necessary for . . . the information of virtue' (i. i. 5).

Many of the early reactions to the *Essay* were critical. Locke was sometimes supposed to be a sceptic; but though he does put limits on our ability to know and understand, he is hardly pessimistic about the human situation. He explicitly aimed to defeat the despairing idea 'that either there is no such thing as truth at all; or that mankind hath no sufficient means to attain a certain knowledge of it' (i. i. 2). Nevertheless, his polemic against innate ideas was taken to imply an impersonal deism, and his suggestion that matter might think (despite stressing that 'all the great ends of morality, and religion, are well enough secured, without philosophical proofs of the soul's immateriality' (iv. iii. 6)) was pointed to with horror. Berkeley, the first great British philosopher after Locke, reacted against what he saw as the sceptical and atheistical consequences of Locke's philosophy.

The framework of Locke's approach to the human mind influenced psychology and epistemology for a long time. David Hartley (1705–57), Joseph Priestley (1733–1804), Francis Hutcheson (1694–1747), James Mill (1733–1836), and Étienne Condillac (1715–80) all

approached this problem by analysing experience, after the manner of Locke, into elements and their combinations and associations.

Many of the ideas in the *Essay* (the stress on observation and the corpuscular theory of matter, the attack on the scholastics, the place of reason in religion) can be found in Locke's lesser contemporaries too. But he was a powerful and vigorous spokesman for them. Along with Isaac Newton, he became one of the figureheads of the Age of \*Enlightenment. Both then, and in our own time, he is valued for a judicious, sober reasonableness, and an individualistic insistence that opinions are to be weighed carefully on their merits by each of us, independently of what others, particularly those in majority or authority, say. 'Trial and examination must give [truth] price.' R.S.W.

**logic, higher-order:** see higher-order logic.

**logic, history of.** Aristotle was the first thinker to devise a logical system. He drew upon the emphasis on universal definition found in Socrates, the use of \**reductio ad absurdum* in Zeno of Elea, claims about propositional structure and \*negation in Parmenides and Plato, and the body of argumentative techniques found in legal reasoning and geometrical proof. Yet the theory presented in Aristotle's five treatises known as the *Organon*—the *Categories*, the *De interpretatione*, the *Prior Analytics*, the

*Posterior Analytics*, and the *De sophisticis elenchis*—goes far beyond any of these.

Aristotle holds that a proposition is a complex involving two terms, a \*subject and a predicate, each of which is represented grammatically with a noun. The logical \*form of a proposition is determined by its quantity (universal or particular) and by its quality (affirmative or negative). Aristotle investigates the relations between two propositions containing the same terms in his theories of opposition (\*square of opposition) and conversion. The former describes relations of \*contradictoriness and \*contrariety, the latter \*equipollences and \*entailments.

The analysis of logical form, opposition, and conversion are combined in syllogistic, Aristotle's greatest invention in logic. A \*syllogism consists of three propositions. The first two, the premisses, share exactly one term, and they logically entail the third proposition, the conclusion, which contains the two non-shared terms of the premisses. The term common to the two premisses may occur as subject in one and predicate in the other (called the 'first figure'), predicate in both ('second figure'), or subject in both ('third figure'). A given configuration of premisses and conclusions is called a 'mood'.

In the scholastic period, mnemonic names for the valid moods canvassed in the *Prior Analytics* were devised. Two first-figure valid moods were considered perfect and not in need of any further validation: \*Barbara (consisting entirely in universal affirmatives) and \*Celarent (consisting in a universal negative and a universal affirmative, concluding in a universal negative). For the validation of the rest, Aristotle used three techniques: reduction, where a given mood is transformed through conversions into Barbara or Celarent; *reductio ad absurdum*; and *ekthesis*, which proceeds by selection of an arbitrary individual. He regularly describes moods by using variables in place of terms. To reject a proposed inference he typically gives a list of terms that, when substituted as values of the term-variables, produce true premisses and false conclusion. This is similar to the modern technique of constructing 'counter-arguments' to establish invalidity.

Aristotle may also be credited with the formulation of several metalogical theses, most notably the law of \*non-contradiction, the principle of \*excluded middle, and the law of \*bivalence. These are important in his discussions of \*modal logic and tense logic. Aristotle referred to certain principles of propositional logic and to reasoning involving hypothetical propositions. He also created two non-formal logical theories: techniques and strategies for devising arguments (in the *Topics*), and a theory of fallacies (in the *De sophisticis elenchis*). Aristotle's pupils Eudemus and Theophrastus modified and developed Aristotelian logic in several ways.

The next major innovations in logic are due to the Megarian–Stoic School. They developed an alternative account of the syllogism, and, in the course of so doing, elaborated a full \*propositional logic which complements Aristotelian term logic. There are fragmentary records of debates over the \*truth-conditions for various

propositional connectives, which include accounts of \*material implication, \*strict implication, and relevant implication. The Megarians and the Stoics also investigated various logical \*antinomies, including the \*liar paradox. The leading logician of this school was Chrysippus, credited with over 100 works in logic.

There were few developments in logic in succeeding periods, other than a number of handbooks, summaries, translations, and commentaries, usually in a simplified and combined form. The more influential authors include Cicero, Porphyry, and Boethius in the later Roman Empire; the Byzantine scholiast Philoponus; and al-Fārābī, Avicenna, and Averroës in the Arab world.

The next major logician known to us is an innovator of the first rank: Peter Abelard, who worked in the early twelfth century. He composed an independent treatise on logic, the *Dialectica*, and wrote extensive commentaries. There are discussions of conversion, opposition, quantity, quality, tense logic, a reduction of *de dicto* to \**de re* modality, and much else. Abelard also clearly formulates several semantic principles, including the Tarski biconditional for the theory of truth, which he rejects. Perhaps most important, Abelard is responsible for the clear formulation of a pair of relevance criteria for logical consequences. (\*Relevance logic.) The failure of his criteria led later logicians to reject relevance implication and to endorse material implication.

Spurred by Abelard's teachings and problems he proposed, and by further translations, other logicians began to grasp the details of Aristotle's texts. The result, coming to fruition in the middle of the thirteenth century, was the first phase of \*supposition theory, an elaborate doctrine about the reference of terms in various propositional contexts. Its development is preserved in handbooks by Peter of Spain, Lambert of Auxerre, and William of Sherwood. The theory of \**obligationes*, a part of non-formal logic, was also invented at this time. Other topics, such as the relation between time and modality, the conventionality of semantics, and the theory of \*truth, were investigated.

The fourteenth century is the apex of medieval logical theory, containing an explosion of creative work. Supposition theory is developed extensively in its second phase by logicians such as William of Ockham, Jean Buridan, Gregory of Rimini, and Albert of Saxony. Buridan also elaborates a full theory of consequences, a cross between entailments and inference rules. From explicit semantic principles, Buridan constructs a detailed and extensive investigation of syllogistic, and offers completeness proofs. Nor is Buridan an isolated figure. Three new literary genres emerged: treatises on syncategoremata (logical particles), which attempted to codify their behaviour and the inferences they license; treatises on sentences, called 'sophisms', that are puzzling or challenging given background assumptions about logic and language; and treatises on insolubles, such as the liar paradox.

The creative energy that drove the logical inquiries of the fourteenth century was not sustained. By the middle of the fifteenth century little if any new work was being

done. There were instead many simplified handbooks and manuals of logic. The descendants of these textbooks came to be used in the universities, and the great innovations of medieval logicians were forgotten. Probably the best of these works is the \**Port Royal Logic*, by Antoine Arnauld and Pierre Nicole, which was published in 1662. When writers refer to 'traditional logic', they usually have this degenerate textbook tradition in mind. (\*Logic, traditional.)

Since the beginning of the modern era most of the contributions to logic have been made by mathematicians. Leibniz envisioned the development of a universal language to be specified with mathematical precision. The syntax of the words is to correspond to the metaphysical make-up of the designated entities. The goal, in effect, was to reduce scientific and philosophical speculation to computation. Although this grandiose project was not developed very far, and it did not enjoy much direct influence, the Universal Characteristic is a precursor to much of the subsequent work in mathematical logic.

In the early nineteenth century Bolzano developed a number of notions central to logic. Some of these, like analyticity and logical consequence, are seen to be relative to a collection of 'variable' concepts. For example, a proposition *C* is a consequence of a collection *P* of propositions relative to a group *G* of variable items, if every appropriate uniform substitution for the members of *G* that makes every member of *P* true also makes *C* true. This may be the first attempt to characterize consequence in non-modal terms, and it is the start of a long tradition of characterizing logical notions in semantic terms, using a distinction between logical and non-logical terminology.

Toward the end of the nineteenth century one can distinguish three overlapping traditions in the development of logic. One of them originates with Boole and includes, among others, Peirce, Jevons, Schröder, and Venn. This 'algebraic school' focused on the relationship between regularities in correct reasoning and operations like addition and multiplication. A primary aim was to develop calculi common to the reasoning in different areas, such as propositions, classes, and probabilities. The orientation is that of abstract algebra. One begins with one or more systems of related operations and articulates a common, abstract structure. A set of axioms is then formulated which is satisfied by each of the system. The system that Boole developed is quite similar to what is now called Boolean algebra. Other members of the school developed rudimentary \*quantifiers, which were sometimes taken to be extended, even infinitary, conjunctions and disjunctions.

The aim of the second tradition, the 'logician school', was to codify the underlying logic of all rational, scientific discourse into a single system. For them, logic is not the result of abstractions from the reasoning in particular disciplines and contexts. Rather, logic concerns the most general features of actual precise discourse, features independent of subject-matter.

The major logicians were Russell, the early Wittgenstein perhaps, and the greatest logician since Aristotle,

Gottlob Frege. In his *Begriffsschrift* (translated in van Heijenoort (ed.), *From Frege to Gödel*), Frege developed a rich formal language with full mathematical rigour. Despite the two-dimensional notation, it is easily recognized as a contemporary \*Higher-order logic. Quantifiers are understood as they are in current logic textbooks, not as extended conjunctions and disjunctions. Unlike the algebraists, Frege did not envision various domains of discourse, each of which can serve as an interpretation of the language. Rather, each (first-order) variable is to range over all objects whatsoever. Moreover, in contemporary terms, the systems of the logicians had no non-logical terminology.

Frege made brilliant use of his logical insights when developing his philosophical programmes concerning mathematics and language. He held that arithmetic and analysis are parts of logic (\*logicism; mathematics, history of the philosophy of), and made great strides in casting number theory within the system of the *Begriffsschrift*. To capture mathematical induction, minimal closures, and a host of other mathematical notions, he developed and exploited the \*ancestral relation, in purely logical terms.

Unfortunately, the system Frege eventually developed was shown to be inconsistent. It entails the existence of a concept  $R$  which holds of all and only those extensions that do not contain themselves. A contradiction, known as \*Russell's paradox, follows.

A major response was the multi-volume *Principia Mathematica*, by Russell and Whitehead, which attempts to recapture the logicist programme by developing an elaborate theory of \*types. (\*Higher-order logic.) Antinomies are avoided by enforcing a \*'vicious-circle principle' that no item may be defined by reference to a totality that contains the item to be defined. Despite its complexity, *Principia Mathematica* enjoyed a wide influence among logicians and philosophers. An elegant version of the theory, called simple type theory, was introduced by Ramsey. It violates the vicious-circle principle, but still avoids formal paradox.

The third tradition dates back to at least Euclid and, in this period, includes Dedekind, Peano, Hilbert, Pasch, Veblen, Huntington, Heyting, and Zermelo. The aim of this 'mathematical school' is the axiomatization of particular branches of mathematics, like geometry, arithmetic, analysis, and set theory. Zermelo, for example, produced an axiomatization of set theory in 1908, drawing on insights of Cantor and others. The theory now known as Zermelo–Fraenkel set theory is the result of some modifications and clarifications, due to Skolem, Fraenkel, and von Neumann, among others.

Unlike Euclid, some members of the mathematical school thought it important to include an explicit formulation of the rules of inference—the logic—in the axiomatic development. In some cases, such as Hilbert and his followers, this was part of a formalist philosophical agenda, sometimes called the Hilbert programme. (\*Formalism.) Others, like Heyting, produced axiomatic versions of the logic of \*intuitionism and intuitionistic

mathematics, in order to contrast and highlight their revisionist programmes (see Brouwer).

A variation on the mathematical theme took place in Poland under Łukasiewicz and others. Logic itself became the branch of mathematics to be brought within axiomatic methodology. Systems of propositional logic, modal logic, tense logic, Boolean algebra, and \*mereology were designed and analysed.

A crucial development occurred when attention was focused on the languages and the axiomatizations themselves as objects for direct mathematical study. Drawing on the advent of non-Euclidean geometry, mathematicians in this school considered alternative interpretations of their languages and, at the same time, began to consider metalogical questions about their systems, including issues of \*independence, \*consistency, \*categoricity, and \*completeness. Both the Polish school and those pursuing the Hilbert programme developed an extensive programme for such 'metamathematical' investigation. (\*Metalanguage; \*metalogic.) Eventually, notions about syntax and proof, such as consistency and derivability, were carefully distinguished from semantic, or model-theoretic counterparts, such as satisfiability and logical consequence.

This metamathematical perspective is foreign to the logicist school. For them, the relevant languages were already fully interpreted, and were not to be limited to any particular subject-matter. Because the languages are completely general, there is no interesting perspective 'outside' the system from which to study it. The orientation of the logicians has been called 'logic as language', and that of the mathematicians and algebraists 'logic as calculus'. Despite problems of communication, there was significant interaction between the schools. Contemporary logic is a blending of them.

In 1915 Löwenheim carefully delineated what would later be recognized as the first-order part of a logical system, and showed that if a first-order formula is satisfiable at all, then it is satisfiable in a countable (or finite) domain. He was firmly rooted in the algebraic school, using techniques developed there. Skolem went on to generalize that result in several ways, and to produce more enlightening proofs of them. The results are known as the Löwenheim–Skolem theorems. (\*Skolem's paradox.)

The intensive work on metamathematical problems culminated in the achievements of Kurt Gödel, a logician whose significance ranks with Aristotle and Frege. In his 1929 doctoral dissertation, Gödel showed that a given first-order sentence is deducible in common deductive systems for logic if and only if it is logically true in the sense that it is satisfied by all interpretations. This is known as Gödel's completeness theorem. A year later, he proved that for common axiomatizations of a sufficiently rich version of arithmetic, there is a sentence which is neither provable nor refutable therein. This is called Gödel's incompleteness theorem, or simply \*Gödel's theorem.

The techniques of Gödel's theorem appear to be general, applying to any reasonable axiomatization that

includes a sufficient amount of arithmetic. But what is 'reasonable'? Intuitively, an axiomatization should be effective: there should be an \*algorithm to determine whether a given string is a formula, an axiom, etc. But what is an 'algorithm'? Questions like this were part of the motivation for logicians to turn their attention to the notions of computability and effectiveness in the middle of the 1930s. There were a number of characterizations of computability, developed more or less independently, by logicians like Gödel (recursiveness), Post, Church (lambda-definability), Kleene, Turing (the \*Turing machine), and Markov (the Markov algorithm). Many of these were by-products of other research in mathematical logic. It was shown that all of the characterizations are coextensive, indicating that an important class had been identified. Today, it is widely held that an arithmetic function is computable if and only if it is recursive, Turing machine computable, etc. This is known as \*Church's thesis.

Later in the decade Gödel developed the notion of set theoretic constructibility, as part of his proof that the axiom of \*choice and Cantor's \*continuum hypothesis are consistent with Zermelo–Fraenkel set theory (formulated without the axiom of choice). In 1963 Paul Cohen showed that these statements are independent of Zermelo–Fraenkel set theory, introducing the powerful technique of forcing. (\*Independence.) There was (and is) a spirited inquiry among set theorists, logicians, and philosophers, including Gödel himself, into whether assertions like the continuum hypothesis have determinate truth-values. (\*Continuum problem; \*mathematics, problems of the philosophy of.)

Alfred Tarski, a pupil of Łukasiewicz, was one of the most creative and productive logicians of this, or any other, period. His influence spreads among a wide range of philosophical and mathematical schools and locations. Among philosophers, he is best known for his definitions of \*truth and logical consequence, which introduce the fruitful semantic notion of \*satisfaction. This, however, is but a small fraction of his work, which illuminates the methodology of deductive systems, and such central notions as completeness, decidability, consistency, satisfiability, and definability. His results are the foundation of several ongoing research programmes.

Alonzo Church was another major influence in both mathematical and philosophical logic. He and students such as Kleene and Henkin have developed a wide range of areas in philosophical and mathematical logic, including completeness, definability, computability, and a number of Fregean themes, such as second-order logic and sense and reference. Church's theorem is that the collection of first-order logical truths is not recursive. It follows from this and Church's thesis that there is no algorithm for determining whether a given first-order formula is a logical truth. Church was a founder of the Association for Symbolic Logic and long-time guiding editor of the *Journal of Symbolic Logic*, which began publication in 1936. Volumes 1 and 3 contain an extensive bibliography of work in symbolic logic since antiquity.

The development of logic in the first few decades of this century is one of the most remarkable events in intellectual history, bringing together many brilliant minds working on closely related concepts.

Mathematical logic has come to be a central tool of contemporary analytic philosophy, forming the backbone of the work of major figures like Quine, Kripke, Davidson, and Dummett. Since about the 1950s special topics of interest to contemporary philosophers, such as modal logic, tense logic, \*many-valued logic (used in the study of \*vagueness), \*deontic logic, relevance logic, and nonstandard logic, have been vigorously studied. The field still attracts talented mathematicians and philosophers, and there is no sign of abatement. P.K.

**logic, informal.** Informal logic examines the nature and function of arguments in natural language, stressing the craft rather than the formal theory of reasoning. It supplements the account of simple and compound statements offered by \*formal logic and, reflecting the character of arguments in natural language, widens the scope to include inductive as well as deductive patterns of inference.

Informal logic's own account of arguments begins with assertions—the premisses and conclusions—whose rich meaning in natural language is largely ignored by formal logic. Assertions have meaning as statements as well as actions and often reveal something about the person who makes them. Not least, they are the main ingredient in patterns of inference. Apart from the crucial action of claiming statements to be true, the assertions found in an argument may play other performative roles, such as warranting a statement's truth (on one's own authority or that of another), conceding its truth, contesting it, or—instead of asserting it at all—assuming the statement as a hypothesis. Assertions also have an epistemic dimension. It is a convention of natural language (though hardly a universal truth) that speakers believe what they assert. Appraising the full meaning of a premiss or conclusion therefore involves gauging whether the statement was asserted merely as a belief or, in addition, as an objective fact or even as an item of knowledge. Finally, assertions have an emotive side. Few arguments of natural language are utterly impersonal. Attitudes and feelings seep from the language of argument and can easily influence what direction a sequence of reasoning may take. Because

informal logic sees assertions and arguments as woven into the fabric of discourse, the threads it traces are extremely varied: embedded but possibly incomplete patterns of deductive and non-deductive inference, hidden assumptions, conversational implications, vagueness, rhetorical techniques of persuasion, and, of course, fallacies. Such topics, though important for understanding arguments in natural language, lead it far from the concerns of formal logic. That informal logic lacks the precision and elegance of a formal theory is hardly surprising, therefore, but it probably comes as close as any enterprise ever will to being a science of argumentation. **logic, intuitionist:** see intuitionist logic.

**logic, many-valued:** see many-valued logic.

**logic, modal:** see modal logic.

**logic, modern.** Logic, whether modern or traditional, is about sound reasoning and the rules which govern it. In the mid-nineteenth century (say from 1847, the date of Boole's book *The Mathematical Analysis of Logic*), logic began to be developed as a rigorous mathematical system. Its development was soon speeded along by controversies about the foundations of mathematics. The resulting discoveries are now used constantly by mathematicians, philosophers, linguists, computer scientists, electronic engineers, and less regularly by many others (for example, music composers and psychologists). Gödel's incompleteness theorem of 1931 was a high point not only for logic but also for twentieth-century culture. Gödel's argument showed that there are absolute limits to what we can achieve by reasoning within a formal system; but it also showed how powerful mechanical calculation can be, and so it led almost directly to the invention of digital computers.

Many arguments are valid because of their *form*; any other argument of the same form would be valid too. For example:

Fifty-pence pieces are large seven-sided coins.  
 This machine won't take large coins.  
 Therefore this machine won't take fifty-pence pieces.  
 An auk is a short-necked diving bird.  
 What Smith saw was not a short-necked bird.  
 Therefore what Smith saw was not an auk.

Both of these arguments can be paraphrased into the form:

- (1) Every X is a Y and a Z.  
 No Y is a W.  
 Therefore no X is a W.

(Thus for the first, X = fifty-pence piece, Y = large coin, Z = seven-sided object, W = thing that this machine will take.) This form (1) is an *argument schema*; it has schematic letters in it, and it becomes an argument when we translate the letters into phrases. Moreover, every argument got from the schema in this way is valid: the conclusion (after 'Therefore') does follow from the premisses (the sentences before 'Therefore'). So we call (1) a *valid argument schema*.

Likewise some statements are true purely by virtue of their form and hence are *logically valid*. We can write down a statement schema to show the form, for example:

If *p* and *q* then *p*.

Here the schematic letters *p*, *q* have to be translated into clauses; but whatever clauses we use, the resulting sentence must be true. Such a schema is logically valid; we can regard it as a valid argument schema with no premisses.

What does it mean to say that a particular argument, expressed in English, has a particular argument schema as its form? Unfortunately this question has no exact answer. As we saw in the examples above, the words in an argument can be rearranged or paraphrased to bring out the form. Words can be replaced by synonyms too; an argument doesn't become invalid because it says 'gramophone' at one point and 'record-player' at another. For the last 100 years or more, it has been usual to split logic into an exact part which deals with precisely defined argument schemas, and a looser part which has to do with translating arguments into their logical \*form.

This looser part has been very influential in philosophy. One doctrine—we may call it the *logical form doctrine*—states that every proposition or sentence has a logical form, and the logical forms of arguments consist of the logical forms of the sentences occurring in them. In the early years of the century Russell and Wittgenstein put forward this doctrine in a way which led to the programme of \*analytic philosophy: analysing a proposition was regarded as uncovering its logical form. Chomsky has argued that each sentence of a natural language has a structure which can be analysed at several levels, and one of these levels is called *LF* for logical form—roughly speaking, this level carries the meaning of the sentence. However, Chomsky's reasons for this linguistic analysis have nothing to do with the forms of valid arguments, though his analysis does use devices from logic, such as quantifiers and variables. One can hope for a general linguistic theory which gives each natural-language sentence a logical form that explains its meaning and also satisfies the logical form doctrine; logicians such as Montague and his student Kamp have made important suggestions in this direction, but the goal is still a long way off.

Let us turn to the more exact part of logic. Experience shows that in valid argument schemas we constantly meet words such as 'and', 'or', 'if'; moreover, the sentences can be paraphrased so that these words are used to connect clauses, not single words. For example, the sentence

Fifty-pence pieces are large seven-sided coins can be paraphrased as

Fifty-pence pieces are large coins AND fifty-pence pieces are seven-sided.

We can introduce symbols to replace these words, for example  $\wedge$  for 'and',  $\vee$  for 'or',  $\neg$  for 'it is not true that ...' and  $\rightarrow$  for 'if ... then'. Unlike the schematic letters, these new symbols have a fixed meaning and they can be translated into English. They are known as \*logical constants.

Round about 1880 Frege and Peirce independently suggested another kind of expression for use in argument schemas. We write

$$\forall x \dots x \dots$$

to mean that ' $\dots x \dots$ ' is true however  $x$  is interpreted. The expression  $\forall x$  can be read as 'For all  $x$ '. For example, the sentence

Fifty-pence pieces are large seven-sided coins can be rewritten as

$$\forall x (\text{if } x \text{ is a fifty-pence piece then } x \text{ is a large seven-sided coin}),$$

or, using the logical constants,

$$(2) \forall x (x \text{ is a fifty-pence piece} \rightarrow (x \text{ is a large coin} \wedge x \text{ is seven-sided})).$$

This last sentence says that whatever thing we consider (as an interpretation for  $x$ ), if it's a fifty-pence piece then it's a large coin and it's seven-sided. The symbol  $x$  is not a schematic letter in (2), because the expression  $\forall x$  becomes nonsense if we give  $x$  an interpretation. Instead it is a new kind of symbol which we call a *bound variable*. The expression  $\forall x$  has a twin,  $\exists x$ , which is read as 'For some  $x$ '. These two expressions are the main examples of logical \*quantifiers.

Quantifiers are somewhere between logical constants and schematic letters. Like logical constants, they do have a fixed meaning. But this meaning needs to be filled out by the context, because we need to know what range of interpretations of the bound variable is allowed. This range is called the *domain of quantification*. (Frege assumed that the domain of quantification is always the class of all objects. But in practice when we say 'everybody' we usually mean everybody in the room, or all adults of sound mind, or some other restricted class of people.)

With the help of the symbols described above, we can translate English sentences into a \*formal language. For example we can translate (2) into

$$\forall x (A(x) \rightarrow (B(x) \wedge C(x))).$$

Here  $A$ ,  $B$ , and  $C$  are schematic letters which need to be interpreted as clauses containing  $x$ , such as ' $x$  is a fifty-pence piece'; this is what the  $(x)$  in  $A(x)$  indicates. The grammar of this formal language can be written down in a mathematical form. By choosing a particular set of symbols and saying exactly what range of interpretations is allowed for the schematic letters and the quantifiers, we single out a precise formal language, and we can start to

ask mathematical questions about the valid argument schemas which are expressible in that language.

For example a *first-order language* is a formal language built up from the symbols described above, where all quantifiers are interpreted as having the same domain of quantification but this domain can be any non-empty set. *First-order logic* is logic based on argument schemas written in a first-order language.

What is the dividing-line between valid and invalid argument schemas? There are two main approaches to this question. In the first approach, which we may call the *rule-based* or *syntactic* one, we suppose that we can intuitively tell when a simple argument is valid, just by looking at it; we count a complicated argument as valid if it can be broken down into simple steps which we immediately recognize as valid. This approach naturally leads us to write down a set of simple valid argument schemas and some rules for fitting them together. The result will be a *logical \*calculus*, i.e. a mathematical device for generating valid argument schemas. The array of symbols written down in the course of generating an argument schema by the rules is called a *formal proof* of the schema.

Once we have a logical calculus up and running, the mathematicians may suggest ways of revamping it to make it easier to teach to undergraduates, or faster to run on a computer. There is a great variety of logical calculuses for first-order logic, all of them giving the same class of valid argument schemas. Two well-known examples are the \*natural deduction calculus (Gentzen, 1934), which breaks down complex arguments into intuitively 'natural' pieces, and the tableau or truth-tree calculus (Beth, 1955) which is very easy to learn and can be thought of as a systematic search for counter-examples (see the next paragraph).

There is another approach to defining validity, the *semantic* approach. In this approach we count an argument schema as valid precisely if every interpretation which makes the premisses true makes the conclusion true too. To phrase this a little differently, a *counter-example* to an argument schema is an interpretation which turns the premisses into true sentences and the conclusion into a false sentence; the semantic definition says that an argument schema is valid if and only if it has no counter-examples.

At first sight this is a very paradoxical definition; it makes the following highly implausible argument schema valid just because the conclusion is true whatever we put for  $X$ :

The Emperor Caligula's favourite colour was  $X$ .

Therefore Omsk today is a town in Siberia with a population of over a million and a large petroleum industry, and  $X = X$ .

Nevertheless, one can argue that the semantic approach works if the language of our logic doesn't contain any words (such as 'Omsk' or 'today') that tie us down to specific features of our world. This is an untidy view, because the notion of a specific feature of our world is not sharp;

should it include the physical laws of the universe, or the mathematical properties of sets? One has to answer questions like these in order to draw a line between logical necessity and other kinds of necessity (physical or mathematical), and probably there will always be philosophical debate about how best to do this.

For first-order logic the problem happily doesn't arise. One can prove that every first-order argument schema which is justified by any of the standard logical calculuses is valid in the semantic sense. This is a mathematical theorem, the *soundness theorem* for first-order logic. Conversely if an argument schema is *not* proved valid by the logical calculuses, then we can show that there is an interpretation of the schema which makes the premisses true and the conclusion false. This again is a mathematical theorem, the *\*completeness theorem* for first-order logic (Gödel, 1930; this is quite different from his incompleteness theorem of 1931). The completeness theorem justifies both the rule-based approach and the semantic one, in the following way. The chief danger with the rule-based approach was that we might have overlooked some rule that was needed. The completeness theorem assures us that any schema not justified by our logical calculus would have a counter-example, so it certainly wouldn't be valid. And conversely the chief danger with the semantic approach was that it might make some argument schema valid for spurious reasons (like the example with Omsk above). The completeness theorem shows that if an argument has no counter-example, then it is justified by the logical calculus. In this way the valid first-order argument schemas are trapped securely on both sides, so we can be very confident that we have the dividing-line in the right place.

For other logics the position is less clear. For example, in *monadic second-order logic* we have some quantifiers whose domain of quantification is required to be the family of subsets of a particular set. Because of this restriction, some truths of set theory can be expressed as valid schemas in this logic, and one consequence is that the logic doesn't admit a completeness theorem. In *temporal logics* there are logical constants such as 'until' or 'it will sometime be true that . . .'; to define validity in these logics, we need to decide what background assumptions we can make about time, for example whether it is continuous or discrete. For these and other logics, the normal practice today is to give a precise mathematical definition of the allowed interpretations, and then use the semantic definition of validity. The result is an exact notion, even if some people are unhappy to call it logical validity.

This is the place to mention a muddle in some recent psychological literature. The question at issue is how human beings carry out logical reasoning. One often reads that there are two possible answers: (1) by rules as in a logical calculus, or (2) by models (which are interpretations stripped down to the relevant essentials) as in the semantic approach. This is a confusion. There is no distinction between rule-based and semantic ways of reasoning. The rule-based and semantic approaches are different explanations of what we achieve when we do perform a proof: on

the rule-based view, we correctly follow the rules, whereas on the semantic view we eliminate counter-examples.

Can we mechanically test whether a given argument schema is logically valid, and if so, how? For first-order logic, half of the answer is positive. Given any standard logical calculus, we can use it to list in a mechanical way all possible valid argument schemas; so if an argument schema is valid, we can prove this by waiting until it appears in the list. In fact most logical calculi do much better than this; we can use them to test the schema systematically, and if it is valid they will eventually say 'Yes'.

The bad news is that there is no possible computer program which will tell us when a given first-order argument schema is invalid. This was proved by Church in 1936, adapting Gödel's incompleteness theorem. (Strictly it also needs Turing's 1936 analysis of what can be done in principle by a computer.) This does *not* mean that there are some first-order argument schemas which are undecidable, in the sense that it's impossible for us to tell whether they are valid or not—that might be true, but it would need further arguments about the nature of human creativity. Church's theorem does mean that there is no purely mechanical test which will give the right answer in all cases.

A similar argument, again based on Gödel's incompleteness theorem, shows that for many other logics including monadic second-order logic, it is not even possible to list mechanically the valid argument schemas. On the other hand there are many less adventurous logics—for example, the logic of Aristotle's *\*syllogisms*—for which we have a decision procedure, meaning that we can mechanically test any argument schema for validity.

A final question: Is there a particular logical calculus which can be used to justify all valid reasoning (say, in science or mathematics)? For the intuitionist school of Brouwer, it is an article of faith that the answer is 'No'. On the other side, Frege believed that he had given a logical calculus which was adequate at least for arithmetic; but *\*Russell's paradox* showed that Frege's system was inconsistent.

For the moment, the heat has gone out of this question. In modern mathematics we assume that every argument can be translated into the first-order language appropriate for set theory, and that the steps in the argument can all be justified using a first-order logical calculus together with the axioms of Zermelo–Fraenkel *\*set theory*. This has become a criterion of sound mathematical reasoning, though nobody ever carries out the translation in practice (it would be horrendously tedious). Versions of this translation are used to check the correctness of computer software, for example where lives may depend on it.

There is a more radical reading of our question. In many situations we carry out reasoning along quite different lines from the logical calculuses mentioned above. For example, when someone pays us money, we normally take for granted that it is legal tender and not a forgery, and so when it adds up correctly we infer that we have

been given the correct change. Strictly this is not logical reasoning, because even when the premisses are true, the conclusion could be false (and occasionally is). But it is reasoning of a kind, and it does follow some rules. Logicians generally disregarded this kind of reasoning until they found they needed it to guide intelligent databases. For this purpose a number of *non-monotonic* logics have been proposed; the name refers to the fact that in this kind of reasoning a valid conclusion may cease to be valid when a new premiss is added (for example, that the five pound note has no metal strip).

Several other alternative logics have been suggested, each for its own purposes. *Linear logic* tries to formalize the idea that there is a cost incurred each time we use a premiss, and perhaps we can only afford to use it once. An older example is *intuitionist logic* (Heyting, 1930), which incorporates a \*verifiability principle: we can't claim to have proved that there is an *A* until we can show how to produce an example of an *A*. Each of these logics must be justified on its own terms. There is no reason to think that the list of useful logics is complete yet.

**logic, paraconsistent.** A logical system is paraconsistent if it does not sanction the principle that anything follows from a contradiction. The rejected inference is called *ex falso quodlibet*, and is expressed in symbols thus:  $p, \neg p \vdash q$ . Paraconsistent logics have application to the logic of belief, and other propositional attitudes, especially if one wants to develop something analogous to \*possible worlds semantics. A person who has contradictory beliefs is not thereby committed to every proposition whatsoever. A 'world' that is 'compatible' with one's beliefs need not be consistent, but it should not trivially make every proposition true. Other applications of paraconsistent logic concern reasoning with faulty data and \*dialetheism, the view that some contradictions are true. Dialetheism is one attempt to deal with paradoxes like the Liar. Most systems of \*relevance logic are paraconsistent.

**logic, relevance:** see relevance logic.

**logic, second-order.** Consider 'Socrates is wise'. In a first-order logic the name 'Socrates' may be replaced by a bound variable to yield 'something is wise'. It is a further question whether the predicate in this sentence may also be replaced by a bound variable. A formal logic that permits this replacement is called 'second-order'. In the standard semantics for second-order logic, first-order variables range over a domain of individuals, whereas second-order variables range over sets, properties, relations, or functions on the range of the first-order variables. So understood, second-order logic is extremely powerful. It is \*incomplete (there can be no finite deductive system in which every second-order logical truth is deducible), \*categorical (any two models that satisfy a set *S* of sentences are isomorphic), and not compact (even if every finite subset of *S* has a model, *S* itself may lack a model). In a non-standard (Henkin) semantics the second-order variables range over a separate domain of individuals. So understood, second-order logic is complete, categorical, and compact.

Stewart Shapiro, *Foundations without Foundationalism: A Case for Second-Order Logic* (Oxford, 1991).

**logic, traditional.** The rough-and-ready title given by later logicians to the methods and doctrines which once dominated the universities, but which were supplanted in the twentieth century by the 'modern' or 'mathematical' logic with which the names of Frege and Russell are especially associated. Sometimes called 'Aristotelian'—or 'syllogistic', or the 'logic of terms'—it originated with Aristotle in the fourth century BC, though it acquired a great many accretions in the intervening 2,000 years.

The older logic was limited, it is customary to say, by the uncritical assumption that propositions are of the subject–predicate form. This contention, however, is misleading; not least because the subject–predicate distinction is actually quite at odds with the formal system which is supposed to be based on it.

Most traditional logicians certainly accepted that non-compound propositions invariably contain \*subjects and predicates. At its vaguest, the idea was perhaps that to make any judgement at all is to say something about something. It is easy to drift from this to the more specific doctrine that every proposition contains two distinct elements: an element which names or refers to something (a 'subject-term'), and an element (the 'predicate-term') which expresses what is said about it. Thus, in 'Socrates is bald', the name 'Socrates' refers to a person, and the expression 'is bald' says something about this person.

The subject of a proposition in this sense—what it is about—is not part of the proposition but something to which part of it refers, not the name 'Socrates' but the

person who bears it. If some traditional logicians failed to stress the difference, this may have reflected uncertainty about the status of the predicate. The difference between 'Socrates' and Socrates is perfectly clear; not quite so clear is the difference between 'is bald' and is bald.

This asymmetry is one aspect of what is really a very considerable difference: subjects and predicates belong to quite distinct categories. Granted that an expression like '*x* is bald' plays a predicative role, a subject is anything of which this may be said. A subject-term is therefore a word or expression which fulfils two conditions: it constitutes a grammatical answer to a question like 'You said that something (someone) is bald: of what (whom) did you say this?' and it must produce good English when it is substituted for *x* in '*x* is bald'. Proper names, referring expressions like 'Plato's teacher', and a variety of other items, satisfy these conditions; but it is obvious that predicative expressions cannot themselves be subject-terms, because 'is bald is bald' makes no sense at all.

The subject–predicate distinction, then, revolves around the difference between naming or referring to something and saying something about it. But no such distinction can sensibly be applied to the traditional system. The crowning glory of that system, it is agreed on all sides, is the doctrine of the syllogism. But this doctrine, as we shall see, requires—as indeed does the rest of the system—that what is the predicate of one proposition can be the subject of another.

Traditional logic was for the most part concerned with the logical properties of four forms of proposition. More often than not these were said to be

- All *S* is *P*.
- No *S* is *P*.
- Some *S* is *P*.
- Some *S* is not *P*.

'All *S* is *P*' was called the 'universal affirmative' or 'A' form, 'No *S* is *P*' the 'universal negative' or 'E' form, 'Some *S* is *P*' the 'particular affirmative' or 'I' form, and 'Some *S* is not *P*' the 'particular negative' or 'O' form. That a proposition is universal or particular was called its quantity, and that it is affirmative or negative was called its quality.

A moment's reflection shows that 'All *S* is *P*' cannot properly belong in the same list as the rest, because 'No Greek is bald' is good English, while 'All Greek is bald' is merely good gibberish. This drawback, though, could be remedied simply by taking 'Every *S* is *P*' to be the correct form. A more serious problem concerns the innuendo in the symbolism, which is in any case frankly espoused by those who use it, that *S* and *P* stand for subjects and predicates. If 'is bald' is a predicative expression, *P* clearly cannot be a predicate in 'No *S* is *P*', since 'No Greek is is bald' looks like a mere typing error.

The stuttering 'is' could be removed in one of at least two ways. One would be to give up the idea that the predicate is 'is bald' in favour of saying that it is merely 'bald'. This is no doubt the ulterior motive behind the half-baked suggestion that pro-positions contain a third element, over

and above the subject and the predicate, namely the copula (i.e. 'is'). Another way would be to give up the practice of writing, for example, 'No *S* is *P*' in favour of 'No *S* *P*'.

But the difficulties do not end there. We have seen that a subject-term is anything that takes the place of *x* in an expression like '*x* is bald'. According to this criterion, 'Every man', 'No man', and 'Some man' are perfectly good subject-terms. But substituting them in the standard forms again produces meaningless repetition: 'Every every man is bald', and so on. Again there are two ways of coping: one is to say that not 'Every *S* is *P*' but the simple *S* *P* is the correct form, the other that not 'Every man' but merely 'man' is the subject-term.

These different ways of coping led our symbolism in quite different directions. One leaves us with only two elements (subject and predicate); the other first with three elements (subject, predicate, copula), then with four (subject, predicate, copula, and a sign of quantity). All these distinct, and mutually inconsistent, ways of analysing propositions are at least hinted at in the traditional textbooks.

As we saw at the outset, the subject–predicate distinction arises in the context of singular propositions like 'Socrates is bald'. In the traditional textbooks, singulars are treated as universals, on the feeble pretext that in 'Socrates is bald' the name 'Socrates' refers to everything it can. This notion was generally expressed in technical terminology: the name was said to be 'distributed' or to 'refer to its whole extension'. These obscurities presumably reflect a disinclination to say something that is obviously absurd (that one is talking about the whole of Socrates), something that is obviously false (that only one person can be called Socrates), or something that is obviously vacuous (that the name is here meant to name everyone it is here meant to name). Be that as it may, it is worth noticing that the singular propositions which are paradigmatic in the exposition of the subject–predicate distinction become quite peripheral in the exposition of the syllogism. What this indicates is that the subject–predicate distinction is merely a nuisance so far as the formal system of traditional logic is concerned.

How then should the propositions discussed in traditional logic be symbolized? The only analysis which is truly consistent with the traditional system is one in which propositions are treated as containing two distinct sorts of elements, but these are not subjects and predicates; they are logical \*constants and \*terms. The constants, four in number, are:

- 'All ... are ...' (A)
- 'No ... are ...' (E)
- 'Some ... are ...' (I)
- 'Some ... are not ...' (O)

These are two-place term-operators, which is to say, expressions which operate on any two terms to generate propositions.

What are terms? Given our operators and the requirement that a term must be capable of filling either place in

them, this question answers itself. A term is typically a plural noun—like ‘baldies’—or any expression—like ‘persons challenged in the hair department’—that does the work of an actual or possible plural noun (‘possible’ because any particular language may or may not have a single word with the same meaning as a complex expression). Small letters from the beginning of the alphabet will be used to stand for terms, i.e. as term-variables, and these will be written after the term-operator. Thus ‘Anyone who disagrees with me is a complete fool’ is of the form  $Aab$ , where  $a$  = ‘persons who disagree with me’ and  $b$  = ‘complete fools’.

The traditional system relied upon two kinds of \*negation. The distinction between ‘Not everything which glisters is gold’ (negating a proposition) and ‘Everything which glisters is not gold’ (negating a term) is worth fighting for, despite the common practice of using the second to mean the first. Propositional-negation will be represented by  $N$  (meaning ‘It is not that . . .’); term-negation by  $n$  (meaning ‘non-’). Term-negation may preface either or both terms. Thus ‘Everything which doesn’t glisters is gold’ is  $Anab$ , ‘Everything which glisters isn’t gold’ is  $Aanb$ , and ‘Everything which doesn’t glisters isn’t gold’ is  $Ananb$ .

We need in our symbolism also ways of representing connections between propositions.  $Aab \& Abc$  will signify the conjunction of these two propositions.  $Aab \rightarrow Anbna$  will signify the (in this case true) assertion that the second proposition follows from the first, and  $Aab \equiv Aba$  the (in this case false) assertion that these two propositions are equivalent, i.e. that each follows from the other.

The laws of the traditional system may be classified under two headings: those which apply to only two propositions, and those which apply to three or more. The square of opposition and immediate inference fall under the first heading, syllogisms and polysyllogisms under the second.

The \*square of opposition depicts various kinds of ‘opposition’ between the four propositional forms.  $A$  and  $E$  are contraries, meaning that, if  $a$  and  $b$  stand for the same terms in  $Aab$  and  $Eab$ , these two propositions cannot both be true but may both be false; hence  $Aab \rightarrow NEab$  and  $Eab \rightarrow NAab$ .  $I$  and  $O$  are subcontraries, meaning that they cannot both be false but may both be true; hence  $NIab \rightarrow Oab$  and  $NOab \rightarrow Iab$ .  $A$  and  $O$  are contradictories, as are  $E$  and  $I$ , meaning that one of each pair must be true, the other false; hence  $Aab \equiv NOab$  and  $Eab \equiv NIab$ .  $I$  is subaltern to  $A$ , as  $O$  is to  $E$ , meaning that in each instance the second implies the first; hence  $Aab \rightarrow Iab$  and  $Eab \rightarrow Oab$ .

\*Immediate inference, which consists in drawing a conclusion from a single premiss, encompasses conversion, obversion, contraposition, and inversion. Conversion consists in reversing the order of terms. It is valid for  $E$  and  $I$ , invalid for  $A$  and  $O$ ; hence  $Eab \rightarrow Eba$  and  $Iab \rightarrow Iba$ . The valid inferences  $Eab \rightarrow Oba$  and  $Aab \rightarrow Iba$  are called conversion *per accidens*. Obversion consists in negating the second term of a proposition and changing its quality. It is valid for all four forms; hence  $Eab \rightarrow Aanb$ ,  $Aab \rightarrow Eanb$ ,  $Oab \rightarrow Ianb$ , and  $Iab \rightarrow Oanb$ . Contraposition consists in

negating both terms and reversing their order. It is valid for  $A$  and  $O$ ; hence  $Aab \rightarrow Anbna$  and  $Oab \rightarrow Onbna$ . Inversion consists in inferring from a given proposition another having for its subject the negation of the original subject. It is valid in the following cases:  $Eab \rightarrow Inab$ ,  $Eab \rightarrow Onanb$ ,  $Aab \rightarrow Onab$ , and  $Aab \rightarrow Inanb$ .

\*Syllogisms draw a conclusion from two premisses. They contain three terms: one (the middle term) is common to the premisses, another is common to the conclusion and one of the premisses, and the third is common to the conclusion and the other premiss. We will use  $b$  to signify the middle term,  $a$  and  $c$  to signify what are called the extreme terms. Perhaps the best-known syllogism (it was called Barbara) may be illustrated by the following simple example:

Any workers who voted for that party were voting for their own unemployment.

Those who vote for their own unemployment are fools to themselves.

Any workers who voted for that party are fools to themselves.

Traditionally syllogisms were set out this way, with the conclusion under the premisses like the lines of a sum. In our symbolism, this example is of the form ( $Aab \& Abc$ )  $\rightarrow Aac$ .

Polysyllogisms have more than two premisses but may be reduced to a series of conventional syllogisms:

Some university teachers profess to believe in academic freedom but do nothing to defend it.

Those who profess such a thing but do nothing about it are not practising what they preach.

Teachers who fail to practise what they preach are a disgrace to their profession.

Some university teachers are a disgrace to their profession.

This has the form ( $Iab \& Abc \& Acd$ )  $\rightarrow Iad$ , but it may be regarded as the summation of two conventional syllogisms, namely ( $Iab \& Abc$ )  $\rightarrow Iac$  and ( $Iac \& Acd$ )  $\rightarrow Iad$ .

It is customary to say that there are 256 forms of syllogism. This number results from a convention concerning how syllogisms are depicted: the order of terms in the conclusion is fixed, but that in the premisses is reversible. The conclusion is thus restricted to taking one of four forms:  $Eac$ ,  $Aac$ ,  $Oac$ , or  $Iac$ . Each premiss, however, may take any one of eight forms: one is  $Eab$ ,  $Eba$ ,  $Aab$ ,  $Aba$ ,  $Iab$ ,  $Iba$ ,  $Oab$ , or  $Oba$ , and the other is  $Ebc$ ,  $Ecb$ ,  $Abc$ ,  $Acb$ ,  $Ibc$ ,  $Icb$ ,  $Obc$ , or  $Ocb$ . The number 256 is simply  $4 \times 8 \times 8$ .

Syllogisms were classified in the traditional textbooks according to their mood and figure. The mood of a syllogism is essentially the sequence of term-operators it contains. The mood of Barbara, for example, is AAA (hence the name). The various moods, 64 in all, are therefore EEE, EEA, EEO, EEI, and so on. The figure of a syllogism is determined by the arrangement of terms in its premisses. Aristotle distinguished three figures; later

logicians, whose conception of figure differed significantly from his, decreed that there are four:

- (1) *ab, bc.*
- (2) *ab, cb.*
- (3) *ba, bc.*
- (4) *ba, cb.*

The identity of a syllogism is completely specified by its mood and figure, so the number 256 is the product of 4 (figures) and 64 (moods). Of these 256, 24 are said to be valid (some authors, for reasons that will be indicated in a moment, say 19, or even 15). Omitting brackets, the 24, arranged in their figures, are:

- |     |                            |                            |                            |
|-----|----------------------------|----------------------------|----------------------------|
| (1) | <i>Aab &amp; Abc → Aac</i> | <i>Aab &amp; Abc → Iac</i> | <i>Iab &amp; Abc → Iac</i> |
|     | <i>Aab &amp; Ebc → Eac</i> | <i>Aab &amp; Ebc → Oac</i> | <i>Iab &amp; Ebc → Oac</i> |
| (2) | <i>Aab &amp; Ecb → Eac</i> | <i>Aab &amp; Ecb → Oac</i> | <i>Eab &amp; Acb → Eac</i> |
|     | <i>Eab &amp; Acb → Oac</i> | <i>Iab &amp; Ecb → Oac</i> | <i>Oab &amp; Acb → Oac</i> |
| (3) | <i>Aba &amp; Abc → Iac</i> | <i>Aba &amp; Ibc → Iac</i> | <i>Iba &amp; Abc → Iac</i> |
|     | <i>Aba &amp; Ebc → Oac</i> | <i>Aba &amp; Obc → Oac</i> | <i>Iba &amp; Ebc → Oac</i> |
| (4) | <i>Aba &amp; Acb → Iac</i> | <i>Eba &amp; Acb → Eac</i> | <i>Eba &amp; Acb → Oac</i> |
|     | <i>Aba &amp; Ecb → Oac</i> | <i>Aba &amp; Icb → Iac</i> | <i>Iba &amp; Ecb → Oac</i> |

Of these, five are ‘weakened’, meaning that they draw particular conclusions from premisses that merit a universal one. If these are omitted, the number of valid forms is 19. Among these 19, 15 either draw a universal conclusion from universal premisses or a particular conclusion from one universal and one particular premiss: these were sometimes called ‘fundamental’.

But the convention behind the numbers given in the traditional textbooks is wholly improper. The effect of reversing the order of terms in E and I propositions is to produce mere equivalents, while in A and O non-equivalents are produced. The textbook account therefore includes duplication. It excludes from the syllogism, moreover, the varieties of negation that are permitted in immediate inferences, and is as a consequence incomplete.

The traditional system encompassed what were really eight logically distinct propositional forms:

- Eab* (Eba, etc.).
- Enab* (Aba, etc.).
- Eanb* (Aab, etc.).
- Enanb* (Anab, etc.).
- NEab* (Iab, etc.).
- NEanb* (Oba, etc.).
- NEanb* (Oab, etc.).
- NEnanb* (Onab, etc.).

Any one of these eight forms is expressible in eight ways. *Eab*, for example, is equivalent to *Eba*, *Aanb*, *Abna*, *Nab*, *Nba*, *NOanb* and *NObna*. A proper account of the syllogism, then, would cover 64 forms of proposition:

the correct number of syllogisms is therefore 262,144 (i.e. 64 × 64 × 64). c.w.

**logic of discovery.** \*Deduction in the testing of scientific theories. For example, the exhibiting of logical relations between the sentences of a theory (such as equivalence, derivability, consistency, inconsistency) or between a theory and established theories; the logical inferring of predictions from a theory. \*Popper argues against the view that scientific theories are conclusively inductively verifiable but argues for their deductive and empirical falsifiability. A claim of the form  $(\forall a)(Fa)$ , ‘Every *a* is *F*’, cannot be confirmed by any finite number of observations of *a*’s that are *F*, because there could always in principle exist an undiscovered *a* that is not *F*, but  $(\forall a)(Fa)$  can be refused by the discovery of just one *a* that is not *F*.

\*Popper has an evolutionary epistemology of scientific discovery. The formulation of theories is analogous to genetic mutation in evolutionary theory. Theories and mutations arise randomly as putative solutions to environmental problems, and only those conducive to the survival of the species in that environment themselves survive through trial and error. Popper adopts a Platonist view of logic, on the grounds that proofs are (sometimes surprising) discoveries not unsurprising inventions. s.p.  
 Karl R. Popper, *The Logic of Scientific Discovery* (London, 1980), ch. 1, sect. 3.

**logical atomism:** see atomism, logical.

**logical constants.** An argument’s logical form is shown by analysing its constituent propositions into constant and variable parts, constants representing what is common to proportions, variables their differing content. The constants peculiar to syllogistic logic are ‘All ... are ...’, ‘No ... are ...’, ‘Some ... are ...’, ‘Some ... are not ...’; those of propositional calculus are truth-functional connectives like implication, conjunction, and disjunction; those of predicate calculus add the quantifiers ‘For all *x* ...’ and ‘There is an *x* such that ...’. Constants concerning identity, tense, modality, etc. may be introduced in more complex systems. c.w.

**logical determinism:** see determinism, logical.

**logical empiricism:** see empiricism, logical.

**logical form:** see form, logical.

**logical laws.** Propositions true on logical grounds alone; logical truths. For example, the laws of non-contradiction, identity, excluded middle, and double negation. In propositional calculus the law of non-contradiction is:

$\neg(p \ \& \ \neg p)$ , 'It is not the case that both  $p$  and not  $p$ '

in predicate calculus:

$(\forall x) \neg(Fx \ \& \ \neg Fx)$  'For any  $x$ , it is not the case that  $x$  is  $F$  and  $x$  is not  $F$ '

In propositional calculus the law of identity is:

$(p \rightarrow p)$ , 'If  $p$  then  $p$ '

in predicate calculus:

$(\forall x) (Fx \rightarrow Fx)$ , 'For any  $x$ , if  $x$  is  $F$  then  $x$  is  $F$ '

in predicate calculus with identity:

$(\forall x) (x = x)$ , 'For any  $x$ ,  $x$  is  $x$ '

in modal predicate calculus with identity:

$\Box(\forall x) (x = x)$ , 'Necessarily, for any  $x$ ,  $x$  is  $x$ '

In propositional calculus the law of excluded middle is:

$p \vee \neg p$ , 'Either  $p$  or not  $p$ '

in predicate calculus:

$(\forall x) (Fx \vee \neg Fx)$ , 'For any  $x$ , either  $x$  is  $F$  or  $x$  is not  $F$ '

In propositional calculus the laws of double negation are:

$\neg\neg p \rightarrow p$ , 'If not not  $p$  then  $p$ ', and

$p \rightarrow \neg\neg p$ , 'If  $p$  then not not  $p$ '

and in predicate calculus:

$(\forall x) (\neg\neg Fx \rightarrow Fx)$  'For any  $x$ , if  $x$  is not not  $F$  then  $x$  is  $F$ '  
and

$(\forall x) (Fx \rightarrow \neg\neg Fx)$ , 'For any  $x$ , if  $x$  is  $F$  then  $x$  is not not  $F$ '.

Aristotle does not distinguish sharply between logical laws, laws of thought, and laws of being, so the consistent, the \*conceivable, and what could exist coincide, and the inconsistent, the inconceivable, and what could not exist coincide. Aristotle's informal statements of the law of non-contradiction include: 'For the same thing to hold good and not to hold good simultaneously of the same thing and in the same respect is impossible' (*Metaphysics*  $\Gamma$  1005<sup>b</sup>):  $(\forall x) \neg(Fx \ \& \ \neg Fx)$  or arguably:  $(\forall x) \neg\Diamond (Fx \ \& \ \neg Fx)$ , and 'Nor [. . .] is it possible that there should be anything in the middle of a contradiction' (1011<sup>b</sup>):  $\neg\Diamond (p \ \& \ \neg p)$ . His statement of the law of excluded middle is 'but it is necessary either to assert or deny any one thing of one thing' (1011<sup>b</sup>),  $(\forall x) (Fx \vee \neg Fx)$  or arguably;  $\Box(\forall x) (Fx \vee \neg Fx)$ . Aristotle says it shows a lack of education to demand a proof of logical laws. He does, however, bring a self-refutation argument against their putative denial by his Pre-Socratic predecessors, Protagoras, who thinks that every claim is true but there is no truth over and above belief by or appearance to persons, and Heraclitus, who thinks that everything is changing in every respect so there is no truth. Aristotle points out that saying anything meaningful or true—for example, making Protagorean or Heraclitean claims—presupposes logical laws.

Mill maintains that logical laws are not a priori or

necessary, but empirical generalizations confirmed by all experience but, so far, refuted by none. He thinks all deduction is really induction.

Quine has suggested revision of the law of excluded middle to simplify quantum mechanics. Plantinga has commented that this is rather like revising a law of arithmetic to simplify the doctrine of the Holy Trinity.

It is widely taken as axiomatic that if the description of a putative phenomenon entails a violation of a logical law, then that phenomenon cannot exist. However, if we are persuaded, for example, that Zeno has found contradictions in the concept of motion (for example: If  $x$  moves, then  $x$  is at a place at a time and  $x$  is not at that place at that time), we do not thereby conclude that nothing moves; 'Foolish, foolish us! We thought things *moved*. But no. That philosopher Zeno has shown that the concept of motion entails a contradiction. Clearly we should give up this widespread, perceptually compelling but incoherent assumption! Motion is *logically impossible*.' Rather, we retain the view that things move and look for a consistent theory of motion. The implications for philosophy, science, and theology are wide. Perhaps time-travel is not logically impossible, it is just that we so far lack a consistent theory of it. Arguably, something is possible if and only if there is at least one consistent description of it.

Perhaps nothing is logically impossible, because contradictions do not pick out any putative states of affairs. If not, they do not pick out any impossible putative states of affairs. 'Ah yes, "Both ( $p \ \& \ \neg p$ )", it is the putative state of affairs picked out by *that* sentence that could not come about!' But what state of affairs could not come about?

**logically perfect language.** Natural \*languages may be thought in various ways to be 'logically imperfect'. Certain grammatical forms may mislead us about logical form; thus, 'It is raining' looks as if it refers to something ('it'). More radically, certain concepts may even involve us in contradiction or incoherence. For example, Tarski argued that the ordinary concept 'true' did this, since it generated such paradoxes as the \*liar. A logically perfect language would be one lacking these faults, as well, perhaps, as some other 'defects', such as ambiguity and redundancy. Frege attempted to create such a language (the *Begriffsschrift*), in which to couch the truths of logic and mathematics. Rather later, the \*Logical Positivists were interested in the idea of a logically perfect language with which to express the whole of natural science. R.P.L.T.

G. Frege, *Begriffsschrift*, in *Translations from the Philosophical Writings of Gottlob Frege*, tr. P. T. Geach and M. Black, 2nd edn. (Oxford, 1960), ch. 1.

**logically proper names.** The term Bertrand Russell uses for names that are logically guaranteed to have a bearer. For Russell the meaning of a logically proper name is the object it stands for. If there is no object that the name stands for, it is literally meaningless. To know the meaning of a logically proper name is to know the object it stands for, where this is a matter of being directly acquainted with the object. Since Russell supposed that the only objects we were directly acquainted with were private items of sensory experience or memory, only these items could be picked out by logically proper names. Conversely, if a name could be used in a sentence meaningfully even if it did not stand for an existing entity, for example 'Santa Claus', then that name could not be a logically proper name, but was instead an abbreviation of a definite description. For Russell ordinary proper names did not count as logically proper names. The only genuine examples of logically proper names in English were expressions such 'this', 'that', and 'I', standing for items with which the thinker was immediately acquainted. Wittgenstein thought Russell had matters the wrong way round. Instead of starting with a logical test of a genuine name, only to discover that hardly any of the expressions we ordinarily called names passed the test, a proper account of names should start by characterizing the expressions we called names. Others maintain that Russell is right about names, but wrong to restrict the entities we can name and know to items in sensory experience. To mean something by a name, we must know who, or what, we are referring to, but such knowledge can take many forms, and is not limited to direct acquaintance with the object itself. B.C.S.

**logical notations:** see notations, logical.

**Logical Positivism.** This twentieth-century movement is sometimes also called logical (or linguistic) empiricism. In a narrower sense it also carries the name of the \*Vienna Circle since such thinkers in this tradition as Rudolph Carnap, Herbert Feigl, Otto Neurath, Moritz Schlick, and Friedrich Waismann formed an influential study group in Vienna in the early 1920s to articulate and propagate the group's positivist ideas. In the broader sense, however, Logical Positivism includes such non-Viennese thinkers as A. J. Ayer, C. W. Morris, Arne Naess, and Ernest Nagel.

Central to the movement's doctrines is the principle of verifiability, often called the \*verification principle, the notion that individual sentences gain their meaning by some specification of the actual steps we take for determining their truth or falsity. As expressed by Ayer, sentences (statements, propositions) are meaningful if they can be assessed either by an appeal directly (or indirectly) to some foundational form of sense-experience or by an appeal to the meaning of the words and the grammatical structure that constitute them. In the former case, sentences are said to be synthetically true or false; in the latter,

analytically true or false. If the sentences under examination fail to meet the verifiability test, they are labelled meaningless. Such sentences are said to be neither true nor false. Famously, some say infamously, many positivists classed metaphysical, religious, aesthetic, and ethical claims as meaningless. For them, as an example, an ethical claim would have meaning only in so far as it purported to say something empirical. If part of what was meant by 'x is good' is roughly 'I like it', then 'x is good' is meaningful because it makes a claim that could be verified by studying the behaviour of the speaker. If the speaker always avoided x, we could verify that 'x is good' is false. But the positivists typically deny that 'x is good' and similar claims can be assessed as true or false beyond this sort of report. Instead, they claim that the primary 'meaning' of such sentences is \*emotive or evocative. Thus, 'x is good' (as a meaningless utterance) is comparable to 'Hooray!' In effect, this sort of analysis shows the positivists' commitment to the fact-value distinction.

Given the role that the verifiability principle plays in their thinking, it is not surprising that the Logical Positivists were admirers of science. One might say they were science-intoxicated. For them it was almost as if philosophy were synonymous with the philosophy of science, which in turn was synonymous with the study of the logic (language) of science. Typically, their philosophy of science treated sense-experience (or sense-data) as foundational and thus tended to be 'bottom up' in nature. That is, it tended to consider the foundational claims of science as being more directly verifiable (and thus more trustworthy) than the more abstract law and theoretic claims that science issues. Their philosophy of science also tended to be 'atomistic' rather than holistic in nature. Each foundational claim was thought to have its own truth-value in isolation from other claims. After the Second World War these doctrines of positivism, as well as the verifiability principle, atomism, and the fact-value distinction, were put under attack by such thinkers as Nelson Goodman, W. V. Quine, J. L. Austin, Peter Strawson, and, later, by Hilary Putnam and Richard Rorty. By the late 1960s it became obvious that the movement had pretty much run its course. N.F.

\*verificationism.

**logical symbols:** see Appendix on Logical Symbols; notations, logical.

**logical theory.** Like all parts of philosophy, logical theory is best seen as a vaguely delimited and shifting group of *problems*. A rough characterization would be that they concern (1) how to understand the activities of logicians and the nature of the systems that logicians construct (philosophy of logic), and (2) how to apply the systems to what has always been logic's primary purpose, the appraisal of

\*arguments. In its heyday, the twentieth century, the subject has also had important ramifications (3)

1. It is possible to see a logical system as something abstract, formal, and uninterpreted (unexplicated). The logician takes a vocabulary of words or symbols (elements), and devises rules of two kinds: rules for concatenating the elements into strings (well-formed formulae), and rules for selecting and manipulating formulae or sequences of them so as to produce other formulae or sequences (derivation rules). Doing logic consists in following these rules; logical results, or theorems, are to the effect 'Such-and-such an output can be got by the rules'. So conceived, the activity has no *use* at all: it is part of pure mathematics.

It is no surprise that, historically, the pure-mathematical approach came late: in its origins, logic was supposed to serve a purpose. If it is to do so, the rules must be designed to detect some property or relation, and if the purpose is to count as logical in the currently accepted sense, that property or relation must be defined in terms of *truth* (or of some allied notion such as satisfaction, or warranted assertibility). The way this works out is as follows: first we define 'Formula  $\phi$  is valid' (a kind of \*logical truth) to mean ' $\phi$  is true on all interpretations', and 'Formula  $\phi$  is a consequence of the set of formulae  $\Gamma$ ' to mean ' $\phi$  is true on all interpretations on which all the members of  $\Gamma$  are true'; and then we understand 'Such-and-such an output can be got by the rules' as asserting that the output is a valid formula or a consequence-related sequence of formulae, provided that the input is (or unconditionally, if there is no input to a particular rule).

This procedure interprets (explicates) the originally abstract claim that some result comes out by the rules; it gives us interpreted logic. But at once it imposes two new obligations on the logician: he must tell us what *he* means by 'interpretation' in his definitions of 'valid' and 'consequence', and he must show us that the rules do establish what we are now to understand their users as asserting. The first of these obligations can, in fact, be discharged in more than one way, but roughly speaking an 'interpretation' (or instance) of a formula is a sentence that results from it by replacing all its schematic letters uniformly by ordinary words. The second obligation requires the logician to prove that his system of rules is *sound*, i.e. does what he (now) says it does.

Proof of soundness depends on ways of telling when an 'interpretation' of a formula is true—or rather, what turns out to be enough, on ways of telling when it's bound to be the case that every 'interpretation' of a given formula is true (or of a given sequence of formulae is 'truth-preserving'). That means that we need truth-conditions for the constant elements in each formula, the elements which are unchanged through all its various 'interpretations'. So soundness depends on truth-conditions of constants. This is something that has come to consciousness in twentieth-century logical theory, but was implicit all along.

Besides soundness, logical theory is concerned with

other properties of logical systems, among them completeness, which is the ability of a system to generate *everything* that is, according to a given set of truth-conditions, valid or a consequence.

2. If you want to apply logic to appraising an argument, two steps are needed: fitting the argument's premisses and conclusion to a sequence of logical formulae, and evaluating the sequence. Evaluation goes by the rules of the logical system, provided they are sound, and is sometimes wholly mechanical. Logical theory must then argue (or assume) that only valid arguments fit the favourably evaluated sequences—the ones for which the consequence relation holds.

Fitting is a quite different kind of operation, not mechanical and often difficult: it is symbolizing or formalizing or 'translating from' ordinary words into a 'logical language'. Pitfalls have long been known: for example, why is this not a valid argument?

Man is a species. Socrates is a man. So Socrates is species.

The twentieth century saw a strong revival of interest in these pitfalls, whose existence is a large part of the reason why in the first half of the century logic seemed to analytic philosophers to lie at the centre of their subject. Here are a few more examples.

The President of New York is or is not black.

Is that true, given that there is no such person? If not, does it falsify the law of \*excluded middle? If not true, is it false? If it is false, is that because the definite \*description 'the President of New York' is, as Russell thought, not its logical subject but an \*incomplete symbol like 'some president'?

If you swallow an aspirin, you will feel better. So if you dip an aspirin in cyanide and swallow it, you will feel better.

If 'if' worked in the same way as its surrogate ' $\rightarrow$ ' in propositional logic, the argument would be valid. If the argument is invalid, as it certainly appears to be, how does 'if' work?

Some things don't exist (Gandalf, for example).

According to Kant 'existence is not a predicate', and this developed into Frege's doctrine that 'exist' 'really' has the syntactic role of a \*quantifier equivalent to 'some existing thing', making a sentence when attached not to a subject but to a predicate. If so, the last proposition above is nonsense, mere bad grammar. Even if we readmit 'exists' as a genuine predicate and symbolize the last proposition in the way of predicate logic as ' $\exists x \neg (x \text{ exists})$ ', that has the unintended feature of being false, or even self-contradictory. One solution is to rejig the truth-conditions of predicate logic so that ' $\exists x \phi(x)$ ' means 'Something is  $\phi$ ', where that is to be distinguished from 'Some existing thing is  $\phi$ ' (free logic).

Everyone who voted could have been a teller. So there could have been voting tellers.

One trouble is that the premiss is three-ways ambiguous. Does it mean 'There's a possible situation in which all those who would then have voted would then have been tellers' or 'There is a possible situation in which all those who actually voted would have been tellers', or 'For any one of those who actually voted, there is a possible situation in which that one would have been a teller'? Only the first meaning licenses the inference, and then only if its 'all' implies 'some'. A second difficulty is that classical predicate logic rejects that implication: 'all', 'every', etc. do not always work in the same way as their logical surrogate 'v'. Examples of similar problems could be multiplied.

3. During the twentieth century logical theory infiltrated three other disciplines: linguistics, mathematics, and metaphysics. The influence on *linguistics* came partly from logicians' interest in well-formedness—what were called above the rules of concatenation. In linguistic study such rules are a part of syntax, which is a part of grammar, and although the grammar of real languages is immensely more complex, and never stable, some linguists have found the logicians' model a helpful one. Also, as logicians came to see that the logical powers of sentences, their interrelations of \*entailment and consistency and the like, depend on truth-conditions, so the thought naturally arose that truth-conditions determine meaning. Frege's distinction of sense and tone had already moderated that enthusiasm, but the theory of meaning (semantics) has remained beholden to logicians' ideas, and philosophy of \*language is still not quite an independent domain.

Logic was assured of an influence on *mathematics* by the circumstance that its nineteenth-century revival was due to mathematicians. At first they wanted foundations for arithmetic and geometry (Frege, Russell). By the 1930s conceptions (e.g.  $\omega$ -consistency) and theorems (e.g. Gödel's \*incompleteness theorems) had emerged which belong to pure logic but which only a mathematical mind could compass.

The infiltration into *metaphysics* was due mainly to Wittgenstein and Russell, and proved short-lived. In 1919 both those philosophers thought that the outline of the way things are is to be discovered by attention to how one must speak if one's speech is to be formalizable into predicate, or even propositional, logic. 'Practically all traditional metaphysics', said Russell, 'is filled with mistakes due to bad grammar' ('The Philosophy of Logical Atomism', 269). Kant's idea that metaphysics explores the bounds of sense came, at the hands of Ryle and also of the \*Logical Positivists, to be combined briefly with the hope that logic could chart those bounds. A bright afterglow remains in the work of Strawson, Quine, D. K. Lewis, Davidson, and very many others.

P. F. Strawson, *Individuals* (London, 1959).

**logical truth.** The expression has various meanings, all connected to the idea of a logical system.

Logical systems have always shared two features: they are at least partly symbolic, using letters or similar devices, and they assert, or preferably prove, results about their symbolic expressions (in the modern jargon, the 'formulae' of their 'logical language'), results such as: any argument of the form 'No Bs are Cs, some As are Bs, so some As are not Cs' is valid; ' $\neg P$ ' is a consequence of ' $(P \rightarrow \neg P)$ '.

1. One current meaning of 'logical truth' is 'result in some sound logical system' ('sound' is not redundant here: it excludes faulty logical systems in which not all the results are true). A true result will usually be a proved result, therefore a theorem, for example (as above):

' $\neg P$ ' is a consequence of ' $(P \rightarrow \neg P)$ '.

2. Sometimes certain symbolic expressions are themselves described as logical truths, for example:

If some As are Bs, then some Bs are As.

$((P \rightarrow \neg P) \rightarrow \neg P)$ .

Here explanation is needed, since strictly speaking these expressions are not truths at all (they do not say anything). What is meant is that all their instances are true, where an instance is what you can express by uniformly replacing certain schematic or—in a loose sense—'variable' symbols (the letters A and B in the first example, the letter P in the second) by syntactically permissible words from an adequately rich vocabulary; or, alternatively, that they are true under all interpretations, where an interpretation assigns meanings uniformly to those same 'variables' from a syntactically limited but adequately rich range of meanings. In this usage, truth and falsity do not exhaust the field: in between logical truths, all of whose instances are true, and logical falsehoods, all of whose instances are false, are symbolic expressions such as 'P or not Q', having some true and some false instances.

3. Finally, and perhaps most commonly, 'logical truth' may mean 'truth that is true in virtue of some result in a sound logical system'. The basic kind of case is a truth that is an instance (or interpretation) of a symbolic expression *all* of whose instances (or interpretations) are true, i.e. an instance of a type 2 logical truth, for example:

If some men are Greeks, then some Greeks are men.

If a condition for your believing erroneously that you exist is that the belief is not erroneous, then it is not erroneous.

The range of type 3 logical truths is indeterminate, since it depends on which sorts of system you are willing to count as logical. Propositional logic, predicate logic, and syllogistic are accredited systems, but not all philosophers are so happy about, say, \*modal logic, epistemic logic, \*tense logic, \*deontic logic, \*set theory, \*mereology. On the other hand it is disputable whether any boundary conditions can rationally be set; certainly none are agreed.

Type 3 logical truths can be defined in other roughly equivalent ways: 'true in virtue of its (logical) form', that is, in virtue of being an instance of some type 2 logical truth; 'true in virtue of the meanings of its logical words', that is, of the words in it that can be represented by constants in some logical system; or 'true under all reinterpretations of its non-logical words', similarly.

Basic type 3 logical truths are often described as 'logically necessary', as if their origin in logic guarantees their necessity. Part (only part) of the guarantee comes from using intuitively satisfying methods to prove the logical results, the type 1 truths, methods which may be *semantic*, resting on the truth-conditions of the system's constants, or *logistic*, resting on self-commending manipulation of ('derivation from') self-commending primitive expressions ('axioms').

Other truths can be deduced from the basic logical truths by means of definitions; for example, 'A mastax is a pharynx' from 'The pharynx of a rotifer is a pharynx' by the definition of 'mastax'. But usually these aren't counted as logical truths, though they are counted as logically necessary.

There's a warning in all the above: it would be mistake to suppose that you can always tell at a glance whether some proposition is a type 3 logical truth. You must know your type 1 truths, the theorems of sound systems, many of which are far from obvious; you must judge whether the systems they belong to deserve to be called logical; you must take care over the notions of 'instance' and 'interpretation' (for example, 'If she's wrong, she's wrong' will not be an instance of the type 2 logical truth 'If  $P$ ,  $P$ ', unless the 'she's' refer to the same person); and definitions—if the use of them is allowed—are often hazy (for example, is water liquid by definition?).

**logicism.** The slogan of the programme is 'Mathematics is logic'. The goal is to provide solutions to problems in the philosophy of \*mathematics, by reducing mathematics, or some of its branches, to logic. There are several aspects of, and variations on, this theme. On the semantic front, logicism can be a thesis about the meaning of some

mathematical statements, in which case mathematical truth would be a species of logical truth and mathematical knowledge would be logical knowledge. Mathematics, or some of its branches, might be seen as either having no ontology at all or else having only the ontology of logic (whatever that might be). In any case, the value of the enterprise depends on what logic is.

The traditional logicist programme consists of systematic translations of statements of mathematics into a language of pure logic. For Frege, statements about natural numbers are statements about the extensions of certain concepts. The number three, for example, is the extension of the concept that applies to all and only those concepts that apply to exactly three objects. Frege was not out to eliminate mathematical ontology, since he held that logic itself has an ontology, containing concepts and their extensions. Frege's complete theory of extensions was shown to be inconsistent, due to the original \*Russell's paradox. For Russell, statements of arithmetic are statements of ramified \*type theory, or \*higher-order logic. Here, too, logic has an ontology, consisting of properties, propositional functions, and, possibly, classes. To complete the reduction of arithmetic, however, Russell had to postulate an axiom of \*infinity; and he conceded that this is not known on logical grounds alone. So statements of mathematics are statements of logic, but mathematical knowledge goes beyond logical knowledge. On the other hand, a principle of infinity is a consequence of the (consistent) arithmetic fragment of Frege's system. Apparently, there was no consensus on the contents and boundaries of logic, a situation that remains with us today.

There are a number of views in the philosophy of mathematics which resemble parts of logicism. It was held by some positivists that mathematical statements are \*analytic, true or false in virtue of the meanings of the terms. Some contemporary philosophers hold that the essence of mathematics is the determination of logical consequences of more or less arbitrary sets of axioms or postulates. As far as mathematics is concerned, the axioms might as well be meaningless. To know a theorem of arithmetic, for example, is to know that the statement is a consequence of the axioms of arithmetic. On such views, mathematical knowledge is logical knowledge.

Today, a number of philosophers think of logic as the study of first-order languages, and it is widely held that logic should have no ontology. Higher-order systems are either regarded as too obscure to merit attention or are consigned to set theory, part of mathematics proper. From this perspective, logicism is an absurd undertaking. Nothing that merits the title of 'logic' is rich enough to do complete justice to mathematics. It is often said that the logicists accomplished (only) a reduction of some branches of mathematics to set theory. On the other hand, a number of logicians do regard higher-order logic, and the like, as part of logic, and there is extensive mathematical study of such logical systems. It is not much of an exaggeration to state that logic is now part of mathematics, rather than the other way round.

Gottlob Frege, *Die Grundlagen der Arithmetik* (Breslau, 1884).

Alfred North Whitehead and Bertrand Russell, *Principia Mathematica* (Cambridge, 1910).

**logistic method.** A postulational method of constructing formalized logical systems by specifying one's symbols, recursively defining the well-formed formulae, and laying down an economical set of axioms and inference rules for proving theorems. Such a procedure is axiomatic, which historically was the norm. The currently more popular variant, \*natural deduction, uses only rules of inference, for proving theorems as well as the validity of derivations. Generally, the notion of proof or of valid derivation is given a strict formal definition. This approach is motivated by a desire for rigour and interpretative versatility.

K.W.

Alonzo Church, *Introduction to Mathematical Logic* (Princeton, NJ, 1956), i, Intro., sect. 7.

**logocentrism.** Term deployed most frequently by Jacques Derrida and the proponents of \*deconstruction in philosophy and literary theory. In this usage a logocentric discourse is one that subscribes to the traditional order of priorities as regards language, meaning, and truth. Thus it is taken for granted first that language (spoken language) is a more or less adequate expression of ideas already in the mind, and second that writing inhabits a realm of derivative, supplementary signs, a realm twice removed from the 'living presence' of the *logos* whose truth can only be revealed through the medium of authentic (self-present) speech.

C.N.

## \*différance.

Jacques Derrida, *Of Grammatology*, tr. G. C. Spivak (Baltimore, 1976).

**logos.** A Greek word, of great breadth of meaning, primarily signifying in the context of philosophical discussion the rational, intelligible principle, structure, or order which pervades something, or the source of that order, or giving an account of that order. The cognate verb *legein* means 'say', 'tell', 'count'. Hence the 'word' which was 'in the beginning' as recounted at the start of St John's Gospel is also *logos*. The root occurs in many English compounds such as biology, epistemology, and so on. Aristotle, in his *Nicomachean Ethics*, makes use of a distinction between the part of the soul which originates a *logos* (our \*reason) and the part which obeys or is guided by a *logos* (our \*emotions). The idea of a generative intelligence (*logos spermatikos*) is a profound metaphysical notion in Neoplatonic and Christian discussion.

N.J.H.D.

As good a place as any to see the notion of *logos* at work in general is in Stoic metaphysics; see J. M. Rist, *Stoic Philosophy* (Cambridge, 1969).

**London philosophy.** For a long time after the foundation of University College London in 1828 the main centres of philosophy in Britain were still Oxford, Cambridge, and the universities of Scotland. There was nothing in London like the circle of philosophers round Mersenne in seventeenth-century Paris or the salons where the \*philosophes met in the eighteenth century until the philosophical radicals came together in the early nineteenth century, presided over by Bentham and united, for a time, by the *Westminster Review*. The first element of what was to become the University of London was brought into existence by this group of Benthamites. Their firmly secular intentions were at first frustrated in philosophy by the appointment of a clerical nonentity as the first professor of the subject.

The official exponents of philosophy in London University, although often worthy and competent, did not have much impact. Croom Robertson, the first editor of *Mind*, James Sully, principally a psychologist, Carveth Read, a follower of Mill who attached evolutionary speculations to his empiricist inheritance, H. Wildon Carr, a businessman who dabbled in Bergson and Croce, and the more professional and durable (he was professor at University College from 1904 to 1928) George Dawes Hicks, a critical realist hostile to the prevailing sense-datum theory, can have set no one's pulses racing. Between the wars there were some more colourful figures in various parts of the university. At Bedford was L. Susan Stebbing, aggressive critic of the metaphysical speculations of such scientists as Jeans and Eddington; at Birkbeck C. E. M. Joad, ardent and useful popularizer after his initial investment in Bergson had proved unrewarding; at University College, John Macmurray, a gifted lecturer and writer, an exponent of British \*idealism in its Scottish and more religious form. But they were intellectually lightweight.

There was, however, an altogether more interesting set of thinkers, concerned with philosophy and of high philosophical capacity, teaching mathematics and science in London: the logician Augustus de Morgan (who impressed his pupil Walter Bagehot), the brilliant, short-lived W. K. Clifford (whose severe ethics of belief was rejected by William James), and his follower, Karl Pearson. Clifford and Pearson, both admirable writers, elaborated a phenomenalist \*positivism closely similar to that of Mach. (London, it may be noted, was the centre of the increasingly sectarian and eccentric English branch of Comtian positivism, a different and philosophically more questionable undertaking.)

Other London professors of philosophical interest whose chairs were not in philosophy were L. T. Hobhouse, the sociologist, and Edward Westermarck, the anthropologist, theorists, respectively, of the evolution and of the relativity of morals. The great reviews of the Victorian age were hospitable to such gifted metropolitan philosophical amateurs as G. H. Lewes, Leslie Stephen, Samuel Butler, and Fredric Harrison.

Philosophy in London came into its own after 1945 and the arrival of K. R. Popper and A. J. Ayer, in their different

ways continuing the tradition of Clifford and Pearson, Popper as a philosopher of science, Ayer as a scientific philosopher. With their respective circles of active followers they greatly enhanced the philosophical vitality of the capital. It came to be a third force, opposed to the amorphous Wittgensteinianism of Cambridge and the minute lexicography of Austin's Oxford. Ayer's seminars of the post-war years were notable for their hard-hitting argumentativeness. His readiness to appear in public, on television and in the press, and the liveliness with which he did so, made him the exemplar of a philosopher for the general public. He conveyed his argumentative energy to a number of influential philosophers, just as Popper passed on his commitment to clarity to others.

Ayer was succeeded by the very different Stuart Hampshire, shortly after the latter's *Thought and Action* came out in 1959, a book whose systematic aim and fine mandarin prose were both unusual for an Oxford philosopher of the time. Also in London throughout the 1950s and 1960s was Michael Oakshott, the even more stylish reanimator of conservative political theory. Through much the same period J. N. Findlay was at King's College, a former Wittgensteinian who proclaimed to a surprised philosophical community in 1955 the merits of Hegelianism. But these imaginative, rather literary philosophers did not succeed in undermining the science-favouring tendency of London philosophy.

A.Q.

\*Cambridge philosophy; Oxford philosophy.

**lore, social:** see social science, philosophy of.

**lottery paradox.** Suppose I buy one ticket in a lottery with a million tickets and one prize. It would be irrational to believe my ticket will win. Some philosophers have thought that because we are so prone to error, we are bound to believe what is no more than highly probable, hence, as here, to believe that my ticket won't win. But the same holds for each ticket, so we are bound to believe that no ticket will win. But one ticket is, *ex hypothesi*, certain to win: hence the paradox. What the paradox shows is that there is a difference between believing that something is—to however great a degree—probable and believing it.

M.C.

L. J. Cohen, *The Probable and the Provable* (Oxford, 1977).

**Lotze, Rudolf Hermann** (1817–81). German physiologist and philosopher, who tried to reconcile the idealist tradition, running from Leibniz to Fichte and Hegel, with natural science. He argued, especially in *Mikrokosmos* (1856–64), that nature, including life, can be explained mechanistically, but the unity of consciousness (our ability to compare two presentations and judge them (un)like) resists mechanical explanation. The causal interactions of nature presuppose that it is an organic unity of relatively permanent entities. Such entities can only be understood as finite spirits, analogues of our consciousness, and their

unity is grounded in an infinite spirit or (personal) God. Natural laws are the mode of God's activity, which aims at the realization of moral value and is to be understood by analysis of the concept of the good. 'His work is characteristic of the woolly and emotional nebulosities which in Germany followed the collapse of the idealist school' (Collingwood).

M.J.I.

H. Schnädelbach, *Philosophy in Germany 1831–1933* (Cambridge, 1984).

**love.** Affection or attachment, especially sexual, and in this sense studied by philosophers since Plato, who viewed love as a desire for beauty, which should transcend the physical and even the personal, culminating in \*philosophy—the love of wisdom itself. In reaction to such lofty views, love has been thought of as reducible either to the sex drive (e.g. Schopenhauer) or to a struggle for power—in its means, war: at bottom, the deadly hatred of the sexes' (Nietzsche). The latter view is close to that of much \*feminist philosophy, which regards love as part of a male ideology for securing the subordination of women. Yet reductionism of these sorts encounters the objection that *true* love must be something over and above these things in virtue of the high value we set on it (as on \*friendship).

P.G.

Irving Singer, *The Nature of Love* (Chicago, 1989).

**love-feast:** see *agapē*.

**Lovejoy, Arthur O.** (1873–1962). American philosopher and historian of ideas at Johns Hopkins University who advocated \*Critical Realism, temporalistic realism, and a method of tracing ideas through history. A dualist in epistemology, he held that there are 'changes in certain physical structures which generate existents that are not physical . . . and these non-physical particulars are indispensable means to any knowledge of physical realities'. '[T]emporalism', he said, 'is the metaphysical theory which maintains . . . the essentially transitive and unfinished and self-augmentative character of reality'. In his conception of intellectual history unit-ideas are assumptions or habits which become 'dialectical motives' when, vague and general as they are, they 'influence the course of men's reflections on almost any subject'. The historian traces each unit-idea 'through . . . the provinces of history in which it figures in any important degree, whether those provinces are called philosophy, science, literature, art, religion or politics'. Lovejoy was also an influential and courageous advocate of academic freedom.

P.H.H.

Daniel J. Wilson, *Arthur O. Lovejoy and the Quest for Intelligibility* (Chapel Hill, NC, 1980).

**loyalty.** A disposition, normally regarded as admirable, by which a person remains faithful and committed to a person or cause, despite danger and difficulty attendant on that allegiance, and often despite evidences that that person or cause may not be quite as meritorious or creditable

as they seem. The fact that loyalty can be blind to or unmoved by such evidences gives rise to problems about its value, as the phrases misguided, misplaced, or unquestioning loyalty suggest. None the less, we are apt to see the capacity for selfless commitment contained in loyalty as presumptively good (if it does not become fanaticism). Loyalty need not be to universal or impartial causes; it is often very limited and exclusive in its scope. In this way, too, it can give rise to injustice. Only rarely has it been seen as a cardinal \*virtue.

N.J.H.D.

\*trust.

J. Royce, *The Philosophy of Loyalty* (New York, 1908) contains an exhaustive discussion.

**Lucretius** (c.95–52 BC). He was a Roman poet whose work *De rerum natura* (On the Nature of Things) is both a major source for Epicurean philosophy and one of the masterpieces of Latin literature. He wrote the poem to transmit into Latin culture the message from Greek \*Epicureanism that nothing infringes our autonomy in securing happiness. The centre-piece of the poem is an extended argument that human beings are purely material things and so they cannot survive the destruction of their physical bodies; religion which seeks to teach otherwise, is damaging superstition. To support his case he had to mount extensive investigations of physical and psychological phenomena, which are described with great literary power. His attempt to prove that people are irrational to be worried about their future non-existence is often cited in contemporary moral philosophy.

C. Bailey, *Titi Lucreti Cari: De rerum natura* (Oxford, 1947), i. 1–171.

D. Sedley, *Lucretius and the Transformation of Greek Wisdom* (Cambridge, 1998).

**Lukács, Georg** (1885–1971). The most prominent Marxist philosopher in the Hegelian tradition, Lukács is best known for his book *History and Class Consciousness* (1923), which attempts a philosophical justification of the Bolshevik enterprise. He stressed the distinction between actual class consciousness and ‘ascribed’ class consciousness—the attitudes that the proletariat would have if they were aware of all the facts. Lukács here emphasized \*dialectics over \*materialism, and made concepts such as \*alienation and reification central to his theory well before the publication of some of Marx’s key earlier writings vindicated this interpretation. Later in his long life, which he divided between his native Hungary and the Soviet Union, Lukács became the leading Marxist theoretician of literature, before producing a monumental work on social ontology in his last decade.

D.McL.

\*Marxist philosophy.

G. Parkinson (ed.), *Georg Lukács: The Man, his Work, and his Ideas* (London, 1970).

**Łukasiewicz, Jan** (1878–1956). Logician who is the author of many innovative ideas in logic, including \*many-valued

logic, bracketless or ‘\*Polish’ notation, a formal axiomatization of \*syllogisms including modal syllogistic, and the historical recognition of Stoic logic as the original form of modern propositional logic. Łukasiewicz intended three-valued logic to reflect Aristotle’s ideas about future contingent propositions in *De interpretatione*. If ‘There will be a sea battle tomorrow’ is true today then the sea battle’s occurrence seems predetermined or inevitable; if false then its non-occurrence seems inevitable. But by the principle of bivalence every proposition is either true or false. To ensure the contingency of future events Łukasiewicz proposed that future-tense propositions be considered neither true nor false, but instead take a third truth-value ‘indefinite’ or ‘possible’. Where 1 is ‘true’, 0 ‘false’, and  $\frac{1}{2}$  ‘indefinite’, Łukasiewicz’s three-valued logic is defined by the following matrices:

$\supset$	1	$\frac{1}{2}$	0	$\sim$	
1	1	$\frac{1}{2}$	0	0	0
$\frac{1}{2}$	1	1	$\frac{1}{2}$	$\frac{1}{2}$	$\frac{1}{2}$
0	1	1	1	1	1

### Lumber of the Schools.

‘Tis you must put us in the Way;  
Let us (for shame) no more be fed  
With antique Reliques of the Dead,  
The Gleanings of Philosophy,  
Philosophy! the Lumber of the Schools. . .

(Jonathan Swift, ‘Ode to Sir William Temple’, line 20)

Virtue, says Swift in this over-long ode, was broken at the Fall, and ancient wisdom will never reconstitute it. To ‘dig the leaden Mines of deep Philosophy’ only produces lifeless leavings—a perverse confirmation, apparently, of Plato’s theory of recollection. The poem’s almost existentialist excoriation of academia is perhaps connected with Swift’s having obtained his degree only by ‘special grace’ three years before writing it. Its dedicatee, Sir William Temple, who was kind enough to employ him, is declared to be the one person fit to discover ‘Virtue’s Terra Incognita’.

J.O’G.

**Luther, Martin** (1483–1546). German theologian, Professor of Philosophy and then of Theology at Wittenberg, leader of the Protestant Reformation. Luther is notorious among philosophers for speaking of \*reason as ‘the Devil’s Whore’, which must be sacrificed as the enemy of God. He sees reason as having being corrupted by original sin, and therefore incapable of coming to a true estimate of the relation between God and man. The Mosaic law, which crushes men but which would at the same time bind God to a human contract, is the fruit of reason. Salvation can only come through the divine gift of grace and revelation. While in human affairs reason ought to be followed, in the

theological realm it must stand aside for the rebirth afforded by grace, confining its efforts to the elucidation of what God reveals through Scripture. Historically and theologically Luther is a pivotal point in the tradition leading from Paul's doctrine of justification through faith and Augustine's two cities through to the anti-rationalism of Karl Barth. A.O'H.

B. A. Gerrish, *Grace and Reason: A Study in the Theology of Luther* (Oxford, 1962).

**Lycan, William G.** (1945– ). Lycan develops a \*truth-conditions theory of sentence-meaning in *Logical Form and Natural Language*, and assays the standard kinds of objections to truth-conditions semantics. These arise from facts about vagueness, indexicality, tense, and other features of language in use, e.g. presupposition and conversational implications of what one says. Lycan's truth-theoretic semantic theory is applied to fundamental questions in psycholinguistics and in an account of linguistic and cognitive abilities.

In *Consciousness* he develops a functionalist theory of the nature of mind, 'homuncular functionalism'. This view emphasizes the levels at which psychological and cognitive accounts of thought and action find application, from the surface level of common sense to the level at which representations are attributed to cognitive systems housed in the brain and thence to subcognitive systems which carry out semi-intelligent roles the execution of which constitute our psychological lives. *Judgement and Justification* contains an application of this form of \*functionalism to the nature and role of belief. Here and elsewhere Lycan defends the representational theory of mind.

D.G.

William G. Lycan, *Consciousness* (Cambridge, Mass., 1987).

— *Judgement and Justification* (Cambridge, 1988).

**lying.** Some church fathers held that lying, almost always prohibited, is occasionally right, as when only thus can the community be protected from invasive inquiries by persecutors. Augustine argued that lying is always prohibited and Aquinas agreed. Later moral philosophers divide

similarly. Kant judged that a lie violates a duty to oneself and to others, because rational beings owe each other truthfulness in communication. Mill severely condemned almost all lying as injurious to human trust and therefore to the social fabric, but judged it right on rare occasions, as when only thus can some great and unmerited evil be averted. An adequate treatment of lying would have to consider whether and how it violates the norms governing speech-acts of assertion and what kind of injury it involves to the trust which constitutes central human relationships. A.MAGI.

\*absolutism, moral; self-deception; noble lie.

Sissela Bok, *Lying* (New York, 1978).

**Lyotard, Jean-François** (1924– ). An exponent of so-called \*'post-modernism', lately much in vogue among cultural and literary theorists. His arguments may be summarized briefly as follows. Our epoch has witnessed the collapse of all those grand 'metanarrative' schemas (Kantian, Hegelian, Marxist, or whatever) that once promised truth or justice at the end of inquiry. What we are left with is an open multiplicity of 'heterogeneous' or strictly incommensurable \*'language-games, each disposing of its own immanent criteria. This requires that we should not presume to judge any one such discourse according to the standards, values, or truth-conditions of any other, but should instead seek to maximize the current range of 'first-order natural pragmatic' narratives. Moreover, anyone who rejects these premisses—who seeks (like Jürgen Habermas) to uphold the values of enlightenment, critique, and rational consensus as against Lyotard's ill-defined notion of 'dissensus' as the touchstone of democratic freedom—must *ipso facto* be arguing from a 'totalitarian' or rigidly doctrinaire standpoint. What this amounts to, in short, is a *mélange* of Wittgensteinian, post-structuralist, and kindred ideas presented in an oracular style that raises bafflement to a high point of principle. C.N.

Jean-François Lyotard, *The Postmodern Condition: A Report on Knowledge*, tr. Geoff Bennington and Brian Massumi (Minneapolis, 1983).

# M

**Mach, Ernst** (1838–1916). Austrian scientist, several times nominated for the Nobel Prize. He made important contributions to optics (Doppler effect), acoustics (shock waves), physiology (Mach bands), and the history and philosophy of \*science. Writing in a vivid style he recommended the ‘bold intellectual move’, emphasized that sensations and physical objects were ‘as . . . preliminary as the elements of alchemy’, and criticized the scientists of his time (the defenders of the theory of relativity included) for neglecting this aspect. Making physics a measure of reality, they blocked the unification of physical, biological, and psychological phenomena. Most of Mach’s demands have by now become commonplace (\*evolutionary epistemology, \*constructivism, \*complementarity), though not always in a way Mach would have enjoyed. P.K.F.

Bibliography, literature, and evaluations in R. S. Cohen and R. J. Seeger (eds.), *Ernst Mach, Physicist and Philosopher* (Dordrecht, 1970); P. K. Feyerabend, *Studies in the History of the Philosophy of Science* (1984); J. T. Blackmore, *Ernst Mach* (Los Angeles, 1972).

**Machiavelli, Niccolò** (1469–1527). Italian statesman and political theorist who turned political thought in a new direction. Whereas traditional political theorists were concerned with morally evaluating the state in terms of fulfilling its function of promoting the common good and preserving justice, Machiavelli was more interested in empirically investigating how the state could most effectively use its \*power to maintain law and order (political science). His famous claim that the end justifies the means also seems to advocate the use of immoral means to acquire and maintain political power. However, what he seems to mean by this is that sometimes in order to maintain law and order it is necessary for a ruler to do things that, considered in themselves, are not right, but which, considered in their context, are right because necessary to prevent great evils. R.D.M.

\*ends and means; dirty hands.

N. Machiavelli, *The Discourses* (1513).  
— *The Prince* (1513).

**MacIntyre, Alasdair C.** (1929– ). MacIntyre is best known for the work he has produced since 1980, although there was significant output before then. His work is primarily concerned with morality, especially with the historical

changes which have shaped moral belief and practice, and also shaped theorizing about morality. Starting with his early *A Short History of Ethics* (London, 1966), MacIntyre has eschewed the close, often narrow, analytical and linguistic work which characterized much academic moral philosophy, preferring to explore the significance of moral ideas (and shifts in moral vocabulary) against the wider background of historical, cultural, sociological, religious, and other influences forming society and the individual. This has given his work an unusual breadth of reference, and has made it more accessible to non-professional persons interested in understanding our moral predicament.

It is central to MacIntyre’s more recent work, as set out in three substantial books *After Virtue* (London, 1981), *Whose Justice? Which Rationality?* (London, 1988), and *Three Rival Versions of Moral Enquiry* (London, 1990, the Gifford Lectures given at the University of Edinburgh in 1988), that what many recent moral philosophers have presented as timeless truths about the nature of moral discourse or the foundations of moral judgement are nothing of the kind. The representation of the individual as a sovereign chooser who by his or her own decision determines the values to live by is, in fact, the obscure manifestation of massive dislocations in society, and the dissolution of social ties and modes of life which alone can give dignity and meaning to human activity. MacIntyre has argued for an attempt to recover an Aristotelian way of viewing the purposes and activities central to human realization and fulfilment.

Born in Scotland and largely educated in England, MacIntyre has worked in America since 1970. N.J.H.D.

\*narrative; histories of moral philosophy.

**Mackie, John L.** (1917–81). Born in Australia, lived and taught in Australia and New Zealand before moving to England, teaching finally at Oxford University. He was the author of six books and numerous papers on a wide range of topics, especially in metaphysics, ethics, philosophy of religion, and the history of philosophy. Mackie was influential for his ‘error theory’ of moral values—the view that there are no objective moral values, yet ordinary moral judgements include an implicit claim to objectivity, and hence are all false. The objectivity-claim is at least partly

prescriptive in pointing to reasons for performing certain actions regardless of one's wants. He thinks it possible and desirable to jettison this objectively prescriptive element in moral discourse and to continue using the same moral terms, not necessarily accepting previously held moral views, but (re)inventing morality as a device for counteracting limited sympathies, and giving it whatever content we think best serves this purpose.

In his comprehensive study of \*causality, which draws extensively on historical sources, Mackie distinguishes an analysis of causation 'as it is in the objects' from an analysis of our ordinary concept of causation, offering a regularity analysis for the former, and a \*counterfactual analysis for the latter, supplementing each with an account of the direction of causation. The regularity analysis is his memorable development from Mill, that a cause is an 'inns' condition of an effect—an insufficient but necessary part of an unnecessary but sufficient condition. His counterfactual analysis is that a cause is necessary in the circumstances for an effect, such counterfactual claims being, according to him, strictly speaking neither true nor false.

**Macmurray, John** (1891–1976). British philosopher who held chairs in London and Edinburgh. He maintained that the error of traditional philosophy consisted in making its starting-point the self as subject—'I think'. Macmurray proposed as the starting-point the self as agent—'I do.' He argued that thought is derivative from action, and that the identity of the self as agent is constituted by its relationships with other agents in communities. His belief that we are members not just of the human community but of the natural world gives his thinking a contemporary flavour reminiscent of much 'applied philosophy'. He held that religion is distinctive of personal life, in that it celebrates and expresses the unity of persons in fellowship. He had a large following among the general public through his many broadcasts in the 1930s and 1940s which illustrated his desire, expressed in his Gifford Lectures, to 'transfer the centre of gravity in philosophy from thought to action'.

**macrocosm and microcosm.** This pair of terms encapsulates the idea that a systematic analogy can be drawn between larger- and smaller-scale phenomena, particularly between the cosmic and the human. Thus it may be supposed that astronomical bodies bear the same mutual relations as do the parts of an individual animal body, or that the universe is ordered in the way that a human society is. The terminology may have been introduced in the fifth century bc by Democritus; but such analogies are also characteristic of Pythagorean, Platonic, and Stoic

philosophy. They are not justified by argument, but they may have heuristic value as facilitating exploration of what would otherwise be hard to access for investigation. Plato certainly supposed natural science could be prosecuted effectively only by one who appreciated the element of value which was implicit in the designation of the universe as *kosmos*, 'order'.

J.D.G.E.

A recent discussion of \*Pre-Socratic philosophy which takes the analogy very seriously is A. Capizzi, *The Cosmic Republic* (Amsterdam, 1990).

**Madhva** (13th century AD). Dualist commentator on \*Vedānta, part of the revealed scriptures of the Hindus. Madhva defends the reality of the external world, including infinitely divisible space, time, souls, bodies, and their unique particularities. Warning that you cannot adore God if you think that you are identical with him, he also celebrates all five differences denied by the idealist monists, namely, God ≠ the world, God ≠ I, I ≠ you, I ≠ the table, the table ≠ the chair. Such pluralism provoked astute rebuttals from the monists and counter-replies from the dualists for centuries. Distinctions, according to Madhva, are objective negative facts witnessed *directly* by the self rather than perceived through outer or inner sense. His rich epistemology tackles issues such as 'If knowledge is self-validating, how can one tell its claim from an error's claim to knowledge?' Liberation, attainable only through devoted worship of the personal God, brings blissful proximity to, but never equality with, God, though some sinners (non-dualists?) remain eternally damned!

S. S. Raghavachar, *Dvaita Vedanta* (Madras, 1977).

**magnitude.** The particular amount, degree, or extent of a quantitative property. Thus 1 metre and 10 metres are different magnitudes of length. Magnitudes are represented mathematically by scales of \*measurement, which assign a unique numerical value to each magnitude of the quantitative property. Scales are typically (but not exclusively) defined by selecting a standard whose magnitude becomes the unit, 1. The \*number assigned to any other magnitude is determined by how many times greater it is than that of the standard. Thus a length ten times greater than that of the standard metre is represented by 10 on the metric scale. Magnitudes are measured by empirically comparing objects directly or indirectly to the standard.

**Maimonides, Moses** (1135–1204). Jewish philosopher, jurist, physician. Exiled from his native Cordoba by the Almohad conquest (1148), Moses ben Maimon (also known as Rambam) settled finally in Egypt, where he became physician to Saladin's wazir. His Arabic *Commentary on the Mishnah*, his *Book of the Commandments*, and his fourteen-volume Code of Jewish Law, the *Mishneh Torah*,

written in Mishnaic Hebrew, established his unparalleled authority in Jewish law. His *Guide to the Perplexed* (written in Arabic), addressed to a philosophically minded disciple, deconstructs the seeming anthropomorphisms of prophetic language to reveal the underlying logic of God's absolute perfection. Neither biblical creationism nor Aristotelian eternalism is demonstrable, it argues. But creation is more probable, and preferable theologically, since it can explain the difference God's act makes in the world and can rely on God's freedom to explain how multiplicity emerges from sheer divine simplicity. Revelation accommodates its recipients intellectually and culturally. Its fundamental demand is that we pursue the human likeness to God by perfecting humanity in ourselves—minimally, by living in peace with one another, as we might have known without revelation. What distinguishes God's law is its further expectation that we perfect ourselves morally and intellectually, improving our character through such exercises as reloading our enemy's fallen ass (Exodus 23: 5); and improving our minds by seeking contact with God through study of nature, mathematics, and human and divine institutions, and contemplating God's perfection. Prophets are (as al-Fārābī claimed) philosophers whose imaginative gifts afford the rhetoric, symbol, and story that transform abstract ideas and values into laws, rituals, and beliefs, allowing non-philosophers access to the moral and intellectual fruits of philosophic insight. Philosophy is universal; but the moral prerequisites of intellectual receptivity and the material prerequisites of prophetic creativity (confidence, contentment, a fertile and wholesome imagination, fostered by appropriate linguistic and cultural traditions) make true prophecy rare. Pagan religions are primitive, superstitious, or perverse; but Islam and Christianity, which have spread monotheism through the world, preparing for the Messianic age, are derivative from Israelite prophecy.

**Maine de Biran, François-Pierre** (1766–1824). French philosopher and politician. Maine de Biran is an empiricist philosopher because he holds that all knowledge is acquired through experience. However, while the classical British Empiricists tend to the view that inner experience is made possible by outer experience, Maine de Biran reverses this picture. For example, while Locke holds that acquaintance with sensations is a necessary condition for the operations of reflection, Maine de Biran holds that unless we were acquainted with the contents of our own minds we could not have knowledge of the external world. He claims that there is a *sens intime* (inner sense) or *lumière intérieure* (inner light) through which each person is aware of his own mental states, especially states of 'croyance' (belief), and aware of his own 'effort voulu' (voluntary physical action).

It is not clear that acquaintance with one's own mental states is a sufficient condition for knowledge of anything else, but it could be argued that Maine de Biran has isolated a necessary condition for knowledge if, for example,

a person's knowing that they know that *P* is a condition for their knowing that *P*. This claim is, however, contentious.

**Mair, John (or John Major)** (1467–1550). Leader of a group of philosopher-logicians, many of them Scots, active in Paris and Scotland in the decades before the Reformation. Educated at Paris, where he rose to become Professor of Theology, he was subsequently Principal of Glasgow University. During his last years, while Provost of St Salvator's College, St Andrews, he was the theology teacher of John Knox. He wrote numerous treatises on formal logic, presenting in great detail a system in direct line of descent from the logic of William Ockham. Many things he had to say on \*supposition and \*quantification, particularly on sentences containing several quantifiers, repay study.

**Maistre, Joseph Marie de:** see de Maistre.

**Malcolm, Norman Adrian** (1911–90). One of the most distinguished of Wittgenstein's pupils and the main conveyor of his ideas to the USA, where Malcolm taught for many years at Cornell. His writings were primarily in epistemology and philosophy of mind. They are distinguished not only by force of argument, but also by lucidity and simplicity of expression. His book *Memory and Mind* is the finest on that subject, submitting both classical empiricist and modern neurological representationalist theories of memory to devastating criticism. In *Consciousness and Causality*, he developed Wittgenstein's ideas on that theme, undermining introspectionist and materialist theories of \*consciousness alike. His *Ludwig Wittgenstein: A Memoir* has rightly been called 'a classic of biographical literature', and his last book, *Nothing is Hidden*, is a valuable study of Wittgenstein's later philosophical criticisms of his own earlier work.

G. H. von Wright, 'Norman Malcolm', *Philosophical Investigations* (1992).

**Malebranche, Nicolas** (1638–1715). Highly regarded in his own day, and long regarded in the francophone world as a philosopher of major importance, the author of *The Search After Truth* (*De la recherche de la vérité* (1674–5)) and the *Dialogues on Metaphysics and Religion* (1688) has only quite recently been brought in from the cold by English-speaking philosophers. The doctrine for which he is chiefly remembered, the theory of \*occasionalism, seems bizarre to many modern readers who tend (following the damning verdict of Leibniz) to see it as a blundering piece of ad hocery: an attempt to plug a logical gap in Cartesian \*dualism (its inability to explain how mind and body,

being incompatible substances, can interact causally) by dumping on to the Deity the task of obligingly ensuring that my jaw moves for me when I want to eat a meal. But in fact Malebranche invokes the efficacious will of God for all causal transactions, not just psychophysical ones. 'A true cause, as I understand it', he wrote in the *Recherche*, 'is one such that the mind perceives a necessary connection between it and its effect'; and if causation implies necessary connection, then the divine will must be involved in all causality, since true necessity applies only to events willed by God (it being a contradiction that anything willed by an omnipotent being should not come about).

In the Malebranchian universe individual objects and events are thus stripped of their causal powers. Talk of causal 'influence' or 'transfer of force' is only a *façon de parler*. In reality, what we call the cause is merely the *occasion* for God to exercise his efficacious will. Malebranche thus radically rejects the scholastic conception whereby each kind of object behaved the way it did in virtue of its specific nature or essence, with properties being 'transmitted' from cause to effect. In the new Cartesian conception of physics (which Malebranche strongly supports), the idea of some kind of essential connection or similarity between causes and effects is ultimately redundant; all that is needed is a specification of initial conditions, and a set of mathematical equations describing the (divinely decreed) regularities that in fact obtain. Seen in this light, Malebranchian occasionalism can be viewed as a bridge theory between Cartesian and the later Humean account of \*causality.

Malebranche subscribed to what is commonly called a \*representative' theory of perception, arguing that 'we do not perceive objects external to us by themselves' since 'it is not likely that the soul should leave the body to stroll about the heavens to behold the sun and the stars'; when we perceive the sun, what we see is 'not the sun but something intimately joined to our soul, which I call an "idea"'. In developing his account of the direct objects of perception, Malebranche went on to advance a distinctive theory of \*ideas, summed up in the slogan that 'we see all things in God'. Condemned by Locke as 'an opinion that spreads not, and is like to die of itself', Malebranche's theory at least tidies up some of the ambiguities in Descartes's broad use of the term 'idea'. Malebranche is careful to distinguish the mental phenomena he calls 'sentiments' (feelings or sensations) which are purely subjective and lack any intentionality (do not have representational content), from what he calls ideas in the strict sense; the latter are abstract objects of cognition whose presence 'in God' may be viewed as a graphic way of conveying their independence from any subjective mode of consciousness. The resulting theory has the merit of making a firm distinction between the province of psychology and that of logic.

A further important subject on which Malebranche takes issue with \*Cartesianism concerns the alleged transparency of the mind—its supposed perfect internal awareness of its own nature as a 'thinking thing'. Descartes has achieved this result by the dubious move of subsuming a

large number of different operations (understanding, willing, imagining, sensing) under the single label 'thought'. Malebranche argues persuasively that the various possible modifications of consciousness are not clearly and distinctly deducible from a known essence (in the way in which the modifications of matter are deducible from the nature of extension); further, introspection can reveal only the presence of conscious activity, not the essential nature of the thinking self: 'to myself, I am but darkness, and my own substance seems something which is beyond my understanding' (*Christian Metaphysical Meditations* (1683)).

**Mandeville, Bernard** (c.1670–1733) was trained in medicine in his native Holland, and settled in England in the early 1690s. He was a polemical writer, and the principal target of his polemics was hypocrisy. For Mandeville, behind the mask of respectability and virtue lay a Hobbesian egoism, which had to be faced up to in any through-going moral, political, and economic theory, and he was prepared to follow the consequences for all three of these areas. His most important work, *The Fable of the Bees*, began as a 433-line poem in 1705, but by the sixth edition of 1729 it had turned into a substantial treatise. It is an extremely witty and provocative book, if somewhat chaotic. Mandeville imagines a hive of bees each going about their own business in their own way and argues that their success is due as much to vice and fraud as it is to industry and virtue: all these are necessary for a flourishing market society, and indeed they mirror the egoistic qualities of the individuals who make up this society.

**Manichaeism.** This widely influential gnostic religion of late antiquity, founded and spread by the Persian Mani (216–77), taught a radical dualism of good and evil that is metaphysically grounded in coeternal and independent cosmic powers of Light and Darkness. This world was regarded as a mixture of good and evil in which spirit represents Light and matter represents Darkness.

Manichaeism was severely ascetic. Before his conversion to Christianity, Augustine was an adherent of Manichaeism.

H. J. Paton, *Kant's Metaphysic of Experience* (New York, 1936).

**Mannheim, Karl** (1893–1947). Hungarian-German-British philosopher, father of the sociology of knowledge. He was originally a member of the Sunday Circle in Budapest, led by Georg Lukács, which opposed \*Kantianism, \*positivism, and individualist liberal \*capitalism, was nostalgic for the Middle Ages, and held a strongly Platonic view of psychic life and art. After his emigration to Germany in 1919 Mannheim tried to initiate a theoretical social science that could replace political philosophy. Social thought expresses rather than explains human life. Implicitly, this relegates political philosophy to the rank of a half-conscious projection of social aspirations. The task of theory is therefore to understand what people think about society rather than propose hypotheses about it. This did not prevent Mannheim from expressing his own political preferences in favour of an *étatiste* (statist-welfarist) democracy led by rational planners and scientists.

G.M.T.

His main works are:

*Ideology and Utopia* (London, 1929).

*Man and Society in an Age of Reconstruction* (London, 1940).

**mantra.** Literally, words which if meditated upon can save us. A subsection of the ritualistic part of the orally preserved sacred texts called Veda was also called 'Mantra' because it consisted of revealed holy words, often addressed to nature-gods, chanted during sacrificial acts. Subsequently, the term signified any mystic syllable or strings thereof which were to be repeated, aloud or subvocally or mentally, often while keeping count on rosary beads. 'Om' is such a syllable, often identified with the word-God which became the world. Elaborate metaphysical and semantic theories developed to support the putative identity between the name and the named which went hand in hand with the worship of sound.

'Mantra', in Mircea Eliade (ed.), *Encyclopedia of Religion*, ix (London, 1987).

**many questions fallacy.** Illustrated by 'Have you stopped beating your wife?', the fallacy was first noticed by Aristotle. It lies not in the question but in what is inferred from

the answer. Putting *B* for 'I have been a wife-beater' and *S* for 'I have stopped', then a negative answer is equivalent to '(*B* and not-*S*) or (not-*B* and not-*S*) or (not-*B* and *S*)'. If the questioner infers that he may disregard one or more of these alternatives, his inference is transparently invalid.

J.WOO.

John Woods and Douglas Walton, *Fallacies: Selected Papers 1972–1982* (Dordrecht, 1989).

**many-valued logic.** Logical systems in which formulae may be assigned truth-values other than merely 'true' and 'false'. The term is often used more narrowly to refer to many-valued *tabular* logics, in which the truth-value of a formula is determined by the truth-values of its subformulae. (This characteristic distinguishes many-valued logics from standard \*modal logics.)

The idea that logic ought to countenance more than two truth-values arose naturally in ancient and medieval discussions of \*determinism and was re-examined by C. S. Peirce, Hugh MacColl, and Nikolai Vasiliev in the first decade of this century. Explicit formulation and systematic investigation of many-valued logics began with writings of Jan Łukasiewicz and Emil Post in the 1920s and D. Bochvar, Jerzy Stupecki, and Stephen Kleene in the late 1930s. There has been some renewed interest in the subject recently, because of perceived connections with programming languages and artificial intelligence.

Łukasiewicz's work is inspired by a view of 'future contingents' often attributed to Aristotle. There is a sense in which whatever happens in the present or past is now unalterable. This idea sometimes finds expression in the doctrine that sentences now true are unalterably true and those now false are unalterably false. But, although it seems that 'There will be a sea battle tomorrow' is now either true or false, it does not seem *unalterably* true or *unalterably* false. Considerations like this led Łukasiewicz to adopt the view that future contingent sentences are not either true or false, but have an *intermediate* truth-value, 'the possible'. He constructed a formal language, taking the conditional ( $\rightarrow$ ) and negation ( $\neg$ ) as primitive connectives and false (0), possible ( $\frac{1}{2}$ ), and true (1) as truth-values. Truth-values of compound formulae are determined by the tables below.

<i>A</i>	$\neg A$	<i>A</i>	<i>B</i>	<i>A</i> $\rightarrow$ <i>B</i>
1	0	1	1	1
$\frac{1}{2}$	$\frac{1}{2}$	1	$\frac{1}{2}$	$\frac{1}{2}$
0	1	1	0	0
		$\frac{1}{2}$	1	1
		$\frac{1}{2}$	$\frac{1}{2}$	1
		$\frac{1}{2}$	0	$\frac{1}{2}$
		0	1	1
		0	$\frac{1}{2}$	1
		0	0	1

To obtain a many-valued logic from a table like this, one specifies certain truth-values as designated. The argument from set *I* to formula *A* is logically valid if *A* gets a designated truth-value under any assignment in which

all the members of  $\Gamma$  do.  $A$  is logically true if it gets a designated value under any assignment. For example, if figure 1 and  $\text{fi}$  are both designated, then  $(P \rightarrow \neg P) \rightarrow \neg P$  is a logical truth by these tables; if (as Łukasiewicz intended) only figure 1 is designated, then it is not. With Łukasiewicz's understanding that  $P \vee Q$  abbreviates  $(P \rightarrow Q) \rightarrow Q$ , the formula in question expresses the law of excluded middle.

It is doubtful that these (or any) truth-tables capture precisely the kind of possibility exhibited by future contingents. Why, for example, should 'If there won't be a sea battle there will be one' be considered true, while 'If  $2 + 2 = 4$  then there will be a sea battle' is merely possible? Nevertheless, Łukasiewicz's original system has been generalized, axiomatized, reinterpreted, modified, and otherwise studied.

Łukasiewicz himself considered generalizations permitting more than one intermediate truth-value:  $\neg A$  gets truth-value 1 minus the truth-value of  $A$ ;  $A \vee B$  gets the greater of the truth-values of  $A$  and  $B$ . Other many-valued systems have been motivated by the idea that additional truth-values might express the notion of a proposition's being paradoxical (its truth implying its falsity and its falsity implying its truth), of its having uncomputable truth-value, of its being approximately true, and of its having failed presuppositions of various sorts. Most of the systems considered generalize classical logic in the sense that, if truth-values other than 0 and 1 are dropped, classical logic is obtained.

Post formulated a technically advantageous system in which Łukasiewicz's negation is replaced by a 'cyclic' negation—the truth-values are 0, 1, . . . ,  $m$  and the truth-value of  $\neg A$  is 0 if the truth-value of  $A$  is  $m$  and it is  $1 +$  the truth-value of  $A$  otherwise. Post's negation and disjunction are truth-functionally complete: any connective in a finite-valued logic (including the conditional and negation of Łukasiewicz's three-valued logic discussed above) can be defined from them. This result has practical significance, for just as the formulae of classical propositional logic correspond to logic circuits, the formulae of  $m$ -valued logics correspond to switching-circuits in which inputs and outputs can assume  $m$  states. More recent investigations have examined the model theory and proof theory of general many-valued logic and of continuous logic, in which the truth-values are assumed to have a topological structure. It is enlightening to see certain results of classical logic proved in a more general setting. S.T.K.

The works cited below are a small sample of the large and varied literature on the subject, but they do contain references to much of the rest.

**Marcel, Gabriel** (1889–1973). French philosopher, playwright, and literary and music critic who converted to Roman Catholicism in 1929. Marcel (despite, in common with the other Existentialists, repudiating the title 'Existentialist') provides Christian solutions to existentialist problems.

In *Être et avoir* (Being and Having (1935)) Marcel draws a distinction between one's being and one's life. 'I am' is existentially prior to 'I live' (meaning, approximately, that being is a necessary condition for living but not vice versa). Marcel takes this as a ground for believing that my life was 'given to me', a fact which is sufficiently impressive to suggest the existence of God.

In a fashion analogous to Heidegger's use of 'being-toward-death' Marcel notes that one's being is at every moment 'in jeopardy' and concludes that the only way to understand the 'ordeal' of living is to have faith in one's being 'beyond' one's life, that is, surviving one's death.

Marcel's existentialist metaphysics faces the difficulty that from the fact that I am not numerically identical with the life that I lead it does not logically follow that I pre-date or post-date that life. Similarly, from the fact that life is a senseless ordeal without God it does not logically follow that God exists. However, neither of these objections is strong enough to show that the central tenets of Marcel's theological \*existentialism are false.

In 'Existence and Freedom' (1946) Marcel criticizes Heidegger, Jaspers, but especially Sartre for their 'dogmatic negativism' (their \*pessimism about human prospects), a charge Sartre attempts to repudiate in his maligned but brilliant 1946 speech 'L'Existentialisme est un humanisme'.

**Marcus, Ruth** (1921– ). Ruth Marcus is known as an early pioneer of \*modal logic, the logic which formalizes the philosophical notions of possibility and necessity. Marcus, originally Ruth Barcan, was instrumental in exploring modal logics with quantifiers and assessing the philosophical implications of mixing modality and quantification. A well-known formula in quantified modal logic, the \*Barcan formula, bears her name; in one version it states that if everything necessarily bears a certain property, then it is a necessary truth that everything bears it. Marcus has also done a great deal of work in other areas of logic, most notably on the substitutional interpretation of quantifiers, an approach which takes quantifiers to range not over ordinary objects but over linguistic symbols (in a prescribed formal language) which produce true substitution instances. G.F.M.

R. Marcus, *Modalities: Philosophical Essays* (Oxford, 1993).

**Marcuse, Herbert** (1898–1979). One of the most original and provocative non-Soviet Marxists of the century, Marcuse received a doctorate in literature (1922) but soon became attracted to Heidegger's philosophy with its focus

on the individual as thrown into a world of objects and populated with others. But the writings of the young Marx convinced Marcuse that a genuine theory of individuality must take into account prevailing socio-economic structures. Joining the \*Frankfurt School in 1933, he contributed to the development of the dialectical criticism characteristic of the school: major concepts were analysed and traced to their material origins, and then reconstructed to show their altered political functions.

His post-Second World War writings, however, present his most characteristic proposals and social critique. Freudian psychology provided a theory of human instincts, which are repressed under capitalism but which, when liberated, can be the basis for a life of sensuousness, playfulness, peace, and beauty. This liberation requires a total transformation of present society: technology would be utilized to abolish poverty and provide for abundance; there would be a different relation to nature in which art and production are unified; the sexes and generations would overcome artificial constraints, and a new kind of person with advanced sensibilities would appear.

Marcuse's optimism for the actual achievement of these transformations was at its lowest in *One Dimensional Man* (1964); the student rebellions of the 1960s gave him renewed hope (e.g. *Essay on Liberation* (1969)). *Counter-revolution and Revolt* (1972) retreats from advocating revolutionary violence and confrontation and recommends working for change within the system. *The Aesthetic Dimension* (1978) argues that the sensuous appearance of beauty in the artwork preserves the memory of a liberated way of living and so escapes the domination of the present, repressive order.

Marcuse's revised Marxism provides both a broad critique of advanced capitalist society and utopian proposals for a post-capitalist world.

**Maritain, Jacques** (1882–1973). The best-known neo-Thomist of the twentieth century. Having become dissatisfied with secularism and scientism, at the age of 24 Maritain converted to Roman Catholicism and spent the following sixty or so years elaborating a comprehensive philosophical system based on the writings of Thomas Aquinas and of his scholastic followers, most especially John of St Thomas (1589–1644). His major contributions are to epistemology (*The Degrees of Knowledge* (1932)), social philosophy (*The Person and the Common Good* (1947)), and aesthetics (*Art and Scholasticism* (1920)). Maritain is a staunch realist in metaphysics and epistemology: he advocates ontological pluralism, claiming that there are various non-reducible levels of existence, e.g. the physical, the biological, the psychological, the social, and the spiritual; and similarly he insists upon the diversity of our ways of knowing reality, emphasizing the role of

rational and creative intuition and thereby linking metaphysics and aesthetics.

**markets.** Originally, places at which independent sellers, who were usually also the producers, made their goods available to consumers coming there specifically to shop for them; terms of exchange (prices) were characteristically established for each individual transaction by haggling. The term 'market' is currently used to refer not only to particular local places but to the entirety of \*free exchanges of goods and services within a society, by contrast with the sphere in which exchanges are enforced by an authority external to the transfer of goods or services. The term 'market' is thus usually used interchangeably with 'free market', the implication being that prices are set by agreement between buyers and sellers. In this more abstract sense, the idea of the market is defined by the set of socially understood or enforced rights of participants: an arena of transfers is a market in so far as the disposition of the goods and services in question is at the will of voluntarily acting individuals or co-operating sets of individuals, terms of exchange (prices) being freely negotiated. Prices are then determined by effective supply and demand on the part of participants.

Constraints imposed by governments, requiring that goods or services transfer on certain terms even though one or both parties would not freely exchange on those terms, is called 'intervention in the market'. \*Socialism involves collective, political control, rather than market determination, of much economic activity, especially of capital (productive) goods; \*capitalism leaves the allocation of capital as well as all consumer goods to private control (ownership). There is extensive political and moral discussion about the proper role of markets in society, ranging from those who think that the allocation of all goods and services should be determined by free market mechanisms (\*'libertarianism') to those who think that none of them should ('collectivism'). The latter, which Stalinism approximated, is defended by no one. The former, or close approximations, has many advocates, due in part to its theoretical elegance and in part to the enormous empirical success of markets. The chief problem for the unlimited advocacy of market methods is what to do about externalities—involuntary effects (especially negative ones) on persons outside the transaction, as with, say, an assassination contract; and especially about public goods, which are roughly externalities, such as pollution, whose involuntary costs are imposed on miscellaneous others rather than some few specific others, making it very difficult to allocate costs and benefits precisely.

For a fascinating radically pro-market book, see David Friedman, *The Machinery of Freedom*, 2nd ed. (La Salle, Ill., 1989). For a good,

brief discussion of many basics, see Allen Buchanan, *Ethics, Efficiency, and the Market* (Totowa, NJ, 1985).

**markets and the public good.** Markets are places or networks where buyers and sellers exchange goods or services for money. Capitalism is the economic system whereby the mass production of goods to be sold in markets is financed by private capital for individual or corporate profit. According to the 'law' of supply and demand, market price rises with the scarcity of items for sale and falls with their abundance; current price thus provides sellers with information enabling them to distribute their resources for maximum profit. This allows for an efficient allocation of resources based entirely on decisions of purchasers and without government or other intervention. A market economy also encourages innovation and individual initiative as incentives for profit. Mass production makes technologically advanced, inexpensive goods widely available, gradually improving the general welfare.

Yet a market economy benefits most those sufficiently well-off to buy its products; those with few financial resources are seriously disadvantaged. Those born into poverty are likely to continue to suffer from economic deprivation. Secondly, unavoidably, there are long periods of unemployment after a period of economic contraction; and market solutions to issues such as inflation, environmental destruction, and pollution are also problematic. Finally, capitalism distributes wealth very unevenly, with investors and management highly rewarded by profits from sales, while workers are limited to labour for wages often lowered by competition among labourers for jobs. This tends to create a small wealthy class with great economic power in contrast to a large number of relatively impoverished, powerless workers.

Liberals try to retain the advantages of capitalism by advocating that government protect basic civil rights but also provide medical services, education, transportation, access to positions of power, and a clean, sustainable environment. Guaranteeing broad rights and also a just distribution of wealth and services is to counterbalance market inequities.

Socialists contend that even under liberal democracy the wealthy will inevitably have disproportionate economic and political power. Their solution is to eliminate or reduce the market system, either gradually through general education and democratic means or quickly through revolution. An economy with state control of production and distribution of goods for the benefit of all will retain the advantages of industrialism without the injustices of the market.

**marriage.** Contractual union for the purpose of raising a family, or, derivatively, for the sex, domestic security, etc.

associated with this. By contrast with the biological phenomenon of mating, marriage is, to taste, 'made in heaven' or instituted by human societies. The former view offers a theological justification for some particular conception of marriage, e.g. as an indissoluble union constituting the only permissible locus of sexual activity. The latter view emphasizes the variety of forms of marriage, e.g. polygamy and polyandry, and typically offers justifications of these in terms of their social function. Forms of marriage may thus be criticized as dysfunctional: so Plato regards monogamous marriage carrying parental responsibilities as a threat to social solidarity, and he recommends instead that wives and children should be shared in common. Other criticisms of marriage complain of the restrictions it imposes on individual liberty. These may be met by noting its voluntary *contractual* character. This reply appears to require that divorce be readily available to terminate the contract and also, perhaps, that different types of marital contract should be possible. Yet an exclusive emphasis upon contracts seems unromantic in the face of the contemporary Western insistence that marriage is only justified by \*love. But in view of the notorious mutability of romantic love, we can either reply that marriage makes possible a commitment that gives conjugal love its value (e.g. Kierkegaard), or conclude that marriage is indefensible, creating 'that moral centaur, man and wife' (Byron).

**Marsilius (Marsiglio) of Padua** (c.1280–1342). Italian medieval political theorist who contested the dominant view of hereditary kingship as the best form of government. Drawing on Aristotle's *Politics*, Cicero (as the defender of republican liberty), and his experience of vibrant Italian city states ruled *de facto* by assemblies, Marsilius elaborately argued a theory of popular sovereignty, opposed to Dante, in *Defender of the Peace* (1324). Legislative power most appropriately resides within the lay citizen body, which may delegate executive power to an aristocracy or even to a monarch, but which does not thereby lose it. Of the three forms of government discussed by Aristotle, monarchy, aristocracy, and the city state or 'polity', only the last for Marsilius fully guarantees political \*liberty, and the flourishing of justice and peace. The two main threats to peace are (1) factionalism and, more serious, (2) the papacy's demands for supreme sovereignty in the secular sphere. Marsilius' arguments were known to fifteenth-century Italian humanist defenders of republicanism.

**Martin, Charles B.** (1924– ). Professor of Philosophy, University of Calgary, formerly Chair of Philosophy,

University of Sydney, past President of the Australasian Philosophical Association, noted for work in metaphysics and the philosophy of mind. Citing Locke as his inspiration, he was an early proponent of causal theories of perception, knowledge, and memory, and a principal architect of Australian metaphysical \*realism. Martin advocates an uncompromising materialist conception of minds as complex neurologically based propensities for the manipulation of sensory materials. The 'ofness' and 'aboutness' of thoughts and images arises from their dispositional realizations in the nervous system. More generally, Martin holds that property instances invariably possess both dispositional and non-dispositional aspects, and that causal transactions are best regarded, not as relations between distinct events, but as the 'mutual manifestations of reciprocal dispositional property partners'.

**Martineau, James** (1805–1900). Leader of the Unitarians in Victorian England and brother of social critic Harriet Martineau, Martineau taught at Manchester New College, where he eventually served as Principal. He was an intuitionist about morality, and a chapter of Sidgwick's *Methods of Ethics* is devoted to criticism of his views. Today he is best remembered for his advocacy of an agent-based form of \*virtue ethics according to which motives are the fundamental objects of moral evaluation (with reverence ranking highest, followed by compassion) and all actions are to be evaluated derivatively in terms of their relation to such motives. Martineau's theory is perhaps the purest example of agent-basing in the entire history of philosophy.

**Marx, Karl Heinrich** (1818–83). Radical social theorist and organizer of the working class, whose thought is widely regarded as the chief inspiration for all forms of modern social radicalism. Born 5 May 1818 in the Rhenish city of Trier, Marx was son of a successful Jewish lawyer of conservative political views who converted to Christianity in 1824. He studied law at the University of Bonn in 1835 and at the University of Berlin in 1836, changing his course of study in that year to philosophy, under the influence of Ludwig Feuerbach, Bruno Bauer, and the Young Hegelian movement. Marx completed his doctorate in philosophy in 1841. With the accession of Friedrich Wilhelm IV in 1840, however, the Young Hegelians came under attack from the government, and Marx lost all chance of an academic career in philosophy. Between 1842 and 1848 he edited radical publications in the

Rhineland, France, and Belgium. He married his childhood sweetheart, Jenny von Westphalen, in 1843; despite their exceedingly hard life after 1850, the marriage was a happy one, and lasted until her death in 1881. (While in London the Marxes' family servant, Helene Demuth, gave birth to an illegitimate child; during the present century it was believed for a time that Marx was the father, but it is now widely held that he was not.)

In 1844, while in Paris, Marx was introduced both to the working-class movement and to the study of political economy by his former fellow student at Berlin, Friedrich Engels, with whom he began a lifetime of collaboration. While in Brussels, he formulated the programme of historical materialism, first expounded in the unpublished manuscript *The German Ideology*. Marx returned from Belgium to Paris in 1848 after the revolution, and then went back to the Rhineland where he worked as a publicist on behalf of the insurrection there. In the same year Marx and Engels played a key role in founding the Communist League (which lasted until 1850); the *Communist Manifesto* was part of their activity in the League. After successfully defending himself and his associates in a Cologne court on charges of inciting to revolt, Marx was expelled from Prussian territories in 1848. After a brief stay in Paris, he took up residence in London. The first years in England were a time of bitter, brutal poverty for the Marx family: three of their six children died of want and Marx's health suffered a collapse from which it never fully recovered. For much of the 1850s his only regular income was from Horace Greeley's *New York Tribune*, for which he served as European correspondent, receiving a fee of £1 per article. Throughout the 1850s and 1860s, when not confined to bed by illness, Marx regularly spent ten hours of every day in the library of the British Museum studying and writing. His first scientific work on political economy, *Contribution to a Critique of Political Economy*, was published in 1859; the Preface to this work contains a succinct statement of the materialist conception of history, usually regarded as the definitive formulation of that doctrine. This was only a prelude to Marx's definitive theory of \*capitalism. Volume I of *Capital* was published in 1867, but two more volumes were left uncompleted at his death. Engels edited and published them in 1884 and 1893 respectively. Marx was instrumental in founding the International Working Men's Association in 1864, and guided it through six congresses in nine years. The demise of the First International in 1876 was brought about by a combination of factors, notably the organization's support for the Paris Commune (see Marx's *The Civil War in France*) and internal intrigues by Mikhail Bakunin (expelled in 1872). Marx died of long-standing respiratory ailments on 13 March 1883, and is buried next to his wife in Highgate Cemetery, London.

Marx's interest in philosophical \*materialism is evident as early as his doctoral dissertation on the philosophy of nature in Democritus and Epicurus. But the dissertation's focus on Epicurus' philosophy of self-consciousness and its historical significance equally displays Marx's

education in German idealist philosophy and his preoccupation with its themes. As a philosopher Marx self-consciously sought to marry the tradition of German idealism, especially the philosophy of Hegel, with the scientific materialism of the radical French Enlightenment. This was to some extent the tendency of the Young Hegelian movement generally, but Marx's emphatic admiration for English and French materialism in contrast to the Young Hegelians' depreciation of it is displayed in a well-known passage from *The Holy Family* (1844).

Of greater significance for Marx's later thought is the way in which his famous Paris manuscripts of 1844 address to the 'materialistic' science of political economy a set of issues which Hegel and his followers had treated as questions of religious subjectivity. German idealism was concerned with problems of human selfhood, the nature of a fulfilling human life, and people's sense of meaning, self-worth, and relatedness to their natural and social environment. They saw modern culture as both a scene of 'alienation' for human beings from themselves, their lives, and others, and also as holding out the promise of the conquest or overcoming of alienation. Hegel, however, saw the task of self-fulfilment and reconciliation as a philosophical-religious one. It was Marx in the Paris manuscripts who first attempted to see it as fundamentally a matter of the social and economic conditions in which people live, of the kind of labouring activities they perform and the practical relationships in which they stand to one another. Marx's concern for the plight of the working class was from the beginning a concern not merely with the satisfaction of 'material needs' in the usual sense, but fundamentally with the conditions under which human beings can develop their 'essential human powers' and attain 'free self-activity'.

The Paris manuscripts view human beings in modern society, human beings as they are understood by the science of political economy, as alienated from themselves because their life-activity takes an alien, inhuman form. Truly human and fulfilling life activity is an activity of free social self-expression. It is free because it is self-determined by human beings themselves; it develops and expresses their humanity because, as Hegel had realized, it is the nature of a spiritual being to create itself by objectifying itself in a world and then comprehending that world as its adequate expression, as the 'affirmation', 'objectification', and 'confirmation' of its nature; and it is social because it is the nature of human beings to produce both with others and for others, and to understand themselves in the light of their mutual recognition of one another and their common work. The social relationships depicted by political economy, however, are relationships in which the life-activity of the majority, the working class, is increasingly stunted, reduced to meaningless physical activity which, far from developing and exercising their humanity, reduces them to abstract organs of a lifeless mechanism. They do not experience the products of their labour as their expression, or indeed as theirs in any sense. For these products belong to a non-worker, the capitalist,

to whom they must sell their activity for a wage which suffices only to keep them alive so that they may sustain the whole absurd cycle of their lives. Political economy, moreover, depicts human beings whose social life and relationships are at the mercy not of their collective choice but of an alien, inhuman mechanism, the market-place, which purports to be a sphere of individual freedom, but is in fact a sphere of collective slavery to inhuman and destructive forces.

Hegel had earlier conceived of alienation in the form of the 'unhappy consciousness' (a misunderstood Christian religiosity which experiences the human self as empty and worthless, and places everything valuable in a supernatural 'beyond'). The cure for alienation in Hegel's view is the recognition that finite nature is not the absence of infinite spirit but its expression. Feuerbach brought to light the latent 'humanism in Hegel's view and attacked all forms of religion (and even Hegel's speculative metaphysics) as forms of alienation. The true being of human individuals, he maintained, is in the enjoyment of sensuous nature and of loving harmony with other human beings. What both Hegel and Feuerbach had in common is the perception of alienation as fundamentally a form of false consciousness, whose cure was a correct perception or interpretation of the world. Alienated consciousness contains both a lament that our natural human life is unsatisfying and worthless, and also the hope of consolation in the beyond. Hegel and Feuerbach agree that the illusion of alienated consciousness consists in its negative attitude toward earthly life; the comforting assurances of religion, according to both philosophers, contain the truth, if only we know how to put the right philosophical interpretation on them. To Marx, however, alienation becomes intelligible as soon as we adopt just the reverse supposition: that the alienated consciousness tells the truth in its laments, not in its consolations. Religion, according to Marx, gives expression to a mode of life which is really empty, unfulfilled, degraded, devoid of dignity. Religious illusions have hold on us because they provide a false semblance of meaning and fulfilment for a mode of life which without this illusion would be seen for the unredeemed meaninglessness that it is. For Marx religious misery is both an expression of actual misery and an attempt to flee from it into a world of imagination: it is the 'opium of the people'. The way out of alienation is not, as Hegel and Feuerbach thought, a new philosophical interpretation of life, but a new form of earthly existence, a new society in which the material conditions for a fulfilling human life would no longer be lacking. 'The philosophers have only *interpreted* the world in different ways; the point is to *change* it.'

For Marx the ultimate tendency of history is the Promethean drive of the human species to develop its 'essential human powers', its powers of production. Under capitalism these powers, and the complex network of human co-operation through which they are exercised, have for the first time grown far enough to put within the reach of human beings themselves the collective, rational

control of the social form of their own production. This self-conscious self-determination is the true meaning of human freedom. But human beings under capitalism are alienated because capitalist social relations, by dispossessing the vast majority of producers and subjecting the form of social production to the market mechanism, frustrate this collective self-determination. The historic mission of the proletariat is to actualize the capacities for human freedom which the capitalist mode of production has put within our reach, by abolishing class society. In this way, historical materialism gives the working class a full conscious understanding of its historic mission, so that unlike previous ruling classes it may fulfil this mission consciously, and thus truly enable the human species to master itself and its destiny. The materialist conception of history thus serves as the link between Marx's concern with the conditions for human fulfilment, his theoretical enterprise as economist and historian, and his practical activity as a working-class organizer and revolutionary.

According to Marx's materialist conception of history, the goals of a class movement are determined by the set of production relations the class is in a position to establish and defend. This implies that historically conscious revolutionaries should not proceed by setting utopian goals for themselves and then looking around for means to achieve them. Revolutionary practice is rather a matter of participating in an already developing class movement, helping to define its own goals and to actualize them through the use of the weapons inherent in the class's historical situation. The definition of these goals, moreover, is an ongoing process; thus it is pointless to speculate about the precise system of distribution which a revolutionary movement will institute after its victory when the movement itself is still in its infancy.

Marx believed that future society would see the abolition of classes, of private ownership of means of production, and even of commodity production (production of goods and services for exchange or sale). He believed communist society would eventually eliminate all systematic social causes of alienation and human unfulfilment. Yet he never thought of future society as an unchanging state of perfection. On the contrary, he thought of the end of class society as the true beginning of human history, of the historical development of human society directed consciously by human beings. Above all, Marx never attempted to 'write recipes for the cookshops of the future' or to say in any detail what distribution relations in future socialist or communist society would be like. He equally scorned those who concerned themselves with formulating principles of distributive justice and condemning capitalism in their name. Marx conceives the justice of economic transactions as their correspondence to or functionality for the prevailing mode of production. Given this conception of justice, Marx very consistently (if rather surprisingly) concluded that the inhuman exploitation practised by capitalism against the workers is not unjust, and does not violate the workers' rights; this conclusion constitutes no defence of capitalism, only an

attack on the use of moral conceptions within the proletarian movement. Marx saw the task of the proletarian movement in his time as one of self-definition and growth through organization, discipline, and self-criticism based on scientific self-understanding. He left for later stages of the movement the task of planning the future society which it is the historic mission of the movement to bring to birth. A.W.W.

**Marxism after communism.** Eastern European and Soviet communism as a political system collapsed after the fall of the Berlin Wall in 1989. Marxism understood as the philosophical basis of this system collapsed at the same time. Whether or not a philosophy can be taken as refuted by a political system's defeat in a kind of war, something like this has been accepted. Leninist Marxism (one-party rule in the name of the working class) and Stalinist Marxism (the 'planned economy' and 'socialism in one country') have all but vanished. Elements of this conjuncture of theory with practice were preserved in Cuba, Vietnam, North Korea, and China. Elsewhere Marxism survives as a politically engaged philosophy.

Marxism after communism is grounded in concepts of human social activity. In particular it is concerned with historical stages of technological development and criticisms of contemporary capitalism. Marxism thus presents many political issues as philosophical problems, and embraces many concepts that belong to history and economics. In Marxism many traditional problems in moral philosophy, metaphysics, and philosophy of mind, for instance, get little attention. The problems addressed by Marxism as a social philosophy are economic exploitation, distributive inequalities, social class, and political change. This makes it a form of 'critical theory'.

Marxism offers philosophically based criticisms of the capitalist economic system, and of the linkage between liberal democracy and commercial interests. It currently presents very little in the way of utopian thinking about communism, even as a philosophical ideal. Instead it has broadened Marx's central notion of class struggle to include a wider variety of human differences and broader movements in identity politics. This gives an economic slant to nationalist and gender conflict, for example, particularly when conceptualized with respect to international capitalism.

For some philosophers Marxism is still a 'grand theory' searching for directionality in human history, and for

mechanisms that determine social change. For other philosophers it represents a science of society, based on a well-grounded ontology (human activities and social consciousness are the basis of existence) and a well-defended 'realist' epistemology (knowledge is derived empirically from social interactions with the material world). More radically, post-modern Marxists have reconceptualized Marxism as grounded in a democratic and egalitarian civil society. This cuts Marxism loose from historical teleology and philosophical determinism, while retaining its critical engagement with politics.

**Marxist philosophy.** The idea of a Marxist philosophy is, at first sight, paradoxical. Marx himself was originally a student of philosophy but soon came to talk of abolishing philosophy: the coming of a socialist society would render philosophy (like religion) redundant. It is, nevertheless, clear that Marx and his followers appropriated much of the philosophy of (at least) Aristotle, the \*materialism of the \*Enlightenment, and Hegelian dialectics. It is equally clear that when Marx talked of the abolition of philosophy, he meant that, in so far as philosophy posed ideal principles or essences, it would lose its function after a socialist revolution which embodied these essences in socio-economic reality. It is far from clear that Marx's \*historical materialism contradicts or supersedes philosophy as such. The century and more that has elapsed since Marx's death has been a largely fruitless search by his followers to establish a distinctively Marxist philosophy. Since the authoritarian Communist regimes established in Marx's name did not encourage philosophical enterprise, their demise is unlikely to have much effect on the future of Marxist philosophy.

Although Marx himself had apparently disparaged philosophy, after his death and with the revolution still a long way off, the 'footnotes to Plato' had to be dealt with and the growing membership of Marxist parties required a 'philosophy' in the sense of a coherent system of principles giving a total explanation of the universe. Given the cultural climate of the late nineteenth century, this had to be couched in scientific—and even positivist—terms. Although the later Marx certainly had traces of such attitudes in his work, it was given systematic form by Engels and culminated in the philosophy of dialectical materialism propagated by Communist orthodoxy.

Engels proclaimed the Marxian \*dialectic to be 'the science of the general laws of motion and development of nature, human society, and thought'. More specifically, the most important of these were the laws of the transformation of quantity into quality, of the interpretation of

opposites, and of the negation of the negation. Engels thought these laws to be operative in a nature that was objectively given and independent of the human mind. Thus the world of nature and the world of human history were two separate fields of study—whereas for Marx one of the central aspects of his dialectic had consisted precisely in the interaction of human beings and their surroundings, a view stemming from Hegel. Engels did indeed claim to be simply applying Hegel's dialectic, and, in a sense, Hegel also saw a dialectic in nature but it was still subject to the universal mediation of human consciousness. The concept of matter as some kind of *materia prima* is entirely foreign to Marx.

For many interpreters of Marx's thought, however, the publication of his early writings around 1930 marked a decisive turning-point. These writings, particularly the *Economic and Philosophical Manuscripts*, revealed a very different Marx from both the rather arid economist of Kautsky and the dialectical materialist of Soviet dogma. Marx appeared to be a philosopher, a humanist not only with a devastating account of the alienation of man in capitalist society but with a rich and varied account of the potential latent in every individual waiting to be realized under communism. This enthusiasm for the early Marx was helped by the pioneering writings of Georg Lukács, who rediscovered in full Marx's debt to Hegel and put concepts such as alienation and reification at the centre of his interpretation. This tradition has been embodied most systematically in the work of the \*Frankfurt School, where 'critical' theorists such as Adorno, Marcuse, and Habermas have aimed to restore a philosophical dimension to Marxism. Retaining an enviable confidence in the power of human rationality, these theorists have developed a series of concepts intended to go beyond Marx in interpreting the changes that have taken place in the world since his death. These consist mainly in adding the dimension of social psychology to Marx's work, and emphasizing the basic proposition that if society is increasingly under the control of technocrats, then any purely empirical approach to social reality must end up as a defence of that control.

In sharp contrast to the evidently Hegelian and humanist elements present in the Marxism of the Frankfurt School, the Marxist philosophy evolved by Althusser and his disciples in the early 1960s attempted to purge Marxism of any such elements. Taking advantage of the current prestige of structuralist linguistics, psychology, and anthropology, it was the aim of Althusser to 'rehabilitate' Marx as a structuralist before his time. Thus Althusser continued the Stalinist division of an early pre-Marxist Marx and a later scientific Marx—though with a conceptual sophistication quite foreign to the previous versions of this view. Roughly speaking, \*structuralism is the view that the key to the understanding of a social system is the structural relationship of its parts—the way these parts are related by the regulative principle of the system. And Althusser's search for a timeless rationality reminiscent of Comte (for whom Marx himself had no time) involved the

banishment of both history and philosophy. When applied to Marx, this involved cutting his work into two separate conceptual structures with the dividing-point around 1845. Any reading of Marx as a humanist, a Hegelian, or a historicist must (since these ideas are clearly contained in his early works) be rejected. Since it has become increasingly implausible to claim (particularly after the publication of the *Grundrisse*) that there are no humanist or Hegelian elements in the later Marx, a 'real' Marx has been uncovered who employs a methodology—never clearly defined—almost totally at variance with concepts that he actually employs.

More recently, there have been attempts to rethink many aspects of Marxism through the medium of rational choice theory. This approach, exemplified in the writings of such authors as Elster and Roehmer, has come to be known as analytical Marxism. Central to it is a \*methodological individualism which borrows concepts and techniques from game theory and contemporary economics. Particularly when combined with \*analytical philosophy, this can yield a highly rigorous discussion. But the conceptual framework is so much at variance with the Marxist tradition that it is not surprising that the theses of the analytical Marxist school are highly revisionary. And the same is true of Marxist attempts to come to terms with the rise of new social movements, particularly those inspired with an ecological or feminist perspective.

The most striking fact about the relation between Marxism and philosophy, in the West at least, is how eclectic Marxists have been in their attitude to philosophy. Marxists have usually tried to articulate their ideas through whatever happened to be the current dominant philosophy. The revival of interest in Hegel between the wars, coupled with the influence of Freud, was decisive for the formulations of the Frankfurt School; the post-war vogue for existentialism led to all sorts of New Left variations on Marxism with a human face, of which Sartre's later work is only the most prominent example; the subsequent prestige of structuralism in the 1960s and 1970s led to the arcanelly theoretical Marxism of Althusser and his disciples; while the rational choice Marxism of more recent years is evidently an effort to come to terms with some of the dominant concepts of the Reagan–Thatcher years.

The inevitable tension in all the above approaches lies in the fact that all the philosophies they invoke are the product of bourgeois societies—the very societies that Marxism is dedicated to superseding. This tension is only exacerbated by the tendency of western Marxists to become more theoretical and more philosophical with the decreasing prospect of success for Marxist practical activity. The migration of Marxism into the universities has necessarily undercut the unity of theory and practice so central to the outlook of Marx himself. For him, all philosophy (like all religion) is ultimately idealist and mystificatory. Holding that 'the dispute over the reality or non-reality of thinking that is isolated from practice is a purely scholastic question', Marx looked forward to a

society which would abolish the division between mental and manual work—which he saw as the root cause of all philosophical mystification. Such a society would be intelligible to its members, since the social relationships in it would be transparent, and would not require philosophical mediation.

The history of Marxist thought has thus been characterized by a strong ambivalence towards the viability of the philosophical enterprise. The result has been the invisibility of a distinctively Marxist philosophy: Marxism has been eclectic in its borrowings from 'bourgeois' philosophy. These borrowings have been extremely fruitful, particularly in the realm of social theory. Indeed here, as elsewhere, Marxism has proved at its strongest as a critique of philosophy rather than in adumbrating a plausible alternative.

Frank Jackson, 'Epiphenomenal Qualia', *Philosophical Quarterly* (1982).

**Masaryk, Tomáš Garrigue** (1850–1937). Czech philosopher, sociologist, and politician who influenced generations of Czech and Slovak thinkers. From 1882 to 1914 he was Professor at Charles University in Prague, from 1918 to 1935 President of the fledgeling Czechoslovakia. He was an opponent of clericalism, monarchism, anti-Semitism, and Bolshevism.

He sought to explain the crisis in Czech and European society at the end of the nineteenth century, a significant feature of which was an increase in suicide (*The Suicide . . .* (1881)). In *The Principles of Concrete Logic* (1885) he follows Comte's classification of sciences, adding logic and psychology, as understood in J. S. Mill's terms. He also dealt with Czech history, and the struggle of every human being and society to attain the human ideal of active love. This religious humanity was more emotional than the political and rational humanity of the French Revolution. In *The Social Question* (1898) he rejects Marxism as

objectivism, positivistic amoralism, and materialistic fatalism, although he admits its temporary political and ideological sense. In *The Spirit of Russia* (1913) he analyses Russian culture in the nineteenth century, emphasizing the thinking of Dostoevsky.

**masculism.** Defining 'masculism' is made difficult by the fact that the term has been used by very few people, and by hardly any philosophers. In its most general meaning, the word \*'feminism' refers to promotion of the interests or rights of women, and a reasonable definition of 'masculism' would have it refer to promoting the interests or rights of men. (This is very different, it must be noted, from promoting attributes of womanliness or manliness, as they might be construed, which could be labelled feminism and masculinism.) Thus defined, the two parallel terms are too vague to be very useful. A more precise definition of both would be something on this order: 'the belief that women/men have been systematically discriminated against, and that that discrimination should be eliminated'. Evidently, such a definition for 'feminism' is commonly understood, and among the few who apply the term 'masculist' to themselves, such is also their intent. Of course, under these meanings there is no necessary conflict between them, and in fact some are happy to call themselves both feminists and masculists. Much more often, the belief that one sex currently faces a much greater threat from discrimination would lead to accepting one label and rejecting the other.

However one understands these particular terms, there is today a fundamental movement of 'men's rights' activists. Their fundamental claim is that very serious discrimination is currently being committed against individual males on account of their sex. These activists fall roughly into two categories, traditionalist and liberal-progressive. The traditionalists hold that inherited gender roles, though 'discriminatory' in the neutral sense of treating the sexes differently, have been more or less fair and just to both, because, they believe, the disadvantages faced by males and females have been comparable (at least in this culture, in this century) and because the traditional sex roles represent more or less the optimal division of benefits and burdens, the best arrangement for children and for society as a whole. What sets 'men's rights' traditionalists apart from traditionalists in general is their belief that contemporary feminism is not only bad for society but seriously unjust to men as well.

In sharp contrast—and in spite of attempts by many to label all talk of men's rights as reactionary, a 'backlash'—progressive men's rights activists regard the traditional differential treatment as seriously unfair to members of both sexes. Inherited \*gender roles and stereotypes are not just burdensome to both men and women, they say, but unjust to both, and must be eliminated. (Unlike traditionalists, they have no need to pronounce the roles equally burdensome, and tend to treat the two sets of injustices as incommensurable.) Progressive masculists

have thus welcomed many feminist efforts toward societal change, adding, however, that feminism addresses only half the problem. Furthermore, they maintain that many feminist efforts ostensibly aimed at ending sexism are actually increasing sexism against men. This has been especially true, they say, in the 1980s and 1990s, as mainstream feminism has left its inclusivist roots in favour of separatist efforts based on an extreme oppressor-oppressed picture of relationships between the sexes.

Thus, both forms of contemporary masculism promote equality between men and women as its adherents envision it. Of course, whether they are mistaken about what moral equality would consist in, or even at some level dishonest about that being their goal, is another matter—as it also is for feminists. This leads us to the extremist versions of masculism and feminism, those that promote some degree of male or female supremacy, and are generally based on belief in the inferiority of the other sex. Many contemporary feminists consider men to be morally and even intellectually inferior, by virtue of being raised in an oppressor class, or even by nature. And of course the long history of male domination since hunter-gatherer times has generally included doctrines of the intellectual inferiority, and, although the record is mixed, sometimes moral inferiority of women. Nicholas Davidson discusses an extreme brand of masculism and masculinism which he dubs 'virism'. In its world-view, he says,

What ails society is 'effeminacy'. The improvement of society requires that the influence of female values be decreased and the influence of male values increased. . . . Contemporary virists perceive themselves to be fighting a last-ditch action against a neutered or feminized society, of which feminism is merely one recent expression. . . . [In movies such as] *Rambo* and *Commando*, the world has gone soft. The protagonists struggle to avert dangers caused by society's loss of the masculine principle.

Davidson sees precise similarities between extremist masculism and extremist feminism, remarking that 'the parallel association of Hellenic virism with a cult of [male] homosexuality and modern feminism with a cult of lesbianism is not accidental'.

However that may be, most men's and women's rights activists profess belief in \*equality, different though their visions of it may be. Indeed, they do not divide strictly along gender lines. Besides feminist (or 'pro-feminist') men, there are many women—some embracing the label 'feminist', some rejecting it, and many ambivalent about it—who actively advocate men's rights. Such groups as the Women's Freedom Network (mostly libertarians) and the Women's International Network (liberal) in the USA have been established largely to oppose the harms they see contemporary mainstream feminism as doing to both sexes. Traditionalist women's groups such as Eagle Forum (USA) and REAL Women (Canada) also often speak out against discrimination toward men, or at least against the recent varieties promoted by feminists.

Space is not available here to describe adequately (much less to argue for and against) the standard men's rights issues. They include discrimination against fathers

in child custody cases (in terms of numbers of activists, this is the largest issue); discrimination against men in the criminal law, military conscription, and various other societal institutions; contemporary discrimination against men in employment, insurance and pensions, and other economic matters; and many others. (See Farrell, *The Myth of Male Power*, and Thomas, *Not Guilty*, for representative treatments of men's rights issues.)

The above discussion describes masculism as a set of political beliefs, not as philosophy in any abstract sense. Apart from advocacy (genuine, not just alleged) of male supremacy, however, there arguably is no masculist philosophy. Consider the traditionalist belief that if nature were allowed to take its course, men would fill most of the leaderships roles (see Goldberg, *Why Men Rule*) and women fill the nurturing roles. The belief is better described as a general philosophy of human nature than as one centred on males and maleness. And liberal advocates for men's rights typically describe their philosophy as egalitarian rather than as either male- or female-orientated. By the same reasoning, however, apart from brands of feminism embracing genetic female superiority, there is no genuine \*feminist philosophy, or at least none with unique relevance to females or femaleness. The perfectly justified desire to open up to women the opportunities, which only men (a small minority of men) have had in the past, to engage in formal philosophy, had led, this writer would judge, to the wishful beliefs that (a) past philosophy, in virtue of having been written by individual males, is somehow specifically male or masculist in its nature, and that (b) there is a distinct type of philosophy that is specifically female in its nature. All the post-Gilligan talk about women's 'special ways of seeing' notwithstanding, as this liberal masculist-feminist writer views the evidence, \*feminist epistemology' and its like is a grand illusion.

**masked man fallacy.** One of a group of puzzles (the \*liar paradox is another) due to Eubulides (third century BC), the masked man, extensively discussed by medieval logicians, is concerned with referentially opaque contexts: 'You say you know your brother, but that masked man is your brother, and you did not know him'. By contrast, normal (extensional) contexts are transparent: if you touched the masked man you thereby touched your brother.

**master and slave.** The master and slave metaphor has occurred in philosophy since ancient times. Aesop admonished that reason should be the master and passion the slave. (Hume was to say otherwise.) Politically, of course, the duality of master and slave and later lord and

serf were quite literal social realities for Aristotle and most feudal thinkers. The master and slave imagery enters into modern philosophy in Rousseau, Fichte, and most famously in Hegel, who made the master-slave interaction the centrepiece of the most famous section of his *Phenomenology*. According to Hegel, the master-slave relationship is the result of an uncompleted fight to the death for 'recognition' or status, and it is marked by a topsy-turvy logic (or \*'dialectic') such that the master, through increasing dependence on the slave, and the slave, who develops independence through labour, switch roles. Hegel is at pains to point out that such roles, dependent on competition and power, are unsatisfactory as a basis for social relationships.

Toward the end of the nineteenth century, Nietzsche picked up the opposition as a metaphor for two distinct modes of morality. Master morality prizes independence, creativity, and excellence. \*Slave morality, by contrast, is servile, fearful, and, above all, resentful. In a Hegelian-type turn-about, Nietzsche traces ethics through history as 'the slave revolt in morals'. Slave morality is victorious, and, according to Nietzsche, servile obedience and mediocrity replace the masterly Greek ideals of virtue and excellence.

**Master Argument.** The Master Argument was highly influential on Hellenistic debates about \*freedom and determinism. Diodorus Cronus (Greek, d. c.284 BC) devised it to support his definition of the possible as that which either is or will be true. Diodorus relied on two premisses: 'Every past truth is necessary' and 'The impossible does not follow from the possible'. He concluded: 'Nothing is possible which neither is nor will be true'. One guess, less fanciful than most, is that Diodorus reasoned: suppose some proposition is and always will be untrue; then at some time in the past, it was going to be untrue at all later times; from that past truth, it follows that our proposition is untrue; but that past truth is necessary; and so is what follows from it; hence our proposition is necessarily untrue.

**master of those who know:** see Aristotelianism.

**material constitution.** That which something is composed of. For example, the statue is not identical with the bronze it is made of, but the bronze is the material constitution of the statue. Nevertheless, there is a constitutive sense of 'is'. Arguably, something is not identical with what it is made of because the two have different persistence conditions. If *a* is composed of constituents, they might continue to exist even if *a* ceases to exist. Also, if *a* is composed of constituents, and if *a* ceases to exist, and then

*b* is made out of those same constituents, it seems wrong to say *a* is therefore *b*. On some quasi-materialist views, if I am not identical with my body, my body is my material constitution. S.P.

**material contradiction.** The idea that \*contradictions exist not only in thought but in material reality has been a distinctively philosophical preoccupation within \*Marxism. It refers to activities within organisms and systems that generate opposing forces (thus, 'capitalism creates its own grave-diggers'), and also the claim, adapted from Hegel, that adequate descriptions of material reality necessarily involve contradictions. It need not, therefore, imply a metaphysical realist conception of contradictions as having an extra-linguistic existence. K.M.

R. Norman and S. Sayers, *Hegel, Marx and Dialectic: A Debate* (Brighton, 1980).

**material implication.** A connection between statements which has sometimes seemed to be supposed by logicians to represent statements of the form 'If... then...'. A statement *p* materially implies another, *q*, when the propositional calculus conditional  $p \rightarrow q$  is true, i.e. if and only if it is not the case that *p* is true and *q* false. One 'paradox' of material implication is that this relation holds between statements wholly unrelated in subject-matter: 'If Oxford is a city, then Italy is sunny'. Another 'paradox' is that the relation holds merely if *p* is false ('If pigs can fly, then...') or merely if *q* is true ('If... then Plato was a philosopher'). These are all ways in which material implication diverges from 'if... then...' as ordinarily used. S.W.

\*Implication; conditionals; relevance logic

**materialism.** Basically the view that everything is made of matter. But what is \*matter? Probably the most innocent and cheerful acceptance of it comes right at the start of materialism with Democritus of Abdera (in northern Greece) in the fifth century BC, for whom the world consisted entirely of 'atoms', tiny, absolutely hard, impenetrable, incompressible, indivisible, and unalterable bits of 'stuff', which had shape and size but no other properties and scurried around in the void, forming the world as we know it by jostling each other and either rebounding (despite being incompressible) or getting entangled with each other because of their shapes. They and the void alone were real, the colours and flavours and temperatures that surround us being merely subjective (see fragment 9). This model has lasted, with various modifications and sophistications, right down until modern times, though the notion of solidity was causing qualms at least as early as Locke. But in the last century all has been thrown into confusion by Einstein's famous  $E = mc^2$  and also by general relativity. Mass, the sophisticated notion

that has replaced crude matter, is interchangeable in certain circumstances with \*energy, and in any case is only a sort of distortion of the \*space in which it was supposed to be floating. Photons and neutrons have little or no mass, and neither do fields, while particles pop out of the void, destroy each other, and pop back in again.

All this, however, has had remarkably little overt effect on the various philosophical views that can be dubbed 'materialism', though one might think it shows at least that materialism is not the simple no-nonsense, tough-minded alternative it might once have seemed to be. What actually seems to have happened is that the various materialist philosophies have tended to substitute for 'matter' some notion like 'whatever it is that can be studied by the methods of natural science', thus turning materialism into \*naturalism, though it would be an exaggeration to say the two outlooks have simply coincided. Materialism concerns the composition of things, while naturalism, though concerned with what exists, ranges more widely, covering properties as well as substances, and its concern with methods of studying things is more direct and central.

So far, however, we have only considered apparent exceptions to naïve materialism like photons and fields; but common sense might regard these as on the material side of the fence, since they are linked to what is unambiguously material in established and fruitful scientific theories. In any case they are of little interest to common sense. Philosophers too, outside philosophy of science perhaps, often take as their starting-point the concerns of common sense, and perhaps it is for these reasons that materialism in philosophy has also been relatively unaffected by these complications.

By far the most important contrast in this area, for philosophy as for common-sense, has been between matter and mind or spirit or consciousness, or the contents of these entities (ideas etc.). Common-sense for all the time and philosophers for much of it (i.e. when they are not being idealists or phenomenologists) accept the reality of the body as relatively unproblematic. But mind or consciousness manifestly exists too in some form, at least in our own case. Does it then exist as a separate entity? This question forms a major part of the \*mind-body problem, and the materialist will answer 'No'. He might hard-headedly deny that mind exists at all, thereby raising a question that has its roots in Protagoras of Abdera (a contemporary of Democritus) and Descartes: what then is the status of the illusion that it does? Don't even illusions need minds to have them? But he is more likely to appeal to some form of non-eliminative materialism and say that minds do exist but not as something separate from matter. Either they belong to a different category, as Ryle would say, so that talk about them is a sort of abbreviation for talk about kinds of behaviour (\*behaviourism), or they are simply identical with brains—or, to put it less crudely, what we call mental phenomena, like pains or thoughts, are identical with phenomena going on in the brain (the \*identity theory of mind): in principle this can leave open whether

there are any substantive minds to have these pains etc., but if there are they must be identical with something material. Although the material item will be identical with the mind or the pain as much as vice versa, the theory counts as materialist because the material items are integrated into a whole set of such items, only a few of which are involved with minds, while the mental items are not (on the theory) similarly integrated into a set of mental items most of which are independent of matter.

There is, however, a mistake to be avoided in this area which goes back at least to Plato. In his relatively early dialogue the *Phaedo* he opposes the soul (to adopt the usual translation of the Greek word *psukhē*) and the body. The soul is a single thing (unlike the tripartite soul of his slightly later dialogue the *Republic*), but it is represented as in conflict with the body, and pulled by bodily desires and passions. These desires and passions are opposed to the soul as such, and are clearly regarded as bodily phenomena, which they are surely not, at least on the sort of view Plato is holding; human bodies no more have desires than tables do. It is true, of course, that the identity theory we have just been discussing would treat these desires as identical with events in the brain or nervous system, but only as part of a doctrine treating all desires as such in this way, including the most spiritual; it would not single out certain desires for such treatment merely because what the desires were *for* involved states of the body, or what caused them were such states. In his later dialogue the *Philebus* Plato revised his view on this point.

Sometimes a distinction is made, as it has been in different ways by Frege and Popper, between three kinds of real things (three 'realms' or 'worlds'). The first contains material things, including the things like photons that are associated with centrally material things and might be called quasi-material. The second contains psychological things like thoughts, feelings, pains, desires, including the substantive minds that have these, if there are any; if there are, then the thoughts etc. that they have will not be independent substantive entities, but will still count as denizens of the second realm. The third contains abstract things like numbers, properties, classes, truths (and perhaps falsehoods), values, or some selection of these, all those selected being treated as substantive entities, though not material nor properly speaking spiritual either. Philosophers have tended to treat these three realms not so much as lying in a straight line, with one in the middle between the other two, as lying in a triangle, so that the rejection of one was compatible with accepting either or both of the other two. Materialists strictly speaking say that only matter exists, but in modern times they have tended to direct their fire primarily against believers in the second realm, and some of them (e.g. Armstrong) accept at least a moderate realism in connection with the third realm. But this was not always so. Plato, with whom so much of philosophy began, was primarily concerned to assert the existence of the third realm (indeed he is commonly taken to have introduced it, and belief in it is often called \*Platonism), and in his dialogue the *Sophist* he contrasts

materialists with certain defenders of that realm. Although he devoted another dialogue, the *Phaedo*, to defending the immortality of the soul, a member of the second realm, its existence he tended to take for granted, leaving its status *vis-à-vis* the other two realms rather uncertain. However, despite all this it is perhaps true that most materialists are thoroughgoing and reject both the other two realms, even if directing their fire primarily at one of them.

We started our discussion by asking 'What is matter?' and finding that our notion of matter was getting a bit frayed at the edges. There is a further difficulty with it, which appears to be what led Berkeley to his version of \*idealism, which he called 'immaterialism'. Aristotle contrasted matter with form, and treated it as a \*substratum for form and thus ultimately for attributes. This led him, at least as traditionally interpreted, to a notion of 'prime matter', which was the ultimate subject for all attributes and therefore had no attributes of its own. Locke, again as traditionally interpreted, took over this notion of prime matter and made it the underlying but unknowable \*substance of all things—unknowable because it had no attributes by which we could know it. Actually Locke's position on this question is open to dispute, but Berkeley rejected the notion as simply ridiculous and a source of scepticism because of the bewilderment it led to. Evidently the materialist, and indeed everyone who accepts matter at all, must give some account of the nature of matter which will rescue it from these strictures. That this task will not be easy is suggested by the growing revival of idealism in current philosophy.

So far we have considered materialism as a metaphysical doctrine. But in ordinary thinking it often refers to a doctrine about values. Here again it is often contrasted with idealism, which now refers to the pursuit of ideals that may be high-flown but are likely to be impossible to achieve in practice. The materialist by contrast pursues ends connected with the bodily pleasures, or the possession of material goods, or else with such things as money, thought of as a means to such pleasures or goods. One might ask, however, just what count as bodily pleasures. If they are those involving states of the body, what happens to the aesthetic pleasures of music and visual art? We should be hard put to it to enjoy these without ears or eyes, and these are not being used simply to give us information as when we hear or read poetry (or philosophy for that matter); to enjoy a piece of music is not simply to know what it sounds like, but to hear it sounding like that, even if only in the 'mind's ear'. It is also possible that the term 'materialist' involves some confusion due to the sort of considerations we discussed concerning Plato above. But in any case we should not confuse two distinctions: that between pleasures that involve the body more closely and those that involve it less closely or not at all, and that between values that are in some sense 'lower' and less worthy of pursuit and those that are 'higher'. The contrast between materialism and idealism in this context suggests such a confusion, but the pleasures, or values, of the

materialist are not necessarily any 'lower', presumably, than those of the pursuit of, say, malice. A.R.L.

**mathematics, history of the philosophy of.** Many areas of philosophy owe their beginning to Plato, and the philosophy of mathematics is a star example. It was he who first reflected on the fact that the geometers speak of *perfect* squares, *perfect* circles, and so on, though no examples are to be found in this world. He thought that the same applied to arithmetic too, on the ground that in arithmetic we study numbers that are composed of units perfectly equal to one another in every way, whereas again there are no such units to be found in this world. So he concluded that mathematics was not about the objects to be found in this world, but about some different 'purely intelligible' objects, which he was apt to think of as inhabiting 'another world'. Moreover, since the objects were not of this world, our knowledge of them must also be independent of our experience of this world, i.e. it must be *a priori*. Initially he attempted to explain this *a priori* knowledge as a recollection of our past experiences of the other world, before birth. Later he appears to have abandoned this explanation, but he never ceased to insist that the knowledge is *a priori*. Mathematics, then, has both a special ontology and a special epistemology.

Aristotle challenged both of these claims. In his philosophy there was no place for a distinctive kind of knowledge that could be called *a priori*, and he equally could not accept Plato's ontological extravagance. So he was the first to propose a consciously 'reductive' account of the objects of mathematics. In his view the geometer is speaking of ordinary and perceptible squares and circles, but considered generally, and in abstraction from the ordinary and perceptible matter that they are made of. Similarly,

the arithmetical thesis that  $2 + 3 = 5$  is to be construed simply as a generalization over such ordinary facts as that if there are 2 horses in this field, and 3 in that, then there are 5 horses altogether. But unfortunately he never did set out a full argument for these claims, so the rival positions were outlined, but battle was never properly joined.

Space does not permit an account of the skirmishes between what were broadly speaking Platonic and Aristotelian positions in the centuries that followed, and we may pick up the tale again with the quite different outlook of the 'modern' period. There we find a dispute between *rationalism* on the one side and *empiricism* on the other, but it is a dispute in which there is actually a large measure of agreement. The ontology is shared, for on both sides the objects of mathematics are taken to be our ideas. And the epistemology is at least partly shared. The difference is that the rationalists suppose (as Plato once did) that the relevant ideas are innate, whereas the empiricists think that our idea of three, or of a triangle, owes its existence to our perceptions of three-membered groups and triangular objects. But both are agreed that, once the relevant ideas are obtained, the further pursuit of mathematical knowledge is independent of any further experience. Yet despite all this agreement there is nevertheless an important opposition: rationalists such as Descartes stress the *importance* of mathematics for our understanding of the world, whereas Empiricists such as Locke and Berkeley and Hume belittle it.

Descartes first extends the sphere of mathematics, so that it includes time, and hence motion, as well as space. Then, just as he supposes that the basic principles of (Euclidean) geometry are known *a priori*, so he presumes that the same will apply to the laws of motion, and he offers an *a priori* derivation of them. (Descartes's supposed laws use only spatio-temporal concepts, such as size and velocity.) With this as a basis he professes to be able to deduce, without any aid from observation, the organization of the solar system as a whole (i.e. as a system of 'vortices'). He also promises us that these same basic laws can in principle explain all further phenomena, from the behaviour of light to the action of the heart. The whole of science, then, in its completed form, will be just an application of *a priori* reasoning from innate principles. This is perhaps the boldest view that there has ever been of the scope and power of pure mathematics. Of course, parts of Descartes's system were soon found to be wrong, and it needed Newton to produce a much better system, which apparently did square with observation. Moreover, Newton himself did not suppose that either his laws of motion or his law of gravitation could claim any *a priori* status. Instead, he made a point of citing experiment and observation in their support. But, even after Newton's 'corrections', Descartes's vision of a wholly *a priori* science remained a temptation to many (including Kant).

It did not tempt Locke, or Berkeley, or Hume. Locke, indeed, was drawn to think that science proper *should* be *a priori* (for only so could it provide genuine explanations), but for that very reason he thought that we should never

attain it. For all three Empiricists were well aware that in practice science must be based upon observation and experiment (and they all failed to see the importance of theorizing). But Berkeley and Hume actually attacked mathematics itself, claiming that it was based upon assumptions about infinite divisibility which had no basis in experience, and which in fact led to intolerable paradoxes. In so far as these charges concerned the notion of the \*infinitesimal, there was indeed some truth in them, and they were not properly answered until Weierstrass (see below). But in any case, Hume's general attitude should be noted: our knowledge of mathematics (so far as it is genuine) is knowledge of 'relations between ideas', and this is to be *contrasted* with knowledge of 'matters of fact and existence'. Hume was interested in the latter. But Kant returned to the former, asking what kinds of 'relations between ideas' these were, and how they were discovered.

Kant thought of an \*analytic truth as one which can be established simply by an analysis of the concepts involved. Since he supposed that conceptual analysis was the mental analogue of taking something to bits, he framed his criterion in terms of concepts and their parts: an analytic truth is one in which the concept of the predicate is contained within the concept of the subject. His point was that it is not surprising that such truths can be known a priori. But he also supposed that some synthetic truths can be known a priori, his chief example being the truths of mathematics, and his main problem was to explain how this could be so. He seems to have thought that, once we are clear about the distinction between the analytic and the synthetic, we will readily agree that the truths of geometry and arithmetic are indeed synthetic. At any rate, his arguments on this point are very superficial. But with hindsight we can now say that he was certainly right about geometry. When this is understood, with Kant, as a theory about the space in which we find ourselves, then certainly its basic assumptions are not analytic. But the difficulty here is with the other claim, that they are known a priori. Kant's argument is just that we cannot imagine things otherwise, and that is why we feel that the knowledge is independent of experience, and could not be falsified by experience. He adds a 'justification' for this last point, namely that the spatial arrangement of what we perceive is *our* contribution to the interpretation of the data of sense. So it is due to our own nature, and not to the nature of the data, that we cannot perceive in any other way.

This account of geometry was forcibly challenged by J. S. Mill. He admitted that we could not imagine things otherwise, but explained that this was due simply to the weakness of our imaginations, which were in practice limited by what we had experienced and how we had understood it. To back this up, he pointed to several instances, from the history of science, of other propositions which once could not be imagined otherwise, but were later rejected (e.g. Aristotle's laws of motion). And he inferred from this that what can be imagined may change as scientific theories change, and is no safe guide to necessary

truth. His application of this line of thought to geometry is nicely done, and we can now say that on this topic he was definitely right. The mathematical development of \*non-Euclidean geometries has provided strong support for his view that if Euclidean geometry does have any special status then that can only be because of its fit with experience; and the fact that modern physical theory actually prefers a non-Euclidean geometry clearly vindicates his refusal to draw any conclusion from the limits to what can be imagined. Mill's views on geometry are now orthodox.

Both Kant and Mill attempted to treat arithmetic in the same way as they had treated geometry, Kant claiming that it was both synthetic and a priori, Mill that it was (synthetic and) empirical. But in this case the arguments on both sides were quite unconvincing, and were well criticized by Frege (see below).

The second half of the nineteenth century saw two important developments in mathematics which together provoked a surge of philosophical thinking amongst the mathematicians themselves, and gave rise to three philosophies of mathematics which are influential even today. The one development began with what is known as 'the arithmetization of analysis'. First Weierstrass (1815–97), building upon work by Cauchy (1789–1857), succeeded in reducing to good order the differential and integral calculus introduced long ago by Newton and Leibniz. For two centuries it had been clear that this method led to many extremely useful results, but its basis had remained mysterious, apparently relying on the incomprehensible notion of the infinitesimal. Weierstrass showed how this notion could simply be eliminated. This work on the 'foundations' of a branch of mathematics was soon carried further. Both Dedekind and Cantor offered foundations for the theory of real numbers, by which it was freed from reliance on geometrical intuition, and derived instead from the theory of rational numbers. (Some \*set theory was also employed in the derivation; this point received little attention at the time.) The theory of rational \*numbers in turn could easily be derived from the theory of the natural numbers, and Dedekind went on to produce a foundation for this latter, i.e. a proper axiomatization of elementary arithmetic. So apparently Dedekind had now provided a foundation for 'all' of traditional mathematics. But the second development was in a different direction: Cantor created an entirely new branch of mathematics, i.e. the theory of \*infinite numbers, which certainly could not be derived from these same foundations. Yet it cried out for foundations of its own, for it appeared to spawn contradictions (e.g. Cantor's paradox) no better than those that had once characterized the differential calculus. So on the one hand there was, for the first time since Greek mathematics, a new emphasis on foundational thinking; and on the other there was a new branch of mathematics, standing outside the area covered by existing foundations, and evidently controversial. This led to three new philosophies of mathematics, namely \*logicism, a special variety of \*formalism due to Hilbert, and \*intuitionism.

The founder of logicism was Frege. Though he was sympathetic to Cantor's theory of the infinite, in his main work he concentrated just upon elementary arithmetic. In opposition to both Kant and Mill, he redefined an analytic truth as one that can be proved just from general logical laws and definitions, and set out to show that arithmetic is in this sense analytic. That is, it needs only logic for its foundation. At the same time he rejected the prevailing 'psychologism', i.e. the assumption that arithmetic is about our ideas, and reinstated the Platonic conception of numbers as abstract objects, existing quite independently of us. Putting these points together, he held that numbers were 'logical objects', and in effect he took them to be sets. This was the cause of his disaster, for it led him to adopt a very general ('logical') principle for the existence of sets, which Russell showed to be inconsistent. (\*Russell's paradox.) Moreover, the inconsistency was clearly very similar to that affecting Cantor's theory of the infinite, and so subsequent developments in the logicist tradition have generally attempted to deal with both problems at once, providing a single foundation both for finite and for infinite numbers. One important example is Russell's theory of *\*types*, which at the same time abandons Frege's Platonism about numbers. But in practice, mathematicians have preferred an explicit set theory as a foundation, and this strongly suggests the Platonist interpretation. In any case, logicism can in principle be combined with either the Platonic or the Aristotelian view of what numbers are. It is also compatible with either view on epistemology. For if we say that the main claim of logicism is that there is no firm boundary to be drawn between logic on the one side and mathematics on the other, then one can accept this claim while holding either that both have an *a priori* status (as Frege and Russell desired), or that both are empirical (as Quine once claimed).

Hilbert is often counted as a formalist, but he differs from most others who are so-called because he wishes to apply the formalist approach, not to all mathematics, but only to some of it. He begins with the thought that Cantor's theory of the infinite should certainly be retained, but must be protected from contradiction in some way. At present it is vulnerable, because we do not really understand the notion of infinity, and so do not attach a clear 'content' to our reasoning. Then he generalizes this thought to all other areas of mathematics that involve infinite totalities, taking this to include not only the theory of the real numbers (since they may be construed as infinite sets, or infinite sequences, of rational numbers), but even the use of quantifiers in elementary arithmetic, since these quantifiers range over all the infinitely many natural numbers. The most basic part of mathematics, then, is limited to what can be done in elementary arithmetic without quantifiers, using only free variables and recursive functions. This part has genuine content, is well understood, and can safely be assumed to be free from error. But in other areas we have no such guarantee. So his programme is first to formalize these other areas, proposing a formal theory that is adequate to represent all ordinary math-

ematical reasoning in that area, and then to argue in the metalanguage that this formal theory is free from contradiction. The metalinguistic argument, of course, must be confined to methods of proof that are guaranteed, i.e. to those already available in quantifier-free arithmetic. (This is one of several proposals on what may be counted as a 'constructive' method of proof. \*Constructivism.)

\*Gödel's incompleteness theorems destroyed this programme. The more far-reaching result was the first theorem, which implies that, for any sufficiently rich formal system, there are methods of reasoning about that system which evidently do establish the truth of a formula of the system, but which go beyond what can be proved within the system. So one cannot even carry out Hilbert's first step, of formalizing the area of mathematics to be proved consistent. But the second theorem shows that in any case the consistency of the system cannot be proved even by the methods available in that system itself, let alone by methods that Hilbert permitted as constructive. So Hilbert may perhaps be right in saying that, in some areas, all that the mathematician needs as a basis for his investigations is a consistent formal system, and that he need not attach any 'content' to that system. But we now know that we cannot use this idea to guarantee the safety of mathematical reasoning.

Brouwer, who founded intuitionism, shared Hilbert's distrust of the infinite and his commitment to constructive reasoning. But whereas Hilbert had aimed to rescue the non-constructive parts of mathematics, Brouwer simply abandons them. Against formalism, then, he sees no merit in formal systems without true 'content', and against logicism he believes that mathematics is prior to logic, and does not need it. However, in 1930 his pupil Arend Heyting did elaborate a logic suitable for intuitionistic reasoning, which Brouwer then endorsed. It is quite different from classical logic, mainly because its leading idea is that truth cannot be distinguished from provability. (\*Logic, intuitionist.) In Brouwer's own thought one can find two bases for this idea. One is that mathematical objects have a special status: they are 'mental constructions'. (This is a Kantian thought; it reverts to the 'psychologism' that Frege had attacked.) Since the objects do not exist independently of human thinking, it may seem to follow that we cannot adopt for them the same theory of truth as we use in other cases, namely a correspondence theory. In their case, then, there is nothing else for truth to be but provability. The other line of thought relies not on the alleged special status of the numbers, but just on the point that there are infinitely many of them. This means that, on the classical conception of truth, there could be some truth about all numbers which we could never verify, even in principle. But the intuitionist rejects this conception of truth as no less 'metaphysical' than the Platonic conception of numbers as independently existing objects.

Intuitionism is a revisionist theory in the philosophy of mathematics, for it involves abandoning much of classical mathematics. A more extreme form of this revisionism is 'strict finitism', which will not allow truth to go beyond

what we can in practice verify. It is disputed whether Wittgenstein should be counted as a strict finitist. D.B.

\*formalism.

**mathematics, knowledge of.** Interpreted at face value, mathematics appears to be a science concerned with an extraordinary array of objects and structures that are abstract, necessary, and infinite (geometrical shapes and patterns, the natural numbers, the real numbers, the set-theoretic hierarchy, and so on). It is, however, deeply mysterious how knowledge of such objects and structures could ever be acquired by us, mundane and finite creatures that we appear to be. Of course, mathematicians employ proofs to confirm their assertions. But proofs only tell us what follow from the axioms of a mathematical theory; they cannot inform us that the axioms are true. A variety of different epistemological strategies have been proposed to overcome this difficulty. According to one popular strategy, mathematical axioms are confirmed by the indispensable (auxiliary) role they perform in scientific practice. But this ties the practice of mathematics to the empirical fortunes of science. To avoid this consequence, \*logicism claims that mathematical axioms are truths of higher-order logic. s.s.

\*logicism; mathematics, problems of the philosophy of. Stewart Shapiro, *Thinking about Mathematics* (Oxford, 2000).

**mathematics, philosophy of, problems of.** The aim of the philosophy of mathematics is to provide an account of the nature and methodology of mathematics and to illuminate the place of mathematics in our overall intellectual lives. The problems fall into categories familiar to contemporary philosophers. There are ontological problems concerning the subject-matter of mathematics. What is mathematics about? There are epistemological problems. How do we know mathematics? What is the methodology of mathematics, and to what extent is this methodology reliable? There are problems of logic and semantics. How are the languages of mathematics understood, learned, communicated, etc.? What do mathematical assertions mean? Are unambiguous mathematical statements objectively true or false? What is the proper logic for mathematics? And there are problems concerning the relationship between mathematics and the rest of the

intellectual enterprise. What is the relationship, if any, between the philosophy of mathematics and the practice of mathematics? (See the text by Shapiro and the collection edited by Benacerraf and Putnam, listed in the selected bibliography.)

Many of the problems and issues in mathematics are counterparts of central items on the agenda of general epistemology and metaphysics. Mathematics provides a good case-study for many of the issues concerning existence, semantics, and knowledge that occur throughout philosophy. Nevertheless, mathematics at least appears to be different in kind from other types of investigation. Its basic assertions enjoy an extremely high degree of certainty. Indeed, theorems of at least elementary mathematics, like ' $2 + 2 = 4$ ' or 'There are infinitely many prime numbers', are often taken to be paradigms of \*necessary truths and \*a priori and infallible knowledge. How can such things be false, and how can any rational being doubt them? Thus, it is incumbent on any complete philosophy of mathematics to account for the necessity and apriority of mathematics, or else to show why mathematics appears that way.

Mathematics also plays an important role in virtually every scientific effort aimed at understanding the natural world. Consider, for example, the prerequisites of just about any natural or social science. It is thus incumbent on any complete philosophy of mathematics to show how mathematics is applied to the material world or, in other words, to show how the subject-matter of mathematics is related to the subject-matter of the sciences, and how the methodology of mathematics fits into the methodology of the sciences.

There are two distinct types of \*realism in the philosophy of mathematics. Realism-in-ontology is the view that the subject-matter of mathematics is a realm of objects that exist independent of the mind, conventions, and language of the mathematician. Most advocates of this view hold that mathematical objects—numbers, functions, points, sets, etc.—are abstract, eternal, and do not enter into causal relationships with material objects. Because of this, realism-in-ontology is sometimes called '\*Platonism', noting the resemblance between mathematical objects and Platonic Forms. This label can be misleading, however. Realism-in-ontology does not, by itself, presuppose anything like a Platonic epistemology, and there are realists-in-ontology who hold that at least some mathematical objects are not eternal and not outside the causal nexus.

Realism-in-truth-value is the view that unambiguous assertions of mathematics are non-vacuously true or false, independent of the mind, language, and conventions of the mathematician. This view is sometimes called \*realism.

There is a natural connection between the two varieties of realism. Consider the following statement:

There is a prime number greater than 1,000,000.

The realist-in-truth-value holds that this is an objective truth. But what does it mean? Prima facie, '1,000,000' is a

singular term, and 'prime number' is a common noun. If the surface grammar of this sentence reflects its \*logical form, and if 'there is' means 'there exists', then the sentence entails that both the number 1,000,000 and a greater prime number exist. For the realist-in-truth-value, this existence is objective, and so we are led to realism-in-ontology. In sum, if one is a realist-in-truth-value, then realism-in-ontology is the result of taking mathematical assertions at face value.

Conversely, realist-in-ontology at least suggests a straightforward, Tarskian semantics. If mathematical objects exist independently of the mathematician, then there is no impediment to a straightforward model-theoretic semantics, which would presumably render assertions true or false objectively.

Despite these natural alliances, the literature reveals no consensus on logical relationships between the two varieties of realism. Each of the four possible positions is articulated and defended by established and influential philosophers of mathematics. Kurt Gödel and Penelope Maddy adopt both forms of realism; Hartry Field and the traditional intuitionists L. E. J. Brouwer and Arend Heyting reject both forms; Geoffrey Hellman and Charles Chihara defend realism-in-truth-value, anti-realism-in-ontology; and Neil Tennant adopts the reverse, realism-in-ontology, anti-realism-in-truth-value (see the selected bibliography, especially the Benacerraf and Putnam anthology).

Typical forms of realism-in-ontology nicely account for the necessity of mathematics and give impetus to the traditional view that mathematical knowledge is a priori. If mathematics is about a realm of eternal, abstract objects, then mathematical truth is surely independent of any contingencies of the material world around us, and mathematics is not known through sensory experience. Of course, this alone does not *account* for the a priori nature of mathematics, until the realist provides an epistemology. It is not clear what these two varieties of realism have to say about the application of mathematics to science. Presumably, there is some sort of connection between the realm of abstract objects and the material world. The problem is to articulate it.

For the most part, alternatives to realism-in-ontology fall into two groups. First, there are those who agree that mathematics has a distinctive subject-matter, but hold that mathematical objects are not independent of the mind, conventions, or language of the mathematician. The most common views in this camp take mathematical objects to be mental constructions, and so are varieties of \*idealism (or applications of idealism to mathematics). Within this group, one unlikely possibility is to hold that mathematics is subjective, and so, presumably, each person has his own mathematics. A problem with this subjective idealism is to account for the fact that for the overwhelming most part, mathematicians agree with each other. It is more common for the idealist to hold that mathematics is both mind-dependent and objective or at least intersubjective in a principled way, perhaps by

following \*Kant in asserting that mathematics deals with structures common to human minds. The Kantian view accounts for the necessity of mathematics by holding that mathematics represents ways we *must* think, perceive, and apprehend, if we are to think, perceive, and apprehend at all. Mathematical knowledge is a priori to the extent that we have a priori access to the structures common to our minds. A Kantian might attempt to account for the application of mathematics to science by relating mathematics to the forms of sense perception. The writings of traditional \*intuitionists, such as Brouwer, have both subjective and Kantian themes, mostly the latter (see also \*constructivism).

The other alternative to realism-in-ontology is to simply deny that mathematics has a subject-matter: there are no numbers, functions, sets, etc. If this view is not to lapse into a general scepticism, denying the truth of ordinary or scientific assertions, the burden is to give an account of mathematics, and its role in the intellectual enterprise, that does not involve a mathematical ontology. One common manoeuvre in this direction is to reconstrue mathematical assertions in modal terms. For example, instead of asserting that there is a natural number with a given property, one asserts that it is possible to construct a certain item with the given property. If the modal assertions have objective truth-values, then the result would be a realism-in-truth value, anti-realism-in-ontology (see the items by Hellman and Chihara in the selected bibliography).

Another irrealist programme construes mathematics as fiction, much like what we read in novels. Statements about prime numbers are akin to statements about Miss Marple. At least *prima facie*, fictional discourse does not have ontological commitments. We do not believe that Miss Marple exists. On this view, mathematical assertions, taken literally, are vacuous. 'There are at least a million prime numbers' is false, for the simple reason that there are no numbers, and so no prime numbers. 'All numbers are prime' is vacuously true. With fiction, we distinguish literal truth from truth-in-the-story. 'Miss Marple is a nosy busybody' is false, but true in the relevant stories (or most of them). In this sense, mathematical assertions get their usual truth-values 'in the story'. To account for the applications of mathematics, a fictionalist might then try to give an account of the role of fictional mathematics in presumably non-fictional discourses, like science. (See the items by Field and Burgess and Rosen in the selected bibliography.)

Another view, developed by \*logicism and adopted by \*Logical Positivism, is to construe mathematical truths as \*analytic, true in virtue of the meanings of its terms. The necessity of mathematics is semantic, or linguistic. Mathematical knowledge is knowledge of meaning, which is presumably a priori. The problem, however, is to square this view with mathematics as practised. One needs to give an explication of the meanings of mathematical terminology according to which every mathematical truth is analytic.

The logicist Gottlob Frege showed how to derive the usual principles of arithmetic from what has come to be known as Hume's principle:

The number of *F*'s is identical to the number of *G*'s if and only if the *F*'s are equinumerous with the *G*'s.

This result has considerable mathematical interest. Who would have thought that so much mathematics can be derived from a simple fact about the application of arithmetic to counting? Contemporary neo-logicists, such as Crispin Wright, propose to make this derivation the foundation of arithmetic. Hume's principle, and \*second-order logic, provide an epistemological \*foundation of mathematics. Neo-logicism accounts for the a priori nature of arithmetic, to the extent that we know Hume's principle a priori, and that second-order derivation preserves a priori knowledge. The neo-logicists are realists-in-ontology, holding that the existence of numbers follows from Hume's principle (together with some uncontroversial logical truths).

Structuralism is a philosophy of mathematics that turns attention away from individual mathematical objects. The subject-matter of arithmetic, for example, is the natural number structure, the form common to any infinite system of objects that has a distinguished initial object, which plays the role of zero, and a successor relation or operation that satisfies the induction principle. The natural number structure is exemplified by the arabic numerals, sequences of characters on an alphabet in lexical order, an infinite sequence of distinct moments of time, etc. Similarly, real analysis is about the real number structure; topology is about topological structures; etc. According to the structuralist, the application of mathematics to science occurs, in part, by discovering or postulating that certain structures are exemplified in the material world. Mathematics is to material reality as pattern is to patterned (see the items by Hellman, Resnik, and Shapiro in the selected bibliography).

Most structuralists are realists-in-truth-value, but they differ among themselves on the question of ontology. *Ante rem* structuralism is a version of realism-in-ontology, taking structures, and their places, to be bona fide objects that exist independently of the mathematician. On this view, mathematical assertions are understood at face value. Against this, eliminative, or modal, structuralism takes statements about structures, and assertions within mathematics generally, to be generalizations over all systems, or possible systems, that exemplify the structure. It is a structuralism without structures.

There is a relatively recent tradition, traced to the later Wittgenstein, that attempts to accommodate mathematics in terms of the normative social practice inherent in a linguistic community. This denies that mathematics is necessary and a priori, but it does account for the perceived necessity of mathematics. We have to accept the basic principles because we cannot imagine living any other way: they are fundamental to our 'form of life'.

To a large extent, epistemology depends on ontology and semantics. How we know mathematics is surely related to what mathematics is about and what its assertions mean. The most difficult problem with realism-in-ontology lies in this area. How can we know anything about a realm of eternal, acausal objects? Indeed, how can we have any confidence that what we say about these objects is true? To produce an adequate epistemology, a realist-in-ontology must tell us something about ourselves, the knowers, and something about mathematical objects, the known. A tall order.

One route is to postulate a special faculty of mathematical intuition, something that gives the mathematician direct or indirect access to the abstract, eternal, acausal mathematical universe. Supposedly, this mathematical *intuition* is analogous to sense perception, which gives us access to material objects. Plato and Gödel proposed epistemologies like this. Despite the eminence of these thinkers, this view is rejected, almost out of hand, by those who put constraints of \*naturalism on epistemology. The idea is that humans must be understood as organisms in the natural world, and, as such, all faculties must be amenable to ordinary scientific scrutiny. For example, many philosophers hold that a person cannot have knowledge about a certain type of object unless he or she has causal contact with at least samples of the objects. This rules out the sort of mathematical intuition envisioned above, assuming that mathematical objects are acausal.

The few varieties of realism-in-ontology that deny that mathematical objects are abstract and eternal do not automatically run afoul of the naturalistic constraint. Presumably, if mathematical objects are material, then knowledge of them is no more problematic than knowledge of any other material objects. Of course, this view gives up realism's prima-facie account of the necessity and apriority of mathematics, but for some, this is a welcome loss. The problem is to square this view with mathematics as practised, and its apparent massively infinite ontology.

W. V. O. Quine and Hilary Putnam, among others, have proposed a hypothetico-deductive account of mathematical epistemology. The view begins with the observation that virtually all of science is formulated in mathematical terms. Moreover, as far as we know, this is the only way to formulate scientific theories. So mathematics is 'confirmed' to the extent that scientific theories are. The argument is that because mathematics is indispensable for science, and science is well-confirmed and (approximately) true, mathematics is well-confirmed and true as well. On this view, mathematical objects, like numbers and functions, are theoretical posits. They are the same kind of thing as electrons, and we know about them the same way we know about electrons—via their role in mature, well-confirmed scientific theories. Articulations of this view should (but usually do not) provide a careful analysis of the role of mathematics in science, rather than just noting the existence of this role. Such an account would shed some light on the 'abstract' nature of mathematical objects and the relationships between

mathematical objects and scientific or ordinary material objects. Typically, an advocate of the Quine–Putnam indispensability argument denies the necessity and apriority of mathematics. Mathematics is *only* known through its role in science, which is clearly a contingent, a posteriori affair. Because mathematics plays a central role in virtually every science, its disconfirmation is unlikely, but still possible in principle. Against such accounts, it does not seem that assertions like ‘ $2 + 3 = 5$ ’ are really of a piece with assertions about small molecules. Indeed, it would seem to follow from the view in question that the mathematical assertions are *less* firmly established than assertions about molecules, since mathematics is more theoretical—it lies further from sensory experience. Moreover, the view in question does not account for branches of mathematics, like higher set theory, that have not found application in science. In general, mathematicians usually do not look for confirmation in science before publishing their results, or otherwise claiming to know them.

A typical strategy among both realists and anti-realists (of any stripe) is to relate mathematics to some other area of knowledge. This allows the philosopher to appropriate epistemological gains from the other area or, more often, to claim that mathematical knowledge is no more problematic than knowledge in the other area (while conceding that the latter has its own epistemological problems).

For example, according to *ante rem* structuralism, a mathematical structure and a pattern are the same kind of thing. Patterns are at least *prima facie* abstract, and yet we manage to have knowledge of them. Thus, some structuralists attempt to account for some mathematical knowledge via the psychological mechanism of pattern recognition. Patterns themselves are abstract, but we know about them, in part, by ordinary perceptual contact with systems of physical objects that exemplify them. At best, however, this suggestion accounts for knowledge of small, finite structures. One still needs to accommodate knowledge about the infinite structures studied in live mathematics.

Along similar lines, modal structuralists and some fictionalists assimilate mathematical knowledge to knowledge of modal assertions. There is no consensus concerning knowledge of what is necessary and possible, but it is generally agreed that we have such knowledge.

In relatively recent history, there have been disputes concerning some principles and inferences within mathematics. These include the law of \*excluded middle, the axiom of \*choice, the \*extensionality of mathematical functions and properties, and \*impredicative definitions, linguistic entities that define an item by reference to a class that contains the object being defined (e.g. ‘the least upper bound’). Such principles have been criticized (and defended) on philosophical grounds. For example, if mathematical objects are mental constructions or creations, as the traditional intuitionists contend, then impredicative definitions are circular. One cannot create or construct an object by referring to a class of objects that

(already) contains the item being created or constructed. On the other hand, for a realist-in-ontology, a definition does not represent a recipe for creating or constructing a mathematical object. Rather, a definition is a characterization or description of an object that already exists. From this point of view, there is nothing illicit in definitions that refer to classes containing the item in question. Characterizing ‘the least upper bound’ of a set is no different from defining the ‘elder jurist’ as ‘the oldest member of the Supreme Court’.

The meaning of mathematical locutions like ‘There is a number such that . . .’ is related to one’s philosophy of mathematics. Intuitionists, for example, take this locution to mean ‘One can construct a number such that . . .’, while realists-in-ontology take existence to be independent of construction, or any human abilities for that matter. It follows that the proper logic of mathematics is also tied to philosophical considerations. No doubt, how mathematics is done, or should be done, has something to do with what mathematical discourse means. Typically, intuitionists propose revisions in mathematical practice, based on philosophical considerations. The arguments concern the nature of mathematics and mathematical objects, with Brouwer, or the learnability of mathematical language and the ability of mathematicians to communicate with each other, with Michael Dummett. There is a substantial technical question of whether mathematics could serve the needs of science if the intuitionistic revisions were adopted. That is, if mathematics were changed to conform to intuitionism, would the rest of the scientific enterprise suffer?

As far as contemporary mathematics is concerned, the aforementioned disputes are substantially over. The law of excluded middle, impredicative definitions, and the like are central parts of the enterprise nowadays. But this battle was not fought on philosophical grounds. Mathematicians did not temporarily don philosophical hats and decide that numbers, say, really do exist independent of the mathematician and, for that reason, that it is correct to engage in the erstwhile disputed methodologies. Rather, the practices in question were found to be conducive to the practice of mathematics.

This raises a meta-question concerning the relationship between mathematics and the philosophy of mathematics. It is a central tenet of the naturalistically minded philosopher that there is no first philosophy that stands prior to science, ready to criticize it. Science should guide philosophy, not the other way around. I presume that the same goes for mathematics. If so, then one must either reject intuitionism or else find some mathematical or scientific reasons to revise mathematics, reasons that mathematicians have overlooked to date, but which they would accept as compelling on mathematical grounds alone. That sort of quest does not seem to be under way—intuitionists are not naturalists, or else they do not extend naturalism to mathematics. s.s.

**matter.** 'What is matter?—Never mind. What is mind?—No matter'. This Victorian joke has some substance to it, in that it draws attention to the fact that it is easier to distinguish matter by contrasting it with something else than to say what it is. The joke also shows that if \**substance* is the ultimate ontological category, the fundamental stuff of \**being* or \**existence*, then matter is not the only candidate for substantial status: common-sense \**ontology* holds that there are two substances, matter and something else, \**mind*, \**soul*, or \**spirit*, the main characteristic of which is that it is non-material! Thus 'contrast' accounts of matter, though in some ways illuminating, are also frustrating.

Alternative, non-contrasting accounts of matter tend merely to substitute something equally puzzling. Does it help to say that matter is *physical* substance, the basic raw material from which everything physical is composed? But some help is at hand through the suggestion (or theory) that matter is what is *preserved* during any process of physical change. The search by the \**Pre-Socratics* for what would later be called matter arose from their adherence to a generalized conservation principle: something cannot be created out of nothing and something cannot disappear into nothing. Thus whatever exists fundamentally can be neither created nor destroyed but persists and is conserved throughout all changes in nature. This doctrine was clearest among the \**atomists*, who claimed that what exists fundamentally is material atoms and the void, and all change or alteration, such as motion, combustion, or the growth and decay of living things, is merely the rearrangement of atoms in the void. But it was left to Aristotle to establish matter as a category, by contrasting it with \**form*.

The contrast between matter and mind also has Greek origins, but it was Descartes who elevated it into the metaphysical dualism that has proved so compelling to

common sense, in spite of obvious difficulties (how do matter and mind interact?). Descartes equated matter and extension, adhering to the ancient principle that empty space is an impossibility, but his seventeenth-century rivals were reviving Greek atomism, or the 'corpuscular philosophy'. Thus in Locke, for example, is found the idea that matter consists of microscopic particles, though this idea coexists uneasily with an influential alternative theory, that matter is the underlying \**substratum* that supports the observable properties of things.

Another contrast is that between matter and life. If matter is simply inert substance, how can it produce the phenomena of \**life* and \**consciousness*? It cannot, according to \**vitalism*: something non-material must be added for living organisms to exist, a vital spark, a soul or spirit. But other theories of matter deny this contrast, and claim that life and consciousness are \**emergent* properties of matter, exhibited at a sufficiently complex level of organization. A variation is \**panpsychism*, according to which matter itself has non-physical properties of life and consciousness, in addition to the usual physical properties.

What then is matter? From the point of view of science, it is matter as what-is-conserved that matters. But hasn't modern physics 'dematerialized' matter, replacing it with energy or something even more abstract, like variations in the \**space-time* curvature? It is true that conservation principles—of mass, of momentum, of energy, etc.—are susceptible to the progress of science. Still, matter can be thought of as both what is fundamental in existence and what is conserved in change, granted that ideas about this are dependent on changing scientific theory. So matter persists. But conceptions of it change, sometimes radically, but only for good theoretical reasons. A.BEL.

**matter, prime:** see *prime matter*.

**maximin and minimax.** Game- and decision-theoretical strategies which require one to make one's worst possible outcome as good as possible (that is, to maximize the minimum). Maximin grounds Rawls's \**'difference principle'*, that political institutions should make the position of the worst-off group as good as possible. 'Minimax' is occasionally used as a synonym for 'maximin'. Used more precisely, it refers to maximin in zero-sum games, where the gain to one equals the loss to another. Maximin rationality is criticized for its extreme risk-aversion, and maximin justice for its insensitivity to the aggregation of welfare. R.CRI.

\**game theory*; decision theory.

J. Rawls, *A Theory of Justice* (Cambridge, Mass., 1971), sect. 26.

**Maxwell's Demon.** A \*thought experiment created by James Clerk Maxwell in which the second law of thermodynamics—that \*entropy always increases—is apparently violated. The demon operates a trap-door in a partition which separates two compartments, A and B, of randomly moving particles of gas, letting those of above average velocity pass into A and those of below average velocity into B. The result will be greater temperature and pressure in A than B, a differential which can be exploited to run a perpetual motion engine. This conclusion is disputed on the grounds that entropy does increase within the whole system of gas plus the demon. S.R.A.

\*energy; time.

**McDowell, John** (1942– ). Oxford philosopher, subsequently professor at the University of Pittsburgh. McDowell has developed a conception of mind, language, and morality that derives its main inspiration from the later work of Wittgenstein. McDowell argues that most contemporary philosophy of mind is committed to the Cartesian picture of the subjective realm as something private, essentially detachable from its relations to the world. This picture leads to an intolerable scepticism about the \*external world, or to the 'darkness within': the inability to explain genuine \*intentionality. Much of McDowell's work is an attempt to free the philosophy of mind from this picture; to this end he has articulated a radically externalist theory of the mind, in which certain thoughts are not thinkable in the absence of the objects they are about ('Russellian Singular Thoughts'; \*Evans). T.C.

\*externalism; anti-individualism; heredity and environment.

— *Meaning, Knowledge, and Reality* (Cambridge, Mass., 1998).

**McGinn, Colin** (1950– ). First studied psychology at Manchester University and then philosophy at Oxford. He won the John Locke Prize at Oxford in 1973, going on to teach at University College London from 1974 to 1985, whereupon he became Wilde Reader in Mental Philosophy at Oxford until 1990, at which time he joined Rutgers University. His early work was mainly in philosophy of language, this giving way to an interest in philosophy of mind and metaphysics. He has written on subjectivity and objectivity, on the content of propositional attitudes, on the later Wittgenstein, and on metaphilosophy. His most recent work is concerned with the solubility or otherwise of philosophical problems, particularly the mind–body problem. He maintains that the deepest metaphysical problems—such as the nature of the self, meaning, free will—have solutions that lie outside the contingent bounds of human cognitive power. N.B.

**McTaggart, John McTaggart Ellis** (1866–1925). Cambridge atheistic idealist now best known for his argument (in *Mind* (1908)) that \*time is unreal. McTaggart distinguished \*'A-series' terms like 'past', 'present', 'future', and 'B-series' terms like 'precede', 'simultaneous', 'follow'. He argued first that the B-series presupposes the A-series (e.g. if *X* precedes *Y*, there must be a time at which *X* is past and *Y* present), and then that the A-series is incoherent, since any event must have all three A-properties ('past', 'present', 'future'), yet these are inconsistent. Saying it has them at different times, the apparently obvious way out, leads to an infinite regress, he claimed, since then we must raise the same question about these different times themselves. The coherence of the A-series is still disputed, but so too is the alleged need for it. A.R.L.

**Mead, George Herbert** (1863–1931). American philosopher of social \*pragmatism and pioneer of sociology who taught at the University of Chicago as a prominent member of the Chicago School. The self, for Mead, 'arises in the process of social experience and activity'. Essential to this process is the role of language as the form of reflexive communication. 'It is in addressing himself in the role of an other that his self arises in experience.' The social in humans generalized as fundamental to all nature is 'sociality', 'the capacity of being several things at once'. '[T]he emergent object belongs to different systems in its passage from the old to the new because of its systematic relationship with other structures, and possesses the characters it has because of its membership in these different systems.' Human minds capable of occupying other systems as well as their own are, Mead said, 'only the culmination of that sociality which is found throughout the universe' P.H.H.

David L. Miller, *George Herbert Mead: Self, Language and the World* (Austin, Tex., 1973).

**mean, doctrine of the.** A central doctrine in Aristotle's account of excellence of \*character. Aristotle describes that excellence as concerned with *pathē*, i.e. motivational impulses, chiefly emotions, and with actions (sc. which issue from those motivations), and defines it as 'a settled state issuing in choice, in a mean determined by a rational principle, viz. the one by which the agent of practical wisdom would determine it'. This settled state is in a mean in the sense that the virtuous agent is neither excessively given to the various motivations prompting to action (e.g. excessively irascible) nor insufficiently sensitive to them, but responsive to the right extent, so as to choose to act on each motivation to the right degree, on the right occasions, for the right reasons, with reference to the right people, etc. The determination of what is right in all these

particular respects cannot be captured in any formula, but has to be the task of the educated judgement of the practically wise agent, responding to the indefinitely variable range of circumstances in which action is required.

C.C.W.T.

J. O. Urmson, 'Aristotle's Doctrine of the Mean', *American Philosophical Quarterly* (1973); repr. in A. Rorty (ed.), *Essays on Aristotle's Ethics* (Berkeley, Calif., 1980).

**meaning.** Twentieth-century philosophy, in both the 'analytic' and 'continental' traditions, was preoccupied with questions about linguistic meaning and the way language relates to reality. In the analytic tradition, this was largely as a consequence of the revolutions in logic initiated by Frege and Russell. Indeed, Michael Dummett has argued that the distinctive feature of \*analytic philosophy is its assumption that 'the philosophy of language is the foundation of the rest of the subject'. Even if one does not accept this claim, it is undeniable that the phenomena of meaning present some of the most intractable problems of philosophy.

The meaning of a word looks, as it were, both 'outwards' into the world, and 'inwards' to other words. The meaning of the word 'tiger', for example, is related both to those things in the world—tigers—to which it applies, and to other words with which it combines to make sentences which can be used to make assertions, ask questions, give warnings, and so on: 'Tigers are animals', 'Is that a tiger?', 'Look out! A tiger!' Whatever else is involved in meaning, it is clear that these two roles are clearly essential: for if one knows the meaning of the word 'tiger', one must have some grasp of how it applies to things in the world, and one must also be able to employ the word in an indefinite number of sentences. A theory of meaning—a 'semantic theory'—is therefore obliged to explain how words can perform this dual function.

In the seminal semantic theory of Gottlob Frege these two roles are explained together. Frege associated with each meaningful part of a \*language something he called its 'Bedeutung', normally translated as 'reference'. The reference of an expression is, intuitively, what it 'stands for': the reference of 'George Orwell', for example, is a particular man. Frege's insight was to see that the references of the parts of a sentence contribute in a systematic way to the truth or falsehood of sentences in which those parts occur. Thus the truth or falsehood of the sentence 'George Orwell wrote 1984' is determined by the references of the individual words and the way they are put together. The overall significance of the sentence—for Frege, its truth or falsehood—is fixed by what the parts of the sentence 'stand for' in the world, and the relations between those parts.

It follows from this claim that if you replace a word in a sentence *S* with a word having the same reference, the truth or falsehood of *S* will not change. But this gives rise to a notorious problem. Suppose that Alf believes that George Orwell wrote 1984, but does not know that Orwell is Blair. Then while the sentence 'Alf believes that George

Orwell wrote 1984' will be true, the sentence 'Alf believes that Eric Blair wrote 1984' will be false. So if meaning is what determines the truth or falsehood of a sentence, there must be more to the meaning of a sentence than the references of its parts.

Frege accounted for this by introducing another notion into the theory of meaning, which he called 'Sinn', usually translated 'sense'. The sense of an expression is, intuitively, not what is referred to by an expression, but the way it is referred to. Each sense determines one reference, but to one reference there may correspond many senses. (\*Sense and reference; \*intension and extension.) Central to Frege's view is that senses are abstract objects, not ideas in people's minds. (\*Psychologism.)

Frege's basic idea is very appealing. However, one natural question arises that Frege's own work (deliberately) doesn't address: given that words do refer to things, how do we *explain* this relation of reference? What makes it the case that any word refers to any object at all? A natural if vague answer is in terms of the psychological capacities of users of a language: words mean what they do because of what speakers of the language do with them. An example of this approach is \*Logical Positivism, which held that the meaning of a sentence is given by an account of what it would take to verify the sentence. Here meaning is explained in terms of the psychological and other abilities of speakers to tell whether a sentence is true.

The demise of Logical Positivism's account of meaning was followed by an outbreak of scepticism about the notion of meaning, most influentially expressed in the work of W. V. Quine. Quine followed the positivists in linking meaning to experience, but argued that experience does not relate to individual sentences but to whole theories. Since he thinks that meaning must be empirically available, Quine frames the question thus: What evidence determines that someone means something by making certain sounds? Quine thinks that the only acceptable evidence is behavioural, and therefore shuns any appeal to introspection or Frege's senses (the latter are 'creatures of darkness' whose criteria of identity are utterly obscure). But no amount of behavioural evidence can *determine* that a person's words mean one thing rather another—it is always possible to construct alternative and incompatible 'translations' of the evidence. From here Quine moves to his famous claim that \*translation is indeterminate, and reference is inscrutable: strictly speaking, there are no facts about what words and sentences mean. This is not an epistemic claim: reference is inscrutable because 'there is nothing to scrutate'. (We also find a very different scepticism about philosophical accounts of meaning in the later writings of Wittgenstein.)

A significant attempt to explain meaning, with one eye towards Quine's scepticism, was propounded by Donald Davidson in the 1960s and 1970s. Sharing Quine's sympathies with \*extensionality, Davidson attempted to account for meaning in terms of truth, which for some time had seemed more logically tractable than meaning. In particular, the Polish logician Alfred Tarski had defined

truth for the sentences of certain \*formal languages in terms of the relation of \*satisfaction holding between the parts of sentences and sequences of objects. A sentence's truth is determined systematically by the satisfaction of its parts; thus Tarski could show how to formally derive, from the axioms and rules of the theory, sentences (so-called 'T-sentences') which state what might intuitively be regarded as the conditions under which any sentence of the language is true. (The apparently banal T-sentence "'Snow is white" is true if and only if snow is white' is a favourite example.)

As we saw, the idea of the parts of a sentence making a systematic contribution to the meaning of the whole sentence was a key idea in Frege's work. But Davidson explains meaning without using the troublesome idea of sense. Instead he proposes using a theory of truth in Tarski's style to 'serve' as a theory of meaning. In outline, the idea is this: a theory of meaning for a language should at least entail, for any sentence of the language, a sentence that 'gives its meaning'. The most obvious sort of case would be the 'homophonic' case: to give the meaning of a sentence would just be to give the sentence itself. For example, we recognize immediately that the sentence "'Snow is white" means that snow is white' gives the meaning of 'Snow is white'. This looks trivial, of course, but that is only because we already know what 'Snow is white' means. (The sentence "'La neve è bianca" means that snow is white' does not look so trivial.) The theory must also show how the individual parts make a systematic contribution to the sentences in which they occur. So now we know what the consequences of a theory of meaning must be—but how can we construct a theory that does actually have these consequences? Davidson's insight was to see that if we replace 'means that' in the above sentence with 'is true if and only if', we will get the T-sentences that Tarski showed how to prove. And Tarski did this by showing how the truth of sentences was systematically determined by the semantic properties of their parts. By employing Tarski's theory of truth as a theory of meaning, Davidson put flesh on the skeletal idea that to give the meaning of a sentence is to give the conditions under which it is true. (\*Truth-conditions.)

But how does Davidson's theory account for the phenomena Frege explained by employing the notion of sense? Giving truth-conditions alone will not do this—since 'Orwell wrote 1984' and 'Blair wrote 1984' have the same truth-conditions. Davidson replies that it is one thing to construct a formal theory that shows how the semantic properties of whole sentences are systematically formed from the semantic properties of their parts; it is another thing to establish how such a theory applies to individual speakers. The latter task is to provide an *interpretative* Tarskian truth-theory. In applying a truth-theory to a speaker, we must apply the constraints of a theory of radical interpretation, notably the 'principle of charity': assume that on the whole speakers are speaking the truth. Interpretation then proceeds as follows: collect the sentences that a speaker 'holds true', and devise a

truth-theory that has these sentences as a formal consequence. To respect the intensionality of meaning, we need a theory that proves sentences like "'Orwell wrote 1984" is true if and only if Orwell wrote 1984', and not "'Orwell wrote 1984" is true if and only if Blair wrote 1984'. But the *theory* that proves the interpretative T-sentences will be purely extensional.

For Davidson, belief and meaning are interdependent—one of the lessons he draws is that nothing can genuinely have beliefs unless it also has a public language. Many philosophers have recoiled from this, both because they think that it is undeniable that certain non-linguistic creatures—such as dogs and apes—do have beliefs, and because they hope that meaning may yet be explained in terms of, or ultimately reduced to, the contents of mental states. One influential proposal is that of H. P. Grice, who suggested that the meanings of sentences can be reduced to a speaker's intention to induce a belief in the hearer by means of their recognition of that intention.

Although Grice's programme is not as popular as it once was, the general idea of reducing meaning to the psychological states of speakers is now widely accepted (*pace* Davidson, Wittgenstein, and their followers). This is illustrated by the fact that, at the time of writing, the philosophy of language has to some extent yielded the centre stage to the philosophy of mind—and the problem of meaning has become the problem of intentionality. r.c.

**measurement.** An empirical procedure for ascertaining the \*magnitude of a given quantitative property possessed by an object. Objects are measured on a scale, which assigns a unique numerical value to each magnitude of the

quantitative property. The same quantitative property may be measured on different scales, and by different procedures. Thus length can be measured in either feet or metres, with a ruler or by triangulation. Scales are typically (but not always) defined by selecting a standard whose magnitude becomes the unit, 1. Other objects are then measured by determining how many times greater their magnitude is than that of the standard. An object found to be five times longer than the standard metre measures five metres. Sometimes scales are defined in terms of other scales, as with the cubic metre scale of volume. In that case, the quantitative property is measured by measuring the quantities in terms of which the scale was defined and then calculating. The metre and cubic metre scales are called ratio scales, since numerical ratios among the scale values represent quantitative ratios among the magnitudes represented by those values. If the numerical value assigned to *A* is twice the numerical value assigned to *B*, then *A* is twice as long or twice as large as *B*. Many important scales of measurement lack this property, such as the Fahrenheit and Celsius scales of temperature, and the Mohs scale of hardness. A 60° day is not twice as hot as a 30° day. Measurement in general has been crucial to scientific and technological progress, which in turn has increased phenomenally the precision and range of measurement.

**mechanism.** In the philosophy of mind, the doctrine that we are machines. Descartes held that other animals are machines, but only to emphasize his own view that human beings are not machines because they have \*minds, which he supposed to be non-physical. The idea that human beings are machines was later urged by La Mettrie. Some form of this idea is widely accepted today. But decisions must be made about how to understand it, and there is resistance to it for other reasons than a commitment to \*dualism.

Leibniz argued in a famous passage that ‘perception, and what depends on it, cannot be explained mechanically’. For ‘if we imagine a machine whose construction ensures that it has thoughts, feelings, and perceptions, we can conceive it to be so enlarged. . . that we could enter it like a mill. On that supposition, when visiting it we shall find inside only components pushing one another, and never anything that could explain perception’ (*Monadologie*, sect. 17). Such reasoning can seem very persuasive, but it begs the question. Leibniz just *assumes* that ‘components pushing one another’ could not amount to the machine’s thinking, feeling, or perceiving. Of course the assumption is easily made. Even mechanists concede that it is difficult to acquire even a faint idea of how a machine might have thoughts and feelings. The difficulty is all the greater if our conception of machinery is restricted to

hydraulic and clockwork systems. However, if Leibniz had known about \*computers he would at least have wanted to supplement his argument.

The mathematical and logical thinking which contributed to the design and construction of computers also produced the basis for a definition of mechanism. According to the ‘Church–Turing thesis’ any mechanical process can be modelled by means of a certain kind of abstract system known as a \*Turing machine, and therefore by any equivalent system, such as a computer program. So we might define mechanism as the view that the workings of human beings exemplify computer programs. It is now clear that decisions have to be made. We are, after all, very complex systems, whose ‘workings’ may be considered from different points of view and at different levels of description and explanation. Assuming we are purely physical systems, we are composed of swarms of elementary particles. But these particles are organized into atoms, and these into molecules. The molecules in their turn make up the organs and other components of our bodies. You might assume that if our workings exemplify computer programs at some level of description and explanation, they must do so at the other levels as well. But conceivably the behaviour of the elementary particles does not exemplify a program (as in effect we learn from \*quantum mechanics) while the behaviour of the bodily organs does. If so, our workings—like those of computers themselves—are in the relevant sense mechanical at some levels of description but not at others. It seems that any variety of mechanism needs to be relativized to a level of description and explanation.

An extreme variety might claim that we instantiate computer programs whose basic data represent the beliefs and desires of everyday psychology. That used to be the claim of some \*artificial intelligence enthusiasts. The practical difficulties of that approach are now fairly well known. One interesting theoretical objection, tenaciously developed by J. R. Lucas but widely attacked, has been that \*Gödel’s theorem implies that human logicians can do things which would be impossible if we instantiated such programs.

**medical ethics.** The study of ethical problems in medicine using the concepts, theories, literature, and techniques of moral philosophy. The phrase is used also to refer to the ethical beliefs or habits of behaviour of doctors and nurses, or to explicit codes governing professional behaviour, such as the International Code of the World Medical

Association. The subject has burgeoned since the 1960s into what amounts to an independent discipline, with its own specialists, centres, and journals. Many medical students are now exposed to at least some medical ethics education.

Much medical ethics involves the deployment of philosophical moral theories in an attempt to solve medical ethical problems. This is useful not only in promoting understanding of the problem and possible solutions, but in elucidating and developing the theories themselves. For example, consider one of the many life-and-death issues which have come to dominate medical ethics: paternalism. A utilitarian philosopher who believes that welfare should be maximized might be tempted to suggest that a doctor should do whatever she believes to be in her patient's best interests. But when she realizes that her theory may allow the doctor completely to ignore the patient's wishes, she may attempt to incorporate the value of autonomy into her theory, perhaps as part of welfare.

Over recent years, antipathy towards ethical theory in an abstract and systematic form (so-called anti-theory) has come to influence some writers in medical ethics, who tend to place weight less on the application of principles than on careful and sensitive appreciation of the particular case. It is worth noting also that pluralistic positions are available, combining, say, a utilitarian principle requiring medical personnel to do the greatest good for their patients with a Kantian principle setting various constraints on maximization. For example, transplant surgeons might be required to do the greatest good, but not at the price of forcibly violating the bodily integrity of involuntary 'donors'. These issues are discussed in great depth in the work of Frances Kamm and Jeff McMahan.

The teaching of medical ethics, especially in the USA, has been dominated by a pluralistic position: the four principles of Beauchamp and Childress—autonomy, non-maleficence, beneficence, and justice. One standard objection to the Beauchamp and Childress position applies to pluralistic views more generally: in cases of conflict, unless we are to advocate some kind of \*incommensurability, we must make some decision, and can that decision not itself be seen as an articulation of a higher-order principle? And, if so, is there not a highest-order principle? Further, while it is true that the four principles are useful in alerting medical students to the various values at stake in ethical dilemmas, it is equally important that emphasis in teaching be placed on the character or virtues involved in everyday 'good practice'.

Other life-and-death issues commonly discussed include \*abortion and \*euthanasia. Utilitarians have found it difficult to show why infanticide, on their view, can be any worse than abortion. The abortion debate has revolved around the partly Kantian question whether the foetus is a \*person with \*rights. Some have argued that the status of the foetus as a *potential* person is important here. At the other end of life, similar theoretical issues arise. If I have a right to life, can I waive it voluntarily, enabling a doctor to administer a lethal dose if I am in the terminal

stages of some illness? Should we administer such doses to decrease overall suffering? These questions have become more urgent as medical life-preserving technology has advanced.

Advances in reproductive technology have also raised several significant issues. Many people have seen techniques such as *in vitro* fertilization for infertility as the first step on a slippery slope to a Brave New World. The nature of the family has also been thrown into doubt: why should a homosexual couple or a single person not bring up a child created using reproductive technology? Is it acceptable that a child might have three 'mothers' (genetic, birth, nurturing)? Genetics too has thrown up many problems, concerning, for example, genetic screening or the genetic modification of non-human animals for xenotransplantation.

Other topics concern the everyday practice of health care personnel more directly. Positions taken on confidentiality, for example, again arise from differences at the level of ethical theory. A Kantian may argue that the promise implied in the contract between doctor and patient forbids any breach of confidentiality for the benefit of others or the patient herself. Or a utilitarian may point to the harm which might occur if people were no longer able to trust doctors, thus supplying a welfare-based ground for the practice of respecting confidentiality. Finally, a philosopher attracted to the \*virtues might stress the importance of confidentiality in the relationship of trust between the patient and the doctor.

The main political issue discussed in medical ethics is the allocation of resources. A popular notion here is the QALY (quality-adjusted life-year), which represents an attempt to make length or quantity of life commensurate with its quality. Thus a year of healthy life is said to be worth 1, while a year of rather poor health might be worth only 0.5. The QALY theory most often used is essentially a health-maximizing version of \*utilitarianism. It therefore runs into the same problems as most versions of utilitarianism: its conception of what is to be maximized, and how, is dubious, and it ignores fairness. R.CRI.

**medicine, philosophy of.** The philosophical, as distinct from the ethical and historical, problems in and around medicine are not largely discussed. There are fragments in

Greek and Arabic writings, but in recent years there have been surprisingly few philosophical, as distinct from ethical, writings on medicine. Yet the philosophical problems of medicine are of great interest, because they include most of those discussed within the philosophy of science and the philosophy of social science, with the added twist that they occur in a distinctive context. Without claiming to cover every area of philosophical interest, I shall briefly mention four problems.

First, there are problems of a kind familiar in the philosophy of science. For example, 'evidence-based medicine' has become a slogan in medical circles. But what is the nature of the evidence? The evidence often cited as the 'gold standard' is that of randomized control trials. Yet such trials are largely statistical correlations of treatments with percentage success rates using volunteer patients who may not be at all typical. Again, the evidence in diagnosis, in identifying the patient's medical problem, is quite different from that in control trials, being more like that used by a detective. And of course familiar problems of realism versus anti-realism arise if we ask 'What is disease?' Secondly, much medical research is qualitative, involving questionnaire-based inquiries into concepts such as 'quality of life'. The problem which arises here is over the attempt to quantify and produce measurement scales for such inquiries. These are problems in the philosophy of social science. Thirdly, there are problems of personal identity thrown up by genetics. How far are my personal traits determined by my genotype? Finally, there are problems of the acceptable limits of medicine. It used to be a set of techniques for repairing the human body when it broke down, but there are some who hold that it has the potential to make us immortal. The charm of the philosophy of medicine is that its problems are at the cutting edge of science, but these problems must be discussed from a humanistic perspective which prevents them from becoming dry abstractions. **medieval philosophy.** Histories of medieval philosophy tend to start with St Augustine (354–430), if not earlier; but Augustine was of the late Roman Empire, centuries before the Middle Ages, and is included in such books not because he was a medieval thinker but because he cast such a long shadow across medieval philosophy. He provided a role model in that he thought deeply, systematically, and in a philosophical way about Christianity. He was familiar with the writings of the philosophers of Greece and Rome, particularly the Stoics and the Neoplatonic schools, and put that knowledge to work in the elucidation of fundamental concepts such as those of God, eternity, time, good and evil, and creation. The first great philosopher of the Middle Ages, St Anselm of Canterbury (1033–1109), was deeply influenced by him, and St Thomas Aquinas (1224/5–74) cited him

far more often than he cited any other of the Church Fathers.

Like St Augustine the medieval thinkers philosophized because they wished to understand Christianity. Indeed Anselm's famous phrase *fides quaerens intellectum* (faith seeking understanding) is a perfect description of the philosophy written in the Christian West throughout the Middle Ages. A major part of their task of clarification involved demonstrating that Christianity is not incompatible with what can be demonstrated by reason. The doctrine of \*double truth, particularly associated with Averroës, which declares that a truth of faith can be incompatible with truths sanctioned by reason, made very little impact upon thinkers in the Christian West. For them it was crucially important to establish that Christianity was not incompatible with any proposition demonstrated by philosophy. For a proposition thus demonstrated must be true and anything incompatible with the truth is false.

At the start of the period Aristotle's works had been unknown except for a few treatises (fewer than was realized at the time since two treatises attributed to him were spurious, the *Theology of Aristotle*, which is really part of Plotinus' *Enneads*, and the *Book of Causes*, which is an Arabic epitome of Proclus). As time passed more of Aristotle's writings became available, reaching the Christian West from the Muslim world, often accompanied by detailed and profound commentaries by Muslim thinkers such as al-Fārābī (died c.950), Avicenna (980–1037), and Averroës (1126–98). These texts with their Arabic commentaries were promptly translated into Latin. Averroës' interpretation of Aristotle was so influential that philosophers of the Christian West referred to him simply as 'the Commentator'. And since Aristotle's was the system to which every philosopher and theologian had to react (indeed he was referred to almost universally simply as *philosophus*—the Philosopher), the crucial question tackled was not whether Christianity and philosophy were compatible, but whether Christianity and Aristotelian philosophy were compatible. For the most part the answer given was affirmative. When, as rarely happened, it was not, then of course Aristotle's position had to be rejected.

Much the most important point of conflict concerned Aristotle's analysis of motion in the *Physics* and *Metaphysics*, which led him to conclude that the world was eternal. Many medieval philosophers, believing that the world had a beginning in time, found it necessary to argue against Aristotle's arguments. It should be noted that most did not attempt to prove that the world did have a beginning in time. A consensus formed round the opinion that the question whether it was eternal or had a temporal beginning was not philosophically demonstrable, and that the doctrine was to be accepted on faith, being the plain meaning of the first sentence of Genesis. Some indeed held that Aristotle did not think that he had demonstrated the eternity of the world but had merely presented the doctrine as a probable opinion. On that interpretation the standard interpretation of Genesis 1:1 was compatible with Aristotle's teaching. Aquinas was one major figure

## MEDIEVAL PHILOSOPHY

AVICENNA is the Latinized name by which the Persian Ibn Sina is known in the West; he was the most brilliant of the Islamic Aristotelians and a leading figure in the vigorous debate which accompanied the development of Islamic philosophy and theology in the fifth century after Muhammad.

THOMAS AQUINAS, born and educated in southern Italy, became the greatest teacher of the Dominican monastic order. In the mid-thirteenth century he developed Aristotle's legacy into an exhaustive, rigorously argued philosophical and theological system.

ROGER BACON was the first great Oxford philosopher; he enlisted scientific method in philosophical and theological enquiry.

DUNS SCOTUS was called Doctor Subtilis for his subtle reconciliation of Aristotelian philosophy with the doctrines of the Franciscan monastic tradition.

who held that the eternity of the world was neither provable nor disprovable. His teacher, Albert the Great, held, to the contrary, that Aristotle's position on this matter was false, and that the doctrine that the world had a beginning in time could be demonstrated.

There is a common belief that the problem of \*universals is the philosophical problem of the Middle Ages. It should be said that that belief, in any case exaggerated, does not address the fact that the problem of universals is not one problem but a large cluster of problems. And indeed problems about universals have always been centre-stage in the history of philosophy; and universals are as much an issue now as they have ever been. Nevertheless, the fact remains that a philosopher's position on whether certain entities were mind-independent (in which case they had real existence, the solution of 'realists') or were mind-dependent (in which case they had nominal existence, the solution of 'nominalists') entered into the interstices of many debates.

One problem concerning universals was this: granted that several individual things have a common nature as a result of which they are members of the same species, what is the mode of existence of this common nature? Does it exist in the individuals that have the nature? Those, for example Wyclif, who replied affirmatively are realists. But there are difficulties associated with this position. For example, if the universal doghood, which must be in an animal if the animal is a dog, is in fact in a given animal, then how can it also be in another animal? Must the universal be divided in two for it to be in a second animal? If so then it surely follows that since each of these animals has only half the universal in it, each must be only half a dog—which is an absurd conclusion. Realists had a problem explaining how a universal can really be in many things at once. Yet they must say that a universal can be in many things at once, for if it cannot, then it cannot be universal. The chief alternative proposal to realism is this, that a universal is the concept that we form under which we can bring all the things in that species, as the nominalists (or conceptualists) such as Ockham thought. On this account the universality of a universal lies in the fact that the concept thus formed is equally predicable of many things. There is a direct line of descent to Ockham's position from that of Abelard, who argued famously that common natures are really utterances (*voces*) or mental entities. For both Abelard and Ockham the doctrine of universals had a central role in the theory of predication.

A version of the debate between realists and nominalists was conducted in the Middle Ages in connection with the existence of values. Does God command us to perform acts of a given kind because they are in any case good, or is their goodness caused by the fact of God's commanding them? (\*Euthyphro problem.) An affirmative answer to the first question implies a realist position, namely that values have a real existence independently of God's will, whereas an affirmative reply to the second question implies a nominalist position, namely that values owe their existence to an act of divine will. This latter doc-

trine, known as voluntarism, was associated, though inaccurately, with Duns Scotus. Secular versions of not only this, but also many other medieval debates, constitute a large part of the philosophical scene today. A.BRO.

**Megarics** (4th century BC). The Megarics scorned analogical reasoning ('If it's from like to like, one should consider the things themselves, rather than those like them; if it's from unlike to unlike, the comparison is pointless'), modalities ('Only the actual is possible; e.g. someone who isn't building cannot build'), and predication ('If we predicate to run of a horse, subject and predicate differ. Since they differ, it's wrong to say that a horse runs'; 'What I'm pointing to isn't cabbage. For cabbage existed ages ago. So this isn't cabbage'). So how could wisdom, God, and intellect all be, as the Megarics insisted, good? Simple: they were 'one thing, with many names'.

In ancient times, 'Megaric' was applied only to the school founded by Euclides of Megara in Greece. Much modern scholarship perversely applies the term to others too. N.C.D.

**Meinong, Alexius** (1853–1920) is one of the most misunderstood and reviled philosophers of recent times. According to a prevalent view, he was a spendthrift metaphysician who delighted in multiplying entities continuously and needlessly. Gilbert Ryle, for example, speaks of him as the 'supreme entity-multiplier in the history of philosophy'. Meinong's fatal mistake allegedly consisted in mistaking the meanings of words for objects. With this distorted perspective, his importance derives entirely from the fact that he forced Russell, Wittgenstein, Ryle, and later English philosophers to realize that \*meanings are not objects. But this conception of Meinong's philosophical importance is quite mistaken.

Meinong attended the University of Vienna in the fall of 1870 and graduated in the summer of 1874 with history as his major. In the fall of the same year, he entered the law school of the University of Vienna. Soon afterwards, under the guidance of Franz Brentano, he turned to philosophy. In his autobiographical notes, Meinong states that he may have jealously guarded his independence of the forceful personality of Brentano, and that this may have caused misunderstandings between him and his teacher. 'But what in life could not be laid to rest', he concludes, 'in death has been reconciled; and before the inner eye of my memory, there stands once again, as a treasure I shall never lose, my admired teacher, a figure of spiritual

beauty, bathed in the golden sunshine of the summer of his own and my youth.' From 1878 until 1882, Meinong was Privatdozent at the University of Vienna. Then he was appointed Extraordinarius of philosophy at the University of Graz, and, later, Ordinarius. He lived and worked for the rest of his life in Graz. The following story, I think, is characteristic of his way of life. When he was repeatedly urged to take a vacation, he finally and very reluctantly consented. He packed a suitcase and moved from his house in Graz to a hotel a few blocks away, where he stayed for two weeks and undoubtedly worked on his philosophy, before he returned to his home!

To understand Meinong's philosophy, it is necessary to see how it develops step by step over many years from an idealistic (Berkeleyan) and most austere beginning into a realistic and ample philosophical system. In his earliest publications, the *Hume Studien I* (1877) and *II* (1882), Meinong deals with two thoroughly traditional philosophical problems, the problem of \*universals and the problem of \*relations. In *Hume Studien I*, Meinong adopts a Berkeleyan ontology. An ordinary perceptual object, like Berkeley's apple, is conceived of as a complex of property instances: a certain colour instance, associated with a certain shape instance, associated with a certain taste instance, etc. These \*property instances (\*individual properties, \*abstract individuals), in turn, are associated with a place and a moment. A complex is individuated, according to Meinong, by these places and moments. The property instances themselves are both particular and universal: if they are viewed, through acts of abstraction, in isolation from the places and moments, they are universal; if viewed as associated with places and moments, they are particular. This is Meinong's early solution of the nominalism–realism problem. Finally, all of these complexes of property instances are identified, in Berkeley's fashion, with complex presentations, that is with mental entities.

This view calls for a closer inspection of the relations required by an ontology of complexes. This is the topic of *Hume Studien II*. Here Meinong discusses the three relations involved in complexes. Firstly, there is the relation of equality among instances which guarantees that property instances can be grouped in the required way. Where a realist speaks of two things as sharing the same property, Meinong speaks of two numerically different but equal property instances. Secondly, there is the relation of association which binds the various instances together into a complex. And thirdly, there is the part–whole relation between an instance and the complex to which it belongs. This relation corresponds in Meinong's scheme of things to predication. The great achievement of the *Hume Studien II* consists in Meinong's eventual recognition that there are mind-independent relations. Like Frege and Russell, he thus breaks with a long philosophical tradition, according to which relations are merely the creations of mental acts of comparison.

But even in the *Hume Studien II*, we find the pervasive idealistic confusion between presentations (\*ideas) and their objects. However, this confusion does not last long.

Meinong, just like another student of Brentano's, Edmund Husserl, realizes that one must distinguish between the \*content of a mental act, on the one hand, and the intention or object of the act, on the other. And just as it does for Husserl, who discovers \*phenomenology, this distinction eventually opens up for Meinong a new field of philosophical inquiry, namely, his so-called theory of objects.

In 1894 there appeared a rather slim book by Kasimir Twardowski, another student of Brentano's, which greatly influenced the course of philosophy: *On the Content and Object of Presentations* (tr. R. Grossmann (The Hague, 1977)). In this book, Twardowski argued that the object of a mental act is not 'immanent' in the act, that is, is not a part of the act. He therefore distinguished between the individual mental act, its content, and its object. Even more importantly, Twardowski argued that the question whether or not an act has an object must be sharply distinguished from the question whether or not the object exists. And he held that even though every mental act has an object or intention, many of these objects do not exist at all. Meinong adopts Twardowski's distinction as well as his contention that there are many objects (of acts) which do not exist. By adopting Twardowski's view, Meinong breaks out of the idealistic prison: a presentation, as a mental act with a content, can now be clearly separated from the object which it intends.

At about the same time, 1899, Meinong also realizes that his implicit \*ontology is much richer than the explicit one consisting of nothing but property instances combined with places and moments. It comprises also complexes of property instances (or properties) and relations. With this realization, Meinong's eyes are opened to his own and other philosopher's ontological commitments. From now on, Meinong's philosophical inquiries are primarily ontological inquiries.

Meinong's most famous book is called *On Assumptions (Über Annahmen)*. The first edition appeared in 1902; the second and more important one in 1910. The topic indicated by its title hardly warrants its fame. The discovery of one more kind of mental act is not the most exciting thing in philosophy. But the title is misleading. What Meinong really discovers, and finally fully appreciates in the second edition, is the \*category of states of affairs, what he calls 'Objektives'. With the discovery of the category of states of affairs as the intentions of judgements and assumptions, Meinong, just like Husserl, breaks decisively with Brentano's philosophy, according to which only individual things exist.

But Meinong's fame, unfortunately, does not rest on this epochal ontological discovery—think of Wittgenstein's later pronouncement that the world is a collection of facts, not of things—but on Meinong's view about intentional objects and their properties.

Like many recent philosophers, Meinong distinguished between two modes of \*being. Let us call them existence and subsistence. Things that are located in space and/or time are said to exist. Things which are not in space and

time subsist. For example, individual things exist; the relation of equality between property instances, on the other hand, subsists. Now, it is clear that there are intentional objects before a mind which neither exist nor subsist, for example, the golden mountain of which someone may be thinking. And this raises the important question whether this intentional object has perhaps a third mode of being. The most important argument that speaks for such a further mode of being starts from the fact that there subsists, according to Meinong, the fact (objective) that the golden mountain does not exist. If one assumes that something can only be a constituent of a fact if it has some sort of being, then it follows immediately that the golden mountain must have being of some sort. Or else, it seems, one must reject this principle and assume that something can be a constituent of a fact even if it has no being at all. Meinong discusses this issue extensively and arrives at the conclusion that the principle must be rejected. Of course, one can escape from the apparent dilemma in Russell's way, namely, by showing that the golden mountain is not a constituent of the fact that the golden mountain does not exist. Meinong does not take this way out. But, contrary to a common misunderstanding, he does not hold that the golden mountain has some kind of being.

However, Meinong does hold a view that is highly suspect, namely the view that the golden mountain, even though it has no being, is nevertheless golden and a mountain. Things without being, in short, are held to have certain quite ordinary properties. I think that it is this view which is most characteristic of Meinong's metaphysics. And it is this view which leads him to claim that there is a whole field of inquiry which has been neglected by philosophy, namely, the so-called theory of objects. The golden mountain, for example, is an intentional object of the mind. Now, if it has no properties, as one is apt to assume, then there can be no theory about it, no informative truths would be forthcoming. Only if one assumes, as Meinong does, that such intentional objects have a number of properties, can there be knowledge about them.

In a review (*Mind* (1905)) of one of Meinong's works, Bertrand Russell raises two objections against Meinong's claim that non-existent objects have common properties. Firstly, Russell objects that if impossible objects, like the round square, really had the properties Meinong attributes to them, like being both round and square, then such objects would violate the law of contradiction. Meinong, in reply, readily admits that this is the case, but points out that nobody has ever tried to apply this law to anything but the actual or possible (*Über die Stellung der Gegenstandstheorie im System der Wissenschaften* (Leipzig, 1907)). Contradictory things, in other words, quite obviously must violate the law of contradiction or they would not be what they are. Perhaps Russell thought that his objection had some force because he thought of logic, at that time, not just as applying to what there is, but as encompassing everything.

Russell's second objection, however, is to the point, and Meinong devotes several paragraphs to it. If the round

square is really round and square, then the existing round square, according to Russell, must also exist. But this is absurd. The round square does not exist. Meinong tries to escape from this objection by distinguishing between ordinary existence and the 'existential determination' to be existing. The latter, he claims, behaves like an ordinary property in that just as the golden mountain is golden, so the existing golden mountain has the existential determination of being existing. It follows that the existing golden mountain is existing, but it does not exist. In a letter to Meinong, Russell replies that he cannot see how one can distinguish between 'to exist' and 'to be existing'.

It may be thought that Meinong could have avoided Russell's objection without the dubious distinction between existence and to be existing by claiming that existence is not a property like being made from gold or being a mountain. While it is true that the golden mountain is golden and the round square is round, it is not the case that the existing golden mountain exists, since existence is not a property. In a way, Meinong makes this move. He holds that while the golden mountain is golden, the existing golden mountain does not exist. But then he adds the so-called existential determination to be existing, and this addition seems merely to cloud the issue. Why does Meinong think that there is a property which somehow corresponds to existence without being existence? An answer follows from Meinong's acceptance of the so-called principle of unlimited freedom of assumption, according to which one can think not only of a round square, but even of an existing round square. Clearly, to think of an existing round square is not the same as to think of a round square. Therefore, the objects before the mind must be different in these two cases. Meinong has to introduce the existential determination in order to distinguish the one intentional object from the other.

In view of these and other difficulties, why is Meinong so convinced that the golden mountain is made from gold and that the round square is both round and square? Surely, this view is rather implausible, to say the least. I think that he may have been misled by his conception of individual objects as complexes of property instances (or of properties). The complex object which is the golden mountain must obviously consist, among other things, of the property of being golden. Now, if inclusion in a complex is conceived of as predication, then it follows immediately that the complex which is the golden mountain, since it contains the property of being golden, must be golden. Hence one arrives at the view that every complex, no matter what its ontological status may be, must have the properties which constitute it. R.G.

Meinong's works have been collected in a *Gesamtausgabe*, 7 vols. (Graz, 1968–78). Some of them have been translated into English, e.g. 'Über Gegenstandstheorie', tr. I. Levi as 'The Theory of Objects', in R. M. Chisholm (ed.), *Realism and the Background of Phenomenology* (New York, 1960); also *Über Annahmen*, 2nd edn., tr. J. Heanue as *On Assumptions* (Berkeley, Calif., 1983). Books about Meinong's philosophy:

J. N. Findlay, *Meinong's Theory of Objects and Values* (Oxford, 1963).  
 R. Grossmann, *Meinong* (London, 1974).

**Melissus** (fl. c. 440 BC). Metaphysician of the Eleatic group (he also had success as a naval commander). While the ground-plan of his philosophical treatise seems to have followed that of Parmenides, he diverged in significant ways. He freely applied spatial and temporal predicates to his reality, suggesting that it stood closer to the world of ordinary experience. Yet his criticism of sense-perception was much more radical than that of Parmenides: he argued not merely that it is not a means to knowledge, but that it is necessarily illusory. E.L.H.

\*Eleatics.

G. S. Kirk, J. E. Raven, and M. Schofield, *The Presocratic Philosophers*, 2nd edn. (Cambridge, 1983), 390–401.

**Mellor, D. H.** (1938– ). British metaphysician and philosopher of science, noted for his work on chance and probability, dispositional properties and laws of nature, the problem of induction, and the philosophy of \*time.

Mellor rejects the dynamic view of time which regards temporal becoming as an objectively real phenomenon. He denies that there are any tensed facts (that is, facts involving pastness or futurity), while conceding that tensed beliefs are not translatable into tenseless beliefs and are indispensable for practical reason and action. According to Mellor it is tenseless facts which make tensed beliefs true, the key to this possibility being the indexical character of tensed expressions like 'now' and 'yesterday'. He endorses McTaggart's argument that tensed language, construed purely realistically, leads to contradiction. Unusually for an adherent of the tenseless view of time, Mellor rejects the doctrine of temporal parts, which holds that persisting objects consist of spatio-temporally continuous and causally connected stages or time-slices. Mellor extends his approach to indexical language to first-person expressions like 'I', as part of an overall metaphysical view which is naturalistic and scientifically informed and yet sceptical of physicalist and reductionist dogmas.

Mellor's approach to issues concerning belief and action, probability and induction, and causality and natural law follows recognizably in the Cambridge tradition of F. P. Ramsey and Richard Braithwaite, whose work he has done much to promote. His Cambridge inaugural lecture, 'The Warrant of Induction' (1988), provides new insight into the solution of an old problem by setting it within the context of an externalist approach to knowledge and warranted belief. This, along with his defence of dispositions and of objective chance in terms of \*propensities, marks him off as a metaphysical realist well able to counter the subjectivist and relativist leanings of many other leading philosophers of science.  — *Matters of Metaphysics* (Cambridge, 1991).

**memory.** To have a good memory is to be able to remember many things, accurately and easily. But what is it to remember anything at all? Evidently the past comes in somehow. A creature with no past, assuming such a creature is possible, would have no memories, even if it had some innate knowledge of facts about the past, or vivid and unexplainably accurate images of past events; this follows simply from the logic of the words 'memory' and 'remember'. What one remembers may refer to, though it cannot be in, the future: one can remember that one will die, but not one's own death. But perhaps one can only remember what one previously knew? Certainly this will not be sufficient; a teacher who forgets the things he taught and relearns them later from his pupils is not remembering, even though he not only previously knew what he now knows but only knows it now *because* he knew it previously. A pure causal theory of remembering, then, whereby to remember something is to have known it in the past and to be caused by this to know it now, is not enough. Perhaps one cannot remember a fact without having previously known it, but if I remember to turn the gas out I need only have previously intended to turn it out—I need not have known something; but the previous intention must not be completely irrelevant to my present condition. Some link then is needed, and though causation may not be enough, if we abandon it what can replace it? But if we keep it what form can it take? Perhaps that of some trace in the brain (but see Bursen, *Dismantling the Memory Machine*)?

Memory, especially of past events which we not only previously knew about but experienced, often seems to involve images: in trying to remember something we think we succeed if we can form an \*image of it. But how can we distinguish remembering it from imagining it? No property intrinsic to the image itself will do, even if we could find one that belonged to all and only memories (of the relevant kind), for how could such a property tell us that something outside the image (the event in question) was real and not imaginary? It is true that a memory may suddenly come upon us in the form of an image, but it is not the image's vividness that makes it a memory, and when we try to remember something we are not looking for an image to tell us about the past, for how would we know what to look for? Rather we must already know what happened in order to create the image, or vet those images that come before us. To remember an event (as opposed to remembering the fact that it occurred) we must have experienced it, and so perhaps remembering it involves remembering our experiencing of it, which involves somehow reproducing it, and how could we reproduce it except by an image? This may be where images are important for memory, but the image still need not constitute the memory. It will probably be both inaccurate and incomplete, and I may know this. The most we can say seems to be that remembering an experience must include having some sort of an image which can be regarded as corresponding to it to some degree.

As the above illustrates, memory is of various kinds. As well as facts, events, people, places, and experiences, one can remember how things looked, where to find them, what to do with them, to do something, and also how to do it; this last (remembering how) has sometimes been singled out for special contrast with another kind involving images (Bergson, Russell), but without much justification, one might think (see Holland, 'The Empiricist Theory of Memory').

A.R.L.

\*quasi-memory; mnemonic causation.

- H. A. Burson, *Dismantling the Memory Machine* (Dordrecht, 1978).  
 R. F. Holland, 'The Empiricist Theory of Memory', *Mind* (1954); repr. in S. Hampshire (ed.), *Philosophy of Mind* (New York, 1966). Includes discussion of images.

**Mencius** (4th century BC). Confucian thinker in China probably best known for his view that human nature is good. His full name was Meng K'o and he was also known as Meng Tzū (Master Meng), latinized as Mencius. He defended the ethical and political ideal of Confucius against challenges from rival schools of thought, and his teachings are recorded in the *Meng Tzū*, a collection of his sayings and conversations with disciples, friends, rulers, and philosophical adversaries. According to him, all human beings share certain ethical predispositions such as an affective concern for others, a sense of shame, love for parents, and respect for elders. The Confucian ideal is a full realization of such predispositions, and self-cultivation involves nurturing them to make possible their full development.

K.-L.S.

*Mencius*, tr. D. C. Lau (Harmondsworth, 1970).

**Mendelssohn, Moses** (1729–86). Jewish \*Enlightenment philosopher, a Leibnizian who admired Spinoza and Maimonides, and was the model for Nathan the Wise in Lessing's play of that name. Supplementing his Hebrew education by learning High German, Latin, Greek, French, and English, Mendelssohn won the Berlin competition (1764) in which Kant took honourable mention. His defence of immortality (*Phaedon* (1776)) won him fame. His *Jerusalem* (1783) brilliantly exposes as incoherent the idea of spiritual authority. His German Pentateuch anchored the Jewish Enlightenment (*Haskalah*). His vision of humanity's vocation to unending progress profoundly influenced Kant, who became his lifelong friend. Mendelssohn is credited with distinguishing beauty from metaphysical perfection, arguing that the latter is unity in multiplicity, known in its purity only to God; the former is a human substitute based on our introducing an artificial uniformity into those objects we perceive as wholes. Managing a silk firm and forced by Christian controversialists into extended defences of his loyalty to Judaism, Mendelssohn lost his health, but campaigned heroically against the civil disabilities imposed on Jews, especially the invidious requirements regarding oaths. His son, a

banker, raised his son Felix as a Christian, composer of the Reformation Symphony.

**Meno's puzzle:** see learning paradox.

**men's rights:** see masculism.

**mental acts:** see acts, mental.

**mental causation.** It is a prevalent view that mental events or states, e.g. desires and beliefs, contribute causally to the bodily movements involved in action. Descartes, holding that mental states are non-material, thought the point of interaction was the pineal gland.

As against this, it is often held nowadays that the notion of non-physical interference is incoherent, since the physical world is a closed system. So Davidson, working with this assumption, has argued that in order for mental states to produce their physical effects they must themselves be physical.

However, dissatisfaction with Davidson's theory arises from three points: (i) Davidson denies the existence of strict \*psychophysical laws, (ii) mental states, even if physical, have mental properties, and (iii) mental states explain action in virtue of their mental properties, which should therefore be assigned a causal role. The objection is that Davidson cannot do justice to this last requirement because of (i), and much current debate has turned on the task of trying to resolve this issue.

Some reject (i), holding that there are psychophysical laws, albeit with *ceteris paribus* clauses attached (Fodor)—a view that is challenged by Schiffer. Crane and Mellor reject the physicalist closed-system assumption, arguing that psycho-physical laws are every bit as genuine as the laws of physics. An alternative position (Honderich) holds a \*union theory according to which mental and neural states operate together as a pair in causal transactions.

Dretske has a structural-cause theory: he fixes on the mental as a representational property of beliefs and holds that it operates, not as the neural event which triggers an appropriate bodily movement, but as the structuring cause which contributes to the setting-up of appropriate neural-event → bodily-movement connections. Mental causation remains very much a subject of live debate.

O.R.J.

\*volition; will.

Donald Davidson, *Essays on Actions and Events* (Oxford, 1980).  
 John Heil and Alfred Mele (eds.), *Mental Causation* (Oxford, 1993).

**mental events.** Deciding what counts as a mental event is not easy. The efficacy of tests like the event's being immaterial, subjective, private, or incorrigibly known have been hotly disputed. A \*privileged-access criterion seems best for sensations, but not for acquiring intentions, beliefs, or desires. Brentano's criterion of intentionality fares better here. This test requires that certain implications of existence or identity do not follow from

attribution of mental events. Falling into Lake Wobegone implies that it exists, but *forming an intention* to find Lake Wobegone does not (nor that it doesn't). Again, hitting Ali implies that I hit Clay (Clay and Ali are identical), not so if I acquire a desire to hit Ali (I might be unaware of the identity). Thus falling and hitting are not mental events; acquiring intentions and desires are.

Having an intention (contrast forming one), or having a belief (contrast acquiring one) are reckoned to be \*mental states rather than events, but if the above-mentioned criteria are good for mental events they are good equally for mental states.

O.R.J.

\*dualism; functionalism; materialism; physicalism.

Donald Davidson, *Essays on Actions and Events* (Oxford, 1980).

**mental indispensability.** The claim of mental indispensability or mental efficacy is that reference to mental events is an essential part of any correct full explanation of behaviour and of the occurrence of other mental events. It has seemed plausible to take the contribution of mental events to be causal. In which case, the claim that the mental is indispensable is a recognition of its causal efficacy and is a denial of \*epiphenomenalism.

P.J.P.N.

\*mental causation.

T. Honderich, *A Theory of Determinism* (Oxford, 1988), ch. 2.

**mentality.** The attribute of having a mind, but what are minds? As many use the word, the \*mind is the *apparatus or mechanism or inner works* which explains how humans are capable of such things as action, rationality, emotion, perception, and imagination. In that sense it has been discovered to be (roughly) the brain or central nervous system, and the remarkable properties of this mind-brain have become the target for the most exciting research projects of our time. Others use the word as a shorthand way of talking of *those capacities and features which qualify us as distinctively human*. Thus there are conceptual debates about the nature and relative importance of rationality, agency, free will, consciousness, social awareness, capacity for abstract thought, and so on. These are elucidations of and suggestions about everyday notions which developed from social interactions in response to practical needs and interests. If listing these qualities gives what makes us human, thereby revealing our mentality, it is *not* the sense in which brain researchers investigate the mental, for they are interested in what makes us human in a causal or theoretical way. Our everyday minds are what they seek to explain by their interesting discoveries about the scientific mind.

In the theoretical or scientific sense, most of us know very little about minds. But in the descriptive or everyday sense, we all know a great deal about them, including and especially our own. Philosophy sometimes just articulates an unwarranted fear of drowning when it seeks to put limits on what brain research could show, but some of its warnings may be salutary. Successive and transient internal models of the scientific mind have been based on

available technology, such as clocks, hydraulic robots, telephone exchanges, \*computers, and \*programs. It is fair criticism to point out when these fall short of simulating human powers. Homing rockets do not exhibit purposes as we do, pocket calculators do not show mathematical intelligence, and so on. Also, by comparing the performance of machines with human performance, we can sharpen our everyday acquaintance with what is involved in the latter. Delineation of everyday mentality is both essential to and aided by the attempt to model how it works.

It is tempting to help the mechanical models out with internal directors or subagents in order to get them to work as explanations of what people do. This is harmless as a linguistic place-holding device, indicating just where more work on the mechanism needs to be done. But it is damaging if the internal operators are transformed into Cartesian \*egos, the kind of invisible metaphysical controller which Ryle caricatured as the \*ghost in the machine. The trouble is that such things are inaccessible (at least in practice), their form or location being unspecified, and there is a danger of endowing them with the kind of powers the mechanism was introduced to explain, thereby duplicating the explanatory project.

What locks the myth of Cartesian egos into place is that we suppose that our knowledge of our own unscientific minds is yielded by a species of continuous inner perception. Our being conscious, it is easy to think, consists in introspecting what goes on in our thinking, feeling, and willing parts. Then it looks as if we all have a hot-line either to the Cartesian ego or to the machinery which the brain researchers posit in their latest models. The everyday and the scientific concepts of mind seem to converge, though it will usually be said that we have access only to a small part of our minds, the bit of the electronic iceberg above the surface. As if someone who tells you what is in her mind and the brain researcher who tells you how her mind works are reporting on the same subject-matter (observed, no doubt, from a different 'aspect').

In my view, this perceptual view of consciousness as \*introspection is a mistake. When we give our motives, state our beliefs, express how we feel, announce the course of our deliberations, or reveal our imaginings, we are not at all describing our scientific minds 'from a subjective point of view', but providing more evidence about how our everyday minds work. The sense in which everyday thoughts may be revealed or hidden is not the sense in which brain mechanisms may be revealed or hidden, and our interpretation of puzzling behaviour by our friends is not in competition with the explanations of brain researchers. On any view, adjudicating skirmishes at the boundaries between the everyday and the scientific concepts of mentality remains important philosophical work.

**mental reductionism.** Reductionism about a given subject-matter *X* is the claim that facts about *X* can be 'reduced' to—that is, can be shown or construed to be—facts about another subject-matter *Y* ('the reduction base'). Reductionism in philosophy of mind is the claim that facts about mentality are reducible to physical facts, i.e. facts about matter and material processes.

What is required to implement mind–body reduction? According to the \*dualism of Descartes, minds exist as 'mental substances', objects wholly outside the physical domain. On this view, facts about mentality would be physically irreducible since they would be facts about these immaterial entities. The first requirement for mind–body reduction, therefore, is the renouncement of minds as non-physical objects. This can be done either by identifying minds with brains or other appropriate physical structures, or by refusing to countenance minds as substantial entities and attributing mental properties to organisms and other physical systems. In either case, it is physical systems that have psychological properties.

The remaining step in mind–body reduction concerns mental properties, e.g. being in pain, sensing a green patch, believing that snow is cold, and their analogues in systematic psychology. Let *M* be a mental property: the physical reduction of *M* is usually thought to require a 'physical correlate' of *M*, i.e. a physical property with which *M* is necessarily coextensive. When a pervasive system of physical correlates is found for mental properties, mental properties could, it is thought, be identified with their physical correlates.

\*Logical behaviourism sought to reduce mental properties by defining them in terms of behaviours and behavioural dispositions. Although mentality seems intimately tied to behaviour, it is now widely agreed that mental terms resist behavioural definitions. The demise of behaviouristic reductionism has led to the hope that the mental might be physically reduced through empirical laws connecting mental and physical properties. Nomological reduction of mental properties would proceed by providing for each mental property *M* a nomologically coextensive physical property *P*—that is, where '*M* occurs if and only if *P* occurs' holds as a matter of empirical law. According to the \*identity theory of mind, every mental property has a neural correlate with which it is to be identified; if pain is uniformly correlated as a matter of law with, say, the activation of c-fibres, pain may be reductively identified with c-fibre activation, and similarly for other mental properties and kinds.

The significance of mind–body reduction is claimed to be twofold: ontological economy and unity of theory. By dispensing with minds as substances of a special sort and their irreducibly psychic features, we simplify our

ontology. By construing mental properties as complex neural properties and taking physical organisms as their bearers, psychology can be integrated with the underlying biological and physical sciences.

Two lines of consideration have been responsible for the decline of reductionism. One is psychophysical anomalism, the claim that there are no laws connecting mental and physical phenomena, and hence no laws of the sort required for the nomological reduction of the former to the latter. The other is the \*variable (or multiple) realizability of mental properties. If a mental property is multiply realized by a variety of physical properties in diverse species and structures, it could not, the argument goes, be identified with any single physical property. These considerations have led many philosophers to favour non-reductive physicalism (\*mind–body problem; \*physicalism; \*functionalism), the doctrine that although all the individuals of this world are physical, certain properties of these individuals, in particular their psychological properties, are not reducible to physical properties. **mental states.** A disputed notion. Many philosophers have held that beliefs, desires, intentions, etc. are real states, but have disagreed profoundly on their nature, some maintaining that they are non-material states (Descartes) and others that they must be physical states if interactions with sense-organs and bodily movements are to be possible. Tough materialists (Churchland) hold that talk of such states will become dispensable in favour of neural descriptions, while others (Dennett) concede the non-reality of mental states but hold that use of psychological terms is indispensable. Ryle held that belief-claims are really claims about \*dispositions to behaviour, but Arthur Collins has recently argued they are epistemic risk claims—'I believe that *p*' means '*p* and I am right, or not-*p* and I am wrong'—with no reference to a state involved.

For questions about criteria for mental states, see the entry on mental events. The above disputes extend to the notion of mental events, since most mental events are reckoned to be the arrival or cessation of mental states.

**mereology.** Mereology is the formal theory of part–whole relations, whose early developers included Leśniewski, Tarski, and Goodman. The standard theory regards any whole as identical with the sum of its parts and

consequently identifies any two objects containing all and only the same parts. This makes it difficult to accommodate the case of organic wholes, such as living organisms, which can survive the replacement of some of their parts and consequently cannot be identified at any one time with the sum of their concurrently existing parts. However, modal and temporal extensions of the standard theory promise solutions to such difficulties.

The relationship of a whole to its proper parts is importantly different from that of a set to its members, though David Lewis has recently argued that a set may be regarded as the mereological sum of its unit subsets.

**meritocracy.** Any society that creates an élite by suitable rewards based on accomplishments that distinguish some from others is a meritocracy. Thus it has been described as a society characterized by 'careers open to talents' (John Rawls). The aristocracy of merit is thought to be natural, since it is grounded on the exercise of esteem-worthy personal traits. Merit is definable as the superior productivity or performance that results when intelligence is joined with effort, popularized in the formula  $I + E = M$  (Michael Young). A meritocracy requires equality of opportunity and some form of central planning; it must prohibit egalitarian levelling as well as any form of nepotism or hereditary aristocracy.

**Merleau-Ponty, Maurice** (1907–61). French phenomenologist and co-founder with Sartre of existential philosophy. Merleau-Ponty's constant target was the subject-object \*dualism of \*Cartesianism, which arguably still continued to dominate Sartre's existentialism. Drawing on Husserl's notion of a pre-predicative \*intentionality and on Heidegger's exposition of human existence as being-in-the-world, Merleau-Ponty developed a description of the world as the field of experience in which I find myself. Descartes's Cogito was transformed to read 'I belong to myself while belonging to the world'. Any attempt to constitute the world as an object of knowledge is always derivative in relation to that primary access to the world that Merleau-Ponty located in the body.

*Phenomenology of Perception* (1945) established Merleau-Ponty as the pre-eminent philosopher of the body. The body is neither subject, nor object, but an ambiguous mode of existence that infects all knowledge. Merleau-Ponty drew on the critical examination of contemporary psychology and physiology presented in his first book, *The Structure of Behaviour* (1942), to argue the primacy of perception. Merleau-Ponty questioned the attempt of traditional philosophy to look to \*perception to provide some

guarantees that mark its difference from hallucination. What is given in perception is ambiguous. However, this does not lead to scepticism, any more than does the experience of disillusionment. The discovery that one was the victim of an illusion does not challenge faith in perception altogether. It is only in the name of a new perception that a previous perception is doubted.

Merleau-Ponty distinguished what reflection reveals from what is given in unreflective experience. This led him to the idea of a radical reflection. Radical reflection was Merleau-Ponty's alternative to \*analysis, which he consistently criticized. Analytic thought on his view breaks up experience into constituents, for example sensations and qualities, and is thus obliged to invent a power of synthesis in an attempt to rebuild the world of experience. In spite of this, his work has found a more receptive audience among analytic philosophers than other phenomenologists have managed to receive.

Throughout his writings Merleau-Ponty sought ways to explore the body's primordial contact with the world prior to the impact of analysis. In doing so, he was resisting a tendency of contemporary scientific and philosophic thought to valorize autonomous knowledge arrived at under experimental conditions. In the late essay 'Eye and Mind' (1961) Merleau-Ponty turned to painting for evidence of the character of the body's relation to the world, evidence that provides no consolation for those in search of definitive conclusions. A similar conclusion arose from his studies on language that introduced Saussurean linguistics into phenomenology. In the abandoned manuscript 'The Prose of the World' and in the collection of essays *Signs* (1960) Merleau-Ponty challenged the ideal of an algorithmic language.

In *The Visible and the Invisible* Merleau-Ponty introduced the notion of flesh in a new attempt to explore the sense in which the seer is caught up in what he or she sees. Merleau-Ponty had come to recognize his earlier conception of the body as still tied to the dualistic metaphysics he was committed to challenging. For that reason flesh was not presented in opposition either to the mind or to the world, but as an element, much as air and water are elements. Unfortunately, the book was still incomplete at the time of his death. Scholars have had to rely heavily on his working notes in order to assess the extent to which the emphasis on ontology in *The Visible and the Invisible* represents a departure from his earlier phenomenological studies and not just their fulfilment.

**meta-ethics** is the philosophical study of the nature of moral judgement. So, instead of being concerned with questions of what actually is right or wrong (or good or bad), it is concerned with the meaning or significance of

calling something right or wrong (or good or bad). Since both of these kinds of inquiry can properly be called ethics, the term *meta-ethics* may be used more precisely to denote the latter kind. Meta-ethics includes both the meaning of moral terms and also such questions as whether moral judgements are objective or subjective. It also includes others of the \*problems of moral philosophy. R.H.

\*moral philosophy, history of; emotivism; prescriptivism; moral realism.

**metalanguage.** The one in which the properties of a language under study, the object language, are stated. The metalanguage may be identical to the object language, as when the grammatical properties of English are stated in English, but it is often distinct from the object language. According to an influential view of Tarski, some semantic properties of a language *L* can be expressed only in a distinct metalanguage, not in *L* itself. A.G.U.P.

A. Tarski, 'The Semantic Conception of Truth', *Philosophy and Phenomenological Research* (1944).

**metalogic.** The mathematical and philosophical study of the components of systems of logic. Examples include rigorous analyses of notions like logical consequence, \*deduction, \*logical form, \*satisfaction, and \*denotation. A typical result of metalogic is a \*completeness theorem establishing that a model-theoretic notion of consequence is captured by the arguments derivable in a given deductive system. S.S.

\*logical theory.

**metaphilosophy.** The philosophy of philosophy. Philosophy is the attempt to solve philosophical problems. 'What is philosophy?' is itself a philosophical problem, so metaphilosophy is essentially the attempt to solve that problem.

On metaphysical conceptions of philosophy, philosophy is the attempt to describe reality as opposed to appearance. For example, Plato draws a distinction between the world of *doxa* (belief, opinion) and the world of *epistēmē* (knowledge). The perfect, unchanging *eidea* (Forms, essences) which exist independently of minds and spatio-temporal objects are the true objects of philosophical study. By this picture, Plato reconciled the competing views of his Pre-Socratic predecessors Parmenides, according to whom there is only unchanging being, and Heraclitus, according to whom there is only becoming, or the transition between being and nothingness. Arguably, Augustine's distinction between the city of God and the earthly city, Descartes's distinction between mental and physical substances, Leibniz's postulation of monads, Spinoza's one substance, Schopenhauer's *Wille* and (partly *malgré eux*) Hegel's *Geist* (Spirit) and Heidegger's *Sein* (Being) are metaphysical doctrines in this broad sense.

On anti-metaphysical conceptions of philosophy, knowledge of reality is impossible, either because of the constraints of the senses or because it leads to contradictions or because it deploys terminology beyond the limits of significance. Hobbes, Locke, Berkeley, and Hume, in very different ways, regard knowledge as constrained by possible sense perception. Kant thinks the attempt to do metaphysics generates seemingly valid pairs of arguments with mutually exclusive conclusions called 'antinomies'.

Since Kant, philosophy has operated within a Kantian anti-metaphysical paradigm. Because metaphysical philosophy is allegedly impossible, attempts have been made to replace it by something else: the overthrow of capitalist society (\*Marxism), the description of appearances (\*phenomenology), natural science (\*Logical Positivism), the description of conceptual schemes (\*structuralism), the analysis of the meanings of ordinary language (\*linguistic philosophy), literary criticism (\*post-structuralism).

In medieval Christian, Jewish, and Islamic philosophy the true object of study is \*God. However, faith and \*revelation are needed because the powers of the finite human intellect are inadequate tools of theological understanding.

Non-Western philosophy exhibits the same tension between metaphysics and anti-metaphysics. The inconsistencies between, say, Taoism and Confucianism, or Tibetan Buddhism and Indian materialism, are at least as difficult to reconcile as those between, say, Plato and Aristotle, Descartes and Hume or Hegel and the Logical Positivists. It is not true that all and only Western philosophy is naturalist and anti-metaphysical and all and only Eastern philosophy is spiritualist and metaphysical.

Whitehead famously said that Western philosophy could be understood as a series of \*footnotes to Plato. It is certainly not misconstrued as an oscillation between Platonic metaphysics and Aristotelian naturalism. In philosophy, the twentieth century was an Aristotelian age. S.P.

**metaphor.** The starting-point for philosophical discussion of metaphor is whether or not metaphors are paraphrasable in literal terms. On what has been called the 'substitution theory' a metaphor is assumed to stand in for a literal equivalent. The metaphor 'Achilles is a lion' can be teased out to give 'Achilles is like a lion in respect of the following features . . .'. However, after Max Black's influential paper in which he proposed what he called an 'interaction' theory, philosophers have become acutely aware of the way in which different hearers or readers pick out

different common features between the terms of a metaphor. Metaphors are interpreted and they are interpreted differently by different readers and hearers. Consequently, the idea that there can be a literal paraphrase of a metaphor which preserves its sense is no longer widely held, for such a literal paraphrase would have to command common agreement as expressing what the metaphor means. A powerful metaphor like Macbeth's 'sleep that knits up the ravell'd sleeve of care' invites us to join in an exploration of points of similarity and difference. Black, in a later paper, speaks of metaphors as 'inciting the hearer' and likens the process to game-playing. Since this also characterizes the understanding of similes, few writers would now make a sharp distinction between metaphor and simile.

Black argued that when we read a metaphor like 'Achilles is a lion', we read it armed with a number of commonplace beliefs about 'lion'; these, metaphorically applied to Achilles, we draw on as we construe it. In Claudius' line in Shakespeare's *Hamlet*, 'When sorrows come, they come not single spies, but in battalions', we may reflect that spies threaten and undermine, carrying the fear of worse to follow; battalions, on the other hand, embody open aggression.

One interesting recent contribution in a philosophical debate that goes back to Aristotle is Donald Davidson's rejection of the idea that there is a special sort of \*meaning which metaphors have, over and above the literal meaning. Taken literally metaphors seem nonsensical or false or only trivially true. For Davidson, it is the use of metaphor which is crucial, in making us aware of some likeness, often surprising, between apparently disparate things but without asserting that likeness.

Metaphors are the growing-points of \*language. A cursory glance shows just how much of the language of mind is metaphorical in origin. These metaphors die, of course, and lose their metaphorical force though their origins may be still visible. In recent decades, philosophers have, as well, become more aware of the role played by metaphor in science and religion.

**metaphysics, history of.** Metaphysics is the most abstract and in some views 'high-falutin' part of philosophy, having to do with the features of ultimate reality, what really exists and what it is that distinguishes that and makes it possible. Nevertheless, the exact nature of the subject has been constantly disputed, as indeed has its validity and usefulness.

Philosophy at its very beginnings with the Pre-Socratics was metaphysical in character, although it was initially presented in a dress which made it sound more like physics, as witness Thales' claim that everything is made of water. Subsequent Pre-Socratics were concerned with other attempts to understand nature and the possibility of change within it, although Parmenides argued (for the

first time by means of a formal argument, even if that was given a poetical dress) that coming to be, ceasing to be, and change in general were impossible, so that his successors had to counter his claim, even if they did not fully understand his arguments. By the time of Plato, with his theory that the true realities were Forms (or Ideas), abstract exemplars or paradigms, of which sensible things were only imperfect copies, the distinction of metaphysics from physics became clear, since these realities were quite distinct from the world with which physics has its concern. Since the Forms were also universal in character his theory also initiated metaphysical arguments concerning the status of \*universals, something that has gone on ever since.

The term 'metaphysics' originated, however, as a title given to some of Aristotle's works in the catalogue of the edition of them produced by Andronicus of Rhodes in the second half of the first century BC (although it may have come from an earlier library classification). It meant simply the works which followed those on physics in the catalogue. But those works, which were concerned with being, both as such and in respect of various \*categories of it, especially \*substance, contain discussions concerning matters which have an obvious continuity with later metaphysical theories. Hence it is reasonable to see Aristotle's *Metaphysics*, untidy though it is in the form in which it has come down to us, as the first systematic treatise in metaphysics, containing not only discussions of the notion of being and what has the best claim to that title but also criticisms of earlier thought on the subject, particularly Plato's Theory of Forms. Those Forms are soundly rejected. Aristotle believes in universals, certainly, but they are features of the world itself, which is made up of things with \*essences, belonging to a system organized in terms of genera and species. The notion of species corresponds to that of \*form as Aristotle construes that, but material things have not only form but \*matter too. Among beings, which Aristotle thought were classifiable in terms of a system of categories, things in the category of substance have the greatest claim to that title, and among them those which are nearest to being pure form. God, whose nature is, in Aristotle's view, pure form, is the highest kind of substance, and thus the highest kind of being, so that what it is for something to be is best seen in God, who comprises the end or goal to which other things tend, and who, as the \*prime mover, is also the so-called \*final cause of the movements of the heavenly bodies.

Post-Aristotelian philosophy saw the world as organized under different principles, though the influence of Aristotle was strong. Epicurus thought that everything, including ourselves, was composed of atoms moving in a void, and was to be explained in those terms. The Stoics, by contrast, thought of matter as forming a continuum, but subject to rational or so-called 'seminal' principles due to *pneuma* (breath or spirit), which gives everything life. Platonism went though many vicissitudes, and at the end of the period of Greek philosophy took a somewhat mystical form in Neoplatonism, led by Plotinus, according to

which the Forms are organized under a unitary principle, the One. At the opposite extreme from this is the world of matter, responsible by its negativity for evil. The mystical goal is an identification with the One, but it is a goal to be reached through philosophy, not by any religious process. Nevertheless, Neoplatonic ideas had a considerable influence on religious thinking, including that of Augustine. Plotinus' main disciple, Porphyry, wrote on, amongst other things, the Aristotelian doctrine of categories, saying that the ontological status of species and genera was uncertain, and Boethius, commenting on that, thereby transmitted to later medieval thought the problem of the status of universals, which loomed large throughout that period.

There was considerable argument between schools of thinking about universals in the early Middle Ages, between realists (e.g. William of Champeaux), nominalists (e.g. Roscelin of Compiègne), and conceptualists (e.g. perhaps Abelard, although his position on the issue is not entirely clear), who respectively claimed that what was general was to be found in nature, words only, or thoughts only. With the rediscovery of Aristotle in the thirteenth century, after a period of ignorance of his philosophy in the West, realism about universals became the accepted view, until a revival of nominalism, particularly with William of Ockham, in the fourteenth century. There was, however, a connection between the issues over universals and theological issues, particularly the doctrine of the Trinity. The other main metaphysical concerns of medieval philosophers were similarly theologically orientated—particularly the existence of God and the nature of the soul. Anselm in the eleventh century became famous or notorious for his so-called \*ontological proof of the existence of God, maintaining that God's existence followed from the fact that God is that than which no greater can be conceived. The great Thomas Aquinas in the thirteenth century took a more Aristotelian line on the arguments for God's existence, relying in the main on considerations (which owe much to Aristotle) concerning the supposed nature of the world which point to the need to assume the existence of a deity. Aquinas also took, with modifications, an Aristotelian line on the nature of the soul as the form of the body, provoking questions, not easily answered, about how this view was to be reconciled with belief in immortality.

After the Renaissance, during which there was a revival of Platonism, often in other forms of mystical dress, Descartes initiated a change in the approach to philosophy, although preoccupation with scholastic notions such as that of substance remained. Descartes's orientation in philosophy was mainly epistemological in character; it might indeed be said that his metaphysics was founded on epistemological considerations. For the thesis for which he has become known—the radical dualism between mind and body as distinct substances—was founded on the claim that we have a more direct access to (and thereby a clearer and more distinct idea of) our minds than to our bodies. His rationalist successors Spinoza and

Leibniz were also very concerned with the \*mind-body problem. Spinoza maintained that mind and body were to be construed simply as different aspects of one substance, but that was in a context of argument which was directed to the conclusion that there can be only one substance, God or nature, and that what we are and what happens to us is strictly determined because we are modifications of that one substance. Spinoza thought, nevertheless, that there was a sense to speaking of freedom which lies in an acceptance of the necessity that the determinism entails. Leibniz, by contrast, thought that there was an infinite number of substances, which were simple, though capable of reflecting an infinite number of points of view. He came to think that these substances could only be what he called \*'monads', which were simple, like the ego in ourselves. Monads were organized in such a way as to fall under a dominant monad, which was God. Leibniz also held that everything that happened to a substance was necessary to it, but that God created the world of substances according to the principle of \*sufficient reason, which made this world the best of all possible worlds. Despite the Spinozistic necessity that this seemed to entail as far as human-beings are concerned, Leibniz thought, but did not convince others, that a form of freedom was still possible.

One might think that the British Empiricists, Locke, Berkeley, and Hume, were, because of the empiricism, mainly epistemologically orientated. This is superficially true of Locke, whose *Essay* tries to set out the structure and limits of human understanding, but he is concerned with substance, for example, although in a way that owes much to Boyle and contemporary physicists. He also presents a theory of \*persons and \*personal identity, which has provoked considerable recent interest, and, in his theory of abstract ideas, he sets out once again a conceptualist theory of universals. Berkeley was more nominalistically inclined, and attacked that theory because he thought that it led to a doctrine of material substance to which he was also opposed. In place of the latter Berkeley put forward the view that 'to be is to be perceived', so that the only things that properly exist are ideas (the objects of perception, as he thought) and spirits (which include ourselves and particularly God). Berkeley's theory is thus the first instance of full-blooded \*idealism. Of the three British Empiricists, Hume was the most anti-metaphysical, but his doctrine of impressions and ideas in a way continues Berkeley's thinking, and Hume admits at one point that his impressions are in one sense what deserve the title of substances. Ontologically, therefore, Hume regards reality as consisting merely of impressions and corresponding ideas, and he expresses a form of scepticism about both material bodies and self. In both cases we have bundles of impressions and ideas which have a certain constancy and coherence, and it is these characteristics which make us believe, but do not justify such belief, in bodies and the self. It has to be said, however, that Hume thought, with some reason, the resulting position over the self particularly worrying.

It is Kant who stands at the culmination of this, being opposed to what he regarded as the speculative metaphysics handed down by the rationalists, but concerned, as the Empiricists were, with the limits of the human understanding in such a way as to allow more than they had done. Kant accepts a form of idealism, which he called 'transcendental', saying that space and time were merely forms of experience and had no application to what he called 'things-in-themselves', the unknowable reality which he thought must be assumed to underlie and in some way be responsible for experience. Kant's idealism was not, however, merely subjective, as Berkeley's was, in that he sees the understanding as bringing to bear in judgement certain principles, derived from the categories or formal concepts which it supplies, in such a way that the forms of objective judgement can be distinguished from merely subjective ones. In particular, Kant thought, objective experience can be seen to involve causality and principles of necessary connection, despite Hume's scepticism on this. All this, a sort of metaphysics of experience, can be regarded as a substitute for traditional metaphysics, which Kant thought of as concerned with God, freedom, and immortality, but as involving an attempt to use reason beyond the boundaries to which it was properly limited. Part of his *Critique of Pure Reason* involves an attempt to show that such improper uses of reason lead to contradictions and the like.

Kant's account of what is necessary about human understanding and the limitations, by comparison, of reason presented a kind of watershed for metaphysics, but philosophers were soon to try to circumvent his conclusions in a variety of ways. Fichte objected to the whole idea of things-in-themselves, arguing that the ego or self actively posits a non-self opposed to it, so that in effect that non-self exists only for the self, while constituting something necessary, an absolute. His idealism is thus the first instance of so-called absolute idealism. Schopenhauer, on the other hand, thought he could produce good reason for believing that there was only one thing-in-itself and that this was to be identified with will. Both philosophers, however, accepted a form of idealism. The most radical development in that respect was the philosophy of Hegel, who thought that reason could certainly do what Kant thought impossible, leading to the idea of an identification of self and object. This form of absolute idealism was worked out in terms of a system of developing categories, culminating in what Hegel called the absolute notion in which 'Spirit knows itself as Spirit'. Hegel's metaphysical system is both monumental and encyclopaedic in character, claiming to bring all phenomena within its terms of reference. It has been seen as either marvellous or repulsive by different commentators.

There were, of course, reactions to it. Existentialists, beginning with Kierkegaard, objected that existence precedes essence, and that Hegel's thought left out individuality. This was an objection to the idea that reality could be seen as such only in terms of an all-comprehensive system. Marx, using, at any rate initially, somewhat Hegelian

terms, tried to turn the system on its head by insisting on the materialist and social basis of all thought and thereby of reality. Hegelian thought had a late influence in England towards the end of the nineteenth century, particularly in F. H. Bradley, although he objected to the more systematic aspects of Hegel's thought. To his monism (the belief that reality was one) there was in turn a reaction in the logical atomism of Russell and perhaps the early Wittgenstein, according to which reality involves a plurality of sense-data, which, like Leibniz's monads, constituted absolute simples. Subsequently, the anti-metaphysical theory of the Logical Positivists, such as Ayer, who, on the basis of the principle that the meaning of a statement is to be found in its method of verification, argued that metaphysical statements were nonsensical, put metaphysics out of fashion, where on many popular views it remains.

In fact, however, it continues, and Strawson's so-called 'descriptive metaphysics', according to which ontological distinctions between individuals or objects of identification are made relative to speaker-hearer discourse, is something of a return to Kant, though without the idealism. Elsewhere in Europe there has been, for example, Heidegger's anti-scientific concern with the nature of being and with *Dasein* or presence in the world. This presence is of a kind that only human individuals have, and Heidegger saw it as having an intimate connection with time, on a view of time which sees it as having fundamentally to do with the ideas of past, present, and future, and not simply temporal relations between events. These alternative conceptions of time have been a central issue in Anglo-Saxon metaphysics too, ever since the Cambridge Hegelian McTaggart argued, early in the twentieth century, that time must, essentially, have to do with past, present, and future (or, as it is sometimes put, 'tense') and that, because every event is all three and thus in possession of incompatible attributes, time is unreal. To the objection that events have all three attributes at different times, McTaggart argued that this only produced an infinite regress. Different philosophers have drawn different morals from these claims, including the moral that time must fundamentally have nothing to do with 'tense'. It is equally arguable that the correct conclusion is that the 'tensed' point of view is indispensable to an account of reality and that it is the attempt to do without it in characterizing reality that causes the trouble. Heidegger has his own and different reasons for emphasizing a 'tensed' conception of time, in that he is concerned to bring out what presence in the world, in his sense, entails—in particular that it must have its end in death, when time ends for us.

In other quarters again, particularly in the USA and Australia, an emphasis on science has produced its own scientific metaphysics, according to which only supposedly scientific characterizations of reality will do. Such views not only reject the kind of 'tensed' conceptions of time which I have noted above, but also underplay the kinds of point of view that are arguably involved in selfhood and thereby in any reality which involves selves.

Such a metaphysics tends inevitably to be materialist, though not necessarily in the kind of way in which Marxian thought is materialist. It is simply assumed that all that exists in the end is particular incidences of matter in motion and that what seems at first not to be that is in fact identical with some form of it. Nevertheless, although Cartesian \*dualism is widely rejected as a great mistake as well as a great obstacle to the successful development of philosophy, the pressures deriving from what led to that dualism in the first place—the first-person point of view—remain, and are emphasized by some philosophers, e.g. Thomas Nagel. And so it goes on.

**metaphysics, opposition to.** Opposition to metaphysics has come from both within philosophy and outside it. \*Logical Positivism, though now defunct, was particularly hostile to what its adherents saw as the meaningless, because unverifiable, claims of metaphysics. These objections floundered on the impossibility of providing an acceptable criterion of \*verifiability. But the deference to empirical science displayed by the Logical Positivists is still a feature of much Anglo-American analytic philosophy, creating an intellectual climate inimical to the pursuit of speculative metaphysics. This hostility is paralleled in the popular writings of many scientists, who seem to think that any legitimate issues once embraced by metaphysics now belong exclusively to the province of empirical science—issues such as the nature of \*space and \*time, and the mind–body problem. Such writers are often blithely unaware of the uncritical metaphysical assumptions pervading their works and the philosophical naïvety of many of their arguments. But it is ironic that the deference shown by many philosophers to the latest scientific theories is not reciprocated by the popularizing scientists, who do not conceal their contempt for philosophy in general as well as metaphysics in particular.

More recent hostility to metaphysics comes from the post-modernists and deconstructionists, who wish to proclaim that philosophy—and certainly metaphysics—is dead. These writers represent metaphysics as a temporary aberration of the Western intellect, denying the notion that it is a pursuit of perennial questions for which timeless answers may legitimately be sought. Of course, these critics of metaphysics, in repudiating any objective conception of truth in favour of a fashionable cultural relativism, can make no common cause with the scientific critics,

whose quite contrary assumption is that science provides the royal road to objective truth and ultimately to a final ‘Theory of Everything’. With enemies so divided amongst themselves, metaphysics may comfort itself with the thought that so many people can’t be right. The very fact of such widespread disagreement over fundamentals demonstrates the need for critical and reflective metaphysical inquiry, pursued not dogmatically but in the spirit of Kant.

Despite all this hostility, metaphysics and \*ontology are currently enjoying a modest revival amongst professional philosophers, who are no longer embarrassed to discuss such issues as the nature of substance and to advance realist theories of \*universals. But much of this work is highly technical, involving sophisticated applications of \*modal logic, and consequently it is difficult to convey its results to a lay public. There is thus a danger that such work will be dismissed as a revival of scholasticism without relevance to everyday concerns. That would be a pity, and so it is not only the duty but also in the interest of metaphysicians to make their work more accessible, with a view to countering the relativistic and scientific dogmas of our time.

Perhaps the most serious intellectual threat to metaphysics as traditionally conceived comes from the movement towards \*naturalism in contemporary philosophy, taking its lead from W. V. Quine’s advocacy of ‘naturalized epistemology’. With the theory of knowledge reconceived as, in effect, a branch of empirical psychology and the concomitant rejection of the traditional distinction between \*a priori and a posteriori truth, the claim of metaphysics to have a distinctive subject-matter and method has been put under some pressure. However, just as the cruder scientific and relativistic enemies of metaphysics may be accused of promoting a particular metaphysical dogma under the guise of an onslaught on metaphysics in general, so too may this charge be levelled at its naturalistic critics. The normative categories of reason and truth transcend naturalistic reduction and cannot, without pragmatic incoherence, be argued out of existence.

**metaphysics, problems of.** In contemporary philosophy, problems of metaphysics often take the form of a trilemma concerning some large and important feature of our lives or discourse, a trilemma whose terms are: illusion, well-founded appearance, and fundamental reality. In recent decades these problems most often tend to arise against the backdrop of a broad \*naturalism and, often, scientific \*realism. The problems themselves may be viewed as demands for possibility explanations: How are values and norms possible in a world of facts? How are minds and mental phenomena possible in a world of matter in motion? How is freedom of action or will possible in a world of scientific law? How can there be abstract

entities in a world of events and other contingent particulars? In each case the same troublesome trilemma presents itself.

Concerning any of these realms or dimensions—e.g. values, the mental, freedom, and abstract—there is the view that it is all a big illusion, that there is really nothing in that realm or dimension. Alternatively, it may be held that there are real denizens of the realm in question, with a reality as fundamental as that of any particle or field postulated by our physics. And according to a third, irenic view, though there are real enough entities or phenomena in the target realm, none is fundamental, all deriving rather from more basic entities or phenomena. All indeed are said to resemble ordinary bodies—tables, quantities of water, cats and dogs, etc.—in being real enough, though derived from the existence and organization of more basic entities: from cells or molecules, etc.

For example, it might be held that values and the normative are a complete illusion. Thus, for the non-cognitivist, normative and evaluative concepts do not represent any mind- or language-independent constituent or aspect of reality. Rather, their significance is only functional: like that of the imperative mood or the exclamation mark. It is an illusion to suppose that the goodness of a juicy, sweet apple attaches to it just as do its redness and its roundness. For others, however, the goodness of an apple is just as objective a property of it as its roundness, or, certainly, its redness: just as objective a property, and just as real, and fundamental. But there is a third, irenic, option, according to which the goodness of the apple and the rightness of biting into it are real and objective enough, but 'well founded' on more fundamental properties: e.g. on the apple's disposition to cause, or on the biting into it actually causing, a sufficient balance of pleasure over pain (especially when compared with the alternatives open to the agent at the time). This third option comes with two interesting suboptions: first, adding further that the evaluative and normative phenomena in question are not only well founded (*bene fundata*) but also actually reducible by definition or analysis to the underlying realities that give rise to them; and, alternatively, remaining deliberately non-committal on that issue, claiming only that the phenomena in question do supervene on underlying realities, whether or not they are reducible to them or definable or analysable in their terms.

Similar issues arise with regard to the realm of \*minds and the mental. Let us assume that reality is constituted of particulars (whether substances or events) with the properties that characterize them and the relations that interrelate them. Just what is included among these particulars, properties, and relations has been a matter of considerable controversy in the history of Western philosophy.

Idealists view reality as ultimately spiritual or mental. For them the basic particulars are subjects of thought or experience, souls or spirits or monads, the world of matter in motion being nothing more than a stable appearance to our minds. If we say there are snowballs, for the idealist we are right at best in the sense that in certain circum-

stances our minds are disposed systematically to experience combinations of whiteness, roundness, and coldness. The *foundation* of the existence of such supposed objects therefore lies in the contents of our minds. For the idealist, physical bodies are rather like images in a rich and stable dream. And we are essentially minds, subjects of thought and consciousness. Leibniz and Berkeley were idealists.

Materialists and physicalists view material or physical objects or events as more fundamental than minds or egos or their modes of thought or experience. Accordingly, they would reduce mind to matter rather than matter to mind. For the materialist there are no fundamental subjects of consciousness, no souls or spirits. We have minds simply because we think, sense, feel, etc., and we do all this as rational animals with properly functioning brains and nervous systems. Hobbes was a materialist, as have been most contemporary philosophers who write in the analytic tradition. The token physicalism (and \*anomalous monism) of Donald Davidson is also a kind of physicalism of particulars, since it accepts events as basic particulars and regards these as without exception physical.

Finally, dualists admit both souls and bodies as fundamental entities. Neither mind nor matter is reducible to the other and there is no problem of reducing either to the other. For the dualist the problem lies rather in understanding how mind and matter can possibly interact. Descartes was a dualist.

So far we have considered metaphysical options on the nature of basic particulars. There are also similar options on the nature of fundamental \*properties or states of affairs. Thus one can be a property phenomenalist, for whom the only fundamental states are mental, e.g. sensory experiences, all other states being 'reducible' to or at least derivative from these.

For a physicalist with regard to states or properties, on the other hand, only physical properties are fundamental; hence any state constituted by a particular having a property, or by a number of particulars related by a certain relation, is a fundamental state only if the particulars are all physical and the properties and relations are all physical. The type-type identity theory is an option open to such a physicalist, and believers in type-type identity might hold the identity to be necessary, as did logical behaviourists, and as do functionalists. Alternatively, a believer in type-type identity might opt for 'contingent identity', as with the functional-specification view of David Lewis.

Finally, property dualists admit both physical properties irreducible to the mental, and mental properties irreducible to the physical. Recent debates over qualia, over the existence of irreducibly qualitative and experiential aspects of one's experience, have divided mentalists on the affirmative (e.g. Ned Block and Jerry Fodor with their 'absent qualia' argument, and Thomas Nagel with his appeal to subjectivity), from physicalists, especially functionalists, on the negative (such as David Armstrong and Daniel Dennett, with their attempt to reduce consciousness in general to propositional attitudes). Some (e.g. Syd-

ney Shoemaker) have tried to reconcile \*functionalism with acceptance of qualia, but for our purposes the acceptance of qualia is the important move, if such qualitative aspects of experience are supposed a fundamental sort of mental property not reducible to the physical, nor supervenient upon it.

With regard to \*freedom of action or of the will, one faces the same set of options. One might hold freedom to be a complete illusion, since we are natural beings caught in the web of physical law from cradle to grave. Or one might alternatively hold that freedom is a basic fact of life: one might rather deny that a human life could ever be wholly caught within a web of natural laws. A third, more irenic, position is possible, moreover, according to which we do enjoy freedom, but a freedom that is after all compatible with the sway of physical law over every detail of human life. There is important support for this alternative, quite apart from the implausibility of any metaphysics that tries to set a priori limits to how much science might achieve in understanding human behaviour. For consider the postulation of libertarian action not produced by antecedent conditions in accordance with physical law. This is what the libertarian believer in fundamental freedom accepts. But it is puzzling how that can help secure the kind of freedom desired: namely, the kind that would support the attribution of responsibility to the agent, and the assignment of praise or blame, reward or punishment. The reconcilist—or compatibilist—camp for its part still owes a large and challenging debt: reconcilists must still explain how such freedom can be reconciled with the fact that, on the assumption of \*determinism, every physical detail of one's life is already determined prior to one's birth. They must introduce, in the teeth of that impressive fact, some crucial distinction among one's actions, between those that are nevertheless not 'compelled' in some appropriate sense, and for which we can remain responsible, and those that *are* thus compelled, which relieves the agent of responsibility.

Metaphysical world-views have derived from epistemological constraints. Thus one might be impressed by the difference between one's own consciousness, to which one enjoys introspective access, on one side, and, on the other, the supposed world of physical fact beyond. Philosophers have long puzzled over how such a fundamental chasm could ever be bridged by reason. How could one ever know about the reality beyond on the basis of what one knows immediately about one's own consciousness? One cannot deduce how it is beyond one's consciousness simply from how it is within it: illusions, hallucinations, dreams, sceptical scenarios like that of the \*brain in a vat and the Cartesian evil demon, establish that impossibility clearly enough. (\**Malin génie.*) So it would seem that at best one must argue one's way to the external world through some inductive form of reasoning. But to many this has seemed hopeless if the world beyond is constituted by phenomena of a wholly different order and inaccessible to our experience. For how could one so much as understand such 'phenomena'? And, besides,

even if one could somehow understand them, how could one know about them? Presumably one would have to establish inductive correlations from which one could then generalize and on the basis of which one could argue from the character of one's experience to what lies outside. Considerations such as these, deriving from the needs of epistemology, have led philosophers in the empiricist tradition to one or another form of idealist \*phenomenalism, to the view that reality is through and through constituted by experience, in the form of impressions and ideas (and, for some, subjects of such experience).

Rationalists for their part have equally reasoned from assumptions concerning knowledge and understanding to metaphysical conclusions of great scope. For the rationalist mind, reality must be comprehensible through and through. It must be *possible* for a mind powerful enough and well enough stocked with information to attain a complete understanding of the universe. Here the following assumptions are in play: (a) the universe is the totality of facts; (b) to understand a fact is to understand why it is a fact, why it obtains; (c) if a fact cannot be understood in its own terms, if it is not self-explanatory, then in order to understand why it obtains one needs an explanation of it, an explanation of why it obtains; (d) a complete understanding of the universe would be an understanding of *all* facts; (e) *X* is an explanation of the fact that *p* (of why it is the case that *p*) only if *X* is a set of true assumptions (facts) that jointly logically imply the fact that *p* via some principle of lawful regularity.

Fundamental \*laws would be (by definition) unexplained, there being no more fundamental laws to explain them. But that would be an obstacle to complete understanding only if the laws in question would *require* explanation in order to be understood. Could any laws or facts be (in a sense) self-explaining? Consider the fact (*F*) that nothing is diverse from itself. What could possibly explain such a fact? It is not easy to think of anything else which might explain anything so fundamental. Even if it turns out that in fact there is nothing external that can supply such explanation, would that show a lack in our understanding of *F*? Don't we understand *F* as well as we ever understand anything, even without need of external explanation? If so, we have then in *F* a fundamental fact that requires no (external) explanation in order to be understood. The two relevant features of *F* are evidently, first, its *necessity*, i.e. the fact that things could not possibly have been otherwise than *F* says they are, and, second, the *obviousness* of that necessity, it being obvious that things could not possibly have been otherwise than *F* says they are. Any such fact will be perfectly well understood in its own terms and will need no further, external explanation.

Suppose the natural order to consist of material particles in various configurations, moving and reconfiguring in accordance with physical law. Even if we assume that the series never had a beginning in time, why is there such a series when there might have been a different one or even a changeless void instead? In answer to this it would

not do to spin an infinite series of explanations of particular contingencies within the series by appeal in each case to other antecedent contingencies in that same series, and expect to have answered thus the legitimate question why there is such a series at all.

Leibniz understands our predicament in roughly these terms and takes it as his own. Here is a very brief sketch of his resolution: (a) the best possible world is necessarily best; (b) \*God, being necessarily omniscient, necessarily sees it to be best; (c) God, being necessarily infinitely good, necessarily wills that world to be; (d) since God is necessarily omnipotent, that world necessarily comes to be, and it is hence, of course, our world.

If a world (or universe) is a totality of facts, then if a world *W* differs from a world *W'* in any detail no matter how small, then *W* and *W'* must be two different worlds. Hence if by Leibniz's account our world necessarily comes to be, then every detail in it, no matter how small, necessarily comes to be. Not one grain of sand could have been different in its qualities or location. But this conclusion is not idiosyncratic to Leibniz's particular proposal for how it might be possible to attain a complete understanding of the universe. For, as we have seen already, however we fill in assumptions and laws in order to explain fully the existence and character of the natural order of events (e.g. of matter in motion from eternity to eternity), the resulting assumptions and laws had better be necessary facts if we are not just to extend the problem to another series of contingencies in the vertical direction. Suppose we lump all the assumptions into one big assumption *A* and all the laws into one big law *L*. If such necessary *A* and *L* are to explain the existence and character of the natural order (at least to an infinite being who could grasp it all), then by our account of explanation, *A* and *L* must jointly entail that the natural order does exist and has exactly the character it does have. But anything thus entailed by what is necessary must itself be necessary. It follows that if we have such explanation, then the natural order must necessarily exist and must necessarily have exactly the character that it does have. So, again, no grain of sand could possibly have been different in its qualities or location. And this result is thus seen to derive not just from anything special in Leibniz's particular explanation, but from the very nature of what a complete explanation would have to be. What is made plausible by our reasoning is that if a complete understanding of the universe is to be attainable to anyone, even to a being with access to all information and with no limit to his faculty of reason, then the universe must be necessary in every detail. (As an alternative to Leibniz's, compare Spinoza's very different but equally rationalistic and equally necessitarian worldview.)

Once again we see how an epistemic commitment drives powerful thinkers to a metaphysical view about broad and fundamental features of reality. One can, of course, deny the commitment, denying that there is anything deeper than the natural order of contingent events. Unless there is some mistake in our reasoning, however,

this would commit one to the view that there is inevitable opacity to reason, inevitable absurdity built into the universe, something that even an omniscient being with infinite reason could not wholly eliminate. And this consequence contributes to a powerful intellectual movement alternative to both the broad empiricism and the broad rationalism already sketched, a movement that culminates in works such as the *Nausea* of Jean-Paul Sartre, obsessed with the contingency of the world, and deriving its existentialist consequences about human life and society.

In the twentieth century linguistic philosophy rejected traditional metaphysics as a pseudo-inquiry whose real point is or should be linguistic. This has taken the form of a linguistic \*relativism (LR) according to which: When we say 'There are three objects here, not eight' we are really saying 'The following is assertible as true in our language *L*: "There are three objects here, not eight".' This is, for example, in the spirit of Carnap's *Logical Syntax of Language*, where Carnap defends the following theses: (i) Philosophy, when cognitive at all, amounts to the logical syntax of scientific language. (ii) But there can be alternative such languages and we are to choose between them on grounds of convenience. (iii) A language is completely characterized by its formation and transformation rules. In that same book Carnap also distinguishes between:

- (s1) object sentences: e.g. 'Five is a prime number', 'Babylon was a big town';
- (s2) pseudo-object sentences: e.g. 'Five is not a thing but a number', 'Babylon was treated in yesterday's lecture';
- (s3) syntactical sentences: e.g. "'Five' is not a thing-word but a number-word", "'Babylon' occurred in yesterday's lecture'.

And he defends the thesis that although s2 sentences seem deceptively like s1 sentences, actually they are really s3 sentences in 'material mode' disguise. Quine agrees that a kind of 'semantic ascent' is possible, as when we shift from talk of miles to talk of 'mile', but he thinks this kind of semantic ascent is *always* trivially available, not just in philosophy but in science generally and even beyond. Thus we can paraphrase 'There are wombats in Tasmania' as "'Wombat" is true of some creatures in Tasmania'. Quine does grant that semantic ascent tends to be especially useful in philosophy. But he explains why as follows (*Word and Object*, 272):

The strategy of semantic ascent is that it carries the discussion into a domain where both parties are better agreed on the objects (*viz.*, words) and on the main terms concerning them. Words, or their inscriptions, unlike points, miles, classes, and the rest, are tangible objects of the size so popular in the marketplace, where men of unlike conceptual schemes communicate at their best . . . No wonder it helps in philosophy.

However, the use of that strategy is clearly limited to discourse about recondite entities of controversial status. No relevant gain is to be expected from semantic ascent when the subject-matter is the inventory of the market-place itself. Tables and chairs, headaches and beliefs, and even good apples are no more controversial than words: in fact,

some at least of these seem less so, by a good margin. No general conceptual or linguistic relativity, no avoidance of metaphysical discourse, can be plausibly supported by the semantic-ascent strategy offered by Quine. In addition, questions of coherence arise concerning LR. When we say something of the form ‘The following is assertible in our language *L*: . . .’ can we rest with a literal interpretation that does not require ascent and relativization? If not, where does ascent stop? Are we then *really* saying ‘The following is assertible in our language *L*: “The following is assertible in our language *L*: . . .”’. This way lies vicious regress. But if we *can* stop the regress with metalinguistic reference to our sentences of *L* (and to ourselves), why can we not stop it with our references to headaches and good apples, and to tables and chairs and other medium-sized dry goods? Other ways of attacking the problems of metaphysics as mere pseudo-problems have also gained prominence and a wide following in recent decades, but this linguistic turn will have to serve as our example, and, as revealed with this example, metaphysics is neither destroyed nor even silenced by such attacks.

This article has focused on the following general facts about metaphysical problems: (a) that many take the form of a trilemma among illusion, well-founded appearance, and fundamental reality, and arise in recent decades against a backdrop of naturalism; (b) that interrelated solutions to them—i.e. broad metaphysical positions—sometimes derive from epistemological assumptions concerning what is comprehensible or knowable, and the ways in which this might be so; and (c) that in contemporary philosophy metaphysical problems have been denigrated by positivist and linguistic philosophers as pseudo-problems or as linguistic issues with a mask of profundity. I have discussed particular metaphysical problems mainly as examples, and there are many that I have not so much as mentioned: problems, for example, about \*space and \*time, about \*substance and attribute, about \*events and states, about \*universals and particulars, and about \*change and \*identity through time. Discussion of these and other metaphysical problems may be found in this Companion under specific headings. E.S.

**metaphysics, revisionary:** *see* revisionary metaphysics.

**metempsychosis:** *see* reincarnation.

**method, joint.** J. S. Mill proposed to unify two of his five canons of experimental inquiry, the \*method of agreement and the \*method of difference, in a third, the ‘joint method’: namely, ‘If two or more instances in which the phenomenon occurs have only one circumstance in common, while two or more instances in which it does not occur have nothing in common save the absence of that circumstance, the circumstance in which alone the two instances differ is the effect or the cause or an indispensable part of the cause of the phenomenon’. However, this canon allows the possibility that a type of phenomenon under investigation may have more than one type of cause or that it may have a single underlying cause that is not revealed. Nor does Mill’s method show how the strength of a causal hypothesis may be only a matter of degree, though he accepts this elsewhere. L.J.C.

\*method of concomitant variations; method of residues.

**method, scientific:** *see* scientific method.

**methodic doubt:** *see* doubt.

**method in philosophy:** *see* philosophical inquiry: first premisses and principles.

**method of agreement.** J. S. Mill’s *A System of Logic* (1843) proposed the ‘method of agreement’ as the first of five canons of experimental inquiry. It determines that ‘If two or more instances of the phenomenon under investigation have only one circumstance in common, the circumstance in which alone all the instances agree is the cause (or effect) of the given phenomenon’. For example, if an alkaline substance is combined with an oil in several otherwise different varieties of circumstance, and in each case a soap results, then the combination of an oil and an alkali causes the production of a soap. It is thus not an observed regularity of co-occurrence that evidences the causation but an observed elimination of all but one hypothesis. However, to secure this elimination we need to test, and may not in fact know, all the eligible hypotheses. L.J.C.

\*method, joint; method of concomitant variations; method of difference; method of residues.

**method of concomitant variations.** The fifth of J. S. Mill’s five canons of experimental inquiry (*A System of Logic* (1843)). Phenomena which vary concomitantly can be assumed to be causally related, whether one causes the other, or they are effects of a common cause. The method is useful, Mill thinks, for cases where the methods of

agreement and difference cannot be applied because we are facing phenomena which can be neither excluded (to see what happens in their absence) nor isolated (to exclude irrelevant factors); but it has limitations, he adds, because we often cannot tell whether *all* of one phenomenon relates causally to the other, and it cannot tell us what happens outside the limits of the observed variations. Like the other canons it assumes that there are causes to be found within the sphere of our present knowledge.

A.R.L.

J. S. Mill, *A System of Logic*, bk. 3, ch. 8 (London, 1843).

**method of difference.** J. S. Mill proposed the 'method of difference' as the second of five canons of experimental inquiry. It determines that 'If an instance in which the phenomenon under investigation occurs, and an instance in which it does not occur, have every circumstance in common save one, that one occurring only in the former; the circumstance in which alone the two instances differ is the effect, or the cause, or an indispensable part of the cause of the phenomenon'. For example, when a man is shot through the heart, it is by this method we know that it was the gunshot which killed him: for he was in the fullness of life immediately before, all circumstances being the same except the wound. But in some cases it may be difficult to establish that two instances have every circumstance in common save one.

L.J.C.

\*method, joint; method of agreement; method of concomitant variations; method of residues.

**method of residues.** J. S. Mill's fourth canon of experimental inquiry was entitled the 'method of residues': namely, 'Subduct from any phenomenon such part as is known to be the effect of certain antecedents, and the residue of the phenomenon is the effect of the remaining antecedents'. For example, said Mill, if the movements of a comet cannot be wholly accounted for by its gravitation towards the sun and the planets, the residual feature must be explained by the resistance of the medium through which it moves. But Mill recognized that in practice we may not be able to be certain that one particular factor is the only antecedent to which the residual phenomenon may be referred. So any induction by the method of residues needs to be confirmed by obtaining the residual phenomenon artificially and trying it separately, or by deriving its operation from otherwise known laws.

L.J.C.

\*method, joint; method of agreement; method of concomitant variations; method of difference.

**methodological holism and individualism.** There are two large debates in \*social philosophy or social ontology, both with methodological ramifications for the \*philosophy of social science (Pettit, *The Common Mind*). One is concerned with how far human beings (non-causally) depend on their social relationships for the possession of the ability to think, or for the possession of some such

characteristic human capacity. The atomist denies any such dependence while the non-atomist asserts that it obtains. The other debate is concerned with whether the existence of aggregate social entities—in particular, the obtaining of aggregate-level regularities—means that human beings do not conform in full to our commonplace psychological image of them as more or less autonomous, more or less rational creatures. The individualist denies that aggregate entities entail any compromise of such commonplace psychology while the non-individualist maintains that there is some more or less significant compromise involved.

There are also many other methodologically relevant debates that are loosely associated with these divisions. Some examples are the debates over whether aggregate-level social theory is reducible to psychological theory; whether individual-level explanation is preferable to aggregate-level explanation in social science; whether social scientific discovery is likely to force any revisions on our commonplace psychology; whether individual subjects are reciprocally influenced by the aggregate entities they constitute, as they form the concepts of such entities; whether individual agents are so constrained by the circumstances of their social setting that we need only attend to those circumstances—we can ignore psychological matters of belief and desire—in predicting what they will do; and whether historically significant individual actions are generally dispensable, in the sense that had the individuals involved not done what they did, there would have been others to take their place.

The term 'methodological individualism' is usually employed with a variety of connotations across the range of positions identified here. The self-described methodological individualist will certainly be an individualist in the sense defined above; he will probably be an atomist; and he will tend to go for the position that is thought most flattering to the status of the individual in each of the other debates. The term 'methodological holism' is less commonly employed and its connotations will vary in the same way.

P.P.

Philip Pettit, *The Common Mind: An Essay on Psychology, Society and Politics* (New York, 1993).

**methodology.** The philosophical study of \*scientific method. The central question arising from this study is how to interpret methodological statements. There are three alternatives: description, convention, prescription.

Under the first option, methodological statements are either interpreted as descriptions of scientific practice, or methodology is seen as a 'science of science' which establishes correlations between practice and results. Just as science has methods which allow the successful study of electrons, so too philosophers could apply the scientific methods of, say, \*cognitive science or \*biology to the study of science itself. Objectors to such an approach point to the lack of a non-contentious stock of results and methods in the human sciences. Therefore, the human sciences would not be able to provide a consensus on what

the methods of science in fact *are*. An obvious reply would be to advocate the application of the methods of physical science itself. Of course, if we do not know what these methods are, we cannot apply them. Thus it seems descriptivism is either question-begging or viciously circular. A common reply to be found in the writings of the \*Vienna Circle and Quine is that a virtuous spiral is a better geometrical analogue than a vicious circle. Under this account, the application of a method to questions of method provides a sharpening of both the method and the questions asked.

If, as Popper has argued, scientific method constitutes the rules which govern scientific behaviour, these rules may be as conventional as the rules which govern the game of chess. A problem arises if two mutually contradictory rule books are proposed: Which game of science should be chosen? The obvious answer is to decide which set of rules is more 'useful' or 'suitable'. This assumes, of course, that we have non-conventional criteria of 'usefulness' and 'suitability'. We could appeal to the intuitions of practitioners about their activity. There are two possible sources of these intuitions. In the first case they result from the practitioner's previous experiences of similar activities, and their association—or lack of association—with some desired outcome. This answer seems to require knowledge about what methods are correlated with what outcomes, which is the central problem of descriptivism. In the second case there is a correct answer to the question what sort of rationality motivates the rules of science. This leads us to our third position.

According to normativists, methodological imperatives are true or false much as ethical norms are under an objectivist account. In its pure form, this view is not widely held, with the exception of decision theorists like Keynes and the later Carnap. A problem arises if we ask whether a transgression of such norms could make an observable difference to the life of the transgressor. On the one hand, if it makes *no* difference, one might question the subject-matter: are judgements of rationality really so much hot air? On the other hand, if transgression does make a difference, the desirability of following the norms of rationality would depend on the factual differences in outcomes that result. Thus this position is also in danger of collapse into descriptivism.

**Meyerson, Émile** (1859–1933). Born in Lublin, became a naturalized Frenchman, and worked for Jewish agencies after a brief spell as an industrial chemist. Meyerson wrote

on philosophy of science and general epistemology, his main interest being the nature of thought as exemplified in its successful products.

An anti-positivist, he argued, for example in *Identity and Reality* (1908), that scientific knowledge attempts to reach beyond mere descriptive and predictive laws to an understanding of the nature of the reality beyond appearances. The human mind seeks the permanent behind phenomenal change, the identity within diversity as exemplified in conservation laws, such as the law of inertia and the law of conservation of energy. And yet this identity which our reason apprehends (or perhaps constructs) cannot embrace the totality of reality, for there is also change.

**Mill, James** (1773–1836). Scottish thinker who, after being educated at Edinburgh University, came to London and worked for a considerable time as assistant and publicist for Bentham. Most famous for the strenuously intellectual education to which he subjected his more famous son, John Stuart Mill, he wrote influential pamphlets on education and government from a utilitarian point of view, as well as a thoroughgoing associationist psychology, *The Analysis of the Phenomena of the Human Mind* of 1829 (which was later republished with extensive notes by his son). His most discussed philosophical work is the short pamphlet *On Government*, which is a rigorous a priori argument for majoritarian \*democracy: since everyone acts in their own interest, only the greatest number can be relied on to protect the greatest happiness of the greatest number.

R.H.

\*utilitarianism.

Jack Lively and John Rees, *Utilitarian Logic and Politics* (Oxford, 1978).

**Mill, John Stuart** (1806–73), son of James Mill. He was the greatest British philosopher of the nineteenth century, bringing Britain's traditions of \*empiricism and \*liberalism to their Victorian apogee.

The *System of Logic*, a product of his thirties, published in 1843, made his reputation as a philosopher. The *Principles of Political Economy*, of 1848, was a synthesis of classical economics which defined liberal orthodoxy for at least a quarter of a century. His two best-known works of moral philosophy, *On Liberty* and *Utilitarianism*, appeared later—in 1859 and 1861. In the 1860s he was briefly a Member of Parliament, and throughout his life was involved in many radical causes. Among them was his enduring support for women's rights—see *The Subjection of Women* of 1869.

The leading element in Mill's thought is his lifelong effort to weave together the insights of enlightenment and romanticism. He subscribed unwaveringly to what he

called the 'school of experience and association'. He denied that there is knowledge independent of experience and held that attitudes and beliefs are the products of psychological laws of association. His view of human beings is \*naturalistic and his ethics is utilitarian. But he redesigned the liberal edifice built on these foundations to the romantic patterns of the nineteenth century. For these he was himself one of the great spokesmen. He learned much of the historical sociology which was so important to his liberalism from Frenchmen; but it was to German romanticism, via his Coleridgean friends, that he owes his deepest ethical theme—that of human nature as the seat of individuality and autonomy, capable of being brought to fruition through the culture of the whole man.

The controversy over Mill's achievement has always centred on whether the synthesis he sought, of enlightenment and romantic-idealist themes, is a possible one. Kant had argued that the naturalism of the \*Enlightenment subverted reason, and idealist philosophers of the nineteenth century followed him in that. Kant and Mill do in fact agree on a vital aspect of this question. They agree that if the mind is only a part of nature, no knowledge of the natural world can be \*a priori. Either all knowledge is a posteriori, grounded in experience, or there is no knowledge. Any grounds for asserting a proposition that has real content must be empirical grounds. However, much more important is the difference between them: whereas Kant thought knowledge could not be grounded on such a basis, and thus rejected naturalism, Mill thought it could. This radically empiricist doctrine is the thesis of the *System of Logic*.

There Mill draws a distinction between 'verbal' and 'real' propositions, and between 'merely apparent' and 'real' inferences. The distinction corresponds, as Mill himself notes, to that which Kant makes between analytic and synthetic judgements. But Mill applies it with greater strictness than anyone had done before, insisting with greater resolution that merely apparent inferences have no genuine cognitive content. He points out that pure mathematics, and logic itself, contain real propositions and inferences with genuine cognitive content. This clear assertion is central to the *System of Logic*, and the basis of its continuing importance in the empiricist tradition. For if Mill is also right in holding that naturalism entails that no real proposition is a priori, he has shown the implications of naturalism to be radical indeed. Not only mathematics but logic itself will be empirical.

His strategy is a pincer movement. One pincer is an indirect argument. If logic did not contain real inferences, all deductive reasoning would be a *petitio principii*, a begging of the question—it could produce no new knowledge. Yet clearly it does produce new knowledge. So logic must contain real inferences. The other pincer is a direct semantic analysis of basic logical laws. It shows them to be real and not merely verbal. The same strategy is applied to mathematics. If it was merely verbal, mathematical reasoning would be a *petitio principii*. But a detailed semantic analysis shows that it does contain real propositions.

Why do we think these real propositions in logic and mathematics to be a priori? Because we find their negations inconceivable, or derive them, by principles whose unsoundness we find inconceivable, from premisses whose negation we find inconceivable. Mill thought he could explain these facts about unthinkability, or imaginative unrepresentability, in associationist terms. His explanations are none too convincing, but his philosophical point still stands: the step from our inability to represent to ourselves the negation of a proposition to acceptance of its truth calls for justification. Moreover, the justification *itself* must be a priori if it is to show that the proposition is known a priori. (Thus Mill is prepared, for example, to concede the reliability of geometrical intuition: but he stresses that its reliability is an empirical fact, itself known inductively.)

All reasoning is empirical. What then is the basis of reasoning? Epistemologically, historically, and psychologically, Mill holds, it is *enumerative induction*, simple generalization from experience. We spontaneously agree in reasoning that way, and in holding that way of reasoning to be sound. The proposition 'Enumerative induction is a valid mode of reasoning' is not a verbal proposition. But nor is it grounded in an a priori intuition. All that Mill will say for it is that people in general, and the reader in particular, in fact agree on reflection in accepting it. It is on that basis alone that he rests its claim.

He does not take seriously Hume's sceptical problem of \*induction; his concern in the *System of Logic* is rather to find ways of improving the reliability of inductive reasoning:

if induction by simple enumeration were an invalid process, no process grounded on it would be valid; just as no reliance could be placed on telescopes, if we could not trust our eyes. But though a valid process, it is a fallible one, and fallible in very different degrees: if therefore we can substitute for the more fallible forms of the process, an operation grounded on the same process in a less fallible form, we shall have effected a very material improvement. And this is what scientific induction does.

So Mill's question is not a sceptical but an internal one—why is it that some inductions are more trustworthy than others? He answers by means of a natural history of induction, which traces how enumerative induction is internally vindicated by its actual success in establishing regularities, and how it eventually gives rise to more searching methods of investigation.

The origins are 'spontaneous' and 'unscientific' inductions about particular unconnected natural phenomena. They accumulate, interweave, and are not disconfirmed by further experience. As they accumulate and interweave, they justify the second-order inductive conclusion that *all* phenomena are subject to uniformity, and, more specifically, that all have discoverable sufficient conditions. In this less vague form, the principle of general uniformity becomes, given Mill's analysis of causation, the law of universal causation. This conclusion in turn provides (Mill believes) the grounding assumption for a new style of reasoning about nature—*eliminative induction*.

Here the assumption that a type of phenomenon has uniform causes, together with a (revisable) assumption about what its possible causes are, initiates a comparative inquiry in which the actual cause is identified by elimination. Mill formulates the logic of this eliminative reasoning in his 'methods of empirical inquiry'. The improved scientific induction which results spills back on to the principle of universal causation on which it rests, and raises its certainty to a new level. That in turn raises our confidence in the totality of particular enumerative inductions from which the principle is derived. This analysis of the 'inductive process' is one of Mill's most elegant achievements.

Mill and Hume then are both naturalistic radicals, but in quite different ways—Hume by virtue of his scepticism, Mill by virtue of his empiricist analysis of deduction. The only cognitive dispositions which Mill recognizes as primitively legitimate are the disposition to rely on memory and the habit of enumerative induction. The whole of science, he thinks, is built from the materials of experience and memory by disciplined employment of this habit.

This is Mill's *inductivism*—the view that enumerative induction is the only *ultimate* method of inference which puts us in possession of new truths. Is he right in thinking it to be so? In his own time the question produced an important, if confused, controversy between him and William Whewell. Whewell argued that fundamental to scientific inquiry was the hypothetical method, in which one argues to the truth of a hypothesis from the fact that it would explain observed phenomena. Mill, on the other hand, could not accept that the mere fact that a hypothesis accounted for the data in itself provided a reason for thinking it true. The point he appealed to is a powerful one: it is always possible that a body of data may be explained equally well by more than one hypothesis.

What he does not see, and this is one of the points of weakness in his philosophy, is how much must be torn from the fabric of our belief if inductivism is applied strictly. Thus, for example, while his case for empiricism about logic and mathematics is very strong, it is his methodology of science which then forces him to hold that we know basic logical and mathematical principles only by an enumerative induction. That is desperately implausible; accepting the hypothetical method would be one, though only one, possible remedy.

Inductivism also plays a key role in Mill's metaphysics. He sets this out in his *Examination of Sir William Hamilton's Philosophy* (1865)—a detailed criticism of the Scottish philosopher who had attempted to bring together the views of Reid and Kant. Here Mill endorses a doctrine which was then accepted, as he says, on all sides (though it would now be treated with greater mistrust). The doctrine is that our knowledge and conception of objects external to consciousness consists entirely in the conscious states they excite in us, or that we can imagine them exciting in us.

This leaves open the question whether objects exist independently of consciousness. It may be held that there

are such objects, although we can only know them by hypothesis from their effects on us. Mill rejects this view—as, given his inductivism, he must. Instead he argues that external objects amount to nothing more than 'permanent possibilities of sensation'. The possibilities are 'permanent' in the sense that they obtain whether or not realized; they would occur if an antecedent condition obtained. (As well as 'permanent' Mill uses other terms, such as 'certified' or 'guaranteed'.)

Our knowledge of mind, like our knowledge of matter, Mill thinks to be 'entirely relative'. But he balks at resolving it into a series of feelings and possibilities of feeling. For 'the thread of consciousness' contains memories and expectations as well as sensations. To remember or expect a feeling is not simply to believe that it has existed or will exist; it is to believe that *I* have experienced or will experience that feeling. Thus if the mind is to be a series of feelings, we would, he thinks, be forced to conclude that it is a series that can be aware of itself as a series. This drives him to recognize in mind, or self, a reality greater than the existence as a permanent possibility which is the only reality he concedes to matter. He fails to note that the doctrine that mind resolves into a series of feelings need not literally *identify* selves with series: it paraphrases talk of selves in terms of talk of series.

Discounting this uncertainty about what to say of the self, all that ultimately exists in Mill's view is experience in a temporal order. But he claims this to be consistent with \*common-sense realism, and he continues to see minds as proper parts of a natural order. The difficulties of this begin to emerge when we ask whether the experiences referred to in Mill's metaphysics are the very same as those referred to by common sense—and explained by physical antecedents. The same difficulties emerge for later \*phenomenalists, but Mill never addresses them.

To the succeeding generation of philosophers, who took Kant's philosophy seriously, Mill's naturalism seemed thoroughly incoherent. He fails to see the need for a synthetic a priori to render any knowledge possible, even though he gives an account of real propositions and inferences which agrees in essentials with Kant. On top of that, in accepting phenomenalism he accepts a doctrine which must lead to a transcendental view of consciousness, yet he remains determinedly naturalistic in his view of the mind. Perhaps present-day naturalism is finding ways of avoiding this second impasse, by being more rigorously naturalistic about experience than Mill was. But it has yet to cope clearly with the first.

In ethics and politics Mill's premisses remain those of enlightenment \*humanism. Value resides in the well-being achieved within individual lives; the interests of all make an equal claim on the consideration of all. Happiness is most effectively attained when society leaves people free to pursue their own ends subject to rules established for the general good. A science of man will ground rational policies for social improvement.

His reason for thinking that \*happiness is the only ultimate human end is just like his reason for thinking

enumerative induction is the only ultimate principle of reasoning. He appeals to reflective agreement, in this case of desires rather than reasoning dispositions: 'the sole evidence it is possible to produce that anything is desirable, is that people do actually desire it. If the end which the utilitarian doctrine proposes to itself were not, in theory and in practice, acknowledged to be an end, nothing could ever convince any person that it was so.'

But do we not, in theory and in practice, desire things under ends other than the end of happiness, for example under the idea of duty? Mill's response to this question has strength and subtlety. He acknowledges that we can will against inclination: 'instead of willing the thing because we desire it, we often desire it only because we will it'. There are, he agrees, conscientious actions, flowing not from any unmotivated desire but solely from acceptance of duty. But his point is that when we *unmotivatedly* desire a thing we desire it under the idea of it as pleasant. He further distinguishes between desiring a thing as 'part' of our happiness and desiring it as a means to our happiness. Virtuous ends can be a part of happiness: consider, for example, the difference between a spontaneously generous man and a conscientious giver. The first wants to give because he takes pleasure in giving. The second gives from a 'confirmed will to do right'. The benefit of another is for the first, but not the second, a 'part' of his own happiness.

The *\*virtues* can become a part of our happiness, and for Mill they ideally should be so. That ideal state is not an unrealistic one, for the virtues have a natural basis and a moral education can build on it by association. More generally, people can come to a deeper understanding of happiness through education and experience. Mill holds that some forms of happiness are inherently preferred as finer by those able to experience them fully—but these valuations are still in his view made from within the perspective of happiness, not from outside it.

So Mill deepened the Benthamite understanding of happiness; however, he never adequately examined the principle of utility itself. It was a philosopher of the generation after Mill's, Henry Sidgwick, who probed its groundings most deeply. But when we turn to Mill's conception of the relationship between the utility principle and the texture of norms by which day-to-day social life proceeds, we find him at his most impressive. His ability to combine abstract moral theory with the human understanding of a great political and social thinker here comes into its own. Benthamite radicalism lacks historical and sociological sense. The philosophes of the eighteenth century, 'attempting to new-model society without the binding forces which hold society together, met with such success as might have been expected'.

The utilitarian, he says, need not and cannot require that 'the test of conduct should also be the exclusive motive of it'. This historical and concrete aspect of Mill's *\*utilitarianism* is the key to his view of the institutions of justice and liberty; though his analysis of rights follows Bentham. A person has a right to a thing, he holds, if there

is an obligation on society to protect him in his possession of that thing. But the obligation itself must be grounded in general utility.

The rights of *\*justice* reflect a class of exceptionally stringent obligations on society. They are obligations to provide to each person 'the essentials of human well-being'. The claim of justice is the 'claim we have on our fellow-creatures to join in making safe for us the very groundwork of our existence'. Because justice-rights protect those utilities which touch that groundwork they take priority over the direct pursuit of general utility as well as over the private pursuit of personal ends.

With *\*liberty* we find again that Mill's liberalism is grounded on a utilitarian base. He appeals to 'utility in the largest sense, grounded on the permanent interests of man as a progressive being'. In that respect, his liberalism stands opposed to the classical natural-rights liberalism of Locke. The famous principle which Mill enunciates in his *On Liberty* is intended to safeguard the individual's freedom to pursue his goals in his private domain: 'the only purpose for which power can be rightfully exercised over any member of a civilised community, against his will, is to prevent harm to others. His own good, either physical or moral, is not a sufficient warrant.'

Mill magnificently defends this principle of liberty on two grounds: it enables individuals to realize their individual potential in their own way, and, by liberating talents, creativity, and dynamism, it sets up the essential precondition for moral and intellectual progress. Yet the limitations of his Benthamite inheritance, despite the major enlargements he made to it, residually constrain him. His defence of the principle would have been still stronger if he had weakened (or liberalized) its foundation—by acknowledging the irreducible plurality of human ends and substituting for aggregate utility the generic concept of general good.

**Millikan, Ruth** (1933– ). In her work *Language, Thought and Other Biological Categories* (Cambridge, Mass., 1984), and in subsequent articles, Ruth Millikan has presented arguably the most detailed application of evolutionary theory to certain philosophical problems. She develops a notion of a thing's function in terms of things of that type, in the past, having been selected to play a particular causal role, so capturing the intuition that a thing can have a function that, in fact, it does not now carry out. She applies this notion to thought and language, claiming that, in each case, representation is the biological function of the

medium of thought and of language. This impels her to espouse a type of realism, and deny what she calls 'meaning rationalism', the view that language-users and thinkers have privileged access to the meanings they have conveyed by their language use, or which constitute their thought.

P.J.P.N.

\*evolution.

**Mill's methods:** *see* method of agreement; method of difference; method, joint; method of residues; method of concomitant variations.

**mimesis.** Imitation, representation. Plato's well-known attack on the poets begins with the assertion that poetry is a kind of 'mimesis'. The word is evidently used in two senses. (1) Playing a dramatic role or reciting a speech from Homer is *imitating* (or impersonating) someone. Such mimesis can harm the actor if the character imitated is bad. (2) Narrative \*poetry *represents* people's behaviour. Mimesis in this sense is also exemplified by reflections in mirrors and representational painting. To produce such representations, Plato says, one does not need knowledge of the thing represented, but only of how it appears. His complaint is that poets achieve with their skills a dangerous reputation as authorities on matters, such as good conduct, of which they are ignorant. 'Children and fools' are similarly taken in by *trompe-l'œil* paintings.

R.J.H.

Plato, *Republic* x. Various translations available, e.g. that by G. M. A. Grube and C. D. C. Reeve (Indianapolis, 1992).

**mind.** You have a mind if you think, perceive, or feel. Your mind is like your life or your weight, an abstract version of an unproblematic property. When minds are thought of as objects in their own right, with parts as if they were spatially extended and with continuity through time as if they were physical objects, then they become much more thought-provoking. They become like souls or selves. We don't have to take minds as objects. They can be features of other objects, such as persons (persons typically have heights and weights and minds) or features of person's lives. Still, we can study minds inasmuch as we can study thinking, perceiving, and feeling. This is psychology.

The concepts of thinking, perceiving, and feeling are among a large family of concepts, including, for example, remembering, loving, and wishing, which every person picks up in childhood when they acquire their culture's conception of mind. Developmental psychologists have differing opinions about whether this conception is a fairly arbitrary theory which could vary in essential respects from one culture to another, or whether there is a core way of thinking about mind to which humans inevitably gravitate. Such a core conception would correspond to what functionalist thinkers in the philosophy of mind, such as Putnam and Fodor, have postulated as the set of essential connections between beliefs, desires, memories, and other states, which characterize mind: a mind is

anything, be it human, animal, or extraterrestrial, which has states connected in the way the core conception describes.

Even if there were a core concept of mind, it could be wrong. That is, the underlying neurological facts about why we act in the ways that we describe as thinking, perceiving, and feeling may be so different from our characterizations of them in everyday or 'folk psychological' terms that to think of people as being or having minds is positively misleading. This is the position of eliminative materialism, associated with Feyerabend, Rorty, and Patricia and Paul Churchland. It is not at all obviously right. There is a lot of philosophical and scientific work to do before we can see where the answer lies.

If minds are real features of people then there may be aspects of these features which are not easily described in terms of everyday concepts such as thinking, perceiving, and feeling. For example, there might be subconscious processes which are best described in the language of psychoanalysis. Psychology, psychoanalysis, and other disciplines might tell us things about what we call mind which are unavailable to common-sense or to introspection. Certainly one conclusion that seems to be emerging from cognitive psychology, for example in the work of Nisbett and Ross, is that the explanations people give of the reasons for their actions are much more often wrong than they imagine. Whatever our limitations in knowing what we are thinking or feeling, our limitations in knowing *why* we think or feel seem to be very much greater. In one way this might not be surprising, for the reasons why we think or feel surely include many physical causes of which a person is completely unaware. And in fact one of the sources of the impression of free will may be the blindness of consciousness to the causes of thought and feeling.

Henry Wellman, *The Child's Theory of Mind* (Cambridge, Mass., 1990).

**mind, history of the philosophy of.** Philosophizing about the mind is as old as philosophy itself, whereas philosophy of mind, proper—a distinctive subfield of philosophy—is of relatively recent advent. Both Plato and Aristotle present mature theories of the nature, structure, and types of psyche, theories that clearly depended on prior theorizing. And every great philosopher of the modern period, most notably Descartes, but also Hobbes, Locke, Berkeley, Hume, and Kant, propose theories of mind. In general, this theorizing takes place within metaphysics, epistemology, or moral theory and not in the service of developing a theory of mind for its own sake. Plato's tripartite division of psyche into rational,

appetitive, and temperamental parts occurs in the *Republic* as part of the rationale for structuring political life in a certain way. Aristotle's distinction among the types of psyche in nature are part of his biological metaphysics; and his vision of the distinctive features of the human psyche as involving the capacity for reason and virtue serves his ethical theory. \*Mind-body dualism emerges as a fundamental truth within Descartes's epistemological project. Hobbes's mechanistic psychology in the first part of *Leviathan* prepares the way for the famous claims about human nature in chapter 13. The laws of association of the Empiricists were attempts to answer distinctively philosophical questions about the nature and limits of human knowledge. And, of course, Kant's Copernican turn in philosophy, the proposal that mind lays down certain a priori conditions for experience, was meant to answer the deep scepticism about causation, \*self, and transcendental matters such as the existence of God generated by Hume's epistemology.

The philosophy of mind now exists as a distinctive subfield of philosophy. There are journals devoted to work in it; job applicants claim to specialize in it; and so on. But its emergence cannot be precisely dated. It is best to think of the philosophy of mind as emerging during the late nineteenth century and first half of the twentieth century. Professional recognition of it as a distinct and important subfield comes only after 1950, despite the fact that one finds 'philosophical anthropology' and 'philosophy of mind' on medieval lists under the entry 'Metaphysics', and works like that of the Scottish philosopher Thomas Brown's *Lectures on the Philosophy of the Mind* appear as early as 1820.

The following developments were seminal in the early stages. First, the founding of scientific psychology as an offshoot from philosophy is, in the lore, dated to Wilhelm Wundt's founding of a psychological laboratory in Leipzig in 1879. Here master introspectors were trained and memory and reaction-time experiments were set up and carried out. All the founding documents of scientific psychology attest to acute self-concern on the part of the founders in making clear and defensible philosophical assumptions and in developing empirically secure methods that would be immune from the scorn the new science brought against a priori theorizing about mind. So psychology was born in the late 1800s as a philosophically self-conscious discipline.

Second, in 1874 Franz Brentano published his *Psychology from an Empirical Standpoint*. It is here that Brentano resurrected Aristotle's and Aquinas's notion of \*intentionality — from the Latin, *intendo*, meaning 'to aim at or point toward'. The idea was that paradigm-case mental states, beliefs, desires, hopes, expectations, and the like, have intentional objects. Beliefs, desires, wishes, expectations, and so on, are of or about something: I believe that [Thatcher was Prime Minister]; I wish that [Reagan had not been President]. What a belief or wish is *about*—Thatcher or Reagan—is its 'object', whereas the propositional thought expressed—that Thatcher was Prime

Minister or that Reagan had not been elected—is its 'content'.

Brentano's thesis is that \*intentionality is the ineliminable mark of the mental. Psychology will need to be intentional, that is, the explanation of human thought and action will require us to make an inventory of all the types of mental state (beliefs, desires, and so on) that human minds are capable of going into, and it will also need to focus on the intentional objects and contents of these states (it remains a possibility that not all mental states are intentional; perhaps pains and moods have no objects or propositional contents and thus are not of or about anything at all). To explain why an individual reaches for that cool drink, we will need to posit not only belief and desire states, but belief and desire states with a particular intentional object, a cool drink, and content, that this is a cool drink.

A lively contemporary debate concerns the issue of whether only conscious mental states can be intentional, and whether other states involved in belief or desire formation are purely computational, not 'mental' at all in any interesting sense. It is noteworthy that Sigmund Freud took three and a half years of elective courses with Franz Brentano while he was in medical school. Indeed, one fruitful way of thinking of psychoanalysis is as involving an extension of Brentano's basic insight. Not only are conscious intentional states causally efficacious, but so too are unconscious intentional states. So just as my desire for a cool drink and my belief that this is a water-fountain in front of me explains my taking a drink, so too my unconscious desire to kill the boss explains my hostile verbal edge towards him.

Third, in 1890 William James published his monumental *Principles of Psychology*. Not only was this great work a compendium of all known psychological knowledge, culled mostly from the new scientific psychologists but also from more traditional philosophical sources, it was also a troubled testimony to James's own recognition that a scientific theory of mind was in deep tension with traditional philosophical ways of thinking about mind. This comes out clearly in the book when James discusses the deterministic assumption made by psychologists and the assumptions about human freedom made in ethics. James indicates that for purposes of living, but not for doing psychology, the assumption of \*free will is the stronger. This same ambivalence carried over to James's ambivalence about what field he himself worked in. Over a brief period in the late 1880s and 1890s, James switched his Harvard appointment several times between medicine, psychology, and philosophy, before finally settling into philosophy for the remainder of his career.

James's *Psychology* treats all the great metaphysical and epistemological problems in the philosophy of mind. In addition to the problem of \*free will and free action, he discusses the status of introspection, the problem of other minds, the nature of the emotions, the mind-body problem. And he takes not only Cartesian dualism, but Malebranche's occasionalism, Leibniz's parallelism, and Huxley's epiphenomenalism, as live options.

Wundt, Brentano, and James together represent some of the most important foundational work in the science of the mind. But it is, at the same time, important work in the philosophy of mind, work filled with philosophical assumptions about the nature of mind, analyses of competing models, and recommendations about the proper methods for studying mind and conceiving its nature. In their hands, mind becomes an important topic in its own right, worthy of attention in a science of its own, the fledgling psychology, and in need of a general philosophical analysis of such questions as: What is this thing called 'mind'? What is its place in nature? How is mind to be known?

The next phase in the development of the philosophy of mind, a phase which leads to its finding a distinctive niche, and to its professional recognition as a subfield, occurs between 1900 and 1950. Roughly, what happens is this: scientific psychology emerges not as a unified theory but as a bundle of theories with radically different methodological approaches. There were introspectionists, and anti-introspectionists, behaviourists, and functionalists, depth psychologists, and their opponents. In 1933 Edna Heidbreder wrote her important *Seven Psychologies*, still an excellent survey of the theory diffusion affecting psychology at its birth. This theoretical diffusion forced debate about the proper methods and assumptions of psychology, both among leading psychologists like Wundt, Titchener, John B. Watson (whose manifesto 'Psychology as a Behaviorist Views It' was published in 1913), and eventually B. F. Skinner—who left a poet's life in Greenwich Village for the halls of psychology (in what is today William James Hall, the philosophy department at Harvard being housed in Emerson Hall) after reading a popular magazine article by Bertrand Russell about \*Logical Positivism—and also among philosophers as diverse as James and Russell, and John Dewey and Rudolf Carnap. Indeed, so close were the relations between \*psychology and philosophy even after the new science had declared its independence that three philosophers, William James, Mary Calkins, James's student and a professor of philosophy and psychology at Wellesley College, and John Dewey, held the presidencies of both the American Philosophical Association and the American Psychological Association during the early years of psychology's development. And it was only in 1974 that *Mind* dropped the fifth and sixth words from its subtitle, 'A Quarterly Review of Psychology and Philosophy'.

Dewey and Carnap can be thought of as representatives of what were to become the two sides of the philosophy of mind, one side concerned primarily with the metaphysics of mind, the other with the methodological foundations of psychology and the epistemic status of first- and third-person psychological reports. In a series of papers published at the turn of the century, Dewey began to defend a picture of mind that was naturalistic without being mechanistic. He rejected the picture of mental action as consisting of simple reflexes or complexes of reflexes, as well as the Cartesian picture of the mind as an incorporeal sub-

stance. Dewey proposed instead a picture of mind inspired by Darwin and James. The human mind is the result of selective forces building the most powerful and adaptive organism ever known. If Dewey was concerned primarily with developing a naturalistic metaphysics of mind consonant with evolutionary theory, Carnap was concerned primarily with the epistemological status of first- and third-person psychological reports. In part this concern was motivated by the appeal the positivists made to observation reports as the rock-bottom foundation for all science. Statements such as 'Water is H<sub>2</sub>O' or 'The atomic number of gold is 79' depend on grounding theory in observation, often observations mediated by instrumentation. Perceptual reports ground all science—even chemistry and physics. How trustworthy are such reports? The positivists were quick to defend intersubjective observation reports, reports made by several independent observers, as reliable enough for the physical sciences. But what about the status of intrasubjective, first-person psychological sentences, such as 'I'm in a good mood' or 'I'm visualizing my mother's face'? What about the whole idea that expertise in introspection could be developed? How could such expertise be measured or verified? In his 1931 paper 'Psychology in a Physical Language', Carnap asserted that first-person psychological reports were 'intertranslatable with some sentence of physical language, namely, with a sentence about the physical state of the person in question'. Such reports refer (inadvertently, we might say) 'to physical processes in the body of the person in question. On any other interpretation' such reports 'become untestable in principle, and thus meaningless'.

The two strands, concern with the metaphysics of mind and with the logical status of sentences about mind, come together in Gilbert Ryle's *The Concept of Mind* (1949). If there is a founding document in the contemporary philosophy of mind proper, Ryle's book is it. First, there is a spirited attack on the Cartesian picture of mind as a \*ghost in the machine'. Second, there is a relentless attack on the doctrine of \*privileged access, the view that the mind is transparent to its owner, and that we each have unmediated and incorrigible access to our own mental states. Third, there is the proposal that \*mind', the Cartesian conception of mind, at any rate, is simply a mystifying way of speaking about certain behavioural dispositions of the organism. According to Ryle's logical behaviourism, just as 'solubility' is nothing mysterious, referring simply to the disposition of a substance to dissolve in liquid, likewise talk of mental states, talk of 'belief' and 'desire', is, in so far as it is meaningful, talk of dispositions of the organism to behave in certain ways. It is ironic that the *locus classicus* of contemporary philosophy of mind argued in a sense that there really was no such thing as 'mind' as traditionally understood.

The work after Ryle constitutes the recent history of the philosophy of mind, a period characterized by two somewhat distinct sorts of work. First, there was work of analysis—work devoted to the analysis of \*sensation and \*perception (Chisholm, Armstrong, Sellars), intentionality,

free action, the \*emotions (Kenny), the debate about \*reasons and causes, the possibility of \*private language, and of knowledge of one's own and \*other minds.

Ryle while claiming to be no behaviourist emphasized the centrality, indeed the indispensability, of behaviour in the ascription of mental terms. Wittgenstein did much the same thing in his *Philosophical Investigations* (Eng. tr. 1953). Wittgenstein's specific argument against the development of a private language was developed, clarified, and defended by Norman Malcolm in his review of the *Philosophical Investigations* in the *Philosophical Review* in 1954. Malcolm pointed out the relevance of the private language argument for the problem of other minds in his 'Knowledge of Other Minds' (1958). Other important work on other minds includes A. J. Ayer's, *The Concept of a Person* (1956) and *The Problem of Knowledge* (1963).

Important works on free action and the question whether reasons can be causes include: G. E. M. Anscombe's *Intention* (2nd edn. 1963), Hart and Honoré's *Causation in the Law* (1959), A. I. Melden's *Free Action* (1961), J. L. Austin's 'Ifs and Cans' (1961), and Donald Davidson's 'Actions, Reasons, and Causes' (1963).

It was P. F. Strawson's *Individuals* (1959), an essay in 'descriptive metaphysics', that made the radical but extremely helpful proposal that the traditional mind-body problem be reconceived along the following lines: the concept of a person is primitive and both mental and physical predicates are ascribable to persons, that is, to one and the same thing.

In addition to the latter work of philosophical analysis of mental concepts and attempts to state more clearly and helpfully traditional philosophical problems, there was a spate of work specifically devoted to developing distinctive materialistic alternatives to Cartesian \*dualism and to each other, and by debates among the proponents of these different theories about the nature of psychological explanation. The three main materialistic theories are \*identity theory, \*eliminative materialism, and \*functionalism.

*Type-identity theory (reductive materialism)*. J. J. C. Smart, U. T. Place, and David Armstrong proposed this simple and compelling solution to the mind-body problem: each type of mental state is identical to some type of yet-to-be-discovered neural state. Just as water is H<sub>2</sub>O and common salt is NaCl and the temperature of a gas is mean molecular kinetic energy, mental terms like 'believing', 'desiring', and 'loving' will be shown to be synonymous with terms that refer to types of neural events, so that some day we shall be able to say 'Love is such-and-such activity in sector 1704'.

*Eliminativism*. Paul Feyerabend and Richard Rorty issued this objection to identity theory: identity theory assumes that our ordinary mentalistic ways of taxonomizing psychological events, in terms of beliefs, desires, and the like, are not only good ways to taxonomize things for ordinary purposes, but in fact map perfectly on to (yet-to-be-discovered) underlying neural kinds. But why think that the case of belief and its kin is more like the case of

water, where the mapping to H<sub>2</sub>O in fact works out, than like the case of our ordinary concept of fish, or, even worse, like the concepts of witch or phlogiston? In the case of fish, whales and dolphins were picked out by the concept for millennia, but are now known not to be fish at all, but mammals. The concepts witch and phlogiston both had great importance in their day, but both are now known to refer to nothing at all. Type identity theory assumes precise mappings from the mental to the neural which warrant a reduction or replacement of the mentalistic vocabulary with the neural vocabulary, and at the same time legitimizes the mentalistic vocabulary by showing that it always (inadvertently) referred to the underlying types of neural events. But Feyerabend and Rorty contend that mental talk was not intended to refer to neural events, nor did it inadvertently succeed in so doing. \*'Folk psychology', with its strong Cartesian roots, was intended as, and succeeded in being, a theory that rivals scientific ways of conceiving of mind. The eliminativist position has been developed further and championed in recent years by Patricia S. Churchland and Paul M. Churchland and is a challenge to 'mental realism', our ordinary way(s) of conceiving of the mental.

*Functionalism* challenges both type-identity theory and eliminativism. An important but iconoclastic paper in this genre is Donald Davidson's 'Mental Events' (1970), in which he proposed the view he called \*anomalous monism. According to this doctrine mental events are physical events but they are not reducible by definition or natural law, nor are they in any other straightforward way intertranslatable with physical terms. Against type-identity theory, the functionalist thinks it implausible that every person's belief that 'snow is white' is or must be realized in the same type of neural state. Functionalists think that all beliefs in the whiteness of snow are physical but allow for multiple physical \*realizations of the belief. Just as 'capital' comes in many different forms, any form of cash or property will do, so too my belief that snow is white, and yours, and a Martian's, could be realized in different ways. The idea of multiple realizations has made functionalism a favourite doctrine among believers in strong artificial intelligence, the view that there is no reason in principle why computers shouldn't have bona fide mental states—indeed even be conscious. Different realization would be consistent with physicalism (token-physicalism), but would dash hopes for smooth type-type reductions since there would be no bridge law translating predicates such as 'believes snow is white', 'is in love', 'wants a drink' into single predicates in physical language (to be fair to identity theory, it can accommodate this idea up to a point by allowing for species-specific type-identities, so that cat-thoughts that 'there is water' and human ones are realized in different ways). Against the eliminativist, the functionalist holds out hope for folk psychology or, better, sees it as a starting-place, subject to refinement and rigour, for the development of an autonomous science of the mind. We start with a conception of mind as roughed out by folk psychology but with a commitment

to physicalism. We then do experiments, draw inferences about how different cognitive subsystems work to produce the phenomenon being studied, e.g. language comprehension, memory, etc., and in so doing arrive at an abstract conception of how the mind works—without ever mentioning how these workings are realized physically.

As identity theory, functionalism, and eliminativism bumped up against each other throughout the 1960s, 1970s, and 1980s, they also began to bump up against the emerging amalgam of disciplines known today as \*cognitive science. Cognitive science was rooted in work of logicians, psychologists, computer scientists, and neuro-scientists, great thinkers such as Alan Turing, Kenneth Craik, Claude Shannon, Norbert Wiener, Warren McCulloch, Walter Pitts, Karl Lashley, and John von Neumann (Howard Gardner dates the birth of cognitive science from the Hixon Conference at Caltech in 1948), who were thrilled by the prospect of blending insights from their different disciplines in order to understand the mind.

The interdisciplinary attitude and the wait-and-see-we-are-early-in-the-game attitude that pervade cognitive science made philosophers of mind aware that we could not know a priori how the relations among folk psychology, more refined cognitive models, and neuroscience would work out. It could be that identity theory is true in certain domains and in species-specific ways, e.g. chimpanzee vision might map neatly in chimps' brains and human vision in human brains. And it might be that neuroscience will spell doom for certain ways of thinking about mind, while certain abstract functional modes of explanation retain their value. The view favoured by most contemporary philosophers of mind is the co-evolutionary idea. P. S. Churchland, cooling recently towards eliminativism, expresses the basic idea in terms of constraining and developing each type of explanation by what is known at other levels of explanation, especially at adjacent levels.

The co-evolutionary strategy has important implications for the very idea of philosophy of mind as traditionally conceived, for it suggests that there is no subfield of philosophy proper that can deepen our understanding of mind. Mind will be understood, if it is understood, by our best science. Philosophers who study work in the relevant sciences will be welcomed in the interdisciplinary quest to understand mind. Quine proposed that philosophy was continuous with science; philosophy of mind as practised today has taken Quine to heart. At the same time it has become somewhat less clear what if anything the distinctively philosophical, as opposed to the scientific, issues are. In what sense, one might ask, is the question of the nature of mind a philosophical question rather than a foundational question within the science of the mind? O.F.

\*consciousness; consciousness, its irreducibility; mental events; mental states; identity theory; eliminativism; functionalism.

**mind, problems of the philosophy of.** Philosophical problems about the mind are among the enduring problems of philosophy; arguably, they are among the most deeply puzzling and challenging issues that philosophy has had to face.

1. *Characterizing the mental.* We come face to face with one of these issues when we try to give an initial delineation of the sphere of the mental. Mental events or states seem to fall under two broad kinds. One is comprised of those involving sensory qualities, or \*'qualia', such as pains and itches, seeing colours and hearing sounds, experiencing pangs of hunger, and having after-images, and the like. As it is often put, there is 'something it is like' to be in one of these states—it is like something to see a yellow field of sunflowers, and that is different from what it is like to see the blue sky above it. These may be called 'qualitative mental states' or, more simply, 'experiences'. The second class of mental states, called 'propositional attitudes' or 'intentional states', includes states that have *content*, such as believing that Mt. Everest is the tallest mountain, being pleased that the home team has won the football match, and remembering one's telephone number. (Some mental states, such as emotions and perceptions, appear to possess both content and sensory aspects; e.g. feeling annoyed that your flight has been cancelled, noticing that the traffic-lights have just turned red.) But it has not been easy to answer the following question: What common property, or properties, do phenomena of these two kinds share in virtue of which they are all mental? What do itches and beliefs have in common that makes both mental?

One might say, following Descartes, that your knowledge that you are in one of these states is in some sense 'immediate' or 'direct' and carries a special sort of first-person authority. However, people often have beliefs and desires of which they are not aware, much less 'immediately aware'; and research in cognitive psychology has shown that much of our perceptual information-processing is not at all accessible to the subject. Moreover, it has been argued that there can be sensations, such as pains, of which the subjects, in the heat of combat or intense absorption in another activity, are unaware. Can we say then, following \*Brentano, that the \*mentality of mental phenomena consists in their \*'intentionality'—their 'aboutness' or 'being directed upon' an object? Thus,

your belief that Mt. Everest is the tallest mountain is about Mt. Everest, and is directed upon it. Or, as we may say, your thought has Mt. Everest as its 'intentional object'. However, it is difficult, if not incoherent, to conceive of a pain, or a tickle, to be 'about', or 'directed upon', anything. There are perhaps other possible approaches to this issue, but the problem of formulating an adequate 'criterion of the mental' has resisted solution. It may be that all mental states are characterized by a certain kind of subjectivity, a 'point of view' or 'perspectivalness'; however, precisely what this subjectivity amounts to is still an open question.

2. *The mind-body problem.* In a broad sense, the problem of accounting for the place of mind in a world that is fundamentally physical is coextensive with philosophy of mind. In a narrower sense, the problem is that of explaining the relationship between mentality and the physical nature of our being. Substance dualism, which posits immaterial souls or minds as bearers of mental states, has largely disappeared from contemporary discussion, and the focus of discussion in the mind-body debate has shifted to the status of mental states, processes, and properties *vis-à-vis* physical states, processes, and properties. We know, from familiar daily experience as well as scientific and clinical observations, that mental phenomena are correlated in lawlike ways with various specific physical processes going on in the body, and neurophysiological research has amassed huge amounts of information on the details of how specific mental capacities, functions, and processes depend on the structure and functioning of our central nervous system. But is it possible that the mental depends on and yet remains distinct from the physical? If so, what is the nature of this dependency? Or is the mental in fact a subspecies of the physical?

The mind-body identity theory, also known as central-state materialism, brain-state theory, and type \*physicalism, holds that mental properties, or kinds, are reducible to, or can be reductively identified with, physical (presumably, neurobiological) properties and kinds. Just as scientific research has shown that light is a form of electromagnetic radiation and that genes are DNA molecules, argues the reductionist, neurophysiological research will show (perhaps, it has already shown) that pain is just the excitation of a certain group of neurons in the hypothalamus, that consciousness is 40 Herz synchronized neuronal oscillation, and, in general, that mental states are just neural processes in the brain. Physical reductionism of this form, however, has not been popular, since the 1970s. \*Functionalism, which has been influential since the late 1960s, maintains that mental kinds are not physical kinds, but rather 'functional kinds', defined by their causal role in relation to sensory inputs, behaviour outputs, and other mental states. On this approach, pain, for example, would be an internal state of an organism that is typically caused by tissue damage and that in turn causes such effects as winces, groans, and a sense of distress. However, the ontological status of functional properties, in particular their status as causal powers, has

remained elusive; and serious doubts have been raised as to whether the sensory or qualitative character of mentality can be captured on the functionalist approach. Moreover, it is not clear exactly how functionalism differs from the identity theory, and it remains an open question whether functionalism is a form of reductionism. Others maintain that the mind-body relation is adequately characterized as one of \*supervenience—that is, in the claim that there could not be two entities, or worlds, that are exactly alike in all physical respects but differ in some mental respect. But it is arguable that supervenience in this sense lacks sufficient content to qualify as a full theory of the mind-body relation; this is perhaps evident in the apparent fact that the reductionist, the functionalist, and even the epiphenomenalist are all committed to mind-body supervenience. There is also the \*eliminativist alternative: mentality, like the posits of discarded scientific theories such as phlogiston and magnetic effluvia, will be expunged from our ontology as the neuroscientific understanding of human nature makes its inexorable advance.

3. *How can my mind move my limbs?* Impingements on our sensory surfaces cause sensations and perceptions, which in turn cause us to form beliefs about our surroundings. Our desires and wants, in concert with the beliefs we hold about the world, cause us to act, by moving our limbs or making our vocal cords vibrate in appropriate ways. Mental causation—that is, causality involving mental events as causes or effects—seems an undeniable fact of daily experience. Evidently, moreover, it is essential to our conception of ourselves as cognizers and agents: the acquisition of knowledge about our surroundings requires our perceptions and beliefs to be appropriately caused by ambient events, and genuine agency requires that the agent's intentions and decisions have the power to cause his limbs to move and thereby alter the arrangements of objects around him.

A fundamental difficulty with Descartes's interactionist dualism of mental and material substances was its perceived inability to explain how mental causation was possible. How could some wholly immaterial substance, entirely outside physical space, affect the motion of even a single molecule? By what mechanism is this miraculous transmission of causal influence accomplished? Moreover, there is reason to believe that the physical domain is *causally closed*; that is, tracing back a causal chain starting with a physical event should not take us out of the physical domain. To deny this would be tantamount to denying the completeness of a physical theory of the physical world; it would be to assert that only by importing non-physical causal agents or forces could physics hope to be a complete explanatory theory of physical phenomena. For these reasons, some have found \*epiphenomenalism attractive: mental phenomena are caused by physical (presumably, neural) phenomena, but they are themselves mere 'epiphenomena' with no causal powers of their own. They are like shadows or afterglows cast by neural processes.

RECENT AMERICAN PHILOSOPHY (I)

DONALD DAVIDSON addressed in seminal articles a variety of the most prominent questions in late twentieth-century philosophy of mind and language; their prominence is largely attributable to his treatment of them.

HILARY PUTNAM has deployed mathematical and scientific expertise to establish a clearer view of the status of scientific and philosophical knowledge and truth.

JOHN SEARLE first came to prominence in the 1960s with his work on the philosophy of language; now he is a leading critic of cognitive science, specifically of the aim of giving a materialist account of the mind.

THOMAS NAGEL has not shrunk from the big questions: What does it all mean? What is it like to be a bat? (The second is about the nature of consciousness.)

*Photographs by Steve Pyke*

Epiphenomenalism, however, has difficulties of its own. For one thing, it isn't clear that physical-to-mental causation is any easier to understand than mental-to-physical causation. Second, and far more importantly, depriving the mental of causal powers simply goes against almost all of what we believe about mentality—that is, about us. To most of us it is just not believable to say that our desires and intentions have nothing to do with what we do, or that the same human civilization would have developed even if no humans had ever had a thought, an idea, or a hope.

Mental causation is a simple matter for physical reductionism, for it identifies mentality with physical processes, and this means that mental causation is simply a species of physical causation. But reductionism has not been a popular option for some time. Non-reductive physicalism, which arguably is the current orthodoxy on the mind-body problem, encounters serious difficulties with the causal closure of the physical: if the physical domain is 'causally closed', as all serious physicalists believe, how can mental states, states that are irreducibly distinct from the physical, inject their causal influence into the physical domain? The problem of mental causation remains a central issue in the continuing debate over the nature of mind.

4. *Intentionality*. Wittgenstein asked: 'What makes my image of him into an image of *him*?' Many mental states, including thoughts, beliefs, and desires, are 'intentional' in Brentano's sense—that is, they are 'about' or 'directed upon' an object. My thought that Boston is to the north of New York is *about*, and is *directed upon* or *refers to*, Boston and New York. As earlier noted, Brentano claimed that intentionality is the defining characteristic of mentality. Earlier debates on intentionality during the twentieth century (notably, R. M. Chisholm's work) focused on the project of validating Brentano's thesis by providing a precise definition of intentionality. Mentality, however, is not the only phenomenon with intentionality; our words and sentences, too, have meanings and can refer to, or be about, things. This gives rise to a profound question: Is the intentionality of mind more basic than, or prior to, the intentionality of language, or is it rather the reverse? Perhaps, neither is prior to the other, both being interdependent. Moreover, we seem to be able to have thoughts about things that do not exist, like Pegasus and the fountain of youth (surely Ponce de León had thoughts about the latter). But how is it possible for our minds to direct themselves upon things that do not exist? We are apt to think that our thoughts about Pegasus and our thoughts about Cerberus are about different things. But how can that be? Given that neither exists, why aren't the thoughts about the same thing, namely nothing?

Lately, however, the focus of discussion has shifted to the project of 'naturalizing' intentionality. It is useful to distinguish two problems here: the problem of 'referential intentionality' (or the problem of reference, for short) and that of 'content intentionality' (the problem of content).

The first is the problem just reviewed, namely that of giving an account of the conditions under which a thought, or an expression, is about, or refers to, an object. The second is the problem of specifying the conditions under which a mental state has the specific 'content' or 'meaning' it has; that is, what it is about your belief that *snow is white* that makes it the case that its content is that *snow is white*, or that it represents the state of affairs of *snow being white*. The naturalization constraint in this context is usually taken to mean that any acceptable account of intentionality of either type must be formulated without the use of any unanalysed intentional or other overtly mentalistic concepts (for example, Frege's notion of 'grasping' a thought or proposition and Chisholm's notion of 'conceiving' a property). The causal approach has been the most popular in developing naturalistic accounts of intentionality. A causal theory of reference would attempt to explain 'expression *x* refers to object *y*' in terms of an appropriate causal relation holding between the uses of term *x* and object *y*; a causal theory of content would try to analyse 'Person *S* has the belief that *p*' in terms of a causal, or lawful, relationship between *S*'s belief that *p* and the state of affairs represented by *p*. Some philosophers have stressed the importance of the inferential relations into which a thought enters in fixing its content; others have focused on the constraints of rationality and coherence as central to the determination of a speaker-thinker's mental contents. As this very brief survey shows, many different approaches and perspectives are in play in this area, and the situation is still very fluid.

One problem about content that has received much attention recently is *content externalism*. This is the view, first advanced by Hilary Putnam and Tyler Burge, that physical and social factors external to the subject play a crucial role in determining the contents of that subject's beliefs and other intentional states. This means that what goes on 'within' you—your mind or your body—does not wholly determine the meanings of your thoughts or words (as it is put sometimes, meanings are not in your head). For example, you have the belief that *water is wet*, whereas your exact twin on 'Twin Earth', where water (that is, H<sub>2</sub>O) is replaced everywhere by a different but observationally indistinguishable substance, XYZ, has the belief that *XYZ is wet*, rather than the belief that *water is wet*. Or take a simpler example: you are looking at an apple, and your twin is also looking at an apple, which, as it happens, is qualitatively exactly similar to the one you are looking at. Your perceptual experience, let us say, is exactly similar to your twin's. However, your thought that *here is a red apple* and your twin's thought that *here is a red apple* have different contents—they are about different objects and their truth-conditions are different. This difference in thought content seems to stem not from any internal physical or mental differences between you and your twin, but from differences in the external environment. Just what the implications of content externalism are in regard to such questions as the truth of materialism, the causal powers of mental states, first-person epistemic

authority on one's own mental states, and the nature of psychology as a science, are open questions.

5. \**Consciousness*. Thanks largely to the influence of behaviourism and positivism early in the twentieth century, consciousness was studiously avoided, or at least ignored, by both psychologists and philosophers as a topic for serious investigation for much of that century, a fact that may strike one as deeply paradoxical. For one might wonder how mentality could be discussed or studied without examining consciousness. The common-sense conception of mentality gives consciousness the pride of place. In 1904, Ivan Pavlov, in his Nobel Prize acceptance speech said: 'In point of fact, only one thing in life is of actual interest for us—our psychic experience.' But by the 1940s and 1950s, behaviourism was firmly established as the reigning orthodoxy in psychology and social science, and a well-known and influential psychology textbook defined psychology as 'the science that studies the behavior of man and other animals' (Ernest Hilgard, *Introduction to Psychology*, 3rd edn. (1953)). As it turned out, however, the reign of behaviourism was short-lived, and since the 1960s there has been a sea change in the philosophical and scientific perspectives on consciousness. With the loosening of behaviourist and hyper-empiricist constraints, consciousness has made a strong come-back, both in systematic psychology and in philosophy, and serious philosophical works on consciousness have been appearing again, in large numbers.

The ill repute of consciousness was due in part to certain questionable characteristics attributed to it by both friend and foe, such as absolute ineffability, immediate and infallible accessibility to the subject combined with a total inaccessibility to the third person, and its interpersonal incomparability. It seemed to many that given these characteristics, consciousness could not be scientifically studied and explained, and, worse, that such essentially private experiences couldn't even be talked about in public language. In so far as we are able to learn and use expressions like 'pain', 'thought', and 'anger' for interpersonal communication, their meanings could not, it was argued, be fixed by some private episodes in an inner theatre accessible only to a single privileged subject. And surely we can, and do, use 'pain' and other mental expressions to communicate public meaning; how else could we explain a simple exchange like this: 'Does this give you pain?' (asks the dentist); 'Yes, it does' (the patient replies). Consciousness conceived as something essentially private and subjective thus seems to drop out of the picture, with no role to play in our public discourse, whether it is the language of science or the common language of everyday life.

Much recent work in cognitive psychology, however, appears to assume all but explicitly that subjects of certain psychological experiments are having specific sorts of conscious experience, such as mentally rotating an image. But the methodological assumptions that govern such references to consciousness are usually left vague and inex-

plicit, and the issue of their justification is seldom openly addressed. There are two broad issues concerning consciousness in psychology: first, how useful consciousness is as an explanatory concept, a concept in terms of which psychological theories can be formulated to explain the data in their domain, and second, whether it is possible to explain consciousness itself scientifically. Views are divided on both questions. There still are those (eliminativists and epiphenomenalists) who either outright reject, or are dubious about, the explanatory utility of consciousness. Some argue, as the classic epiphenomenalist did, that any intelligent behaviour for whose explanation we are apt to invoke conscious states can be explained perfectly well in terms of the underlying neural processes, and that this shows the dispensability of consciousness in psychology and cognitive science. Others have stressed the differences that consciousness supposedly makes to behaviour—e.g. performance levels of activities that require monitoring and control. There is also the metaphysical issue of whether or not it is ever necessary to invoke conscious states over and above their underlying neural substrates in the causal explanation of behaviour.

Can consciousness be explained scientifically? There are those who accept consciousness as a natural phenomenon arising out of physiological processes but despair of ever fully understanding it. Some have argued that the essential subjectivity of consciousness (i.e. the purported fact that all experiences involve a 'point of view' and are accessible only from the subject's point of view) precludes scientific understanding, which, being entirely objective, is unable to accommodate subjectivity. More optimistic are those who pin their hopes on the concerted efforts of neuroscience and cognitive psychology for an eventual naturalistic understanding of consciousness. What isn't clear in this debate is what exactly is required of a 'scientific understanding' of consciousness—that is, what specific factual or theoretical information we need to obtain if we are to gain a scientific understanding of consciousness. Some who think that consciousness can be neurobiologically explained appear to think that all that is needed for the success of their project is to identify a neural substrate for every type of conscious experience and for consciousness itself. Many will challenge this assumption, however, holding that these correlations are exactly what is in need of explanation. Suppose we discover that pains and itches are correlated respectively with neural states *M* and *N*. Why is it that pains, not itches, occur when *M* occurs? Why is it that pains occur only when *M* occurs and not when *N* occurs? (Can neurobiology explain why pains, not itches, mediate between tissue damage and wincing, and why itches, not pains, come between mosquito bites and scratching?) Why does consciousness emerge *at all* when *M* or *N* occurs? Even the noted biologist-neuroscientist Francis Crick has observed: 'we may be able to say that you perceive red if and only if certain neurons (and/or molecules) in your head behave in a certain way. This may, or may not, suggest *why* you experience the vivid sensation of color and why one sort of neural behavior

necessarily makes you see red while another makes you see blue, rather than vice versa' (*The Astonishing Hypothesis* (New York, 1994), 10). Perhaps, these questions have no answers, and these correlations have to be taken as 'brute facts' of the world that resist further explanation—facts which Samuel Alexander, a leading emergentist, once claimed we must accept with 'natural piety'. This of course would be to admit that consciousness could not be fully understood on a neurobiological or any other kind of physical basis.

It is not an exaggeration to say that the 'mystery of the mind' is by and large the mystery of consciousness, and this mystery consists in our seeming inability to understand the phenomenon of consciousness as part of a world that is essentially physical, and, what is worse, not knowing just what it is that we need to know if we are to achieve such an understanding.

6. \*Persons. The nature of personhood has been a topic of perennial philosophical interest; it is one where philosophy of mind and moral philosophy come together, since a person is also an agent, someone who is able to deliberate, form intentions, and perform actions, and hence is evaluable from the moral point of view. The question 'What is a person?' can be approached in two ways, synchronically and diachronically.

Synchronically, the question concerns the properties and powers something must possess at a time to be a person at that time. It will generally be agreed that a person must have a rich mental life and be endowed with certain psychological capacities and functions. But what exactly is required? Evidently, a person must be capable of having intentional states such as beliefs, desires, and the rest if he, as an agent, is to be able to form intentions and decisions. Should a person also be conscious? Should she also be self-conscious in the sense of having a sense of self-identity and being aware of her distinctiveness as an individual person among others? Should a person be rational in some clear and determinate sense? There is also the following metaphysical question: Must a person be embodied or could there in principle be persons who are immaterial? A traditionalist, especially one who is religiously inclined, might answer that not only can a person be wholly immaterial but she must be possessed of an immaterial soul, an answer that will be rejected by most naturalistically inclined philosophers. At any rate, these are some of the questions that arise with respect to being a person at a time.

The diachronic question, however, has received far more attention historically, and this continues to be true today. This is the so-called problem of 'personal identity': what makes a person existing at a given time (say, the retired general) *the same person as* one that existed at an earlier time (the little boy in the photograph). Persons, like anything else, change over time; both your mental and bodily characteristics change, sometimes rather strikingly, over a period of time, without your ceasing to be the same person. Changes could of course be so huge and

drastic that it would be correct to say that you have ceased to exist, or that another person has come into being. But what general principles govern our judgements about such cases? There are two important approaches to this issue, both commanding the allegiance of many philosophers. One is the bodily continuity theory; it says that for you to be the same person as a person existing at another time, your body, or an appropriate part of your body, must be continuous, in some appropriate sense, with the body of that person—namely, that the continuity of embodiment is what underlies the identity of a person over time. The second is the psychological continuity theory, according to which the continuity of mental life—that is, the continuity of character, personality, and, in particular, memory—rather than bodily continuity, is what is constitutive of the sameness of a person. Many details need to be supplied: e.g. precisely what the supposed 'continuity' is supposed to consist in, and just when the required continuity must be considered broken. There is also the question whether psychological continuity can be considered independent, conceptually or nomologically, of bodily continuity. In any case, each of the two approaches appears vulnerable to persuasive counterexamples, and plausible arguments have been presented in recent years for the position that personal survival is a matter of degree, not an all-or-nothing affair, and that there are situations in which no clear-cut answer exists to the question 'Has the same person survived?' Although our understanding of these problems has been deepened in many ways in recent years, the concept of personhood continues to test our philosophical ingenuity and imagination. J.K.

**mind-body problem.** The mind-body problem is the problem of giving an account of how minds are related to bodies, or how mental states and processes are related to bodily states and processes. That they are intimately related seems beyond doubt, and has not been seriously disputed. Evidently, our perceptual experiences depend on the way external physical stimuli impinge on our sensory surfaces, and, ultimately, on the processes going on in the brain; your desire for a drink of water somehow causes your body to move in the direction of the water-cooler; a bruised elbow causes you pain when it is touched, and the pain in turn causes you to groan and wince; and so on. But how do conscious experiences emerge out of the electrochemical processes in a grey mass of neural fibres? How do our beliefs and desires manage to get the appropriate neurons to fire and thereby cause the right muscles to contract? Schopenhauer called the mind-body problem 'the world knot', a puzzle that is beyond our capacity to solve.

The mind-body problem as it is now debated, like much else in contemporary philosophy of mind, has been inherited from Descartes. Descartes conceived of the mind as an entity in its own right, a 'mental substance', the essential nature of which is \*thinking', or \*consciousness. In contrast, the defining nature of material bodies, or material substances, was claimed to be spatial extendedness—that is, having a bulk in physical space. Thus, Descartes envisaged two disjoint domains of entities, one consisting of immaterial minds with their mental properties (e.g. thinking, willing, feeling) and the other of material bodies with their physical properties (e.g. size, shape, mass, motion). For Descartes, not only did minds lack spatial extension; they were not in physical space at all. However, the two domains are not to be entirely unconnected: a mind and a body can form a 'union', resulting in a human being. Although the nature of this 'union' relationship was never made completely clear, (Descartes claimed it to be a primitive notion that is intelligible in its own right), it evidently involved the idea that a mind and a body joined in such a union are involved in intimate and direct causal interaction with each other.

Thus, Descartes's mind-body doctrine combines *substance dualism*, i.e. a dualism of mind and body, each conceived as an independent substance, with the idea that there is causal interaction between the two. Many of his contemporaries, like Leibniz and Malebranche, were substance dualists, but they rejected the idea of mind-body causal interaction. They found it difficult to make sense of the idea that immaterial minds with neither extension nor mass, and not even in physical space, could somehow move material bodies with mass and inertia. Substance dualism, however, has largely dropped out of contemporary discussions, although it has by no means disappeared; few philosophers now find the idea of minds as immaterial substances coherent or fruitful. There has been a near consensus, one that has held over almost a century, that the world is essentially physical, at least in the following sense: all that exists in the space-time world are bits of

matter, and the space-time world is the whole world. If all matter were to be removed from this world, nothing would remain—no minds, no 'entelechies', no 'vital forces', and not even an empty space-time. According to this physical monism (or 'ontological physicalism'), mental states and processes are to be understood as states and processes occurring in certain complex physical systems, such as advanced biological organisms, not as states of some ghostly immaterial beings. This means that the principal remaining project for contemporary discussions of the mind-body problem is that of explaining how the mental character of an organism or system is related to its physical nature.

The heart of contemporary \*physicalism is the primacy and priority of physical properties and the laws that govern them. The following \*'supervenience thesis' is one way of expressing this idea: once all the physical facts about your body are fixed, that fixes all the facts about your mental life. That is to say, what mental properties you instantiate is wholly determined by the features and characteristics of your bodily processes. In fact, the physical facts of a world determine what mental facts will hold in that world; that is, if God were to make an exact physical duplicate of this world, it would necessarily be a mental duplicate as well. This thesis, often called 'supervenience physicalism', can be given different formulations of varying degrees of strength. But there is a sense in which emergentism, a form of non-physicalist dualism, is committed to mind-body supervenience; the emergentist will surely accept the claim that if two systems are physically identical, they must be identical in respect of the non-physical (e.g. mental) properties that emerge in them. Many physicalists, therefore, want something stronger than mind-body supervenience. Granted that mental properties are supervenient on physical ones, they may yet be distinct from them, just as aesthetic properties of works of art, in spite of their supervenience on the works' physical properties, seem to remain distinct from them. We know that mentality is subserved and determined by neural processes. But are mental properties 'over and above' their neural correlates?

A negative response to this question constitutes the \*identity theory of mind, or 'type physicalism', which identifies mental properties with their neural-physical correlates. So pain is identified with the excitation of C-fibres (assuming this to be its neural correlate); pain isn't some shadowy epiphenomenon of a brain process—it is a brain process. And similarly for all other mental states and properties. This is a classic form of mind-body reductionism: mentality is not renounced or eliminated, but conserved as a neural process, and thereby becomes a legitimate subject of scientific inquiry. Among the arguments for this view of the mind-body relation are the following: the argument that this gives us the simplest overall picture of the world in which physical science can explain all the phenomena; the argument that the identification of a mental property (pain) with its neural correlate (C-fibre stimulation) gives the simplest and best

explanation of the observed correlation between them; and the argument that only by identifying mentality with a neural-physical process is it possible to explain how mentality can have a causal influence in the physical world.

Like \*behaviourism, an earlier form of reductionism which attempted to identify mentality with facts about observable behaviour, type physicalism has failed to win enduring support. The most influential objection has been the variable (or multiple) realizability of mental kinds. Consider pain: there is no reason to expect that the same neural process underlies pain for all the different actual and possible pain-capable organisms (the neural substrate of pain is probably very different in humans and in octopuses). Moreover, there seems no a priori reason to deny the capacity for pain to all inorganic, or non-biological, systems. There seems then no single physical kind with which pain, as a mental kind, can be identified. Note, however, that supervenience physicalism as such is perfectly consistent with the variable realizability of mental properties.

These considerations have led to the formulation of \*functionalism, arguably the most influential position on the mind-body relation during the past four decades. Functionalism conceives of mental kinds as 'functional kinds', not physical kinds. Pain, for example, is to be understood in terms of its function as a causal intermediary between sensory input (e.g. tissue damage), behaviour output (e.g. wincing, groaning, and escape behaviour), and other mental states (e.g. desire to be rid of it). An internal state of an organism that serves this function, which can vary from species to species (and perhaps from individual to individual), is said to be a 'realizer' of pain. Most functionalists are physicalists in that they hold that only appropriate physical states could serve as realizers of mental states functionally conceived. But they differ from type-physicalists in holding that, on account of their variable realizability, mental states cannot be identified with physical-biological states. Functionalism construes psychology as an autonomous science of these functional properties and kinds, specified in terms of their causal roles and abstracted from their specific physical-biological realizations. This view of psychology has been influential; it can be considered the received view of the nature of cognitive science. The question whether or not functionalism is a non-reductive form of physicalism depends crucially on exactly what physical reduction requires, and it must be considered an open question.

\*Eliminativism urges that our commitment to mentality is nothing more than an outdated folklore, and that it is certain to be superseded by a more scientific understanding of our nature. Thus, the standard eliminativist argument begins with the premiss that vernacular ('folk') psychology—in particular, the psychology of beliefs, desires, and other 'propositional attitudes'—is infested with massive and irremediable systemic errors and gaps, and concludes that it will be made obsolete as the scientific—in particular, neuroscientific—understanding of our behaviour continues to advance. Beliefs and desires will ultimately meet the fate that befell phlogiston and

magnetic effluvia, the forgotten posits of discarded theories. This eliminativist argument is sometimes advanced against intentional psychology countenancing cognitive states that are analogous to propositional attitudes of vernacular psychology.

Recently, the Schopenhauerian \*pessimism has been resurrected by some philosophers, who argue that the mind-body problem is insoluble, and that we will never be able to understand how consciousness, subjectivity, and intentionality can arise from material processes. In any case, one thing that is certain is that the mind-body problem is one of the deepest puzzles in philosophy, and that it will continue to test our philosophical intelligence and imagination. **mind, syntax, and semantics.** Mental phenomena such as beliefs, desires, hopes, fears, love, hate, perception, and intention are said to be \*'intentional' in the sense that they are directed at or about or of objects and states of affairs in the world. These phenomena may be conscious or unconscious. All of these intentional mental phenomena have mental contents. Thus, for example, a belief is always a belief that such and such is the case, where the 'that' clause specifies the content of the belief.

Some efforts have been made to analyse intentional mental states as computational states, but such efforts suffer from the following objection: The computational states could not be identical with the mental states because computational states are defined solely in terms of their syntax. That is, computation is a matter of the manipulation of symbols, for example, 0s and 1s, and these are defined purely in terms of their formal or syntactical features. But these could not be equivalent to mental states, because though mental states often have a syntax, they also have a semantics—a thought content or an experiential content. Thus, a person who thinks that the earth is round has not only the appropriate symbols going through his mind, but he attaches a \*meaning, interpretation, or understanding to these symbols. It is this meaning, interpretation, or understanding which constitutes semantics. The argument against the view that intentionality can be reduced to computation is simply that syntax is not equivalent to nor sufficient for semantics. J.R.S.

**minimax:** see maximin.

**minimalism.** The term describes philosophical positions that draw on few conceptual or ontological resources. One example would be Noam Chomsky's use of the term to describe his recent attempt to rationally reconstruct our grasp of grammar; another would be the \*redundancy theory of truth—the view that 'p is true' says no more than 'p'. 'Minimalism' also describes a movement in the arts, which featured highly undifferentiated objects. This was philosophically problematic, but arguably rested on confusing the different roles played by some property of an object when considered as a work of art and when considered as a mere real thing.

D.M.

Richard Wollheim, 'The Work of Art as Object', in *On Art and the Mind* (London, 1973).

**miracles.** Usually defined as violations of a \*law of nature by a supernatural being. Questions have been raised about how to articulate a notion of law of nature which is not exceptionless by definition, and how and whether such a definition applies to indeterministic laws of nature. Any argument that a miraculous event has occurred faces the tough challenge of showing both that the event in question did occur and that it was miraculous. A famous argument from Hume's chapter 'Of Miracles' shows how difficult a challenge this is to meet: to suppose that a miracle has occurred is to suppose that something has happened contrary to the entire weight of inductive evidence supporting the law of nature. In Hume's words 'no testimony is sufficient to establish a miracle, unless the testimony be of such a kind, that its falsehood would be more miraculous, than the fact, which it endeavours to establish'.

David Hume, *An Enquiry Concerning Human Understanding*, sect. x.

**mixture of labour.** According to John Locke, if an individual has laboured upon a previously unowned resource and left enough for others, then he has acquired private property rights in it irrespective of their consent. Thus, 'Labour being the unquestionable Property of the Labourer, no Man but he can have right to what is once joynted to, at least where there is enough and as good left in common for others' (ii. v. 27). Locke's belief that God gave the world 'to the use of the Industrious and Rational, (and Labour was to be his Title to it)' (ii. v. 34) suggests a religious basis for his view. The foremost modern Lockean advocate of private property, Robert Nozick, notes that pouring a can of tomato juice into the sea can be regarded as *losing* rather than *acquiring* rights, and consequently stresses not the mixture of owned with unowned resources but the alleged non-detrimental effects of appropriation.

\*property.

John Locke, *Two Treatises of Government* (Cambridge, 1988).

**mnemonic causation.** According to Russell (*The Analysis of Mind* (London, 1921)), a 'kind of causation . . . in which the proximate cause consists not merely of a present event, but of this together with a past event'. The term originated with psychologist Richard Semon, who held that 'mnemonic phenomena' like remembering necessitate the postulation of intervening 'engrams' or 'traces', because 'what is past cannot operate now', a suggestion Russell, undeterred by the prospect of action at a distance, thought unduly 'metaphysical'.

**modality.** The modal *value* of a statement is the way, or 'mode', in which it is true or false: e.g. certainly so (epistemic modality), currently so (temporal modality), necessarily so (logical modality). In logic, 'modality' usually means 'logical modality', that is, the logical \*necessity or possibility of a statement's truth or falsity. A modal \*statement is one in which some (usually logical) modality is actually claimed: e.g. 'It is not impossible that pigs should fly', 'Necessarily not everyone is below average intelligence'. On a simple view these features interconnect: e.g. the modal statement 'Necessarily P' is true just when 'P' has the modal value necessarily true. \*Modal logic studies the logical relations of modal statements.

A. N. Prior, *Formal Logic* (Oxford, 1962), pt. III, ch. 1.

W. V. Quine, 'Three Grades of Modal Involvement', in *The Ways of Paradox* (New York, 1966).

**modality and metaphysics.** There is an intimate relation between modality and metaphysics, because not only are the nature and ground of modal truth fundamental issues for metaphysics, but the primary task of metaphysics itself may be seen as that of charting the realm of possibilities. Empirical sciences such as physics may tell us, on the basis of observation and experiment, what kinds of objects, events, and processes actually do exist, but they cannot tell us what *must* exist, nor what *could* (but actually does not) exist. A priori sciences such as mathematics may disclose a limited range of necessary truths to us, such as the truths

of arithmetic, but appear to be limited in their scope of inquiry to certain domains of abstract entities, such as the numbers. Moreover, even the empirical sciences cannot tell us what actually does exist, in the absence of a principled account of what could and could not exist, of the sort that metaphysics alone is equipped to provide. For empirical evidence can only be evidence for the actual existence of something if the existence of that thing is at least possible.

E.J.L.

E. J. Lowe, *The Possibility of Metaphysics* (Oxford, 1998).

**modal logic.** In classical \*propositional logic all the operators are truth-functional. That is to say, the truth or falsity of a complex formula depends only on the truth or falsity of its simpler propositional constituents. Modal logic is concerned to understand propositions about what *must* or about what *might* be the case, and it is not difficult to see how you might have two propositions alike in truth-value, both true say, where one is true and could not possibly be false while the other is true but might easily have been false. For instance, it *must* be that  $2 + 2 = 4$ , but while it is true that I am writing this entry it might easily not have been. Modal logic extends the well-formed formulae (wffs) of classical logic by the addition of a one-place sentential operator  $L$  (or  $\Box$ ) interpreted as meaning 'it is necessary that'. Using this operator a one-place operator  $M$  (or  $\Diamond$ ) meaning 'it is possible that' may be defined as  $\sim L\sim$ , where  $\sim$  is a (classical) negation operator, and a two-place operator  $\rightarrow$  may be defined as  $\alpha \rightarrow \beta =_{\text{df}} L(\alpha \supset \beta)$ , where  $\supset$  is classical material implication. In fact any one of  $L$ ,  $M$ , or  $\rightarrow$  can be taken as primitive and the others defined in terms of it.

In the early days of modal logic disputes centred round the question whether a given principle of modal logic was correct or not. Typically these disputes involved formulae in which one modal operator occurs within the scope of another—formulae like  $Lp \supset LLp$ . Is a necessary proposition necessarily necessary? A number of different modal systems were produced which reflected different views about which principles were correct. Until the early 1960s, however, modal logics were discussed almost exclusively as axiomatic systems without access to a notion of validity of the kind used, for example in the truth-table method, for determining the validity of wffs of the classical propositional calculus. The semantical breakthrough came by using the idea that a necessary proposition is one true in all \*possible worlds. But whether another world counts as possible may be held to be relative to the world of origin. So an interpretation or *model* for a modal system would consist of a set  $W$  of possible worlds and a relation  $R$  of *accessibility* between them. For any wff  $\alpha$  and world  $w$ ,  $L\alpha$  will be true at  $w$  if and only if  $\alpha$  itself is true at every  $w'$  such that  $wRw'$ . It can then happen that whether a principle of modal logic holds or not can depend on properties of the accessibility relation. Suppose that  $R$  is required to be transitive, i.e. suppose that for any worlds  $w_1$ ,  $w_2$ , and  $w_3$ , if  $w_1Rw_2$  and  $w_2Rw_3$  then  $w_1Rw_3$ . If so then  $Lp \supset LLp$  will be valid, but if non-transitive models are permitted it need

not be. If  $R$  is reflexive, i.e. if  $wRw$  for every world  $w$ , then  $Lp \supset p$  is valid. So different systems of modal logic can represent different ways of restricting necessity.

First-order predicate logic can also be extended by the addition of modal operators. The most interesting consequences of such extensions are those which affect 'mixed' principles, principles which relate quantifiers and modal operators and which cannot be stated at the level of modal propositional logic or non-modal predicate logic. Thus  $\exists xL\alpha \supset L\exists x\alpha$  is valid but  $L\exists x\alpha \supset \exists xL\alpha$  is not. (Even if a game must have a winner there need be no one who must win.) In some cases the principles of the extended system will depend on the propositional logic on which it is based. An example is the formula  $\forall xL\alpha \supset L\forall x\alpha$ , which is provable in some modal systems but not in others. If both directions are assumed, so that we have  $\forall xL\alpha \equiv L\forall x\alpha$ , then this formula expresses the principle that the domain of individuals is held constant over all possible worlds.

When identity is added even more questions arise. The usual axioms for identity easily allow the derivation of  $(x = y) \supset L(x = y)$ , but should we really say that all identities are necessary? Questions like this bring us to the boundary between modal logic and metaphysics and remind us of the rich potential that the theory of possible worlds has for illuminating such issues. The possible-worlds semantics can be generalized to deal with any operators whose meanings are operations on propositions as sets of possible worlds and form a congenial tool for those who think that the meaning of a sentence is its truth-conditions, and that these should be taken literally as a set of possible worlds—the worlds in which the sentence is true.

B. F. Chellas, *Modal Logic: An Introduction* (Cambridge, 1980).

G. E. Hughes and M. J. Cresswell, *An Introduction to Modal Logic* (London, 1968; repr. corr. 1972).

——— *A Companion to Modal Logic* (London, 1984).

**modal realism.** Rightly or wrongly, modal realism has come to be identified with David Lewis's seemingly extravagant view of the ontological status of \*possible worlds, according to which each possible world is an aggregate of spatio-temporally and causally interrelated concrete objects, and all such worlds equally exist. On this view, the world that we inhabit—what we call the actual world—is in no way ontologically privileged, since every world is 'actual' to its own inhabitants. Modal realism, thus understood, involves a commitment to \*counterpart theory, which denies that objects existing in different possible worlds can ever be identical, allowing each object only to have 'counterparts' in other worlds. For Lewis, modal realism is to be contrasted with *ersatzism*, which takes possible worlds to be linguistic or abstract entities, such as maximal consistent sets of sentences or propositions. Arguably, however, the term 'modal realism' might better have been employed to denote the more sober view that modal truths simply have an objective and mind-independent status.

E.J.L.

D. Lewis, *On the Plurality of Worlds* (Oxford, 1986).

**mode.** 'Mode' is a term of traditional metaphysics used correlatively with \*'substance' and 'attribute'. An example would be the square shape of a particular piece of wood. Here the wood is the substance possessing the mode, and spatial extension is the attribute of which the mode is an instance. Another example would be a particular thought or experience enjoyed by someone. Here the person (or \*self) qualifies as the 'substance' possessing the mode, and consciousness is the attribute.

A crucial logical feature of modes is that they depend for their identity upon the identity of the particular substances which possess them. Thus, that a thought is the particular thought it is partly determined by *whose* thought it is. For two different people cannot share numerically the same thought. The modern term closest in sense to 'mode' is 'particular quality' or \*'individual property'.

E.J.L.

E. J. Lowe, 'Real Selves: Persons as a Substantial Kind', in D. Cockburn (ed.), *Human Beings* (Cambridge, 1991).

**model theory.** When a set of sentences contain symbols that need interpreting, an interpretation that makes the sentences true is called a 'model' of the set. In 1954 Alfred Tarski introduced the name 'model theory' for the study of this notion when the sentences are mathematical axioms and the interpretations are mathematical structures in which the axioms are true or false. A structure *M* is said to be a model of a set *S* of formal sentences if the sentences in *S*, when their formal symbols are interpreted as being about *M*, are all true. An early result of model theory says that if *T* is a set of sentences in a first-order language and every finite subset of *T* has a model, then *T* itself has a model. Within mathematics, model theory became a vehicle for studying definability, with applications in algebra and geometry; an offshoot was non-standard analysis, which justified the use of infinitesimals in calculus. Within philosophy and linguistics, an approach is called model-theoretic if it involves set-theoretical criteria for the truth of sentences, as for example in \*Montague semantics.

W.A.H.

K. Doets, *Basic Model Theory* (Stanford, Calif., 1996).

**models.** These are used extensively by scientists, coming in different forms and guises. All types involve some kind of analogy between the model and either reality or some other scientific claim. Most familiar are physical models, usually small- or large-scale material constructions—a famous example being the metal macro-model of the double helix, built by Watson and Crick. As or even more important are theoretical models, where scientists try to map limited aspects of reality, introducing simplifying assumptions, which are adjusted or removed in the light of the models' predictive successes. There is a school of thought which argues that scientific \*theories are best understood semantically, in the sense of being families of theoretical models—interpreted according to specific empirical circumstances—rather than as general systems

attempting to explain selected chunks of reality at one fell swoop. Even if one protests that such families could never capture completely what one aims for in a theory, it is hard to deny that sets of interrelated models are what face scientists most of their working lives.

**modernism.** On the longest view, modernism in philosophy starts out with Descartes's quest for a knowledge self-evident to reason and secured from all the demons of sceptical doubt. It is also invoked—with a firmer sense of historical perspective—to signify those currents of thought that emerged from Kant's critical 'revolution' in the spheres of epistemology, ethics, and aesthetic judgement. Thus 'modernity' and 'enlightenment' tend to be used interchangeably, whether by thinkers (like Habermas) who seek to sustain that project, or by those—the post-modernist company—who consider it a closed chapter in the history of ideas.

\*post-modernism.

Jürgen Habermas, *The Philosophical Discourse of Modernity*, tr. Frederick Lawrence (Cambridge, 1987).

**modus ponens.** The 'affirming mode'. In \*propositional calculus, any inference of the form 'If *p* then *q*, and *p*; therefore *q*' is an instance of *modus ponens*. In the \*traditional logic of terms, inferences like 'If *A* is *B*, it is *C*; *A* is *B*; therefore *A* is *C*' were said to be in the *modus ponens*. Not really \*syllogisms at all, such inferences were often called 'hypothetical syllogisms'.

c.w.

\*affirming the antecedent.

J. N. Keynes, *Formal Logic*, 4th edn. (London, 1906), 352.

**modus tollens.** The 'denying mode'. In \*propositional calculus, any inference of the form 'If *p* then *q*, and not *q*; therefore not *p*' is an instance of *modus tollens*. In the \*traditional logic of terms, inferences like 'If *A* is *B*, it is *C*; *A* is not *C*; therefore *A* is not *B*' were said to be in the *modus tollens*. Like *modus ponens* inferences, not really \*syllogisms at all. These inferences too were often called 'hypothetical syllogisms'.

c.w.

\*denying the consequent.

J. N. Keynes, *Formal Logic*, 4th edn. (London, 1906), 352.

**Molina, Luis de** (1535–1600). Jesuit theologian and philosopher, born in Cuenca, Spain. He studied and taught at various leading Iberian universities. Molina is best known for his doctrine of middle knowledge (*scientia media*), expounded in *Concordia liberi arbitrii cum gratiae donis* (1588). This doctrine's aim was to preserve human \*free will while maintaining the Christian doctrine of the efficacy of divine grace. For Molina, although God has foreknowledge of what human beings will choose to do, neither that knowledge nor God's grace determine human will. Middle knowledge, God's knowledge of what persons would do under any set of circumstances, enables

God to arrange for certain human acts to occur by prearranging the circumstances surrounding a choice without determining the human will. God's grace is concurrent with the act of the will and does not predetermine it, rendering the Thomistic distinction between sufficient and efficacious grace superfluous.

**Mollā Ṣadrā** (?–1641). Persian philosopher Ṣadr al-Dīn Shīrāzī is widely considered to be one of the most original thinkers in post-classical Islamic philosophy. His most widely quoted philosophical problem (one of twelve considered original contributions) is 'substantial \*motion', the unifying principle underlying all of philosophy and capable of describing existence, time, motion, and change pertaining to all physical, psychological, and non-corporeal things. This problem, encountered in every domain from semantics to eschatology, consists of: essential motion initially observed in external reality, never ceasing, and covering all physical and ontological distinctions, resulting in the continual 'evolution' of higher beings, transformation of material existence, intensely moving from one level to another into the unchanging *mundus imaginalis* beyond ordinary time and space where individual 'evolved' essences with 'formal', or 'imaginalis' bodies will then permanently exist.

H.Z.

Fazlur Rahman, *The Philosophy of Mullā Ṣadrā* (Albany, NY, 1975).

**Molyneux problem.** A problem about correlating visual and tactual \*perception, one of several that William Molyneux of Dublin posed in letters to John Locke. (Molyneux was also interested in the visual perception of distance.) Suppose that a blind person who can distinguish spheres from cubes by touch suddenly becomes able to see. Will this person be able to distinguish these shapes visually before correlating sight and touch? Locke (*Essay Concerning Human Understanding*, II. ix. 8) and Berkeley (*Essay Towards a New Theory of Vision*, sects. 121–46) answer negatively. Berkeley went on to deny that sight and touch ever perceive the same property, strictly speaking. Leibniz (*New Essays Concerning Human Understanding*, sections that correspond to Locke) answers positively on the basis of structural properties in common to tactual and visible shapes. Careful observations of patients who acquired vision by surgery, such as cataract removal, have not resolved the Molyneux problem.

Michael J. Morgan, *Molyneux's Question* (Cambridge, 1977).

**monadology.** A philosophical system usually associated with the mature metaphysics of Leibniz, as outlined in the *Monadology* (1714).

The fundamental thesis of Leibniz's monadology is that the basic individual \*substances that make up the universe are soul-like entities, the monads, which are

non-extended, hence immaterial, entities. The properties of the monads may all be reduced to perceptions and appetites. Whatever other entities we may wish to recognize must be reduced to this base. Thus Leibniz treated material objects as appearances of collections of monads.

R.C.SLE.

**monism, anomalous:** see anomalous monism.

**monism, neutral:** see neutral monism.

**monism and pluralism.** These are doctrines concerning how many \*substances exist, and may relate either to kinds of substances or to their individual instances. Monism regarding the kinds of substance holds that only one such kind exists, whereas pluralism admits a multiplicity of kinds. Monism regarding the instances of a given substantial kind holds that only one such individual does or can exist, pluralism that many do or may. Thus a materialist who is also an atomist is a monist as regards the kinds of substance that exist but a pluralist with regard to how many individual substances of that kind there are. By contrast, Descartes was a pluralist as regards the kinds of substance that exist and also a pluralist regarding the number of individual mental substances—but, rejecting \*atomism, he was a monist regarding the number of individual material substances.

D. W. Hamlyn, *Metaphysics* (Cambridge, 1984).

**Montague, Richard** (1930–71). American philosophical logician. During the 1960s he developed a mathematical formalism to define what it is for a sentence of a precisely defined fragment of English to be true at a time and place in a possible world. Under the name of 'Montague semantics' his proposals soon became accepted among linguists as a paradigm for formalizing the semantics of natural languages. Two characteristic points were his treatment of the meaning of a sentence as a homomorphic copy of its syntax (following Tarski's truth definitions for formalized languages) and his proposal to treat proper names like 'John' as a special case of quantifier phrases such as 'every man' or 'a fish'. Montague's other contributions include work on the metamathematics of set theory, a study with David Kaplan of the paradox of the unexpected examination, a logical analysis of determinism, and unsurpassed standards of rigour and accuracy in philosophical logic.

W.A.H.

R. Montague, *Formal Philosophy*, ed. R. H. Thomason (New Haven, Conn., 1974).

**Montaigne, Michel Eyquem de** (1533–92). A fluent essayist who mistrusted the pretensions of systematic philosophy, Montaigne's writings are richer in allusion and anecdote than in formal argumentation, but none the less sparkle with philosophical insights. His *Apology for Raymond Sebond* (1580) is an entertaining and discursive essay, steeped in the classical learning which typifies the humanist movement of which he was a notable exemplar. The

book examines some of the sceptical theses of Sextus Empiricus (whose writings had recently been translated into Latin), and maintains the need for faith and divine revelation to overcome the inherent limitations of human reason. It also suggests that the supposed superiority of human reason over the natural instincts of animals is largely illusory. Montaigne's writings set the scene for the attempts of rationalists such as Descartes to establish a new system of knowledge whose foundations would be independent of the deliverance of the senses. J.COT.

**Monte Carlo fallacy:** *see* gambler's fallacy.

**Montesquieu, Charles-Louis de Secondat, Baron de** (1689–1755). French philosopher and jurist, who contributed to political sociology and to philosophy of history. *Persian Letters* (1711, tr. New York, 1973) initiated the fashion of criticizing European culture by comparing it with the Orient. *Considerations on the Causes of the Greatness of the Romans and their Decline* (1734, tr. New York, 1965) and *The Spirit of the Laws* (1748, tr. Cambridge, 1989) distinguish three forms of government, each with its special structure and each animated by its own 'principle'. Republics are animated by virtue (patriotism and egalitarian fraternity rather than moral virtue), monarchies by honour, and despotisms by fear. Forms of government depend in part on physical, especially climatic, factors. But wise legislators can counteract physical disadvantages by intellectual and moral forces, especially once they know the laws governing the social world. Montesquieu's advocacy of a division of powers (legislative, executive, and judicial), which he saw in the English constitution, greatly influenced the American founding fathers. M.J.I.

M. Richter (ed.), *The Political Theory of Montesquieu* (Cambridge, 1977).

**Monty Hall problem.** Game show host Monty Hall conceals a prize behind one of three curtains, *A*, *B*, or *C*. Asked to guess where the prize is, you choose *A*. Before disclosing the prize's location, Monty opens *B*, revealing that it is not there, and offers you the option of sticking with *A* or switching to *C*. You reason as follows: once Monty opens curtain *B*, the \*probability that the prize is behind *A* or *C* is the same:  $\frac{1}{2}$ ; so switching affords no advantage. But is this right? Assuming that Monty opens a curtain only if the prize is not behind it, the relevant probability is the \*conditional probability that the prize is behind *A* given that Monty has revealed that it is not behind *B*. Bayes's theorem shows that this probability is  $\frac{1}{3}$ , so the probability that the prize is behind *C* is  $\frac{2}{3}$ . You should switch! For those not steeped in probability theory, there is a simple way to see the point. Once Monty opens a curtain, you will win by switching just in case your original choice was wrong. Assuming your original choice is wrong

two-thirds of the time, you will win by switching two-thirds of the time, so you should switch. J.HEIL

Martin Gardner, 'Probability Paradoxes', *Skeptical Inquirer* (1992).

**mood.** States of mind of an emotional cast which are temporary, yet which colour a person's responses and reactions quite generally, qualify as *moods*, as when someone is said to be in a sombre, sullen, or sunny mood. The focus is on a pattern of behaviour manifesting a current state of mind, and not, as with motives, on the intended consequences of the behaviour.

'Mood' also enjoys a use with respect to language. Commonly misconstrued in this connection, mood is properly a feature of verbal phrases—indicative, imperative, subjunctive, optative. As embodying the different speech-acts of asserting and asking a question, utterances of, say, 'He is out' and 'Is he out?' are said to differ in *force*. However, they agree in mood, the verb in either receiving the same description, 'third-person singular present indicative'. B.B.R.I.

**moods of the syllogism:** *see* syllogism.

**Moore, George Edward** (1873–1958). Moore was a philosopher of immense, even revolutionary, influence by reason—most unusually—of the extreme simplicity and directness, even seeming naïvety, of his approach to philosophy. He was moved in his early days, as he recorded in 1942, not by any perplexities about 'the world or the sciences', but by the baffling things said about the world and the sciences by other philosophers. In the tradition prevailing at that time he found it usually taken for granted that ordinary language was probably defective, that commonly held beliefs were probably false or at any rate inadequate, and that the task of philosophy was to work its way towards deeper, perhaps odd-looking truths set out in purer, probably novel and unfamiliar terms. Moore was sincerely amazed by this. Why was it thought necessary? He insisted ('A Defence of Common Sense' (1925)) that there is actually a vast body of shared convictions about 'the world', expressible in quite ordinary propositions whose meanings are perfectly clear, and which are known for certain to be true—even by those philosophers who appear to deny them. Take, say, 'There exist conscious beings other than oneself'—everyone knows what that means; or take, say, 'There exist material objects, such as shoes and inkstands'—everyone knows that that is certainly true. But if so, Moore concluded, philosophers must have been radically confused as to the nature, or perhaps the purpose, of their own activities. They cannot really have been confronting problems about meaning, since typically there were, he held, simply no such problems; nor can they really have been denying, or even doubting, that certain propositions were true,

since typically we all—themselves included—knew that they *were* true. What then was seriously, genuinely problematic? Moore's answer—highly influential for most of the twentieth century—was: the *analysis* of propositions. Among English-language philosophers, at any rate, this seemed radically to transform the philosophical agenda. We know what a given proposition means, and we know it to be true; the question, then, is not 'Is it true?' or even 'Do we know it to be true?', but 'What is its correct analysis?'

The notion of \*analysis was itself always controversial, but Moore's own most persistent pursuit of analyses dealt with very ordinary propositions about familiar objects, for example 'This is a hand'. He held that the analysis of these must always bring in the very puzzling items he called \*sense-data'—the proposition is really about a sense-datum that one has, and the problem is how in the analysis the relation between sense-datum and object should be spelled out. He never believed that he had worked this out quite satisfactorily.

Also vastly influential was Moore's work in ethics, notably in *Principia Ethica* (1903). Here his insistence on the indefinability of 'good' and his exposition of the so-called \*naturalistic fallacy' were long regarded by many as path-breaking advances in moral philosophy. In historical perspective, however, this work looks a good deal less impressive and durable than his contributions in other fields. See also his *Ethics* (1912).

Moore's working life was spent mainly in Cambridge, though he taught for some years in America during the Second World War. He was a university lecturer from 1911, and Professor of Philosophy and Fellow of Trinity College from 1925 to 1939. He was editor of the periodical *Mind* from 1921 to 1947, and was appointed to the Order of Merit in 1951.

**Moore's paradox.** '[S]uch a thing as "I went to the pictures last Tuesday, but I don't believe that I did" is a perfectly absurd thing to say, although what is asserted is something perfectly possible logically' (Moore 1959). Perhaps I have my dates mixed up, and someone else says, 'You went to the pictures last Tuesday, but you don't believe that you did'. If what is asserted here is true, why is it an absurd thing for me to say about myself? The task is to give an account of the absurdity. Moore's attempt turns on the notion of implied belief—saying or asserting *p* implies believing *p*—and in the case above the belief implied by the first clause conflicts with the belief asserted in the second. Hence the absurdity. But what should we make of a philosophically inclined scientist, who sincerely says, 'Although I believe our current theories are true, I

have good inductive grounds based on the dramatic failures of past science for my belief that some of our current theories are false?' Some expressions, at least akin to Moore Paradoxical ones, are not perfectly absurd things to say, and debates about the nature of such claims continue.

**morality, sexual:** see sexual morality.

**morality, slave:** see slave morality.

**morality and art:** see art and morality.

**morality and religion:** see religion and morality.

**morality in political philosophy.** Whether morality has a role to play in political philosophy is controversial. Political economists of the eighteenth century argued that the good of the collective was best achieved by encouraging agents to act in their self-interest, not by rousing their moral sentiments or their pity for the unfortunate. Marx maintained that morality is a figment of the imagination, though his political theory is arguably influenced by moral values. Gauthier's conception of the ideal market as a 'morally free zone' that is a model of social justice reflects the conviction that at least some sectors of political philosophy can be given non-moral foundations and that the notions of virtue and self-sacrifice that are central to the concept of morality can be expunged from the theory of just distributions. Yet the claim that agents are entitled to retain or exchange all resources they have extracted from the human or non-human environment through the market and need not bestow them *gratis* on other claimants is itself morally controversial.

Many pressing issues in political philosophy, including socio-economic inequality, racism and sexism, conscription and war, punishment, rights of self-determination, and free speech appear to have an ineliminable moral dimension. They raise the question how much security, utility, or liberty *A* should be called upon sacrifice in order to improve *B*'s lot, when *A* and *B* are differently situated, and what motives should induce *A* to make any sacrifice whatsoever. Socio-economic inequality is implausibly treated as requiring a bargaining solution in the form of a deal struck between wealthy *A* and poor *B*. For *B*'s best option from amongst those *A* is prepared to offer or threaten may be an improvement relative to his current level, but not just, and all *B*'s offers except the *status quo*

may be unacceptable to *A*. The postulate that *A* should be prepared to accept his own offer, were he *B*, changes nothing. Justice is a feature of the offer or threat we observers will judge that *A* ought to make and *B* to accept, given the respective positions of *A* and *B*.

CATH.W.

David Gauthier, *Morals by Agreement* (Oxford, 1986).

**moral judgement.** Is \*'judgement' the most appropriate word for what properly terminates moral deliberation? Or are we seeking, when we reflect on a morally perplexing situation, rather to elicit and stabilize some response of feeling, whether of attraction or repulsion? Or again, do we (more accurately) decide on our moral stance—in a personally inventive or even creative way, much as a painter decides after thought to add a highlight here or to deepen a shadow there, where there is no pre-existing reality to guide or constrict him?

Against the ultimacy of feelings and \*emotions, it may be argued that our feelings themselves are properly subject to moral judgement: even love needs to be monitored, as it may take selfish and corrupt forms.

There may well be room for creativity in the moral life, but with basic moral values and principles, the agent's characteristic experience is: 'Here I have no option: my will and judgement are constrained'. I cannot decide that a life dedicated, say, to the expression of sadistic impulses is a morally fine life. It is not up to me. Even my rebellion against a particular moral code or principle or practice will be fuelled by a commitment to values to which there seem to be no alternatives—I grasp these as (judge them to be) basic or ultimate. Early and immature anticipations of moral judgement may be nothing more than unreflective responses of feeling learned in early childhood. Somewhat later, the pressures of peer group and 'society' may modify these—but still as external pressures to conform. Crucial for moral maturity, however, is the possibility of distancing oneself from all pressures from without, reflectively and critically sifting the evaluations of others, endorsing some and rejecting others, forming a ranking of one's own. Not, however, wilfully and idiosyncratically; rather with the sense of clarifying, 'tuning', or 'focusing' more accurately on moral values, principles, goals that are not of one's own contriving. For all this activity of discrimination—without which there can be no moral growth, moral reform, necessary dissidence—the vocabulary of 'judgement', with its cognitive and rational connotations, is more appropriate by far than its rivals.

What are the proper objects of moral judgement?—the particular acts of responsible agents, their general policies, their traits of character: but these considered in a special (moral) context or from a special point of view. Understanding these is a major task of normative ethical theory. However humanly complex and specific the situation in which I have to act, to reach a distinctively moral judgement on how I \*ought to act is to introduce an impersonal note. It is to ask what universal rules or principles bear upon my situation, and what are their relative urgencies? Does a strong requirement of \*justice or fairness take

precedence, for instance, over all other, even benevolent, actions? Am I considering the interests of everyone involved, not self-deceivingly masking, giving privilege to, my personal inclinations?

For a serious and convincing moral judgement, there are both formal and substantive requirements to be met. The readiness to universalize, the impersonal note: but also deference to basic human values that alone can make these procedures and attitudes intelligible, and a concern with the regulation of life that furthers their realization and enjoyment.

In some moral contexts, 'judgement' refers not to an epistemological act, but rather to the quality possessed by someone with a particular sensitivity to complex moral situations, where no rule of thumb, no simple appeal to a single principle, can ensure a rational outcome. A case in which none of the conflicting factors loses its serious claim to compliant action calls upon, not arbitrary decision, but fine or 'nice' moral judgement.

R.W.H.

\*good; right; right action; moral philosophy, histories of; moral philosophy, problems of.

J. Finnis, *Fundamentals of Ethics* (Oxford, 1983).

J. McDowell, 'Are Moral Requirements Hypothetical Imperatives?', *Proceedings of the Aristotelian Society*, supp. vol. (1978) and later articles on moral philosophy.

**moral knowledge** presupposes that there are moral truths accessible to us. It is often said that the opposing view that moral judgements are devoid of truth-value does not do justice to our conviction that having true moral beliefs matters in a way that having certain, e.g. aesthetic, preferences does not.

It is not easy, however, to make sense of the hypothesis that there are reliable methods for acquiring moral knowledge. Clear and distinct perception of wrong-making features in actions by a competent moral observer might be proposed as the criterion of their truth. Thus I might be supposed to know that torturing cats is morally wrong on the grounds that when I observe or merely think about the action of torturing cats I perceive immediately its wrongness. However, my claim to be a competent observer is established by my delivering judgements taken by others to be correct. If moral perception is as uniform across the species as colour perception, and if incompetent observers can be identified by ingenious tests, we might accept this account of moral knowledge. If there are no such convenient tests, it will be impossible to obtain moral knowledge in controversial matters, since claims to perceive wrong-making features in e.g. wearing leather shoes leave the competence of the perceiver an open question.

Another approach to the problem of moral knowledge, more appropriate to the settling of controversial moral questions, involves supposing that the provision of new evidence and argument has the effect of reinforcing or transforming beliefs about how morally good and bad agents behave. If the evidence supplied consists of true propositions, and if the arguments employed are valid, the resulting moral beliefs should count as moral knowledge,

provided they are sufficient to decide the question. This account lends itself to an interpretation of how we came to know that slavery was wrong when this was formerly a controversial proposition. However, it is unclear that apprehension of this allegedly previously unknown fact can be distinguished from the formation of a new preference, formally analogous to an aesthetic preference, for abolishing slavery. Whether widely shared preferences acquired in this manner should be termed 'knowledge' remains controversial.

CATH.W.

John McDowell, *Mind, Value and Reality* (Cambridge, Mass., 1998).

**moral law.** Most generally, the idea of the moral law is the idea of that set of standards or principles, cast in the form of 'Thou shalt's' or 'Thou shalt not's', which set down how one should behave morally. The Ten Commandments provide the classic model for what moral laws will be like. More specifically, the notion of the moral law is central to Kant's moral philosophy. He argues that moral requirements have the form of \*categorical imperatives which prescribe what is to be done regardless of what one may want. He then proposes that the (singular) moral law is a test by which to determine whether or not we should do what we intend. It states that we should act only on those maxims (rules of action) which we can will to be a universal law for all agents. Both Hume and Schopenhauer think it is a fundamental mistake to conceive of morality as a form of law.

N.J.H.D.

\*right action.

I. Kant's *The Groundwork of the Metaphysics of Morals* should be read on this topic.

**moral luck.** Phenomenon that, supposedly, challenges traditional ideas about moral assessment. For Kant and others, moral judgement ought not (unfairly) to depend on factors not under the agent's control. Reflection on our actual judgements, however, reveals their widespread determination by various kind of luck. A driver who neglects to check his brakes is guilty, if no harm ensues, of mere negligence. But if (through bad luck) the driver kills a child in his path, he is judged (and judges himself) more harshly, even though his input is the same.

S.D.R.

Thomas Nagel, 'Moral Luck', reprinted in his *Mortal Questions* (Cambridge, 1979).

Bernard Williams, 'Moral Luck' reprinted in his *Moral Luck* (Cambridge, 1981).

**moral motivation.** Motivation to do what one (believes one) morally ought to do or what one (believes one) has moral reasons to do. A central topic of debate is whether moral motivation differs from other kinds of motivation only in its subject-matter or in a deeper way. Some philosophers maintain that, necessarily, anyone who believes that she herself morally ought to help Joe has motivation to help him, even though they would deny that the same is true of people who believe that they legally ought to help Joe. Other philosophers argue that

the former claim is true of rational agents, even though they would reject a parallel claim about rational agents who believe that they legally ought to help Joe. There are also philosophers who reject both claims about moral motivation and argue that such motivation is on a par with non-moral motivation.

A.R.M.

M. Smith, *The Moral Problem* (Oxford, 1994).

**moral particularism.** The particularist holds that the possibility of moral thought and judgement in no way depends on an adequate supply of moral principles or general rules. Moral judgement is primarily concerned with the particular case. Experience can help us discover moral generalities, such as that it is normally or standardly wrong to lie. Such generalities are as important in morality as elsewhere. But they can serve only as rules of thumb; the moral aspects of a particular situation are not constructed out of relations between its non-moral features and relevant principles. Particularists tend to base their view on the claim that what is a moral reason in one case may be an opposite reason, or no reason at all, in another—a sort of moral reasons-holism. They argue for this either by appeal to examples, or by trying to show that this sort of holism is true of all reasons, and *a fortiori* of moral ones.

**moral philosophy, history of.**

*Greek Ethics.* Ethical thought, in the sense of the attempt to formulate codes and principles of moral behaviour, has always been a necessary feature of human cultures, but moral philosophy in the more precise sense can be said to begin with the \*Sophists of the Greek world in the fifth century bc. They were the first thinkers we know to have raised critical questions about the very idea of moral conduct, about what morality is and why it should exist. Their teaching of rhetoric and of techniques of persuasion invited the charge that such techniques could be used to make wrong more persuasive than right, and would enable people to flout moral standards with impunity. The more conservative Sophists such as Protagoras defended the idea of moral codes as useful human creations, sets of customs and conventions which make social life possible, and were thus committed to a form of ethical relativism and to the denial of any universal code of morality or any absolute moral truth. The more radical of their followers, such as the perhaps fictional Callicles and Thrasymachus portrayed in Plato's dialogues, concluded that, since traditional moral standards are mere conventions, they have no binding force, and the rational way to live is therefore to pursue one's own interests and power, acting unjustly if one can get away with it. These challenges to traditional moral codes thus raised the

fundamental question 'Why be moral?' The moral philosophies of Plato and Aristotle can be seen as systematic attempts to answer that question.

Plato's early dialogues, which probably reflect the activity of the historical Socrates, portray him searching for definitions of the traditional \*virtues—temperance, courage, justice, piety. The theme which emerges is that if these are good qualities, this must be because they make for a good life for those who possess them, and underlying all the virtues must therefore be the ability to know what constitutes the human good. Plato's own positive attempt to answer that question obtains its classic formulation in the *Republic*. There Plato argues that the good life consists in the harmony of the soul, with each part of the soul—reason, spirit, and appetite—performing its proper function. The traditional virtues can then all be defined as aspects of this underlying condition of psychic harmony. Since such a condition is one in which the person is happy and flourishing, the morally good life lived in accordance with the virtues is thereby shown to be the best life for human beings. This is Plato's answer to the question 'Why should I be moral?'

Although there are important differences between the moral philosophies of Plato and Aristotle, the latter employs the same broad framework. In the *Nicomachean Ethics* (generally regarded as the definitive version of his lectures on ethics), Aristotle asserts that the ultimate end of all human action is \*happiness (\**eudaimonia*). To know what this happiness or flourishing consists in, Aristotle suggests that we must identify the distinctive function of human beings, and this he takes to be activity in accordance with reason. This then provides the basis for a general account of the moral virtues; they are dispositions in which our feelings and emotions are guided by reason so that our behaviour is appropriate to the situation. In particular the guidance of reason requires the avoidance of excess or deficiency, and therefore each virtue is, in Aristotle's famous phrase, a \*'mean' between these extremes.

The later Greek schools shared this same broad ethical framework, the concern with the relation between the virtues and happiness, but we should note two ideas introduced by the \*Epicureans and the \*Stoics which were to play important roles in the philosophical tradition. Epicurean ethics was a form of \*hedonism, identifying the good with \*pleasure. Plato appears, at least in his *Protagoras*, to have given hedonism serious consideration, though later decisively rejecting it, and some of Plato's pupils explicitly defended hedonism, but the doctrine finds its classic formulation with the Epicureans. For this reason the word 'epicurean' has become a label for the pursuit of sensuous pleasures, but unjustly so, for the pleasure which they advocated was principally that of mental tranquillity, to be achieved by banishing superstitious fears of the gods and the afterlife. The influential concept introduced by the Stoics was that of the good life as one lived 'in accordance with nature' or 'the natural law'. Such an idea had been to some extent implicit in the ethics of Plato and Aristotle, and the Stoics followed them in equating the

idea of living 'according to nature' with that of acting in accordance with reason. Since for the Stoics this meant especially rendering oneself immune to the disturbances of the emotions, their ideal was in practice akin to the mental tranquillity of the Epicureans. The concept of \*'natural law' can, however, lend itself to a variety of interpretations, and was subsequently to do so.

*Christian Ethics.* Popular conceptions of morality often assume some kind of link between morality and religion, equating moral precepts with divine commands. Although both Plato and Aristotle were theists, their ethics is not a religious ethics and their god is not a divine lawgiver; at most he is an exemplar of the ideal life. The moral philosophy of medieval Christendom, however, involved an attempt to marry Christian morality to Greek philosophy, and the most influential version of this enterprise was that of Thomas Aquinas. Aristotle had talked of a human 'function', but had made no use of the idea that this function might be seen as a purpose with which human beings are endowed by a divine creator. Such was the idea which enabled Aquinas to effect the synthesis he needed. From an understanding of human nature we can identify the natural purposes proper to human beings, and to fulfil these purposes is to follow 'natural law'. Since this natural law reflects our participation in the eternal law by which the universe is governed, it is exhibited also in the divine law laid down for us by the divine creator, and the moral precepts of natural law will therefore coincide with the moral rules revealed by the Christian religion.

It is doubtful whether this synthesis can be a stable one. Any attempt to identify moral principles with divine commands must run up against a dilemma first formulated in Plato's *Euthyphro*. Is the good good because God commands it, or does God command it because it is good? If the former, then morality is the product of arbitrary will, and obedience to morality is mere obedience to authority. If the latter, then morality is independent of God's will, and knowledge of the divine will is at best redundant. Aquinas's synthesis is therefore liable to collapse in one of two directions. If we maintain that morality is to be found in the commands of God revealed in a particular organized religion, these commands will have to be taken on trust and moral philosophy will have no role to play. Alternatively, if philosophical understanding can lead to the formulation of moral theory, religious belief will play no distinctive part in this process. The second alternative is the one adopted by moral philosophy in the modern epoch; the mainstream tradition has been essentially a secular one.

*Ethical Naturalism.* A moral philosophy which looks to 'nature' as the foundation for moral beliefs, independently of any religious framework, is most likely to appeal to the facts of human psychology. The tradition often referred to as that of the 'British Moralists' in the seventeenth and eighteenth centuries is a prime example of this way of doing moral philosophy. Two questions dominate the tradition: the question whether morality is ultimately

grounded in \*self-love' or \*benevolence', and the question whether moral judgements are the product of \*reason' or 'sentiment'.

The first question is posed sharply by Hobbes, whose egoistic view of human nature and morality is the controversial stimulus for the work of his successors in much the same way as the Sophists were for Plato and Aristotle. Hobbes is usually thought of as a political philosopher rather than a moral philosopher, and that is essentially the point: morality, for him, can have no authority over our behaviour unless backed by political authority. All human passions are manifestations of the desire for good for oneself. In a state of nature, men's desire for happiness brings them into conflict with one another, their lives are governed by a 'perpetual and restless desire of power after power', and their condition is therefore one of 'a war of every man against every man'. It is in everyone's interest to escape from this condition of war. Hobbes uses the vocabulary of natural law to express this requirement of self-interest; it is the fundamental law of nature 'that every man ought to endeavour peace'. This law of nature is not yet, however, a moral law, since in a state of nature the ideas of right and wrong, justice and injustice, have no meaning. A law of nature is merely a rule of reason directing one to the effective means of self-preservation. This law dictates that men should contract with one another to restrict their liberty for the sake of peace, provided others do likewise. Hobbes's egoistic theory entails, however, that in a state of nature there can be no moral obligation to abide by such a contract. Men therefore have to establish a sovereign who will enforce the contract, for 'covenants without the sword are but words'. Thus the constraints of morality, though they are in everyone's interests, are binding only in so far as they are backed by political authority.

Attempts to answer Hobbes took two forms. One was the 'rationalist' response: that our reason acquaints us with moral duties which are, in some sense, part of the natural order of the universe, and which are independent both of the divine will and of any social contract or political authority. Samuel Clarke, for instance, claims it to be a requirement of reason that we should 'deal with every man as in like circumstances we could reasonably expect he should deal with us', and that we should 'endeavour, by an universal benevolence, to promote the welfare and happiness of all men'. This 'rule of righteousness' is part of our knowledge of the natural relations and 'fitnesses' of things. Our certainty of its truth is comparable to our certainty of the truths of mathematics. Similar claims about the capacity of reason to apprehend moral truths were made by Ralph Cudworth, John Balguy, and Richard Price.

The other response to Hobbes was to question his view of human nature and of human passions and affections. Shaftesbury asserts that human beings have not only an 'affection towards private good' but also a natural 'affection towards public good', though these are not in opposition to one another since virtue, grounded in the social

affections, is to the advantage of everyone. Hutcheson claims that the moral virtues all flow from our feelings of benevolence towards others, and that there is no need to trace them back to self-love. Butler argues that the egoistic view of \*human nature is in any case incoherent. Self-love is the desire for our own happiness, but this, he says, we can experience only through the satisfaction of our 'particular passions' for external things. Therefore self-love cannot possibly be the only passion. It presupposes and is consistent with the 'particular passions', and there is no reason why these should not include also benevolence, an affection to the good of our fellow creatures.

With such anti-Hobbesian views of human nature goes also a view of the basis of moral judgements. If human beings are naturally benevolent, then it can be similarly supposed that they have a natural liking for virtue, which Shaftesbury calls a 'sense of right and wrong' akin to our natural sense of the sublime and beautiful, and which Hutcheson calls a 'moral sense'. Though they regard this capacity to perceive moral qualities of good and evil as unique to rational beings, their description of it as a 'sense' implies something different from the rationalists' apprehension of moral truths, and more akin to sense-perception.

The high point in the tradition of the British Moralists is generally acknowledged to be the moral philosophy of Hume. A key concept for Hume is that of \*sympathy', which he also calls 'humanity' and 'fellow-feeling'. By this he means our capacity to share other people's feelings of happiness and misery. Hume rejects the 'self-love' hypothesis; though sympathy may often lack the strength to have a decisive influence on our conduct, all human beings are to some extent moved by it. It is through the operation of sympathy that we regard as 'virtues' those qualities which are useful or agreeable to their possessor (such as 'courage' and 'industry') and those qualities which are useful or agreeable to others (such as 'benevolence', 'justice', and 'fidelity'). In the last analysis, therefore, our moral judgements stem from this sentiment rather than from reason. Reason is necessary to instruct us in the consequences of actions, but when all such facts are known, some feeling or sentiment is necessary to lead us to a judgement of approbation or disapprobation. Reason by itself, says Hume, is no motive to action, but it is in the nature of our moral principles that they should guide our actions. Hence, though reason has a part to play, sentiment must be decisive in the forming of moral conclusions.

*Utilitarianism.* Hume stressed the *utility* of the virtues. Hutcheson suggested that, since benevolence is the foundation of all moral virtue, 'that action is best which procures the greatest happiness for the greatest numbers'. These phrases went to the making of the moral theory which was the most important successor to the work of the British Moralists—the theory of \*utilitarianism. Though it builds on much previous thought, the first classic formulation of modern utilitarianism is the work of

Jeremy Bentham. The 'principle of utility' is, according to Bentham, the test of all morals and legislation. Actions are right or wrong to the extent that they tend to increase or diminish the general happiness.

The attraction of utilitarianism is its apparent simplicity. It purports to provide a succinct criterion to settle all moral disputes. Its weakness is that it seems over-simple. Bentham's version is certainly pretty crude. He suggests (as Hutcheson had done) that one can quantify the amounts of pleasure or pain to be produced by any action, and by a process of addition and subtraction one can then determine which action ought to be performed. The general happiness is thus envisaged as a sum of \*pleasures, minus the pains, and these pleasures and pains differ from one another only in quantitative respects such as their duration and intensity. Critics of utilitarianism were not slow to point out how limited a view of the good life this appeared to be. The most influential attempt to produce a more plausible version of the theory was that of John Stuart Mill. He allowed that pleasures may differ from one another not only in quantity but also in quality. The pleasures of the intellect, of the feelings, and the imagination are what Mill calls the 'higher pleasures', and a good human life is one in which such pleasures are predominant. It is debatable whether Mill can consistently maintain this within a utilitarian context, for if pleasure is itself the only criterion of value, it is not clear how one pleasure can be better than another, other than by being greater in quantity. Nevertheless, utilitarianism as refined by Mill and by others such as Henry Sidgwick has occupied a dominant place in the moral philosophy of the nineteenth and twentieth centuries.

*Kant and Post-Kantian Ethics.* In stark contrast to utilitarian ethics is the moral philosophy of Kant. The only thing which is good without qualification is, according to Kant, 'the good will', which is good not because of the effects which it produces in the world, not because of its utility, but simply in its character as will. It is the motivation to perform one's \*duty simply for its own sake. Since duty gets its distinctive character from its contrast with our natural inclinations, including both our desire for our own happiness and our benevolent inclinations towards others, no understanding of these natural inclinations can contribute to our understanding of morality, and Kant's ethics therefore stands opposed not only to utilitarianism but to ethical naturalism in general. Kant nevertheless thinks that reason, without any reference to the inclinations, can determine the form of our moral duty. Since the requirement of duty is that of acting in accordance with the \*moral law, and since this moral law cannot get its content from any consideration of desirable consequences, there remains simply the formal requirement that one's actions should conform to the idea of moral law as such. One must therefore act in such a way that one can will the maxim of one's action to be a universal law. This requirement is what Kant calls the '\*categorical imperative'. From such exiguous resources Kant nevertheless

thinks that we can arrive at concrete judgements about the morality of particular actions. It would, for instance, be wrong to make a false promise, one which I do not intend to keep, for if it were a universal law that people made false promises, promises would themselves become impossible, and this is therefore not something which I can consistently will.

Kant offers also a second formulation of the categorical imperative. This uses in a different way the idea of the universality of reason which is shared by all moral agents. Morality requires that I should respect this capacity for rational agency, and therefore that I should treat all persons never merely as means to an end but always also as ends in themselves. This idea of 'respect for persons' may again conflict with utilitarian morality. Utilitarianism can set no absolute limit to the evils which I might, in certain circumstances, be justified in inflicting on others, provided that the overall sum of human happiness is maximized by my so doing. In contrast, 'respect for persons' implies that I may not use others simply as instruments for however worthy an aim. It thus reflects the common idea that morality imposes certain constraints on the permissible treatment of others, that all human beings have certain basic moral rights which may not be overridden, and it is this dimension of Kantian ethics which has perhaps been the most influential.

Within this section we may notice briefly three nineteenth-century philosophers who have in common only their reaction against Kantian ethics. Schopenhauer rejects Kant's separation of morality from natural human feelings of compassion. This can be seen as a reversion to the British Moralists' emphasis on natural benevolence, but in Schopenhauer's case it is linked with an ambitious metaphysical thesis: that the 'principle of individuation' is an illusion, that the essential being of all persons is literally one and the same, and that our moral concern for the suffering of others is a recognition of this.

Hegel reacts against what he sees as the empty formalism of Kant's categorical imperative, particularly in its first version. Any maxim can in itself, according to Hegel, be willed as a universal law. If our willing it generates a contradiction, this must be because it contradicts some moral content which is already presupposed. Where does this content come from? According to Hegel, from the institutions and practices of society. What prevents us from willing the making of false promises as a universal law, for instance, is the social institution of promising which is already presupposed by the moral dilemma. More generally, the substantial content of our moral lives is drawn from 'ethical life', from the ethical institutions of the family, civil society, and the state. Ethics is essentially a social phenomenon.

That conclusion is one with which Nietzsche could agree. Where Hegel, however, sees different historical societies as stages in the evolving self-consciousness of reason, Nietzsche has no such unifying conception. For him, therefore, there is no such thing as morality, there are only different moralities. He is particularly

preoccupied with the opposition between two types of morality, 'master morality' (in which ideas of nobility, courage, and honesty have a central place) and '\*slave morality' (which he tends to identify with Christian morality and ideas of duty and self-sacrifice). Nietzsche appears to oscillate between seeing any distinctive morality as an achievement of human creativity, and denigrating slave morality as the psychological veneer of concealed resentment and vindictiveness.

*Twentieth-Century Ethics.* For much of the century, philosophers within the English-language tradition have been preoccupied with questions of \*meta-ethics. The tone was set by G. E. Moore's book *Principia Ethica* of 1903. Moore espoused a normative theory akin to utilitarianism, but much more influential was his criticism of what he called the '\*naturalistic fallacy'—the fallacy of identifying the simple and unanalysable property 'good' with some 'natural' property. According to Moore, no argument can be offered to show that something is good as an end in itself. We cannot, for instance, argue, as Moore thinks that the classical Utilitarians were guilty of arguing, that pleasure is good because that is part of the meaning of the word 'good'. It may be true that pleasure is good, but it is not true by definition, and this we can see, Moore thinks, when we recognize that any question of the form 'Is pleasure good?' is always an \*open question. Moore's rejection of naturalism as fallacious seems to rule out any attempt to base ethics on an understanding of human nature or human psychology. No facts about features of human existence, nor indeed any metaphysical facts about the nature of reality, can entail any conclusion about what is good. Moore himself thinks that, once the question is properly understood, people can recognize that the most important things which are good in themselves are the pleasures of human intercourse and the enjoyment of beautiful objects. No argument, however, can be provided in support of these truths. They are simply self-evident.

Other philosophers, however, took issue with the very idea of moral truths which are 'self-evident' or can be known 'intuitively'. If such supposed truths cannot be supported by any argument, then, it was suggested, they cannot be called 'truths' at all, they are merely expressions of personal feeling. Bertrand Russell, for instance, who had at one time accepted Moore's theory, subsequently came to reject it and to maintain instead that if two people disagree over whether, say, the enjoyment of beautiful objects is good in itself, and if neither can offer any argument, then they are not disagreeing about facts which can be true or false, but simply expressing their differing feelings and desires.

The suggestion that, strictly speaking, there are no moral facts was developed further within the context of \*Logical Positivism. If, as philosophers such as A. J. Ayer maintained, the only meaningful statements are either empirically verifiable propositions or analytic truths, value-judgements do not fall into either category and are

therefore not meaningful statements at all; they are merely expressions of feelings and emotions. A more accommodating version of this \*emotive theory of ethics was formulated by Charles Stevenson, who maintained not that moral utterances are meaningless but that they have a distinctive kind of meaning, \*emotive meaning', to be distinguished from descriptive meaning. The emotive meaning of ethical terms consists in their lending themselves to use, not only to express the speaker's own feelings, but also to arouse or affect the feelings and attitudes of others. Moral discourse is thus seen by Stevenson as a kind of behaviour modification.

Critics retorted that this account of moral discourse made it indistinguishable from emotionally manipulative practices such as advertising and propaganda. What many philosophers retained, however, was the idea that there is a distinction between 'prescriptive' and 'descriptive' meaning, and that the distinctive feature of moral terms is their prescriptive meaning, their use to guide actions and tell people what to do. 'Values', it was suggested, must not be confused with 'facts'. Much writing of the 1950s and 1960s was concerned with meta-ethical questions about the validity of the \*fact-value distinction', the relation between \*is' and 'ought', and whether 'is' statements can ever logically entail an 'ought' conclusion.

More recently there has been a revival of interest in substantive moral theory. Utilitarianism was the first of the traditional normative theories to be resurrected. R. M. Hare, for instance, argued that moral terms are not only 'prescriptive' but also 'universalizable', and that when properly understood the \*universalizability of moral language commits us to some form of utilitarianism. The revival of utilitarian thinking has been particularly apparent in work on \*applied ethics.

Other normative theories which were current in the 1970s and 1980s can usefully be seen as responses to the perceived shortcomings of utilitarianism. One principal criticism of it has been that it is an aggregative theory. It allows the interests of some to be outweighed by the interests of others, and can therefore justify the infliction of terrible atrocities on some persons for the sake of the greater good. What this shows, it has been said, is that utilitarianism, by aggregating interests into a single 'general good', fails to recognize the separateness of individuals. Two forms of ethical theory which have aspired to incorporate that recognition have been 'contractarian' theories and 'rights-based' theories. Contractarianism came to the fore in political philosophy with John Rawls's theory of \*justice. The idea of basing principles of justice on a hypothetical \*contract is that, if they are principles which everyone can agree to, then no one's basic interests will be sacrificed to anyone else's. Contractarian attempts to develop a general moral theory include those of Russell Grice and David Gauthier. Gauthier's theory is very much in the spirit of Hobbes as an attempt to show how morality can be generated by agreement between self-interested individuals. Basing morality on rights has likewise been seen as a way of building in the requirement that no one's basic interests

should be sacrificed. The focus on rights, like contractarianism, first emerged in political philosophy, and the work of Robert Nozick and that of Ronald Dworkin have, in contrasting ways, emphasized the importance of \*rights as a counter to utilitarian social theory. Alan Gewirth and John Mackie are among those who have proposed a comprehensive moral theory based on the concept of rights.

Other critics of utilitarianism have argued that by focusing exclusively on outcomes it gives insufficient importance to the significance of moral agency. A more 'agent-centred' approach can be found, for instance, in the work of Bernard Williams. He suggests that a person's moral identity is constituted by his or her 'ground projects' and 'commitments' and that utilitarianism, in so far as it would require one to abandon these whenever the actions of others so order the consequences as to make it necessary, can give no adequate account of concepts such as 'moral integrity'. Another approach which can be called 'agent-centred' is the work of Philippa Foot and others which refocuses attention on the \*virtues. Whereas utilitarianism assesses actions by their production of good consequences, virtue ethics aims rather to identify those ways of acting which go to make up a good human life. Foot, indeed, has argued that the idea of 'the best state of affairs', which is supposed to serve as the utilitarian criterion of right action, does not as it stands have any clear sense.

Contemporary virtue ethics traces its ancestry to Aristotle, and rights-based theories look to Kant. Considering also the continuing vitality of utilitarianism, and of contractarian ethics in the Hobbesian mode, we may fairly conclude that the main ethical traditions of previous centuries are still, in one incarnation or another, alive and well.

**moral philosophy, problems of.** If we include in moral philosophy the entire history of ethics going back all the way (at least) to Socrates, the topic of right and wrong action is perhaps the most important single issue in the discipline. Although in the present century scepticism about the possibility of moral truth or objectivity has led philosophers to pay attention to semantical issues in ethics, to questions about the meaning of terms like 'right', 'wrong', and 'obligatory', most ethicists have been and still are interested in offering, debating, and criticizing substantive conceptions of moral rightness and wrongness. Perhaps the major problem of current and traditional moral

philosophy, then, is coming up with a rationally defensible theory of right and wrong action. Such a theory would presumably ground or defend certain principles of right action (or, as with Aristotle, show us why rightness cannot be captured by general principles and must be perceived situationally).

The current scene in moral philosophy is dominated by five basic views or theories of right and wrong action. (Here I exclude approaches that are principally concerned with the political sphere.) Utilitarians (or at least 'act-utilitarians', who represent, I think, a current majority among all utilitarians) hold that \*right action must be understood in terms of human good or well-being. The latter is conceived hedonistically in terms of pleasure, desire-satisfaction, or, more broadly, happiness, and right action is then said to be action that leads, or is likely to lead, to the greatest balance of human (or sentient) pleasure or happiness over pain or unhappiness. (This is one version of the so-called \*principle of utility.) Such a purely instrumental or consequentialistic conception of morality and also virtue—in effect, any means can be justified by a good enough end—has always been controversial, but in fact one of the biggest problems now facing \*utilitarianism is to defend itself against less monolithic forms of \*consequentialism that are willing to accommodate intrinsic human goods other than pleasure or desire-satisfaction and to acknowledge considerations of equality and fairness and even of natural beauty and diversity that go considerably beyond the purely quantitative utilitarian approach. A consequentialist can say, for example, that (a fair degree of) equality in happiness or income is itself a good that should be taken into account in seeking to act for the best, and on such a view and contrary to act-utilitarianism an act might produce more pleasure on balance than any alternative but be wrong because of how unequally it caused the pleasure to be distributed.

By contrast with the utilitarian emphasis on human desire-satisfaction, \*Kantianism argues that morality must be understood independently of all empirical or sensuous motives. For Kant and many contemporary Kantians, moral rightness in behaviour is a matter of acting consistently and rationally, and a major challenge and burden of Kantianism has been to show how ordinary immoralities like promise-breaking, stealing, and indifference to the welfare of others can be fundamentally understood as forms of conative or practical inconsistency. Formulations of the \*'categorical imperative' in terms of one or another form of inconsistency (or in terms of the idea that people should never be used simply as means) have typically ruled out too little or too much as morally wrong. Or else they have been unacceptably vague in their implications. However, present-day Kantians are actively engaged in trying to make good on these deficiencies.

A third approach to right and wrong, intuitionism or common-sensism, insists, against both Kant and utilitarianism, that there can be no unified or unifying account of our moral obligations; these, it claims, are irreducibly plural, and the only general moral principles it is willing to

RECENT AMERICAN PHILOSOPHY (2)

JOHN RAWLS's *A Theory of Justice* galvanized political philosophy in the early 1970s: it was a careful elaboration of an original approach to the eternal problem of accommodating egalitarianism and liberalism.

ALASDAIR MACINTYRE's distinctive and often polemical approach to moral enquiry insists on the historical dimension of ethics.

SAUL A. KRIPKE published innovations in logic in his teens, but later became reluctant to commit his ideas to print. In his published lectures on *Naming and Necessity* he examined standard theories of reference and pulled back the curtain to reveal a metaphysics of modality and necessity.

DANIEL C. DENNETT has been one of the leading figures in the project of fertilizing the philosophy of mind with the findings of the sciences of the mind. After arguing for a scientific explanation of consciousness, he looked to evolution, 'Darwin's dangerous idea', for the explanation of humanity's place in the natural universe.

recognize are prima-facie principles (it is prima-facie wrong to harm another person, it is prima-facie wrong to break a promise, etc.) that are individually defeasible and cannot be ranked in any absolute order of precedence. But, unlike Kantianism, intuitionism doesn't even attempt to explain why it is wrong, e.g., to kill an innocent person in order to prevent a greater number of deaths. The latter claim is typical of \*deontological theories like intuitionism and Kantian ethics, and definitely runs counter to act-utilitarianism. But the intuitionist can only insist on the intuitive implausibility of the implications of act-utilitarianism for such cases and has no (further) philosophical argument against it.

A fourth way of dealing with substantive issues of right and wrong action can be found in Thomas Scanlon's 'contractualist' view of the morality of obligation (of what we 'owe to each other'). This new approach in part derives from \*John Rawls's contract theory of social justice, but, unlike the latter, its principal focus is on issues of personal morality. It holds, roughly, that an act is wrong if it would be disallowed by any principle that no one seeking an agreement on moral principles for the general regulation of behaviour could reasonably reject. This form of contractualism has encountered the criticism that it builds too much of morality into its claims about reasonableness; but others worry that the approach isn't strong enough to justify all the claims that are plausible within the sphere of moral obligation.

The final (major contemporary) way of dealing theoretically with right and wrong can be found in virtue ethics, a kind of moral theory with origins in the schools of ancient philosophy. Virtue ethicists think right and wrong cannot be captured by independently or basically valid moral rules or principles, but are a matter rather of situational sensitivity (Aristotle) or of the expression or maintenance of fundamentally good or admirable inner motives or states (Plato, Hume). Among the chief problems for such views are explaining how agents can perceive what is right to do in given situations without the help of general principles and/or showing how evaluations based *in* the moral agent can sufficiently constrain what the agent does *outside, in the world, to other people*.

However, ethics or moral philosophy in the broadest sense includes much more than attempts to describe or explain the nature of moral right and wrong. As I indicated just above, the utilitarians attempt to ground our understanding of right and wrong in an independent understanding of human good. But all systematic theories of ethics seek to understand human good, or the good life, and not just the issue of right and wrong action. What is good for a person is not necessarily morally good (there is nothing morally good about enjoying a sauna bath), and the distinction, therefore, between moral good and obligation, on the one hand, and non-moral personal, human, or life goods, on the other, raises two further important problems for ethics.

First, the nature of human good and the good life is not self-evident. Utilitarians think of human or personal good

in hedonistic terms, but it is not necessary to do so, and some self-realization theorists and \*virtue ethicists have, for example, held that (some of) the greatest human, personal, or life goods are things like knowledge, autonomy, achievement, honour, and virtue itself. One of the main problems of ethics, then, is to determine what things are (basic) personal goods in addition to such obvious goods as pleasure and desire-satisfaction. But this problem raises a second interesting issue. The utilitarians understand right and wrong derivatively from human good: the moral is what is instrumental to the greatest abundance of personal good(s). But it is possible to reverse the order, in the manner of the Stoics, and claim that human well-being or good is confined to and understandable in terms of human virtue: to be well-off is simply to be virtuous. (This means pain is no evil, is not a bad thing in one's life, unless it undermines one's virtue.) But there is also the possibility that neither well-being nor virtue is ethically prior to the other, so that ethics is faced with a dualism of fundamental concepts (this is Kant's and Ross's view). And so ethics faces a general issue about its basic values that goes beyond the confines of morality proper: the question how to connect moral values with personal well-being and the question whether either of these notions or notion-types is the basis for the other.

I mentioned earlier that recent moral philosophy has been greatly concerned with issues about the meaning of moral terms. In fact, \*meta-ethics', which deals not only with semantic issues but also with questions about the objectivity and verifiability of moral judgements, practically dominated English-speaking philosophy during the first half of the twentieth century. The reason has something to do with the emergence of \*Logical Positivism during the early part of that period. The positivists questioned whether moral, religious, or metaphysical discourse was cognitively meaningful; and the force of their sceptical views, and of questions raised by G. E. Moore about whether goodness was a natural or non-natural property, led many or even most ethicists to abandon substantive issues of right and wrong and good for a consideration of questions about the meaning and rational or epistemic status of moral and other value-claims.

In the heyday of meta-ethics, certain schools of thought dominated the scene and their disagreements constituted the main substance of moral-philosophical discussion. Non-naturalists like Moore held that goodness and rightness were not understandable in terms of purely natural phenomena or properties, but were metaphysically real and rationally intuitable ethical properties none the less. Their targets, the naturalists, argued that ethical terms or concepts were analysable in terms of such natural notions as pleasure, evolutionary fitness, or (more complexly) what would be chosen by a totally informed and dispassionate human(-like) observer. Against such anti-sceptical 'cognitivist' views, another school of meta-ethics, the emotivists, held that there is no property of goodness or rightness and that moral discourse simply expresses the emotions or preferences of speakers rather than making

any claim about the world. Subjectivists, by contrast, deflated ethics by treating moral and evaluative claims as mere *descriptions* of the emotions or preferences of speakers—‘this is good’ being equivalent in meaning to ‘I like (or prefer) this’. Finally, prescriptivists likened moral and indeed all evaluative claims to imperatives—‘this is good (or right)’ being regarded as meaning the same as ‘choose this (sort of thing)!’—and sought to induce a certain rationality into moral discourse via a logic of imperatives.

More recently, meta-ethicists have focused more directly on the question whether moral and other value-claims correspond to reality or are in any sense objective, and there have been a wide variety of different and opposing responses to that question. Given the apparent widespread disagreement about ethical (and other) values that has existed between different societies and different epochs of the same society, there is reason to wonder whether there really are any facts or truths for ethics to discover, and although most ethicists ever since Socrates have tended to believe in one or another form of moral objectivity, the problem remains of justifying such objectivity in the face of continually different forms of scepticism about its possibility.

However, in addition to meta-ethical questions, ethics naturally leads to certain substantive (non-semantic) metaphysical issues, and perhaps most important among these is the question of \*free will. If human beings lack free will, then, it has traditionally been argued, they cannot be held responsible for their actions and cannot be bound by moral obligations any more than animals or small children are. So those who have systematically elaborated one or another view of moral right and wrong and of human good have also usually thought it necessary to defend (or at least explicitly assume) the existence of human freedom, and that defence, in the first instance, has usually involved saying something about freedom in relation to causal \*determinism. If the universe is universally governed by causal laws, then human freedom would seem to be very much in jeopardy. So defenders of morality typically feel called upon either to deny determinism and argue that human beings are in important ways not subject to causal determination or else to show that causal determinism does not in fact deprive us of free agency.

Another metaphysical or quasi-metaphysical issue that moral philosophers have devoted attention to concerns the human capacity for morality. Most moral codes and moral philosophies require, for example, that people occasionally put aside self-interest in the name of honour, fairness, decency, loyalty, or the general good, but if one is a *psychological* egoist, one will hold that people lack the capacity for these forms of self-sacrifice, and it then becomes problematic whether human beings really have the obligations that various ethically non-egoistic theories or views claim they do. As a result, psychological egoism, most notably at the hands of Bishop Butler, has been the target of philosophical criticisms on the part of philosophers wishing to defend one or another substantive, ethically non-egoistic morality.

But even if one rejects both forms of egoism, there are questions about how much morality validly or fairly can demand of people, and some of these issues arise in connection with utilitarianism and Kantianism. Utilitarianism is usually stated in a ‘maximizing’ form that treats it as a necessary and sufficient condition of right action that one do the best one circumstantially can for humankind as a whole (or for all sentient beings). But such a doctrine seems to entail that if one is in a position to relieve the suffering, hunger, or disease of others, one is morally obligated to do so, even if that means giving up one’s life plans and most of what one really cares about in life. Unless one’s current life does as much good on the whole for people, one must give up one’s life plans to the extent necessary to confer greater benefits on (prevent greater harm to) other people. The utilitarian moral standard is thus very demanding, and some philosophers have questioned whether morality can properly, or, one might say, fairly, require so much of people. In particular, it may be wondered whether people, most people, have the capacity to live up to such a stringent morality as maximizing utilitarianism presents. Utilitarianism requires that one always do the most good one can for people and in effect leaves no room for what are called supererogatory degrees of morality, for going *beyond* the call of duty. And this seems too demanding because it means, in effect, that if one fails always to do the most for humankind that one can, if one isn’t like Schweitzer or Mother Teresa, one acts wrongly and fails to fulfil one’s moral obligations. Thus if ethical egoism is too undemanding, morally speaking, so too, on the other side, does utilitarianism seem too demanding upon human nature.

Kantianism can likewise be seen as grating against our human nature or capacities, not by demanding too much sacrifice of self-interest, but by insisting that only moral conscientiousness is a proper and laudable moral motive. If one gives out of fellow-feeling or friendship to another human being, one’s act lacks all moral worth, according to Kant, because one’s action was not performed out of a sense of duty and respect for the moral law. Many philosophers have thought such a view of moral virtue to be too narrow and out of keeping with human psychology, and feminists like Carol Gilligan and Nel Noddings have argued, contrary to Kant, that a morally good person will directly focus on other people and their welfare, rather than be guided by a sense of duty. In fact, there has been and remains a great deal of disagreement over what kinds of motive really are morally praiseworthy and worthy of encouragement.

Today moral philosophers are very much engaged in all the kinds of issue we have discussed here. There may be no generally accepted solutions to (most of) these problems, but there is also no doubt that moral philosophers have been developing a better critical understanding of their nature and of what solutions to them might look like.

 B. A. O. Williams, *Morality: An Introduction to Ethics* (New York, 1972).

**moral pluralism** holds that the foundational level of morality consists of a plurality of values or duties. For example, \*equality and aggregate \*well-being are often claimed to be values that serve as the foundation for the rest of morality. According to other pluralistic theories, the foundational level of morality is instead composed of duties not to physically harm others, not to harm or take others' possessions, not to break one's promises, not to tell lies, plus general duties to do good for others, and duties of extra concern for those with whom one has special connections. Different versions of moral pluralism add to or subtract from such lists of foundational duties or values.

Most moral pluralists hold that we do not have strict principles of priority that will resolve all conflicts among the foundational values or duties. These moral pluralists hold that we thus to need to exercise judgement in order to resolve some conflicts among these values or duties. Giving judgement such a large role, however, strikes critics of moral pluralism as failing to provide a defensible decision procedure for moral deliberation.

**moral psychology.** A part of moral theory devoted to the analysis of concepts used to describe the psychological make-up of persons as moral \*agents, and the examination of normative issues involving those concepts. Some of these concepts may be explored for their own sake, e.g. the ideas of fear, anxiety, despair, or \*love, and here the aim is to understand emotional states, motivations, or relationships of major importance in the lives of human beings.

Moral psychology also explores moral-emotional aspects of important moral practices. When the actions of responsible persons are morally wrong, those who hold them to account typically expect the wrongdoers to experience such negative moral \*emotions as guilt, shame, remorse, or regret. Moral psychology attempts to understand the cognitive and phenomenological structures of such emotions, the differences among them, and the conditions under which they are justified or not. These emotions are usually thought of as painful, and as reflecting a change in a person's standing in the moral community.

Ordinarily, pain is construed as a condition from which a person is entitled to seek immediate relief. In the case of the negative moral emotions, then, how long must a person suffer them? And how may a person suffering them gain release from them, and perhaps restoration to good standing in the moral community? Here the notions of forgiveness, mercy, excuse, and repentance become important, and the practices of making amends and of moral or legal punishment need investigation. Accordingly, moral-psychological inquiry may lead on to the theory of punishment and the philosophy of law.

There are positive moral-emotional states to be understood, too, such as the satisfaction, contentment, or pride one may take in doing right, and the humility that may be recommended when such positive states turn toward arrogance. Approaches to these issues concerning the negative and positive moral emotions may be influenced by prior inquiries into the ideas of freedom and intentionality, and into the logic of moral deliberation and practical reasoning. Under a wide interpretation, moral psychology may be considered to include these latter inquiries as well.

 Owen Flanagan and Amelie Oksenberg Rorty (eds.), *Identity, Character, and Morality* (Cambridge, Mass., 1990).  
 Herbert Morris, *On Guilt and Innocence* (Berkeley, Calif., 1976).

**moral realism.** The view that moral beliefs and judgements can be true or false, that there exist moral properties to which moral agents are attentive or inattentive, sensitive or insensitive, that moral values are discovered, not willed into existence nor constituted by emotional reactions. Far from being a function of wishes, wants, and desires, moral demands furnish reasons for acting, reasons that take precedence over any other reasons. Debate centres on the nature and credentials of moral properties as the moral realist understands them. In what sense are they 'real'? Real, as irreducible to discrete affective experiences of individuals. In this and other respects they share characteristics of the \*'secondary qualities' of our life-world: filtered by our mentality, but not on that account illusory. They can be well-founded, making a real difference to situations and individuals that possess (or lack) them.

Moral realists are arguably justified in displaying the inadequacies of subjectivist moral theories; but less successful so far in developing a convincing positive account of the 'reality' of values.

**morals and law:** see law and morals.

**morals, enforcement of:** see enforcement of morals.

**moral scepticism.** We must distinguish two kinds of \*scepticism about the possibility of objectively valid moral judgements. *Internal* scepticism argues that it is a mistake in moral judgement to make certain kinds of moral evaluation or criticism or (in the case of global internal scepticism) to make any such judgements at all. Examples of the latter, global scepticism, include the argument that morality is ridiculous because there is no God, that it is misconceived because all human decisions and acts are predetermined, and that it is barren because there is no point or purpose in human life anyway. Such scepticism is internal to morality because it is based on normative, ethical assumptions about the true or adequate ground of moral claims: it assumes that a basis for morality would exist if there were a God, or if human acts were genuinely free, or if the universe including human life could be understood as planned and purposeful. Each of these assumptions represents an abstract normative judgement—an assumption about the true grounds of moral commitment—even though each claims to generate sceptical conclusions. Internal scepticism is powerful and threatening, for those who find its underlying assumptions persuasive, because it is practical: it must change the behaviour of anyone who is converted to it. People who sincerely believe that morality is bunk because free will is an illusion must reject moral restraints for themselves, and refuse to criticize others for behaving dishonestly or in ways other people find morally wicked.

*External* scepticism, on the other hand, is supposedly based not on abstract or general normative assumptions about the adequate grounds of moral commitment or responsibility, but rather on wholly non-moral, philosophical assumptions about the possibility of any kind of objective \*truth or \*knowledge. Contemporary examples include Gilbert Harman's argument that moral judgements cannot count as objective knowledge because moral beliefs are not caused by anything in the world, and John Mackie's argument that there cannot be moral facts because moral properties would be such 'queer' entities. External scepticism is widely thought to have only theoretical rather than practical consequences—someone who is converted to the philosophical opinion that morality is a matter not of objective truth or falsity but rather of subjective reaction need not, on this view, change his first-order moral convictions—he may still think that dishonesty is detestable or that genocide is wicked—though he will now recognize that these are not ordinary beliefs about some objective reality, but are only expressions of his own subjective state of mind.

It is very difficult, however, to make any real sense of the idea of external moral scepticism. Consider the statements that supposedly express this kind of scepticism: that genocide is not 'really' or 'objectively' immoral, or that its immorality is not 'out there, in the universe', or that its immorality is not 'part of the fabric of the universe', for example. It is, in fact, impossible to assign any sceptical sense to such philosophically loaded or metaphorical statements that does not make them equivalent in mean-

ing to the simple internally sceptical statement (which is, of course, full of practical consequences) that genocide is not immoral. Since the latter is plainly a moral judgement, and could be supported, if at all, only through internally sceptical abstract moral claims of the kind I mentioned, there is no such thing as external scepticism. The only intelligible moral scepticism is internal to morality.

That is an important conclusion, among other reasons because many philosophers have assumed that \*subjectivism, \*relativism, and other forms of moral scepticism can be established by default; that is, that since we cannot prove that abortion or taxation or racial discrimination are or are not morally wicked to those who think the contrary, it follows that there is no objective truth in moral matters. But if we understand the denial of objective moral truth as a piece of internal rather than supposedly external scepticism, we see that it is as much in need of a positive moral argument as any other moral position, and its supporters can no more win by default than can their non-sceptical opponents. Whether you accept some general sceptical position about morality—for example, the subjectivist position that moral obligations only hold for those who accept them, or the relativist position that moral obligations hold only within a community whose conventional morality endorses that obligation—must depend on whether you accept whatever moral arguments can be made for these particular forms of scepticism—that it is wrong to condemn people morally unless they act in a way they themselves believe to be wrong, for instance. In fact, very few people (including those philosophers who claim to be external sceptics) find that they can actually accept those arguments or embrace and act on the internally sceptical conclusions they recommend.

**moral sense.** 'Moral sense' is the name given by, for example, Francis Hutcheson and David Hume to the capacity we have to distinguish virtue from vice. Such moral philosophers are referred to as sentimentalists, because we are supposed by them to feel things to be good or bad rather than to reason that they are so. However, in Hume's philosophy such feelings are not divorced from judgement. A feeling of admiration for virtuous action is properly called 'moral sense' only if it arises from disinterested reflection on the good tendencies of such actions in general. Moral sense, like aesthetic taste, may be ill-founded or well-founded. This view was taken for granted by, for example, Jane Austen, who thought it a fault if someone did not 'feel as he ought'. Since the moral theories of Kant, however, it has generally been held that moral judgements are matters either of reason or of purely personal preference.

M.WARN.

\*conscience; moral realism.

J. L. Mackie, *Hume's Moral Theory* (London, 1980).

**moral sentiments.** States of mind associated with moral character and response, including guilt, anger, shame, pride, sympathy, hatred, resentment, and other feelings and emotions connected with approval and disapproval. According to the eighteenth-century sentimentalists, moral distinctions are explicable in terms of non-rational sentiments experienced by agents in response to states of the world, including states of character. Thus to be virtuous is to be such as to elicit approval or sympathy in others. On some views, including that of Hume, moral judgements of approval and disapproval are themselves a kind of experienced sentiment. The distinction between sentimentalists and their opponents is undermined by cognitivist theories of the \*emotions, according to which propositionally articulated emotions are partly constituted by beliefs with their own conditions of correctness. If moral sentiments have distinctive conditions of correctness as given by the nature of their objects, then the eighteenth-century distinction between reason and sentiment is put into question.

**moral virtues:** see virtues.

**more things in heaven and earth**

There are more things in heaven and earth, Horatio,  
Than are dreamt of in your philosophy.

(Shakespeare, *Hamlet*)

What Hamlet says to his friend Horatio could be an indictment of \*philosophy in general or specifically of Horatio's philosophy. Or if, as some Shakespearean scholars contend, the correct reading is 'our', the philosophy referred to could be that of Horatio and Hamlet, whose undergraduate faith in rationality Hamlet may be mocking, or of all humans. No amount of scholarship, however, will dislodge people's tendency to counter scepticism about the supernatural, or philosophical stringency, with this quotation. The quoter usually purports to ally him or herself to 'the Bard', and flourishes Hamlet's rhetoric as if it were Shakespeare's own assertion—and decisive proof of the existence of God, the paranormal, or anything else that it is thought desirable to believe in.

J.O'G.

**mortalism.** The mortalist heresy (that human \*souls are mortal—punishable by \*death in the 1648 Blasphemy Ordination) was connected with a burning mid-seventeenth-century controversy: sentience requires a soul; all animals perceive; so do 'brutes' have immortal souls? or do we have mortal ones? Both alternatives were championed; neither was generally accepted. The mortalist Richard Overton offered a surprising compromise: body and soul both die, but both are resurrected.

J.J.M.

\*immortality.

N. T. Burns, *Christian Mortalism from Tyndale to Milton* (Cambridge, Mass., 1972).

**motion.**  $x$  moves if and only if  $x$  is at some place,  $P_1$ , at some time,  $t_1$ , and  $x$  is at some numerically distinct place,  $P_2$ , at some later time,  $t_2$ , and  $x$  exists at some juxtaposed set of places between  $P_1$  and  $P_2$  and at all times between  $t_1$  and  $t_2$ .

Philosophical problems about motion include: What is it to begin to move? How long does starting to move last? as well as the proof or refutation of both the materialist thesis that all change is motion and the Parmenidean thesis that change (and, *a fortiori*, motion) does not exist. Four of \*Zeno's paradoxes are philosophical problems about motion: Achilles and the tortoise, the dichotomy, the flying arrow, and the stadium.

**motives and motivation.** Explanations of behaviour may be in terms of reasons—someone waves because he wants to attract our attention and thinks he may do so thereby—or in terms of causes—a person shivers as a result of the cold. But may not reasons themselves be causes? There are indeed contexts in which 'cause' and 'reason' may interchange, as in the phrases 'give cause' and 'give reason', and we may use 'because' with reference to either. However, there is a use of 'cause' in which experimentation is in principle required to verify that  $C$  caused  $E$ , as with cold and shivering, whereas it requires no more than the agent's honest word for his reason for acting for this to be so. Motives have their place among the latter.

Or so it would seem in the simpler cases. But 'motive' is often invoked precisely when there is a departure from normal reasons. A person goes into a shop to buy a newspaper. That, he says, is his reason. We wonder about his motive if we suspect that there is more than meets the eye, something beyond the declared reason for acting thus. Might he not be unaware of his true motive?

We may wish to speak of an *unconscious* motive in such a case, but it is questionable whether we should sever all connection with the agent's awareness. The explanation why the agent acted can still count as a motive explanation provided we leave open the possibility that he should come round to acknowledging that he did indeed act for the reason suggested. Rule out any such possibility and, while we may be able to speak in terms of a cause of the behaviour, we rule out any justification for speaking in terms of desire, intention, trying, and the like. But, despite his sincere protestations to the contrary, might it not be true that a person is acting out of such motives as greed, vanity, or ambition? That could be so, but in a way that does not undermine the agent's honestly avowed reason. Rather, in the circumstances, we may say, acting as he did

counts as acting out of vanity; or, whatever the protester may say, 'greedy' is just the word for that sort of behaviour. So long as this is the point of dispute, it is not one on which the agent's authority is final. But nor is it a question of identifying a cause.

While motive explanations are not causal, an appeal to causes may explain why such-and-such counts as a reason for the agent; why, for instance, reasons for acting which would show a person to be vain carry so much weight with that person. Relatedly, the cause–reason division provides a way of finding room for considerations of self-interest while allowing the possibility of disinterested motives. Why did *A* come to *B*'s assistance? His sincerely avowed reason: He thought he must, that it was the proper thing to do. No suggestion that there was anything in it for *A*; indeed, the thought that he might in some way benefit from his act, or at least avoid the guilt which would come with inaction, did not even enter his head. On the other hand, there is also the question why *A* is disposed to respond altruistically to those in need, and the answer to this may well lie not with *A*'s reasons for acting, but with his upbringing. Perhaps it has taken rewards and punishments to bring him to a state where such other-regarding considerations weigh with him. Similarly, abuse suffered by a person as a child may explain how he comes to have the motives he has, but as a cause, not as something which figures among his reasons. B.B.R.

\*choosing and deciding; egoism and altruism; mental causation; reasons and causes; volition.

A. Kenny, *Action, Emotion and Will* (London, 1963).

G. Ryle, *The Concept of Mind* (London, 1948).

**Mo Tzu** (579–438 BC?). Born in the year of Confucius' death, Mo Tzu was his major philosophical rival. He criticized Confucians for what he perceived to be their élitism, partiality, nepotism, fatalism, extravagance, and wastefulness. He founded an extraordinary guild of religious, pacifist, itinerant, artisan soldiers, who practised their idealistic philosophy of impartial concern *jianai* ('universal love') by defending weak states against aggressors. According to Mo Tzu, social values (*yi*) must be imposed with laws and punishments, to prevent reversion to state of individualist antagonism. Mo Tzu proclaimed three standards for the evaluation of social doctrines: success of historical precedent, observations of the people, projected utility. The later Mohists developed theories of optics, and a logical system of dichotomous distinctions, both linguistic and evaluative: *shi* affirmation, *fei* denial/rejection. S.C.  
*Later Mohist Logic, Ethics, and Science*, ed. A. C. Graham (London, 1978).

**moving rows paradox:** see stadium paradox.

**multiculturalism.** Most countries today are 'multicultural' in the sense that they contain many distinct

ethno-cultural groups, as a result of the historic incorporation of minority groups or the admission of new immigrants. Multiculturalism, understood as a normative claim or political \*ideology, argues that this ethno-cultural diversity should be accommodated, not suppressed, and celebrated, not feared. In this sense, multiculturalism stands opposed to traditional models of nation building and \*nationalism that sought to create homogeneous national societies within each state. Multiculturalism is a widespread movement in both Western political theory and Western political practice, but its defenders face two key challenges. First, what are the limits to the legitimate accommodation of diversity? In particular, should traditional cultural practices that violate liberal-democratic norms be tolerated? Second, what holds multicultural societies together? In particular, can the celebration of multicultural differences be reconciled with the promotion of common national identities and loyalties? These issues remain a matter of lively ongoing debate. W.K.

W. Kymlicka, *Multicultural Citizenship: A Liberal Theory of Minority Rights* (Oxford, 1995).

**mundus imaginalis** (*'ālam al-khayāl*). The term was used first by Sohrawardī to define a 'boundary' realm that connects the sensory and the abstract intellectual segments of the whole continuum of being, and is the distinguishing component of non-Aristotelian \*cosmology in \*Islamic philosophy. It is constructed as the locus of visions, prophecy, and sorcery, and also defines \*eschatology. This wonderland is described by negating Aristotelian logical principles and laws of physics, and is employed to explain non-standard experiences such as 'true dreams' and 'miraculous powers'. As the individual subject moves away from the centre of the sensory segment of the continuum nearing the boundary realm, qualitative change takes place. Material bodies change to *imaginalis* ones; time changes, no longer confined to measure of linear space; and space is no longer limited by the Euclidean. H.Z.

\*possible worlds.

Fazlur Rahman, 'Dream, Imagination and *'Ālam al-Mithāl*', *Islamic Studies* (1964).

**Murdoch, Iris** (1919–99). Iris Murdoch DBE, better known as a novelist than as a philosopher, taught philosophy in Oxford for fifteen years. In 1954 she wrote the first book in English on Jean-Paul Sartre, relating his early philosophy to his plays and novels. The crossing of boundaries between literature and philosophy marks all her work. Her main philosophical interest is in ethics, and she held that goodness has a real, though abstract, existence in the world. This thesis was expounded at length in *Metaphysics as a Guide to Morals* (1993). She could be called a modern Platonist, and wrote perceptively on Plato (e.g. *The Fire and the Sun* (1977)). She also wrote about education and religion. The actual existence of goodness is, in

her view, the way it is now possible to understand the idea of God.

M. WARN.

\*Platonism; novel, the philosophical.

**music.** Although we can find philosophical writing on music as early as Plato and Aristotle, and discussion of it by philosophers outside the analytic tradition such as Schopenhauer, Adorno, and Nietzsche, the philosophical problems which we now identify as comprising the aesthetics of music received their first classic treatment by the Viennese critic Eduard Hanslick. Although his treatment is not always lucid, and debate continues as to what Hanslick meant, it seems fairly clear that his prime target was a Romantic conception of music which subsequently became known as the expressionist theory of art, that beauty in music depends upon the accurate representation or expression of the feelings of the composer. (Expressionist theories characteristically maintain that a psychological state of the artist is communicated via the work to the listener.) Of most philosophical significance in his objections are the claim that there is a cognitive element in the feelings of hope, anger, etc. A judgement is involved that may be a necessary component in individuating the particular feeling. Such an element of judgement is absent in music. The English writer Edmund Gurney, in a large and rambling book, *The Power of Sound*, developed, apparently independently, a parallel line of criticism. Both emphasize the looseness of fit between music and the expressive descriptions we make of it. Both are, not unfairly, viewed as formalists who believe that the worth of music lies in the beauty of its patterns rather than in its expressive power.

The aesthetics of music has flowered since the 1980s. The debate as to how music can be properly described as 'sad' or 'exuberant' has continued apace. The most widely held view is probably the view that it is the music itself which is sad, and not the composer, listener, or performer, and that we describe the music in this way because of the way the music moves, because of its pace or the angularity or otherwise of its lines. However, this orthodoxy has been challenged by a number of writers, who have argued that sad music does have a tendency to make the listener sad, a position which has become known as 'arousalism'.

There has been much recent philosophical discussion of what it is for something to be a work of music. The debate has largely been between Platonists, such as Peter Kivy, and others. Platonists have tended to argue that the work of music is an abstract sound pattern which is discovered, rather than created, by its composer. It is fair to say that the centre of controversy here is how we should understand the creativity of the composer: Does he create *ex nihilo*, or is he more in the position of the great and innovative scientist whose genius enables him to see what others have missed? A more moderate Platonism, such as that of Jerrold Levinson, allows that the work of music is a pattern or a type of which performances or interpretations are tokens, but that it is a type which is created by a

composer. Recently, there has been a greater realization of the extent to which the concept of a work of music is itself a historical phenomenon which developed as the concert-hall became the sonic equivalent of the art gallery or museum, a place where works can be displayed through performance. Through this, a deep distinction between work and performance became the norm, with the notion of fidelity to the work coming progressively to the fore.

Consequent on this, philosophers have become increasingly interested in a concept which has been central to musical performance over the last half-century, the notion of 'authentic performance' or, as it is now sometimes called, the 'historically informed performance'. The debate is very involved. Should we attempt to re-create the sound the composer would have heard or the effect his music had on the first audiences? Do we have a moral duty to the composer to present his work as he wished? Should we give precedence to the tradition of playing the work, incorporating the insights of generations of interpreters?

There is also a growing interest in the ontology of music outside the Western classical tradition, such as jazz, rock, and world music. All in all the aesthetics of music is currently the liveliest branch of the philosophy of the arts.

**mysticism.** The concept of mysticism is closely related to that of religious experience, but probably they should not be thought to be identical. It seems useful to distinguish mystical experience from numinous experience of the sort described by Rudolf Otto, and from the more 'ordinary' sort of experience of the presence and activity of \*God, which is well illustrated by John Baillie. William James characterized mystical experience by four marks: transiency, passivity, noetic quality, and ineffability. Perhaps we should add a fifth, that mystical experiences often, perhaps characteristically, involve what is now called an 'altered state of consciousness'—trance, visions, suppression of cognitive contact with the ordinary world, loss of the usual distinction between subject and object, weakening or loss of the sense of the self, etc. These features constitute an interesting 'syndrome'. Not all \*religious experience is mystical and not every mystical experience includes all of the features of this syndrome, but there is a large body of individual testimonies and descriptions derived from all the major religious traditions (and perhaps from minor traditions also) which involve many of these features.

Much of this mystical experience is taken to be religiously significant by the subject, but there is an interesting and difficult question about whether all mysticism is inherently religious, with some (e.g. William Stace) suggesting that it need not be. Some mystical experience is overtly theistic, having an ostensible reference to God, roughly as he is conceived in the theistic religions. And it is dualistic, in the sense of retaining the distinction between the mystic and the God who is ostensibly experienced. St Teresa of Avila, a Spanish Catholic of the sixteenth century, is a good example of such a mystic. Other mystics, however, even within the Catholic tradition, tend towards monism, emphasizing the unity of all things and the lack of real distinctions, even between the mystic and the divine reality. Mysticism of the theistic, dualistic sort seems to generate no particular difficulty for Christian metaphysics, and indeed often includes specifically Christian elements, such as visions of Christ. Strongly monistic mysticism, however, is harder to square with a Christian view, and when such mystics have themselves been Christians they have often been suspected of heresy. This sort of mysticism is likely to find a more comfortable religious home in the great non-theistic religions.

There are two principal ways of trying to derive some religious significance from mysticism. The first way is indirect and inferential, and it is accessible to non-mystics. It takes the prevalence of reported mystical experience as a premiss, and derives some conclusion from it in conjunction with some auxiliary principles. Often an analogy is drawn with sense-experience. C. D. Broad, for example, holds that a widely shared sort of experience, tending towards a similar interpretation, is plausibly taken to be the result of contact with some corresponding objective reality (unless we have some special reason to think otherwise). This, he says, is the way we treat sense-experience, and mystical experience should be treated likewise.

The other way is especially attractive for the subjects of mystical experiences which have a strong noetic element.

For in those experiences the subject is strongly convinced that he or she is acquiring a piece of knowledge, a sort of revelation, in the course of the experience itself. Such subjects may well take that element of their experience at face value. Indeed, they may find that the convictions which are thus generated are among the very strongest in their entire intellectual life (for example, St Teresa). This way of assessing the significance of mysticism is, however, not readily accessible to non-mystics. Normally these powerful convictions are generated by the experience itself, in those who have had that experience, and not in others who have only the reports of such experiences. In James's terminology, mystical experience is 'authoritative' for those who have it, but not for others. G.I.M.

**myth of the given.** Expression introduced by \*Wilfred Sellars to suggest there is no uninterpreted content of experience that is foundational in epistemology: e.g. Locke's ideas, Hume's impressions, the sense-data of the Logical Positivists. The myth of the given implies that facts can in principle be known non-inferentially. No non-inferentially known fact presupposes knowledge of any other fact or general truth. Such non-inferentially known facts are ultimately authoritative. The attack on the given is arguably anticipated by Vico and Kant. s.p.

# N

**Nāgārjuna** (fl. 150 AD). Greatest sceptic-mystic dialectician of the Voidist school of Mahāyāna Buddhism. Nāgārjuna interpreted Buddha's 'middle way' as emptiness of all things. This emptiness, best shown through silence, is realized when assent is withheld from all four logically possible answers to a metaphysical question (yes, no, both, neither). For example: 'Entities do not originate from themselves, from a wholly other entity, or from both, and nor do they originate without a cause'. This relegates Buddha's own teachings about dependent origination, suffering, selflessness, and \*nirvana to the level of relative rather than absolute truth. These levels of truth are distinguished to meet the charge of self-refutation which Nāgārjuna anticipates: 'Isn't the Voidist yelling "Don't yell"?' Somewhat like the sentences of Wittgenstein's *Tractatus*, the Voidist's own utterances count as therapeutically useful nonsense.

A.C.

\*Buddhist philosophy.

M. Sprung, *Lucid Exposition of the Middle Way* (London, 1979).

**Nagel, Ernest** (1901–85). A leading figure in the logical empiricist movement, Nagel was perhaps somewhat unfortunate in that he published his definitive work, *The Structure of Science*, just one year before Thomas Kuhn published his *The Structure of Scientific Revolutions*. This latter effectively spelt the end for the ahistorical, prescriptive approach to the philosophy of science that Nagel epitomized. Nevertheless, by virtue of his clear, comprehensive, and unemotional approach to the problems of science, Nagel did continue to have much influence, particularly in his standard account of 'reduction', the process where one science or theory is absorbed into another.

Seeing this relationship as essentially one of deductive consequence, the older of the newer, and everything of physics, Nagel came to consider in some detail the *prima facie* distinctive nature of the biological sciences, especially inasmuch as they use 'teleological' or 'functional' language. Unexpectedly, inasmuch as he thought this language significant, he thought it eliminable, and inasmuch as it is uneliminable, it is insignificant. Forty subsequent years of discussion of this subject suggests that this was a mistaken judgement.

M.R.

\*logical empiricism; reductionism; teleological explanation.

E. Nagel, *The Structure of Science* (New York, 1961).

M. Ruse, *The Philosophy of Biology Today* (Albany, NY, 1988).

**Nagel, Thomas** (1937– ). American philosopher, Professor at New York University. Nagel's philosophical work has been dominated by concern over how to reconcile the personal, subjective, first-person view we have of events, the world, of what is valuable and important, and the impersonal, objective, impartial view we have of these things, a view which is ordinarily thought of as more likely to be true just because impartial, untainted by local or personal concerns and horizons. His first book, *The Possibility of Altruism* (Oxford, 1970), considered issues of this character in connection with reasons for action of a personal or impersonal kind, but he has pursued related themes into questions in the philosophy of mind, epistemology, free will, and general metaphysics. Possibly his most influential piece is his journal paper 'What Is It Like to Be a Bat?', published in 1974, where he contends that all materialist and functionalist theories of mind and consciousness omit the central fact of \*mentality—that there is something it feels like to be in a certain material or functional state. In this case, we see a tension between the lived experience intimate to the individual subject and the generalizing theoretical accounts which seem to provide the best overall explanations. This paper is in his collection *Mortal Questions* (Cambridge, 1979). He has explored this cluster of issues most fully in *The View from Nowhere* (Oxford, 1986).

Nagel's writing is characterized by a lightness which makes it accessible to a very wide range of readers. He has written a brief and witty introduction to philosophy, *What Does It All Mean?* (Oxford, 1987).

N.J.H.D.

\*dualism; inequality; functionalism.

**naïve realism.** A theory of \*perception that holds that our ordinary perception of physical objects is direct, unmediated by awareness of subjective entities, and that, in normal perceptual conditions, these objects have the properties they appear to have. If a pickle tastes sour, the sun looks orange, and the water feels hot, then, if conditions are normal, the pickle is sour, the sun orange, and the

water hot. Tastes, sounds, and colours are not in the heads of perceivers; they are qualities of the external objects that are perceived. Seeing an object is not (as \*representative theorists maintain) seeing it, so to speak, on mental television where the properties of a subjective \*sense-datum or \*percept (e.g. colour) represent or 'stand in for' the objective, scientific properties of the external object (wavelength of reflected light). Although this theory bears the name 'naïve', and is often said to be the view of the person on the street, it need not deny or conflict with scientific accounts of perception. It need only deny that one's perceptual awareness of objective properties involves an awareness of the properties of subjective (mental) intermediaries.

F.D.

H. H. Price, *Perception* (London, 1932).

**names.** In the broadest sense of the term 'name', names divide into two classes—proper names and common names, these being species of singular and general terms respectively. Proper names are names of individuals, such as 'London', 'Mars', and 'Napoleon', whereas common names are names of kinds of individuals, such as 'city', 'planet', and 'man'. Not all singular terms are proper names; for instance, pronouns like 'I' and 'he' are not, nor are demonstrative noun phrases like 'this city' and 'that man'. Definite descriptions, such as 'the capital city of England', are also commonly contrasted with proper names (though Frege treated them as belonging to the same semantic category). Similarly, not all general terms are common names; for instance, adjectival or characterizing general terms like 'red' are not, nor are abstract nouns like 'redness' and 'bravery' (if indeed the latter are deemed to be general terms).

Recently, philosophical debate has focused on proper names much more than on common names (apart from the special case of natural-kind terms). A prominent issue has been whether such names have both sense and reference, as Frege believed, or whether they are purely referential devices, as J. S. Mill held and as Kripke now contends. (An implication of the latter position is that proper names do not have linguistic meanings specifiable by way of \*definition.) Frege's claim draws sustenance from the fact that an identity statement involving two different proper names—for instance, 'George Orwell is Eric Blair'—can be informative, which seems to imply that it expresses a different proposition from that expressed when one of those names is merely repeated, as in 'George Orwell is George Orwell'. On the other hand, Kripke plausibly argues that speakers can use proper names to refer to individuals about whom they possess no uniquely identifying information, as when a speaker affirms that Kurt Gödel proved the \*incompleteness theorem even though she cannot clearly differentiate in thought between Gödel and many other eminent logicians. (A Fregean \*'sense' is supposed to provide just such identifying information about, or a 'mode of presentation' of, its reference.)

For Kripke, proper names are \*rigid designators—in which respect they differ from (most) definite

descriptions—and their reference is secured not by some 'sense' which a speaker attaches to them, but rather by an external causal chain linking the speaker's use of a name to an original 'baptism' in which the name was first assigned to a certain individual. As the name is passed on from speaker to speaker, all that is required for a later recipient of the name to use it successfully to refer to the individual originally named by it is that each speaker in the chain should use it with the intention to refer to the *same* individual as it was used to refer to by the speaker from whom he received the name. However, this so-called causal theory of reference is not without its difficulties; for instance, Gareth Evans has argued that it cannot accommodate some of the ways in which names *change* their reference over time.

The Kripkean account of proper names (and natural-kind terms) as rigid designators is linked to certain metaphysical doctrines of an essentialist character—such as the theses of the necessity of identity and of origin—because of the ways in which such names are thought to behave in modal contexts. For instance, it is held that, given that George Orwell is Eric Blair, George Orwell *could not* have been different from Eric Blair—though this impossibility is a posteriori rather than a priori. Similarly, given that George Orwell was in fact born of certain parents, it is held to be an a posteriori \*metaphysical necessity that he was born of just those parents.

**names, fictional:** *see* fictional names.

**names, logically proper:** *see* logically proper names.

**narrative.** A narrative in its widest sense is a representation of a sequence of events between which there is some connection. In this wide sense, a film, for example, can count as a narrative, even in the absence of an explicit narrator. Not every representation counts as a narrative, however. A minimal criterion is that the represented events exhibit some temporal order. The sentence 'Lucy is wearing pink today' thus fails on this criterion to be a narrative. But mere temporal structure is not sufficient. Consider the following: '833: Two comets appeared. 834: In this year Bishop Wulfstan passed away. 835: There were great floods.' This is simply a chronicle of events. In a true narrative, the represented events should exhibit some causal connectedness, making each event more intelligible than it would be if reported in isolation, or as part of a mere chronicle. Within this broad category we can go on to distinguish historical from fictional narrative.

The concept of narrative has of course great interest and importance for literary theorists, but it has also been of interest to philosophers. It has, for example, been used by Alasdair MacIntyre to express the way in which a human life is a structured, unified whole, and not simply a series of discrete events. Human actions are made

intelligible though being part of a narrative. (This is in marked contrast to the view expressed in Sartre's *Nausea*, that any narrative misrepresents human life, which in reality is unstructured and has no *denouement*.) Philosophies of action that attempt to isolate what are sometimes called 'basic actions' that are considered simply as behaviour that is the outcome of an intention, and then analyse agency in terms of such actions, thus run the risk of providing an unduly artificial and idealized picture of what intentional action consists in. The point can be put in ethical terms: in so far as we construct our ethical theory from consideration of actions, choices, and situations that are abstracted from any wider narrative that would give them meaning, that theory will be correspondingly impoverished.

The link between narrative and our understanding of \*time has been explored within the continental tradition by Paul Ricœur.

**nasty, brutish, and short.** '... and which is worst of all, continual fear, and danger of violent death; and the life of man, solitary, poor, nasty, brutish, and short' (*Leviathan*, I. xiii. 9). This is one of Hobbes's most memorable phrases and comes at the end of his description of what life is like in the \*state of nature when 'men live without a common power to keep them all in awe'. This powerful description, like everything Hobbes writes on moral and political matters, has as its goal the attempt to persuade people to obey the law and thereby to avoid civil war. For civil war leads to the state of nature with all of the horrors mentioned in the above quote.

B. G.

**national and regional philosophies:** see African; American; Australian; Canadian; Chinese; continental; Croatian; Czech; Danish; English; Finnish; French; German; Greek philosophy, modern; Indian; Irish; Islamic; Italian; Japanese; Korean; Latin American; Netherlands; New Zealand; Norwegian; Polish; Russian; Scottish; Serbian; Slovene; Spanish; Swedish.

**national character.** From the time of Vico, it has been widely held that \*human nature develops through history, with pervasive patterns of thought and behaviour in any one group of people distinguishing it from others. What, then, gives the language, culture, and collective experience of a group its particular identity? For Herder, to whom the very term \*nationalism' is attributed, it was the soul of the nation to which the group belonged. He argued, against liberal universalism, that an individual could develop spiritually only within a national community, though, unlike Fichte, he did not think any one nation favoured over the rest. Recognizing the cultural significance of national character and history need not be militaristic or supremacist or

based on race. But, if not tempered by a substratum of timeless and universal values, it can, as demonstrated in Herder himself, lead to the relativistic conclusion that the values of different nations are incommensurable, and criticizable only from within.

A. O' H.

\*conservatism; people, the.

Isaiah Berlin, *Vico and Herder* (London, 1976).

**nationalism.** A doctrine which holds that national identity ought to be accorded political recognition, that nations have rights (to autonomy, \*self-determination, and/or sovereignty), and that the members of the nation ought to band together in defence of those rights. Nationalism can be distinguished from, though it is often in practice indistinct from, chauvinism, which makes one's own national identity the overriding moral-political consideration. The theoretical distinction here runs parallel to the distinction between individualism and egoism, and it can be elucidated in the following way: national rights (like individual \*rights) are properly reiterated for each newly arriving nation (individual). Hence, the limits of these rights are necessarily fixed by the rights of the nation that comes next. Chauvinism, by contrast, acknowledges no limits except those dictated by national interest. It is entirely possible, then, to be a liberal nationalist, defending the rights of nations other than one's own and seeking negotiated settlements, compromises, even in disputes involving one's own. But this position is relatively rare in political life or, better, it is a position that seems to erode rapidly whenever the disputed issues touch upon (what are taken to be) vital national interests.

As an \*ideology of identity, attaching political significance to the history and culture of an *ethnos* or \*people, nationalism is a modern phenomenon, though it is not without precedents and parallels in the ancient world. Similarly, nations, conceived as groups whose members are prospective nationalists, are modern creations, politically fashioned out of diverse social materials. Citizenship, religious faith, common language, some defining historical experience: all these in some cases, any one of them in others, have played a formative part (or, in another version of the story, have been exploited by publicists and politicians) in shaping national identity. The resulting nationalisms differ among themselves—more political and open, more ethnic and exclusive—depending on the achieved shape. But it does not appear that national rights are dependent in a similar way. They must be (like individual rights again) the same for all nations that are prepared to recognize their limits.

**natural.** Belonging to or concerned with the world of \*nature, and so accessible to investigation by the natural sciences. 'Natural' may be contrasted with various terms, such as 'artificial', 'unnatural', 'supernatural', 'non-natural'. The first three of these occur in ordinary language, though 'unnatural' in particular leads to problems about its real meaning. But 'non-natural' is a philosopher's term, and (with 'non-naturalistic') is the usual contrast term to 'natural' or 'naturalistic' in philosophy. Roughly it refers to what cannot be studied by the methods of the natural sciences, or defined in terms appropriate to them, and is applied to subject-matters that are essentially abstract, or outside space and time. A famous use of it was made by G. E. Moore, who applied it to the term *good*, which he regarded as indefinable.

A.R.L.

\*naturalistic fallacy; naturalism.

G. E. Moore, *Principia Ethica* (Cambridge, 1903), sects. 5–14, 'Natural' and 'Non-natural'.

**natural aristocracy:** see aristocracy, natural.

**natural deduction.** A method of formalizing logic, introduced independently by S. Jaśkowski in 1934 and Gerhard Gentzen in 1935. All previous mathematical logicians—including Frege, Russell and Whitehead, Hilbert, and Heyting (\*intuitionism, mathematical)—had formalized logic axiomatically, their method being modelled on the misleading analogy of formal \*theories. In these formalizations, certain logically valid formulae were assumed as axioms, from which a minimum of rules of derivation preserving logical validity yielded the rest. This older method required *ad hoc* definitions of derivability from a set of premisses (since not all rules of derivation preserved truth under a given interpretation of the schematic letters); it often demanded much ingenuity to obtain the formal \*theorems. Worse, it concentrated philosophical and logical attention on the notion of \*logical truth in place of that of logical consequence.

By contrast, a natural \*deduction system has no \*axioms, but only rules of \*inference, thus placing the emphasis where it belongs, on the relation of logical consequence from premisses to conclusion, and making a formalized deduction resemble far more closely the reasoning used in ordinary life. A formula representing one of the premisses of a deduction can be introduced at any stage; its introduction requires no justification. The price of dispensing with logical truths assumed axiomatically is that the rules must include some that 'discharge' hypotheses. One such rule is \**reductio ad absurdum*: under this, not-*A* can be asserted as following from a set  $\Gamma$  of premisses if a contradiction has been derived from  $\Gamma$  together with *A* as hypothesis; a hypothesis, like a premiss, may be introduced at any stage. The use of such rules makes it necessary to keep track of the hypotheses on which each line of a deduction depends. In order to do this, these lines may be shown as *sequents*—pairs  $\Gamma : A$  consisting of a finite set  $\Gamma$  of formulae and another formula *A*; the introduction

of a premiss or a hypothesis is then displayed as a *basic sequent* of the form  $A : A$ . No formal distinction between premisses and hypotheses is needed: a premiss of the whole deduction is simply a hypothesis that is never discharged, but is among those on which the final conclusion depends.

In a natural deduction system, the rules governing the logical \*constants are divided into *introduction rules* and *elimination rules*. An introduction rule allows the derivation of a formula with the given constant as principal operator from premisses in which it does not occur essentially; an elimination rule allows an inference from such a formula, perhaps together with additional minor premisses. Thus the introduction rule for  $\&$  allows the derivation of  $\Gamma : A \& B$  from  $\Gamma : A$  and  $\Gamma : B$  and the elimination rules allow the derivation of  $\Gamma : A$  or of  $\Gamma : B$  from  $\Gamma : A \& B$ . As this example shows, the rules are very natural and simple, and it is usually very straightforward to devise a deduction of a given conclusion from premisses from which it follows. Logically valid formulae fall out as a by-product, being those formulae deducible from, or as depending on, no premisses at all.

M.D.

\*normalization.

Dag Prawitz, *Natural Deduction* (Stockholm, 1965).

**naturalism.** In general the view that everything is \*natural, i.e. that everything there is belongs to the world of \*nature, and so can be studied by the methods appropriate for studying that world, and the apparent exceptions can be somehow explained away. In central philosophy the term has been applied in two main ways, both stemming from the above definition, one more general and the other more particular.

The more particular one is \*ethical naturalism, which is concerned with rejecting \*non-natural properties in that sphere and rejecting the idea that ethics is a *sui generis* subject which involves special methods of argument.

The more general application is to philosophy as a whole, and again involves both the objects studied and the methods used in studying them, i.e. both metaphysics and epistemology. In metaphysics naturalism is perhaps most obviously akin to \*materialism, but it does not have to be materialistic. What it insists on is that the world of nature should form a single sphere without incursions from outside by souls or spirits, divine or human, and without having to accommodate strange entities like non-natural values or substantive abstract \*universals. But it need not reject the phenomena of consciousness, nor even identify them somehow with material phenomena, as the materialist must, provided they can be studied via the science of psychology, which can itself be integrated into the other sciences. One naturalist in fact, Hume, was rather ambivalent about whether there was really a material world at all, except in so far as it was constructed out of our experiences, or impressions and ideas, as he called them. The important thing for the naturalist in the metaphysical sphere is that the world should be a unity in the sense of

being amenable to a unified study which can be called the study of nature, though it may not always be easy to say what counts as a sufficient degree of unification. Obviously there are different sciences, which to some extent employ different methods as well as studying different subject-matters. What seems to be needed is that they should form a continuous chain, and all be subject to certain general requirements regarded as necessary for a science as such, like producing results which are amenable to empirical testing. Whatever entities such sciences come up with must then be allowed into the naturalistic framework, and these will include 'theoretical' entities which cannot be directly observed, but whose existence is postulated to explain various phenomena, such as the electrons of physics, whether this existence is taken to be real or only 'logically constructed' in the way in which the average man is logically constructed out of ordinary men.

But the main thrust of naturalism is probably best taken to be epistemological. Throughout most of the twentieth century, in particular, and for at least part of the nineteenth, epistemology was taken to be the study of how we can properly come to have knowledge of the world around us, or indeed of anything else for that matter, the emphasis being on the 'properly'. How people do think has been taken to be the subject of empirical psychology, and no doubt most of us think in atrocious ways at times, but that seems irrelevant to how we ought to think if we are going to find out about the world effectively. A stock question for philosophers is 'How do you know?', and on the face of it it can be given two kinds of answers. We might simply offer a historical or biographical account of how we came by the belief in question, or, if the 'we' is not an individual but a, or the, scientific community, then an account of the relevant part of the history of science up to the time in question. But this may seem an irrelevance. The question was not 'Why do you believe?' but 'How do you know?', and the questioner probably has in mind the further question 'Why should I believe?' But if so, he wants a justification for believing, and how could a mere history of somebody else's belief give him that? Similarly, in ethics, if I ask for a justification for thinking some things to be morally wrong I shall not be very impressed if I am simply told how our moral sense grows out of childhood fears of parental authority. If anything, I might take that to undermine the belief and show it to be illusory (though it would not in fact do the latter, since there is nothing to stop us holding the right beliefs for the wrong, or even no, reasons). For this sort of reason a vigorous reaction occurred towards the end of the nineteenth century against naturalism, especially in its epistemological form, often called \*psychologism, though to some extent in its metaphysical form too, notably in Moore's rejection of the \*'naturalistic fallacy' in ethics, which involved him in denying that values, and *good* in particular, formed a *sui generis* class of entities, whose presence could not be empirically observed or inferred but could only be detected by some special intuition. Logic in particular was to be purified from any contamination by psychology, and the epistemological writings of

philosophers like Locke, Hume, and J. S. Mill were often regarded as asking the wrong questions. (Though it should be added that Hume himself was responsible for what has become in the twentieth century a famous attack on one form of the naturalistic fallacy, albeit a form more on the metaphysical side of the fence, since it consisted in connecting certain ethical and metaphysical notions; Hume wanted to disconnect the ethical ones—though, some might say, only to reconnect them in a different way with certain psychological ones.)

However, this purist attitude, though dominant for much of the twentieth century, has also sparked off a certain reaction to itself, largely through despair. \*Empiricism tends to move towards extremism in its attempts to beat off the ever-present challenge of the sceptic, the extremism appearing because of the concessions it is forced to make. How can we really know anything except perhaps a few things we are immediately confronted with? In particular, how can we justify the belief we all have in the ordinary world of common sense outside us? Here we return to Hume again, who in what might seem a final capitulation to the sceptic decided that we could not. What we could do, he thought, was to show that it was impossible—psychologically impossible—to take the sceptic seriously once we leave the philosopher's study. In order to do this, starting from his extreme empiricist base, he elaborated an account of how we (or he himself—but for convenience of exposition he takes the existence of other people for granted at this point) do in fact come to think in terms of an external world. No one would complain at this as a programme in its own right. What is controversial, and is rejected by anti-naturalists, is the claim that this is all that can be done in the face of the sceptic, or, even worse, the claim that this somehow is a justification of our knowledge. The twentieth-century reaction in favour of naturalism really took the form of a repeat performance of Hume's enterprise, though put in the terms of a later framework of thought.

Following the title of a famous article by Quine this programme is now known as \*'naturalized epistemology'. It can take a moderate or an extreme form. The extreme, and less common, form abandons all hope of justification and in effect amounts to a philosophy of 'anything goes': whatever the scientists, or the astrologers, do, we must simply describe or analyse it, and leave it at that—a policy with echoes outside philosophy of science in the mid-twentieth century \*linguistic philosophy ushered in by Wittgenstein.

The moderate form does not abandon all hopes of justification, but claims that the history of a scientific theory is not irrelevant to its justification. (Twentieth-century naturalism in both its forms tended to concentrate on science as the most disciplined and self-conscious area of human reasoning.) The main reason for this appeal to history is that we cannot break free from the context in which our thought arises. We must start from where we are. We may pass judgements on a theory or procedure, it is thought, but to ignore its content—what *could* have been

known at the time in question etc.—and demand some exercise in pure thought starting from nothing is to cry for the moon. The issue remains open. To what extent is it worth trying to construct a pure logic of inquiry if it could only be applied in ideal circumstances to which we can never attain? But there is in any case some connection of thought with \*reliabilism, since on that view in order to decide whether a certain belief amounts to knowledge we must ask not about the reasons that the belief's holder can produce for it but about the method by which the belief was reached, and whether that method has in fact proved to be a reliable method in other cases—in other words we must ask about the actual history of the method and about its success-rate.

In aesthetics 'naturalism' refers not so much to an aesthetic theory but to a movement in art associated particularly with the nineteenth century and related to that called realism; it claimed that art or literature should aim to represent the world as it is in itself, in ways that will appeal to our aesthetic feelings or draw our attention to aspects that we might have overlooked, but without distorting it in order to produce special effects, as Turner tried to do in the case of light, or appealing to certain standard conventions concerning the representation of attributes, as in medieval iconography, or introducing conventions of the artist's own, as in symbolist poetry, or in general deliberately representing the world otherwise than as one would normally take it to be. Naturalism in this sense is also of course to be contrasted with abstract art, as represented by, say, Mondrian.

**naturalism, biological:** *see* biological naturalism.

**naturalism, ethical.** The views that (i) ethical terms are definable in non-ethical, natural terms, (ii) ethical conclusions are derivable from non-ethical premisses, (iii) ethical properties are natural properties. A 'natural' term or property is one that can be employed or referred to in natural scientific explanations. Version (i) was attacked by G. E. Moore for committing the \*naturalistic fallacy. 'Good' could not mean, say, 'pleasurable', since it is an open question whether what is pleasurable is good. Emotivists and prescriptivists object that ethical terms have non-reducible 'attitudinal' content. (\*Descriptivism.) Version (ii) is open to Hume's 'is' and 'ought' objection: valid 'ought' conclusions require an 'ought' in at least one premiss. (\*Fact–value distinction.) Version (iii) is criticized by non-naturalists such as Wiggins for \*scientism—the claim that genuine properties must be scientific. R.CRI.

\*emotivism; prescriptivism.

G. Harman, *The Nature of Morality* (Oxford, 1977), ch. 2.

G. E. Moore, *Principia Ethica* (Cambridge, 1903), chs. 2–3.

**naturalistic fallacy.** G. E. Moore (*Principia Ethica* (1903)) argued that no matter what definition of 'good' is proposed (e.g. as what satisfies desire, maximizes happiness, or furthers evolution), it can always be asked, 'But is that good?' The question always remains open, and never becomes trivial. 'Good' resists definition or analysis: and the attempt to pin it down to an invariable, specific content is, in Moore's phrase, the 'naturalistic fallacy'.

Moore was concerned to retain an objectivist position over judgements about \*good. If these could not refer to natural properties (he argued), they must refer to \*'non-natural' ones. It is questionable, however, whether objectivism needs such a concept, and whether 'non-natural' can be defended from emptiness. R.W.H.

\*open question argument.

Bernard Williams, *Ethics and the Limits of Philosophy* (London, 1985), ch. 7.

**naturalized epistemology.** Whereas traditional epistemology is concerned with analysing the concepts of knowledge, justification, etc., and with explaining what should count as good reasons for forming and retaining beliefs, proponents of naturalized epistemology think that the theory of knowledge is a branch of the scientific enterprise. Such theorists deny that we can find a fixed point outside science from which to scrutinize the credentials of our beliefs and the tenability of our practices of acquiring knowledge. Naturalized epistemology sees itself as concerned primarily with exploring the mechanisms by which perceptual information about the world is transformed into the complex edifice of scientific and everyday knowledge. The naturalized approach to epistemology goes hand in hand with a rejection of the traditional distinction between \*analytic and synthetic statements. Naturalized epistemologists tend to be externalists about justification, holding that what makes a belief justified is the overall reliability of the mechanisms that generated it. J.BER.

\*naturalism.

H. Kornblith (ed.), *Naturalizing Epistemology* (Cambridge, Mass., 1985).

**natural kind:** *see* kind, natural.

**natural law.** Moral standards which, on a long-dominant but now disfavoured type of account of morality, political philosophy, and \*law, can justify and guide political authority, make legal rules rationally binding, and shape concept-formation in even descriptive social theory.

The sounder versions (e.g. of Plato, Aristotle, and Aquinas) consider morality 'natural' precisely because reasonable (in an understanding neither consequentialist nor Kantian). Likewise, contemporary versions plead not guilty of the 'is–ought' fallacy: natural law's first (not yet

specifically moral) principles identify basic reasons for action, basic human goods which are-to-be (ought to be) instantiated through choice. Practical knowledge of these presupposes, but is not deduced from, an 'is' knowledge of possibilities; full 'is' knowledge of human nature is partly dependent on, not premiss for, practical ('is-to-be') understanding of the flourishing (including moral reasonableness) of human individuals and communities. J.M.F.

\*good; well-being; 'is' and 'ought' Pufendorf.

John Finnis (ed.), *Natural Law* (New York, 1993).

**natural or scientific laws:** see natural or scientific.

**natural rights.** Human rights, as articulated in a moral or political theory of \*natural law. Of high philosophical and historical interest is the still inadequately understood linguistic and conceptual transformation of the Roman term *ius* from its primary sense (roughly, what is right, just, lawful) to its late-medieval and modern sense: a power, liberty, immunity, or claim—i.e. a right (in justice or law) relationship between persons articulated precisely from the standpoint of the relationship's *beneficiary*. This terminological specialization facilitates understanding of the wrong in abuse of one person by another: its unreasonableness (e.g. violation of the \*golden rule, or choice precisely to damage a basic human good) not only deforms the agent, but also offends the victim's fundamental equality of human dignity, in a respect specified in the natural right thus violated. J.M.F.

John Finnis, *Natural Law and Natural Rights* (Oxford, 1980).

**natural theology.** The acquisition of truths about God through the natural human capacity to know, rather than by \*revelation. The study of God through the exercise of human reason, especially as legitimated by Romans 1: 18ff. Natural theology includes the study of God through his works and the drawing of conclusions about God from premisses about creation. All putative proofs of the existence and nature of God belong to natural theology.

Kant and the Logical Positivists think natural theology impossible, Kant on the ground that the transcendent misuse of the categories generates contradictions, the Logical Positivists partly on the Humean ground that there is no valid inference from empirical premisses to transcendent conclusions, but also on the ground that the sentences of theology are without meaning because in principle unverifiable. Aquinas takes the view that human reason provides only a limited perspective on reality, which needs to be supplemented by faith. Faith is by \*grace. s.p.

Aquinas, *Summa Theologiae* (London, 1963–75).

David Hume, *Dialogues Concerning Natural Religion*, ed. Norman Kemp Smith (Indianapolis, 1962).

*Immanuel Kant's Critique of Pure Reason*, tr. Norman Kemp Smith (London, 1978).

**nature.** As with a very large number of concepts important to philosophers, 'nature' is a term with various meanings. Three seem especially worthy of note.

First, by 'nature' we mean everything that there is in the physical world of experience, very broadly construed. The universe and its contents, in short. To be natural is to be part of this world, and its distinguishing feature is usually taken to be the universal action of \*laws, meaning unbroken regularities. For philosophers like Plato, as well as for those standing in the Christian tradition, the Creator necessarily exists outside his creation, although able to intervene miraculously in it. A matter of some dispute has been the question whether nature, as God's creation, is thereby necessarily good. If this be so, how then do we account for the apparent existence of evil in the world? Well known are such saving explanations as that based on the effects of human \*freedom.

It is not altogether easy to maintain a reasoned belief in a dimension of existence beyond nature considered in this broad sense. Almost by definition, such a supernatural world has to be unknowable, and if (as in the Thomistic tradition) one attempts to achieve understanding through analogy, the temptation is to slide into a description of a state which seems remarkably like our own. For instance, even though God may be outside our law, does this mean that he is outside law altogether? Many have thought not, and this has proven a slippery slope, as was the case for the \*Naturphilosophen, who started by seeing God's patterns being repeated through the world, inorganic and organic, and who ended with something close to pantheism, identifying God with his creation. Thomas Carlyle's 'natural supernaturalism', taking the change of office into water to be miraculous, speaks to the confusion.

The second sense of 'nature' identifies with the living world (past and present) as opposed to the non-living. It is such a distinction that one intends when one speaks of a museum of *natural* history. The burning philosophical problem here is chiefly that of definition and demarcation. Today we think that the world of organisms is the product of \*evolution, beginning (on our earth) almost four million years ago. Does this then mean that we can distinguish a mammal from a lump of rock only in terms of their respective histories, or will there be essential defining characteristics of the living which set the two aside?

From Aristotle on it has been argued that organisms are distinguishable from the inert world by virtue of the fact that they possess some sort of life force—most recently called the \*entelechy' by the vitalist Driesch. However, although it is true that organisms manage to do some remarkable things—for instance, sustaining themselves by taking in energy from the outside—it is not easy to see how an explanation of such facts as these is aided by reference to unseen vital powers. Modern opinion therefore inclines to the belief that the distinguishing mark of the organic lies in its high degree of organization rather than anything physical as such.

To the Darwinian, as to the natural theologian, the mark of such organization is that it sustains 'adaptation', whereby the features of organisms promote the survival and reproduction of their possessors. It should be noted that, although this may all be of value to the individual

organism, in a world which has produced the AIDS virus it is not immediately obvious that because something is living it thereby inherently possesses absolute value. Many—from Plato to the socio-biologist Edward O. Wilson—believe nevertheless that value does emerge from the living world, because organic organization permits an ordering according to some scale of progress. However, especially inasmuch as this progress is linked to evolution, there are as many who are adamant in their opposition.

The third sense of 'nature' is that which sees everything, especially the organic world, set off against humans and the consequences of their labours. It is this sense which is being invoked when breakfast cereals are described as 'natural', and the real point of philosophical controversy arises over whether one should argue that it is nature in its raw pristine state which is truly good and worth while, or if one should argue that it is only inasmuch as nature has been altered and cultivated by humans that true worth appears. Although the organic-food industry thrives on the first disjunct, there have been many ready to endorse the second. To John Stuart Mill, for instance, it was clear that 'the very aim and object of action is to alter and improve Nature'.

Perhaps the best way out of this seemingly insoluble dilemma is to recognize that, as with those who have tried to characterize \*human nature, the very attempt to draw the distinction is to invite sterile disputes. Although the science of ecology is still at a relatively primitive state, it is very clear that interference in one part of nature (in the present sense) is liable to have unexpected and unwelcome consequences elsewhere. But not to interfere is no less liable to be disastrous, especially if the animal side of \*human beings is included in this conception of nature and only our intellectual abilities are excluded and barred from taking action.

**Naturphilosophie.** Generally associated with the philosopher Schelling, *Naturphilosophie* was a widely supported although much derided general view of \*nature, popular in Romantic German circles at the beginning of the last century. Owing much to Kantian \*idealism, with a generous dash of \*Platonism, the *Naturphilosoph* saw the whole of reality underpinned by certain basic archetypes, which have ever more perfect manifestations as one moves up the chain of being. Significant in such areas as the newly developing theory of electricity, *Naturphilosophie* made its greatest impact in the biological sciences, especially through such notions as the vertebrate theory of the skull,

where one sees all the bones of the mammalian body as variations on one theme, namely that of a typical piece of the backbone. Even in today's biology, there are whispers of *Naturphilosophie*, especially through such claims as that of the American evolutionist Stephen Jay Gould that the key to understanding animal form is the repetition and modification of certain shared blueprints or *Bauplane*.

**necessary and contingent existence.** Entities are held to exist necessarily if \*natural processes will not lead to their cessation, contingently if such processes will lead to their cessation. The distinction stems from Plato, who, concentrating on the contrast with mathematical and other abstract entities, emphasized the corruptibility of ordinary spatio-temporal objects. Aristotle provided a physics which accounts for and indeed requires such (sublunary) corruptibility, and the distinction was famously utilized by Aquinas in the third of his five ways. By the later Middle Ages a number of such necessarily existing entities were known, such as human souls, angels, demons, the 'heavenly luminaries', and God, who, unlike the others, does not have his 'necessity from another'. In this sense of 'necessary' there is no entailment from 'X has necessary existence' to 'Necessarily, x exists'.

J.J.M.

Patterson Brown, 'St Thomas' Doctrine of Necessary Being', *Philosophical Review* (1964); repr. in A. Kenny (ed.), *Aquinas: A Collection of Critical Essays* (London, 1969).

**necessary and sufficient conditions.** If a \*conditional of the form 'If *p*, then *q*' is true, then the state of affairs expressed by *p* is said to be a sufficient condition of the state of affairs expressed by *q* and, correlatively, the state of affairs expressed by *q* is said to be a necessary condition of the state of affairs expressed by *p*. If the conditional in question is true of logical necessity, as in the case of 'If this table is round, then it is not square', then we may speak of *logically* necessary and sufficient conditions. Weaker conditionship relations are expressed by correspondingly weaker conditionals—for instance, the conditional 'If this match is struck, it will light' implies that striking this match is, in the circumstances in which the conditional is asserted, a *causally* sufficient condition of the match's lighting.

**necessitarianism:** see determinism.

**necessity:** see causality; contingent and necessary statements; natural or scientific laws; necessary and contingent

existence; necessary and sufficient conditions; necessity, epistemic; necessity, logical; necessity, metaphysical; necessity, nomic.

**necessity, epistemic.** Sometimes the modal auxiliaries 'must' and 'may' appear to be used in an epistemic sense to express, respectively, what is entailed by and what is consistent with what a thinker knows. Thus, someone who knows that a train is due but has not yet arrived may assert 'It must be late', and one who knows that it is due but does not know whether it has yet arrived may assert 'It may be late'. Epistemic necessity is often expressed in terms of \*certainty, as in 'The train is certainly late'. E.J.L.

\*knowledge.

A. R. White, *Modal Thinking* (Oxford, 1975).

**necessity, logical.** In the narrowest sense, what is logically necessary is what follows from the laws of logic alone (though there is some debate over what those laws are). Thus, a statement like 'Either it will rain or it will not rain' expresses a logically necessary truth, because it is an instance of the law of excluded middle. Again, 'If all men are mortal and Socrates is a man, then Socrates is mortal' expresses a logically necessary truth, because in standard logic if we may deduce the consequent of a \*conditional from its antecedent, then the truth of the conditional follows from the laws of logic alone.

A sentence expressing a logically necessary truth, in this narrow sense, is true solely in virtue of its logical form: the meanings of any non-logical terms which it contains are irrelevant to its status as expressing a logical necessity. Thus 'Either it will rain or it will not rain' expresses a logically necessary truth because it has the logical form 'Either  $p$  or not  $p$ '. However, in a wider sense a sentence may be said to express a logical necessity if, although not itself a sentence true solely in virtue of its logical form, it may be transformed into such a sentence by replacing certain terms in it by other, definitionally equivalent terms. For example, 'All bachelors are unmarried' does, in this wider sense, express a logically necessary truth, because 'bachelor' may be defined as 'unmarried man', and 'All unmarried men are unmarried' is true solely in virtue of its logical form. In this wider sense, logically necessary truths are often identified with \*analytic truths.

In a still broader sense, a logical necessity may be characterized as a proposition which is true in every \*possible world, without restriction—that is to say, in every *logically* possible world, the assumption being that every such world is at least a world in which the laws of logic hold. This is sometimes called 'broadly' logical necessity and is assumed to conform to the principles of a system of modal logic known as S5, first formulated by C. I. Lewis. In that system—to give a simple example—if it is possible that  $p$ , then it is *necessarily* possible that  $p$  (because if proposition  $p$  is true in *some* possible world, then in *every* possible world it is true that  $p$  is true in some possible world. If the ontological argument is valid, then 'God exists' expresses a

logically necessary truth in this broad sense, because the argument can be construed as concluding that that sentence is true in every possible world.

It does not appear that 'God exists' could be said to express a logical necessity in either of the *narrower* senses previously mentioned, for at least two reasons. First, it is clear that 'God exists' is not a sentence which is true solely in virtue of its logical form—and it is doubtful whether the term 'God' could be replaced by a definitionally equivalent term, since 'God' appears to be a proper \*name. Secondly, it is very arguable, in any case, that no \*existential proposition follows from the laws of logic alone. Broadly logical necessity seems to be closely akin to \*metaphysical necessity, though the latter is, in general, assumed not to be knowable \*a priori. E.J.L.

\*modal logic.

A. Plantinga, *The Nature of Necessity* (Oxford, 1974).

W. V. Quine, *From a Logical Point of View*, 2nd edn. (Cambridge, Mass., 1961).

**necessity, metaphysical.** The notion that there is a kind of objective necessity which is at once stronger than physical necessity and yet not simply identifiable with \*logical necessity owes much to the work of Kripke. Logically necessary truths are, it seems, knowable a priori, but Kripke argues that metaphysical necessity is, typically, only discoverable a posteriori—that is, on the basis of empirical evidence. For instance, Kripke holds that if an identity statement like 'Water is  $H_2O$ ' is true, then it is *necessarily* true—in the sense that it is true in every \*possible world in which water exists. However, plainly, we can only know that water is  $H_2O$  on empirical grounds, through scientific investigation—and we *might* be mistaken about this. It is vital, then, not to confuse metaphysical necessity with epistemic necessity. E.J.L.

S. A. Kripke, *Naming and Necessity* (Oxford, 1980).

**necessity, nomic.** The world of experience seems to be understandable and user-friendly primarily because it is reliable, in the sense that it is regular. This is not to say that everything happens in the same way on every occasion. Some people die of lung cancer, some do not. But underlying the contingent happenstances of existence there seems to be order and regularity. The world runs according to rules or laws. Moreover, for all that these laws lead to different effects, it seems to us that in themselves they are *necessary*. It is not mere chance that water boils when it is heated, any more than it is chance that blue-eyed parents tend to have blue-eyed children or that spring follows winter as winter follows autumn.

Wherein lies the source of this necessity? For Plato it lay in the relations between the Forms, and thus had at least the status of mathematical and logical necessity. For Christian philosophers, down to and beyond Descartes, it was a consequence of God's power and goodness, and our

ability to recognize it (given the right precautions and training) lay in the powers he had conferred on us. God could break this necessity at will, as he did whenever he decided to intervene miraculously in his Creation.

But sceptics, most notoriously David Hume, have challenged this presumption. They argue that there seems to be no logic to the necessity of experience. We may expect the sun to rise tomorrow, but (as Bertrand Russell pointed out) logically we are in no different position from the turkey who expects his lunch on Christmas Eve on the reasonable grounds that he has had such a lunch on every day previously. Things could go wrong at any time.

Yet this is not to deny such necessity—generally called ‘nomic’ (meaning ‘lawlike’) to distinguish it from other sorts of necessity, like ‘logical’. Nor that it does seem to be marked by its ability to bear counter-factual conditionals. Suppose someone asks if a particular sample of a metal is copper. You heat it and find that it melts at 1,000 degrees centigrade. Thus you reply: ‘This cannot be copper, because if it were, it would melt at 1083.4 degrees’. If there is no such necessity, there can be no such counter-factual.

Obviously, none of this explains nomic necessity or, perhaps more importantly, why we believe some claims about the world are thus necessary. With the coming of scepticism it has generally been realized that there does not seem to be something ‘out there’ guaranteeing that the world must run in a regular manner, and that even if God is maintaining his Creation, this in itself does not account for our feeling of necessity.

Famously, Kant tried to explain things in terms of our psychology, namely that it is we ourselves who put the necessity into our perceptions, thus ensuring that it ends up in our understanding. Trying to regain some of the old security, he argued also that, as rational beings, this is the way that we must think. The imputation of nomic necessity therefore becomes a condition of rational thought. But although many would agree with Kant about the psychology, fewer would go on to agree about the additional claim. In a world which has challenged the necessity of traditional mathematics as well as traditional concepts of causation, it seems rash to suggest that we must think in the ways that we have always thought.

One might argue that there can be no proof of nomic necessity and that therefore we should abandon it. This seems to be the position of Karl Popper, but most of us are not that convinced that one should throw out what seems to be a generally good guide to life. In any case, such advice is more easily given than followed. Can one or should one go through life pretending that every move into the future is a leap into the dark?

One seems therefore to be thrown back just on psychology, which was essentially the position of Hume. Frankly, you cannot justify your belief in necessity, but fortunately your nature makes you believe in it, and that is quite enough for human living. The one point where some today think that they can go beyond Hume is in showing that our conviction about necessity is surely linked to our evolutionary origins, and that those would

be ancestors who assumed necessity tended to outsurvive and outbreed those that did not. We may all be turkeys fast approaching Christmas Eve, but at least we are the descendants of those who had the biology to get through the summer.

**needs.** An organism’s (basic, fundamental) needs are what it requires to live the normal life of its kind—flourishing rather than merely surviving—and if a need is unmet, the organism will suffer harm. Applying this analysis to human needs raises three related questions. Are human needs objective? Are they distinguishable from wants? Are they universal or culturally relative? It seems indisputable that human beings objectively and universally need air, water, food, and shelter, whatever cultural wants, desires, or preferences they happen to have. Objective human needs can plausibly be defined more abstractly as the necessary conditions for flourishing through the exercise of essential human capacities; in brief, physical and psychological health, and freedom. This account links needs to ‘human nature and naturalistic ethics. Needs are also the basis for an influential explanation of distributive justice.

**negation and double negation.** Negation is denial. When a person denies something, (1) her *act*, and (2) her *assertion* (i.e. what she asserts in so acting), are negations. (3) A *proposition*, even if not being used to assert anything, is the negation of another when it would, if asserted, deny—i.e. be the negation of—what the other would, if asserted, affirm. A negative particle or other expression, e.g. ‘not’, is one which can (amongst other things, and when suitably placed) take a sentence suitable for affirming something and transform it into a sentence suitable for denying the same thing. (4) The resulting negative *sentence* is also called a negation.

Is the negation of the negation of *A* equivalent to *A*? That depends on what denial is, and hence what negative particles mean. In logic the classical answer is ‘yes’, and accordingly operations of eliminating and introducing double negatives are permitted. Intuitionist logic disallows the elimination.

**neo-Confucianism.** A revival of Confucian philosophy in Sung dynasty China, distinguished by an interest in ontology prompted by influences from Taoism and Buddhism, and with a later efflorescence in Japan. The major figure was Chu Hsi (1130–1200), who developed a sophisticated philosophy according to which a dynamic universe results from the interplay of a supreme ordering principle (*t'ai ch'i*, or *li*) with a medium of matter–energy (*ch'i*). Chu Hsi's thought was developed with greater emphasis on ethical issues by Wang Yang-ming (1472–1529), who made the idea of the human heart–mind (*hsin*) foundational. Schools based on their teachings came to flourish in Japan, together with a movement known as the Kogaku ('ancient learning') school, whose primary representatives were Itō Jinsai (1627–1705) and Ogyū Sorai (1666–1728). Placing unprecedented emphasis on philological concerns, these thinkers led a return to the careful study of the earliest texts of the classical Chinese canon. G. R. P.

**neo-Kantianism.** Neo-Kantianism was a family of schools in \*German philosophy from about 1870 to about 1920. It was marked by repudiation of \*irrationalisms, speculative \*naturalisms, and \*positivisms. It was motivated by the conviction that philosophy can become a science (and not just a world-view) only if it goes back to the spirit of Kant, in whom epistemology was seen as propaedeutic to metaphysics and all other philosophical disciplines. There were, of course, many ways to understand and follow so complex a thinker as Kant, and the historian of philosophy Windelband was correct in saying that 'To understand Kant means to go beyond Kant.' So numerous were the philosophers who sought Kantian foundations for their diverse systems that historians cannot agree on how many neo-Kantian schools there were (two? seven?) or on which school to assign many philosophers to. In spite of (or, perhaps, because of) this diversity, neo-Kantianism was the

dominant philosophy in the Wilhelmine universities and it maintained this hegemony until phenomenology, positivism, and philosophy of life began capturing the best minds in the early twentieth century.

After the death of Hegel in 1831 Germany entered a period of philosophical sterility during which the flourishing natural sciences and their reflection in materialism and positivism reigned in the universities. Especially after the Revolution of 1848 the position of philosophy in the universities had become politically compromised. A few philosophers who attempted to maintain some traditional philosophical position (e.g. theism) or to develop their own philosophical system (e.g. Eduard von Hartmann) bowed in the direction of Königsberg. Outstanding among these proto-neo-Kantians was Hermann von Helmholtz (1821–94), the great scientist who gave a genetic, physiological account of sense-perception with empirical analogies to Kant's transcendental psychology. But there was no concerted effort to rehabilitate Kant; perhaps there were neo-Kantians, but no neo-Kantianism.

*Marburg neo-Kantianism.* In 1865 Otto Liebmann (1840–1912) published his *Kant and the Epigoni*, in which all the epigoni were accused of a common fault, the acceptance, sometimes disguised, of unknowable \*things-in-themselves. Each chapter of this manifesto closed with the epigraph: 'We therefore must go back to Kant!' This book was followed a year later by Friedrich Albert Lange's classic *History of Materialism*, in which Lange showed that there were Kantian epistemological foundations for materialistic science, but rejected the metaphysics of Kant's Dialectic and regarded all talk of unknowable supersensible things as mere fantasy. Lange became *ordinarius* in Marburg in 1872, and one year later he was joined by a student of Adolf Trendelenburg in Berlin, Hermann Cohen (1842–1918), who succeeded Lange upon his death in 1876. Thus was established the Marburg School.

Cohen began his career writing commentaries on Kant's three *Critiques*, and he expounded his own philosophy in three volumes corresponding to the three volumes of commentary. All six volumes tried to replace Kant's psychologicist theories (intuitions as passively received; thought as organizing intuitions; the creation of images, etc.) with Cohen's own understanding of the transcendental method. This method begins not with the facts of perception or self-observation, but with the fact (*Facta*) that science, ethics, and law exist as cultural products. Only that which the mind has conceptually established can be known a priori. Science is not the study of *given facts*—nothing is \*given (*gegeben*), says Cohen; 'all is assigned (*aufgegeben*) as a task' of producing categorially constituted scientific facts. Cohen interprets this production on the model of integration in mathematical knowledge. There is no thing-in-itself; but the *concept* of the thing-in-itself is essential as a limiting concept of the goal of knowledge approached asymptotically.

Paul Natorp (1854–1924), Cohen's disciple and successor, carried through investigations in the foundations

of post-Einstein physics; then he applied Cohen's transcendental method to psychology itself. In his *Platons Ideenlehre* (1902) he gave a Platonistic account of Kant's categories and transcendental ideas (or, alternatively, he Kantianized Plato's theory of Ideas). After Cohen's retirement Natorp became a more independent thinker, and the distance between Heidelberg and Marburg became noticeably less.

The last important representative of Marburg neo-Kantianism was Ernst Cassirer (1874–1945), who replaced the cognitive categories with a series of 'symbolic forms' which generate a priori structures not only in science but also in mythology, language, and politics.

*The Heidelberg School.* The Heidelberg School does not show the simple pattern (*Gestalt*) of the Marburg. In fact it is sometimes called the Baden or the South-West German School, since its masters were sometimes in the Universities of Zurich, Freiburg, and Strasbourg; the founding father of the school, Kuno Fischer, was for a time banished from Heidelberg. The long (1865–72), vituperative, and scurrilous controversy between him and Adolf Trendelenburg (Cohen's teacher in Berlin) over whether Kant had shown that space and time were only forms of intuition or also forms of things-in-themselves divided German philosophers into two camps, with adherents of both sides publishing more than fifty polemical papers on the quarrel. Köhnke wittily says: 'Just as in Charlottenburg, in Berlin, two parallel streets, a Kuno Fischer Strasse and a Trendelenburg Strasse lead to the Neue Kant Strasse, so the road to Neo-Kantianism led either through the school of Fischer or that of Trendelenburg' (*The Rise of Neo-Kantianism*, 170).

Kuno Fischer was pre-eminent as a historian of philosophy, and his influence was felt in the second and third generation of the Heidelberg School. Wilhelm Windelband (1848–1915), as a historian of philosophy, was the natural heir to Fischer, and Heinrich Rickert (1863–1936) was at his best in providing a philosophy of historiography. Windelband produced only one large work—his *The History of Philosophy* (still a classic)—and one must gather his systematic thoughts from scattered papers, or by reading Rickert, who had a more systematic mind than his master.

The basic fact with which Heidelberg neo-Kantianism begins is that there is a cognitive as well as an ethical imperative; logic is the ethics of thinking. The world is not as we perceive it, but as we *must* perceive it, where this *must* has the modality of ethical or more generally of a *Geltungs*-imperative (*Geltung* = validity). There is an absolute *ought* and *must* whose categorical structure we establish, and this is specified into truth, goodness, beauty, and holiness. Philosophy is the study of the validity (*Geltung*) of norms, universal rational necessities, and a priori forms of all culture.

Windelband's successor, Heinrich Rickert, likewise extended Kant's primacy of practical reason to theoretical philosophy. He interpreted valid norms as anchored in the a priori structure of a value-world (*Wertwelt*). Perhaps

Rickert's most important contribution was developing Windelband's distinction between the nomothetic sciences, which generalize (e.g. the natural sciences), and the ideographic sciences, which individuate (the historical and human sciences). Each has its own a priori categorical structure.

This hasty review of neo-Kantianism has had to omit many German philosophers who did not found, or did not belong in, any school, but whose contribution to an understanding and use of Kant in later philosophy was perhaps as great as that of the philosophers reported on here. We can only mention the most prominent names: Hans Vaihinger, Friedrich Paulsen, Aloys Riehl, Leonard Nelson, and Georg Simmel.

**Neoplatonism.** A later form of Platonic philosophy that had its primary development as a school of thought in the Roman Empire from the third to the fifth century AD. Countering dualistic interpretations of Plato's thought, it is a highly monistic version, namely, one that posits a superexistent Source of all being that extends itself into various lower levels of being, with each lower level being a weaker extended expression of the level just above it. Its founder was Plotinus (204–70), a Hellenized Egyptian who at the age of 40 established an academy of philosophy in Rome and taught in it for the next twenty-five years. Some of its basic tenets, however, likely came from his teacher, Ammonius Saccas (185–250), with whom he had studied philosophy in Alexandria for eleven years when he was a young man. The term 'Neoplatonism' itself is of fairly recent origin, going back only to the mid-nineteenth century when German scholars first used it to distinguish the views of the later Greek and Roman Platonists from those of Plato.

Plotinus saw himself as a latter-day disciple of Plato, and urged his Roman contemporaries to return to Plato's teachings. He wrote only one book, a series of fifty-four carefully reasoned philosophical essays composed over a period of fourteen years late in his life. His disciple, fellow teacher, biographer, and critic Porphyry (c.232–304) later edited and arranged them into a book with six divisions of nine essays each, called the *Enneads* (the Nines).

Although in the *Enneads* he always defers to Plato, Plotinus is very much aware of the teachings of Aristotle, and mentions Aristotle more times than he does Plato. More specifically, he is aware of Aristotle's objections to Plato and seeks to overcome them through his own revised version of \*Platonism, a version in which he endeavours to retain the basic teachings of Plato, but to reshape them in a new rational metaphysical system similar in type to the

metaphysical system of Aristotle. In this sense, he can be considered to be an Aristotelian Platonist, or even, as one scholar has suggested, a neo-Aristotelian. He also shows his knowledge of both Gnosticism and \*Stoicism and integrates some elements of the latter into parts of his own system. He was familiar with some of the purely mystical philosophies that flourished in the Roman Empire at the time, and presents his own philosophy as a strong form of rationalism in reaction to them.

In the *Enneads*, he affirms the same themes common to the general Platonic tradition, namely, (1) the non-materiality of the highest form of reality, (2) belief that there must be a higher level of reality than visible and sensible things, (3) preference for intellectual intuition over empirical forms of knowing, (4) belief in some form of immortality, and (5) belief that the universe is essentially good. The difference, however, is that Plotinus affirms all of these as a monist interested in asserting a real identity between the natural and the supernatural both in man and throughout all of nature.

In his metaphysics Plotinus sets forth his vision of the logical structure of all being and sees two movements running throughout the whole of nature, namely, the coming-out of all things from their original unitary source, and their subsequent return back to that source. He attempts to answer the primary question of Greek metaphysics 'How does the one become many?', by positing an Ultimate Being, the One, as supernatural, incorporeal, self-caused, absolutely free, and absolutely good. Since it is absolutely good it necessarily extends its goodness and power into all lower beings. Without any loss of any of its own essence, it projects itself into lower stages of itself to form lower and weaker beings. The first stage of this projection is \**Nous*, or Mind, and the second is *Psykhē*, or Soul, which in turn is a projection of *Nous*. All things in nature, namely, all life-forms and all corporeal beings, including man, are souls. As such they are both in a state of becoming and dependent upon *Nous* for the fixed orders of their being. Thus the one becomes many by the necessary extension (*proōdos*) of the One into lower, progressively weaker multiple phases of itself as the principles (*Nous*) and life-forms (*Bios*) of all natural things. The many, in turn, always seek to return to the one, for all natural things seek to return (*epistrophē*) to some higher unity as their source.

Most of the credit for the survival of Neoplatonism must go to Porphyry, Plotinus' successor in his academy. Porphyry differed from Plotinus on some points; and by denying some of the categories that Plotinus affirmed, and substituting for them some of Aristotle's categories, he created another type of Neoplatonism. As a matter of fact, his version of Neoplatonism later had a greater impact on the development of early European philosophy than did the Neoplatonism of Plotinus.

Other versions of early Neoplatonism also emerged in later centuries. One of Porphyry's students, Iamblichus (c.250–326), returned to his native Syria and founded the Syrian School around 300. The Pergamum School was

founded around 330 by Aedesius, a former student of Iamblichus. Its most famous member was the Roman Emperor Julian, called Julian the Apostate, who died in 363. The School of Athens was founded by Plutarch of Athens, at the end of the fourth century. Its most famous proponent was Proclus (410–85). Proclus is now regarded as the third most important Neoplatonist after Plotinus and Porphyry. His ploy was to use the concept of triads, or evolutionary development by triadic extensions, both vertically and horizontally to explain the interconnectedness of all things. This school continued in Athens until 529 when it was closed by decree of the Emperor Justinian.

One of Proclus' pupils, Ammonius, was instrumental in establishing the Alexandrian School in the fifth century, a school which lasted until the end of the sixth century. Among its members were Simplicius, Olympiodorus, and Hypatia, the famous female philosopher and mathematician who was pulled from her carriage and killed by a mob of Christians.

Both Plotinus and Porphyry rejected Christianity because of its personalistic brand of supernaturalism and doctrine of salvation by grace through faith. Porphyry even wrote a book entitled *Against the Christians*. But their rejection of Christianity did not prevent some later Christian philosophers from importing large elements of Neoplatonism into their own philosophies. Notable among these were: some of the Greek Church fathers, such as the Cappadocians, Basil and the two Gregories, the great Latin Church father St Augustine (354–430), Boethius (470–525), Eriugena (c.820–70), and St Thomas Aquinas (1225–74).

Marsilio Ficino's translation of the *Enneads* into Latin in 1492 introduced Plotinian Neoplatonism with its broader humanism into Italy and later into some other European countries. It was taken to England in the late 1490s by John Colet, who paved the way for the emergence in the seventeenth century of a group of English Christian Neoplatonists known as the \*Cambridge Platonists.

Certain medieval Jewish thinkers also imported elements of Neoplatonism into their philosophies. Notable among these were Isaac ben Solomon Israeli (850–950), Avicebrol (1020–70), and Abraham Ibn Ezra (c.1092–1167). Some Islamic philosophers did the same. Notable among them were al-Kindī (d. c.866), al-Fārābī (c.870–950), Avicenna (980–1037), and Averroës (1126–98). Neoplatonic themes may also be found in Meister Eckhart (1260–1327), in Nicholas of Cusa (1401–64), in most of the German idealist philosophers, in a few French philosophers, especially in Bergson, and in some British poets (Blake, Shelley, Keats). They also occur in Jonathan Edwards and Emerson and the \*New England Transcendentalists in America.

Neoplatonism emphasizes the necessity of both reason and experience in philosophy and sanctions the idea that human experience may even go beyond metaphysics on rare occasions. As a holistic form of thinking it can serve as a prototype for the production of some greatly needed forms of holistic philosophy for our own age. R. B. H.

**neo-pragmatism.** Recent philosophical movement embracing a radical form of social and practical contextualism that denies the possibility of universal conceptions of truth or reality. Neo-pragmatism emerged as a critical reaction to traditional and \*analytic philosophy. Building mainly on Dewey, Wittgenstein, Quine, and Sellars, Richard Rorty's *Philosophy and the Mirror of Nature* (1979) initiated a return to a \*pragmatism. Because all philosophical attempts to distinguish in principle between analytical and empirical, necessary and contingent, universal and historical, reality and fiction are taken to have failed, truth and meaning are taken to be nothing but moments of specific social practices. Philosophical questions, however, remain: How can the social pragmatist avoid self-refuting relativism? Is all social practice just 'coping with entities', regardless of whether these are objects or persons? And how about the ethical and political consequences of a 'frank ethnocentrism' (Rorty) that privileges one's own interpretative perspective without constraint? H.-H.K.

**neo-realism:** see New Realism.

**neo-Thomism.** 'Neo-Thomism' is an imprecise term applied since the nineteenth century to diverse authors, doctrines, procedures, and topics that have or claim to have some relation to the thought of Thomas Aquinas. Its origin is usually located in Pope Leo XIII's letter *Æterni Patris* (1879). The letter urges Catholic philosophers to demonstrate the existence and attributes of \*God and to combat the speculative and practical errors of modern philosophy by reappropriating the teachings of the major Christian writers from the European Middle Ages. Leo picks out as chief among these writers Thomas Aquinas, who is supposed to have unified in his teaching the best of patristic and medieval theology. While *Æterni Patris* did mobilize large-scale ecclesiastical support for a new \*Thomism, its programme had been worked out in Catholic educational circles during the previous four decades. For example, a number of thinkers in or about the Jesuits' Roman and German Colleges began in the 1840s and 1850s to advocate a systematic Thomism as the only philosophically adequate alternative to various modern \*empiricisms and \*idealisms. Among these thinkers were Matteo Liberatore and Joseph Kleutgen. If Liberatore represents the Italian side of the new movement, with its combative sense of philosophical system, Kleutgen brought to Rome from Münster and Fribourg an attention to the historical context for medieval thought. *Æterni Patris* ratified and institutionalized the labour of these and similar teachers.

Of course, by the date of *Æterni Patris* neo-Thomism was already beginning to break up into camps. These camps were partly determined by institutional arrangement and partly by avowed task or purpose. So, for example, the different religious orders maintained separate educational systems and tended to teach rather different versions of Thomism. Some orders were also concerned to promote their own medieval authors as alternatives to Thomas. The Franciscans regularly espoused Bonaventure or Scotus, while a few Jesuits taught from Suarez. Again, neo-Thomism from its inception was both exegetical and constructive or polemical. If it wanted to be considered Thomism, it had to ground itself in a historically sensitive reading of Thomas. If it wanted to be a neo-Thomism, it had to extract from Thomas principles or arguments useful in dispute with modern philosophies. By the early decades of this century there were neo-Thomists who were principally known as able interpreters of medieval thought and neo-Thomists who were principally known as builders of 'Thomistic' systems and debaters of modern doctrines. The interpreters would include Martin Grabmann, Pierre Mandonnet, and Maurice De Wulf; the builders and debaters, Réginald Garrigou-Lagrange and Désiré Mercier. Some neo-Thomists, most famously Étienne Gilson, were able to do both.

The principal neo-Thomists tend to be classified by their attachment to some particular theme or preoccupation. One persistent theme has been the engagement with epistemological questions raised by Kant and the neo-Kantians. This kind of neo-Thomism, called 'transcendental Thomism', is associated with Joseph Maréchal and Karl Rahner. A different kind of transcendental analysis, more driven by the concerns of experimental science, is offered in the Thomist writings of Bernard J. F. Lonergan. Another class of neo-Thomists is associated with questions in metaphysics and chiefly with expounding the Thomist doctrine about being (*esse*). Writers put into this class include Gilson and Jacques Maritain. But these classifications are at best a preliminary guide to complex authors, each of whom wrote on a wide range of philosophical topics.

The Roman Catholic Church's institutional support for neo-Thomism was much weakened during and after the second Vatican Council (1961–5). Since then, neo-Thomism has tended to become largely historical and to be submerged in the study of the history of medieval philosophy. M.D.J.

**Netherlands philosophy.** As one would expect of a philosophy within a culture which has always been so open to foreign influences, the Dutch philosophical tradition has given rise to many interesting variations on well-known

international movements. It is in many respects an ideal microcosm of Western European philosophical developments from the thirteenth century onwards.

Siger of Brabant (1240–81), as Dante realized when he placed him in the Fourth Heaven, and allowed Aquinas to characterize him as one of the noblest champions of Christian philosophy, left works which take us to the very heart of the thirteenth-century confrontation between Augustinianism and Aristotelianism. Arnout Geulincx (1624–69) provides us with a unique insight into the transition from Descartes to Spinoza.

If Dutch philosophy has been very open to foreign influence, it is also true that many Dutch thinkers have had at least a considerable influence upon European intellectual history. Spinoza is of course the outstanding case. (His influence on philosophy within the Netherlands, however, by contrast with that of Descartes, was minimal prior to the second half of the nineteenth century. Even then, it consisted of very little more than free-wheeling speculative interpretations of the first book of the *Ethics*.) Spinoza was by no means the only Dutch philosopher who affected the history of philosophy. Rudolf Agricola (1444–85), now known mainly on account of the ways in which his humanism foreshadowed that of Erasmus, did in fact write the first work to break decisively with the medieval logical tradition. Hugo Grotius (1583–1645) laid the philosophical foundations of international law. Those concerned with the roots of German Romanticism are aware of the enthusiasm with which the dialogues of Frans Hemsterhuis (1721–90) were read by Kant, Jacobi, Goethe, and Novalis.

Prior to the founding of the Universities of Louvain (1425) and Leiden (1575), nearly all the most distinguished thinkers were obliged of necessity to pursue their careers abroad—Siger of Brabant in Italy, Buridan in Paris, Marsilius of Inghen in Heidelberg, Agricola in Italy, Erasmus in Europe at large.

Philosophy was for long only a propaedeutic subject in the universities, leading on to the study of theology, law, and medicine. A Royal Decree of 1815 and an Act of Parliament of 1876 left it with one professor in each university, with no assistants. However, things have looked up. Faculties of philosophy, with philosophy regarded mainly as an interdisciplinary activity, were made obligatory for university status in 1960. The interdisciplinary policy came to be seen as a failure, and in 1985 truer faculties of philosophy came into being.

**Neumann, John von** (1903–57). American mathematician born in Budapest. His genius ranged from logic to atomic energy. He introduced the Foundation Axiom of set theory, which excludes 'paradoxical' sets such as those which are members of themselves. Building on Alan Turing's idea that a program is a form of data, his blueprint for the first electronic digital computers was the influential 'von Neumann architecture', now criticized because it does not allow parallelism. The theory of games is largely his creation. With Oskar Morgenstern he laid the foundations of econometrics. He gave the first mathematically rigorous treatment of quantum theory, including a proof that the theory cannot be made deterministic by assuming that there are hidden parameters. In philosophy he confined himself to advertising the programme of Hilbert. W.A.H. Norman Macrae, *John von Neumann* (Providence, RI, 1999).

**Neurath, Otto** (1882–1945). Born in Vienna. Died in Oxford a refugee from the Nazis. Member of the 'left wing' of the Vienna Circle, famous for his anti-foundationalist boat metaphor. In the protocol-sentence debate with Carnap, Neurath insisted that knowledge is intersubjective and historically conditioned. Neurath rejected both metaphysics and epistemology, admitting only positive knowledge about happenings in space and time. He argued against all fictional idealizations, such as reductionism or completed science, and opposed foundations and fixed methods, urging instead judgement, technique, negotiation, and, finally, decision and action. Marxism was for Neurath a science and science was a tool for change. He headed Bavaria's programme for full socialization in 1919, invented easily readable 'picture statistics', founded the Vienna Social and Economic Museum, was active in adult education, and spearheaded the Unity of Science Movement—to unite the separate sciences locally 'at the point of action'.

**neuroscience, the philosophical relevance of.** Neuroscience has philosophical relevance even if minds are distinct from brains or, as it is better to say, mental properties are distinct from neural properties. We would still need to look to neuroscience to determine whether mental events and properties had a causal influence upon neural events and thereby on the human body and behaviour. If neuroscientists were unable to find signs of causal influence, some form of epiphenomenalism would appear to be true. In the eyes of many, the implausibility of epiphenomenalism implies that either the neuroscientists should carry on looking for signs of influence, or that it is

wrong to think of mental properties as distinct from neural properties.

Neuroscience may also show that we are not free if, as seems plausible, there is a sense of freedom which is incompatible with determinism. (\*Freedom and determinism.) Its investigations have given some support to the claim that there is an intimate relationship between mental and neural events. (\*Psychoneural intimacy.) If relations between neural events, and between neural events and behaviour, are shown by neuroscience to be governed by deterministic laws, then we are not free in the sense of freedom mentioned. Unfortunately, it is debatable whether neural indeterminism makes us any freer. In this respect, neuroscience may only have the capacity to disappoint.

If minds are not distinct from but identical with brains, neuroscience will be potentially relevant to other philosophical issues. At first, it may look as if you will merely discover more about things which have philosophical currency, such as beliefs, desires and their role in the explanation of action, the nature of reasoning and mental representation, and the means by which we arrive at justified beliefs and learn concepts. In this anodyne light, it is possible that the study of neuroscience is relevant to philosophy, but the upshot may just be that neuroscience in a way fills in the story for which philosophy has given us some headlines. It will tell us more about what these things are, but not unsettle, to any great extent, the distinctions upon which philosophy has already alighted.

However, certain philosophers have boldly suggested that the influence of neuroscience is likely to be altogether different. Neuroscience will be no lackey. It will be in the driving-seat. Philosophy will be seen to have appealed to distinctions or categories that neuroscience provides us with reasons to replace. For instance, according to this view, there may be no such things as beliefs as we have understood them—no things which fall under concepts of our \*folk psychology. Naturally, this would alter our approach to a number of the issues identified above and more than likely radically alter our conception of ourselves. (\*Eliminativism.)

Is this likely to happen? Here is an analogy. Zoology is the relevant discipline for the study of zebras. It is possible that zoologists will come to the conclusion that there are no zebras because we should categorize those stripy animals in a different way. But it is reasonable to think that any such changes will not radically alter our familiar appreciation of these animals. If neuroscience is the relevant discipline by which we may understand minds and their contents, one might expect, at worst, a like degree of reform of our mental categories. A philosopher who is non-committal at the appropriate points, and who speaks at a suitable level of abstraction, is only likely to blanch at something different, a veritable revolution. It is not clear why we should expect one unless the analogy breaks down, and it is not obvious that it will. To think otherwise, we would need to be told a thoroughly convincing story of why we grossly misconceive our minds.

Finally, the extent to which neuroscience makes good its initial promise to provide us with some scientific understanding of much of what we understand by our talk of minds may have a more general philosophical relevance. It would be a further vindication of what may be loosely called 'the scientific picture of the world' and thereby the philosophy that underpins it. Some spiritual and religious concerns may look very different as a consequence. It would probably be more difficult to believe reasonably in certain doctrines such as the \*immortality of the human soul.

**neustic and phrastic.** This pair of terms was coined by R. M. Hare in 1952 to distinguish the content (phrastic) from the mood or force (neustic) of a sentence. Thus commands and statements could agree phrastically, while differing neustically. Hare concludes from this analysis that the same logical principles can apply in ethical as in non-ethical language. There is an inconsistency between posting a letter and burning it; and that logical point affects commands, wishes, etc. which may arise in this connection.

**neutral monism.** The theory, associated with William James and Bertrand Russell, that the world is composed of *one* sort of entity, or stuff, the fundamental nature of which is neither mental nor physical. The mind consists of these entities under one aspect, and matter consists of them under another. The theory was intended to preserve the advantages of \*monism, in particular ontological parsimony, while avoiding the problems of reduction present in both pure \*idealism and \*materialism. It never became popular both because no proper characterization of the basic neutral stuff could be given, and because it had some tendency to appear as a notational variant on idealism. Something like it is occasionally revived, for example by T. Nagel in *The View from Nowhere* (1986).

Mark Sainsbury, *Russell* (London, 1979), 261–8.

**Newcomb's paradox.** Paradox about prediction and choice. There are two boxes before you, *A* and *B*, and you are allowed to choose either just box *A* or alternatively both boxes. You may keep anything you find in any box you choose. You know that a very powerful Being, with an untarnished record of successfully predicting human behaviour, has acted in the following way: he has put

£1,000 in box B; and he has put £1,000,000 in box A if and only if he predicts that you will choose just box A. What should you do?

1. You should choose just box A. For the Being will have predicted this, and so filled it with £1,000,000, so you will be rich; whereas if you choose both boxes, he would have predicted *that*, and you would only get £1,000.

2. You should choose both boxes. For either the Being has predicted this or he hasn't. If he hasn't (but has instead predicted you will choose just box A), you will end up with £1,001,000 as opposed to £1,000,000 had you chosen just A. If he has, then you will at least get £1,000, as opposed to nothing had you chosen just A. Either way, you'll be better off choosing both boxes.

The paradox consists in the incompatibility between these apparently well-argued recommendations. R.M.S.

**New England Transcendentalism.** A religious, philosophical, literary, and social movement that flourished in the 1830s and 1840s and whose leaders tended to live around Concord or Boston, Massachusetts. Transcendentalism reacted against 'corpse-cold' Unitarianism, which limited itself to the 'understanding', the faculty employed in practical affairs and scientific theorizing. As German and British \*philosophical romanticism had discovered, there is also 'reason', a faculty able to range beyond sensation and intuit spiritual and metaphysical truths. Reason allows one to dispense with religious texts and institutions, philosophical argumentation, and social and ethical traditions. In *Nature* (1836) Ralph Waldo Emerson claimed that reason reveals that we are one with nature, which has a spiritual source beyond definitive comprehension. Henry David Thoreau in *Civil Disobedience* (1849) appealed to higher law in rejecting immoral civil laws, and in *Walden* (1854) provided a sweeping critique of American society. Transcendentalists also initiated influential reforms in education and developed model communities intended to unify the practical with the ideal. C.C.

### new philosophy calls all in doubt.

And new philosophy calls all in doubt,  
And element of fire is quite put out;  
The sun is lost, and th' earth, and no man's wit  
Can well direct him where to look for it.'

(John Donne, 'An Anatomy of the World:  
The First Anniversary', lines 205–8)

Donne published the 'Anatomy' in 1611, the year after Galileo published the first accounts of his observations with the telescope, and when Descartes was 15. It balances on the brink between medievalism and the Renaissance—regret about the Fall and original sin and assumptions that

the world is running down like a clock come together with references to Copernicus, Brahe, and Kepler and debate over whether the fire round the world really exists. The 'new philosophy' seemed to threaten disruption and chaos.

Twelve years later Galileo under threat of torture disavowed belief in a revolving earth (muttering 'yet it does move'), and Descartes, hearing of this, suppressed publication of his *Le Monde*, which also taught the Copernican system. J.O.G.

**New Realism** (also called neo-Realism). An American philosophical movement against Royce's idealism, led by his former students and young colleagues at Harvard (Ralph Barton Perry, William P. Montague, and E. B. Holt). It was a co-operative movement involving a common manifesto and joint publications, and as such was a significant factor in the professionalization of American philosophy. Its members had allegiances to other compatible intellectual movements (e.g. \*behaviourism and \*pragmatism), but all held a theory of direct acquaintance with physical objects. They were unable to work out a common theory of \*illusion, and gave way to attacks from \*Critical Realism. L.W.B.

**new riddle of induction:** see grue.

**New Right, political:** see Right, the political New.

**Newton, Isaac** (1642–1727). Strongly interested in both theology and alchemy, to each of which he devoted a great deal more time and intellectual energy than he did to his more orthodox scientific pursuits, Newton none the less found time to be an outstanding mathematician and theoretical and experimental physicist. He invented the \*calculus earlier than, and independently of, its first publisher, Leibniz. Side-stepping Aristotle's question 'What keeps moving things moving?', Newton took inertial laws as axiomatic. Deducing Kepler's empirical laws of planetary motion from the inverse square principle, Newton held that gravity was not an *occult* force, nor an *essential* quality of bodies, but, perhaps influenced by the \*Stoics, tacitly accepted mechanically inexplicable forces. In religious terms Newton was an Arian, believing that the Church had taken a wrong turning when it opted for the Athanasian doctrine of the Trinity. J.J.M.

R. S. Westfall, *Never at Rest: A Biography of Isaac Newton* (Cambridge, 1980).

**New Zealand philosophy.** Academic philosophy in New Zealand belongs to the British side of the bicultural partnership established by the Treaty of Waitangi between Maori and the Crown in 1840. Accordingly, it has developed in tandem with the prevailing Anglo-American traditions in philosophy, and in strong mutual relationship with \*Australian philosophy. New Zealand's professional philosophical association continues to count as a 'division' of the Australasian Association of Philosophy,

which is responsible for the editorship of the *Australasian Journal of Philosophy*.

New Zealand philosophers have not been, however, merely consumers and transmitters of Northern philosophical culture. They have been active contributors to the discipline, and in many cases innovators influencing its direction internationally. Karl Popper wrote *The Poverty of Historicism* (not published in book form until 1957) and the two volumes of *The Open Society and its Enemies* (1945) while holding a lectureship at Canterbury College of the University of New Zealand from 1937 to 1945. It was there that Popper met the neurophysiologist (and Nobel Prize winner) John Eccles, with whom he later collaborated in *The Self and its Brain* (1977). Canterbury, too, was home to the New Zealander Arthur Prior, as lecturer from 1945, and then as Professor from 1952 to 1959. While there, Prior published his *Formal Logic* (1955) and *Time and Modality*, the John Locke lectures for 1955/6, providing a systematic presentation of modern tense logic. John Passmore's *Hume's Intentions* (1952) appeared while he held the Chair at Otago: his successor was J. L. Mackie, whose publications at that time include 'Evil and Omnipotence', *Mind* (1955).

Since 1960 some areas of special concentration can be discerned. Prior's influence set a focus on logic that became the most distinctive feature of New Zealand philosophy for three or more decades after he left for a chair at Manchester and eventually a fellowship at Balliol (from 1966). This focus is exemplified by the work of George Hughes and Max Cresswell at Victoria University of Wellington (*An Introduction to Modal Logic* (1968) and *Cresswell's Logics and Languages* (1973)), Pavel Tichy's work in type theory, logic, and the philosophy of logic at Otago (*The Foundations of Frege's Logic* (1988)), and Krister Segerberg's development of dynamic logic at Auckland.

Work in the philosophy of the arts has been prominent in New Zealand, with the main contributors being Greg Currie (previously at Otago), Stephen Davies at Auckland, and David Novitz and Denis Dutton, editor of the journal *Philosophy and Literature*, at Canterbury. New Zealand has participated in an international trend towards greater emphasis on applied ethics, with a Bioethics Centre established at Otago in 1988, and a Diploma in Professional Ethics at Auckland in 1992. Old divisions between 'continental' and 'analytic' philosophy have become less relevant—consider, for example, Julian Young's work on Nietzsche and Heidegger at Auckland—and New Zealanders are well represented in many areas of emerging importance, such as the philosophy of biology (Kim Sterelny at Victoria University of Wellington edits *Biology and Philosophy*), the philosophy of artificial intelligence (Jack Copeland, of Canterbury, is director of the Turing Archive for the History of Computing), and virtue ethics (Rosalind Hursthouse and Christine Swanton at Auckland).

The sixty or so members of the community of academic professional philosophers in New Zealand (as in 2003) contribute across all main areas of philosophy, however: note, for example, Alan Musgrave's contributions in

epistemology and the philosophy of science since his appointment to the Otago chair in 1970. Yet the question does arise whether New Zealanders should take opportunities to develop distinctively regional philosophies. The challenge to achieve this has been presented by the New Zealander Richard Sylvan—whose work on non-classical logics has been influential in Australasia and beyond—in his 'Prospects for Regional Philosophies in Australasia' (*Australasian Journal of Philosophy* (1985)). An interest in philosophical engagement with Maori culture has emerged with the work of John Patterson at Massey (*Exploring Maori Values* (Dunmore Press, 1992)), and the prospect of philosophical work on the Maori side of the bicultural partnership is held out by the development of whare wananga (Maori universities). Issues in social and political philosophy of special reference to the New Zealand context have also received attention: see e.g. Graham Oddie and Roy Perrett (eds.), *Justice, Ethics and New Zealand Society* (Oxford, 1992). Perhaps the most distinctive feature of contemporary New Zealand philosophy, however, is something widely remarked by visitors: the congeniality and friendliness which seem to be a function both of the small size of the academic community and of the national ethos of Aotearoa-New Zealand. J. BISH.

**Nicholas of Autrecourt** (c.1300–?). A student at Paris, he later taught there, delivering a series of lectures on the *Sentences* of Peter Lombard. Certain of his theological views caused offence in the Church and under pressure from the Church he burned his writings and retracted his offensive views. He is in some respects a forerunner of David Hume, placing emphasis on the principle that if two things are really different from each other then it is not possible to argue with certainty from one to the other. On this basis he presents an account of \*causality very similar to the account that Hume was later to present. Nicholas's account of the relation between \*substance and accident also anticipates Hume. A. BRO.

J. Weinberg, *Nicholas of Autrecourt* (Princeton, NJ, 1948).

**Nicholas of Cusa** (1401–64). A student at Heidelberg and Padua, he subsequently became active in Church politics, making an impact at the Council of Basle (1432), and seeing some of his ecumenical work bearing fruit some years later at the Council of Florence. He became a cardinal in 1448. Nicholas is famous for his teaching on *docta ignorantia* (educated ignorance), in which he focuses upon the ineffability of \*God, and the implication that those who think they have affirmative knowledge of God are truly ignorant, the knowledgeable ones being those who are aware that they are ignorant of him. The unknowability of God follows from Nicholas's doctrine of the 'coincidence of opposites', that in God there exist as identities what are utterly distinct in us. For example, the existence of a created thing is distinct from its \*essence, for it is not of the essence of any created thing that it exists. But in God his essence and existence are identical. Also God is the maximum, the greatest possible being, and is also the

minimum, the least, for he does not occupy any part of space, however small.

J. Hopkins, *A Concise Introduction to the Philosophy of Nicholas of Cusa* (Minneapolis, 1978).

**Nietzsche, Friedrich Wilhelm** (1844–1900). German philosopher and critic *par excellence*. A classical philologist by training and academic profession, Nietzsche's philosophical efforts—deriving chiefly from the last dozen years of his short productive life—were little heeded until long after his physical and mental collapse in 1889 (at the age of only 44). He subsequently emerged as one of the most controversial, unconventional, and important figures in the history of modern philosophy. His influence upon European philosophy in the twentieth century has been profound; and he has belatedly come to receive considerable attention in the English-speaking world as well, as the shadow cast by the travesty of his appropriation by the Nazis and Fascists has receded, along with the sway of philosophical fashions inhospitable to his kind of thinking and writing. He gave his *Beyond Good and Evil* the subtitle *Prelude to a Philosophy of the Future*; and in this he may well have been prophetic.

Nietzsche's philosophical enterprise grew out of his background as a philologist schooled in the study of classical languages and literatures, his deep concern with issues relating to the quality of life in the culture and society of his time, his conviction that the interpretative and evaluative underpinnings of Western civilization are fundamentally flawed, and his determination to come to grips with the profound crisis he believed to be impending as this comes to be recognized. He sought both to comprehend this situation and to help provide humanity with a new lease on life, beyond what he called 'the death of God' and 'the advent of nihilism' following in its wake. He deemed traditional forms of religious and philosophical thought to be inadequate to the task, and indeed to be part of the problem; and so he attempted to develop a radical alternative to them that might point the way to a solution.

Nietzsche had no formal philosophical training. His introduction to philosophy came through his discovery of Schopenhauer's *The World as Will and Representation* while studying philology at the university at Leipzig. This encounter with Schopenhauer's thought profoundly influenced him, as can be seen in his first book *The Birth of Tragedy* (1872), which he published soon after being appointed to a professorship of philology at Basle University (at the astonishingly early age of 24, before he had even been awarded his doctorate). He was convinced of the soundness of Schopenhauer's basic conception of the world as a godless and irrational affair of ceaseless striving and suffering; but he was repelled by Schopenhauer's starkly pessimistic verdict with respect to the worth of existence in such a world, and sought some way of arriving at a different conclusion. In *The Birth of Tragedy* he made his first attempt to do so, looking to the Greeks and their art for guidance, and to Wagner (with whom he had become acquainted and enthralled) for contemporary

inspiration. His attachment to Wagner subsequently gave way to disenchantment and then to scathing criticism (culminating in his late polemic *The Case of Wagner*), and he gradually emancipated himself from Schopenhauer as well; but the fundamental problem of how \*nihilism might be overcome and life affirmed without illusions remained at the centre of his concern throughout his life.

Nietzsche's brief academic career ended in 1879, owing to the drastic deterioration of his health. His only significant publications after *The Birth of Tragedy* prior to its final year were the four essays he subsequently gathered together under the title *Untimely Meditations*, of which 'The Uses and Disadvantages of History for Life' and 'Schopenhauer as Educator' (both 1874) are of the greatest interest. Then in 1878 he published the first of a series of volumes of aphorisms and reflections under the title *Human, All Too Human*. It was followed during the next few years by two supplements which became a second volume under the same title, by *Daybreak* in 1881, and then by the initial four-part version of *The Gay Science* in 1882. In these works, which he described as 'a series of writings . . . whose common goal is to erect a new image and ideal of the free spirit', Nietzsche found his way to his kind of philosophy.

It was only in 1886, however, with the publication of *Beyond Good and Evil*, that he pursued it further in something like the same manner. In the interval (1883–5) he published only the four parts of his great literary-philosophical experiment *Thus Spoke Zarathustra*. A mere three more years remained to him prior to his collapse in January of 1889, from which he never recovered. During this brief but phenomenally productive period he wrote prefaces to new editions of most of his pre-*Zarathustra* writings, added a fifth part to a new edition of *The Gay Science* (1887), published *On the Genealogy of Morals* in the same year, and then in the final year of his active life (1888) wrote *Twilight of the Idols*, *The Case of Wagner*, *The Antichrist*, and his autobiographical *Ecce Homo*—all the while filling many notebooks with reflections and thought experiments. (The significance of this 'Nachlass' material is much debated. After his collapse and death, selections from it were gathered into a volume published under the title *The Will to Power*.)

From his early essays to these last works, Nietzsche showed himself to be an astute, severe, and provocative critic on many fronts. Cultural, social, political, artistic, religious, moral, scientific, and philosophical developments and phenomena of many kinds drew his polemical attention. Everywhere he looked he saw much that was lamentably 'human, all too human', even among those things and thinkers generally held in the highest regard. This has given rise to the common impression that the basic thrust and upshot of his thought is radically negative, contributing greatly to the advent of nihilism that he announced (and of worse things as well).

This impression, however, is deeply mistaken. Nietzsche actually was a profoundly positive thinker, concerned above all to discover a way beyond the nihilistic

reaction he believed to be the inevitable consequence of the impending collapse of traditional values and modes of interpretation, to a new 'affirmation' and 'enhancement' of life. His critical fire was only a means to this end, preliminary to the twin philosophical tasks of *reinterpretation* and *revaluation* he advocated and pursued with growing explicitness and determination from *The Gay Science* onward.

As a further means to this end, and likewise preliminary to these tasks, Nietzsche developed and undertook a variety of forms of analysis, of which the kind of 'genealogical' inquiry exemplified by his investigations in *On the Genealogy of Morals* is one notable and important example. His analytical acumen was as extraordinary as his critical astuteness; and his writings both before and after *Zarathustra* contain a wealth of cultural, social, psychological, linguistic, and conceptual analyses from many different perspectives, upon which he drew not only in his critiques but also in his reinterpretative and revaluative efforts. His recognition of the importance of engaging in and drawing upon a multiplicity of such analyses in philosophical inquiry is reflected in his insistence that such inquiry is inescapably perspectival—and that this circumstance is by no means fatal to it, if one can learn to capitalize upon the possibility of bringing a variety of perspectives to bear upon many of the matters with which it may concern itself. This is his practice as well as his prescription, in his explorations of issues ranging from moral and religious phenomena to aspects of our human nature and to knowing and reasoning themselves.

The form of Nietzsche's philosophical writings both before and after *Zarathustra*, which for the most part consist of collections of relatively brief aphorisms and reflections on such issues rather than sustained systematic lines of argument, is well suited to this multiply perspectival tactic. It greatly complicates the task of understanding him; but it also makes his thinking far more subtle and complex than is commonly supposed. He returned to problems repeatedly, in one work after another, approaching them from many different angles; and it is only if account is taken of his many diverse reflections on them that anything approaching justice to his thinking about any of them can be done. Even then he can be—and has been, and no doubt will continue to be—interpreted in quite different ways. Precisely for this reason, however, and because he has so much of interest to say (on almost any such interpretation) about so many things, he is certain to continue to attract, deserve, and reward philosophical attention.

Nietzsche was greatly concerned with basic problems he discerned in contemporary Western culture and society, which he believed were becoming increasingly acute, and for which he considered it imperative to try to find new solutions. Chief among them were questions of meaning and value, and of our understanding of ourselves and our place in the world, which can no longer be answered in traditional religious and philosophical ways. He prophesied the advent of a period of nihilism, with the

death of God and the demise of metaphysics, and the discovery of the inability of science to yield anything like absolute knowledge; but this prospect deeply worried him. He was firmly convinced of the untenability of the \*'God-hypothesis' and associated religious interpretations of the world and our existence, and likewise of their metaphysical variants. Having also become persuaded of the fundamentally non-rational character of the world, life, and history, Nietzsche took the basic challenge of philosophy to be that of overcoming both these ways of thinking and the nihilism resulting from their abandonment. This led him to undertake to reinterpret ourselves and the world along lines which would be more tenable, and would also be more conducive to the flourishing and enhancement of life. The 'de-deification of nature', the tracing of the 'genealogy of morals' and their critique, and the elaboration of 'naturalistic' accounts of knowledge, value, morality, and our entire 'spiritual' nature thus came to be among the main tasks with which he took himself and the 'new philosophers' he called for be confronted.

Unlike most philosophers of importance before him, Nietzsche was openly and profoundly hostile to most forms of \*morality and religious thought. He declared 'war' upon them, on the grounds that they not only are indefensible and untenable, but moreover feed upon and foster weakness, life-weariness, and *ressentiment*, poisoning the wellsprings of human vitality in the process by 'devaluing' all 'naturalistic' values. He further rejected not only the God-hypothesis (as a notion utterly without warrant, owing its acceptance to naivety, error, need, or ulterior motivation), but also any metaphysical postulation of a 'true world of "being"' transcending the world of life and experience, and with them the related 'soul-' and 'thing-hypotheses', taking these notions to be ontological fictions reflecting our artificial (though convenient) conceptual shorthand for products and processes. In place of this cluster of traditional ontological categories and interpretations, he conceived of the world in terms of an interplay of forces without any inherent structure or final end, ceaselessly organizing and reorganizing themselves as the fundamental disposition he called \*'will to power' gives rise to successive arrays of power relationships among them. It is debatable whether his thoughts along these lines amount to a kind of philosophical cosmology; but if so, it is a very minimalistic one, because for him there is little more to the general character of life and the world than this, and so there is little more about it to be said, other than to give perspectival accounts of contingently obtaining states of affairs accessible in one way or another to us.

There is a good deal about our own human reality that is accessible to us in various ways, however; and so, even if there is nothing immutable (let alone divine) about it, its comprehension is a task to which Nietzsche thought it would be well for philosophers to turn their attention, learning what they can from the human sciences, but supplementing what these sciences can tell us about ourselves by way of other attainable perspectives upon human life as well. So he construed our human nature and existence

naturalistically, insisting upon the necessity of 'translating man back into nature', in origin and fundamental character, as one form of animal life among others. 'The soul is only a word for something about the body,' he has Zarathustra say; and the body is fundamentally an arrangement of natural forces and processes. At the same time, however, he insisted upon the importance of social arrangements and interactions in the development of human forms of awareness and activity, and moreover upon the possibility of the emergence of exceptional human beings capable of an independence and creativity elevating them beyond the level of the general human rule.

So Nietzsche stressed the difference between 'higher types' and 'the herd', and through Zarathustra proclaimed the 'over-man' (*Übermensch*) to be 'the meaning of the earth', representing the overcoming of the 'all too human' and the attainment of the fullest possible 'enhancement of life'. Far from seeking to diminish our humanity by stressing our animality, he sought to direct our attention and efforts to the emergence of a 'higher humanity' capable of endowing existence with a human redemption and justification. Nietzsche has long been associated with such existential philosophers as Kierkegaard, Heidegger, and Sartre; but his general approach to the reinterpretation of human reality actually differs markedly from theirs, and is better conceived as an important naturalistic alternative and rival to theirs, inaugurating the project of a kind of human—scientifically, psychologically, historically, and culturally sensitive—philosophical anthropology as one of the tasks of his 'philosophy of the future'.

Nietzsche proposed that life and the world be interpreted in terms of his conception of 'will to power'; and he framed his 'Dionysian value-standard', and the 'revaluation of values' that he called for, in terms of this interpretation as well. The only positive and tenable value-scheme possible, he maintained, must be based upon a recognition and affirmation of the world's fundamental character, and so must posit as a general standard the attainment of a kind of life in which the assertive-transformative 'will to power' is present in its highest intensity and quality. This in turn led him to take the 'enhancement of life' and creativity to be the guiding ideas of his revaluation of values and development of a naturalistic value-theory; for he thought that naturalistic sense can be made of both of these ideas, and that they can also be utilized to breathe new life into the idea of value, making possible a constructive 'revaluation' rather than a bleakly nihilistic devaluation of all received values and human possibilities.

This way of thinking carried over into Nietzsche's thinking with respect to morality as well. Insisting that moralities as well as other traditional modes of valuation ought to be understood and assessed 'in the perspective of life', he argued that most of them are contrary rather than conducive to the enhancement of life, reflecting the all-too-human needs and weaknesses and fears of less-favoured human groups and types. Distinguishing between 'master' and \*'slave' moralities, he found the latter increasingly to have eclipsed the former in human

history, and to have become the dominant type of morality at the present time, in the form of a 'herd-animal' morality well suited to the requirements and vulnerabilities of the mediocre who are the human rule, but stultifying and detrimental to the development of potential exceptions to that rule. He further suggested the possibility and desirability of a 'higher' type of morality for the exceptions, in which the content and contrast of the basic 'slave-herd-morality' categories of 'good and evil' would be replaced by categories more akin to the 'good and bad' contrast characteristic of master morality, with a revised (and variable) content.

Nietzsche's naturalistic approach to normativity, however, allows for the conception of differing sorts of moralities attuned and conducive to the flourishing and development of different forms of individual, social, institutional, and cultural life, and so appropriate to them and to whoever might participate in them to the extent that they do so, rather than for their conception as the moralities of distinct types of human beings. So he did not advocate the abolition of 'herd-animal' morality, but rather its restriction to 'herd-animal' human types and human situations; and so he likewise did not advocate a general human reversion to the 'master morality' he supposes to have prevailed among barbaric 'beasts of prey', but rather a shift of some human beings in areas of their lives in which they have exceptional ability to norms better suited to the cultivation and expression of that ability.

The strongly creative flavour of Nietzsche's notions of such a higher humanity and associated higher morality reflects his linkage of both to his conception of \*art, to which he attached great importance. Art, as the creative transformation of the world as we find it (and of ourselves thereby) on a small scale and in particular media, affords us a glimpse of the possibility of a kind of life that would be lived more fully in this manner, and constitutes a step in the direction of its emergence. In this way, Nietzsche's mature thought expanded upon the idea of the basic connection between art and the justification of life which was his general theme in his first major work, *The Birth of Tragedy*.

Nietzsche was highly critical of traditional and commonplace ways of thinking about truth and knowledge, maintaining that as they are usually construed there is and can be nothing of the kind (except in highly artificial contexts), that all thinking is 'perspectival', and that 'there are no facts, only interpretations'. This has led some to suppose that he rejected the idea of truth and knowledge altogether, and so was a radical epistemological nihilist. Yet he manifested a passionate commitment to 'truthfulness', and pursued philosophical tasks which he quite clearly supposed to have something like knowledge as their aim. (So, for example, this is the avowed objective of his 'genealogical' investigations in *On the Genealogy of Morals*, as well as in many of the lines of inquiry he pursues in *The Gay Science*.) He did reject various *absolutist* conceptions and criteria of truth and knowledge (or, alternatively, contended that, on such conceptions and by such criteria, there is no 'truth' and can be no 'knowledge'). But

he also sought to replace traditional ways of thinking about truth and knowledge with viable alternatives that make important sense of them, and to give a significant array of forms of cognitive inquiry—including various forms of natural- and human-scientific inquiry—new post-absolutist, anti-nihilist credentials and legitimacy.

Both in principle and in practice Nietzsche's thinking was avowedly interpretative, multiply perspectival, experimental, and tentative, and made free use of language that is highly metaphorical and figurative. He preferred to offer suggestions, hazard guesses, and propose hypotheses rather than attempt to construct rigorous lines of reasoning. He further acknowledged that the upshot of what he (or anyone else) has to say on any substantive issue neither is nor can ever be beyond all dispute. Yet he repeatedly insisted upon the distinction between the plausibility and soundness of various ideas on the one hand, and their 'value for life' on the other (between their 'truth-value' and their 'life-value', as it were). Although some of his unguarded remarks may seem to suggest otherwise, he inveighed explicitly against the conflation of the two—even while also arguing that the *value* of all knowledge and truthfulness ultimately must be referred to their 'value for life' for human beings with differing constitutions and conditions of preservation, flourishing, and growth, and judged before that tribunal.

Philosophy for Nietzsche involves the *making of cases* for and against various proposed interpretations and evaluations. For the most part he did not present arguments of the sort that one usually finds in the writings of philosophers and expects of them. He attempted to make his criticisms stick and his own ideas stand in other ways. On the attack, he typically sought to make cases against ways of thinking he found wanting by presenting an array of considerations intended collectively first to make us suspicious of them and aware of just how problematical they are, and then to deprive them of their credibility. He generally did not claim that the considerations he marshals actually *refute* the targets of his criticism. Rather he typically aimed to *dispose* of them by undermining them sufficiently to lay them to rest, exposed as unworthy of being taken seriously any longer.

When advancing alternatives to them Nietzsche proceeded in a somewhat similar manner, presenting various supporting considerations—both general and specific—none of which by themselves may be decisive, but which taken together are intended to be compelling. They are purported to establish his 'right' to the ideas he puts forward, notwithstanding the novelty they may have, and the reluctance many may feel to entertain and embrace them. And he conceived this 'right' as a cognitive one. Here, too, he was generally prepared to acknowledge that the cases he makes do not actually *prove* his points, and couched his hypotheses and conclusions in tentative and provisional language. He also not only admitted but insisted that they leave open the possibility of other interpretations as well as of subsequent modifications, as further considerations are hit upon and introduced. But it is

clear that he supposed it to be possible to make cases for his interpretations and evaluations, the positive upshot of which is strong and clear enough to warrant confidence that he is at least on the right track, and has got hold of something important. He often did say things to the effect that these are 'his truths', to which others may not easily be entitled. But this way of speaking may be understood as a challenge to others to *earn their right* to lay like claim to understand what he has grasped, rather than as an admission that they are nothing more than figments of his own creative imagination.

A consequence of the perspectival approach Nietzsche favoured is that one must employ models and metaphors drawn from whatever resources are available to one in conceptualizing and articulating what may be discerned from the perspectives adopted—and, indeed, that these perspectives themselves are to no little extent framed by means of such resources. He himself took his models and metaphors from literature and the various arts, from the natural sciences, and also from the social and behavioural sciences, from economics to psychology. He further availed himself of conceptual resources and images drawn from a multitude of other domains of discourse, including law, medicine, linguistics, and even theology. In this way he was able to take advantage of the different ways of thinking associated with and suggested by them, and to play them off against each other, thereby avoiding becoming locked into any one or particular cluster of them. They afforded him the means of discovering and devising an expanding repertoire of perspectives upon the matters with which he was concerned, and so of developing and sharpening what he called the many and different 'eyes' needed to contribute to a growing and deepening comprehension of them. This has an important bearing upon the question of how his perspectivism is to be understood, and how it works in practice.

Nietzsche clearly held that neither this sort of inquiry nor any other that is humanly possible will suffice to enable one to attain the sort of knowledge to which metaphysicians have traditionally aspired. It by no means follows, however, that for him there is nothing of any significance to be comprehended. He considered the forms of morality that have arisen in the course of human events to admit of better-than-ordinary comprehension if approached in this manner and spirit, for example; and he clearly supposed that the same applies to a broad range of other such phenomena that are to be encountered within the compass of human life, history, and experience—and indeed to our attained and varying human reality itself, down to its basic character and general conditions. Rather like a latter-day Vico, he seized upon the idea that it is humanly possible to comprehend at least something of whatever has been humanly constituted. He came to take this idea quite seriously, concluding that it has important implications for the possibility of knowledge, and that its scope is very wide indeed. For what he called 'the world that concerns us'—which includes ourselves—consists in phenomena that are in various and very real respects 'our doing'.

Nietzsche thus in effect proposed to replace the Holy Grail of an ultimate reality conceived along the lines of a transcendent deity or 'true world' of 'being', and the quest for it conceived as the proper mission and picture of true knowledge, with a different paradigm of reality and associated conception of comprehension. Suppose we take as our paradigm the sort of reality in which human life and the world of our activities and experience consist, and conceive of knowledge in terms of the kind of comprehension of them of which they admit and we are capable. Making them our point of departure, we then can consider how far it is possible to go by expanding the scope of their application into the world with which we find ourselves confronted—while devoting our main efforts to the exploration of those things that are to be encountered *within* the realm of the human, and to the devising of the strategies of inquiry that will be most appropriate to their comprehension. If in this way we manage to achieve some measure of understanding of the kind of world in which our human reality has emerged and taken the various forms and associated expressions it has, so much the better. But even if we cannot do much more than comprehend ourselves and things human, this will at least be something—and something quite significant and well worth achieving at that.

We can, however, do something more than this—and something that is, for Nietzsche, in the end, a good deal more important: we can come to understand what meaning and value amount to, and how it is possible to endow life with forms of meaning and value that it may not have in the first place, but is capable of attaining. Nietzsche's reinterpretative efforts are not pursued for their own sake, but rather for what they can contribute to the revaluative part of his philosophical agenda. If humanity is to outgrow its childish need for absolutes without despairing at their absence and winding up nihilistically willing either nothing or nothingness, we must find a new and more viable way to the affirmation of life than those that have been based on fictions, illusions, impossible dreams, and leaps of faith. We must rethink meaning and value, and find ways to attune ourselves sufficiently to attainable forms of them that this 'disillusioned' affirmation becomes not only humanly possible, but humanly compelling. Nietzsche's kind of philosophy is not itself intended to be the answer, meeting this need out of its very own resources and accomplishments; for that requires more than thought. It requires life, lived in ways that creatively enhance its quality. What Nietzsche's kind of philosophy is intended to be here is rather like what Nietzsche's *Thus Spoke Zarathustra* is intended to be: a reflection on meaning and value that can open our eyes to what they are or can be all about, and a call to make them come true. **nihilism.** The extreme view that there is no justification for values and, in particular, no justification for morality. It is sometimes used to mean the active rejection of and attack on such values. The word was invented by the Russian novelist Turgenev to describe young rebels in Tsarist Russia. Ever since, the word has been used to condemn those who refuse to accept certain preferred prevailing values. Philosophically, 'nihilism' is often employed as an ominous alternative characterization of \*relativism and other views that deny the existence of 'absolute' moral standards. Friedrich Nietzsche, for example, is often called a nihilist. His case is instructive. Nietzsche is said to be a nihilist because he questions the value of such ideals as truth and morality, but he does so because they eclipse other, more important values. He thus accuses the Judaeo-Christian tradition of nihilistic tendencies by emphasizing the 'other-worldly' and rejecting 'naturalistic' values. By definition, the nihilist believes in nothing and disdains all values. But it is worth asking, along with Nietzsche, whether any such stance is possible, in theory or in practice. R.C.SOL.

F. Nietzsche, *The Will to Power* (New York, 1968).

**nirvana.** In \*Buddhist philosophy, the blowing out of the flame of the self. Hence the end of all suffering—by living without craving or by dying never to be reborn. Commonly understood as pure extinction, it is described by some Buddhist scriptures as a positive state of perpetual peace. 'Since the self, strictly speaking, does not exist anyway, *who* enjoys this permanent painlessness?' 'Is it *real*—since nothing real can be permanent?' These remain questions to be answered by silence. A.C.

T. Stcherbatsky, *The Conception of Buddhist Nirvāna* (Benares, 1989).

**Nishida Kitarō** (1870–1945). Foremost Japanese philosopher of the twentieth century and founding father of the Kyoto School, Nishida is best known for his path-breaking work of 1911, *An Inquiry into the Good* (*Zen no kenkyū*). With this book he began to articulate a system of thought based on the \*Zen Buddhist experience in terms borrowed from French, German, and Anglo-American philosophy, psychology, and natural science. Drawing on William James and Henri Bergson, Nishida developed a philosophy based on 'pure experience' as that which underlies the subject-object relation. A thinker of great erudition and learning, he developed and refined his system over several decades to encompass the social and historical worlds as

well as the world of religion. Central to Nishida's thinking are the ideas of the 'topos of nothingness' and of the world as the 'self-identity of absolute contradictories'. G.R.P.

\*nothingness, absolute.

Nishitani Keiji, *Nishida Kitarō*, tr. Yamamoto Seisaku and James Heisig (Berkeley, Calif., 1991).

**Nishitani Keiji** (1900–90). Deeply influenced by such Western figures as Meister Eckhart, Dostoevsky, Nietzsche, and Heidegger, and yet firmly rooted in the Chinese and Japanese \*Zen traditions, Nishitani was the major figure of the 'second generation' Kyoto School and a consummately existential religious philosopher. More prepared than his mentor Nishida to engage the Western philosophical tradition on its own terms, Nishitani was a pioneer in the field of East–West philosophical dialogue. Concerned throughout his career with the problem of nihilism, he developed an existential philosophy in which, if the self is plumbed to sufficient depth, the *nihilum* or void at its base may be realized as the absolute \*nothingness (*mu*) or fertile emptiness (*kū*) of Mahāyāna Buddhist philosophy. The philosophical synthesis effected in his masterwork, *Religion and Nothingness* (1962), matches the achievements of Kierkegaard, Nietzsche, and Heidegger in depth of insight. G.R.P.

*The Religious Philosophy of Nishitani Keiji* ed. Taitetsu Unno (Berkeley, Calif., 1989).

**Nkrumah, Kwame** (1909–72). African statesman and philosopher, who was educated in the United States and Great Britain, Kwame Nkrumah spearheaded the movement that led Ghana to independence from colonialism in 1957, and became Prime Minister and subsequently President of Ghana. He expounded a comprehensive, physicalist theory of nature and society, which he applied to his vision of a political economy for the whole of Africa in a Pan-African Union. W.E.A.

\*philosopher-king.

Basil Davidson, *A View of the Life and Times of Kwame Nkrumah* (London, 1973).

**noble lie.** A myth proposed in Plato's *Republic* according to which when human beings were formed in the earth, those who should rule had gold mixed with them, the soldiers silver, and farmers and craftsmen iron. The aim of the myth is to keep individuals happy with their designated roles, but would anyone believe it, even after generations of indoctrination? The speakers in the dialogue are doubtful, while insisting firmly, scandalously, and possibly defensibly that rulers may legitimately lie for reasons of state. A.O'H.

\*ideology; teaching and indoctrinating.

Plato, *The Republic*, 414–15, 459–60.

**nocturnal council:** *see* Plato.

**no false lemmas principle:** *see* lemma.

**nom.** A term meaning *scientifically* lawlike, thus distinguishing a claim both from the merely contingent (as 'John is very happy') and the moral or legal (as 'You ought to keep promises'). Nomic statements, like 'All bodies attract each other with a force inversely proportional to the square of the distance between them', are generally thought both *universal* and *necessary*. The analysis of the exact nature of the latter, especially as it has been thought to be causal, has provided a good living for a good many philosophers for a good many years. M.R.

\*causation; necessity, nomic.

E. Nagel, *The Structure of Science* (New York, 1961).

**nominalism.** Nominalism, traditionally understood, is a doctrine which denies the real existence of \*universals, conceived as the supposed referents of general terms like 'red' and 'table'. In order to explain how and why we classify different individual things alike as being red or as being tables, nominalists appeal to particular resemblances between those things. Realists object that such an account involves tacit reliance on universals because resemblance is always similarity *in some general respect*, pointing out that different things resemble each other in many different ways. But nominalists reply that such objections are misconceived and question-begging.

In more recent usage, 'nominalism' is often employed as a label for any repudiation of \*abstract entities, whether universals or particulars, and thus embraces the rejection of such things as propositions, sets, and numbers. E.J.L.

\*realism.

D. M. Armstrong, *Nominalism and Realism* (Cambridge, 1978).

**nomological:** *see* nomic.

**nomological danglers:** *see* identity theory of mind.

**non-being and nothing.** Negative events, which seem to be needed as the worldly correspondents of true \*negative propositions, are troublesome because we lack criteria of identity for them, there being no non-arbitrary answer to 'How many forest fires did not occur yesterday?' To avoid commitment to them attempts have been made to analyse negative into positive propositions. That Theaetetus does not fly is analysed either as that every property of Theaetetus is other than being in flight or that there is some positive property of Theaetetus that is incompatible with being in flight, such as being planted on the ground. It is objected that these analyses are viciously circular, since otherness and incompatibility are themselves negative relations. To settle this dispute an adequate criterion for distinguishing between negative and positive properties must be formulated, the most promising of which is based on a difference in their degree of specificity or entailment relations. Positive properties, unlike negative ones, entail properties of both the same and different qualities than themselves; for example, non-red entails only non-crimson and other properties of the same quality, while

red entails both coloured and non-green, the former being of the same and the latter of a different quality than itself.

In contrast with absences within the world, Nothing is the absence of the world itself—a total absence of every positive contingent reality. Bergson utilized the above incompatibility analysis to show that the concept of Nothing is contradictory, since every absence requires an existent positive reality that logically excludes it. The application of this analysis to 'No contingent beings exist' results in 'Every existent being has some positive property that is incompatible with being existent', but it is unclear what this positive property of existent being could be.

A. N. Prior, 'Negation', in P. Edwards (ed.), *Encyclopedia of Philosophy* (New York, 1967).

**non-cognitivism.** The name of a position in ethics. Like many such names it is used more by its opponents than by its supporters. This one is used to designate that family of ethical positions in which it is supposed that moral judgements do not possess truth-value and hence can not be known. An example of a non-cognitivist position is \*emotivism; that is, the claim that moral judgements are merely expressions of emotion.

R.H.

\*moral realism; quasi-realism; prescriptivism.

**non-contradiction, law of.** The conjunction of a proposition and its negation is a \*contradiction and is necessarily false. In \*traditional logic the principle was sometimes taken to be a law of thought, along with the principles of \*identity and \*excluded middle. In the \*propositional calculus the principle is reflected in the theorem  $\sim (P \cdot \sim P)$ , which is a \*tautology.

A theory in which this law fails, where a proposition  $P$  and its contradictory not- $P$  are deducible, is an inconsistent theory.

**non-Euclidean geometry.** Any geometry some of whose axioms and theorems contradict Euclid's. Euclid's axiomatization was often thought to provide the paradigm of \*knowledge, by making deductive steps from necessary and self-evident truths. But as the parallel axiom, in particular, seemed less obvious than the others, many attempts were made to derive it from them. If it were derivable, then by adding its negation to the others a contradiction would be deducible from the new axiom set.

Over several centuries many propositions were deduced from the new set which appeared self-contradictory, so the work then petered out; but no plain contradiction of the form ' $P$  and not- $P$ ' was produced. In the nineteenth century Bolyai, Lobachevsky, and Riemann deduced

more theorems, and proposed these systems as independent 'non-Euclidean' geometries. It has since been shown that if Euclid's geometry is consistent then so are the others, so presumably all are. Most physicists now believe that \*space is non-Euclidean. At least it is not necessarily Euclidean, as many philosophers had argued or assumed.

A.J.L.

\*space-time.

Morris Kline, *Mathematics in Western Culture* (London, 1954), ch. 26.

**non-natural properties.** To ethical naturalists, moral terms refer to 'natural' properties, properties most often confirmable by sensory experience. Other philosophers have argued that the distinctiveness of moral properties is lost in such an analysis (\*naturalistic fallacy), and have claimed that moral terms refer to 'non-natural' properties, detectable by 'intuition' alone. This was how G. E. Moore understood \*'good'. Others again have challenged the credentials of intuition as a mode of knowledge and questioned how appeal to such properties could, intelligibly, guide the action of moral agents.

R.W.H.

\*ethical naturalism.

G. E. Moore, *Principia Ethica* (Cambridge, 1903).

**nonsense.** A favoured term of condemnation in philosophy, 'nonsense' tends to enjoy here a different range of application from that found in everyday usage. In the latter, statements are often pronounced nonsense on the grounds that they are outrageously improbable or patently false, whereas nonsense is commonly taken by philosophers to be such a fundamental defect as to exclude even falsity. The everyday usage may be hard to avoid. Suppose that a proposition,  $P$ , is declared to be nonsense because unverifiable. If, by reflecting on  $P$ , we come to see that it must indeed elude all attempts at verification, this realization is one which would in all likelihood depend on our grasp of the meaning of  $P$ , in which case falsity rather than unintelligibility would appear the most that could coherently be claimed.

B.B.R.

\*verification principle.

A. J. Ayer, *Language, Truth and Logic* (London, 1946).

**nonsense upon stilts.** How Bentham described the claim of the French Revolutionary Declaration of the Rights of Man and the Citizen that there were 'natural and imprescriptible' rights. The claim that there were \*natural rights was, to him, 'simple nonsense'; it was the claim that these rights were imprescriptible (that is, unrevisable) which made it into 'nonsense upon stilts'.

R.H.

Jeremy Bentham, *Anarchical Fallacies* (Edinburgh, 1843), article II.

**no-ownership theory.** The theory that experiences do not require a real \*subject to whom they must belong. Mental occurrences are treated as independent events, and our normal language for describing them, with its

apparent reference, using personal pronouns, to subjects who have them, is viewed either as not designating anything, as with the first person, or as designating the body to which the experiences are causally linked, in the third person. The theory was attributed by P. F. Strawson to middle-period Wittgenstein and to Schlick. Its point is to avoid non-physical selves, but independent, unowned, experiences are counter-intuitive, and, although Strawson's charge of incoherence may be unfounded, there are less extreme alternatives to \*cartesianism. P.F.S.

\*mind-body problem; mind, problems of the philosophy of; persons; other minds.

P. F. Strawson, *Individuals* (London, 1959), ch. 3.

**normalization.** Dag Prawitz proved (1965) an analogue for \*natural deduction systems of Gentzen's cut-elimination theorem: every derivation could be transformed into a normalized one. The concept of a normalized proof is more complicated to explain than that of a cut-free proof in the sequent calculus, but the essential idea is the same, the basic step being that of removing any part of the formal \*proof in which a formula is first derived by means of an introduction rule and thereupon eliminated as the major premiss of an elimination rule: an unnecessary detour. Suppose, for instance, that  $A \& B$  is inferred from separate premisses  $A$  and  $B$ , and that  $A$  is then immediately inferred from it. Plainly, the detour through  $A \& B$  was redundant; the two lines on which stood, first,  $A \& B$  and then  $A$  can be excised, together with the entire part of the derivation leading to the premiss  $B$ . This is the basic step in a normalization. If the application of the elimination rule was delayed, the derivation must first be rearranged to make it follow immediately upon the application of the introduction rule.

Building on a remark of Gentzen's that a logical \*constant is *defined* by the introduction rules, of which the elimination rules are consequences, Prawitz has explored means of justifying elimination rules by appeal to the introduction rules. The strategy is to show that canonical proofs of the premisses of an elimination rule can be transformed into a canonical proof of its conclusion, a canonical proof being one whose last line is inferred by means of an introduction rule: this is a justification only under the assumption that, if a logically complex statement is known to be true, its truth could be known by a canonical proof of it. The condition that an elimination rule can be so justified is precisely that the basic step of normalization can be carried out. M.D.

D. Prawitz, *Natural Deduction* (Stockholm, 1965).

— 'On the Idea of a General Proof Theory', *Synthese* (1974).

**normative.** 'Normative' is the adjective derived from the noun 'norm', which signifies *either* the average or usual level of attainment or performance for an individual or

group; *or*, and more usually in philosophical discussion, a standard, rule, principle used to judge or direct human conduct as something to be complied with. The phrase 'moral norm' is used generically to mean anything which proffers moral guidance, instruction, or a basis for appraisive judgement. It is a term of fairly recent coinage, but having the same root as the more familiar 'normal' in the Latin word *norma*, a carpenter's rule or square. 'Normal' and 'normative' are importantly distinct, however, since it is not plainly the case that what is normal represents a standard to be complied with. The same issues arise over what is \*'natural' or 'unnatural' being used as a standard. N.J.H.D.

See G. H. von Wright, *Norm and Action* (London, 1963) for a treatment of issues in this area.

**norms, epistemic.** Epistemic norms are the rules or standards by which we epistemically evaluate beliefs. For example, we often criticize beliefs that are formed in ways that are not appropriately sensitive to the available evidence, and this has led some commentators to suggest that the rule *proportion one's belief to the evidence that one has in favour of that belief* is an epistemic norm, although this is controversial. Epistemological theories which analyse the key epistemic concepts like \*justification entirely in terms of whether the agent in question adheres to (or at least does not flout) the epistemic norms are known as deontological theories, though such accounts have fallen out of favour in contemporary epistemology. Instead, the currently dominant view of epistemic norms is that they should play only a peripheral role in one's epistemological theory. Indeed, the view that a deontological conception of justification is not an essential component of \*knowledge is often thought to be a defining thesis of epistemological externalism, a subspecies of which is \*naturalised epistemology. D.PRI.

R. W. Miller, 'The Norms of Reason', *Philosophical Review*, 104 (1995).

J. Pollock, 'Epistemic Norms', in his *Contemporary Theories of Knowledge* (Lanham, Md., 1986), ch. 5.

**Norwegian philosophy.** Norway enjoys a varied and vigorous philosophical life. Yet by European and even Scandinavian standards her academic institutions are of quite recent origin. The 400-year Dano-Norwegian union meant that between the founding of the universities of Uppsala in Sweden and Copenhagen in the 1470s and that in 1811 of Norway's first, the King Frederick University in Christiania (now, as the University of Oslo, Scandinavia's largest) Copenhagen was the centre of Norwegian academic life. In 1802 a Norwegian-born philosopher, scientist, and writer, Henrich (Henrik) Steffens (1773–1845), first set in motion the Romantic movement in Denmark, and when the new university opened in 1813 (a year before the dissolution) it was a Norwegian philosopher with ten years of tenure in Copenhagen who became Norway's first Professor of Philosophy. Niels Treschow (1751–1833) was a Spinozistically inclined critic of Kant and the first notable Scandinavian proponent of determinism. He pro-

pounded a dual-aspect theory of mind and body and argued for the primacy of particulars over universals. Treschow's thought is summed up in a late three-volume work *Om Gud, Idee- og Sandseverdenen* (On God and the Worlds of Idea and Sensation) (Christiania, 1831–3). Anticipating later evolutionary theories, Treschow surmised that the human ability to react inwardly to outward stimuli has its origins in some animal species. The ability to react to a diverse environment interacts dynamically with a formative impulse to unity and generates the idea of the One, combining the idea of God's immanence in all things with that of God's transcendence and bringing with it a teleological notion of the unity of mankind.

It was the Danish philosopher, aphorist, and novelist Poul Martin Møller (1794–1838), later Kierkegaard's mentor, who introduced Norway to Hegel, in 1827–31. The Hegelian tradition was consolidated by Marcus Jacob Monrad (1816–97), the first major thinker to succeed Treschow (in 1851). An orthodox Hegelian, Monrad was critical of most post-Hegelian thought including that of Schelling, Feuerbach, and Kierkegaard. His opposition to these, as well as to Millian politics, Comptean positivism, and Darwinism ('purposefulness without purpose'), put him at odds with the spirit of the age, but Monrad's objections—these views and movements were one-sided and therefore latently dualistic—were acute and even prescient. He saw a paradigmatic case in point in what he called the Englishman's predilection for 'facts' at the expense of the 'universal idea'.

What followed may seem to confirm Monrad's diagnosis. The early twentieth century saw a turn towards empirical psychology (facts) and psychoanalysis, the universal idea being entrusted to historians of ideas (among them notably A. H. Winsnes (1889–1972)). In 1928 one of two philosophy chairs was converted during its incumbency by Harald K. Schjelderup (1895–1974) into a chair in psychology. Until after the Second World War the remaining chair, to which Arne Naess (b. 1912) was appointed in 1939, was Norway's single tenured position in philosophy. Philosophy's present place in Norwegian academic life, as in the society at large, is due in large measure to Naess. In the 1930s he had participated in Moritz Schlick's seminar and retained regular contact with the \*Vienna Circle despite disagreement with some of its tenets. Opposed to the views that traditional philosophical puzzles are pseudo-problems and that empirical investigation plays no part in philosophical discussion, Naess claimed that empirical investigations can play an evidential role in philosophical discussions. In a seminal work written in the 1930s (*Erkenntnis und wissenschaftliches Verhalten* (Cognition and Scientific Behaviour (Oslo, 1936)), Naess anticipated many themes familiar in post-war \*analytic philosophy. His ideas had a marked influence on social research in Norway, the promise of collaboration between philosophers and social scientists giving rise to the journal *Inquiry*, which Naess founded in 1958. Philosophers themselves were divided. Some exploited the methodology of Naess's 'empirical semantics'

(e.g. Harald Ofstad (1920–93)) or reconstructed it (Ingemund Gullvåg (1925–98)). Others, provoked by a residual \*positivism and \*behaviourism in Naess's programme, followed a path marked out by Hans Skjervheim (1926–99) in *Objectivism and the Study of Man* (1959), a work which had an early influence on \*Jürgen Habermas. These philosophers—among them Audun Øfsti (b. 1938) and Gunnar Skirbekk (b. 1937)—pursued inquiries into what Karl Otto Apel has labelled 'transcendental pragmatics', stressing discontinuities between explanation in natural science and understanding in social science. Meanwhile Naess himself, after a period of concern with systemic aspects of his combined empirical and philosophical enterprise, resigned his chair in 1970 to concentrate on ecological issues.

In Norway mathematical logic is famously represented by Thoralf Skolem (1887–1963), Professor of Mathematics in Oslo from 1938 to 1957. A classical tradition is maintained by E. A. Wyller (b. 1923). The Wittgenstein Archives are located in Bergen, where a Wittgensteinian tradition in aesthetics has also taken root. From the late 1980s, several philosophers, notably Knut Erik Tranøy (b. 1918), have co-operated in the work of new centres for research into ethical and normative aspects of science, medicine and politics. Today's Norwegian philosophy departments house many non-Norwegians and many Norwegians have pursued their graduate studies abroad. This accounts for a degree of cross-fertilization between the 'analytic' and 'continental' traditions (Jon Elster (b. 1940) (Marx), Dagfinn Føllesdal (b. 1932) (Husserl), and Alastair Hannay (b. 1932) (Kierkegaard)).

A long-established introductory course (*examen philosophicum*) required of all university students, together with the founding of universities in Bergen, Trondheim, and Tromsø in the post-war years, has meant that a rapidly increasing university-trained population is conversant with philosophical traditions and thought, while the University of Oslo's Institute of Philosophy has become one of Europe's largest.

**notations, logical.** We still have not emerged from the symbolic turmoil of the early history of modern logic. A wide variety of notations are currently employed even for the simplest of logical calculi, the variety stemming from a number of competing interests ranging from typographical economy to the ease with which the logical structure of formulae can be determined and proofs devised. There

are two dimensions of variation: the system of punctuation and the symbols of the logical and non-logical vocabulary. There are three main systems of punctuation used to prevent syntactic ambiguity: the use of brackets, the dot notation of *Principia Mathematica*, and the bracket-free Polish notation of Łukasiewicz. Differences of non-logical vocabulary are usually trivial differences in the choice of letters and their case. Below is a table, admittedly selective, of variations in logical vocabulary, the more common symbols beginning each row, Polish notation at the end.

Negation	$\neg P, \sim P, \neg P, P', \bar{P}, Np$	
Disjunction	$P \vee Q, Apq$	
Conjunction	$P \& Q, P \wedge Q, P \cdot Q, PQ, Kpq$	
Material conditional	$P \rightarrow Q, P \supset Q, Cpq$	
Material biconditional	$P \leftrightarrow Q, P \equiv Q, P \sim Q, Epq$	
Universal quantifier	$(x)Fx, (\forall x)Fx, \forall xFx, IIfx$	
Existential quantifier	$(\exists x)Fx, \exists xFx, (Ex)Fx, ExFx, \Sigma xFx$	
Necessity operator	$\square, L$	
Possibility operator	$\diamond, M$	A.D.O.

**nothing:** see non-being and nothing; nothingness; nothingness, absolute.

**nothingness.** Philosophers have often seen nothingness as an ontological, not simply a logical, category. Plato and Plotinus regarded matter, in contrast to form, as non-being. Heidegger claimed in *Being and Time* and *What is Metaphysics?* (1929; 5th edn. 1949, tr. in *Basic Writings*, ed. D. Krell (London, 1967)) that the nothing, which becomes apparent in objectless *Angst*, is crucial to our experience; it is prior to, and forms the basis of, logical negation. Human *Existenz* has no ground; it arises from the abyss of nothing. It culminates in the nothingness of death, and its meaning consists in the anticipation of death. The natural interpretation of this (though one rejected by Heidegger) is that \**Dasein* confers meaning, i.e. being, on non-human beings and on itself, and thus draws them out of meaningless chaos, i.e. nothing. To avoid saying that the nothing *is*, he says 'The nothing nihilates' (*Das Nichts selbst nichtet*), which Carnap regarded as a paradigm of metaphysical \*nonsense. For Sartre, specifically human being consists in nothing or self-negation; this is why we can discern 'negative realities', such as the absence of a guest. For both philosophers, man's radical \*freedom is rooted in nothingness. M.J.I.

H. Kühn, *Encounter with Nothingness* (Hinsdale, Ill., 1949).

M. Murray (ed.), *Heidegger and Modern Philosophy: Critical Essays* (New Haven, Conn., 1978).

**nothingness, absolute.** In modern Japanese philosophy, this idea is central for many of the Kyoto School philosophers. It stems from the Mahāyāna Buddhist notion of 'emptiness', according to which nothing is what it is in isolation, but arises and perishes only within a network of relationships with everything else. In Buddhist practice,

however, one must avoid cleaving to the experience of emptiness: the nothingness that, as non-being, is the negation of beings, must itself be negated before one can arrive at *absolute* nothingness. For Nishida the 'locus of nothingness' is the basis of all experience; for Tanabe absolute nothingness is mediation through absolute 'Other-power' (of Amida Buddha); in Watsuji's ethics the individual self has to undergo absolute negation to be fully integrated into society; and for Nishitani nothingness is above all to be *experienced*—since it loses its absolute character if it is merely 'thought'. There are thought-provoking parallels with *das Nichts* in Heidegger's philosophy. G.R.P.

\*non-being and nothing; nothingness.

Robert E. Carter, *The Nothingness beyond God: An Introduction to the Philosophy of Nishida Kitarō* (New York, 1989).

**nothing so absurd.**

Pythagoras and Plato, who are most respectable authorities, bid us, if we would have trustworthy dreams, to prepare for sleep by following a prescribed course in conduct and in eating. The Pythagoreans make a point of prohibiting the use of beans, as if thereby the soul and not the belly was filled with wind! There is nothing so absurd but some philosopher has said it.

(Cicero, *De divinatione* II. lxviii. 120)

Cicero's dialogue *De divinatione* attacks divination. Its apologist Quintus cites the important philosophers who have believed in it, but Marcus, his opponent, argues that 'those superstitious and half-cracked philosophers of yours would rather appear absurd than anything else in the world'. The Stoics, for instance, regarded current disbelief in the Delphic oracle not as a sign of superstition's abatement but as abatement of the 'virtue' of local subterranean exhalations, which, if it had really ever existed, would obviously have been eternal. Yet Cicero himself practised augury, and defended it on other occasions in the belief that it promoted law-abiding behaviour. J.O'G.

\*Stoicism.

**nothing so extravagant and irrational.**

Those unhappy people were proposing schemes for persuading monarchs to choose favourites upon the score of their wisdom, capacity and virtue; of teaching ministers to consult the public good; of rewarding merit, great abilities and eminent services; of instructing princes to know their true interest by placing it on the same foundation with that of their people; of choosing for employments persons qualified to exercise them; with many other wild and impossible chimeras, that never entered before into the heart of man to conceive, and confirmed in me the old observation, that there is nothing so extravagant and irrational which some philosophers have not maintained for truth.

(Jonathan Swift, *Gulliver's Travels*, ch. 6)

Like their scientific colleagues trying to cure flatulence by applying bellows to the rectum, philosophers at the imagined Academy of Lagado reach absurd conclusions, presuming that the world conforms to their principles.

Swift was a Tory from the age of 43, and regarded the human as not 'animal rationale', only 'animal rationis capax', and wickedness as 'all according to the due course of things'. Yet the aim of his satires was in fact social improvement, and, even if Tory pessimism pillories these as chimeras, it is after all the unworkable utopian measures that are *really* \*common-sense. Swift's reactionary thrust is double-edged, for it ridicules the engrained human folly that engenders and necessitates it. J.O'G.

**noumena:** *see* phenomena and noumena.

**nous.** In Greek philosophy, the highest form of rationality which is capable of grasping the fundamental principles of reality. In contrast to perception, which delivers awareness of the changing, accidental properties of things, *nous* consists in understanding their essential, immutable nature. Moreover, it supersedes belief, which may attain truth but falls short of explaining the why and wherefore of things. For Aristotle, the unmoved mover of the universe was a cosmic *Nous*. O.R.J.

\*prime mover.

F. E. Peters, *Greek Philosophical Terms* (New York, 1967).

**novel, the philosophical.** The philosophical novel is usually understood as that subspecies of \*fiction which endeavours to present a specific philosophical viewpoint, sometimes metaphysical, sometimes ethical, and sometimes aesthetic. Thus it is perhaps closer to the allegory or *roman-à-clef* than to fiction proper. For whereas it is usually a defect in a work of fiction that it ally itself closely with a particular viewpoint, for a philosophical novel, a grasp of the fact that a particular world-view is embodied is a pre-condition of understanding the novel.

Henry Fielding's *Tom Jones*, for example, embodies a particular moral philosophy, one in which the virtues of an unpremeditated warmth and responsiveness are valued above an alternative morality which is essentially conceived as rule-governed, though Fielding's *Bildungsroman* also charts the dangers and limitations of a morality which is so reactive and spontaneous. Other examples which leap to mind are the novels of George Eliot or Proust's analysis of memory and identity in *A la recherche du temps perdu*. Characteristically, such philosophical ideas are illustrated rather than asserted, as in *Middlemarch*, where George Eliot shows us various forms of egoism. In the twentieth century the novels of Sartre presented existential themes more memorably and vividly than his philosophical writing, and Camus's *The Outsider* is a paradigm of the philosophical novel.

The free exploration of literary space in interpretation is thereby placed within bounds set by the philosophical presuppositions of the novelist. \*Interpretation is not only limited by the text but also by the recognition that a certain philosophical standpoint is involved. The decision to place a novel within this genre is consequently as much a critical act as a matter of pre-critical classification. R.A.S.

Stephen D. Ross, *Literature and Philosophy* (New York, 1969).

**Nozick, Robert** (1938–2002). A philosopher of remarkably varied interests, whose most influential work presented an articulate defence of a bare-bones \*libertarianism. Nozick argued that the state cannot have a very large role in the economy and society if the libertarian rights of individuals are to prevail. In general, he argued against end-state theories, such as \*utilitarianism or John Rawls's theory of \*justice, and in favour of process theories that focus on the rightness of piecemeal actions independently of their contribution to a final state of affairs. Nozick had a gift for finding memorable cases to represent his problems and an energetic style that pulls readers into debate. He also worked on decision theory, epistemology, theory of value, and the good life. R.HAR.

***n*-tuple:** *see* ordered set.

**number.** There are several kinds. Ordinal numbers provide the structure to order collections of distinct objects (first, second, third, etc.); cardinal numbers are used to indicate the sizes of collections of distinct objects (zero, one, two). Natural numbers are finite cardinal numbers. Integers are whole numbers, including negative numbers. Rational numbers are ratios of integers, sometimes called 'fractions'. Real numbers are used to measure (potentially) continuous quantities in terms of a unit, such as length in meters and mass in grams. Complex numbers include so-called 'imaginary numbers', which are square roots of negative real numbers. Arithmetic, number theory, and real and complex analysis study the structures of the various number systems. There are philosophical problems concerning the ontological status of the various numbers—do they exist, are they mental, etc.—and there are epistemological problems concerning how we know anything about numbers.

There are theories of infinitely large numbers. Contemporary \*set theory, derived from the work of Georg Cantor and Ernst Zermelo, studies both infinite cardinals and infinite ordinals. It can be shown that there are just as many integers and rational numbers as there are natural numbers, in that there is a one-to-one correspondence between the sets. Nevertheless, Cantor showed that there are distinct infinite cardinal numbers and, in particular, that for any set *S*, the set of all subsets of *S* is larger than *S*. A set is said to be 'countable' or 'denumerable' if it is the same size as or smaller than the natural numbers, the smallest infinite set. (\*Continuum problem.)

There are also theories of 'infinitesimals', which are like real numbers, but are infinitely small. Infinitesimals came up in the study of continuous change, such as motion,

both in the medieval period and in the original development of the calculus. The theory of infinitesimals saw a rebirth in the twentieth century, through certain results in mathematical logic.

**numinous:** *see* holy, numinous, and sacred.

**Nussbaum, Martha C.** (1947– ). Nussbaum first came to prominence as a scholar of classical philosophy: her substantial book *The Fragility of Goodness* was the culmination of her work on questions to do with the meaning of life and sources of value as these are treated in Plato and Aris-

totle and also in Greek tragedy. The scope of her work subsequently broadened greatly. She has sought to illuminate issues of moral inquiry and insight by examining how philosophy and literature overlap and show cognate concerns; she has examined questions of social justice and the ethics of development with particular reference to women's place in society; and she has presented an ambitious theory of the emotions. She holds a joint chair in philosophy and law at the University of Chicago, with associate appointments in classics, political science, and even the divinity school.

# O

**Oakeshott, Michael** (1901–92). British philosopher, who read history at Cambridge and taught it there for many years before taking the chair of political science at the London School of Economics in 1950. Oakeshott's basic philosophical orientation was idealist. He believed that reality is mediated to us only in a number of distinct human practices, such as history, morality, politics, science, philosophy, and poetry. Each practice is a specifically human achievement, each reveals only part of the whole, and none is superior to the rest. In becoming apprised of a practice, we enter something which must be lived and which cannot be reduced to formulae or analysed in terms of extrinsic goals. The rationalist, Oakeshott's great bugbear, thinks it can. Particularly in politics, he attempts to turn what should be a conversation between friends, a mode of living together, into an enterprise or set of enterprises. The enterprise state will be deformed by ideology, by managerial techniques and abstractions, and by ceaseless legislation and litigation. Oakeshott's work has obvious affinities with Wittgenstein's and some of the same difficulties. Oakeshott's practices, like Wittgenstein's \*language-games, are elusive, and while Oakeshott's targets are clear enough, his alternative to the modern managerial state is fastidiously underdefined. None the less, all politicians and most philosophers would benefit from a closer acquaintance with Oakeshott than they generally manifest.

**oar in water.** Favourite example of how circumstances can affect the \*perception of an object, and make it seem other than it is. 'The same object seems to us bent or straight, according to whether we see it in water or out of water' (Plato, *Republic* x. 602c). Familiar in philosophy after Aristotle, the example divided sceptics (like Sextus Empiricus), who thought it showed that the senses give us no knowledge of an objective world, from Epicureans, who insisted that if there is mistake or ignorance in such cases, it must be attributed to the judgement, and not the senses (Lucretius, *De rerum natura* iv. 439ff). Employed later by Descartes and Berkeley, the example was hack-

neyed enough by the time of Hume to count as one of the 'trite topics, employed by sceptics in all ages, against the evidence of sense'. It continued to feature in twentieth-century discussion, used, for example, by Ayer in support of a \*sense-datum theory of perception.

J. L. Austin's dry comment was: 'What is wrong, what is even faintly surprising, in the idea of a stick's being straight but looking bent sometimes? Does anyone suppose that if something is straight, then it jolly well has to *look* straight at all times and in all circumstances? Obviously no one [does] . . . So . . . what is the difficulty?'

J. L. Austin, *Sense and Sensibilia* (Oxford, 1962), iii.

**objectivism and subjectivism.** Theories that various kinds of judgement are, respectively, objective, i.e. pertain to objects, or subjective, i.e. pertain to subjects (people). (1) 'Fish have fins' is an objective claim: its truth or falsity is independent of what anyone thinks or feels about the matter. (2) 'Raw fish is delicious' is a subjective claim: its truth or falsity is not thus independent, and indeed arguably it is neither true nor false, even though taste can be sophisticated, discriminating, insensitive, etc. The statement (3) 'Most Japanese find raw fish delicious (while most Britons do not)' is an *objective* truth or falsehood *about* subjects. It is therefore perhaps surprising that one theory labelled 'subjectivism' about morality, aesthetics, etc. is the view that evaluative claims within these fields are of kind (3), while another theory asserts they are of kind (2).

It is counter-productive to use a different term, 'relativism', to mean the same as 'subjectivism'. If by 'relativism' we mean the theory that what is valuable (or even true) depends on changing circumstances, then it does not entail subjectivism.

A.J.L.

Richard Lindley, 'The Nature of Moral Philosophy', in G. H. R. Parkinson (ed.), *An Encyclopaedia of Philosophy* (London, 1988).

**objectivism and subjectivism, ethical.** There is a range of views about moral judgements. At the subjectivist pole, they are taken to be discrete feeling-responses of

individuals to situations actual or imagined. To move towards the objectivist pole is to argue that moral judgements can be rationally defensible, true or false, that there are rational procedural tests for identifying morally impermissible actions, or that moral values exist independently of the feeling-states of individuals at particular times. To dismiss 'objective moral values' as illusions or fictions—claims the objectivist—violates our experience of the pressure they put on our will and on our emotions and interests. Only if they are misconceived as mysterious entities, lacking perceptual qualities, can they be deemed too 'queer' or fanciful to be taken seriously.

That there can be protracted disagreement over moral issues does not rebut the objectivist: equally persistent disagreement in other fields—e.g. historical study—hardly calls in question the objective occurrence of historical events.

Subjectivism too has more and less plausible forms. If it sees moral judgements as simply individual avowals of feeling, then certainly no adequate account, in these terms, can be given of moral disagreement—or of deliberation either. To understand them as the expression and evocation of emotions and attitudes still does no justice to the logic of moral discourse. A distinctively moral point of view must be acknowledged, and the moral requirement to 'be objective'—in the minimal but crucial sense of discounting selfish bias. If such a view still rests upon contingently common human 'sentiments', as for Hume it did, we have a mid-position—intersubjectivism. That has obvious attractions, but it is no less open to the objectivists' complaint, that this account still badly underestimates the resources of practical reasoning. R.W.H.
