**mega-** **1.** Symbol M. A prefix used in the metric system to denote one million times. For example,  $10^6$  volts = 1 megavolt (MV). **2.** A prefix denoting large size; e.g. meganucleus, megasporangium.

**megaphyll** A type of foliage leaf in ferns and seed plants that has branched or parallel vascular bundles running through the lamina. The megaphylls of ferns are large pinnate leaves called **fronds**. A megaphyll was formerly called a **macrophyll**. Compare MICROPHYLL.

**megaspore** See SPOROPHYLL.

**megasporophyll** See SPOROPHYLL.

**megaton weapon** A nuclear weapon with an explosive power equivalent to one million tons of TNT. Compare KILOTON WEAPON.

**meiosis (reduction division)** A type of cell division that gives rise to four reproductive cells (gametes) each with half the

chromosome number of the parent cell. Two consecutive divisions occur (see illustration). In the first, \*homologous chromosomes become paired and may exchange genetic material (see CROSSING OVER) before moving away from each other into separate daughter nuclei. This is the actual reduction division because each of the two nuclei so formed contains only half of the original chromosomes. The daughter nuclei then divide by mitosis and four \*haploid cells are produced. See also PROPHASE; METAPHASE; ANAPHASE; TELOPHASE.

**Meissner effect** The falling off of the magnetic flux within a superconducting metal when it is cooled to a temperature below the critical temperature in a magnetic field. It was discovered by Walther Meissner (1882-1974) in 1933 when he observed that the earth's magnetic field was expelled from the interior of tin crystals below 3.72 K, indicating that as \*superconductivity appeared the material became perfectly diamagnetic. See MAGNETISM.

**Meitner, Lise** (1878-1968) Austrian-born Swedish physicist, who went to Berlin to study \*radioactivity with Otto \*Hahn. In 1917 they discovered \*protactinium. After World War I Meitner and Hahn returned to Berlin, where in 1935 they bombarded uranium with neutrons. In 1938 she left Germany, with other Jewish scientists, and went to the Nobel Institute in Stockholm. In 1939 she and Otto Frisch (1904-79) explained Hahn's results in terms of \*nuclear fission.

**meitnerium** Symbol Mt. A radioactive \*transactinide element; a.n. 109. It was first made in 1982 by Peter Armbruster and a team in Darmstadt, Germany, by bombarding bismuth-209 nuclei with iron-58 nuclei. Only a few atoms have ever been detected.

**melamine** A white crystalline compound,  $C_3N_6H_6$ . Melamine is a cyclic compound having a six-membered ring of alternating C and N atoms, with three  $NH_2$  groups. It can be copolymerized with methanal to give thermosetting **melamine resins**, which are used particularly for laminated coatings.

**melanin** Any of a group of polymers, derived from the amino acid tyrosine, that cause pigmentation of eyes, skin, and hair in vertebrates. Melanins are produced by specialized epidermal cells called

**melanophores** (or **melanocytes**); their dispersion in these cells is controlled by \*melanocyte-stimulating hormone and \*melatonin. Certain invertebrates, fungi, and microorganisms also produce melanin pigments. The 'ink' of the octopus and squid is a notable example. Hereditary \*albinism is caused by the absence of the enzyme tyrosinase, which is necessary for melanin production.

**melanism** Black coloration of the body caused by overproduction of the pigment melanin, often as a reaction to the environment. There are several species of melanic moths in industrially polluted areas (see INDUSTRIAL MELANISM) and the panther is a melanic form of leopard.

**melanocyte-stimulating hormone (MSH)** A hormone, secreted in the anterior region of the pituitary gland, that stimulates the concentration of melanin granules in the \*chromatophores of the skin of lower vertebrates, such as amphibians. The role of MSH in humans and other mammals is not clearly understood.

**melatonin** A hormone derived from \*serotonin and secreted by the pineal gland and retinas of vertebrates. Melatonin secretion by the pineal is linked to the dark-light cycle of the organism's environment, being greatest at night and lowest by day. The hormone is involved in regulating certain diurnal and seasonal changes in the body, such as the reproductive cycle in seasonally breeding animals. Melatonin also controls pigmentation changes; it triggers aggregation of the pigment \*melanin into melanophores in the skin, causing the skin to turn pale.

**melting point (m.p.)** The temperature at which a solid changes into a liquid. A pure substance under standard conditions of pressure (usually 1 atmosphere) has a single reproducible melting point. If heat is gradually and uniformly supplied to a solid the consequent rise in temperature stops at the melting point until the fusion process is complete.

**membrane** A thin sheet of tissue or other material that lines a body cavity, forms a partition, or connects various structures. Any of the various flexible sheetlike structures, composed predominantly of lipids and proteins, that occur in living cells, such as the \*plasma membrane forming the cell boundary. See CELL MEMBRANE.

**membrane bone (dermal bone)** \*Bone formed directly in connective tissue, rather than by replacing cartilage (*compare* CARTILAGE BONE). Some face bones, skull bones, and part of the clavicle are membrane bones. Small areas of membrane become jelly-like and attract calcium salts. Bone-forming cells break down these areas forming a bone lattice, which eventually fills in.

**membranous labyrinth** The soft tubular sensory structures that form the \*inner ear of vertebrates and are housed within the bony labyrinth.

**memory 1.** (in biology) The means by which information is stored in the brain. The exact mechanism of processing and storing information is not known but is thought to involve the construction of circuits of \*neurons, which are strengthened by repeated use. Memory is essential to the processes of \*learning and recognition of individuals and objects. **2.** (in computing) The part of a computer in which data is stored while it is being worked on. A typical microcomputer, for example, has a comparatively small amount of read-only memory (see ROM) and a large amount of random-access memory (see RAM). Only data in ROM is preserved when the machine is switched off; any data in RAM must be saved to disk if it is wanted again.

**memory cell** See B CELL.

**Mendel, Johann Gregor** (1822–84) Austrian geneticist, who from 1843 lived as a monk in Brünn (now Brno, in the Czech Republic). His fame rests on the plant-breeding experiments he began in 1856, which eventually produced the rules of inheritance summarized in \*Mendel's laws. His work was ignored during his lifetime and only rediscovered

in 1900 by Hugo de Vries (1848–1935) and others. See MENDELISM.

**Mendeleev, Dmitri Ivanovich** (1834–1907) Russian chemist, who became professor of chemistry at St Petersburg in 1866. His most famous work, published in 1869, was the compilation of the \*periodic table of the elements, based on the \*periodic law.

**Mendeleev's law** See PERIODIC LAW.

**mendelevium** Symbol Md. A radioactive metallic transuranic element belonging to the \*actinoids; a.n. 101; mass number of the first discovered nuclide 256 (half-life 1.3 hours). Several short-lived isotopes have now been synthesized. The element was first identified by Albert Ghiorso, Glenn Seaborg (1912–99), and associates in 1955. The alternative name **unilunium** has been proposed.

**Mendelism** The theory of heredity that forms the basis of classical \*genetics, proposed by Gregor Mendel in 1866 and formulated in two laws (see MENDEL'S LAWS; PARTICULATE INHERITANCE). Mendel suggested that individual characteristics were determined by inherited 'factors', and when improved microscopes revealed details of cell structure the behaviour of Mendel's factors could be related to the behaviour of chromosomes during \*meiosis.

**Mendel's laws** Two laws summarizing Gregor Mendel's theory of inheritance (see also MENDELISM). The **Law of Segregation** states that each hereditary characteristic is controlled by two 'factors' (now called \*alleles), which segregate (separate) and pass into separate germ (reproductive) cells. The **Law of Independent Assortment** states that pairs of 'factors' segregate independently of each other when germ cells are formed (see also INDEPENDENT ASSORTMENT). These laws are the foundation of genetics.

**Mendius reaction** A reaction in which an organic nitrile is reduced by nascent hydrogen (e.g. from sodium in ethanol) to a primary amine:

**meninges** The three membranes that

surround the brain and spinal cord of vertebrates: the \*pia mater, the \*arachnoid membrane, and the outer \*dura mater. The pia and arachnoid are separated by the **subarachnoid space**, which contains \*cerebrospinal fluid.

**meniscus 1.** A concave or convex upper surface that forms on a liquid in a tube as a result of \*surface tension. **2.** See CONCAVE.

**menopause** The time in a woman's life when ovulation and menstruation cease (see MENSTRUAL CYCLE). It normally occurs between the ages of 45 and 55. The effects of the gonadotrophic hormones, \*follicle-stimulating hormone and \*lutinizing hormone, in the ovaries decrease so that the follicles do not develop properly. There is a change in the balance of the hormones oestrogen and progesterone, secreted by the ovaries, which may be associated with certain physical symptoms, such as weight gain and 'hot flushes', and there may also be mood changes. These symptoms can be treated by hormone replacement therapy (HRT) with oestrogens and progestogens.

**menstrual cycle** The approximately monthly cycle of events associated with \*ovulation that replaces the \*oestrous cycle in most primates (including humans). The lining of the uterus becomes progressively thicker with more blood vessels in preparation for the \*implantation of a fertilized egg cell (blastocyst). Ovulation occurs during the middle of the cycle (the fertile period). If fertilization does not occur the uterine lining breaks down and is discharged from the body (**menstruation**); the discharge is known as a 'period'. In women the fertile period is 11–15 days after the end of the last menstruation.

**menstruation** See MENSTRUAL CYCLE.

**menthol** A white crystalline terpene alcohol,  $\text{C}_{10}\text{H}_{18}\text{OH}$ ; r.d. 0.89; m.p.  $42^\circ\text{C}$ ; b.p.  $103\text{--}104^\circ\text{C}$ . It has a minty taste and is found in certain essential oils (e.g. peppermint) and used as a flavouring.

**mercaptans** See THIOLS.

**mercapto group** See THIOLS.

**mercuric compounds** Compounds of

mercury in its +2 oxidation state; e.g. mercuric chloride is mercury(II) chloride,  $\text{HgCl}_2$ .

**mercurous compounds** Compounds of mercury in its +1 oxidation state; e.g. mercury(I) chloride is mercurous chloride,  $\text{HgCl}$ .

**mercury** Symbol Hg. A heavy silvery liquid metallic element belonging to the \*zinc group; a.n. 80; r.a.m. 200.59; r.d. 13.55; m.p.  $-38.87^\circ\text{C}$ ; b.p.  $356.58^\circ\text{C}$ . The main ore is the sulphide cinnabar ( $\text{HgS}$ ), which can be decomposed to the elements. Mercury is used in thermometers, barometers, and other scientific apparatus, and in dental amalgams. The element is less reactive than zinc and cadmium and will not displace hydrogen from acids. It is also unusual in forming mercury(I) compounds containing the  $\text{Hg}_2^{2+}$  ion, as well as mercury(II) compounds containing  $\text{Hg}^{2+}$  ions. It also forms a number of complexes and organomercury compounds.

**Mercury** The smallest of the major planets in the \*solar system and the nearest to the sun ( $57.91 \times 10^6$  km distant). Its equatorial diameter is 4879.4 km and its \*sideral period 86.70 days. The Mariner 10 spacecraft passed within 1000 km of Mercury in 1975 and revealed surface features similar to the moon, with impact craters dominating a bleak landscape that has been bombarded for some thousand million years by meteoric debris. There is no atmosphere and a maximum surface temperature of 700 K at the equator at perihelion, which rapidly cools to 110 K at night.

**mercury cell** A primary \*voltaic cell consisting of a zinc anode and a cathode of mercury(II) oxide ( $\text{HgO}$ ) mixed with graphite. The electrolyte is potassium hydroxide (KOH) saturated with zinc oxide, the overall reaction being:

The e.m.f. is 1.35 volts and the cell will deliver about 0.3 ampere-hour per  $\text{cm}^3$ .

**mercury(I) chloride** A white salt,  $\text{Hg}_2\text{Cl}_2$ ; r.d. 7.15; sublimes at  $400^\circ\text{C}$ . It is made by heating mercury(II) chloride with mercury and is used in calomel cells (so

called because the salt was formerly called **calomel**) and as a fungicide.

**mercury(II) chloride** A white salt,  $\text{HgCl}_2$ ; r.d. 5.4; m.p.  $276^\circ\text{C}$ ; b.p.  $302^\circ\text{C}$ . It is made by reacting mercury with chlorine and used in making other mercury compounds.

**mercury(II) fulminate** A grey crystalline solid,  $\text{Hg}(\text{CNO})_2 \cdot \frac{1}{2}\text{H}_2\text{O}$ , made by the action of nitric acid on mercury and treating the solution formed with ethanol. It is used as a detonator for cartridges and can be handled safely only under cold water.

**mercury(II) oxide** A yellow or red oxide of mercury,  $\text{HgO}$ . The red form is made by heating mercury in oxygen at  $350^\circ\text{C}$ ; the yellow form, which differs from the red in particle size, is precipitated when sodium hydroxide solution is added to a solution of mercury(II) nitrate. Both forms decompose to the elements at high temperature. The black precipitate formed when sodium hydroxide is added to mercury(I) nitrate solution is sometimes referred to as mercury(I) oxide ( $\text{Hg}_2\text{O}$ ) but is probably a mixture of  $\text{HgO}$  and free mercury.

**mercury(II) sulphide** A red or black compound,  $\text{HgS}$ , occurring naturally as the minerals cinnabar (red) and metacinnabar (black). It can be obtained as a black precipitate by bubbling hydrogen sulphide through a solution of mercury(II) nitrate. The red form is obtained by sublimation. The compound is also called **vermilion** (used as a pigment).

**mercury-vapour lamp** A type of discharge tube in which a glow discharge takes place in mercury vapour. The discharge takes place in a transparent tube of fused silica or quartz into the ends of which molybdenum and tungsten electrodes are sealed; this tube contains argon and a small amount of pure mercury. A small arc is struck between a starter electrode and one of the main electrodes causing local ionization of some argon atoms. The ionized atoms diffuse through the tube causing the main discharge to strike; the heat from this vaporizes the mercury droplets, which become ionized current carriers. Radiation is confined to four visible wavelengths in the visible spectrum

and several strong ultraviolet lines. The light is bluish but can be changed by the use of \*phosphors on an outer tube. The outer tube is also usually used to filter out excessive ultraviolet radiation. The lamp is widely used for street lighting on account of its low cost and great reliability and as a source of ultraviolet radiation.

**mericarp** See SCHIZOCARP.

**meridian** **1.** See LATITUDE AND LONGITUDE. **2. (magnetic meridian)** An imaginary great circle on the earth's surface that passes through the north and south magnetic poles. A compass needle on the earth's surface influenced only by the earth's magnetic field (see GEOMAGNETISM) comes to rest along a magnetic meridian. **3. (celestial meridian)** A great circle of the \*celestial sphere that passes through the zenith and the celestial poles. It meets the horizon at the north and south points.

**mer-isomer** See ISOMERISM.

**meristem** A plant tissue consisting of actively dividing cells that give rise to cells that differentiate into new tissues of the plant. The most important meristems are those occurring at the tip of the shoot and root (see APICAL MERISTEM) and the lateral meristems in the older parts of the plant (see CAMBIUM; CORK CAMBIUM).

**merocrine secretion** See SECRETION.

**meromictic lake** See DIMICTIC LAKE.

**mesencephalon** See MIDBRAIN.

**mesentery** A thin sheet of tissue, bounded on each side by \*peritoneum, that supports the gut and other organs in the body cavities of animals. Vertebrates have a well-developed dorsal mesentery that anchors the stomach and intestine and contains blood vessels and nerves supplying the gut. The reproductive organs and their ducts are also supported by mesenteries.

**mesocarp** See PERICARP.

**mesoderm** The layer of cells in the \*gastrula that lies between the \*ectoderm and \*endoderm. It develops into the muscles, circulatory system, and sex organs and in vertebrates also into the excretory system and skeleton. See also GERM LAYERS.

**mesoglea** The gelatinous noncellular layer between the endoderm and ectoderm in the body wall of coelenterates. It may be thin, as in *Hydra*, or tough and fibrous, as in the larger jellyfish and sea anemones. It often contains cells that have migrated from the two body layers but these do not form tissues and organs and the mesoglea is not homologous with the mesoderm of \*triploblastic animals.

**meso-isomer** See OPTICAL ACTIVITY.

**mesomerism** A former name for \*resonance in molecules.

**meson** Any of a class of \*elementary particles that are a subclass of the \*hadrons. According to current quark theory mesons consist of quark-antiquark pairs. They exist with positive, negative, and zero charges, but when charged the charge has the same magnitude as that of the electron. They include the **kaon**, **pion**, and **psi** particles. Mesons are believed to participate in the forces that hold nucleons together in the nucleus. The muon, originally called a mu-meson, was thought to be a meson but is now recognized as a \*lepton.

**meson-catalysed fusion** See NUCLEAR FUSION.

**mesophyll** The internal tissue of a leaf blade (lamina), consisting of \*parenchyma cells. There are two distinct forms. **Palisade mesophyll** lies just beneath the upper epidermis and consists of cells elongated at right angles to the leaf surface. They contain a large number of \*chloroplasts and their main function is photosynthesis. **Spongy mesophyll** occupies most of the remainder of the lamina. It consists of spherical loosely arranged cells containing fewer chloroplasts than the palisade mesophyll. Between these cells are air spaces leading to the \*stomata.

**mesophyte** Any plant adapted to grow in soil that is well supplied with water and mineral salts. Such plants wilt easily when exposed to drought conditions as they are not adapted to conserve water. The majority of flowering plants are mesophytes. Compare HALOPHYTE; HYDROPHYTE; XEROPHYTE.

**mesoscopic** Designating a size scale in-

intermediate between those of the \*microscopic and the \*macroscopic states. Mesoscopic objects and systems require \*quantum mechanics to describe them. Many devices in \*electronics are mesoscopic.

**mesothelium** A single layer of thin platelike cells covering the surface of the inside of the abdominal cavity and thorax and surrounding the heart, forming part of the \*peritoneum and \*pleura (see SEROUS MEMBRANE). It is derived from the \*mesoderm. *Compare* ENDOTHELIUM; EPITHELIUM.

**mesotrophic** Describing a body of water, such as a lake, that is intermediate between a \*eutrophic lake and an \*oligotrophic lake in the amount of nutrients contained within it.

**Mesozoic** The geological era that extended from the end of the \*Palaeozoic era, about 248 million years ago, to the beginning of the \*Cenozoic era, about 65 million years ago. It comprises the \*Triassic, \*Jurassic, and \*Cretaceous periods. The Mesozoic era is often known as the **Age of Reptiles** as these animals, which included the dinosaurs, pterosaurs, and ichthyosaurs, became the dominant life-form; most became extinct before the end of the era.

**messenger RNA** *See* RNA.

**Messier Catalogue** A list of nebulae, galaxies, and star clusters, originally published (with 45 entries) in 1774. Such objects are referred to by their Messier numbers; e.g. the Andromeda galaxy is M31. It is named after its originator, Charles Messier (1730-1817).

**meta-** **1.** Prefix designating a benzene compound in which two substituents are in the 1,3 positions on the benzene ring. The abbreviation *m-* is used; for example, *m*-xylene is 1,3-dimethylbenzene. *Compare* ORTHO-; PARA-. **2.** Prefix designating a lower oxo acid, e.g. metaphosphoric acid. *Compare* ORTHO-.

**metabolic pathway** *See* METABOLISM.

**metabolic rate** A measure of the energy used by an animal in a given time period. The metabolic rate of an animal is affected by several interacting factors, in-

cluding temperature and the level of activity. The metabolic rate of a resting animal is known as the \*basal metabolic rate (BMR).

**metabolic waste** The \*waste products, collectively, of metabolism.

**metabolism** The sum of the chemical reactions that occur within living organisms. The various compounds that take part in or are formed by these reactions are called **metabolites**. In animals many metabolites are obtained by the digestion of food, whereas in plants only the basic starting materials (carbon dioxide, water, and minerals) are externally derived. The synthesis (\*anabolism) and breakdown (\*catabolism) of most compounds occurs by a number of reaction steps, the reaction sequence being termed a **metabolic pathway**. Some pathways (e.g. \*glycolysis) are linear; others (e.g. the \*Krebs cycle) are cyclic. The changes at each step in a pathway are usually small and are promoted by efficient biological catalysts - the enzymes. In this way the amounts of energy required or released at any given stage are minimal, which helps in maintaining a constant \*internal environment. Various \*feedback mechanisms exist to govern \*metabolic rates.

**metabolite** *See* METABOLISM.

**metabolome** The entire complement of metabolites found within a cell under defined conditions, such as a particular physiological or developmental state. The metabolome is determined using various forms of high-throughput mass spectroscopy. It excludes nucleic acids and other large molecules, giving a 'snapshot' of the cell's metabolic state. *See* METABOLOMICS.

**metabolomics** The study of how the pool of metabolites (see METABOLOME) of cells changes under various physiological or developmental conditions or in response to genetic modification (e.g. mutation).

**metaboric acid** *See* BORIC ACID.

**metacarpal** One of the bones in the \*metacarpus.

**metacarpus** The hand (or corresponding part of the forelimb) in terrestrial ver-

tebrates, consisting of a number of rod-shaped bones (**metacarpals**) that articulate with the bones of the wrist (see *CARPUS*) and those of the fingers (see *PHALANGES*). The number of metacarpals varies between species: in the basic \*pentadactyl limb there are five, but this number is reduced in many species.

**metal** Any of a class of chemical elements that are typically lustrous solids that are good conductors of heat and electricity. Not all metals have all these properties (e.g. mercury is a liquid). In chemistry, metals fall into two distinct types. Those of the *s*- and *p*-blocks (e.g. sodium and aluminium) are generally soft silvery reactive elements. They tend to form positive ions and so are described as electropositive. This is contrasted with typical nonmetallic behaviour of forming negative ions. The \*transition elements (e.g. iron and copper) are harder substances and generally less reactive. They form coordination complexes. All metals have oxides that are basic, although some, such as aluminium, have \*amphoteric properties.

**metaldehyde** A solid compound,  $C_4O_4H_4(CH_3)_4$ , formed by polymerization of ethanal (acetaldehyde) in dilute acid solutions below 0°C. The compound, a tetramer of ethanal, is used in slug pellets and as a fuel for portable stoves.

**metal fatigue** A cumulative effect causing a metal to fail after repeated applications of \*stress, none of which exceeds the ultimate \*tensile strength. The **fatigue strength** (or **fatigue limit**) is the stress that will cause failure after a specified number (usually  $10^7$ ) of cycles. The number of cycles required to produce failure decreases as the level of stress or strain increases. Other factors, such as corrosion, also reduce the fatigue life.

**metallic bond** A chemical bond of the type holding together the atoms in a solid metal or alloy. In such solids, the atoms are considered to be ionized, with the positive ions occupying lattice positions. The valence electrons are able to move freely (or almost freely) through the lattice, forming an 'electron gas'. The bonding force is electrostatic attraction between the positive metal ions and the electrons.

The existence of free electrons accounts for the good electrical and thermal conductivities of metals. See also *ENERGY BAND*.

**metallic crystal** A crystalline solid in which the atoms are held together by \*metallic bonds. Metallic crystals are found in some \*interstitial compounds as well as in metals and alloys.

**metallized dye** See *DYES*.

**metallocene** A type of organometallic complex in which one or more aromatic rings (e.g.  $C_5H_5^-$  or  $C_6H_6$ ) coordinate to a metal ion or atom by the pi electrons of the ring. \*Ferrocene was the first such compound to be discovered.

**metallography** The microscopic study of the structure of metals and their alloys. Both optical \*microscopes and \*electron microscopes are used in this work.

**metalloid (semimetal)** Any of a class of chemical elements intermediate in properties between metals and nonmetals. The classification is not clear cut, but typical metalloids are boron, silicon, germanium, arsenic, and tellurium. They are electrical semiconductors and their oxides are amphoteric.

**metallurgy** The branch of applied science concerned with the production of metals from their ores, the purification of metals, the manufacture of alloys, and the use and performance of metals in engineering practice. **Process metallurgy** is concerned with the extraction and production of metals, while **physical metallurgy** concerns the mechanical behaviour of metals.

**metamagnet** A material that is an anti-ferromagnet in the absence of an external magnetic field but undergoes a first-order transition to a phase in which there is a non-zero ferromagnetic moment when the external magnetic field becomes sufficiently large. Iron(II) chloride is an example of a metamagnet.

**metameric segmentation (metamerism; segmentation)** The division of an animal's body (except at the head region - see *CEPHALIZATION*) into a number of compartments (**segments** or **metameres**) each containing the same organs. Metameric segmentation is most strongly

marked in annelid worms (e.g. earthworms), in which the muscles, blood vessels, nerves, etc. are repeated in each segment. In these animals the segmentation is obvious both externally and internally. It also occurs internally in arthropods and in the embryonic development of all vertebrates, in which it is confined to parts of the muscular, skeletal, and nervous systems and does not show externally.

**metamict state** The amorphous state of a substance that has lost its crystalline structure as a result of the radioactivity of uranium or thorium. **Metamict minerals** are minerals whose structure has been disrupted by this process. The metamictization is caused by alpha particles and the recoil nuclei from radioactive disintegration.

**metamorphic rocks** One of the three major rock categories (see also IGNEOUS ROCKS; SEDIMENTARY ROCKS). Metamorphic rock is formed when pre-existing rock is subjected to either chemical or physical alteration by heat, pressure, or chemically active fluids. It involves three main processes of formation. **Contact metamorphism** results from the intrusion of a mass of molten rock into sedimentary rock. Heat from the intrusion spreads into the surrounding sediments causing mineralogical changes to take place. **Regional metamorphism** is developed over large areas and is associated with mountain building. Sediments collect in large depressions, known as geosynclines, in the earth's crust. As successive layers accumulate the lower layers subside into the crust and are subjected to increasing heat and pressure, causing the rocks to be metamorphosed. Eventually these rocks may also be uplifted and folded to form mountain chains. **Dislocation metamorphism** results from the more localized mechanical shearing and crushing of rocks, for example along fault planes.

Metamorphic rocks are characteristically resistant and tend to form upland areas. Examples of metamorphic rocks include marble (metamorphosed limestone) and slate (metamorphosed shale).

**metamorphosis** The rapid transformation from the larval to the adult form that

occurs in the life cycle of many invertebrates and amphibians. Examples are the changes from a tadpole to an adult frog and from a pupa to an adult insect. Metamorphosis often involves considerable destruction of larval tissues by lysosomes, and in both insects and amphibians it is controlled by hormones.

**metaphase** The stage of cell division during which the membrane around the nucleus breaks down, the \*spindle forms, and centromeres attach the chromosomes to the equator of the spindle. In the first metaphase of \*meiosis pairs of chromosomes (bivalents) are attached, while in \*mitosis and the second metaphase of meiosis, individual chromosomes are attached.

**metaphosphoric acid** See PHOSPHORIC(V) ACID.

**metaplasia** The transformation of a tissue into a different type. This is an abnormal process; for example, metaplasia of the epithelium of the bronchi may be an early sign of cancer.

**metaplumbate** See PLUMBATE.

**metastable state** A condition of a system in which it has a precarious stability that can easily be disturbed. It is unlike a state of stable equilibrium in that a minor disturbance will cause a system in a metastable state to fall to a lower energy level. A book lying on a table is in a state of stable equilibrium; a thin book standing on edge is in metastable equilibrium. Supercooled water is also in a metastable state. It is liquid below 0°C; a grain of dust or ice introduced into it will cause it to freeze. An excited state of an atom or nucleus that has an appreciable lifetime is also metastable.

**metastannate** See STANNATE.

**metastasis** See CANCER.

**metatarsal** One of the bones in the \*metatarsus.

**metatarsus** The foot (or corresponding part of the hindlimb) in terrestrial vertebrates, consisting of a number of rod-shaped bones (**metatarsals**) that articulate with the bones of the ankle (see TARSUS) and those of the toes (see PHALANGES). The

number of metatarsals varies between species: in the basic \*pentadactyl limb there are five, but this number is reduced in some species.

**Metatheria** An infraclass of mammals containing the marsupials. The female bears an abdominal pouch (**marsupium**) into which the newly born young, which are in a very immature state, move to complete their development. They obtain nourishment from the mother's mammary teats. Modern marsupials are restricted to Australasia (where they include the kangaroos, koala bears, phalangers, and bandicoots) and America (the opossums). Marsupials evolved during the late Cretaceous period, 80 million years ago. In Australia, where the marsupials have been isolated for millions of years, they show the greatest diversity of form, having undergone \*adaptive radiation to many of the niches occupied by placental mammals elsewhere. *Compare* EUTHERIA; PROTOTHERIA.

**metathesis** See DOUBLE DECOMPOSITION.

**Metazoa (Eumetazoa)** A subkingdom comprising all multicellular animals. It excludes the \*Porifera (sponges) and \*Placozoa, which are placed in a separate subkingdom, Parazoa.

**meteor** A streak of light observable in the sky when a particle of matter enters the earth's atmosphere and becomes incandescent as a result of friction with atmospheric atoms and molecules. These particles of matter are known collectively as **meteoroids**. Meteoroids that survive their passage through the atmosphere and strike the earth's surface are known as **meteorites**. Only some 2500 meteorites are known, excluding the **micrometeorites** (bodies less than 1 mm in diameter). Meteorites consist mainly of silicate materials (stony meteorites) or iron (iron meteorites). It is estimated that the earth collects over  $10^8$  kg of meteoritic material every year, mostly in the form of micrometeorites. Micrometeorites survive atmospheric friction because their small size enables them to radiate away the heat generated by friction before they vaporize.

**meteorite** See METEOR.

**meteoroid** A particle of dust (from a comet) or rock (from an asteroid) in space on a collision course with the earth. When it enters the earth's atmosphere, it burns up as a \*meteor or hits the ground as a meteorite.

**meteorology** The study of the physical phenomena and processes taking place in the atmosphere and its interactions with the ground surface. This knowledge is applied to weather forecasting. The chief branches of meteorology are \*dynamical meteorology, \*micrometeorology, and \*synoptic meteorology.

**methacrylate** A salt or ester of methacrylic acid (2-methylpropenoic acid).

**methacrylate resins** \*Acrylic resins obtained by polymerizing 2-methylpropenoic acid or its esters.

**methacrylic acid** See 2-METHYLPROPENOIC ACID.

**methanal (formaldehyde)** A colourless gas, HCHO; r.d. 0.815 (at  $-20^{\circ}\text{C}$ ); m.p.  $-92^{\circ}\text{C}$ ; b.p.  $-21^{\circ}\text{C}$ . It is the simplest \*aldehyde, made by the catalytic oxidation of methanol ( $500^{\circ}\text{C}$ ; silver catalyst) by air. It forms two polymers: \*methanal trimer and polymethanal. See also FORMALIN.

**methanal trimer** A cyclic trimer of methanal,  $\text{C}_3\text{O}_3\text{H}_6$ , obtained by distillation of an acidic solution of methanal. It has a six-membered ring of alternating  $-\text{O}-$  and  $-\text{CH}_2-$  groups.

**methane** A colourless odourless gas,  $\text{CH}_4$ ; m.p.  $-182.5^{\circ}\text{C}$ ; b.p.  $-164^{\circ}\text{C}$ . Methane is the simplest hydrocarbon, being the first member of the \*alkane series. It is the main constituent of natural gas ( $\sim 99\%$ ) and as such is an important raw material for producing other organic compounds. It can be converted into methanol by catalytic oxidation.

**methanide** See CARBIDE.

**methanoate (formate)** A salt or ester of methanoic acid.

**methanogen** Any of various archaeobacteria (see BACTERIA) that produce methane; they include such genera as *Methanobacillus* and *Methanotherix*. Methanogens are obligate anaerobes (see ANAEROBIC RESPIRATION) found in oxygen-deficient environ-

ments, such as marshes, swamps, sludge (formed during \*sewage treatment), and the digestive systems of ruminants. They mostly obtain their energy by reducing carbon dioxide and oxidizing hydrogen, with the production of methane:

Formate, methanol, or acetate may also be used as substrates by certain methanogens. Methanogenic bacteria are important in the production of \*biogas.

**methanoic acid (formic acid)** A colourless pungent liquid,  $\text{HCOOH}$ ; r.d. 1.2; m.p.  $8^\circ\text{C}$ ; b.p.  $101^\circ\text{C}$ . It can be made by the action of concentrated sulphuric acid on the sodium salt (sodium methanoate), and occurs naturally in ants and stinging nettles. Methanoic acid is the simplest of the \*carboxylic acids.

**methanol (methyl alcohol)** A colourless liquid,  $\text{CH}_3\text{OH}$ ; r.d. 0.79; m.p.  $-93.9^\circ\text{C}$ ; b.p.  $64.96^\circ\text{C}$ . It is made by catalytic oxidation of methane (from natural gas) using air. Methanol is used as a solvent (see METHYLATED SPIRITS) and as a raw material for making methanal (mainly for urea-formaldehyde resins). It was formerly made by the dry distillation of wood (hence the name **wood alcohol**).

**methionine** See AMINO ACID.

**method of mixtures** A method of determining the specific heat capacities of liquids or a liquid and a solid by mixing known masses of the substances at different temperatures and measuring the final temperature of the mixture.

**methoxy group** The organic group  $\text{CH}_3\text{O}-$ .

**methyl acetate** See METHYL ETHANOATE.

**methyl alcohol** See METHANOL.

**methylamine** A colourless flammable gas,  $\text{CH}_3\text{NH}_2$ ; m.p.  $-93.5^\circ\text{C}$ ; b.p.  $-6.3^\circ\text{C}$ . It can be made by a catalytic reaction between methanol and ammonia and is used in the manufacture of other organic chemicals.

**methylated spirits** A mixture consisting mainly of ethanol with added methanol (~9.5%), pyridine (~0.5%), and blue dye. The additives are included to

make the ethanol undrinkable so that it can be sold without excise duty for use as a solvent and a fuel (for small spirit stoves).

**methylation** A chemical reaction in which a methyl group ( $\text{CH}_3-$ ) is introduced in a molecule. A particular example is the replacement of a hydrogen atom by a methyl group, as in a \*Friedel-Crafts reaction.

**methylbenzene (toluene)** A colourless liquid,  $\text{CH}_3\text{C}_6\text{H}_5$ ; r.d. 0.9; m.p.  $-95^\circ\text{C}$ ; b.p.  $111^\circ\text{C}$ . Methylbenzene is derived from benzene by replacement of a hydrogen atom by a methyl group. It can be obtained from coal tar or made from methylcyclohexane (extracted from crude oil) by catalytic dehydrogenation. Its main uses are as a solvent and as a raw material for producing TNT.

**methyl bromide** See BROMOMETHANE.

**2-methylbuta-1,3-diene** See ISOPRENE.

**methyl chloride** See CHLOROMETHANE.

**methylene** The highly reactive \*carbene,  $:\text{CH}_2$ . The divalent  $\text{CH}_2$  group in a compound is the **methylene group**.

**methylene blue** A blue dye used in optical microscopy to stain nuclei of animal tissues. It is also suitable as a vital stain and a bacterial stain.

**methyl ethanoate (methyl acetate)** A colourless volatile fragrant liquid,  $\text{CH}_3\text{COOCH}_3$ ; r.d. 0.92; m.p.  $-98^\circ\text{C}$ ; b.p.  $54^\circ\text{C}$ . A typical \*ester, it can be made from methanol and methanoic acid and is used mainly as a solvent.

**methyl ethyl ketone** See BUTANONE.

**methyl group or radical** The organic group  $\text{CH}_3-$ .

**methyl methacrylate** An ester of methacrylic acid (2-methylpropenoic acid),  $\text{CH}_2\text{C}(\text{CH}_3)\text{COOCH}_3$ , used in making \*methacrylate resins.

**methyl orange** An organic dye used as an acid-base \*indicator. It changes from red below pH 3.1 to yellow above pH 4.4 (at  $25^\circ\text{C}$ ) and is used for titrations involving weak bases.

**methylphenols (cresols)** Organic compounds having a methyl group and a hy-

droxyl group bound directly to a benzene ring. There are three isomeric methylphenols with the formula  $\text{CH}_3\text{C}_6\text{H}_4\text{OH}$ , differing in the relative positions of the methyl and hydroxyl groups. A mixture of the three can be obtained by distilling coal tar and is used as a germicide and antiseptic.

**2-methylpropenoic acid (methacrylic acid)** A white crystalline unsaturated soluble carboxylic acid,  $\text{CH}_2=\text{C}(\text{CH}_3)\text{COOH}$ , used in making \*methacrylate resins.

**methyl red** An organic dye similar in structure and use to methyl orange. It changes from red below pH 4.4 to yellow above pH 6.0 (at 25°C).

**metre** Symbol m. The SI unit of length, being the length of the path travelled by light in vacuum during a time interval of  $1/299\,792\,458$  of a second. This definition, adopted by the General Conference on Weights and Measures in October 1983, replaced the 1960 definition based on the krypton lamp, i.e.  $1\,650\,763.73$  wavelengths in a vacuum of the radiation corresponding to the transition between the levels  $2p^{10}$  and  $5d^5$  of the nuclide krypton-86. This definition replaced the older (1927) definition of a metre based on a platinum-iridium bar of standard length. When the \*metric system was introduced in 1791 in France, the metre was intended to be one ten-millionth of the earth's meridian quadrant passing through Paris. However, the original geodetic surveys proved the impracticability of such a standard and the original platinum metre bar, the *mètre des archives*, was constructed in 1793.

**metre bridge** See WHEATSTONE BRIDGE.

**metric system** A decimal system of units originally devised by a committee of the French Academy, which included J. L. Lagrange and P. S. Laplace, in 1791. It was based on the \*metre, the gram defined in terms of the mass of a cubic centimetre of water, and the second. This centimetre-gram-second system (see C.G.S. UNITS) later gave way for scientific work to the metre-kilogram-second system (see M.K.S. UNITS) on which \*SI units are based.

**metric ton (tonne)** A unit of mass equal to 1000 kg or 2204.61 lb. 1 tonne = 0.9842 ton.

**metrology** The scientific study of measurement, especially the definition and standardization of the units of measurement used in science.

**MHC** See MAJOR HISTOCOMPATIBILITY COMPLEX.

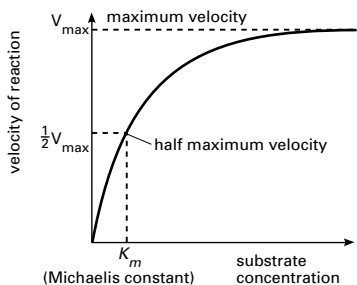

**MHD** See MAGNETOHYDRODYNAMICS.

**mho** A reciprocal ohm, the former name of the unit of electrical \*conductance now known as the siemens.

**mica** Any of a group of silicate minerals with a layered structure. Micas are composed of linked  $\text{SiO}_4$  tetrahedra with cations and hydroxyl groupings between the layers. The general formula of the micas is  $\text{X}_2\text{Y}_{4-6}\text{Z}_6\text{O}_{20}(\text{OH},\text{F})_4$ , where X = K, Na, Ca; Y = Al, Mg, Fe, Li; and Z = Si, Al. The three main mica minerals are: \*muscovite,  $\text{K}_2\text{Al}_4(\text{Si}_6\text{Al}_2\text{O}_{20})(\text{OH},\text{F})_4$ ; \*biotite,  $\text{K}_2(\text{Mg},\text{Fe}^{2+})_{6-4}(\text{Fe}^{3+},\text{Al},\text{Ti})_{0-2}(\text{Si}_{6-5}\text{Al}_{2-3}\text{O}_{20})(\text{OH},\text{F})_4$ ; lepidolite,  $\text{K}_2(\text{Li},\text{Al})_{5-6}(\text{Si}_{6-7}\text{Al}_{2-1}\text{O}_{20})(\text{OH},\text{F})_4$ . Micas have perfect basal cleavage and the thin cleavage flakes are flexible and elastic. Flakes of mica are used as electrical insulators and as the dielectric in capacitors.

**micelle** An aggregate of molecules in a \*colloid. For example, when soap or other \*detergents dissolve in water they do so as micelles - small clusters of molecules in which the nonpolar hydrocarbon groups are in the centre and the hydrophilic polar groups are on the outside solvated by the water molecules. Phospholipids in aqueous solution also form micelles. The products of fat digestion are dispersed into micelles by the action of bile salts, which facilitates their absorption in the small intestine.

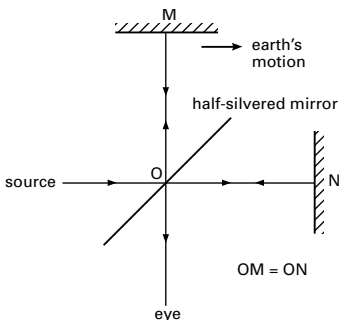

**Michaelis-Menten curve** A graph that shows the relationship between the concentration of a substrate and the rate of the corresponding enzyme-controlled reaction. It is named after Leonor Michaelis (1875-1949) and L. M. Menten. The curve only applies to enzyme reactions involving a single substrate. The graph can be used to calculate the **Michaelis constant** ( $K_m$ ), which is the concentration of a substrate required in order for an enzyme to act at half of its maximum velocity ( $V_{\text{max}}$ ). The Michaelis constant is a measure of the affinity of an

Michaelis-Menten curve

enzyme for a substrate. A low value corresponds to a high affinity, and vice versa. See also ENZYME KINETICS.

**Michelson-Morley experiment** An experiment, conducted in 1887 by Albert Michelson (1852-1931) and Edward Morley (1838-1923), that attempted to measure the velocity of the earth through the \*ether. Using a modified **Michelson interferometer** (see illustration) they expected to observe a shift in the interference fringes formed when the instrument was rotated through  $90^\circ$ , showing that the speed of light measured in the direction of the earth's rotation, or orbital motion, is not identical to its speed at right angles to this direction. No shift was observed. An explanation was finally provided by the \*Lorentz-Fitzgerald contraction, which provided an important step in the formulation of Einstein's special theory of \*relativity and the abandonment of the ether concept.

Michelson interferometer

**micro-** 1. A prefix denoting very small size; e.g. microgamete, micronucleus.

2. Symbol  $\mu$ . A prefix used in the metric system to denote one millionth. For example,  $10^{-6}$  metre = 1 micrometre ( $\mu\text{m}$ ).

**microarray** A glass slide or bead on which are deposited biomolecules or other material in a regular micro-scale pattern to enable automated simultaneous multiple assays of target substances or activities. Microarrays are powerful analytical tools with wide-ranging applications. They can be designed to carry small DNA molecules (see DNA MICROARRAY), proteins (e.g. antibodies or antigens), carbohydrates or other organic molecules, or even individual living cells. These reagents are applied to the glass substrate in a regular microscopic grid pattern, each being identified by its unique coordinate, or address, on the grid. Interaction of a target substance (e.g. an antibody or a complementary nucleic acid) with a particular address on the microarray activates or attaches a label (e.g. a fluorescent dye). The microarray can then be 'read' by a scanner, which automatically assesses the amount of label at each address, and hence the amount of target substance. Even smaller-scale **nanarrays** are already being developed, to increase further the scope and speed of this technology.

**microbalance** A sensitive \*balance capable of weighing masses of the order  $10^{-6}$  to  $10^{-9}$  kg.

**microbiology** The scientific study of microorganisms (e.g. bacteria, viruses, and fungi). Originally this was directed towards their effects (e.g. in causing disease and decay), but during the 20th century the emphasis shifted to their physiology, biochemistry, and genetics. Microbes are now recognized as important vehicles for the study of biochemical and genetic processes common to all living organisms, and their rapid growth enables their laboratory culture in large numbers for studies in genetics.

**microclimate** The local climate of a small area or of a particular \*habitat, which is different from the **macroclimate** of the larger surrounding geographical area.

**microcomputer** A \*computer in which the central processing unit is implemented by means of a semiconductor chip or chip set, known as a **microprocessor**. The power of a microcomputer is determined not only by the speed and power of the processor but also by features of the other components in the computer, such as the storage capacity of the main (\*RAM) memory and the disks used as \*backing store, as well as the operating system and other software used. Microcomputers are used in a wide variety of forms, including \*personal computers, electronic point-of-sales terminals, and cash-dispensing automated teller machines.

**microdissection (micromanipulation)** A technique used for the dissection of living cells under the high power of an optical microscope. It utilizes minute mechanically manipulated instruments, such as needles, scalpels, \*micropipettes, and lasers. For example, the instruments may be used to remove a single nucleus from one cell and to implant it in another (see NUCLEAR TRANSFER).

**microelectronics** The techniques of designing and making electronic circuits of very small size. As a result of these techniques a single \*silicon chip measuring less than a centimetre in either direction can contain many thousands of transistors and may constitute the central processing unit of a microcomputer. In addition to an enormous drop in size, compared to an equivalent valve-operated device, these microelectronic circuits are some 100 000 times more reliable than their thermionic predecessors.

**microfauna 1.** Animals that cannot be seen with the naked eye. They are normally observed with the aid of a microscope. *Compare* MACROFAUNA. **2.** The animals that live in a particular \*microhabitat.

**microfibril** A microscopic fibre. Plant cell walls contain microfibrils, about 5 nm in diameter, each consisting of parallel cellulose chains that are associated together to form a rod or a flat ribbon. Cellulose microfibrils are arranged in layers at right angles to each other.

**microflora 1.** Plants and algae that cannot be seen with the naked eye. They are normally observed with the aid of a microscope. **2.** The plants and algae that live in a particular \*microhabitat.

**microfossil** A \*fossil that is so small that it can only be studied under a microscope. Microfossils include bacteria, diatoms, and protozoa and parts of organisms, such as plant pollen and skeletal fragments. Microfossils are important in the correlation of rocks where only small samples are available. The study of microfossils, particularly pollen, is known as \*palynology.

**microglia** *See* GLIA; MACROPHAGE.

**microhabitat** The local habitat of a particular organism or microorganism. There are normally a number of different microhabitats within a large \*habitat (**macrohabitat**), each with its distinct set of environmental conditions. For example, in a stream macrohabitat there will exist different microhabitats, depending on oxygen content, pH, speed of water flow, and other factors in localized areas of the stream.

**micromanipulation** *See* MICRODISSECTION.

**micrometeorite** *See* METEOR.

**micrometeorology** The branch of meteorology concerned with small-scale processes at work within the lowest layers of the atmosphere, including the interaction of the atmosphere with the ground surface. Examples of the processes studied include mountain and valley winds and land and sea breezes.

**micrometer** A gauge for measuring small diameters, thicknesses, etc., accurately. It consists of a G-shaped device in which the gap between the measuring faces is adjusted by means of an accurately calibrated screw, the end of which forms one of the measuring faces.

**micron** The former name for the \*SI unit now called the micrometre, i.e.  $10^{-6}$  m.

**micronutrient** A chemical element required by plants in relatively small quantities. Micronutrients are typically found in

cofactors and coenzymes. They include copper, zinc, molybdenum, manganese, cobalt, and boron. *See* ESSENTIAL ELEMENT. *Compare* MACRONUTRIENT.

**microorganism (microbe)** Any organism that can be observed only with the aid of a microscope. Microorganisms include bacteria, viruses, protozoans, and some algae and fungi. *See* MICROBIOLOGY.

**microphagous** Describing the method of feeding of those heterotrophic organisms that take in their food in the form of tiny particles. \*Filter feeding and \*ciliary feeding are examples of this type of feeding. *Compare* MACROPHAGOUS.

**microphone** A \*transducer in which sound waves are converted into corresponding variations in an electrical signal for amplification, transmission to a distant point, or recording. Various types of device are used. In the **dynamic microphone** the sound waves impinge on a conductor of low mass supported in a magnetic field and cause it to oscillate at the frequency of the sound waves. These movements induce an e.m.f. in the conductor that is proportional to its velocity. The moving conductor consists of a metal ribbon, a wire, or a coil of wire. In the **moving-iron microphone**, sound waves cause a light armature to oscillate so that it varies the reluctance of a magnetic circuit. In a coil surrounding this path the varying reluctance is experienced as a variation in the magnetic flux within it, which induces a corresponding e.m.f. In the **carbon microphone**, widely used in telephones, a diaphragm constitutes a movable electrode in contact with carbon granules, which are also in contact with a fixed electrode. The movement of the diaphragm, in response to the sound waves, varies the resistance of the path through the granules to the fixed electrode. *See also* CAPACITOR MICROPHONE; CRYSTAL MICROPHONE.

**microphyll** A type of foliage leaf in clubmosses and horsetails that has a single unbranched midrib. Such leaves are generally no more than a few millimetres long. *Compare* MEGAPHYLL.

**micropipette** A glass pipette with an ultrafine tip, typically less than 1  $\mu\text{m}$  in di-

ameter. It can be inserted into single cells or other microscopic structures and used, for example, to inject materials. The micropipette is usually held by a **micro-manipulator**, a mechanical device that allows precise movement of the tip.

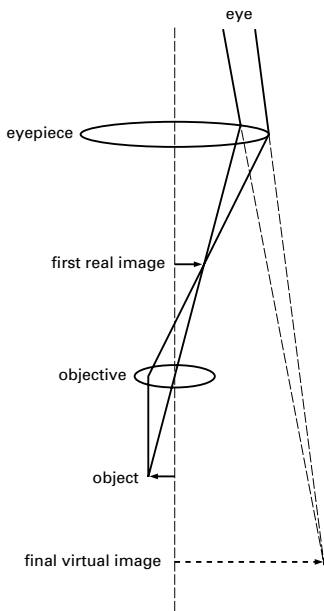

**microprocessor** *See* COMPUTER.

**micropropagation** The *in vitro* propagation of plants by cloning (*see* CLONE). Typically, this involves culturing excised meristematic tissue on a special medium that encourages axillary bud development. The new shoots are then separated and cultured, and the cycle is repeated until finally the shoots are transferred to a medium that promotes root development, to produce plantlets. Micropropagation is used in agriculture, horticulture, and forestry as special genotypes can be bred and maintained, the process is rapid, and plants can be kept disease-free.

**micropyle 1.** A small opening in the surface of a plant ovule through which the pollen tube passes prior to fertilization. It results from the incomplete covering of the nucellus by the integuments. It remains as an opening in the testa of most seeds through which water is absorbed. **2.** A small pore in some animal cells or tissues; for example, in insect eggs (*see* CHORION).

**microsatellite DNA** *See* REPETITIVE DNA.

**microscope** A device for forming a magnified image of a small object. The **simple microscope** consists of a biconvex magnifying glass or an equivalent system of lenses, either hand-held or in a simple frame. The **compound microscope** (*see* illustration) uses two lenses or systems of lenses, the second magnifying the real image formed by the first. The lenses are usually mounted at the opposite ends of a tube that has mechanical controls to move it in relation to the object. An optical condenser and mirror, often with a separate light source, provide illumination of the object. The widely used **binocular microscope** consists of two separate instruments fastened together so that one eye looks through one while the other eye looks through the other. This gives stereoscopic vision and reduces eye strain. *See*

Compound microscope

also ATOMIC FORCE MICROSCOPE; ELECTRON MICROSCOPE; FIELD-EMISSION MICROSCOPE; FIELD-IONIZATION MICROSCOPE; PHASE-CONTRAST MICROSCOPE; SCANNING TUNNELLING MICROSCOPE; ULTRAVIOLET MICROSCOPE. See also Chronology: Microscopy.

**microscopic** Designating a size scale comparable to the subatomic particles, atoms, and molecules. Microscopic objects and systems are described by \*quantum mechanics. Compare MACROSCOPIC; MESOSCOPIC.

**microsome** A fragment of \*endoplasmic reticulum formed when cells or tissues are disrupted. Microsomes can be isolated by centrifugation and are commonly used to investigate the functional properties of endoplasmic reticulum, such as enzymic activity and protein synthesis.

**microspore** See SPOROPHYLL.

**microsporophyll** See SPOROPHYLL.

**microtome** A machine used to cut thin sections (3–5  $\mu\text{m}$  thick) of plant or animal tissue for microscopical observation.

There are various designs of microtome, each basically consisting of a steel knife, a block for supporting the specimen, and a device for moving the specimen towards the knife. The specimen is usually supported by being embedded in wax; if a **freezing microtome** is used, the specimen is frozen. An **ultramicrotome** is used to cut much thinner sections (20–100 nm thick) for electron microscopy. The biological material is embedded in plastic or resin, sectioned with a glass or diamond knife, and the cut sections are allowed to float on the surface of water in an adjacent water bath.

**microtubule** A microscopic tubular structure in eukaryotic cells that is composed of the protein **tubulin** and occurs singly or in pairs, triplets, or bundles. Microtubules help cells to maintain their shape (see CYTOSKELETON); they also occur in cilia and flagella (see UNDULIPODIUM) and in the \*centrioles and they form the \*spindle during nuclear division.

**microvillus** One of a number of minute finger-like projections on the free surfaces of epithelial cells. Microvilli are covered with plasma membrane and their cytoplasm is continuous with the main cell cytoplasm. Their purpose is probably to increase the absorptive or secretory surface area of the cell, and they are abundant on the villi of the intestine, where they form a \*brush border.

**microwave background radiation** A cosmic background of radiation in the frequency range  $3 \times 10^{11}$  hertz to  $3 \times 10^8$  hertz discovered in 1965. Believed to have emanated from the primordial fireball of the big bang with which the universe is thought to have originated (see BIG-BANG THEORY), the radiation has an energy density in intergalactic space of some  $4 \times 10^{-14} \text{ J m}^{-3}$ . See also COBE; WMAP.

**microwave optics** The study of the behaviour of microwaves by analogy with the behaviour of light waves. On the large scale microwaves are propagated in straight lines and, like light waves, they undergo reflection, refraction, diffraction, and polarization.

**microwaves** Electromagnetic waves

**MICROSCOPY**

- c. 1590 Dutch spectacle-makers Hans and Zacharias Janssen invent the compound microscope.
- 1610 Johannes Kepler invents the modern compound microscope.
- 1675 Anton van Leeuwenhoek invents the simple microscope.
- 1826 British biologist Dames Smith (d. 1870) constructs a microscope with much reduced chromatic and spherical aberrations.
- 1827 Italian scientist Giovanni Amici (1786–1863) invents the reflecting achromatic microscope.
- 1861 British chemist Joseph Reade (1801–70) invents the kettledrum microscope condenser.
- 1912 British microscopist Joseph Barnard (1870–1949) invents the ultramicroscope.
- 1932 Dutch physicist Frits Zernike (1888–1966) invents the phase-contrast microscope.
- 1936 German-born US physicist Erwin Mueller (1911–77) invents the field-emission microscope.
- 1938 German engineer Ernst Ruska (1906–88) develops the electron microscope.
- 1940 Canadian scientist James Hillier (1915– ) makes a practical electron microscope.
- 1951 Erwin Mueller invents the field-ionization microscope.
- 1978 US scientists of the Hughes Research Laboratory invent the scanning ion microscope.
- 1981 Swiss physicists Gerd Binnig (1947– ) and Heinrich Rohrer (1933– ) invent the scanning tunnelling microscope.
- 1985 Gerd Binnig invents the atomic force microscope.
- 1987 James van House and Arthur Rich invent the positron microscope.

with wavelengths in the range  $10^{-3}$  to 0.03 m.

**microwave spectroscopy** A sensitive technique for chemical analysis and the determination of molecular structure (bond lengths, bond angles, and dipole moments), and also relative atomic masses. It is based on the principle that microwave radiation (*see* MICROWAVES) causes changes in the rotational energy levels of molecules and absorption consequently occurs at characteristic frequencies. In a microwave spectrometer a microwave source, usually a klystron valve, produces a beam that is passed through a gaseous sample. The beam then impinges on the detector, usually a crystal detector, and the signal (wavelength

against intensity) is displayed, either as a printed plot or on an oscilloscope. As microwaves are absorbed by air the instrument is evacuated.

**midbrain (mesencephalon)** One of the three sections of the brain of a vertebrate embryo. Unlike the \*forebrain and the \*hindbrain, the midbrain does not undergo further subdivision to form additional zones. In mammals it becomes part of the \*brainstem, but in amphibians, reptiles, and birds the roof of the midbrain becomes enlarged as the **tectum**, a dominant centre for integration, and may include a pair of **optic lobes**.

**middle ear (tympanic cavity)** The air-filled cavity within the skull of vertebrates that lies between the \*outer ear and the

\*inner ear. It is linked to the pharynx (and therefore to outside air) via the \*Eustachian tube and in mammals contains the three \*ear ossicles, which transmit auditory vibrations from the outer ear (via the \*tympanum) to the inner ear (via the oval window).

**middle lamella** A thin layer of material, consisting mainly of pectins, that binds together the walls of adjacent plant cells.

**midgut 1.** The middle section of the alimentary canal of vertebrates, which is concerned with digestion and absorption. It comprises most of the small intestine. **2.** The middle section of the alimentary canal of arthropods. *See also* FOREGUT; HINDGUT.

**mid-ocean ridge** A long chain of underwater mountains, several thousand metres high, that runs for a total of about 50 000 km across the floors of the major oceans. The ridge corresponds to tectonic plate margins (*see* PLATE TECTONICS), at which upwelling magma breaches the comparatively thin oceanic crust. The sea floor spreads as the plates gradually move apart. Underwater volcanoes are a feature of some ridges.

**migration 1.** (in chemistry) The movement of a group, atom, or double bond from one part of a molecule to another. **2.** (in physics) The movement of ions under the influence of an electric field. **3.** (in biology) The seasonal movement of complete populations of animals to a more favourable environment. It is usually a response to lower temperatures resulting in a reduced food supply, and is often triggered by a change in day length (*see* PHOTOPERIODISM). Migration is common in mammals (e.g. porpoises), fish (e.g. eels and salmon), and some insects but is most marked in birds. The Arctic tern, for example, migrates annually from its breeding ground in the Arctic circle to the Antarctic - a distance of some 17 600 km. Migrating animals possess considerable powers of orientation; birds seem to possess a compass sense, using the sun, pole stars, and (in cloud) the earth's magnetic lines of force as reference points (*see* NAVIGATION).

**milk** The fluid secreted by the \*mammary glands of mammals. It provides a balanced and highly nutritious food for offspring. Cows' milk comprises about 87% water, 3.6% lipids (triglycerides, phospholipids, cholesterol, etc.), 3.3% protein (largely casein), 4.7% lactose (milk sugar), and, in much smaller amounts, vitamins (especially vitamin A and many B vitamins) and minerals (notably calcium, phosphorus, sodium, potassium, magnesium, and chlorine). Composition varies among species; human milk contains less protein and more lactose.

**milk of magnesia** *See* MAGNESIUM HYDROXIDE.

**milk sugar** *See* LACTOSE.

**milk teeth** *See* DECIDUOUS TEETH.

**Milky Way** *See* GALAXY.

**Miller indices** A set of three numbers that characterize a face of a crystal. The French mineralogist René Just Haüy (1743–1822) proposed the **law of rational intercepts**, which states that there is always a set of axes, known as **crystal axes**, that allows a crystal face to be characterized in terms of intercepts of the face with these axes. The reciprocals of these intercepts are small rational numbers. When the fractions are cleared there is a set of three integers. These integers are known as the **Miller indices** of the crystal face after the British mineralogist William Hallows Miller (1810–80), who pointed out that crystal faces could be characterized by these indices. If a plane is parallel to one of the crystal axes then its intercept is at infinity and hence its reciprocal is 0. If a face cuts a crystal axis on the negative side of the origin then the intercept, and hence its reciprocal, i.e. the Miller index for that axis, are negative. This is indicated by a bar over the Miller index. For example, the Miller indices for the eight faces of an octahedron are (III), ( $\bar{\text{III}}$ ), (III), (III), (II $\bar{\text{I}}$ ), (II $\bar{\text{I}}$ ), (II $\bar{\text{I}}$ ), and (III).

**milli-** Symbol m. A prefix used in the metric system to denote one thousandth. For example, 0.001 volt = 1 millivolt (mV).

**millibar** *See* BAR.

**Millikan, Robert Andrews** (1868–1953) US physicist, who after more than

20 years at the University of Chicago went to the California Institute of Technology in 1921. His best-known work, begun in 1909, was to determine the charge on the \*electron in his oil-drop experiment, which led to the award of the 1923 Nobel Prize for physics. He then went on to do important work on \*cosmic radiation.

**millipedes** See DIPLOPODA.

**mimicry** The resemblance of one animal to another, which has evolved as a means of protection. In one form of mimicry the markings of certain harmless insects closely resemble the \*warning coloration of another insect (the **model**). Predators that have learnt to avoid the model will also avoid good mimics of it. This phenomenon is often found among butterflies. A second form of mimicry involves the mutual resemblance of a group of animals, all harmful, such as the wasp, bee, and hornet, so that a predator, having experienced one, will subsequently avoid them all.

**mineral** A naturally occurring substance that has a characteristic chemical composition and, in general, a crystalline structure. The term is also often applied generally to organic substances that are obtained by mining (e.g. coal, petroleum, and natural gas) but strictly speaking these are not minerals, being complex mixtures without definite chemical formulas. Rocks are composed of mixtures of minerals. Minerals may be identified by the properties of their crystal system, hardness (measured on the Mohs' scale), relative density, lustre, colour, cleavage, and fracture. Many names of minerals end in *-ite*.

**mineral acid** A common inorganic acid, such as hydrochloric acid, sulphuric acid, or nitric acid.

**mineral deficiency** Lack of any essential mineral nutrient, such as nitrogen, phosphorus, or potassium, in living organisms, which can result in mineral deficiency diseases. In humans, for example, lack of calcium causes poor bone development, and lack of nitrogen can cause the disease kwashiorkor, due to a deficiency in protein intake (see MALNUTRITION). In

plants mineral deficiency results in stunted growth and \*chlorosis. A deficiency of trace elements (see ESSENTIAL ELEMENT) also leads to diseases; for example, a deficiency of iron can cause anaemia in humans and chlorosis in plants.

**mineralocorticoid** See CORTICOSTEROID.

**mineralogy** The branch of geology concerned with the study of \*minerals.

**mineral salts** Inorganic salts that need to be ingested or absorbed by living organisms for healthy growth and maintenance. They comprise the salts of the trace elements in animals (see ESSENTIAL ELEMENT) and the \*micronutrients of plants.

**minicomputer** A \*computer that is intermediate between a mainframe and a \*microcomputer in processing power, and can be used by several people at once.

**minisatellite DNA** See REPETITIVE DNA.

**minority carrier** See SEMICONDUCTOR.

**minor planets** See ASTEROIDS.

**minute** 1. One sixtieth of an hour.  
2. One sixtieth of a degree (angle).

**mirabilite** A mineral form of \*sodium sulphate,  $\text{Na}_2\text{SO}_4 \cdot 10\text{H}_2\text{O}$ .

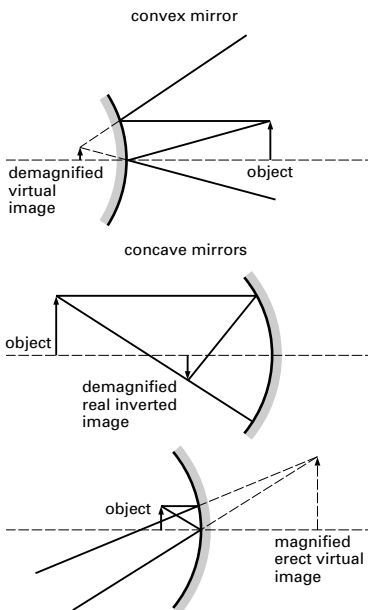

**mirage** An optical phenomenon that occurs as a result of the bending of light rays through layers of air having very large temperature gradients. An **inferior mirage** occurs when the ground surface is strongly heated and the air near the ground is much warmer than the air above. Light rays from the sky are strongly refracted upwards near the surface giving the appearance of a pool of water. A **superior mirage** occurs if the air close to the ground surface is much colder than the air above. Light is bent downwards from the object towards the viewer so that it appears to be elevated or floating in the air.

**Mira-type variable star (Mira Ceti variable)** A star in the red giant or red supergiant category whose radiated energy varies regularly. Pulsation of the surface layers is thought to be the cause of the variation, which recurs every 2 to 30

months. The stars are named after their prototype, Mira Ceti.

**mirror** A surface that reflects most of the light falling on it. A **plane mirror** is a flat surface that produces an erect virtual \*image of a real object, in which front and back are reversed. **Spherical mirrors** are formed from the surfaces of spheres and form images of real objects in much the same way as lenses. A convex mirror forms erect virtual images. They are commonly used as rear-view mirrors in road vehicles, and give a diminished wide-angle image. A concave mirror can form either inverted real images or erect virtual images. (See illustrations.) Spherical mirrors obey the \*lens equation (using the real-positive sign convention) and are subject to some \*aberrations similar to those of lenses.

#### Mirrors

**misch metal** An alloy of cerium (50%), lanthanum (25%), neodymium (18%), praseodymium (5%), and other rare earths. It is used alloyed with iron (up to 30%) in lighter flints, and in small quantities to

improve the malleability of iron. It is also added to copper alloys to make them harder, to aluminium alloys to make them stronger, to magnesium alloys to reduce creep, and to nickel alloys to reduce oxidation.

**missing mass** The mass of matter in the universe that cannot be observed by direct observations of its emitted or absorbed electromagnetic radiation. There are a number of astrophysical observations that suggest that the actual mass of the universe is much greater than that estimated by observations using optical telescopes, radiotelescopes, etc. It is thought that there is a considerable amount of **dark matter** (or **hidden matter**) causing this discrepancy. Various explanations have been put forward for the missing mass, including black holes, brown dwarfs, cosmic strings, axions, neutrinos, monopoles, and various exotic particles, such as **weakly interacting massive particles (WIMPs)**.

**mitochondrial DNA (mtDNA)** A circular ring of DNA found in mitochondria. In mammals mtDNA makes up less than 1% of the total cellular DNA, but in plants the amount is variable. It codes for ribosomal and transfer RNA but only some mitochondrial proteins (up to 30 proteins in animals), the nuclear DNA being required for encoding most of these. Human mtDNA codes for 13 proteins and some RNA and is inherited only via the female line. *See also* MITOCHONDRIAL EVE.

**mitochondrial Eve** The hypothetical female claimed by some biologists to be the ancestor of all humankind. Analysis of \*mitochondrial DNA (mtDNA) from groups of people throughout the world suggests that mitochondrial Eve lived around 200 000 years ago, probably in Africa (hence she is also known as 'African Eve'). Mitochondrial DNA is particularly useful for investigating recent genetic history as it mutates quickly (ten times more rapidly than nuclear DNA) and in humans is inherited solely through the female line (therefore it does not undergo recombination by \*crossing over). The uniformity of the different samples of mtDNA indicates that modern humans evolved relatively recently from a

single region in Africa. This view has been reinforced by studies of Y chromosomes from different groups around the world, which are transmitted only through the male line.

**mitochondrion** A structure within the cytoplasm of eukaryotic \*cells that carry out aerobic respiration: it is the site of the \*Krebs cycle and \*electron transport chain, and therefore the cell's energy production. Mitochondria vary greatly in shape, size, and number but are typically oval or sausage-shaped and bounded by two membranes, the inner one being folded into finger-like projections (**cristae**); they contain their own DNA (see MITOCHONDRIAL DNA). They are most numerous in cells with a high level of metabolic activity.

**mitosis** The division of a cell to form two daughter cells each having a nucleus containing the same number and kind of chromosomes as the mother cell. The changes during divisions are clearly visible with a light microscope. Each chromosome divides lengthwise into two \*chromatids, which separate and form the chromosomes of the resulting daughter nuclei. The process is divided into four stages, \*prophase, \*metaphase, \*anaphase, and \*telophase, which merge into each other (see illustration). Mitotic divisions ensure that all the cells of an individual are genetically identical to each other and to the original fertilized egg. See also CELL CYCLE.

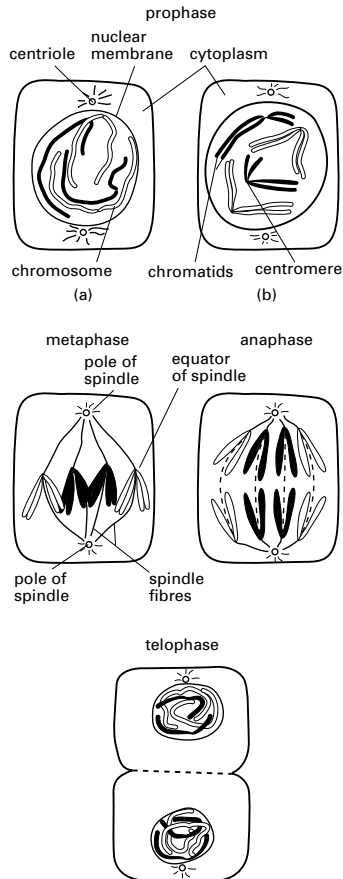

**mitral valve** See BICUSPID VALVE.

**Mitscherlich's law (law of isomorphism)** Substances that have the same crystal structure have similar chemical formulae. The law can be used to determine the formula of an unknown compound if it is isomorphous with a compound of known formula. It is named after Eilhard Mitscherlich (1794–1863).

**mixed function oxygenase (mono-oxygenase)** An enzyme that introduces an oxygen atom into a substrate. Mixed function oxidases are essential components of many important metabolic pathways. An example of such an enzyme is \*cytochrome oxidase.

**mixture** A system of two or more dis-

tinct chemical substances. **Homogeneous mixtures** are those in which the atoms or molecules are interspersed, as in a mixture of gases or in a solution. **Heterogeneous mixtures** have distinguishable phases, e.g. a mixture of iron filings and sulphur. In a mixture there is no redistribution of valence electrons, and the components retain their individual chemical properties. Unlike compounds, mixtures can be separated by physical means (distillation, crystallization, etc.).

The stages of mitosis in a cell containing two pairs of homologous chromosomes

**m.k.s. units** A \*metric system of units devised by A. Giorgi (and sometimes known as **Giorgi units**) in 1901. It is based on the metre, kilogram, and second and grew from the earlier \*c.g.s. units. The electrical unit chosen to augment these three basic units was the ampere and the \*permeability of space (magnetic constant) was taken as  $10^{-7} \text{ H m}^{-1}$ . To simplify electromagnetic calculations the magnetic constant was later changed to  $4\pi \times 10^{-7} \text{ H m}^{-1}$  to give the **rationalized MKSA system**. This system, with some modifications, formed the basis of \*SI units, now used in most scientific work.

**m.m.f.** See MAGNETOMOTIVE FORCE.

**mmHg** A unit of pressure equal to that exerted under standard gravity by a height of one millimetre of mercury, or 133.322 pascals.

**mobility** (of an ion) Symbol  $u$ . The terminal speed of an ion in an electric field divided by the field strength.

**mobility edge** See LOCALIZATION.

**model** A simplified description of a physical system intended to capture the essential aspects of the system in a sufficiently simple form to enable the mathematics to be solved. In practice some models require \*approximation techniques to be used, rather than being exactly soluble. When exact solutions are available they can be used to examine the validity of the approximation techniques.

**modem** (derived from modulator/demodulator) A device that can convert a digital signal (consisting of a stream of \*bits) into an analogue (smoothly varying) signal, and vice versa. Modems are therefore required to link digital devices, such as computers, over an analogue telephone line.

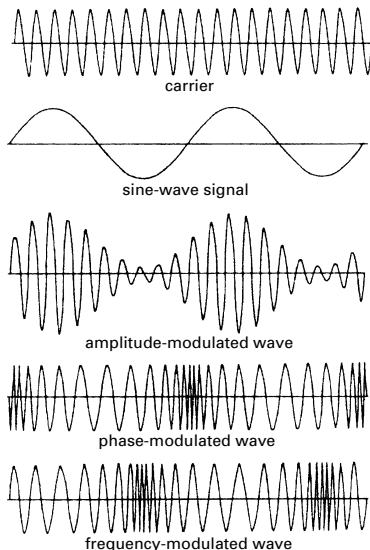

**moderator** A substance that slows down free neutrons in a \*nuclear reactor, making them more likely to cause fissions of atoms of uranium-235 and less likely to be absorbed by atoms of uranium-238. Moderators are light elements, such as deuterium (in heavy water), graphite, and beryllium, to which neutrons can impart some of their kinetic energy on collision without being captured. Neutrons that

have had their energies reduced in this way (to about 0.025 eV, equivalent to a speed of  $2200 \text{ m s}^{-1}$ ) are said to have been **thermalized** or to have become **thermal neutrons**.

**modern synthesis** See NEO-DARWINISM.

**modifier gene** A gene that influences the expression of another gene. For example, one gene controls whether eye colour is blue or brown but other (modifier) genes can also influence the colour by affecting the amount or distribution of pigment in the iris.

**modulation** The process of changing an electrical signal. In radio transmission, it is the process of superimposing the characteristics of a periodic signal onto a \*carrier wave so that the information contained in the signal can be transmitted by the wave. The simplest form of modulation is **amplitude modulation (AM)**, in which the amplitude of the carrier is increased or diminished as the signal amplitude increases and diminishes. The modulated wave is composed of the carrier wave plus upper and lower sidebands. In **single-sideband modulation (SSB)** the

Modulation

carrier and one of the sidebands of an amplitude-modulated waveform are suppressed. This saves on bandwidth occupancy and signal power. In **frequency modulation (FM)**, the frequency of the carrier is increased or diminished as the signal amplitude increases and diminishes but the carrier amplitude remains constant. In **phase modulation**, the relative phase of the carrier is varied in accordance with the signal amplitude. (See illustrations.) Both frequency modulation and phase modulation are forms of **angle modulation**.

In **pulse modulation** the information is transmitted by controlling the amplitude, duration, position, or presence of a series of pulses. Morse code is a simple form of a pulse modulation.

**modulus** See ABSOLUTE VALUE.

**modulus of elasticity** See ELASTIC MODULUS.

**Moho (Mohorovičić discontinuity)** A discontinuity within the \*earth that marks the junction between the crust and the underlying mantle. Below the discontinuity earthquake seismic waves undergo a sudden increase in velocity, a feature that was first observed in 1909 by the Croatian geophysicist Andrija Mohorovičić (1857–1936), after whom the discontinuity was named. The Moho lies at a depth of about 10–12 km below the oceans and about 33–35 km below the continents.

**Mohs' scale** A hardness scale in which a series of ten minerals are arranged in order, each mineral listed being scratched by and therefore softer than those below it. The minerals are: (1) talc; (2) gypsum; (3) calcite; (4) fluorite; (5) apatite; (6) orthoclase; (7) quartz; (8) topaz; (9) corundum; (10) diamond. As a rough guide a mineral with a value up to 2.5 on this scale can be scratched by a fingernail, up to 4 can be scratched by a coin, and up to 6 by a knife. The scale was devised by Friedrich Mohs (1773–1839).

**molal concentration** See CONCENTRATION.

**molality** See CONCENTRATION.

**molar 1.** (in physics and chemistry) Denoting that an extensive physical property

is being expressed per \*amount of substance, usually per mole. For example, the molar heat capacity of a compound is the heat capacity of that compound per unit amount of substance; in SI units it would be expressed in  $\text{J K}^{-1} \text{mol}^{-1}$ . **2.** (in chemistry) Having a concentration of one mole per  $\text{dm}^3$ . **3.** (in anatomy) A broad ridged tooth in the adult dentition of mammals (see PERMANENT TEETH), found at the back of the jaws behind the premolars. There are two or more molars on each side of both jaws; their surfaces are raised into ridges or \*cusps for grinding food during chewing. In man the third (and most posterior) molar does not appear until young adulthood: these molars are known as **wisdom teeth**.

**molar conductivity** Symbol  $\Lambda$ . The conductivity of that volume of an electrolyte that contains one mole of solution between electrodes placed one metre apart.

**molar heat capacity** See HEAT CAPACITY.

**molarity** See CONCENTRATION.

**molar latent heat** See LATENT HEAT.

**molar volume (molecular volume)** The volume occupied by a substance per unit amount of substance.

**mole** Symbol mol. The SI unit of \*amount of substance. It is equal to the amount of substance that contains as many elementary units as there are atoms in 0.012 kg of carbon-12. The elementary units may be atoms, molecules, ions, radicals, electrons, etc., and must be specified. 1 mole of a compound has a mass equal to its \*relative molecular mass expressed in grams.

**molecular beam** A beam of atoms, ions, or molecules at low pressure, in which all the particles are travelling in the same direction and there are few collisions between them. They are formed by allowing a gas or vapour to pass through an aperture into an enclosure, which acts as a collimator by containing several additional apertures and vacuum pumps to remove any particles that do not pass through the apertures. Molecular beams

are used in studies of surfaces and chemical reactions and in spectroscopy.

**molecular biology** The study of the structure and function of large molecules associated with living organisms, in particular proteins and the nucleic acids \*DNA and \*RNA. **Molecular genetics** is a specialized branch, concerned with the analysis of genes (see DNA SEQUENCING).

**molecular chaperone** Any of a group of proteins in living cells that assist newly synthesized or denatured proteins to fold into their functional three-dimensional structures. The chaperones bind to the protein and prevent improper interactions within the polypeptide chain, so that it assumes the correct folded orientation. This process requires energy in the form of ATP. One class of chaperones, called **chaperonins**, occur in *E. coli*, chloroplasts, and mitochondria. They are **heat-shock proteins**, manufactured in response to raised temperature, and are presumed to help protect the cell from damage by refolding proteins that have been partially denatured by heat.

**molecular clock** The concept that during evolution the number of substitutions in the nucleotides of nucleic acids (DNA or RNA), and hence in the proteins encoded by the nucleic acids, is proportional to time. Hence, by comparing the DNA or proteins of species that diverged a known length of time ago (e.g. determined from fossil evidence), it is possible to calculate the average substitution rate, thereby calibrating the 'molecular clock'. Comparative studies of different proteins in various groups of organisms tend to show that the average number of amino-acid substitutions per site per year is typically around  $10^{-9}$ . These results indicate a fairly constant rate of molecular evolution in comparable sequences of macromolecules in different organisms.

**molecular distillation** Distillation in high vacuum (about 0.1 pascal) with the condensing surface so close to the surface of the evaporating liquid that the molecules of the liquid travel to the condensing surface without collisions. This technique enables very much lower temperatures to be used than are used with distillation at atmospheric pressure and

therefore heat-sensitive substances can be distilled. Oxidation of the distillate is also eliminated as there is no oxygen present.

**molecular flow (Knudsen flow)** The flow of a gas through a pipe in which the mean free path of gas molecules is large compared to the dimensions of the pipe. This occurs at low pressures; because most collisions are with the walls of the pipe rather than other gas molecules, the flow characteristics depend on the relative molecular mass of the gas rather than its viscosity. The effect was studied by M. H. C. Knudsen (1871-1949).

**molecular formula** See FORMULA.

**molecular imprinting** The phenomenon in which there is differential expression of a gene depending on which parent it is inherited from. Genes are now thought to carry either a female or a male 'imprint', which influences their expression in offspring. For example, the development of Huntington's disease in humans is delayed until midlife if the gene is inherited from the father (as occurs in the majority of cases), whereas inheritance from the mother causes the onset of symptoms early in childhood.

**molecularity** The number of molecules involved in forming the activated complex in a step of a chemical reaction. Reactions are said to be **unimolecular**, **bimolecular**, or **trimolecular** according to whether 1, 2, or 3 molecules are involved.

**molecular marker** Any site (locus) in the genome of an organism at which the DNA base sequence varies among the different individuals of a population. Such markers generally have no apparent effect on the phenotype of the individual, but they can be determined by biochemical analysis of the DNA and are used for a variety of purposes, including chromosome mapping, DNA fingerprinting, and genetic screening. The advent of such genetic tools as restriction enzymes and the polymerase chain reaction plus the growing abundance of DNA sequence data, coupled with automated high-throughput assays, have revealed several classes of molecular markers, including \*restriction fragment length polymorphisms (RFLPs), minisatellite and microsatellite DNA (see

REPETITIVE DNA), and \*single nucleotide polymorphisms (SNPs).

**molecular orbital** See ORBITAL.

**molecular sieve** Porous crystalline substances, especially aluminosilicates (see ZEOLITE), that can be dehydrated with little change in crystal structure. As they form regularly spaced cavities, they provide a high surface area for the adsorption of smaller molecules.

The general formula of these substances is  $M_nO \cdot Al_2O_3 \cdot xSiO_2 \cdot yH_2O$ , where  $M$  is a metal ion and  $n$  is twice the reciprocal of its valency. Molecular sieves are used as drying agents and in the separation and purification of fluids. They can also be loaded with chemical substances, which remain separated from any reaction that is taking place around them, until they are released by heating or by displacement with a more strongly adsorbed substance. They can thus be used as cation exchange mediums and as catalysts and catalyst supports. They are also used as the stationary phase in certain types of \*chromatography (**molecular-sieve chromatography**).

**molecular systematics (biochemical taxonomy)** The use of amino-acid or nucleotide-sequence data in determining the evolutionary relationships of different organisms. Essentially it involves comparing the sequences of functionally homologous molecules from each organism being studied, and determining the number of differences between them. The greater the number of differences, the more distantly related the organisms are likely to be. Moreover, since the number of nucleotide substitutions, and hence substitutions of corresponding amino acids, is generally proportional to time, some indication of the time scale involved can be obtained (see MOLECULAR CLOCK). This information has proved particularly useful where there are gaps in the fossil record and can be combined with other evidence from morphology, physiology, and embryology to produce more accurate phylogenetic trees. In microbiology molecular systematics has transformed bacterial phylogeny, in particular prompting the view that there are two quite distinct lineages of

\*bacteria, the archaeobacteria and eubacteria.

**molecular volume** See MOLAR VOLUME.

**molecular weight** See RELATIVE MOLECULAR MASS.

**molecule** One of the fundamental units forming a chemical compound; the smallest part of a chemical compound that can take part in a chemical reaction. In most covalent compounds, molecules consist of groups of atoms held together by covalent or coordinate bonds. Covalent substances that form \*macromolecular crystals have no discrete molecules (in a sense, the whole crystal is a molecule). Similarly, ionic compounds do not have single molecules, being collections of oppositely charged ions.

**mole fraction** Symbol  $X$ . A measure of the amount of a component in a mixture. The mole fraction of component  $A$  is given by  $X_A = n_A/N$ , where  $n_A$  is the amount of substance of  $A$  (for a given entity) and  $N$  is the total amount of substance of the mixture (for the same entity).

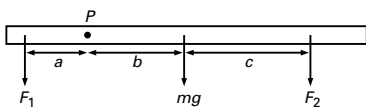

**Molisch's test** See ALPHA-NAPHTHOL TEST.

**Mollusca** A phylum of soft-bodied invertebrates characterized by an unsegmented body differentiated into a **head**, a ventral muscular **foot** used in locomotion, and a dorsal **visceral hump** covered by a fold of skin – the \*mantle – which secretes a protective shell in many species. Respiration is by means of gills or a lunglike organ and the feeding organ is a \*radula. Molluscs occur in marine, freshwater, and terrestrial habitats and there are six classes, including the \*Gastropoda (snails, slugs, limpets, etc.), \*Bivalvia (e.g. mussels, oysters), and \*Cephalopoda (squids and octopuses).

**molybdenum** Symbol Mo. A silvery hard metallic \*transition element; a.n. 42; r.a.m. 95.94; r.d. 10.22; m.p. 2617°C; b.p. 4612°C. It is found in molybdenite ( $MoS_2$ ), the metal being extracted by roasting to give the oxide, followed by reduction with hydrogen. The element is used in alloy steels. Molybdenum(IV) sulphide ( $MoS_2$ ) is used as a lubricant. Chemically, it is unre-

active, being unaffected by most acids. It oxidizes at high temperatures and can be dissolved in molten alkali to give a range of molybdates and polymolybdates. Molybdenum was discovered in 1778 by Karl Scheele.

**moment of a force** A measure of the turning effect produced by a force about an axis. The magnitude of the moment is the product of the force and the perpendicular distance from the axis to the line of action of the force. An object will be in rotational equilibrium if the algebraic sum of all the moments of the forces on it about any axis is zero. See illustration.

**Moment of a force.** For equilibrium  $mgb + F_2(b + c) = F_1a$ , where  $mg$  is the weight of the beam acting through its centre of mass.

**moment of inertia** Symbol  $I$ . The moment of inertia of a massive body about an axis is the sum of all the products formed by multiplying the magnitude of each element of mass ( $\delta m$ ) by the square of its distance ( $r$ ) from the line, i.e.  $I_m = \sum r^2 \delta m$ . It is the analogue in rotational dynamics of mass in linear dynamics. The basic equation is  $T = I\alpha$ , where  $T$  is the torque causing angular acceleration  $\alpha$  about the specified axis.

**momentum** The linear momentum ( $p$ ) of a body is the product of its mass ( $m$ ) and its velocity ( $v$ ), i.e.  $p = mv$ . See also ANGULAR MOMENTUM.

**monatomic molecule** A 'molecule' consisting of only one atom (e.g. Ar or He), distinguished from diatomic and polyatomic molecules.

**Mond process** A method of obtaining pure nickel by heating the impure metal in a stream of carbon monoxide at 50–60°C. Volatile nickel carbonyl ( $\text{Ni}(\text{CO})_4$ ) is formed, and this can be decomposed at higher temperatures (180°C) to give pure nickel. The method was invented by the German-British chemist Ludwig Mond (1839–1909).

**Monel metal** An alloy of nickel (60–70%), copper (25–35%), and small quantities of iron, manganese, silicon, and carbon. It is used to make acid-resisting equipment in the chemical industry.

**Monera** See PROKARYOTE.

**monoamine oxidase (MAO)** An enzyme that breaks down monoamines (e.g. \*adrenaline and \*noradrenaline) in the body by oxidation. Drugs that inhibit this enzyme are used to treat forms of depression.

**monobasic acid** An \*acid that has only one acidic hydrogen atom in its molecules. Hydrochloric (HCl) and nitric ( $\text{HNO}_3$ ) acids are common examples.

**monochasium** See CYMOSE INFLORESCENCE.

**monochromatic radiation** Electromagnetic radiation, especially visible radiation, of only one frequency or wavelength. Completely monochromatic radiation cannot be produced, but \*lasers produce radiation within a very narrow frequency band. Compare POLYCHROMATIC RADIATION.

**monochromator** A device that provides \*monochromatic radiation from a polychromatic source. In the case of visible radiation, for example, a prism can be used together with slits to select a small range of wavelengths.

**monoclinic** See CRYSTAL SYSTEM.

**monoclonal antibody** A specific \*antibody produced by one of numerous identical cells derived from a single parent cell. (The population of these cells comprises a \*clone and each cell is said to be **monoclonal**.) The parent cell is obtained by the fusion of a normal antibody-producing cell (a lymphocyte) with a cell derived from a malignant tumour of \*lymphoid tissue of a mouse. This hybrid cell then multiplies rapidly and yields large amounts of antibody. Monoclonal antibodies are used to identify a particular antigen within a mixture and can therefore be used for identifying blood groups; they also enable the production of highly specific, and therefore effective, \*vaccines.

**Monocotyledoneae** One of the two classes of flowering plants (see ANTHOPHYTA), distinguished by having one seed leaf (\*cotyledon) within the seed. The monocotyledons generally have parallel leaf veins, scattered vascular bundles within the stems, and flower parts in threes or multiples of three. Monocotyledon species include some crop plants (e.g. cereals, onions, fodder grasses), ornamentals (e.g. tulips, orchids, lilies), and a very limited number of trees (e.g. the palms). Compare DICOTYLEDONEAE.

**monoculture** See AGRICULTURE.

**monocyte** The largest form of white blood cell (\*leucocyte) in vertebrates. It has a kidney-shaped nucleus and is actively phagocytic, ingesting bacteria and cell debris (see PHAGOCYTE).

**monoecious** Describing plant species that have separate male and female flowers on the same plant. Examples of monoecious plants are maize and birch. Compare DIOECIOUS.

**monohybrid cross** A genetic cross between parents that differ in the alleles they possess for one particular gene, one parent having two dominant alleles and the other two recessives. All the offspring (called **monohybrids**) have one dominant and one recessive allele for that gene (i.e. they are hybrid at that one locus). Cross-

ing between these offspring yields a characteristic 3:1 (monohybrid) ratio in the following generation of dominant:recessive phenotypes (see illustration). Compare DIHYBRID CROSS.

**monohydrate** A crystalline compound having one mole of water per mole of compound.

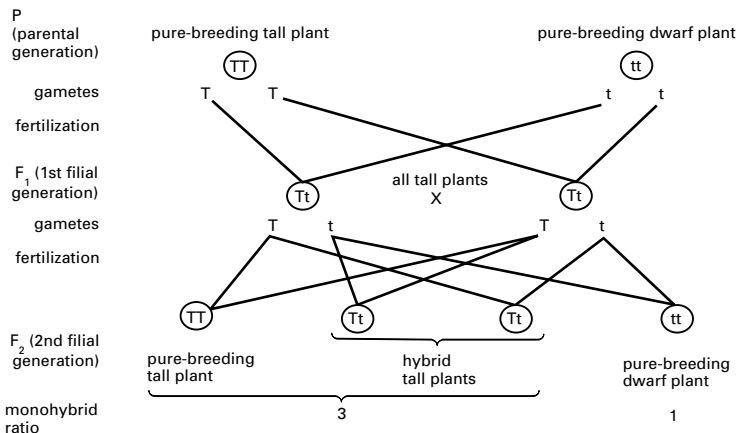

**monokine** See CYTOKINE.

**monomer** A molecule (or compound) that joins with others in forming a dimer, trimer, or polymer.

**mononuclear phagocyte system (reticuloendothelial system)** See MACROPHAGE.

**mono-oxygenase** See MIXED FUNCTION OXYGENASE.

**monophyletic** Denoting any group of organisms that are assumed to have originated from the same ancestor, i.e. any family, class, etc., of a natural classification. Sometimes the term has a more limited meaning and designates only those groups that include *all* the descendants of a common ancestor. In this restricted sense the birds are considered monophyletic because they are the sole descendants of a group of arboreal Triassic reptiles but the modern reptiles are not, because their common amphibian ancestor also gave rise to the birds and mam-

**Monohybrid cross.** The inheritance of stem lengths in garden peas.

mals. Such groups as the reptiles are described as **paraphyletic**. Compare POLYPHYLETIC.

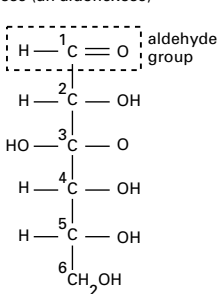

**monophyodont** Describing a type of dentition that consists of a single set of teeth that last for the entire lifespan of an animal. Compare DIPHYODONT; POLYPHYODONT.

**monopodium** The primary axis of growth in such plants as pine trees. It consists of a single main stem that continues to grow from the tip and gives rise to lateral branches. Compare SYMPODIUM.

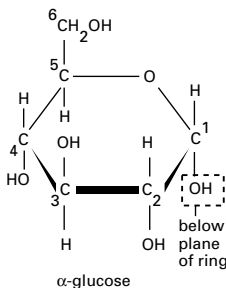

**monosaccharide (simple sugar)** A carbohydrate that cannot be split into smaller units by the action of dilute acids. Monosaccharides are classified according to the number of carbon atoms they pos-

sess: **trioses** have three carbon atoms; **tetroses**, four; **pentoses**, five; **hexoses**, six; etc. Each of these is further divided into **aldoses** and **ketoses**, depending on whether the molecule contains an aldehyde group (-CHO) or a ketone group (-CO-). For example glucose, having six carbon atoms and an aldehyde group, is an **aldohexose** whereas fructose is a **ketohexose**. These aldehyde and ketone groups confer reducing properties on monosaccharides: they can be oxidized to yield sugar acids. They also react with phosphoric acid to produce phosphate esters (e.g. in \*ATP), which are important in cell metabolism. Monosaccharides can exist as either straight-chain or ring-shaped molecules (see illustration). They also exhibit \*optical activity, giving rise to

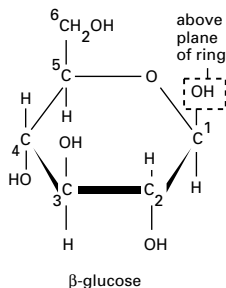

glucose (an aldohexose)

straight-chain form

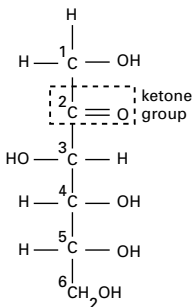

$\alpha$ -glucose

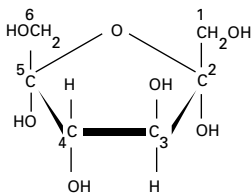

$\beta$ -glucose

Monosaccharides

m

both dextrorotatory and laevorotatory forms.

**monosodium glutamate (MSG)** A white solid,  $C_8H_8NNaO_4 \cdot H_2O$ , used extensively as a flavour enhancer, especially in convenience foods. It is a salt of glutamic acid (an \*amino acid), from which it is prepared. It can cause an allergic reaction in some susceptible people who consume it.

**monotremes** See PROTOTHERIA.

**monotropy** See ALLOTROPY.

**monovalent (univalent)** Having a valency of one.

**monozygotic twins** See IDENTICAL TWINS.

**Monte Carlo simulation** A method that involves random sampling for the mathematical simulation of physical systems. Monte Carlo calculations are applied to problems that can be formulated in terms of probability and are usually carried out by computer. Such calculations have been performed for nuclei, atoms, molecules, solids, liquids, and nuclear reactors. The technique is named after the gambling centre in Monaco, renowned for its casino.

**moon** The earth's only natural satellite, which orbits the earth at a mean distance of 384 400 km. It has a diameter of 3476 km. It has no atmosphere or surface water. Its surface temperature varies between 80 K (night minimum) and 400 K (noon at the equator). It is the only celestial body outside the earth to have been reached by man (1969). See Chronology: Moon Exploration.

**moraine** A deposit of rock debris scoured from a valley floor by a glacier and left behind when the ice melts. The pieces of rock vary in size from boulders to fine sand, typically resembling \*boulder clay. There are various types: a ground moraine forms underneath the glacier; a lateral moraine forms at the sides; a medial moraine occurs where two lateral moraines, from different glaciers, meet; and a terminal moraine is deposited at the lower end or toe of the glacier, usually indicating the farthest point reached by the ice. See also ESKER; KAME.

**mordant** A substance used in certain dyeing processes. Mordants are often inorganic oxides or salts, which are absorbed on the fabric. The dyestuff then forms a coloured complex with the mordant, the colour depending on the mordant used as well as the dyestuff. See also LAKE.

**Morgan, Thomas Hunt** (1866–1945) US geneticist, who held professorships at Bryn Mawr College (1891–1904), Columbia University (1904–28), and the California Institute of Technology (1928–45). He is best known for his discovery of \*crossing over during \*meiosis, so modifying Mendel's law of \*independent assortment. For this work Morgan was awarded the 1933 Nobel Prize for physiology or medicine.

**morph** Any of the distinct common forms found in a population displaying \*polymorphism.

**morphine** An alkaloid present in opium. It is an analgesic and narcotic, used medically for the relief of severe pain.

**morphogenesis** The development, through growth and differentiation, of form and structure in an organism.

**morphology** The study of the form and structure of organisms, especially their external form. Compare ANATOMY.

**mortality** See DEATH RATE.

**mosaic evolution** The evolution of different parts of an organism at different rates. For example, many aspects of the human phenotype have evolved relatively slowly or not at all since the hominids diverged from their primate ancestors, one notable exception being the nervous system, which has given humans their overwhelming selective advantage. This high degree of evolutionary independence among different aspects of the phenotype permits flexibility; for example, when a population is faced with new selection pressures in a changing environment, only the most crucial components need to evolve, not the entire phenotype.

**mosaic gold** See TIN(IV) SULPHIDE.

**Moseley's law** The frequencies of the lines in the \*X-ray spectra of the elements

**MOON EXPLORATION**

- c.150 BC Greek astronomer Hipparchus of Nicaea (c. 190–c. 120 BC) determines the distance to the moon.
- 1610 Galileo uses a telescope to observe the surface features of the moon.
- 1647 German astronomer Johannes Hevelius (1611–87) draws first map of the moon.
- 1757 French mathematician Alexis Clairaut (1713–65) calculates the mass of the moon.
- 1840 British-born US chemist William Draper (1811–82) takes photographs (daguerrotypes) of the moon.
- 1959 Soviet space probe Lunik I flies past the moon; Lunik II crashes on the moon; Lunik III bypasses the moon and returns pictures of the far side.
- 1962 US Ranger 4 space probe hits the moon.
- 1964 US Ranger 7 photographs the moon before crash-landing.
- 1965 US Ranger 8 returns TV pictures from the surface of the moon.
- 1966 US Lunar Orbiters 1 and 2 orbit the moon, returning photographs; US Surveyors 5 and 6 make soft landings. Soviet Luna 9 and 13 make soft landings; Luna 10 and 11 orbit the moon.
- 1967 US Surveyors 3, 5, and 6 make soft landings; Lunar Orbiters 3 and 4 photograph the surface.
- 1968 US Surveyor 7 lands on the moon. Soviet Zond 5 and 6 orbit the moon and return to earth.
- 1969 Astronauts from Apollo 11 and 12 land on the moon.
- 1970 Soviet Luna 16 lands on the moon and releases Lunakod I robot vehicle.
- 1971 Astronauts from Apollo 14 and 15 land on the moon.
- 1972 Astronauts from Apollo 16 and 17 land on the moon.
- 1973 Soviet Luna 21 lands on the moon and releases Lunakod II robot vehicle.
- 1990 Japanese scientists launch satellite Hagoromo (from another space probe) to orbit the moon.
- 1994 US orbiting probe Clementine maps the moon.
- 1998 US Lunar Prospector orbits the moon.

are related to the atomic numbers of the elements. If the square roots of the frequencies of corresponding lines of a set of elements are plotted against the atomic numbers a straight line is obtained. The law was discovered by Henry Moseley (1887–1915).

**moss agate** See AGATE.

**Mössbauer effect** An effect occurring when certain nuclides decay with emission of gamma radiation. For an isolated nucleus, the gamma radiation would usu-

ally have a spread of energies because the energy of the process is partitioned between the gamma-ray photon and the recoil energy of the nucleus. In 1957 Rudolph Mössbauer (1929– ) found that in certain solids, in which the emitting nucleus is held by strong forces in the lattice, the recoil energy is taken up by the whole lattice. Since this may typically contain  $10^{10}$ – $10^{20}$  atoms, the recoil energy is negligible and the energy of the emitted photon is sharply defined in a very narrow energy spread.

The effect is exploited in **Mössbauer spectroscopy** in which a gamma-ray source is mounted on a moving platform and a similar sample is mounted nearby. A detector measures gamma rays scattered by the sample. The source is moved slowly towards the sample at a varying speed, so as to continuously change the frequency of the emitted gamma radiation by the Doppler effect. A sharp decrease in the signal from the detector at a particular speed (i.e. frequency) indicates resonance absorption in the sample nuclei. The effect is used to investigate nuclear energy levels. In chemistry, Mössbauer spectroscopy can also give information about the bonding and structure of compounds because **chemical shifts** in the resonance energy are produced by the presence of surrounding atoms.

**mosses** See BRYOPHYTA.

**MOT** See LASER COOLING.

**moths** See LEPIDOPTERA.

**motion** A change in the position of a body or system with respect to time, as measured by a particular observer in a particular \*frame of reference. Only relative motion can be measured; absolute motion is meaningless. See also EQUATION OF MOTION; NEWTON'S LAWS OF MOTION.

**motivation** The internal conditions responsible for temporary reversible changes in the responsiveness of an animal to external stimulation. Thus an animal that has been deprived of food will accept less palatable food than one that has not been deprived: the difference is attributed to a change in feeding motivation. Changes in responsiveness due to maturation, \*learning, or injury are not usually readily reversible and are therefore not considered to be due to changes in motivation. Early attempts to describe motivation in terms of a number of separate 'drives' (e.g. food drive, sex drive) have not found general favour, partly because 'drives' interact with one another; for example, water deprivation often affects an animal's willingness to feed.

**motor** Any device for converting chemical energy or electrical energy into mechanical energy. See ELECTRIC MOTOR;

INTERNAL-COMBUSTION ENGINE; LINEAR MOTOR.

**motor generator** An electric motor mechanically coupled to an electric generator. The motor is driven by a supply of specified voltage, frequency, or number of phases and the generator provides an output in which one or more of these parameters is different to suit a particular purpose.

**motor neuron** A \*neuron that transmits nerve impulses from the central nervous system to an effector organ (such as a muscle or gland) and thereby initiates a physiological response (e.g. muscle contraction).

**Mott insulator** A substance that is an insulator because of electron correlation and in which the highest occupied energy band is not necessarily full. Certain transition metal oxides in which there are narrow bands are Mott insulators. The concept was put forward and developed by the British physicist Sir Nevill Francis Mott (1905–1996), starting in 1949.

**moulting 1.** The seasonal loss of hair, fur, or feathers that occurs in mammals and birds. **2.** The periodic loss of the integument of arthropods and reptiles. See ECDYSIS.

**mouse** A simple device that is connected to a personal computer by cable and can be moved by hand over a flat surface, its movements being sensed by the rotation of a ball in its base. These movements are communicated to the computer and cause corresponding movements of the cursor on the screen; the cursor indicates the active position on the screen. One or more buttons on the mouse can be pressed to initiate an action, for example to indicate a desired cursor position for typing or to select an item from a menu of options.

**mouth** The opening of the \*alimentary canal, which in most animals is used for the \*ingestion of food. It leads to the \*buccal cavity (mouth cavity).

**mouth cavity** See BUCCAL CAVITY.

**mouthparts** Modified paired appendages on the head segments of arthropods, used for feeding. A typical insect has

a \*labium (lower lip), one pair each of \*mandibles and \*maxillae, and a \*labrum (upper lip), although in many the mouthparts are modified to form piercing stylets or a sucking proboscis. Crustaceans, centipedes, and millipedes have one pair of mandibles and two pairs of maxillae used for cutting and holding the food. Crustaceans also have several pairs of **maxillipedes**.

**moving-coil instrument** A measuring instrument in which current or voltage is determined by the couple on a small coil pivoted between the poles of a magnet with curved poles, giving a radial magnetic field. When a current flows through the coil it turns against a return spring. If the angle through which it turns is  $\alpha$ , the current  $I$  is given by  $I = k\alpha/BA N$ , where  $B$  is the magnetic flux density,  $A$  is the area of the coil, and  $N$  is its number of turns;  $k$  is a constant depending on the strength of the return spring. The instrument is suitable for measuring d.c. but can be converted for a.c. by means of a rectifier network. It is usually made as a \*galvanometer and converted to an ammeter or voltmeter by means of a \*shunt or a \*multiplier.

**moving-iron instrument** A measuring instrument in which current or voltage is determined by the force of attraction on a bar of soft iron pivoted within the magnetic field of a fixed coil or by the repulsion between the poles induced in two soft iron rods within the coil. As the deflection caused by the passage of a current through the coil does not depend on the direction of the current, moving-iron instruments can be used with either d.c. or a.c. without a rectifier. They are, however, less sensitive than \*moving-coil instruments.

**moving-iron microphone** See MICROPHONE.

**mRNA** See RNA.

**MRSA** See STAPHYLOCOCCUS.

**MSG** See MONOSODIUM GLUTAMATE.

**MSH** See MELANOCYTE-STIMULATING HORMONE.

**mtDNA** See MITOCHONDRIAL DNA.

**mucilage** Any of a large group of com-

plex polysaccharides frequently present in the cell walls of aquatic plants and in the seed coats of certain other species. Mucilages are hard when dry and slimy when wet. Like \*gums they probably have a general protective function or serve to anchor the plant.

**mucopolysaccharide** See GLYCOSAMINOGLYCAN.

**mucous membrane (mucosa)** A layer of tissue comprising an epithelium supported on connective tissue. Within the epithelium are special **goblet cells**, which secrete \*mucus onto the surface, and the epithelium often bears cilia. Mucous membranes line body cavities communicating with the exterior, including the alimentary and respiratory tracts. Compare SEROUS MEMBRANE.

**mucus** The slimy substance secreted by goblet cells onto the surface of a \*mucous membrane to protect and lubricate it and to trap bacteria, dust particles, etc. Mucus consists of water, various **mucoproteins** (glycoproteins), cells, and salts. The mucoprotein chains, in which the carbohydrate component is a large polysaccharide, are joined by disulphide bridges to form long **mucin** strands, which readily form gels with water.

**multiaccess system** A system allowing several users of a computer, at different terminals, to make apparently simultaneous use of the computer without being aware of each other.

**multicellular** Describing tissues, organs, or organisms that are composed of a number of cells. Compare UNICELLULAR.

**multicentre bond** A bond formed between three, and sometimes more, atoms that contains only a single pair of electrons. The structure of \*boranes can be explained by considering them to be \*electron-deficient compounds containing multicentre bonds.

**multidecker sandwich** See SANDWICH COMPOUND.

**multifactorial inheritance** See POLYGENIC INHERITANCE.

**multimedia** A combination of various media, such as text, sound, and moving

and still images, now often held on \*CD-ROM. The user can make use of the different media in an integrated way.

**multimeter** An electrical measuring instrument designed to measure potential differences or currents over a number of ranges. It also usually has an internal dry cell enabling resistances to be measured. Most multimeters are moving-coil instruments with a switch to enable series resistors or parallel resistors to be incorporated into the circuit.

**multiple alleles** Three or more alternative forms of a gene (\*alleles) that can occupy the same \*locus. However, only two of the alleles can be present in a single organism. For example, the \*ABO system of blood groups is controlled by three alleles, only two of which are present in an individual.

**multiple bond** A bond between two atoms that contains more than one pair of electrons. Such bonds primarily involve sigma bonding with secondary contribution from pi bonding (or, sometimes, delta bonding). See ORBITAL.

**multiple proportions** See CHEMICAL COMBINATION.

**multiplet 1.** A spectral line formed by more than two (see DOUBLET) closely spaced lines. **2.** A group of \*elementary particles that are identical in all respects except that of electric charge.

**multiplication factor** Symbol  $k$ . The ratio of the average number of neutrons produced in a \*nuclear reactor per unit time to the number of neutrons lost by absorption or leakage in the same time. If  $k = 1$ , the reactor is said to be **critical**. If  $k > 1$  it is **supercritical** and if  $k < 1$  it is **subcritical**. See also CRITICAL REACTION.

**multiplicity** A quantity used in atomic \*spectra to describe the energy levels of many-electron atoms characterized by \*Russell-Saunders coupling given by  $2S + 1$ , where  $S$  is the total electron \*spin quantum number. The multiplicity of an energy level is indicated by a left superscript to the value of  $L$ , where  $L$  is the resultant electron \*orbital angular momentum of the individual electron orbital angular momenta  $l$ .

**multiplier** A fixed resistance used with a voltmeter, usually a \*moving-coil instrument, to vary its range. Many voltmeters are provided with a series of multipliers from which the appropriate value can be selected. If the original instrument requires  $i$  amperes for full-scale deflection and the resistance of the moving coil is  $r$  ohms, the value  $R$  of the resistance of the multiplier required to give a full-scale deflection when a voltage  $V$  is applied across the terminals is given by  $R = V/i - r$ .

**multivibrator** An electronic \*oscillator consisting of two active devices, usually transistors, interconnected in an electrical network. The purpose of the device is to generate a continuous square wave with which to store information in binary form in a logic circuit. This is achieved by applying a portion of the output voltage or current of each active device to the input of the other with the appropriate magnitude and polarity, so that the devices are conducting alternately for controllable periods.

**mu-mesic atom** See MUONIC ATOM.

**Mumetal** The original trade name for a ferromagnetic alloy, containing 78% nickel, 17% iron, and 5% copper, that had a high \*permeability and a low \*coercive force. More modern versions also contain chromium and molybdenum. These alloys are used in some transformer cores and for shielding various devices from external magnetic fields.

**Muntz metal** A form of \*brass containing 60% copper, 39% zinc, and small amounts of lead and iron. Stronger than alpha-brass, it is used for hot forgings, brazing rods, and large nuts and bolts. It is named after G. F. Muntz (1794-1857).

**muon** See LEPTON; ELEMENTARY PARTICLES.

**muonic atom (mu-mesic atom)** An atom in which one of the electrons has been replaced by a muon. Since the mass of a muon is 207 times that of an electron, the average radius of the orbit of a muon is much smaller than that of a corresponding electron. Muonic atoms provide tests for quantum electrodynamics. They are also used in research into muon-catalysed fusion (see NUCLEAR FUSION).

**Musci** See BRYOPHYTA.

**muscle** A tissue consisting of sheets or bundles of cells (**muscle fibres**) that are capable of contracting, so producing movement or tension in the body. There are three types of muscle. \*Voluntary muscle produces voluntary movement (e.g. at joints); \*involuntary muscle mainly effects the movements of hollow organs (e.g. intestine and bladder); and \*cardiac muscle occurs only in the heart.

**muscle spindle** A receptor in vertebrate muscle that is sensitive to stretch (see PROPRIOCEPTOR). Muscle spindles run parallel to normal muscle fibres; each consists of a capsule containing small striated muscle fibres (**intrafusal fibres**). Muscle spindles are responsible for the adjustment of muscle tone and play an important role in the subconscious maintenance of posture and movement. See also STRETCH REFLEX.

**muscovite (white mica; potash mica)** A mineral consisting of potassium aluminosilicate,  $K_2Al_4(Si_6Al_2)O_{20}(OH,F)_4$ ; one of the most important members of the \*mica group of minerals. It is chemically complex and has a sheetlike crystal structure (see INTERCALATION COMPOUND). It is usually silvery-grey in colour, sometimes tinted with green, brown, or pink. Muscovite is a common constituent of certain granites and pegmatites. It is also common in metamorphic and sedimentary rocks. It is widely used in industry, for example in the manufacture of electrical equipment and as a filler in roofing materials, wallpapers, and paint.

**mustard gas** A highly poisonous gas,  $(ClCH_2CH_2)_2S$ ; dichlorodiethyl sulphide. It is made from ethene and disulphur dichloride ( $S_2Cl_2$ ), and used as a war gas.

**mutagen** An agent that causes an increase in the number of mutants (see MUTATION) in a population. Mutagens operate either by causing changes in the DNA of the \*genes, so interfering with the coding system, or by causing chromosome damage. Various chemicals (e.g. \*colchicine) and forms of radiation (e.g. X-rays) have been identified as mutagens.

**mutant** (Denoting) a gene or an organism that has undergone a heritable

change, especially one with visible effects (i.e. the change in \*genotype is associated with a change in \*phenotype). See MUTATION.

**mutarotation** Change of optical activity with time as a result of spontaneous chemical reaction.

**mutation** A sudden random change in the genetic material of a cell that may cause it and all cells derived from it to differ in appearance or behaviour from the normal type. An organism affected by a mutation (especially one with visible effects) is described as a **mutant**. **Somatic mutations** affect the nonreproductive cells and are therefore restricted to the tissues of a single organism but **germ-line mutations**, which occur in the reproductive cells or their precursors, may be transmitted to the organism's descendants and cause abnormal development.

Mutations occur naturally at a low rate but this may be increased by radiation and by some chemicals (see MUTAGEN). Most are \*point mutations, which consist of invisible changes in the DNA of the chromosomes, but some (the \*chromosome mutations) affect the appearance or the number of the chromosomes. An example of a chromosome mutation is that giving rise to \*Down's syndrome.

The majority of mutations are harmful, but a very small proportion may increase an organism's \*fitness; these spread through the population over successive generations by natural selection. Mutation is therefore essential for evolution, being the ultimate source of genetic variation.

**mutual inductance** See INDUCTANCE.

**mutualism** An interaction between two species in which both species benefit. (The term \*symbiosis is often used synonymously with mutualism.) A well-known example of mutualism is the association between termites and the specialized protozoans that inhabit their guts. The protozoans, unlike the termites, are able to digest the cellulose of the wood that the termites eat and release sugars that the termites absorb. The termites benefit by being able to use wood as a foodstuff, while the protozoans are supplied with food and a suitable environment. See also MYCORRHIZA.

**mycelium** A network of \*hyphae that forms the body of a fungus. It consists of feeding hyphae together with reproductive hyphae, which produce \*sporangia and \*gametangia.

**mycology** The scientific study of \*fungi.

**Mycophycophyta** See LICHENS.

**mycoplasmas** A group of bacteria that lack a rigid cell wall and are among the smallest living cells (diameter 0.1  $\mu\text{m}$ –0.8  $\mu\text{m}$ ). They are either saprotrophic or parasitic and are found on animal mucous and synovial membranes, in insects, and in plants (in which they seem to inhabit sieve tubes). They cause a variety of diseases, including pleuropneumonia in cattle – hence they were formerly also known as **pleuropneumonia-like organisms (PPL0)**. Due to their small size and flexible cell wall they can pass through a 0.2- $\mu\text{m}$ -diameter filter and they represent a major contaminant of biotechnological products, such as monoclonal antibodies and vaccines, and of other cell cultures, in which they may exist symbiotically with the cells. Eight genera have been described (including *Mycoplasma*) with over 120 species.

**mycorrhiza** The mutually beneficial association (see MUTUALISM) formed between fungi and the roots of plants. This is a very common form of mutualism: the absorption of mineral ions by the plant roots is enhanced by the presence of the fungus, which benefits by obtaining soluble organic nutrients from the root cells. **Ectotrophic** mycorrhizas form a network of hyphae around the root and grow into the air spaces between the cells of the root. The hyphae of **endotrophic** mycorrhizas enter the cortex cells of the roots.

**Mycota** In older classification systems, a kingdom comprising the \*fungi.

**myelin** A \*phospholipid produced by the \*Schwann cells of the nervous system. Myelin forms an insulating layer around the nerve fibres (see MYELIN SHEATH).

**myelin sheath (medullary sheath)** The layer of fatty material that surrounds and electrically insulates the axons of most vertebrate and some invertebrate neurons. The myelin sheath enables a more

rapid transmission of nerve impulses (at speeds up to 120  $\text{m s}^{-1}$ ). It consists of layers of membrane derived from \*Schwann cells. The sheath is interrupted at intervals along the axon by **nodes of Ranvier**; myelinated sections of axon are called **internodes**.

**myeloid tissue** Tissue within red \*bone marrow that produces the blood cells. It is found around the blood vessels and contains various cells that are precursors of the blood cells. See HAEMOPOIETIC TISSUE.

**myeloma** See CANCER.

**myofibril** See VOLUNTARY MUSCLE.

**myogenic** Originating in or produced by muscle cells. The contractions of \*cardiac muscle fibres are described as myogenic, since they are produced spontaneously, without requiring stimulation from nerve cells (see PACEMAKER).

**myoglobin** A globular protein occurring widely in muscle tissue as an oxygen carrier. It comprises a single polypeptide chain and a \*haem group, which reversibly binds a molecule of oxygen. This is only relinquished at relatively low external oxygen concentrations, e.g. during strenuous exercise when muscle oxygen demand outpaces supply from the blood. Myoglobin thus acts as an emergency oxygen store.

**myopia** Short-sightedness. It results from the lens of the eye refracting the parallel rays of light entering it to a focus in front of the retina generally because of an abnormally long eyeball. The condition is corrected by using diverging spectacle lenses to move the image back to the retina.

**myosin** A contractile protein that interacts with \*actin to bring about contraction of muscle or cell movement. The type of myosin molecule found in muscle fibres consists of a tail, by which it aggregates with other myosin molecules to form so-called 'thick filaments'; and a globular head, which has sites for the attachment of actin and ATP molecules. See SARCOMERE.

**myotatic reflex** See STRETCH REFLEX.

**myotome** One of a series of segmented muscle blocks found in fishes and lancelets. Myotomes are arranged in pairs on either side of the body that work antagonistically (see ANTAGONISM) against the backbone (or notochord), providing a means of locomotion by causing the tail to sweep from side to side.

**Myriapoda** In some classifications, a subphylum of arthropods of the phylum Uniramia that comprises the classes \*Chilopoda (centipedes), \*Diplopoda (mil-

lipedes), Pauropoda (pauropods), and Symphyla (symphilids). In other classifications the Myriapoda is a class containing only the centipedes and millipedes.

**Myxomycota** See SLIME MOULDS.

**myxovirus** One of a group of RNA-containing viruses associated with various diseases of humans and other vertebrates.

**Orthomyxoviruses** produce diseases of the respiratory tract, e.g. influenza; **paramyxoviruses** include the causal agents of mumps, measles, and fowl pest.

**NAD (nicotinamide adenine dinucleotide)**

A \*coenzyme, derived from the B vitamin \*nicotinic acid, that participates in many biological dehydrogenation reactions.

NAD is characteristically loosely bound to the enzymes concerned. It normally carries a positive charge and can accept one hydrogen atom and two electrons to become the reduced form, NADH. NADH is generated during the oxidation of food, especially by the reactions of the \*Krebs cycle. It then gives up its two electrons (and single proton) to the \*electron transport chain, thereby reverting to NAD<sup>+</sup> and generating three molecules of ATP per molecule of NADH.

NADP (**nicotinamide adenine dinucleotide phosphate**) differs from NAD only in possessing an additional phosphate group. It functions in the same way as NAD although anabolic reactions (see ANABOLISM) generally use NADPH (reduced NADP) as a hydrogen donor rather than NADH. Enzymes tend to be specific for either NAD or NADP as coenzyme.

**nadir** The point opposite the \*zenith on the \*celestial sphere.

**NAND circuit** See LOGIC CIRCUITS.

**nano-** Symbol n. A prefix used in the metric system to denote 10<sup>-9</sup>. For example, 10<sup>-9</sup> metre = 1 nanometre (nm).

**nanoarray** See MICROARRAY.

**nanotechnology** The development and use of devices that have a size of only a few nanometres. Research has been carried out into very small components, which depend on electronic effects and may involve movement of a countable number of electrons in their action. Such devices would act much faster than larger components. Considerable interest has been shown in the production of structures on a molecular level by suitable sequences of chemical reactions. It is also possible to manipulate individual atoms

on surfaces using a variant of the \*atomic force microscope.

**nanotube** See BUCKMINSTERFULLERENE.

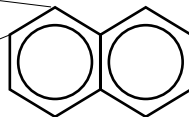

**napalm** A substance used in incendiary bombs and flame throwers, made by forming a gel of petrol with aluminium soaps (aluminium salts of long-chain carboxylic acids, such as palmitic acid).

**naphtha** Any liquid hydrocarbon or mixture obtained by the fractional distillation of petroleum. It is generally applied to higher \*alkane fractions with nine or ten carbon atoms. Naphtha is used as a solvent and as a starting material for \*cracking into more volatile products, such as petrol.

**naphthalene** A white volatile solid, C<sub>10</sub>H<sub>8</sub> (see formula); r.d. 1.025; m.p. 80.55°C; b.p. 218°C. Naphthalene is an aromatic hydrocarbon with an odour of mothballs and is obtained from crude oil. It is a raw material for making certain synthetic resins.

α or 1 position

β or 2 position

Naphthalene

**naphthols** Two phenols derived from naphthalene with the formula C<sub>10</sub>H<sub>7</sub>OH, differing in the position of the -OH group. The most important is naphthalen-2-ol (β-naphthol), with the -OH in the 2-position. It is a white solid (r.d. 1.28; m.p. 123–124°C; b.p. 295°C) used in rubber as an antioxidant. Naphthalen-2-ol will couple with diazonium salts at the 1-position to form red \*azo compounds, a reaction used in testing for the presence of primary amines (by making the diazonium salt and adding naphthalen-2-ol).

**naphthyl group** The group  $C_{10}H_7-$  obtained by removing a hydrogen atom from naphthalene. There are two forms depending on whether the hydrogen is removed from the 1- or 2-position.

**Napier, John** (1550–1617) Scottish mathematician, who is best known for devising \*logarithms, announced in 1614. His tables, which used the base  $e$ , were later modified by Henry Briggs (1561–1630) to base 10.

**Napierian logarithm** See LOGARITHM.

**narcotic** Any drug that induces stupor and relieves pain, especially morphine and other \*opiates. Such narcotics are addictive and cause dependence, and their medical use is strictly controlled.

**nares (nostrils)** The paired openings of the \*nasal cavity in vertebrates. All vertebrates have **external nares**, which open to the exterior; in some species these are situated on a \*nose. **Internal nares** (or **choanae**) are present only in air-breathing vertebrates (including lungfish) and open into the mouth cavity. In mammals they open posteriorly, beyond the secondary \*palate.

**nasal cavity** The cavity in the head of a vertebrate that is lined by a membrane rich in sensitive olfactory receptors (see OLFACTION). It is connected to the exterior by external nostrils and (in air-breathing vertebrates) to the respiratory system by internal \*nares.

**nascent hydrogen** A reactive form of hydrogen generated *in situ* in the reaction mixture (e.g. by the action of acid on zinc). Nascent hydrogen can reduce elements and compounds that do not readily react with 'normal' hydrogen. It was once thought that the hydrogen was present as atoms, but this is not the case. Probably hydrogen molecules are formed in an excited state and react before they revert to the ground state.

**nastic movements** Movements of plant organs in response to external stimuli that are independent of the direction of the stimuli. Examples are the opening of crocus and tulip flowers in response to a rise in temperature (**thermonasty**), the opening of evening primrose flowers at

night (**photonasty**), and the folding up and drooping of leaves of the sensitive plant (*Mimosa pudica*) when lightly touched (**haptonomy**). Compare TROPISM. See also NYCTINASTY.

**natality** See BIRTH RATE.

**natron** A mineral form of hydrated sodium carbonate,  $Na_2CO_3 \cdot H_2O$ .

**Natta process** See ZIEGLER PROCESS.

**natural abundance** See ABUNDANCE.

**natural frequency** **1.** The frequency of the free oscillation of a system. **2.** The frequency at which resonance occurs in an electrical circuit.

**natural gas** A naturally occurring mixture of gaseous hydrocarbons that is found in porous sedimentary rocks in the earth's crust, usually in association with \*petroleum deposits. It consists chiefly of methane (about 85%), ethane (up to about 10%), propane (about 3%), and butane. Carbon dioxide, nitrogen, oxygen, hydrogen sulphide, and sometimes helium may also be present. Natural gas, like petroleum, originates in the decomposition of organic matter. It is widely used as a fuel and also to produce carbon black and some organic chemicals. Natural gas occurs on every continent, the major reserves occurring in the USA, Russia, Kazakhstan, Turkmenistan, Ukraine, Algeria, Canada, and the Middle East. See also LIQUEFIED PETROLEUM GAS.

**natural group** A group of organisms of any taxonomic rank that are believed to be descended from a common ancestor (see MONOPHYLETIC). For example, humans and apes are often regarded as a natural group, descended from fossil ancestors, the dryopithecines (or their near relatives). In an ideal natural classification all taxa should be natural groups. See also CLADISTICS.

**natural history** **1.** The study of living organisms in their natural habitats. **2.** The study of all natural phenomena.

**natural logarithm** See LOGARITHM.

**natural order** In the classification of plants, the former name for a \*family.

**natural selection** The process that, ac-

ording to \*Darwinism, brings about the evolution of new species of animals and plants. Darwin noted that the size of any population tends to remain constant despite the fact that more offspring are produced than are needed to maintain it. He also saw that variations existed between individuals of the population and concluded that disease, competition, and other forces acting on the population eliminated those individuals less well adapted to their environment. The survivors would pass on any heritable advantageous characteristics (i.e. characteristics with survival value) to their offspring and in time the composition of the population would change in adaptation to a changing environment. Over a long period of time this process could give rise to organisms so different from the original population that new species are formed. *See also* ADAPTIVE RADIATION. *Compare* PUNCTUATED EQUILIBRIUM.

**natural units** A system of units, used principally in particle physics, in which all quantities that have dimensions involving length, mass, and time are given dimensions of a power of energy (usually expressed in electronvolts). This is equivalent to setting the rationalized \*Planck constant and the speed of light both equal to unity. *See also* GAUSSIAN UNITS; GEOMETRIZED UNITS; HEAVISIDE-LORENTZ UNITS; PLANCK UNITS.

**nature and nurture** The combined effects of inherited factors (nature) and environmental factors (nurture) on the development of an organism. The genetic potential of an organism will only be realized under appropriate environmental conditions. *See also* PHENOTYPE.

**nautical mile** A measure of distance used at sea. In the UK it is defined as 6080 feet but the international definition is 1852 metres. 1 international nautical mile is therefore equivalent to 1.15078 land (statute) miles.

**navigation** (in biology) The complex process that enables animals to travel along a particular course in order to reach a specific destination. Navigation is an important aspect of behaviour in many animals, particularly those, such as birds, fish, and some insects, that undergo \*mi-

grations. Landmarks, such as coastlines and mountain ranges, are important reference points for navigation but many animals can navigate successfully without the aid of these, by using the sun, stars, magnetic fields, odours, and polarized light. For example, birds use the sun and stars as landmarks and are sensitive to the earth's magnetic fields, while salmon can identify the unique odour of their home river. *See also* DANCE OF THE BEES.

**Neanderthal man** A form of fossil human that lived in Europe and western Asia between about 200 000 and 30 000 years ago, when the climate was much colder than today. Neanderthals were thought to be a subspecies of *Homo sapiens* but are now generally regarded as a distinct species, *H. neanderthalensis*. The fossil remains indicate that Neanderthals were fairly short, strongly built, and had low brows but that the brain size was the same as, or larger than, modern humans'. They were nomadic cave dwellers who buried their dead. Neanderthals became extinct abruptly; they may have been exterminated by incoming modern humans, with their more advanced stone tool technology. The name is derived from the site in the Neander valley, Germany, where fossils were found in 1856.

**near point** The nearest point at which the human eye can focus an object. As the lens becomes harder with age, the extent to which accommodation can bring a near object into focus decreases. Therefore with advancing age the near point recedes – a condition known as \*presbyopia.

**nebula** Originally a fixed, extended, and somewhat fuzzy white haze observed in the sky with a telescope. Many of these objects can now be resolved into clouds of individual stars and have been identified as \*galaxies. They are still sometimes referred to as **extragalactic nebulae**. The **gaseous nebulae**, however, cannot be resolved into individual stars and consist, for the most part, of interstellar dust and gas. In some of these gaseous nebulae the gas atoms have been ionized by ultraviolet radiation from nearby stars and light is emitted as these ions interact with the free electrons in the gas. These are called **emission nebulae**. In the **dark nebulae**,

there are no nearby stars and these objects are consequently dark; they can only be detected by what they obscure.

**nectar** A sugary liquid produced in plants by **nectaries**, regions of secretory cells on the receptacle or other parts of a flower. It attracts pollinating insects or other animals.

**Néel temperature** The temperature above which an antiferromagnetic substance becomes paramagnetic (see **MAGNETISM**). The \*susceptibility increases with temperature, reaching a maximum at the Néel temperature, after which it abruptly declines. The phenomenon was discovered around 1930 by Louis Néel (1904–2000).

**Ne'eman, Yuval** See **GELL-MANN, MURRAY**.

**negative charge** See **CHARGE**.

**negative feedback** See **FEEDBACK**.

**nekton** \*Pelagic organisms that actively swim through the water. Examples are fish, jellyfish, turtles, and whales. Compare **PLANKTON**.

**nematic crystal** See **LIQUID CRYSTAL**.

**nematoblast** See **THREAD CELL**.

**Nematoda** A phylum of invertebrates comprising the roundworms. They are characterized by a smooth narrow cylindrical unsegmented body tapered at both ends. They shed their tough outer cuticle four times during life to allow growth. The microscopic free-living forms are found in all parts of the world, where they play an important role in the destruction and recycling of organic matter. The many parasitic nematodes are much larger; they include the filaria (*Wuchereria*) and Guinea worm (*Dracunculus*), which cause serious diseases in humans.

**neo-Darwinism (modern synthesis)** The current theory of the process of \*evolution, formulated between about 1920 and 1950, that combines evidence from classical genetics with the Darwinian theory of evolution by \*natural selection (see **DARWINISM**). It makes use of modern knowledge of genes and chromosomes to explain the source of the genetic variation upon which selection works. This aspect

was unexplained by traditional Darwinism.

**neodymium** Symbol Nd. A soft silvery metallic element belonging to the \*lanthanoids; a.n. 60; r.a.m. 144.24; r.d. 7.004 (20°); m.p. 1021°C; b.p. 3068°C. It occurs in bastnaesite and monazite, from which it is recovered by an ion-exchange process. There are seven naturally occurring isotopes, all of which are stable, except neodymium-144, which is slightly radioactive (half-life  $10^{10}$ – $10^{15}$  years). Seven artificial radioisotopes have been produced. The metal is used to colour glass violet-purple and to make it dichroic. It is also used in misch metal (18% neodymium) and in neodymium-iron-boron alloys for magnets. It was discovered by Carl von Welsbach (1856–1929) in 1885.

**neo-Lamarckism** Any of the comparatively modern theories of evolution based on Lamarck's theory of the inheritance of acquired characteristics (see **LAMARCKISM**). These include the unfounded dogma of \*Lysenkoism and the controversial experiments on the inheritance of acquired immunological tolerance in mice.

**Neolithic** The New Stone Age, beginning in the Middle East approximately 9000 BC and lasting until 6000 BC, during which humans first developed agriculture. Grinding and polishing of stone tools was also practised.

**neon** Symbol Ne. A colourless gaseous element belonging to group 18 (formerly group 0) of the periodic table (the \*noble gases); a.n. 10; r.a.m. 20.179; d.  $0.9 \text{ g dm}^{-3}$ ; m.p.  $-248.67^\circ\text{C}$ ; b.p.  $-246.05^\circ\text{C}$ . Neon occurs in air (0.0018% by volume) and is obtained by fractional distillation of liquid air. It is used in discharge tubes and neon lamps, in which it has a characteristic red glow. It forms hardly any compounds (neon fluorides have been reported). The element was discovered in 1898 by Sir William Ramsey and M. W. Travers.

**neon lamp** A small lamp consisting of a pair of electrodes, treated to emit electrons freely, sealed in a glass bulb containing neon gas at low pressure. When a minimum voltage of between 60 and 90 volts is applied across the electrodes, the

kinetic energy of the electrons is sufficient to ionize the neon atoms around the cathode, causing the emission of a reddish light. With d.c. the glow is restricted to the cathode; with a.c. both electrodes act alternately as cathodes and a glow appears to emanate from both electrodes. The device consumes a very low power and is widely used as an indicator light showing that a circuit is live.

**neoplasm (tumour)** Any new abnormal growth of cells, forming either a harmless (benign) tumour or a malignant one (see CANCER).

**neoprene** A synthetic rubber made by polymerizing the compound 2-chlorobutadiene. Neoprene is often used in place of natural rubber in applications requiring resistance to chemical attack.

**neoteny** The retention of the juvenile body form, or particular features of it, in a mature animal. For example, the axolotl, a salamander, retains the gills of the larva in the adult. Neoteny is thought to have been an important mechanism in the evolution of certain groups, such as humans, who are believed to have developed from juvenile forms of apes.

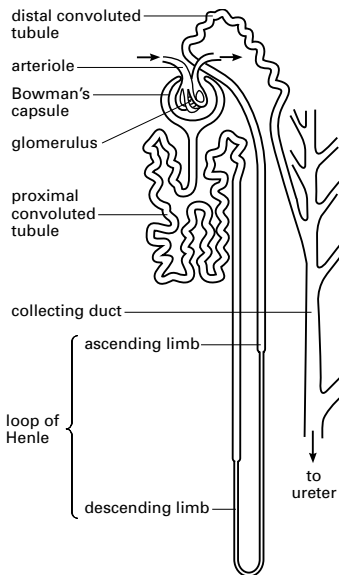

**neper** A unit used to express a ratio of powers, currents, etc., used especially in telecommunications to denote the attenuation of an amplitude  $A_1$  to an amplitude  $A_2$  as  $N$  nepers, where

$$N = \log_e (A_2/A_1).$$

1 neper = 8.686 decibels. The unit is named after John Napier.

**nephrite** See JADE.

**nephron** The excretory unit of the vertebrate \*kidney (see illustration). Many constituents of the blood are filtered from the glomerulus into the Bowman's capsule at one end of the nephron. The \*glomerular filtrate passes along the length of the nephron and some of its water, plus some salts, glucose, and amino acids, are reabsorbed into the surrounding blood capillaries (see PROXIMAL CONVOLUTED TUBULE; LOOP OF HENLE; DISTAL CONVOLUTED TUBULE). More water is reabsorbed in the \*collecting duct, and the resulting concentrated solution of nitrogen-containing waste matter (\*urea)

Structure of a single nephron

plus inorganic salts drains from the collecting ducts of the nephrons and is discharged as urine into the ureter.

**Neptune** A planet in the \*solar system, the eighth in order from the sun (4498.25  $\times 10^6$  km distant). Its diameter is 49 528 km and its \*sidereal period is 163.72 years. It was discovered in 1846 by Johann Galle (1812–1910) on the basis of predictions made by John Couch Adams and Urbain Leverrier (1811–77), who had separately observed perturbations in the orbit of Uranus. Spectroscopic evidence suggests that there is an atmosphere predominantly composed of methane and hydrogen. The surface temperature appears to be about  $-200^\circ\text{C}$ . Neptune has two main satellites; the inner one, Triton, has a diameter of about 4025 km, while the outer one, Nereid, is about one tenth of this size. Six other smaller satellites were discovered by the US Voyager II probe in 1989. Since then five more satellites have been discovered.

**neptunium** Symbol Np. A radioactive metallic transuranic element belonging to

the \*actinoids; a.n. 93; r.a.m. 237.0482. The most stable isotope, neptunium-237, has a half-life of  $2.2 \times 10^6$  years and is produced in small quantities as a by-product by nuclear reactors. Other isotopes have mass numbers 229–236 and 238–241. The only other relatively long-lived isotope is neptunium-236 (half-life  $5 \times 10^3$  years). The element was first produced by Edwin McMillan (1907–91) and Philip Abelson (1913– ) in 1940.

**neptunium series** See RADIOACTIVE SERIES.

**neritic zone** The region of the sea over the continental shelf, which is less than 200 metres deep (approximately the maximum depth for organisms carrying out photosynthesis). Compare OCEANIC ZONE.

**Nernst effect** An effect in which a temperature gradient along an electric conductor or semiconductor placed in a perpendicular magnetic field, causes a potential difference to develop in the third perpendicular direction between opposite edges of the conductor. This effect, an analogue of the \*Hall effect, was discovered in 1886 by Walter Nernst (1864–1941).

**Nernst heat theorem** A statement of the third law of \*thermodynamics in a restricted form: if a chemical change takes place between pure crystalline solids at \*absolute zero there is no change of entropy.

**nerve** A strand of tissue comprising many \*nerve fibres plus supporting tissues (see GLIA), enclosed in a connective-tissue sheath. Nerves connect the central nervous system with the organs and tissues of the body. A nerve may carry only motor nerve fibres (**motor nerve**) or only sensory fibres (**sensory nerve**) or it may be mixed and carry both types (**mixed nerve**). Although the nerve fibres are in close proximity within the nerve, their physiological responses are independent of each other.

**nerve cell** See NEURON.

**nerve cord** A large bundle of nerve fibres, running down the longitudinal axis of the body, that forms an important part of the \*central nervous system. Most in-

vertebrates have a pair of solid nerve cords, situated ventrally and bearing segmentally arranged \*ganglia. All animals of the phylum \*Chordata have a dorsal hollow nerve cord; in vertebrates this is the \*spinal cord.

**nerve fibre** The \*axon of a \*neuron together with the tissues associated with it (such as a \*myelin sheath). The length and diameter of nerve fibres are very variable, even within the same organism. See also GIANT FIBRE.

**nerve growth factor (NGF) 1.** A polypeptide produced by neurons and their supporting tissues (e.g. astrocytes and Schwann cells) that stimulates the growth of neurons. It is also produced in various other tissues, having a stimulatory effect on B lymphocytes (see B CELL) and triggering histamine release by \*mast cells. **2.** Any of various related polypeptides that promote the growth and maintenance of neurons, including **neurotrophins**.

**nerve impulse** See IMPULSE.

**nerve net** A network of nerve cells connected with each other by synapses or fusion. The nervous system of certain invertebrates (e.g. coelenterates and echinoderms) consists exclusively of a nerve net in the body wall.

**nervous system** The system of cells and tissues in multicellular animals by which information is conveyed between sensory cells and organs and effectors (such as muscles and glands). It consists of the \*central nervous system (in vertebrates the \*brain and \*spinal cord; in invertebrates the \*nerve cord and \*ganglia) and the \*peripheral nervous system. Its function is to receive, transmit, and interpret information and then to formulate appropriate responses for the effector organs. It also serves to coordinate responses that require more than one physiological process. Nervous tissue consists of \*neurons, which convey the information in the form of \*impulses, and supporting tissue.

**nesquehonite** A mineral form of \*magnesium carbonate trihydrate,  $\text{MgCO}_3 \cdot 3\text{H}_2\text{O}$ .

**Nessler's reagent** A solution of mercury(II) iodide ( $\text{HgI}_2$ ) in potassium iodide and potassium hydroxide. It is used in testing for ammonia, with which it forms a brown coloration or precipitate.

**Net** See INTERNET.

**Neumann's law** The magnitude of an electromagnetically induced e.m.f. ( $E$ ) is given by  $E = -d\Phi/dt$ , where  $\Phi$  is the magnetic flux. This is a quantitative statement of \*Faraday's second law of electromagnetic induction and is sometimes known as the Faraday-Neumann law.

**neural network** A network of processors designed to mimic the transmission of impulses in the human brain. Neural networks are either electronic constructions or, often, computer-simulated structures. Each processor ('neurone') multiplies its input signal by a weighting factor and the final output signal depends on these factors, which can be adjusted. Such networks can be 'taught' to recognize patterns in large amounts of data. They are used in research into artificial intelligence and have also been applied in predicting financial market trends.

**neural tube** A hollow tube of tissue in the early embryo of vertebrates that subsequently develops into the brain and spinal cord. It forms by folding of the ectodermal **neural plate**, and has a central canal running through it. Sometimes the folds of the neural plate fail to close properly, resulting in **neural tube defects** (such as spina bifida) in the fetus.

**neuroendocrine system** Any of the systems of dual control of certain activities in the body of some higher animals by nervous and hormonal stimulation. For example, the posterior \*pituitary gland and the medulla of the \*adrenal gland receive direct nervous stimulation to secrete their hormones, whereas the anterior pituitary gland is stimulated by \*releasing hormones from the hypothalamus.

**neurohormone** Any hormone that is produced not by an endocrine gland but by a specialized nerve cell and is secreted from nerve endings into the bloodstream or directly to the tissue or organ whose growth or function it controls (see NEUROSECRETION). Examples of neurohormones

are \*noradrenaline, \*antidiuretic hormone, and hormones associated with metamorphosis and moulting in insects (see ECDYSONE; JUVENILE HORMONE). Compare NEUROPEPTIDE.

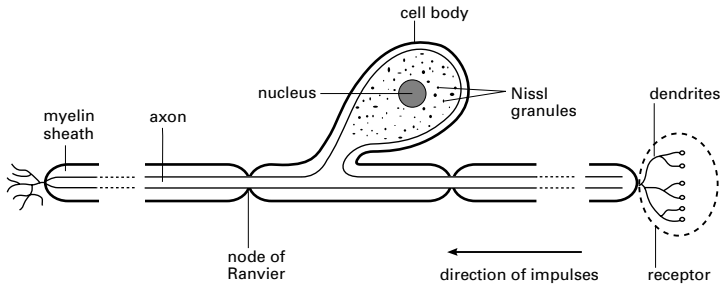

**neuromuscular junction** The point where a muscle fibre comes into contact with a motor neuron carrying nerve impulses from the central nervous system. The impulses travel from the neuron to the muscle fibre by means of a neurotransmitter, in a similar way to the transmission of impulses across a \*synapse between two neurons. The neurotransmitter is released from vesicles at the end of the motor neuron into a small gap (the cleft), where it diffuses to the \*end plate of the muscle fibre and depolarizes the membrane. When depolarization has reached a certain threshold an action potential is triggered in the muscle fibre.

**neuron (neurone; nerve cell)** An elongated branched cell that is the fundamental unit of the \*nervous system, being specialized for the conduction of \*impulses. A neuron consists of a \*cell body, containing the nucleus and \*Nissl granules; \*dendrites, which receive incoming impulses and pass them towards the cell body; and an \*axon, which conducts impulses away from the cell body, sometimes over long distances. Impulses are passed from one neuron to the next via \*synapses. \*Sensory neurons transmit information from receptors to the central nervous system. \*Motor neurons conduct information from the central nervous system to \*effectors (e.g. muscles). See illustration.

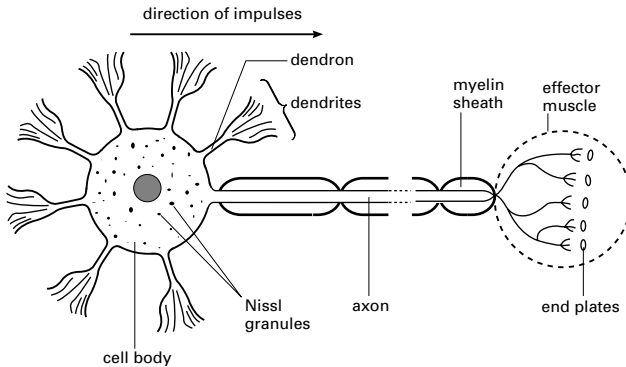

**neuron theory** The hypothesis, now accepted, that the nervous system consists of nerve cells (\*neurons), which are functionally linked at \*synapses but are physically separate. This theory has superseded the idea that the cytoplasm of the cells of the nervous system is continuous.

**neuropeptide** Any of numerous peptides that influence the activity of neurons. Examples include the hypothalamic \*releasing hormones, \*antidiuretic hormone, and the gastric peptides (e.g. \*VIP) released from cells in the duodenal wall. Neuropeptides may act as neurotransmitters, as cotransmitters to modify the ac-

Sensory neuron

Motor neuron

tion of neurotransmitters, and/or as \*neurohormones.

**neurosecretion** The secretion of \*neurohormones by **neurosecretory cells**, which possess characteristics of both nerve cells and endocrine cells. They are found, for example, in the hypothalamus, where they receive nerve impulses from other parts of the brain but transmit these signals to the pituitary gland by neurohormones that are released into the blood.

**neurotransmitter** A chemical that mediates the transmission of a nerve impulse across a \*synapse. Examples are \*adrenaline and \*noradrenaline (in adrenergic nerves) and \*acetylcholine (in cholinergic nerves). The neurotransmitter is released at the synaptic knob at the tip of the axon into the synaptic cleft. It diffuses across to

the opposite membrane (the postsynaptic membrane), where it initiates the propagation of a nerve impulse in the next neuron.

**neurotrophin** See NERVE GROWTH FACTOR.

**neuter** An organism that does not possess either male or female reproductive organs. Cultivated ornamental flowers that have neither pistils nor stamens are called neuters.

**neutral** Describing a compound or solution that is neither acidic nor basic. A neutral solution is one that contains equal numbers of both protonated and deprotonated forms of the solvent.

**neutralization** The process in which an acid reacts with a base to form a salt and water.

**neutrino** A *\*lepton* (see also ELEMENTARY PARTICLES) that exists in three forms, one in association with the electron, one with the muon, and one with the tau particle. Each form has its own antiparticle. The neutrino, which was postulated in 1930 to account for the 'missing' energy in *\*beta* decay, was identified tentatively in 1953 and, more definitely, in 1956. Neutrinos have no charge and travel at speeds very close to the speed of light. In some *\*grand* unified theories they are predicted to have nonzero mass and there is now a large amount of indirect evidence for this, although the values of neutrino masses have not been determined.

**neutron** A neutral hadron (see ELEMENTARY PARTICLES) that is stable in the atomic nucleus but decays into a proton, an electron, and an antineutrino with a mean life of 12 minutes outside the nucleus. Its rest mass (symbol  $m_n$ ) is slightly greater than that of the proton, being  $1.674\ 9286(10) \times 10^{-27}$  kg. Neutrons occur in all atomic nuclei except normal hydrogen. The neutron was first reported in 1932 by James Chadwick (1891-1974).

**neutron bomb** See NUCLEAR WEAPONS.

**neutron diffraction** The scattering of neutrons by atoms in solids, liquids, or gases. This process has given rise to a technique, analogous to *\*X-ray* diffraction techniques, using a flux of thermal neutrons from a nuclear reactor to study solid-state structure and phenomena. Thermal neutrons have average kinetic energies of about 0.025 eV ( $4 \times 10^{-21}$  J) giving them an equivalent wavelength of about 0.1 nanometre, which is suitable for the study of interatomic interference. There are two types of interaction in the scattering of neutrons by atoms: one is the interaction between the neutrons and the atomic nucleus, the other is the interaction between the *\*magnetic* moments of the neutrons and the spin and orbital magnetic moments of the atoms. The latter interaction has provided valuable information on antiferromagnetic and ferrimagnetic materials (see MAGNETISM). Interaction with the atomic nucleus gives diffraction patterns that complement those from X-rays. X-rays, which interact with the extranuclear electrons, are not

suitable for investigating light elements (e.g. hydrogen), whereas neutrons do give diffraction patterns from such atoms because they interact with nuclei.

**neutron drip** See NEUTRON STAR.

**neutron excess** See ISOTOPIC NUMBER.

**neutron number** Symbol  $N$ . The number of neutrons in an atomic nucleus of a particular nuclide. It is equal to the difference between the *\*nucleon* number and the *\*atomic* number.

**neutron star** A compact stellar object that is supported against collapse under self-gravity by the *\*degeneracy* pressure of the neutrons of which it is primarily composed. Neutron stars are believed to be formed as the end products of the evolution of stars of mass greater than a few (4-10) solar masses. The core of the evolved star collapses and (assuming that its mass is greater than the *\*Chandrasekhar* limit for a *\*white* dwarf), at the very high densities involved (about  $10^{14}$  kg m<sup>-3</sup>), electrons react with protons in atomic nuclei to produce neutrons. The neutron-rich nuclei thus formed release free neutrons in a process known as **neutron drip**. The density increases to about  $10^{17}$  kg m<sup>-3</sup>, at which most of the electrons and protons have been converted to a *\*degenerate* gas of neutrons and the atomic nuclei have lost their separate identities. If the mass of the core exceeds the Oppenheimer-Volkoff limit for a neutron star, then further collapse will occur, leading to the formation of a *\*black* hole.

*\*Pulsars* are believed to be rapidly rotating magnetized neutron stars and many X-ray sources are thought to be neutron stars in binary systems with another star, from which material is drawn into an accretion disc. This material, heated to a very high temperature, emits radiation in the X-ray region.

**neutron temperature** A concept used to express the energies of neutrons that are in thermal equilibrium with their surroundings, assuming that they behave like a monatomic gas. The neutron temperature  $T$ , on the Kelvin scale, is given by  $T = 2E/3k$ , where  $E$  is average neutron energy and  $k$  the *\*Boltzmann* constant.

**neutrophil** A type of white blood cell

(\*leucocyte) that has a lobed nucleus and granular cytoplasm (see GRANULOCYTE). Neutrophils engulf bacteria (see PHAGOCYTOSIS) and release various substances, such as \*lysozyme and oxidizing agents.

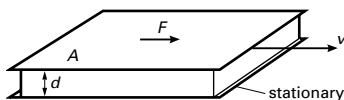

**New General Catalogue (NGC)** A list of nonstellar objects, originally published (with 7840 entries) in 1888 by J. L. E. Dreyer. Such objects are referred to by their New General Catalogue numbers; e.g. the Orion nebula is NGC1976.

**Newlands' law** See LAW OF OCTAVES.

**newton** Symbol N. The \*SI unit of force, being the force required to give a mass of one kilogram an acceleration of  $1 \text{ m s}^{-2}$ . It is named after Sir Isaac Newton.

**Newton, Sir Isaac** (1642–1727) English mathematician and physicist, one of the world's greatest scientists. He went to Cambridge University in 1661 and stayed for nearly 40 years except for 1665–67, when he returned to his home at Woolsthorpe in Lincolnshire (because of the Plague), where some of his best work was done. In 1699 he was made Master of the Royal Mint. He was reluctant to publish his work and his great mathematical masterpiece, the *Principia*, did not appear until 1687. In it he introduced \*calculus and formulated \*Newton's laws of motion. In 1665 he derived \*Newton's law of gravitation, and in optics he produced \*Newton's formula for a lens and, in 1672, his theories about \*light and the spectrum (see also NEWTON'S RINGS); these were summarized in his *Opticks* of 1704. Also in the late 1660s he constructed a reflecting \*telescope. The SI unit of force is named after him.

**Newtonian fluid** A fluid in which the velocity gradient is directly proportional to the shear stress. If two flat plates of area  $A$  are separated by a layer of fluid of thickness  $d$  and move relative to each other at a velocity  $v$ , then the rate of shear is  $v/d$  and the shear stress is  $F/A$ , where  $F$  is the force applied to each (see illustration). For a Newtonian fluid  $F/A = \mu v/d$ , where  $\mu$  is the constant of proportionality and is called the Newtonian \*viscosity. Many liquids are Newtonian fluids over a wide range of temperatures and pressures. However, some are not; these are called

Newtonian fluid

**non-Newtonian fluids.** In such fluids there is a departure from the simple Newtonian relationships. For example, in some liquids the viscosity increases as the velocity gradient increases, i.e. the faster the liquid moves the more viscous it becomes. Such liquids are said to be **dilatant** and the phenomenon they exhibit is called **dilatancy**. It occurs in some pastes and suspensions. More common, however, is the opposite effect in which the viscosity depends not only on the velocity gradient but also on the time for which it has been applied. These liquids are said to exhibit **thixotropy**. The faster a **thixotropic liquid** moves the less viscous it becomes. This property is used in nondrip paints (which are more viscous on the brush than on the wall) and in lubricating oils (which become thinner when the parts they are lubricating start to move). Another example is the non-Newtonian flow of macromolecules in solution or in polymer melts. In this case the shearing force  $F$  is not parallel to the shear planes and the linear relationship does not apply. In general, the many types of non-Newtonian fluid are somewhat complicated and no theory has been developed to accommodate them fully.

**Newtonian mechanics** The system of \*mechanics that relies on \*Newton's laws of motion. Newtonian mechanics is applicable to bodies moving at speeds relative to the observer that are small compared to the speed of light. Bodies moving at speeds comparable to the speed of light require an approach based on \*relativistic mechanics, in which the mass of a body changes with its speed.

**Newtonian telescope** See TELESCOPE.

**Newton's formula** For a lens, the distances  $p$  and  $q$  between two conjugate points and their respective foci is given by  $pq = f^2$ , where  $f$  is the focal length of the lens.

**Newton's law of cooling** The rate at

which a body loses heat is proportional to the difference in temperature between the body and the surroundings. It is an empirical law that is only true for substantial temperature differences if the heat loss is by forced convection or conduction.

**Newton's law of gravitation** There is a force of attraction between any two massive particles in the universe. For any two point masses  $m_1$  and  $m_2$ , separated by a distance  $d$ , the force of attraction  $F$  is given by  $F = m_1 m_2 G/d^2$ , where  $G$  is the \*gravitational constant. Real bodies having spherical symmetry act as point masses positioned at their centres of mass.

**Newton's laws of motion** The three laws of motion on which \*Newtonian mechanics is based. (1) A body continues in a state of rest or uniform motion in a straight line unless it is acted upon by external forces. (2) The rate of change of momentum of a moving body is proportional to and in the same direction as the force acting on it, i.e.  $F = d(mv)/dt$ , where  $F$  is the applied force,  $v$  is the velocity of the body, and  $m$  its mass. If the mass remains constant,  $F = mdv/dt$  or  $F = ma$ , where  $a$  is the acceleration. (3) If one body exerts a force on another, there is an equal and opposite force, called a **reaction**, exerted on the first body by the second.

**Newton's rings** **1.** (in optics) \*Interference fringes formed by placing a slightly convex lens on a flat glass plate. If monochromatic light is reflected by the two close surfaces into the observer's eye at a suitable angle, the point of contact of the lens is seen as a dark spot surrounded by a series of bright and dark rings. The radius of the  $n$ th dark ring is given by  $r_n = \sqrt{nR\lambda}$ , where  $\lambda$  is the wavelength and  $R$  is the radius of curvature of the lens. The phenomenon is used in the quality testing of lens surfaces. With white light, coloured rings are formed. **2.** (in photography) The irregular patterns produced by thin film interference between a projected transparency and its cover glass.

**niacin** See NICOTINIC ACID.

**niche** See ECOLOGICAL NICHE.

**Nichrome** Trade name for a group of

nickel-chromium alloys used for wire in heating elements as they possess good resistance to oxidation and have a high resistivity. Typical is Nichrome V containing 80% nickel and 19.5% chromium, the balance consisting of manganese, silicon, and carbon.

**nickel** Symbol Ni. A malleable ductile silvery metallic \*transition element; a.n. 28; r.a.m. 58.70; r.d. 8.9; m.p. 1450°C; b.p. 2732°C. It is found in the minerals pentlandite (NiS), pyrrhoite ((Fe,Ni)S), and garnierite ((Ni,Mg)<sub>6</sub>(OH)<sub>6</sub>Si<sub>4</sub>O<sub>11</sub>.H<sub>2</sub>O). Nickel is also present in certain iron meteorites (up to 20%). The metal is extracted by roasting the ore to give the oxide, followed by reduction with carbon monoxide and purification by the \*Mond process. Alternatively electrolysis is used. Nickel metal is used in special steels, in Invar, and, being ferromagnetic, in magnetic alloys, such as \*Mumetal. It is also an effective catalyst, particularly for hydrogenation reactions (see also RANEY NICKEL). The main compounds are formed with nickel in the +2 oxidation state; the +3 state also exists (e.g. the black oxide, Ni<sub>2</sub>O<sub>3</sub>). Nickel was discovered by Axel Cronstedt (1722–65) in 1751.

**nickel-cadmium cell** See NICKEL-IRON ACCUMULATOR.

**nickel carbonyl** A colourless volatile liquid, Ni(CO)<sub>4</sub>; m.p. -25°C; b.p. 43°C. It is formed by direct combination of nickel metal with carbon monoxide at 50–60°C. The reaction is reversed at higher temperatures, and the reactions are the basis of the \*Mond process for purifying nickel. The nickel in the compound has an oxidation state of zero, and the compound is a typical example of a complex with pi-bonding \*ligands, in which filled  $d$ -orbitals on the nickel overlap with empty  $p$ -orbitals on the carbon.

**nickelic compounds** Compounds of nickel in its +3 oxidation state; e.g. nickelic oxide is nickel(III) oxide (Ni<sub>2</sub>O<sub>3</sub>).

**nickel-iron accumulator (Edison cell; NIFE cell)** A \*secondary cell devised by Thomas Edison (1847–1931) having a positive plate of nickel oxide and a negative plate of iron both immersed in an elec-

trolyte of potassium hydroxide. The reaction on discharge is

the reverse occurring during charging. Each cell gives an e.m.f. of about 1.2 volts and produces about 100 kJ per kilogram during each discharge. The **nickel-cadmium cell** is a similar device with a negative cadmium electrode. It is often used as a \*dry cell. Compare LEAD-ACID ACCUMULATOR.

**nickelous compounds** Compounds of nickel in its +2 oxidation state; e.g. nickelous oxide is nickel(II) oxide (NiO).

**nickel(II) oxide** A green powder, NiO; r.d. 6.6. It can be made by heating nickel(II) nitrate or carbonate with air excluded.

**nickel(III) oxide (nickel peroxide; nickel sesquioxide)** A black or grey powder, Ni<sub>2</sub>O<sub>3</sub>; r.d. 4.8. It is made by heating nickel(II) oxide in air and used in \*nickel-iron accumulators.

**nickel silver** See GERMAN SILVER.

**Nicol prism** A device for producing plane-polarized light (see POLARIZER). It consists of two pieces of calcite cut with a 68° angle and stuck together with Canada balsam. The extraordinary ray (see DOUBLE REFRACTION) passes through the prism while the ordinary ray suffers total internal reflection at the interface between the two crystals, as the refractive index of the calcite is 1.66 for the ordinary ray and that of the Canada balsam is 1.53. Modifications of the prism using different shapes and cements are used for special purposes. It was devised in 1828 by William Nicol (1768-1851).

**nicotinamide** See NICOTINIC ACID.

**nicotinamide adenine dinucleotide** See NAD.

**nicotinamide adenine dinucleotide phosphate (NADP)** See NAD.

**nicotine** A colourless poisonous \*alkaloid present in tobacco. It is used as an insecticide.

**nicotinic acid (niacin)** A vitamin of the \*vitamin B complex. It can be manufactured by plants and animals from the

amino acid tryptophan. The amide derivative, **nicotinamide**, is a component of the coenzymes \*NAD and NADP. These take part in many metabolic reactions as hydrogen acceptors. Deficiency of nicotinic acid causes the disease \*pellagra in humans. Apart from tryptophan-rich protein, good sources are liver and groundnut and sunflower meals.

**nictitating membrane** A clear membrane forming a third eyelid in amphibians, reptiles, birds, and some mammals (but not humans). It can be drawn across the cornea independently of the other eyelids, thus clearing the eye surface and giving added protection without interrupting the continuity of vision.

**nidation** See IMPLANTATION.

**nido-structure** See BORANE.

**nielsbohrium** See TRANSACTINIDE ELEMENTS.

**NIFE cell** See NICKEL-IRON ACCUMULATOR.

**ninhydrin** A brown crystalline solid, C<sub>9</sub>H<sub>4</sub>O<sub>3</sub>·H<sub>2</sub>O, which decomposes at 242°C. It is used as a test for amino acids, peptides, and proteins, with which it gives a deep blue colour. For this reason it has been used as a spray reagent for 'developing' paper chromatograms.

**niobium** Symbol Nb. A soft ductile grey-blue metallic transition element; a.n. 41; r.a.m. 92.91; r.d. 8.57; m.p. 2468°C; b.p. 4742°C. It occurs in several minerals, including niobite (Fe(NbO<sub>3</sub>)<sub>2</sub>), and is extracted by several methods including reduction of the complex fluoride K<sub>2</sub>NbF<sub>7</sub> using sodium. It is used in special steels and in welded joints (to increase strength). Niobium-zirconium alloys are used in superconductors. Chemically, the element combines with the halogens and oxidizes in air at 200°C. It forms a number of compounds and complexes with the metal in oxidation states 2, 3, or 5. The element was discovered by Charles Hatchett (c. 1765-1847) in 1801 and first isolated by Christian Blomstrand (1826-97) in 1864. Formerly, it was called **columbium**.

**nipple** See MAMMARY GLANDS.

**Nissl granules (Nissl bodies)** Particles seen within the cell bodies of \*neurons. They are rich in RNA and stain strongly with basic dyes. They are named after F. Nissl (1860–1919), the German neurologist who discovered them.

**nit** A unit of \*luminance equal to one \*candela per square metre.

**nitrate** A salt or ester of nitric acid.

**nitrating mixture** A mixture of concentrated sulphuric and nitric acids, used to introduce a nitro group ( $-\text{NO}_2$ ) into an organic compound. Its action depends on the presence of the nitronium ion,  $\text{NO}_2^+$ . It is mainly used to introduce groups into the molecules of \*aromatic compounds (the nitro group can subsequently be converted into or replaced by others) and to make commercial \*nitro compounds, such as the explosives cellulose trinitrate (nitrocellulose), glyceryl trinitrate (nitroglycerine), trinitrotoluene (TNT), and picric acid (trinitrophenol).

**nitration** A type of chemical reaction in which a nitro group ( $-\text{NO}_2$ ) is added to or substituted in a molecule. Nitration can be carried out by a mixture of concentrated nitric and sulphuric acids. An example is electrophilic substitution of benzene (and benzene compounds), where the electrophile is the nitril ion  $\text{NO}_2^+$ .

**nitre (saltpetre)** Commercial \*potassium nitrate; the name was formerly applied to natural crustlike efflorescences, occurring in some arid regions.

**nitre cake** See SODIUM HYDROGENSULPHATE.

**nitric acid** A colourless corrosive poisonous liquid,  $\text{HNO}_3$ ; r.d. 1.50; m.p.  $-42^\circ\text{C}$ ; b.p.  $83^\circ\text{C}$ . Nitric acid may be prepared in the laboratory by the distillation of a mixture of an alkali-metal nitrate and concentrated sulphuric acid. The industrial production is by the oxidation of ammonia to nitrogen monoxide, the oxidation of this to nitrogen dioxide, and the reaction of nitrogen dioxide with water to form nitric acid and nitrogen monoxide (which is recycled). The first reaction ( $\text{NH}_3$  to  $\text{NO}$ ) is catalysed by platinum or platinum/rhodium in the form of fine wire

gauze. The oxidation of  $\text{NO}$  and the absorption of  $\text{NO}_2$  to form the product are noncatalytic and proceed with high yields but both reactions are second-order and slow. Increases in pressure reduce the selectivity of the reaction and therefore rather large gas absorption towers are required. In practice the absorbing acid is refrigerated to around  $2^\circ\text{C}$  and a commercial 'concentrated nitric acid' at about 67% is produced.

Nitric acid is a strong acid (highly dissociated in aqueous solution) and dilute solutions behave much like other mineral acids. Concentrated nitric acid is a strong oxidizing agent. Most metals dissolve to form nitrates but with the evolution of nitrogen oxides. Concentrated nitric acid also reacts with several nonmetals to give the oxo acid or oxide. Nitric acid is generally stored in dark brown bottles because of the photolytic decomposition to dinitrogen tetroxide. See also NITRATION.

**nitric oxide** See NITROGEN MONOXIDE.

**nitrides** Compounds of nitrogen with a more electropositive element. Boron nitride is a covalent compound having macromolecular crystals. Certain electropositive elements, such as lithium, magnesium, and calcium, react directly with nitrogen to form ionic nitrides containing the  $\text{N}^{3-}$  ion. Transition elements form a range of interstitial nitrides (e.g.  $\text{Mn}_4\text{N}$ ,  $\text{W}_2\text{N}$ ), which can be produced by heating the metal in ammonia.

**nitriding** The process of hardening the surface of steel by producing a layer of iron nitride. One technique is to heat the metal in ammonia gas. Another is to dip the hot metal in a bath of molten sodium cyanide.

**nitrication** A chemical process in which nitrogen (mostly in the form of ammonia) in plant and animal wastes and dead remains is oxidized at first to nitrites and then to nitrates. These reactions are effected mainly by the nitrifying bacteria *Nitrosomonas* and *Nitrobacter* respectively. Unlike ammonia, nitrates are readily taken up by plant roots; nitrification is therefore a crucial part of the \*nitrogen cycle. Nitrogen-containing compounds are often applied to soils deficient in this el-

ement, as fertilizer. Compare DENITRIFICATION.

**nitrile rubber** A copolymer of buta-1,3-diene and propanonitrile. It is a commercially important synthetic rubber because of its resistance to oil and many solvents.

**nitriles (cyanides)** Organic compounds containing the group  $-CN$  bound to an organic group. Nitriles are made by reaction between potassium cyanide and haloalkanes in alcoholic solution, e.g.

An alternative method is dehydration of amides

They can be hydrolysed to amides and carboxylic acids and can be reduced to amines.

**nitrite** A salt or ester of nitrous acid. The salts contain the dioxonitrate (III) ion,  $NO_2^-$ , which has a bond angle of  $115^\circ$ .

**nitrobenzene** A yellow oily liquid,  $C_6H_5NO_2$ ; r.d. 1.2; m.p.  $6^\circ C$ ; b.p.  $211^\circ C$ . It is made by the \*nitration of benzene using a mixture of nitric and sulphuric acids.

**nitrocellulose** See CELLULOSE NITRATE.

**nitro compounds** Organic compounds containing the group  $-NO_2$  (the **nitro group**) bound to a carbon atom. Nitro compounds are made by \*nitration reactions. They can be reduced to aromatic amines (e.g. nitrobenzene can be reduced to phenylamine). See also EXPLOSIVE.

**nitrogen** Symbol N. A colourless gaseous element belonging to \*group 15 (formerly VB) of the periodic table; a.n. 7; r.a.m. 14.0067; d.  $1.2506 \text{ g dm}^{-3}$ ; m.p.  $-209.86^\circ C$ ; b.p.  $-195.8^\circ C$ . It occurs in air (about 78% by volume) and is an essential constituent of proteins and nucleic acids in living organisms (see NITROGEN CYCLE). Nitrogen is obtained for industrial purposes by fractional distillation of liquid air. Pure nitrogen can be obtained in the laboratory by heating a metal azide. There are two natural isotopes: nitrogen-14 and nitrogen-15 (about 3%). The element is used in the \*Haber process for making ammonia and is also used to provide an

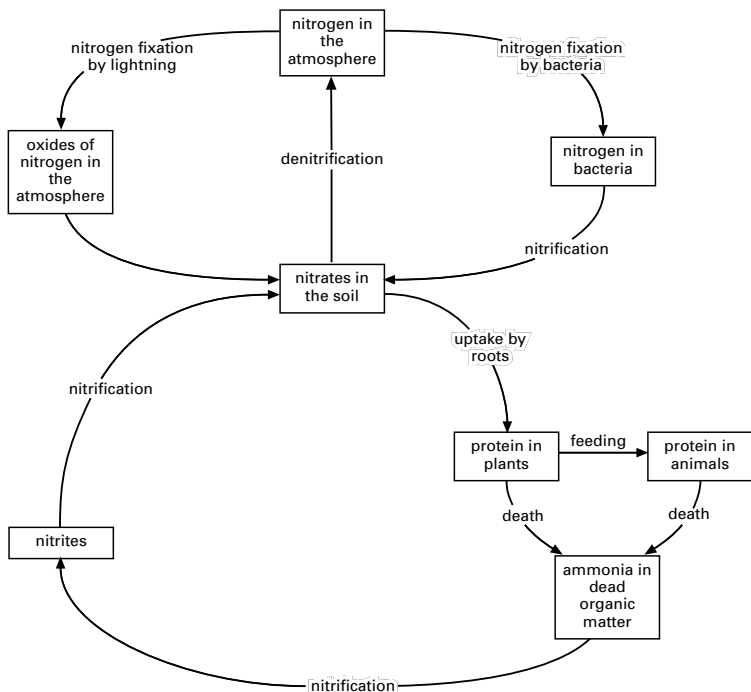

inert atmosphere in welding and metallurgy. The gas is diatomic and relatively inert – it reacts with hydrogen at high temperatures and with oxygen in electric discharges. It also forms \*nitrides with certain metals. Nitrogen was discovered in 1772 by Daniel Rutherford (1749–1819).

**nitrogenase** An important enzyme complex that is present in those microorganisms that are capable of fixing atmospheric nitrogen (see NITROGEN FIXATION). Nitrogenase catalyses the conversion of atmospheric nitrogen into ammonia, which can then be used to synthesize nitrites, nitrates, or amino acids. The two main enzymes within the nitrogenase complex are **dinitrogenase reductase** and **dinitrogenase**.

**nitrogen cycle** One of the major cycles of chemical elements in the environment (see BIOGEOCHEMICAL CYCLE). Nitrates in the soil are taken up by plant roots and may then pass along \*food chains into animals. Decomposing bacteria convert nitrogen-containing compounds (especially ammonia) in plant and animal wastes and dead remains back into nitrates, which are released into the soil and can again be taken up by plants (see NITRIFICATION). Though nitrogen is essential to all forms of life, the huge amount present in the atmosphere is not directly available to most organisms (compare CARBON CYCLE). It can, however, be assimilated by some specialized bacteria (see NITROGEN FIXATION) and is thus made available to other organisms indirectly. Lightning flashes also make some nitrogen available to plants by causing the combination of atmospheric nitrogen and oxygen to form oxides of nitrogen, which enter the soil and form nitrates. Some nitrogen is returned from the soil to the atmosphere by denitrifying bacteria (see DENITRIFICATION). See illustration.

**nitrogen dioxide** See DINITROGEN TETROXIDE.

**nitrogen fixation** A chemical process in which atmospheric nitrogen is assimilated into organic compounds in living organisms and hence into the \*nitrogen cycle. The ability to fix nitrogen is limited to certain bacteria (e.g. *Azotobacter*, *Anabaena*). Some bacteria (e.g. *Rhizobium*) are

The nitrogen cycle

able to fix nitrogen in association with cells in the roots of leguminous plants, such as peas and beans, in which they form characteristic \*root nodules; cultivation of legumes is therefore one way of increasing soil nitrogen. Various chemical processes are used to fix atmospheric nitrogen in the manufacture of \*fertilizers. These include the \*Birkeland-Eyde process, the cyanamide process (see CALCIUM DICARBIDE), and the \*Haber process.

**nitrogen monoxide (nitric oxide)** A colourless gas,  $\text{NO}$ ; m.p.  $-163.6^\circ\text{C}$ ; b.p.  $-151.8^\circ\text{C}$ . It is soluble in water, ethanol, and ether. In the liquid state nitrogen monoxide is blue in colour (r.d. 1.26). It is formed in many reactions involving the reduction of nitric acid, but more convenient reactions for the preparation of reasonably pure  $\text{NO}$  are reactions of sodium nitrite, sulphuric acid, and either sodium

iodide or iron(II) sulphate. Nitrogen monoxide reacts readily with oxygen to give nitrogen dioxide and with the halogens to give the nitrosyl halides  $\text{XNO}$  ( $\text{X} = \text{F}, \text{Cl}, \text{Br}$ ). It is oxidized to nitric acid by strong oxidizing agents and reduced to dinitrogen oxide by reducing agents. The molecule has one unpaired electron, which accounts for its paramagnetism and for the blue colour in the liquid state. This electron is relatively easily removed to give the **nitrosyl ion**  $\text{NO}^+$ , which is the ion present in such compounds as  $\text{NOClO}_4$ ,  $\text{NOBF}_4$ ,  $\text{NOFeCl}_4$ ,  $(\text{NO})_2\text{PtCl}_6$  and a ligand in complexes, such as  $\text{Co}(\text{CO})_3\text{NO}$ .

In mammals and other vertebrates, nitrogen monoxide plays several important roles. For example, it acts as a gaseous mediator in producing such responses as dilation of blood vessels, relaxation of smooth muscle, and inhibition of platelet aggregation. In certain cells of the im-

immune system it is converted to the peroxyxynitrite ion ( $\text{O}-\text{O}-\text{N}=\text{O}$ ), which has activity against tumour cells and pathogens.

**nitrogenous base** A basic compound containing nitrogen. The term is used especially of organic ring compounds, such as adenine, guanine, cytosine, and thymine, which are constituents of nucleic acids. See AMINE SALTS.

**nitrogen oxides** Oxides of nitrogen ( $\text{NO}_x$ ), such as nitrogen monoxide ( $\text{NO}$ ) and dinitrogen oxide ( $\text{N}_2\text{O}$ ), many of which are pollutants contributing to \*acid rain. Nitrogen oxides are expelled in the emissions from car exhausts, aircraft, and factories. See also AIR POLLUTION.

**nitroglycerine** An explosive made by reacting 1,2,3-trihydroxypropane (glycerol) with a mixture of concentrated sulphuric and nitric acids. Despite its name and method of preparation, it is not a nitro compound, but an ester of nitric acid,  $\text{CH}_2(\text{NO}_3)\text{CH}(\text{NO}_3)\text{CH}_2(\text{NO}_3)$ . It is used in dynamites.

**nitro group** See NITRO COMPOUNDS.

**nitronium ion** See NITRYL ION.

**nitrosyl ion** The ion  $\text{NO}^+$ . See NITROGEN MONOXIDE.

**nitrous acid** A weak acid,  $\text{HNO}_2$ , known only in solution and in the gas phase. It is prepared by the action of acids upon nitrites, preferably using a combination that removes the salt as an insoluble precipitate (e.g.  $\text{Ba}(\text{NO}_2)_2$  and  $\text{H}_2\text{SO}_4$ ). The solutions are unstable and decompose on heating to give nitric acid and nitrogen monoxide. Nitrous acid can function both as an oxidizing agent (forms  $\text{NO}$ ) with  $\text{I}^-$  and  $\text{Fe}^{2+}$ , or as a reducing agent (forms  $\text{NO}_3^-$ ) with, for example,  $\text{Cu}^{2+}$ ; the latter is most common. It is widely used (prepared *in situ*) for the preparation of diazonium compounds in organic chemistry. The full systematic name is **dioxonitric(III) acid**.

**nitrous oxide** See DINITROGEN OXIDE.

**nitryl ion (nitronium ion)** The ion  $\text{NO}_2^+$ , found in mixtures of nitric acid and sulphuric acid and solutions of nitrogen oxides in nitric acid. Nitryl salts, such as  $\text{NO}_2^+\text{ClO}_4^-$ , can be isolated but are extremely reactive. Nitryl ions generated *in*

*situ* are used for \*nitration in organic chemistry.

**NMR** See NUCLEAR MAGNETIC RESONANCE.

**nobelium** Symbol No. A radioactive metallic transuranic element belonging to the \*actinoids; a.n. 102; mass number of most stable element 254 (half-life 55 seconds). Seven isotopes are known. The element was first identified with certainty by Albert Ghiorso and Glenn Seaborg (1912–99) in 1966. The alternative name **unnibium** has been proposed.

**noble gases (inert gases; rare gases; group 18 elements)** A group of monatomic gaseous elements forming group 18 (formerly group 0) of the \*periodic table: helium (He), neon (Ne), argon (Ar), krypton (Kr), xenon (Xe), and radon (Rn). The electron configuration of helium is  $1s^2$ . The configurations of the others terminate in  $ns^2np^6$  and all inner shells are fully occupied. The elements thus represent the termination of a period and have closed-shell configuration and associated high ionization energies (He 2370 to Rn 1040  $\text{kJ mol}^{-1}$ ) and lack of chemical reactivity. Being monatomic the noble gases are spherically symmetrical and have very weak interatomic interactions and consequent low enthalpies of vaporization. The behaviour of the lighter members approaches that of an ideal gas at normal temperatures; with the heavier members increasing polarizability and dispersion forces lead to easier liquefaction under pressure. Four types of 'compound' have been described for the noble gases but of these only one can be correctly described as compounds in the normal sense. One type consists of such species as  $\text{HHe}^+$ ,  $\text{He}_2^+$ ,  $\text{Ar}_2^+$ ,  $\text{HeLi}^+$ , which form under highly energetic conditions, such as those in arcs and sparks. They are short-lived and only detected spectroscopically. A second group of materials described as inert-gas-metal compounds do not have defined compositions and are simply noble gases adsorbed onto the surface of dispersed metal. The third type, previously described as 'hydrates' are in fact clathrate compounds with the noble gas molecule trapped in a water lattice. True compounds of the noble gases were first described in 1962 and several fluorides,

oxyfluorides, fluoroplatinates, and fluoroantimonates of \*xenon are known. A few krypton fluorides and a radon fluoride are also known although the short half-life of radon and its intense alpha activity restrict the availability of information. Apart from argon, the noble gases are present in the atmosphere at only trace levels. Helium may be found along with natural gas (up to 7%), arising from the radioactive decay of heavier elements (via alpha particles).

**noble metal** A metal characterized by its lack of chemical reactivity, particularly to acids and atmospheric corrosion. Examples include gold, palladium, platinum, and rhodium.

**no-cloning theorem** A result stating that it is not possible to copy quantum information perfectly. This is the case because the Heisenberg uncertainty principle means that it is not possible to obtain complete information about a quantum state and because examining a quantum state alters that state. This theorem was proved by William Wootters and Wojciech Zurek in 1982.

**nodal points** Two points on the axis of a system of lenses; if the incident ray passes through one, the emergent ray will pass through the other.

**node 1.** (in botany) The part of a plant stem from which one or more leaves arise. The nodes at the stem apex are very close together and remain so in species of monocotyledons that form bulbs. In older regions of the stem they are separated by areas of stem called **internodes**. **2.** (in anatomy) A natural thickening or bulge in an organ or part of the body. Examples are the **sinoatrial node** that controls the heartbeat (see **PACEMAKER**) and the \*lymph nodes. **3.** (in physics) A point of minimum disturbance in a \*stationary-wave system. **4.** (in astronomy) Either of two points at which the orbit of a celestial body intersects a reference plane, usually the plane of the \*ecliptic or the celestial equator (see **CELESTIAL SPHERE**).

**node of Ranvier** See **MYELIN SHEATH**.

**nodule** (in botany) See **ROOT NODULE**.

**no-hair theorem** See **BLACK HOLE**.

**noise 1.** Any undesired sound. It is measured on a \*decibel scale ranging from the threshold of hearing (0 dB) to the threshold of pain (130 dB). Between these limits a whisper registers about 20 dB, heavy urban traffic about 90 dB, and a heavy hammer on steel plate about 110 dB. A high noise level (industrial or from over-amplified music, for example) can cause permanent hearing impairment. **2.** Any unwanted disturbance within a useful frequency band in a communication channel.

**nomad** (in cytology) A cell that migrates or wanders from its site of formation. Certain types of \*phagocytes are nomads.

**nomogram** A graph consisting of three lines, each with its own scale, each line representing the values of a variable over a specified range. A ruler laid between two points on two of the lines enables the value of the third variable to be read off the third line.

**nonhydrate** A crystalline compound that has nine moles of water per mole of compound.

**nonbenzenoid aromatics** Aromatic compounds that have rings other than benzene rings. Examples are the cyclopentadienyl anion,  $C_5H_5^-$ , and the tropylium cation,  $C_7H_7^+$ . See also **ANNULENES**.

**noncompetitive inhibition** See **INHIBITION**.

**noncyclic phosphorylation (noncyclic photophosphorylation)** See **PHOTOPHOSPHORYLATION**.

**non-equilibrium statistical mechanics** The statistical mechanics of systems not in thermal equilibrium. One of the main purposes of non-equilibrium statistical mechanics is to calculate \*transport coefficients and inverse transport coefficients, such as \*conductivity and \*viscosity, from first principles and to provide a basis for \*transport theory. The non-equilibrium systems easiest to understand are those near thermal equilibrium. For systems far from equilibrium, such possibilities as \*chaos, \*turbulence, and \*self-organization can arise due to nonlinearity.

**non-equilibrium thermodynamics**

The thermodynamics of systems not in thermal \*equilibrium. The non-equilibrium systems easiest to understand are those near thermal equilibrium. For systems far from equilibrium, more complicated patterns, such as \*chaos and \*self-organization, can arise due to non-linearity. Which behaviour is observed depends on the value of certain parameters in the system.

**non-Euclidean geometry** A type of geometry that does not comply with the basic postulates of \*Euclidean geometry, particularly a form of geometry that does not accept Euclid's postulate that only one straight line can be drawn through a point in space parallel to a given straight line. Several types of non-Euclidean geometry exist.

**nonferrous metal** Any metal other than iron or any alloy that does not contain iron. In commercial terms this usually means aluminium, copper, lead, nickel, tin, zinc, or their alloys.

**nonlinear optics** A branch of optics concerned with the optical properties of matter subjected to intense electromagnetic fields. For nonlinearity to manifest itself, the external field should not be negligible compared to the internal fields of the atoms and molecules of which the matter consists. \*Lasers are capable of generating external fields sufficiently intense for nonlinearity to occur. Indeed, the subject of nonlinear optics has been largely developed as a result of the invention of the laser. In nonlinear optics the induced \*electric polarization of the medium is not a linear function of the strength of the external \*electromagnetic radiation. This leads to more complicated phenomena than can occur in **linear optics**, in which the induced polarization is proportional to the strength of the external electromagnetic radiation.

**nonmetal** An element that is not a \*metal. Nonmetals can either be \*insulators or \*semiconductors. At low temperatures nonmetals are poor conductors of both electricity and heat as few free electrons move through the material. If the conduction band is near to the valence band (see ENERGY BAND) it is possible for nonmetals to conduct electricity at high

temperatures but, in contrast to metals, the conductivity increases with increasing temperature. Nonmetals are electronegative elements, such as carbon, nitrogen, oxygen, phosphorus, sulphur, and the halogens. They form compounds that contain negative ions or covalent bonds. Their oxides are either neutral or acidic.

**non-Newtonian fluid** See NEWTONIAN FLUID.

**nonpolar compound** A compound that has covalent molecules with no permanent dipole moment. Examples of nonpolar compounds are methane and benzene.

**nonpolar solvent** See SOLVENT.

**nonreducing sugar** A sugar that cannot donate electrons to other molecules and therefore cannot act as a reducing agent. Sucrose is the most common nonreducing sugar. The linkage between the glucose and fructose units in sucrose, which involves aldehyde and ketone groups, is responsible for the inability of sucrose to act as a \*reducing sugar.

**nonrelativistic quantum theory** See QUANTUM THEORY.

**nonrenewable energy sources** See RENEWABLE ENERGY SOURCES.

**nonsense mutation** A mutation in one of the nucleotides in a DNA sequence that generates a \*stop codon, resulting in the premature termination of synthesis of a protein.

**nonstoichiometric compound (Berthollide compound)** A chemical compound in which the elements do not combine in simple ratios. For example, rutile (titanium(IV) oxide) is often deficient in oxygen, typically having a formula  $TiO_{1.8}$ .

**noradrenaline (norepinephrine)** A hormone produced by the \*adrenal glands and also secreted from nerve endings in the \*sympathetic nervous system as a chemical transmitter of nerve impulses (see NEUROTRANSMITTER). Many of its general actions are similar to those of \*adrenaline, but it is more concerned with maintaining normal body activity than with preparing the body for emergencies.

**Nordhausen sulphuric acid** See DISULPHURIC(VI) ACID.

**norepinephrine** See NORADRENALINE.

**normal 1.** (in mathematics) A line drawn at right angles to a surface. **2.** (in chemistry) Having a concentration of one gram equivalent per  $\text{dm}^3$ .

**normal distribution** (Gaussian distribution) In \*statistics, a probability distribution that, when plotted as a graph, has a symmetrical bell shape. The distribution is continuous, with the mean, median, and mode coinciding (see AVERAGE). Some natural frequencies and quantitative measurements (such as errors) have a normal distribution. See also POISSON DISTRIBUTION; T-DISTRIBUTION.

**normalizing** The process of heating steel to above an appropriate critical temperature followed by cooling in still air. The process promotes the formation of a uniform internal structure and the elimination of internal stress.

**Northern blotting** See SOUTHERN BLOTTING.

**nose** The protuberance on the face of some vertebrates that contains the nostrils (see NARES) and part of the \*nasal cavity. It therefore forms part of the olfactory system (see OLFACTION) and the external opening of the respiratory system.

**nostrils** See NARES.

**NOT circuit** See LOGIC CIRCUITS.

**note 1.** A musical sound of specified pitch. **2.** A representation of such a sound in a musical score. Such a representation has a specified duration as well as a specified pitch.

**notochord** An elastic skeletal rod lying lengthwise beneath the nerve cord and above the alimentary canal in the embryos or adults of all chordate animals (see CHORDATA). Its function is to strengthen and support the body and act as a protagonist for the muscles. It is found in both adult and larval lancelets but in adult vertebrates it is largely replaced by the \*vertebral column.

**nova** A star that, over a period of only a few days, becomes  $10^3$ - $10^4$  times brighter

than it was. Some 10-15 such events occur in the Milky Way each year. Novae are believed to be close \*binaries, one component of which is usually a \*white dwarf and the other a \*red giant. Matter is transferred from the red giant to the white dwarf, on whose surface it accumulates, eventually leading to a thermonuclear explosion. See also SUPERNOVA.

**N.T.P.** See S.T.P.

**n-type conductivity** See SEMICONDUCTOR; TRANSISTOR.

**nucellus** The tissue that makes up the greater part of the ovule of seed plants. It contains the \*embryo sac and nutritive tissue. It is enclosed by the integuments except for a small gap, the \*micropyle. In certain flowering plants it may persist after fertilization and provide nutrients for the embryo.

**nuclear battery** A single cell, or battery of cells, in which the energy of particles emitted from the atomic nucleus is converted internally into electrical energy. In the high-voltage type, a beta-emitter, such as strontium-90, krypton-85, or tritium, is sealed into a shielded glass vessel, the electrons being collected on an electrode that is separated from the emitter by a vacuum or by a solid dielectric. A typical cell delivers some 160 picoamperes at a voltage proportional to the load resistance. It can be used to maintain the voltage of a charged capacitor. Of greater use, especially in space technology, are the various types of low-voltage nuclear batteries. Typical is the gas-ionization device in which a beta-emitter ionizes a gas in an electric field. Each beta-particle produces about 200 ions, thus multiplying the current. The electric field is obtained by the contact potential difference between two electrodes, such as lead dioxide and magnesium. Such a cell, containing argon and tritium, gives about 1.6 nanoamperes at 1.5 volts. Other types use light from a phosphor receiving the beta-particles to operate photocells or heat from the nuclear reaction to operate a thermopile.

**nuclear-cytoplasmic ratio** A measure of the size of a cell nucleus in relation to the cytoplasm. The nuclear-cytoplasmic

ratio is often used as an index in the comparison of cells from normal and abnormal tissues. For example, cultured cancer cells show an increase in the nuclear-cytoplasmic ratio.

**nuclear energy** Energy obtained as a result of \*nuclear fission or \*nuclear fusion. The nuclear fission of one uranium atom yields about  $3.2 \times 10^{-11}$  joule, whereas the combustion of one carbon atom yields about  $6.4 \times 10^{-19}$  joule. Mass for mass, uranium yields about 2 500 000 times more energy by fission than carbon does by combustion. The nuclear fusion of deuterium to form helium releases about 400 times as much energy as the fission of uranium (on a mass basis).

**nuclear fission** A nuclear reaction in which a heavy nucleus (such as uranium) splits into two parts (**fission products**), which subsequently emit either two or three neutrons, releasing a quantity of energy equivalent to the difference between the rest mass of the neutrons and the fission products and that of the original nucleus. Fission may occur spontaneously or as a result of irradiation by neutrons. For example, the fission of a uranium-235 nucleus by a \*slow neutron may proceed thus:

The energy released is approximately  $3 \times 10^{-11}$  J per  $^{235}\text{U}$  nucleus. For 1 kg of  $^{235}\text{U}$  this is equivalent to 20 000 megawatt-hours – the amount of energy produced by the combustion of  $3 \times 10^6$  tonnes of coal. Nuclear fission is the process used in \*nuclear reactors and atom bombs (see NUCLEAR WEAPONS).

**nuclear force** A strong attractive force (resulting from the strong interaction) between \*nucleons in the atomic nucleus that holds the nucleus together. At close range (up to about  $2 \times 10^{-15}$  metre) these forces are some 100 times stronger than electromagnetic forces. See FUNDAMENTAL INTERACTIONS.

**nuclear fuel** A substance that will sustain a fission chain reaction so that it can be used as a source of \*nuclear energy. The \*fissile isotopes are uranium-235, uranium-233, plutonium-241, and plutonium-239. The first occurs in nature as 1

part in 140 of natural uranium, the others have to be made artificially.  $^{233}\text{U}$  is produced when thorium-232 captures a neutron and  $^{239}\text{Pu}$  is produced by neutron capture in  $^{238}\text{U}$ .  $^{232}\text{Th}$  and  $^{238}\text{U}$  are called \*fertile isotopes.

**nuclear fusion** A type of \*nuclear reaction in which atomic nuclei of low atomic number fuse to form a heavier nucleus with the release of large amounts of energy. In \*nuclear fission reactions a neutron is used to break up a large nucleus, but in nuclear fusion the two reacting nuclei themselves have to be brought into collision. As both nuclei are positively charged there is a strong repulsive force between them, which can only be overcome if the reacting nuclei have very high kinetic energies. These high kinetic energies imply temperatures of the order of  $10^8$  K. As the kinetic energy required increases with the nuclear charge (i.e. atomic number), reactions involving low atomic-number nuclei are the easiest to produce. At these elevated temperatures, however, fusion reactions are self-sustaining; the reactants at these temperatures are in the form of a \*plasma (i.e. nuclei and free electrons) with the nuclei possessing sufficient energy to overcome electrostatic repulsion forces. The fusion bomb (see NUCLEAR WEAPONS) and the stars generate energy in this way. It is hoped that the method will be harnessed in the \*thermonuclear reactor as a source of energy for man's use.

Typical fusion reactions with the energy release in joules are:

By comparison the formation of a water molecule from atoms of hydrogen and oxygen is accompanied by the release of  $1.5 \times 10^{-19}$  J.

A large amount of work has been done on **cold fusion**; i.e. fusion that can occur at lower temperatures than those necessary to overcome the electrostatic repulsion between nuclei. The most productive approach is **meson-catalysed fusion**, in which the deuterium atoms have their electrons replaced by negative muons to

give 'muonic atoms' of deuterium. The muon is 207 times heavier than the electron, so the muonic deuterium atom is much smaller and is able to approach another deuterium atom more closely, allowing nuclear fusion to occur. The muon is released to form another muonic atom, and the process continues. The limiting factor is the short lifetime of the muon, which restricts the number of fusion reactions it can catalyse. The term 'cold fusion' is also applied to the technique of producing new  $\alpha$ -transactinide elements by bombarding nuclei of one element with nuclei of another at an energy precisely chosen to allow the fusion reaction to occur.

**nuclear isomerism** A condition in which atomic nuclei with the same number of neutrons and protons have different lifetimes. This occurs when nuclei exist in different unstable quantum states, from which they decay to lower excited states or to the ground state, with the emission of gamma-ray photons. If the lifetime of a particular excited state is unusually long it is said to be isomeric, although there is no fixed limit separating isomeric decays from normal decays.

**nuclear magnetic resonance (NMR)** The absorption of electromagnetic radiation at a suitable precise frequency by a nucleus with a nonzero magnetic moment in an external magnetic field. The phenomenon occurs if the nucleus has nonzero  $\alpha$ -spin, in which case it behaves as a small magnet. In an external magnetic field, the nucleus's magnetic moment vector precesses about the field direction but only certain orientations are allowed by quantum rules. Thus, for hydrogen (spin of  $\frac{1}{2}$ ) there are two possible states in the presence of a field, each with a slightly different energy. Nuclear magnetic resonance is the absorption of radiation at a photon energy equal to the difference between these levels, causing a transition from a lower to a higher energy state. For practical purposes, the difference in energy levels is small and the radiation is in the radiofrequency region of the electromagnetic spectrum. It depends on the field strength.

NMR can be used for the accurate determination of nuclear moments. It can also

be used in a sensitive form of magnetometer to measure magnetic fields. In medicine, **magnetic resonance imaging (MRI)** has been developed, in which images of tissue are produced by magnetic-resonance techniques. See Feature.

The main application of NMR is as a technique for chemical analysis and structure determination, known as **NMR spectroscopy**. It depends on the fact that the electrons in a molecule shield the nucleus to some extent from the field, causing different atoms to absorb at slightly different frequencies (or at slightly different fields for a fixed frequency). Such effects are known as **chemical shifts**. There are two methods of NMR spectroscopy. In **continuous wave (CW) NMR**, the sample is subjected to a strong field, which can be varied in a controlled way over a small region. It is irradiated with radiation at a fixed frequency, and a detector monitors the field at the sample. As the field changes, absorption corresponding to transitions occurs at certain values, and this causes oscillations in the field, which induce a signal in the detector. **Fourier transform (FT) NMR** uses a fixed magnetic field and the sample is subjected to a high-intensity pulse of radiation covering a range of frequencies. The signal produced is analysed mathematically to give the NMR spectrum. The most common nucleus studied is  $^1\text{H}$ . For instance, an NMR spectrum of ethanol ( $\text{CH}_3\text{CH}_2\text{OH}$ ) has three peaks in the ratio 3:2:1, corresponding to the three different hydrogen-atom environments. The peaks also have a fine structure caused by interaction between spins in the molecule. Other nuclei can also be used for NMR spectroscopy (e.g.  $^{13}\text{C}$ ,  $^{14}\text{N}$ ,  $^{19}\text{F}$ ) although these generally have lower magnetic moment and natural abundance than hydrogen. See also ELECTRON-SPIN RESONANCE.

**nuclear moment** A property of atomic nuclei in which lack of spherical symmetry of the nuclear charge gives rise to electric moments and the intrinsic spin and rotational motion of the component nucleons give rise to magnetic moments.

**nuclear physics** The physics of atomic nuclei and their interactions, with particular reference to the generation of  $\alpha$ -nuclear energy.

## MAGNETIC RESONANCE IMAGING

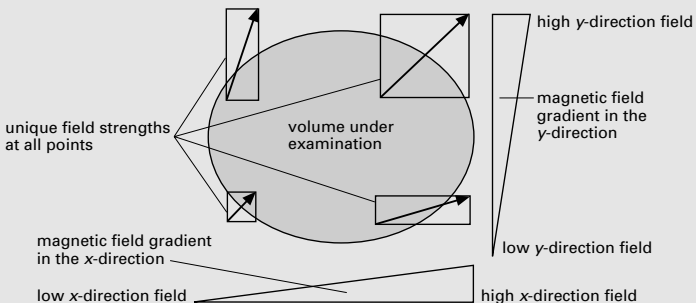

A diagnostic imaging technique based on the phenomenon of \*nuclear magnetic resonance (NMR). NMR is a process in which \*protons interact with a strong magnetic field and with radio waves to generate electrical pulses that can be processed in a similar way to computerized \*tomography. The medical application of NMR, began in the 1950s, but the first images of live patients were not produced until the late 1970s. Images produced by MRI are similar to those produced by computerized tomography using X-rays, but without the radiation hazard.

A major factor in the high costs of MRI is the need for a \*superconducting magnet to produce the very strong magnetic fields (0.1 – 2 tesla). A niobium-titanium alloy, which becomes superconducting at  $-269^{\circ}\text{C}$ , is used to construct the field coils. These need to be immersed in liquid helium. Superimposed on this large magnetic field are smaller fields, with known gradients in two directions. These gradient fields produce a unique value of the magnetic field strength at each point within the instrument (see illustration).

Some nuclei in the atoms of a patient's tissues have a \*spin, which makes them behave as tiny nuclear magnets. The purpose of the large magnetic field is to align these nuclear magnets. Having achieved this alignment, the area under examination is subjected to pulses of radiofrequency (RF) radiation. At a resonant frequency of RF pulses the nuclei under examination undergo \*Larmor precession. This phenomenon may be thought of as a 'tipping' of the nuclear magnets away from the strong field alignment. The nuclear magnets then precess or 'wobble', about the axis of the main field as the nuclei regain their alignment with that field.

The speed at which the nuclei return to the steady stage gives rise to two parameters, known as **relaxation times**. Because these relaxation times for nuclei depend on their atomic environment, they may be used to identify nuclei. Small changes in the magnetic field produced as the nuclei precess induce currents in a receiving coil. These signals are digitized before being stored in the memory of a computer.

The resulting set of RF pulse sizes and sequences identify a variety of resonance situations. By analysing these sequences and knowing the unique value of magnetic field strength within the volume under investigation, the resonance signals may be decoded to give estimates of the compositions of the patient's tissues. A three dimensional map of the composition can then be produced, using colour to indicate contrast between differing tissue compositions.

**MRI.** The way unique field strengths are produced at different points in a specimen

**nuclear power** Electric power or motive power generated by a \*nuclear reactor.

**nuclear reaction** Any reaction in which there is a change to an atomic nucleus. This may be a natural spontaneous disintegration or an artificial bombardment of a nucleus with an energetic particle, as in a \*nuclear reactor. Nuclear reactions are commonly represented by enclosing within a bracket the symbols for the incoming and outgoing particles; the initial nuclide is shown before the bracket and the final nuclide after it. For example, the reaction:

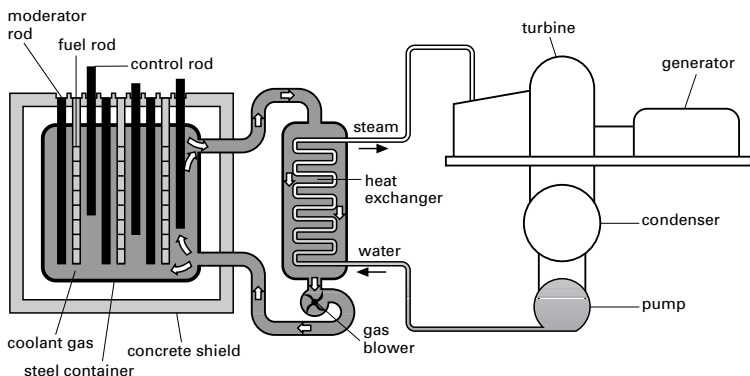

is shown as  $^{12}\text{C}(d,n)^{13}\text{N}$ , where *d* is the symbol for a deuteron.

**nuclear reactor** A device in which a \*nuclear fission \*chain reaction is sustained and controlled in order to produce \*nuclear energy, radioisotopes, or new nuclides. The fuels available for use in a fission reactor are uranium-235, uranium-233, and plutonium-239; only the first occurs in nature (as 1 part in 140 of natural uranium), the others have to be produced artificially (see NUCLEAR FUEL). When a uranium-235 nucleus is made to undergo fission by the impact of a neutron it breaks into two roughly equal fragments, which release either two or three very high-energy neutrons. These \*fast neutrons need to be slowed down to in-

crease the probability that they will cause further fissions of  $^{235}\text{U}$  nuclei and thus sustain the chain reaction. This slowing down process occurs naturally to a certain extent when the neutrons collide with other nuclei; unfortunately, however, the predominant uranium isotope,  $^{238}\text{U}$ , absorbs fast neutrons to such an extent that in natural uranium the fission reaction is not self-sustaining. In order to create a controlled self-sustaining chain reaction it is necessary either to slow down the neutrons (using a \*moderator in a **thermal reactor**) to greatly reduce the number absorbed by  $^{238}\text{U}$ , or to reduce the predominance of  $^{238}\text{U}$  in natural uranium by enriching it with more  $^{235}\text{U}$  than it normally contains. In a **fast reactor** the fuel used is enriched uranium and no moderator is employed.

In thermal reactors, neutrons are slowed down by collisions with light moderator atoms (such as graphite, deuterium, or beryllium); they are then in thermal equilibrium with the surrounding material and are known as **thermal neutrons**. In a **heterogeneous thermal reactor** the fuel and moderator are in separate solid and liquid phases (e.g. solid uranium fuel and a heavy water moderator). In the **homogeneous thermal reactor** the fuel and moderator are mixed together, for example in a solution, molten dispersion, slurry, or suspension.

In the reactor **core** the **fuel elements** encase the fuel; in a heterogeneous reactor

A schematic diagram of a gas-cooled reactor

the fuel elements may fit into a lattice that also contains the moderator. The progress of the reaction is controlled by  $\ast$ control rods, which when lowered into the core absorb neutrons and so slow down or stop the chain reaction. The heat produced by the nuclear reaction in the core is used to generate electricity by the same means as in a conventional power station, i.e. by raising steam to drive a steam turbine that turns a generator. The heat is transferred to the steam-raising boiler or heat-exchanger by the  $\ast$ coolant. Water is frequently used as the coolant; in the case of the **boiling-water reactor (BWR)** and the **pressurized-water reactor (PWR)** water is both coolant and moderator. In the BWR the primary coolant drives the turbine; in the PWR the primary coolant raises steam in a secondary circuit for driving the turbine. In the **gas-cooled reactor** the coolant is a gas, usually carbon dioxide with an outlet temperature of about 350°C, or 600°C in the case of the **advanced gas-cooled reactor (AGR)**.

In fast reactors, in which there is no moderator, the temperature is higher and a liquid-metal coolant is used, usually liquid sodium. Some fast reactors are used as converters or breeders. A **converter reactor** is one that converts  $\ast$ fertile material (such as  $^{238}\text{U}$ ) into  $\ast$ fissile material (such as  $^{239}\text{Pu}$ ). A **breeder reactor** produces the same fissile material as it uses. For example, a **fast breeder reactor** using uranium enriched with  $^{239}\text{Pu}$  as the fuel can produce more  $^{239}\text{Pu}$  than it uses by converting  $^{238}\text{U}$  to  $^{239}\text{Pu}$ . See also THERMONUCLEAR REACTOR.

**nuclear transfer** A technique used in cloning animals in which a nucleus from a donor cell (adult or embryo) is injected into an unfertilized egg cell from which the chromosomes have been removed by micropipette; this is then stimulated by electrical pulses to begin dividing and develop as an embryo (see CLONE). The technique has been used successfully with various mammal species, most famously producing Dolly the sheep in 1997. Dolly was the first mammal to be cloned from a fully differentiated adult body cell. The donor cells were taken from a culture of sheep udder cells and starved into a state of quiescence in a low-nutrient medium.

This was done to switch off all but essential genes and better mimic a natural fertilization. There are several advantages in using adult body cells: cultures are easier to obtain and maintain, and there is greater scope for genetically engineering such cells and screening them to select successfully modified cells. Nuclear transfer is now used increasingly to replicate elite animals in the livestock industry, to produce genetically engineered mammals for commercial use (e.g. goats that secrete human proteins in their milk), and to replicate endangered species. However, the failure rate is generally high, and even the few live clones produced often have congenital defects that shorten their lives. This shows that 'reprogramming' differentiated body cells poses formidable technical obstacles.

**nuclear waste** See RADIOACTIVE WASTE.

**nuclear weapons** Weapons in which an explosion is caused by  $\ast$ nuclear fission,  $\ast$ nuclear fusion, or a combination of both. In the fission bomb (**atomic bomb** or **A-bomb**) two subcritical masses (see CRITICAL MASS) of a  $\ast$ fissile material (uranium-235 or plutonium-239) are brought together by a chemical explosion to produce one supercritical mass. The resulting nuclear explosion is typically in the  $\ast$ kiloton range with temperatures of the order  $10^8$  K being reached. The fusion bomb (**thermonuclear weapon**, **hydrogen bomb**, or **H-bomb**) relies on a nuclear-fusion reaction, which becomes self-sustaining at a critical temperature of about  $35 \times 10^6$  K. Hydrogen bombs consist of either two-phase fission-fusion devices in which an inner fission bomb is surrounded by a hydrogenous material, such as heavy hydrogen (deuterium) or lithium deuteride, or a three-phase fission-fusion-fission device, which is even more powerful. The  $\ast$ megaton explosion produced by such a thermonuclear reaction has not yet been used in war. A special type of fission-fusion bomb is called a **neutron bomb**, in which most of the energy is released as high-energy neutrons. This neutron radiation destroys people but provides less of the shock waves and blast that destroy buildings.

**nuclease** Any enzyme that breaks down

nucleic acids to nucleotides. Nucleases are found in the small intestine. *See also* DNASE; ENDONUCLEASE; EXONUCLEASE.

**nucleic acid** A complex organic compound in living cells that consists of a chain of \*nucleotides. There are two types: \*DNA (deoxyribonucleic acid) and \*RNA (ribonucleic acid).

**nucleoid (nuclear region)** The part of a cell of a bacterium (i.e. a prokaryotic \*cell) that contains the genetic material \*DNA and therefore controls the activity of the cell. It corresponds to the nucleus of the more advanced eukaryotic cells but is not bounded by a membrane.

**nucleolus** A small dense round body within the nondividing \*nucleus of eukaryotic cells that consists of protein, DNA, and ribosomal \*RNA. It plays an important role in \*ribosome manufacture (and therefore protein synthesis).

**nucleon** A \*proton or a \*neutron.

**nucleon emission** A decay mechanism in which a particularly unstable \*nuclide regains some stability by the emission of a nucleon, i.e. a proton or neutron. Proton emitters have fewer neutrons than their stable isotopes. Proton emitters are therefore found below the \*Segrè plot stability line. For example,  $^{17}\text{Ne}$  has three fewer neutrons than its most abundant stable isotope,  $^{20}\text{Ne}$ . There are no naturally occurring proton emitters. Neutron emitters have many more neutrons than their stable isotopes. For this reason, neutron emitters are found above the stability line on the Segrè plot and in most cases can also decay by negative \*beta decay. There are no naturally occurring neutron emitters. They are usually produced in nuclear reactors by the negative beta decay of fission products. An example is  $^{99}\text{Y}$ , which has 10 more neutrons than the stable isotope  $^{89}\text{Y}$ .

**nucleonics** The technological aspects of \*nuclear physics, including the design of nuclear reactors, devices to produce and detect radiation, and nuclear transport systems. It is also concerned with the technology of \*radioactive waste disposal and with radioisotopes.

**nucleon number (mass number)** Sym-

bol A. The number of \*nucleons in an atomic nucleus of a particular nuclide.

**nucleophile** An ion or molecule that can donate electrons. Nucleophiles are often oxidizing agents and Lewis bases. They are either negative ions (e.g.  $\text{Cl}^-$ ) or molecules that have electron pairs (e.g.  $\text{NH}_3$ ). In organic reactions they tend to attack positively charged parts of a molecule. *Compare* ELECTROPHILE.

**nucleophilic addition** A type of addition reaction in which the first step is attachment of a \*nucleophile to a positive (electron-deficient) part of the molecule. \*Aldehydes and \*ketones undergo reactions of this type because of polarization of the carbonyl group (carbon positive).

**nucleophilic substitution** A type of substitution reaction in which a \*nucleophile displaces another group or atom from a compound. For example, in

the nucleophile is the  $\text{OH}^-$  ion. There are two possible mechanisms of nucleophilic substitution. In **S<sub>N</sub>1 reactions**, a positive carbonium ion is first formed:

This then reacts with the nucleophile

The  $\text{CR}_3^+$  ion is planar and the  $\text{OH}^-$  ion can attack from either side. Consequently, if the original molecule is optically active (the three R groups are different) then a racemic mixture of products results.

The alternative mechanism, the **S<sub>N</sub>2 reaction**, is a concerted reaction in which the nucleophile approaches from the side of the R groups as the other group (Cl in the example) leaves. In this case the configuration of the molecule is inverted. If the original molecule is optically active, the product has the opposite activity, an effect known as **Walden inversion**. The notations S<sub>N</sub>1 and S<sub>N</sub>2 refer to the kinetics of the reactions. In the S<sub>N</sub>1 mechanism, the slow step is the first one, which is unimolecular (and first order in  $\text{CR}_3\text{Cl}$ ). In the S<sub>N</sub>2 reaction, the process is bimolecular (and second order overall).

**nucleoplasm (karyoplasm)** The material contained within the \*nucleus of a cell.

The nucleoplasm is bound by the nuclear envelope, which separates it from the cytoplasm.

**nucleoprotein** Any compound present in cells of organisms that consists of a nucleic acid (DNA or RNA) combined with a protein. Chromosomes consist of DNA and proteins, mostly histones, as do ribosomes (see RIBONUCLEOPROTEIN).

**nucleoside** An organic compound consisting of a nitrogen-containing \*purine or \*pyrimidine base linked to a sugar (ribose or deoxyribose). An example is \*adenosine. Compare NUCLEOTIDE.

**nucleosynthesis** The synthesis of chemical elements by nuclear processes. There are several ways in which nucleosynthesis can take place. **Primordial nucleosynthesis** took place very soon after the \*big bang, when the universe was extremely hot. This process was responsible for the cosmic abundances observed for light elements, such as helium. Explosive nucleosynthesis can also occur during the explosion of a \*supernova. However, **stellar nucleosynthesis**, which takes place in the centre of stars at very high temperatures, is now the principal form of nucleosynthesis. The exact process occurring in stellar nucleosynthesis depends on the temperature, density, and chemical composition of the star. The synthesis of helium from protons and of carbon from helium can both occur in stellar nucleosynthesis. See also CARBON CYCLE; EARLY UNIVERSE; STELLAR EVOLUTION.

**nucleotide** An organic compound consisting of a nitrogen-containing \*purine or \*pyrimidine base linked to a sugar (ribose or deoxyribose) and a phosphate group. \*DNA and \*RNA are made up of long chains of nucleotides (i.e. **polynucleotides**). Compare NUCLEOSIDE.

**nucleus** (of atom) The central core of an atom that contains most of its mass. It is positively charged and consists of one or more nucleons (protons or neutrons). The positive charge of the nucleus is determined by the number of protons it contains (see ATOMIC NUMBER) and in the neutral atom this is balanced by an equal number of electrons, which move around the nucleus. The simplest nucleus is the

hydrogen nucleus, consisting of one proton only. All other nuclei also contain one or more neutrons. The neutrons contribute to the atomic mass (see NUCLEON NUMBER) but not to the nuclear charge. The most massive nucleus that occurs in nature is uranium-238, containing 92 protons and 146 neutrons. The symbol used for this \*nuclide is  $^{238}_{92}\text{U}$ , the upper figure being the nucleon number and the lower figure the atomic number. In all nuclei the nucleon number ( $A$ ) is equal to the sum of the atomic number ( $Z$ ) and the neutron number ( $N$ ), i.e.  $A = Z + N$ .

**nucleus** (of cell) The large body embedded in the cytoplasm of all plant and animal \*cells (but not bacterial cells) that contains the genetic material \*DNA organized into \*chromosomes. The nucleus functions as the control centre of the cell. It is bounded by a double membrane (the **nuclear envelope**), which is perforated by many **nuclear pores** for the selective transfer of water-soluble molecules between the nucleus and cytoplasm. When the cell is not dividing, a \*nucleolus is present in the nucleus and the chromosomal material (\*chromatin) is dispersed throughout the nucleus. In dividing cells the chromosomes become much shorter and thicker and the nucleolus disappears. The contents of the nucleus constitute the **nucleoplasm**. In certain protozoans there are two nuclei per cell, a **macronucleus** (or **meganucleus**) concerned with vegetative functions and a **miconucleus** involved in sexual reproduction.

**nuclide** A type of atom as characterized by its \*atomic number and its \*neutron number. An \*isotope is a member of a series of different atoms that have the same atomic number but different neutron numbers (e.g. uranium-238 and uranium-235 are isotopes of uranium); a nuclide refers only to a particular nuclear species (e.g. the nuclides uranium-235 and plutonium-239 are fissile). The term is also used for a type of nucleus.

**null method** A method of making a measurement in which the quantity to be measured is balanced by another similar reading by adjusting the instrument to read zero (see WHEATSTONE BRIDGE).

**numerical analysis** The analysis of

problems by means of calculations involving numbers rather than analytical formulae. Numerical analysis is used extensively for problems too complicated to be solved analytically (either exactly or approximately). Numerical analysis can be performed using either electronic calculators or computers.

**numerical taxonomy** See TAXONOMY.

**nut** A dry single-seeded fruit that develops from more than one carpel and does not shed its seed when ripe. The fruit wall is woody or leathery. Many nuts are enclosed in a hard or membranous cup-shaped structure, the \*cupule. The term nut is often loosely used of any hard fruit. For example, the walnut is in fact a \*drupe and the Brazil nut is a seed.

**nutatation 1.** (in astronomy) An irregular periodic oscillation of the earth's poles. It causes an irregularity of the precessional circle traced by the celestial poles and results from the varying distances and relative directions of the sun and the moon.

**2.** (in botany) The spiral movement of a plant organ during growth, also known as **circumnutation**. It is seen in climbing plants and helps the plant find a suitable support to twine around. Examples are the coiling movements of the shoot tips of runner beans and of the tendrils of sweet peas.

**nutrient** Any substance that is required for the nourishment of an organism, providing a source of energy or structural components. In animals nutrients form part of the \*diet and include the **major nutrients**, i.e. carbohydrates, proteins (see also ESSENTIAL AMINO ACID), and lipids (see also ESSENTIAL FATTY ACIDS), as well as vitamins and certain minerals (see ESSENTIAL ELEMENT). Plant nutrients, derived from carbon dioxide in the atmosphere and

water (containing minerals) absorbed from the soil by the roots, are \*macronutrients or \*micronutrients.

**nutrition** The process by which organisms obtain energy (in the form of food) for growth, maintenance, and repair. There are two main types of nutrition: \*heterotrophic nutrition, employed by animals, fungi, and certain bacteria; and \*autotrophic nutrition, found in most plants and bacteria.

**nyctinasty (sleep movements)** \*Nastic movements of plant organs in response to the changes in light and temperature that occur between day and night (and vice versa). Examples are the opening and closing of many flowers and the folding together of the leaflets of clover and other plants at night.

**nylon** Any of various synthetic polyamide fibres having a protein-like structure formed by the condensation between an amino group of one molecule and a carboxylic acid group of another. There are three main nylon fibres, nylon 6, nylon 6,6, and nylon 6,10. Nylon 6, for example Enkalon and Celon, is formed by the self-condensation of 6-aminohexanoic acid. Nylon 6,6, for example Bri nylon, is made by polycondensation of hexanedioic acid (adipic acid) and 1,6-diaminohexane (hexamethylenediamine) having an average formula weight between 12 000 and 15 000. Nylon 6,10 is made by polymerizing decanedioic acid and 1,6-diaminohexane.

**nymph** The juvenile stage of certain insects, such as dragonflies, grasshoppers, and earwigs, which resembles the adult except that the wings and reproductive organs are undeveloped. There is no pupal stage, and the nymph develops directly into the adult. *Compare* LARVA.

**OB association** An area in space in which young high-mass O and B type stars predominate. The stars emit strong ultraviolet radiation, which ionizes the surrounding hydrogen and forms emission nebulae. Shock waves compress dust and gas, which may collapse under the force of gravity and begin the formation of more stars.

**objective** The \*lens or system of lenses nearest to the object being examined through an optical instrument.

**occipital condyle** A single or paired bony knob that protrudes from the occipital bone of the skull and articulates with the first cervical vertebra (the \*atlas). In humans there is a pair of occipital condyles, one on each side of the \*foramen magnum. Occipital condyles are absent in most fish, which cannot move their heads.

**occluded front** See FRONT.

**occlusion 1.** The trapping of small pockets of liquid in a crystal during crystallization. **2.** The absorption of a gas by a solid such that atoms or molecules of the gas occupy interstitial positions in the solid lattice. Palladium, for example, can occlude hydrogen.

**occultation** The disappearance of a star, planet, or other celestial body behind the moon or another planet, while it is being observed. A solar \*eclipse is a form of occultation.

**oceanic zone** The region of the open sea beyond the edge of the continental shelf, where the depth is greater than 200 metres. Compare NERITIC ZONE.

**oceanography** The study of the oceans. It includes the origin, structure, and form of the oceans, the nature of the seafloor and its sediments, the characteristics of the ocean waters (e.g. tides, salinity, and currents), and the types of flora and fauna living within the oceans. The

effects of human intervention also form an important aspect of oceanography.

**ocean trench** A deep narrow depression in the ocean floor, often thousands of metres deep (the Mariana Trench in the Pacific Ocean is 10 850 m deep). Trenches usually form near the edge of a continent where the tectonic plate carrying the ocean is being subducted beneath the continental plate (see PLATE TECTONICS). They are often associated with earthquakes and island arcs.

**ocellus** A simple eye occurring in insects and other invertebrates. It typically consists of light-sensitive cells and a single cuticular lens.

**ochre** A yellow or red mineral form of iron(III) oxide,  $\text{Fe}_2\text{O}_3$ , used as a pigment.

**octadecanoate** See STEARATE.

**octadecanoic acid** See STEARIC ACID.

**octadecenoic acid** A straight-chain unsaturated fatty acid with the formula  $\text{C}_{17}\text{H}_{33}\text{COOH}$ . **Cis-octadec-9-enoic acid** (see OLEIC ACID) has the formula  $\text{CH}_3(\text{CH}_2)_7\text{CH}=\text{CH}(\text{CH}_2)_7\text{COOH}$ . The glycerides of this acid are found in many natural fats and oils.

**octahedral** See COMPLEX.

**octahydrate** A crystalline hydrate that has eight moles of water per mole of compound.

**octane** A straight-chain liquid \*alkane,  $\text{C}_8\text{H}_{18}$ ; r.d. 0.7; m.p.  $-56.79^\circ\text{C}$ ; b.p.  $125.66^\circ\text{C}$ . It is present in petroleum. The compound is isomeric with 2,2,4-trimethylpentane,  $(\text{CH}_3)_3\text{CCH}_2\text{CH}(\text{CH}_3)_2$ , **iso-octane**). See OCTANE NUMBER.

**octane number** A number that provides a measure of the ability of a fuel to resist \*knocking when it is burnt in a spark-ignition engine. It is the percentage by volume of iso-octane ( $\text{C}_8\text{H}_{18}$ ; 2,2,4-trimethylpentane) in a blend with normal

heptane (C<sub>7</sub>H<sub>16</sub>) that matches the knocking behaviour of the fuel being tested in a single cylinder four-stroke engine of standard design. *Compare* CETANE NUMBER.

**octanoic acid (caprylic acid)** A colourless liquid straight-chain saturated \*carboxylic acid, CH<sub>3</sub>(CH<sub>2</sub>)<sub>6</sub>COOH; b.p. 239.3°C.

**octavalent** Having a valency of eight.

**octave 1.** The interval between two musical notes that have fundamental frequencies in the ratio 2:1; the word describes the interval in terms of the eight notes of the diatonic scale. **2.** *See* LAW OF OCTAVES.

**octet** A stable group of eight electrons in the outer shell of an atom (as in an atom of a noble gas).

**ocular** *See* EYEPIECE.

**odd-even nucleus** An atomic nucleus containing an odd number of protons and an even number of neutrons.

**odd-odd nucleus** An atomic nucleus containing an odd number of protons and an odd number of neutrons. There are very few stable odd-odd nuclei.

**Odonata** An order of insects containing the dragonflies and damselflies, most of which occur in tropical regions. Adult dragonflies have a pair of prominent \*compound eyes, a compact thorax bearing two pairs of delicate membranous wings, and a long slender abdomen. They are strong fliers and prey on other insects, either in flight or at rest. The eggs are laid near or in water, and the newly hatched nymphs are aquatic and resemble the adults, with rudimentary wings. They breathe through gills and feed on small aquatic animals. The nymph leaves the water for its final moult into the terrestrial adult.

**odontoblast** A cell that is responsible for producing the \*dentine of vertebrate teeth. Odontoblasts are found around the lining of the \*pulp cavity and have processes that extend into the dentine.

**oersted** Symbol Oe. The unit of magnetic field strength in the \*c.g.s. system. A field has a strength of one oersted if it exerts a force of one dyne on a unit mag-

netic pole placed in it. It is equivalent to  $10^3/4\pi$  A m<sup>-1</sup>. The unit was named after Hans Oersted.

**Oersted, Hans Christian** (1777-1851) Danish physicist, who became a professor at Copenhagen in 1806. His best-known discovery came during a lecture in 1820, when he observed the deflection of a compass needle near a wire carrying an electric current. He had discovered electromagnetism.

**oesophagus (gullet)** The section of the \*alimentary canal that lies between the \*pharynx and the stomach. It is a muscular tube whose function is to transfer food to the stomach by means of wavelike contractions (\*peristalsis) along its length.

**oestrogen** One of a group of female sex hormones, produced principally by the ovaries, that promote the onset of \*secondary sexual characteristics (such as breast enlargement and development in women) and control the \*oestrous cycle (\*menstrual cycle in humans). **Oestradiol** is the most important. Oestrogens are secreted at particularly high levels during ovulation, stimulating the uterus to prepare for pregnancy. They are used in \*oral contraceptives (with \*progestogens) and as treatment for various disorders of the female reproductive organs. Small amounts of oestrogens are produced by the adrenal glands and testes.

**oestrous cycle** The cycle of reproductive activity shown by most sexually mature nonpregnant female mammals except most primates (*compare* MENSTRUAL CYCLE). There are four phases:

- (1) **pro-oestrus** - \*Graafian follicles develop in the ovary and secrete oestrogens;
- (2) **oestrus (heat)** - ovulation normally occurs, the female is ready to mate and becomes sexually attractive to the male;
- (3) **metoestrus** - \*corpus luteum develops from ruptured follicle;
- (4) **dioestrus** - \*progesterone secreted by corpus luteum prepares uterus for implantation.

The length of the cycle depends on the species: larger mammals typically have a single annual cycle with a well-defined breeding season (they are described as **monoestrous**). The males have a similar cycle of sexual activity. Other species may

have many cycles per year (i.e. they are **polyoestrous**) and the male may be sexually active all the time.

**oestrus (heat)** See OESTROUS CYCLE.

**offset** See RUNNER.

**offspring (progeny)** New individual organisms that result from the process of sexual or asexual reproduction. See also  $F_1$ ;  $F_2$ .

**ohm** Symbol  $\Omega$ . The derived \*SI unit of electrical resistance, being the resistance between two points on a conductor when a constant potential difference of one volt, applied between these points, produces a current of one ampere in the conductor. The former **international ohm** (sometimes called the 'mercury ohm') was defined in terms of the resistance of a column of mercury. The unit is named after Georg Ohm.

**Ohm, Georg Simon** (1787-1854) German physicist, who taught in Cologne, Berlin, Nuremberg, and finally (1849) Munich. He is best known for formulating \*Ohm's law in 1827. The unit of electrical resistance is named after him.

**ohmmeter** Any direct-reading instrument for measuring the value of a resistance in ohms. The instrument commonly used is a \*multimeter capable of measuring also both currents and voltages. To measure resistance a dry cell and resistor are switched in series with the moving coil \*galvanometer and the unknown resistance is connected across the instrument's terminals. The value of the resistance is then read off an ohms scale. Such instruments are increasingly being replaced by electronic digital multimeters.

**Ohm's law** The ratio of the potential difference between the ends of a conductor to the current flowing through it is constant. This constant is the \*resistance of the conductor, i.e.  $V = IR$ , where  $V$  is the potential difference in volts,  $I$  is the current in amperes, and  $R$  is the resistance in ohms. The law was discovered in 1827 by Georg Ohm. Most materials do not obey this simple linear law; those that do are said to be **ohmic** but remain so only if physical conditions, such as temperature,

remain constant. Metals are the most accurately ohmic conductors.

**oil** Any of various viscous liquids that are generally immiscible with water. Natural plant and animal oils are either volatile mixtures of terpenes and simple esters (e.g. \*essential oils) or are \*glycerides of fatty acids. Mineral oils are mixtures of hydrocarbons (e.g. \*petroleum).

**oil-immersion lens** See IMMERSION OBJECTIVE.

**oil of vitriol** See SULPHURIC ACID.

**oil of wintergreen** Methyl salicylate (methyl 2-hydroxybenzoate,  $C_8H_8O_3$ ), a colourless aromatic liquid ester, b.p.  $223^\circ\text{C}$ . It occurs in the essential oils of some plants, and is manufactured from salicylic acid. It is easily absorbed through the skin and used in medicine for treating muscular and sciatic pain. Because of its attractive smell it is also used in perfumes and food flavourings.

**oil sand (tar sand; bituminous sand)** A sandstone or porous carbonate rock that is impregnated with hydrocarbons. The largest deposit of oil sand occurs in Alberta, Canada (the Athabasca tar sands); there are also deposits in the Orinoco Basin of Venezuela, Russia, USA, Madagascar, Albania, Trinidad, and Romania.

**oil shale** A fine-grained carbonaceous sedimentary rock from which oil can be extracted. The rock contains organic matter - **kerogen** - which decomposes to yield oil when heated. Deposits of oil shale occur on every continent, the largest known reserves occurring in Colorado, Utah, and Wyoming in the USA. Commercial production of oil from oil shale is generally considered to be uneconomic unless the price of petroleum rises above the recovery costs for oil from oil shale. However, threats of declining conventional oil resources have resulted in considerable interest and developments in recovery techniques.

**Oklo reactors** Naturally occurring nuclear fission reactors that are believed to have existed in uranium deposits at Oklo in Gabon, West Africa, about 2000 million years ago. In 1972, French scientists noticed a slight difference in the normal

$^{235}\text{U}/^{238}\text{U}$  ratio in uranium ore from Oklo. Further detailed investigations showed that there had been 15 natural reactors in the ore deposits at Oklo, operating intermittently for about 1 million years. It is thought that the geology of the mine was an important factor in the creation of these reactors, in particular, the seepage of water through overlying rock, which functioned as a moderator. A similar natural reactor has been found at Bangombe, some miles south of Oklo, but no other comparable reactors have been found anywhere in the world. The Oklo reactors are of considerable interest. They involve basic nuclear processes occurring occurring 2000 million years ago and might give insights into the time dependence of \*fundamental constants. More practically, Oklo can be regarded as a 2000-million-year experiment in the containment of nuclear waste. The reactors shut down naturally when the proportion of  $^{235}\text{U}$  decreased, and - for the same reason - natural reactors of this type could not occur today. The products of the reactor have, however, been localized because of the geology of the region, in particular, beds of granite underlying the ore deposits.

**Olbers' paradox** If the universe is infinite, uniform, and unchanging the sky at night would be bright, as in whatever direction one looked one would eventually see a star. The number of stars would increase in proportion to the square of the distance from the earth; the intensity of light reaching the earth from a given star is inversely proportional to the square of the distance. Consequently, the whole sky should be about as bright as the sun. The paradox, that this is not the case, was stated by Heinrich Olbers (1758-1840) in 1826. (It had been discussed earlier, in 1744, by J. P. L. Chesaux.) The paradox is resolved by the fact that, according to the \*big-bang theory, the universe is not infinite, not uniform, and not unchanging. For instance, light from the most distant galaxies displays an extreme \*redshift and ceases to be visible.

**oleate** A salt or ester of \*oleic acid.

**olefines** See ALKENES.

**oleic acid** An unsaturated \*fatty acid

with one double bond,  $\text{CH}_3(\text{CH}_2)_7\text{CH}=\text{CH}(\text{CH}_2)_7\text{COOH}$ ; r.d. 0.9; m.p.  $13^\circ\text{C}$ . Oleic acid is one of the most abundant constituent fatty acids of animal and plant fats, occurring in butterfat, lard, tallow, groundnut oil, soya-bean oil, etc. Its systematic chemical name is **cis-octadec-9-enoic acid**.

**oleum** See DISULPHURIC(VI) ACID.

**olfaction** The sense of smell or the process of detecting smells. This is achieved by receptors in **olfactory organs** (such as the \*nose) that are sensitive to air- or water-borne chemicals. Stimulation of these receptors results in the transmission of information to the brain via the **olfactory nerve**.

**Oligocene** The third geological epoch of the \*Tertiary period. It began about 38 million years ago, following the Eocene epoch, and extended for about 13.5 million years to the beginning of the Miocene epoch. The epoch was characterized by the continued rise of mammals; the first pigs, rhinoceroses, and tapirs made their appearance.

**Oligochaeta** A class of hermaphrodite annelid worms that bear only a few bristles (\*chaetae). Oligochaetes are very abundant in freshwater and terrestrial habitats. The most familiar members of the class are the earthworm (*Lumbricus*) and the freshwater bloodworm (*Tubifex*).

**oligopeptide** See PEPTIDE.

**oligosaccharide** A carbohydrate (a type of \*sugar) whose molecules contain a chain of up to 20 united monosaccharides. Oligosaccharides are formed as intermediates during the digestion of \*polysaccharides, such as cellulose and starch.

**oligotrophic** Describing a body of water (e.g. a lake) with a poor supply of nutrients and a low rate of formation of organic matter by photosynthesis. Compare DYSTROPHIC; EUTROPHIC.

**olivine** An important group of rock-forming silicate minerals crystallizing in the orthorhombic system. Olivine conforms to the general formula  $(\text{Mg},\text{Fe})_2\text{SiO}_4$  and comprises a complete series from pure magnesium silicate (forsterite,  $\text{Mg}_2\text{SiO}_4$ ) to pure iron silicate (fayalite,

$\text{Fe}_2\text{SiO}_4$ ). It is green, brown-green, or yellow-green in colour.

**omasum** The third of four chambers that form the stomach of ruminants. See RUMINANTIA.

**omega-minus particle** A spin 3/2 \*baryon made up three strange quarks (see STRANGENESS). The existence of the omega-minus particle, as well as its properties, were predicted by Murray Gell-Mann in 1962 as part of a scheme to classify baryons, called the **eightfold way**. The omega-minus particle was subsequently discovered experimentally, thus demonstrating the validity of the eightfold way. This discovery was historically very important in the theoretical understanding of the \*strong interactions. The mass of the omega mass particle is 1672.5 MeV and its average lifetime is  $0.8 \times 10^{-10}$  s. The omega minus particle has an electric charge of -1 (its \*antiparticle has a charge of +1). See ELEMENTARY PARTICLES.

**ommatidium** See COMPOUND EYE.

**omnivore** An animal that eats both animal and vegetable matter. Pigs, for example, are omnivorous. Compare CARNIVORE; HERBIVORE.

**oncogene** A dominant mutant allele of a cellular gene (a **proto-oncogene**) that disrupts cell growth and division and is capable of transforming a normal cell into a cancerous cell. Mutations in proto-oncogenes tend to relax mechanisms that control the cell cycle and accelerate cell division, leading to the cell proliferation that is characteristic of cancer. Some oncogenic mutations cause inhibition of programmed cell death (\*apoptosis), so that cancerous cells are less likely to be destroyed by the body's defences. Certain oncogenes of vertebrates are derived from viruses (see ONCOGENIC).

**oncogenic** Describing a chemical, organism, or environmental factor that causes the development of cancer. Some viruses are oncogenic to vertebrates, notably the \*retroviruses (including the Rous sarcoma virus of chickens), and some are suspected of being oncogenic (e.g. some of the \*adenoviruses and \*papovaviruses). Many of these viruses contain genes (known as \*oncogenes) that

are responsible for the transformation of a normal host cell into a cancerous cell. See also GROWTH FACTOR.

**one gene-one polypeptide hypothesis** The theory that each \*gene is responsible for the synthesis of a single \*polypeptide. It was originally stated as the **one gene-one enzyme hypothesis** by the US geneticist George Beadle (1903-89) in 1945 but later modified when it was realized that genes also encoded nonenzyme proteins and individual polypeptide chains. It is now known that some genes code for various types of RNA involved in protein synthesis.

**one-pot synthesis** A method of synthesizing organic compounds in which the materials used are mixed together in a single vessel and allowed to react, rather than conducting the reaction in a sequence of separate stages.

**onium ion** An ion formed by adding a proton to a neutral molecule, e.g. the hydroxonium ion ( $\text{H}_3\text{O}^+$ ) or the ammonium ion ( $\text{NH}_4^+$ ).

**ontogeny** The developmental course of an organism from the fertilized egg through to maturity. It has been suggested that "ontogeny recapitulates \*phylogeny", i.e. the stages of development, especially of the embryo, reflect the evolutionary history of the organism. This idea is now discredited.

**oocyte** See OOGENESIS.

**oogamy** Sexual reproduction involving the formation and subsequent fusion of a large, usually stationary, female gamete and a small motile male gamete. The female gamete may contain nourishment for the development of the embryo, which is often retained and protected by the parent organism.

**oogenesis** The production and growth of the ova (egg cells) in the animal ovary. Special cells (**oogonia**) within the ovary divide repeatedly by mitosis to produce large numbers of prospective egg cells (**oocytes**). When mature, these undergo meiosis, which halves the number of chromosomes. During the first meiotic division a **polar body** and a secondary oocyte are produced. At the second mei-

otic division the secondary oocyte produces an ovum and a second polar body. Oocytes may be present in the ovaries at birth and may represent the total number of eggs to be produced.

**ogonium 1.** The female sex organ (\*gametangium) of algae and fungi.

**2.** Any of the immature sex cells in the animal ovary that give rise to oocytes by mitotic divisions (see OOGENESIS).

**Oort cloud** A spherical region on the edge of the solar system thought to be the source of most long-period \*comets. It is estimated to contain up to  $10^{12}$  comets and to extend from 4500 billion to 15 000 billion kilometres from the sun. Disturbances caused by a passing star push the comets into solar orbits. It is named after Jan Oort (1899–1971).

**oosphere (ovum; egg cell)** The non-motile female gamete in plants and some algae. In angiosperms (flowering plants) it is a cell in the \*embryo sac of the ovule. In other plants it is situated in an \*archegonium. In algae, such as *Fucus*, the oosphere is protected by an **oogonium** until it is shed into the water prior to fertilization. Many oospheres store food in the form of starch or oil droplets.

**oospore** A zygote that is produced as a result of \*oogamy in certain algae and fungi. It contains food reserves, develops a protective outer covering, and enters a resting phase before germination. Compare ZYGOSPORE.

**opacity** The extent to which a medium is opaque to electromagnetic radiation, especially to light. It is the reciprocal of the \*transmittance. A medium that is opaque to X-rays and gamma rays is said to be **radiopaque**.

**opal** A hydrous amorphous form of silica. Many varieties of opal occur, some being prized as gemstones. Common opal is usually milk white but the presence of impurities may colour it yellow, green, or red. Precious opals, which are used as gemstones, display the property of **opalescence** – a characteristic internal play of colours resulting from the interference of light rays within the stone. Black opal has a black background against which the colours are displayed. The chief sources of

precious opals are Australia and Mexico. Geyselite is a variety deposited by geysers or hot springs. Another variety, diatomite, is made up of the skeletons of diatoms.

**open chain** See CHAIN.

**open cluster (galactic cluster)** See STAR CLUSTER.

**open-hearth process** A traditional but now obsolete method for manufacturing steel by heating together scrap, pig iron, etc., in a refractory-lined shallow open furnace heated by burning producer gas in air. It has been replaced by the \*basic-oxygen process.

**open reading frame** See READING FRAME.

**opera glasses** See BINOCULARS.

**operator** A mathematical symbol indicating that a specified operation should be carried out. For example, the operator  $\sqrt{\quad}$  in  $\sqrt{x}$  indicates that the square root of  $x$  should be taken; the operator  $d/dx$  in  $dy/dx$  indicates that  $y$  should be differentiated with respect to  $x$ , etc.

**operculum 1.** (in zoology) A lid or flap of skin covering an aperture, such as the gill slit cover of fish and larval amphibians and the horny calcareous operculum secreted by many gastropod molluscs, which closes the opening of the shell when the animal is inside. **2.** (in botany) The cone-shaped lid of the \*capsule of mosses, which is forcibly detached to release the spores.

**operon** A functionally integrated genetic unit for the control of gene expression in bacteria, as proposed in the \*Jacob–Monod hypothesis. Typically it comprises a closely linked group of **structural genes**, coding for protein, and adjacent loci controlling their expression – an **operator site** and a **promoter site**. The structural genes tend to encode enzymes concerned with a particular biochemical pathway. \*Transcription of the structural genes is prevented by binding of a **repressor** molecule to the operator site. Another molecule, the **inducer**, can bind to the repressor molecule, preventing it from binding to the operator and thus allowing the promoter site to bind the enzyme RNA polymerase, thereby initiating transcrip-

tion. The repressor molecule is encoded by a **regulator gene**, which may be close to or distant from the operon. Some operons also have an **attenuator region** preceding the first structural gene, where transcription may either stall or proceed according to the amount of end-product in the cell. See also LAC OPERON.

**opiate** One of a group of drugs derived from **opium**, an extract of the poppy plant *Papaver somniferum* that depresses brain function (a **narcotic** action). Opiates include \*morphine and its synthetic derivatives, such as \*heroin and codeine. They are used in medicine chiefly to relieve pain, but the use of morphine and heroin is strictly controlled since they can cause drug dependence and tolerance.

**Oppenheimer-Volkoff limit** The maximum mass a neutron star can have before it undergoes gravitational collapse to a \*black hole. It is more difficult to estimate this limit than the analogous \*Chandrasekhar limit for white dwarf stars. It is thought that the Oppenheimer-Volkoff limit is between two and three times the mass of the sun. It was first calculated by Robert Oppenheimer and George Volkoff in 1939.

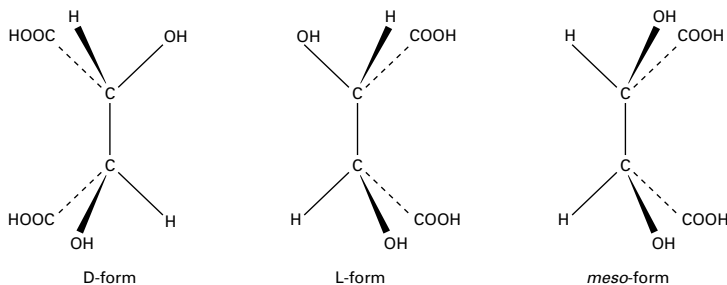

**opposition** The moment at which a planet having its orbit outside that of the earth is in a line with the earth and the sun. When a planet is in opposition it can be observed during the night and is near to its closest point to the earth; it is therefore a favourable opportunity for observation.

**opsin** The lipoprotein component of

\*rhodopsin, the light-sensitive pigment that occurs in the rod cells of the retina.

**optical activity** The ability of certain substances to rotate the plane of plane-polarized light as it passes through a crystal, liquid, or solution. It occurs when the molecules of the substance are asymmetric, so that they can exist in two different structural forms each being a mirror image of the other (see CHIRALITY ELEMENT). The two forms are **optical isomers** or **enantiomers**. The existence of such forms is also known as **enantiomorphism** (the mirror images being **enantiomorphs**). One form will rotate the light in one direction and the other will rotate it by an equal amount in the other. The two possible forms are described as \*dextrorotatory or \*laevorotatory according to the direction of rotation. An equimolar mixture of the two forms is not optically active. It is called a **racemic mixture** (or **racemate**). Prefixes are used to designate the isomer: (+) (dextrorotatory), (-) (laevorotatory), and (±) (racemic mixture) are now preferred to, and increasingly used for, the former *d*-, *l*-, and *dl*-, respectively. In addition, certain molecules can have a **meso-isomer** in which one part of the molecule is a mirror image of the other. Such molecules are not optically active.

Molecules that show optical activity have no plane of symmetry. The commonest case of this is in organic compounds in which a carbon atom is linked to four different groups. An atom of this type is said to be a **chiral centre**. Asymmetric molecules showing optical activity can also

**Optical activity.** Isomers of tartaric acid.

occur in inorganic compounds. For example, an octahedral complex in which the central ion coordinates to six different ligands would be optically active. Many naturally occurring compounds show optical isomerism and usually only one isomer occurs naturally. For instance, glucose is found in the dextrorotatory form. The other isomer, (-)- or *l*-glucose, can be synthesized in the laboratory, but cannot be synthesized by living organisms. *See also* ABSOLUTE CONFIGURATION.

**optical axis (principal axis; optic axis)**

The line passing through the \*optical centre and the centre of a curvature of a \*lens or spherical \*mirror.

**optical brightener** *See* BRIGHTENERS.

**optical centre** The point at the geometrical centre of a \*lens through which a ray of light entering the lens passes without deviation.

**optical fibre** A \*wave guide through which light can be transmitted with very little leakage through the sidewalls. In the **step-index fibre** a pure glass core, with a diameter between 6 and 250 micrometres, is surrounded by a coaxial glass or plastic cladding of lower refractive index. The cladding is usually between 10 and 150 micrometres thick. The interface between core and cladding acts as a cylindrical mirror at which \*total internal reflection of the transmitted light takes place. This structure enables a beam of light to travel through many kilometres of fibre. In the **graded-index fibre**, each layer of glass, from the fibre axis to its outer wall, has a slightly lower refractive index than the layer inside it. This arrangement also prevents light from escaping through the fibre walls by a combination of refraction and total internal reflection, and can be made to give the same transit time for rays at different angles.

**Fibre-optic systems** use optical fibres to transmit information, in the form of coded pulses or fragmented images (using bundles of fibres), from a source to a receiver. They are also used in medical instruments (**fibrescopes**) to examine internal body cavities, such as the stomach and bladder.

**optical flat** A flat glass disc having very

accurately polished surfaces so that the deviation from perfect flatness does not exceed (usually) 50 nanometres. It is used to test the flatness of such plane surfaces as gauge anvils by means of the \*interference patterns formed when parallel beams of light pass through the flat and are reflected by the surface being inspected.

Surfaces are said to be **optically flat** if the deviation from perfect flatness is smaller than the wavelength of light.

**optical glass** Glass used in the manufacture of lenses, prisms, and other optical parts. It must be homogeneous and free from bubbles and strain. **Optical crown glass** may contain potassium or barium in place of the sodium of ordinary crown glass and has a refractive index in the range 1.51 to 1.54. **Flint glass** contains lead oxide and has a refractive index between 1.58 and 1.72. Higher refractive indexes are obtained by adding lanthanoid oxides to glasses; these are now known as lanthanum crowns and flints.

**optical isomers** *See* OPTICAL ACTIVITY.

**optical lever** An experimental device used to measure angular rotation (e.g. in a \*galvanometer or \*torsion balance). Typically, a small mirror is attached to the rotating object, and a beam of light is directed onto the mirror and reflected onto a scale. The angle turned through by the beam is twice the angle turned through by the mirror.

**optical microscope** *See* MICROSCOPE.

**optical molasses** *See* LASER COOLING.

**optical pumping** *See* LASER.

**optical pyrometer** *See* PYROMETRY.

**optical rotary dispersion (ORD)** The effect in which the amount of rotation of plane-polarized light by an optically active compound depends on the wavelength. A graph of rotation against wavelength has a characteristic shape showing peaks or troughs.

**optical rotation** Rotation of plane-polarized light. *See* OPTICAL ACTIVITY.

**optical telescope** *See* TELESCOPE.

**optical temperature** See RADIATION TEMPERATURE.

**optic axis** **1.** The direction in a doubly refracting crystal in which light is transmitted without double refraction. **2.** See OPTICAL AXIS.

**optic lobes** See MIDBRAIN.

**optic nerve** The second \*cranial nerve: a paired sensory nerve that runs from each eye to the brain. It is responsible for conveying visual stimuli received by the rods and cones in the retina to the brain for interpretation.

**optics** The study of \*light and the phenomena associated with its generation, transmission, and detection. In a broader sense, optics includes all the phenomena associated with infrared and ultraviolet radiation. **Geometrical optics** assumes that light travels in straight lines and is concerned with the laws controlling the reflection and refraction of rays of light. **Physical optics** deals with phenomena that depend on the wave nature of light, e.g. diffraction, interference, and polarization.

**oral cavity** See BUCCAL CAVITY.

**oral contraceptive** Any hormonal preparation taken in the form of a pill to prevent conception (see BIRTH CONTROL). The most common form is the combined pill, which contains an \*oestrogen and a \*progestogen. Both act to suppress ovulation, while the progestogen additionally causes changes in the viscosity of cervical mucus and alters the lining of the womb, both of which decrease the chances of fertilization should ovulation occur. The so-called 'minipill' contains only a progestogen and has fewer side effects than the combined pill. Emergency contraception (the so-called 'morning-after pill'), to prevent pregnancy after unprotected sexual intercourse, consists of two spaced doses of either a combined oestrogen-progestogen preparation or an oestrogen alone, the first dose being taken within 72 hours of intercourse.

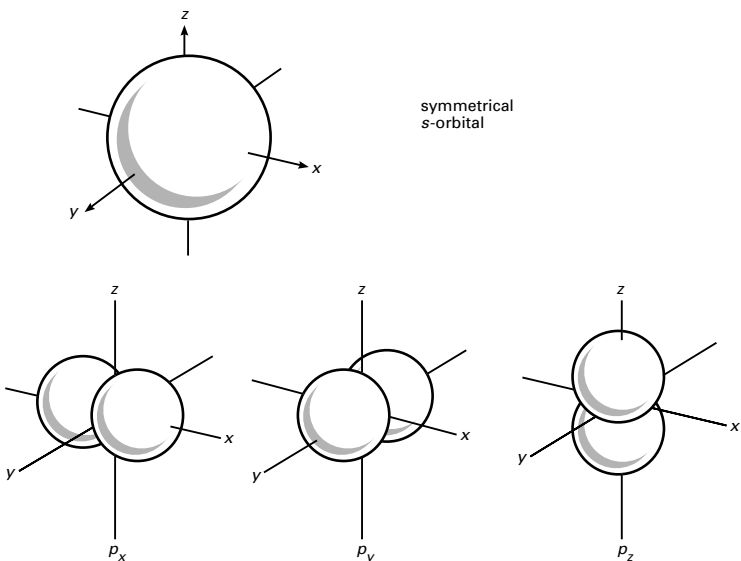

**orbit** **1.** (in astronomy) The path through space of one celestial body about another. For one small body moving in the gravitational field of another the orbit is a \*conic section. Most such orbits are elliptical and

most planetary orbits in the solar system are nearly circular. The shape and size of an elliptical orbit is specified by its eccentricity,  $e$ , and the length of its semimajor axis,  $a$ . **2.** (in physics) The path of an electron as it travels round the nucleus of an atom. See ORBITAL. **3.** (in anatomy) Either of the two sockets in the skull of vertebrates that house the eyeballs.

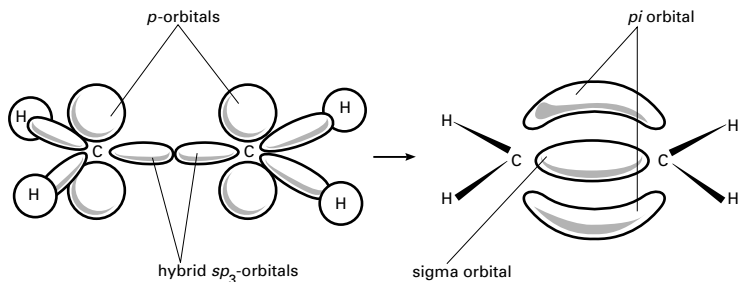

**orbital** A region in which an electron may be found in an atom or molecule. In the original \*Bohr theory of the atom the electrons were assumed to move around the nucleus in circular orbits, but further advances in quantum mechanics led to the view that it is not possible to give a definite path for an electron. According to \*wave mechanics, the electron has a certain probability of being in a given element of space. Thus for a hydrogen atom the electron can be anywhere from close to the nucleus to out in space but the maximum probability in spherical shells of equal thickness occurs in a spherical shell around the nucleus with a radius equal to the Bohr radius of the atom. The probabilities of finding an electron in different regions can be obtained by solving the Schrödinger wave equation to give the wave function  $\psi$ , and the probability of location per unit volume is then proportional to  $|\psi|^2$ . Thus the idea of electrons in fixed orbits has been replaced by that of a probability distribution around the nucleus - an **atomic orbital** (see illustration). Alternatively, the orbital can be thought of as an electric charge distribution (averaged over time). In representing orbitals it is convenient to take a surface enclosing the space in which the electron is likely to be found with a high probability.

The possible atomic orbitals correspond to subshells of the atom. Thus there is one  $s$ -orbital for each shell (orbital quantum number  $l = 0$ ). This is spherical. There are three  $p$ -orbitals (corresponding to the three values of  $l$ ) and five  $d$ -orbitals. The shapes of orbitals depend on the value of  $l$ . For instance,  $p$ -orbitals each have two lobes; most  $d$ -orbitals have four lobes.

In molecules, the valence electrons move under the influence of two nuclei (in a bond involving two atoms) and there are corresponding **molecular orbitals** for electrons (see illustration). It is convenient

three equivalent  $p$ -orbitals, each having 2 lobes

atomic orbitals

molecular orbitals: formation of the double bond in ethene

## Orbitals

in considering these to regard them as formed by overlap of atomic orbitals. In a hydrogen molecule the  $s$ -orbitals on the two atoms overlap and form a molecular orbital between the two nuclei. This is an example of a **sigma orbital**. In a double bond, as in ethene, one bond is produced by overlap along the line of axes to form a

sigma orbital. The other is produced by sideways overlap of the lobes of the  $p$ -orbitals (see illustration). The resulting molecular orbital has two parts, one on each side of the sigma orbital – this is a **pi orbital**. It is also possible for a **delta orbital** to form by lateral overlap of two  $d$ -orbitals. In fact, the combination of two

atomic orbitals produces two molecular orbitals with different energies. The one of lower energy is the **bonding orbital**, holding the atoms together; the other is the **antibonding orbital**, which would tend to push the atoms apart. In the case of valence electrons, only the lower (bonding) orbital is filled.

In considering the formation of molecular orbitals it is often useful to think in terms of **hybrid** atomic orbitals. For instance, carbon has in its outer shell one *s*-orbital and three *p*-orbitals. In forming methane (or other tetrahedral molecules) these can be regarded as combining to give four equivalent  $sp^3$  hybrid orbitals, each with a lobe directed to a corner of a tetrahedron. It is these that overlap with the *s*-orbitals on the hydrogen atoms. In ethene, two *p*-orbitals combine with the *s*-orbital to give three  $sp^2$  hybrids with lobes in a plane pointing to the corners of an equilateral triangle. These form the sigma orbitals in the C-H and C-C bonds. The remaining *p*-orbitals (one on each carbon) form the pi orbital. In ethyne,  $sp$  hybridization occurs to give two hybrid orbitals on each atom with lobes pointing along the axis. The two remaining *p*-orbitals on each carbon form two pi orbitals. Hybrid atomic orbitals can also involve *d*-orbitals. For instance, square-planar complexes use  $sp^2d$  hybrids; octahedral complexes use  $sp^3d^2$ .

**orbital quantum number** See ATOM.

**orbital velocity (orbital speed)** The speed of a satellite, spacecraft, or other body travelling in an \*orbit around the earth or around some other celestial body. If the orbit is elliptical, the orbital speed, *v*, is given by:

$$v = \sqrt{gR^2(2/r - 1/a)},$$

where *g* is the acceleration of free fall, *R* is the radius of the orbited body, *a* is the semimajor axis of the orbit, and *r* is the distance between the orbiting body and the centre of mass of the system. If the orbit is circular,  $r = a$  and  $v = \sqrt{gR^2/r}$ .

**OR circuit** See LOGIC CIRCUITS.

**order 1.** (in chemistry) In the expression for the rate of a chemical reaction, the sum of the powers of the concentrations

is the overall order of the reaction. For instance, in a reaction

the rate equation may have the form

$$R = k[A][B]^2$$

This reaction would be described as **first order** in A and **second order** in B. The overall order is three. The order of a reaction depends on the mechanism and it is possible for the rate to be independent of concentration (**zero order**) or for the order to be a fraction. See also MOLECULARITY; PSEUDO ORDER.

**2.** (in mathematics) The number of times a variable is differentiated.  $dy/dx$  represents a first-order derivative,  $d^2y/dx^2$  a second-order derivative, etc. In a \*differential equation the order of the highest derivative is the order of the equation.  $d^2y/dx^2 + 2dy/dx = 0$  is a second-order equation of the first degree. See also DEGREE.

**3.** (in taxonomy) A category used in the \*classification of organisms that consists of one or several similar or closely related families. Similar orders form a class. Order names typically end in *-ales* in botany, e.g. Rosales (roses and orchard fruits), and in *-a* in zoology, e.g. Carnivora (flesh eaters).

**4.** (in physics) A category of \*phase transition.

**order of magnitude** A value expressed to the nearest power of ten.

**order parameter** A quantity that characterizes the order of a phase of a system below its \*transition temperature. An order parameter has a non-zero value below the transition temperature and a zero value above the transition temperature. An example of an order parameter is magnetization (see MAGNETISM) in a ferromagnetic system. If the phase transition is continuous (i.e. there is no \*latent heat), the order parameter goes to zero continuously as the transition temperature is approached from below. **Disorder parameters** are quantities that are non-zero above the transition temperature and zero beneath it. Order parameters are associated with the \*broken symmetry of a system.

**ordinary ray** See DOUBLE REFRACTION.

**ordinate** See CARTESIAN COORDINATES.

**Ordovician** The second geological period of the Palaeozoic era, following the Cambrian and preceding the Silurian periods. It began about 505 million years ago and lasted for about 67 million years. The period was named by the British geologist Charles Lapworth (1842–1920) in 1879. \*Graptolites, in deep-water deposits, are the dominant fossils. Other fossils include \*trilobites, brachiopods, bryozoans, gastropods, bivalves, echinoids, crinoids, nautiloid cephalopods, and the first corals.

**ore** A naturally occurring mineral from which a metal and certain other elements (e.g. phosphorus) can be extracted, usually on a commercial basis. Metals may be present in ores in the native form, but more commonly they occur combined as oxides, sulphides, sulphates, silicates, etc.

**ore dressing** See BENEFICIATION.

**oregonator** A type of chemical reaction mechanism that causes an \*oscillating reaction. It is the type of mechanism responsible for the \*B-Z reaction, and involves five steps of the form:

Autocatalysis occurs as in the \*Lotka–Volterra mechanism and the \*brusselator. The mechanism was named after Oregon in America, where the research group that discovered it is based.

**organ** Any distinct part of an organism that is specialized to perform one or a number of functions. Examples are ears, eyes, lungs, and kidneys (in animals) and leaves, roots, and flowers (in plants). A given organ will contain many different \*tissues.

**organ culture** The culture of complete living organs (**explants**) of animals and plants outside the body in a suitable culture medium. Animal organs must be small enough to allow the nutrients in the culture medium to penetrate all the cells. Whole plant roots and even root systems

can be kept alive in such conditions for a considerable period of time. See also EXPLANTATION.

**organelle** A minute structure within a eukaryotic \*cell that has a particular function. Examples of organelles are the nucleus, mitochondria, and lysosomes.

**organic chemistry** The branch of chemistry concerned with compounds of carbon.

**organic evolution** The process by which changes in the genetic composition of populations of organisms occur in response to environmental changes. See ADAPTATION; EVOLUTION. Compare BIOCHEMICAL EVOLUTION.

**organism** An individual living system, such as an animal, plant, or \*microorganism, that is capable of reproduction, growth, and maintenance.

**organizer** An area of an animal embryo that causes adjacent areas of the embryo to develop in a certain way. The **primary organizer** (blastopore lip or archenteron roof) causes the \*gastrula to develop as a complete organism.

**organo-** Prefix used before the name of an element to indicate compounds of the elements containing organic groups (with the element bound to carbon atoms). For example, lead(IV) tetraethyl is an organo-lead compound.

**organogenesis** The formation of organs during embryonic development. In animals this begins following the re-arrangement of the cells at gastrulation, when the three germ layers are fully formed in their correct positions. Dividing cells of the \*gastrula begin to differentiate and the rudimentary organs and organ systems begin to form. See DIFFERENTIATION; ECTODERM; ENDODERM; MESODERM.

**organometallic compound** A compound in which a metal atom or ion is bound to an organic group. Organometallic compounds may have single metal-carbon bonds, as in the aluminium alkyls (e.g.  $\text{Al}(\text{CH}_3)_3$ ). In some cases, the bonding is to the pi electrons of a double bond, as in complexes formed between platinum and ethene, or to the pi electrons of a ring, as in \*ferrocene.

**orgasm** The climax of sexual excitement in humans, which - in males - coincides with \*ejaculation. A sense of physiological and emotional release is accompanied by a feeling of extreme pleasure.

**origin** See CARTESIAN COORDINATES.

**origin of life** The process by which living organisms developed from inanimate matter, which is generally thought to have occurred on earth between 3500 and 4000 million years ago. It is supposed that the primordial atmosphere was like a chemical soup containing all the basic constituents of organic matter: ammonia, methane, hydrogen, and water vapour. These underwent a process of chemical evolution using energy from the sun and electric storms to combine into ever more complex molecules, such as amino acids, proteins, and vitamins. Eventually self-replicating nucleic acids, the basis of all life, could have developed. The very first organisms may have consisted of such molecules bounded by a simple membrane. See PROTEINOID.

**origin of the elements** The nuclear processes that give rise to chemical elements. There is not one single process that can account for all the elements. The abundance of the chemical elements is determined not just by the stability of the nuclei of the atoms but also how readily the nuclear processes leading to the existence of these atoms occur. Most of the helium in the universe was produced by fusion in the early universe when the temperature and the pressure were very high. Most of the elements between helium and iron were made in nuclear fusion reactions inside stars. Since iron is at the bottom of an energy valley of stability, energy needs to be put into a nucleus heavier than iron for a fusion reaction to occur. Inside stars some heavy elements are built up by the **s-process**, where s stands for slow, in which high-energy neutrons are absorbed by a nucleus, with the resulting nucleus undergoing beta decay to produce a nucleus with a higher atomic number. Other heavy elements are produced by the **r-process**, where r stands for rapid, which occurs in supernova explosions.

**ornithine (Orn)** An \*amino acid,  $H_2N(CH_2)_3CH(NH_2)COOH$ , that is not a constituent of proteins but is important in living organisms as an intermediate in the reactions of the \*urea cycle and in arginine synthesis.

**ornithine cycle** See UREA CYCLE.

**orogenesis** The process by which major mountain chains are formed. This includes the deformational processes of thrusting, folding, and faulting that result from the collision of two continents. Examples of mountains formed through orogenesis include the Alpine-Himalayan, Appalachian, and Cordilleran orogenic belts.

**orpiment** A natural yellow mineral form of arsenic(III) sulphide,  $As_2S_3$ . The name is also used for the synthetic compound, which is used as a pigment.

**ortho-** **1.** Prefix indicating that a benzene compound has two substituted groups in the 1,2 positions (i.e. on adjacent carbon atoms). The abbreviation *o*- is used; for example *o*-dichlorobenzene is 1,2-dichlorobenzene. Compare META-; PARA-. **2.** Prefix formerly used to indicate the most hydrated form of an acid. For example, phosphoric(V) acid,  $H_3PO_4$ , was called orthophosphoric acid to distinguish it from the lower metaphosphoric acid,  $HPO_3$ , which is actually  $(HPO_3)_n$ .

**orthoboric acid** See BORIC ACID.

**orthoclase** See FELDSPARS.

**orthogenesis** An early theory of the nature of evolutionary change, which proposed that organisms evolve along particular paths predetermined by some factor in their genetic make-up. More recent understanding of selection pressure and other external forces that can be shown experimentally to affect the survival of organisms has proved the improbability of the theory.

**orthohydrogen** See HYDROGEN.

**orthophosphoric acid** See PHOSPHORIC(V) ACID.

**orthoplumbate** See PLUMBATE.

**orthopositronium** See POSITRONIUM.

**Orthoptera** A large order of insects con-

taining the grasshoppers, locusts, crickets, and – in some classification systems – the cockroaches (see DIPTOPTERA). They are characterized by enlarged hind legs modified for jumping and biting mouthparts and produce sounds by \*stridulation. The crickets and long-horned grasshoppers (e.g. *Gryllus*, *Tettigonia*) have long threadlike antennae and stridulate by rubbing together modified veins on their forewings. The hearing organs are on the front legs. The short-horned grasshoppers and locusts (e.g. *Chorthippus*, *Locusta*) have short antennae and stridulate by rubbing pegs on the hind leg against a hardened vein on the forewing. The hearing organs are on the abdomen.

**orthorhombic** See CRYSTAL SYSTEM.

**orthosilicate** See SILICATE.

**orthostannate** See STANNATE.

**orthotropism** The tendency for a \*tropism (growth response of a plant) to be orientated directly in line with the stimulus concerned. An example is the vertical growth of main stems and roots in response to gravity (**orthogeotropism**). Compare PLAGIOTROPISM.

**oscillating reaction (clock reaction)** A type of chemical reaction in which the concentrations of the products and reactants change periodically, either with time or with position in the reacting medium. Thus, the concentration of a component may increase with time to a maximum, decrease to a minimum, then increase again, and so on, continuing the oscillation over a period of time. Systems are also known in which spirals and other patterns spread through the reacting medium, demonstrating a periodic spatial variation. Oscillating chemical reactions have certain features in common. They all occur under conditions far from chemical equilibrium and all involve \*autocatalysis, i.e. a product of a reaction step acts as a catalyst for that step. This autocatalysis drives the oscillation by a process of positive feedback. Moreover, oscillating chemical reactions are associated with the phenomenon known as **bistability**. In this, a reaction may be in a steady-state condition, with reactants flowing into a reaction zone while products are flowing out

of it. Under these conditions, the concentrations in the reaction zone may not change with time, although the reaction is not in a state of chemical equilibrium. Bistable systems have two possible stable steady states. Interaction with an additional substance in the reaction medium causes the system to oscillate between the states as the concentrations change. Oscillating chemical reactions are thought to occur in a number of biochemical processes. For example, they occur in glycolysis, in which ATP is produced by enzymecatalysed reactions. They are also known to regulate the rhythm of the heartbeat. Most have highly complex reaction mechanisms. See LOTKA-VOLTERRA MECHANISM; BRUSSELETOR; OREGONATOR. See also CHAOTIC REACTION.

**oscillator** An electronic device that produces an alternating output of known frequency. If the output voltage or current has the form of a sine wave with respect to time, the device is called a **sinusoidal** (or **harmonic**) oscillator. If the output voltage changes abruptly from one level to another (as in a \*square wave or \*sawtooth wave) it is called a **relaxation oscillator**. A harmonic oscillator consists of a frequency-determining circuit or device, such as a \*resonant circuit, maintained in oscillation by a source of power that by positive feedback also makes up for the resistive losses. In some relaxation oscillators the circuit is arranged so that in each cycle energy is stored in a reactive element (a capacitor or inductor) and subsequently discharged over a different time interval. See also MULTIVIBRATOR.

**oscilloscope** See CATHODE-RAY OSCILLOSCOPE.

**osmiridium** A hard white naturally occurring alloy consisting principally of osmium (17–48%) and iridium (49%). It also contains small quantities of platinum, rhodium, and ruthenium. It is used for making small items subject to wear, e.g. electrical contacts or the tips of pen nibs.

**osmium** Symbol Os. A hard blue-white metallic \*transition element; a.n. 76; r.a.m. 190.2; r.d. 22.57; m.p. 3045°C; b.p. 5027°C. It is found associated with platinum and is used in certain alloys with platinum and iridium (see OSMIRIDIUM).

Osmium forms a number of complexes in a range of oxidation states. It was discovered by Smithson Tennant (1761–1815) in 1804.

**osmium(IV) oxide (osmium tetroxide)**

A yellow solid,  $\text{OsO}_4$ , made by heating osmium in air. It is used as an oxidizing agent in organic chemistry, as a catalyst, and as a fixative in electron microscopy.

**osmometer** See OSMOSIS.

**osmoreceptor** A receptor situated in the hypothalamus of the brain that responds to an increase in the concentration of the extracellular fluid. This results in the release of \*antidiuretic hormone (ADH) and the subsequent conservation of water, thereby maintaining the \*homeostasis of the body fluids.

**osmoregulation** The control of the water content and the concentration of salts in the body of an animal or protozoan. In freshwater species osmoregulation must counteract the tendency for water to pass into the animal by \*osmosis. Various methods have been developed to eliminate the excess, such as \*contractile vacuoles in protozoans and \*kidneys with well-developed glomeruli in freshwater fish. Marine vertebrates have the opposite problem: they prevent excessive water loss and enhance the excretion of salts by having kidneys with few glomeruli and short tubules. In terrestrial vertebrates the dangers of desiccation are reduced by the presence of long convoluted kidney tubules, which increase the reabsorption of water and salts.

**osmosis** The passage of a solvent through a **semipermeable membrane** separating two solutions of different concentrations. A semipermeable membrane is one through which the molecules of a solvent can pass but the molecules of most solutes cannot. There is a thermodynamic tendency for solutions separated by such a membrane to become equal in concentration, the water (or other solvent) flowing from the weaker to the stronger solution. Osmosis will stop when the two solutions reach equal concentration, and can also be stopped by applying a pressure to the liquid on the stronger-solution side of the membrane. The pressure re-

quired to stop the flow from a pure solvent into a solution is a characteristic of the solution, and is called the **osmotic pressure** (symbol  $\Pi$ ). Osmotic pressure depends only on the concentration of particles in the solution, not on their nature (i.e. it is a \*colligative property). For a solution of  $n$  moles in volume  $V$  at thermodynamic temperature  $T$ , the osmotic pressure is given by  $\Pi V = nRT$ , where  $R$  is the gas constant. Osmotic-pressure measurements are used in finding the relative molecular masses of compounds, particularly macromolecules. A device used to measure osmotic pressure is called an **osmometer**.

The distribution of water in living organisms is dependent to a large extent on osmosis, water entering the cells through their membranes. A cell membrane is not truly semipermeable as it allows the passage of certain solute molecules; it is described as **partially permeable**. Osmosis in plants is now usually described in terms of \*water potential: water moves from an area of high (less negative) water potential to an area of low (more negative) water potential (see also PLASMOLYSIS; TURGOR; WILTING). Animals have evolved various means to counteract the effects of osmosis (see OSMOREGULATION); in water relations in animals solutions are still described in terms of osmotic pressure.

**osmotic pressure** See OSMOSIS.

**ossification** The process of \*bone formation. It is brought about by the action of special cells called \*osteoblasts, which deposit layers of bone in connective tissue. Some bones are formed directly in connective tissue (see MEMBRANE BONE); others are formed by the replacement of cartilage (see CARTILAGE BONE).

**Osteichthyes** The class of vertebrates comprising the bony fishes – marine and freshwater fish with a bony skeleton. All have gills covered with a bony operculum, and a layer of thin overlapping bony \*scales covers the entire body surface. Bony fish have a \*swim bladder, which acts as a hydrostatic organ enabling the animal to remain suspended in the water at any depth. In some fish this bladder acts as a lung. See also DIPNOI; TELEOSTEI. Compare CHONDRICHTHYES.

**osteoblast** Any of the cells, found in \*bone, that secrete collagen and other substances that form the matrix of bone. Osteoblasts are derived from **osteoprogenitor cells** in the bone marrow; they eventually become \*osteocytes (bone cells). *See also* OSSIFICATION.

**osteoclast** Any of the cells in \*bone that are involved in the breakdown of bone matrix to enable the further development and remodelling of bone during growth and repair.

**osteocyte** Any of the cells, found in bone, that are derived from \*osteoblasts and perform activities required for the maintenance of the bone tissue.

**Ostogradsky's theorem** *See* DIVERGENCE THEOREM.

**Ostwald's dilution law** An expression for the degree of dissociation of a weak electrolyte. For example, if a weak acid dissociates in water

the dissociation constant  $K_a$  is given by

$$K_a = \alpha^2 n / (1 - \alpha) V$$

where  $\alpha$  is the degree of dissociation,  $n$  the initial amount of substance (before dissociation), and  $V$  the volume. If  $\alpha$  is small compared with 1, then  $\alpha^2 = KV/n$ ; i.e. the degree of dissociation is proportional to the square root of the dilution. The law was first put forward by Wilhelm Ostwald (1853–1932) to account for electrical conductivities of electrolyte solutions.

**otolith** A gelatinous mass containing a high concentration of particles of calcium carbonate, which forms part of the \*macula of the inner ear.

**Otto engine** *See* INTERNAL-COMBUSTION ENGINE.

**ounce** **1.** One sixteenth of a pound (avoirdupois), equal to 0.028 349 kg. **2.** Eight drachms (Troy), equal to 0.031 103 kg. **3. (fluid ounce)** Eight fluid drachms, equal to 0.028 413 dm<sup>3</sup>.

**outbreeding** Mating between unrelated or distantly related individuals of a species. Outbreeding populations usually show more variation than \*inbreeding ones and have a greater potential for

adapting to environmental changes. Outbreeding increases the number of \*heterozygous individuals, so that disadvantageous recessive characteristics tend to be masked by dominant alleles.

**outer ear (external ear)** The part of the ear external to the \*tympanum (eardrum). It is present in mammals, birds, and some reptiles and consists of a tube (the **external auditory meatus**) that directs sound waves onto the tympanum. In mammals it may include an external \*pinna, which extends beyond the skull.

**oval window (fenestra ovalis)** A membrane-covered opening between the middle ear and the inner ear (*see* EAR), situated above the \*round window. Vibrations of the tympanum are transferred across the middle ear by the \*ear ossicles and transmitted to the inner ear by the oval window, which is connected to the third ear ossicle (stapes).

**ovarian follicle** *See* GRAAFIAN FOLLICLE.

**ovary** **1.** The reproductive organ in female animals in which eggs (ova) are produced. In most vertebrates there are two ovaries (in some fish the ovaries fuse together to form a single structure and in birds the left ovary only is functional). As well as eggs, they produce steroid hormones (*see* OESTROGEN; PROGESTERONE). In mammals each ovary is situated close to the opening of a \*fallopian tube; it contains numerous follicles in which the eggs develop and from which they are released in a regular cycle. *See also* GRAAFIAN FOLLICLE; MENSTRUAL CYCLE; OOGENESIS; OVULATION; REPRODUCTIVE SYSTEM. **2.** The hollow base of the \*carpel of a flower, containing one or more \*ovules. After fertilization, the ovary wall develops into the fruit enclosing the seeds. In some species, the carpels are fused together to form a complex ovary.

**overdamped** *See* DAMPING.

**overpopulation** The situation that arises when rapid growth of a population, usually a human population, results in numbers that cannot be supported by the available resources, such as space and food. This occurs when the birth rate exceeds the death rate, or when immigration exceeds emigration, or when a

combination of these factors exists. See POPULATION GROWTH.

**overpotential** A potential that must be applied in an electrolytic cell in addition to the theoretical potential required to liberate a given substance at an electrode. The value depends on the electrode material and on the current density. It is a kinetic effect occurring because of the significant activation energy for electron transfer at the electrodes, and is particularly important for the liberation of such gases as hydrogen and oxygen. For example, in the electrolysis of a solution of zinc ions, hydrogen ( $E^{\ominus} = 0.00 \text{ V}$ ) would be expected to be liberated at the cathode in preference to zinc ( $E^{\ominus} = -0.76 \text{ V}$ ). In fact, the high overpotential of hydrogen on zinc (about 1 V under suitable conditions) means that zinc can be deposited instead.

**overtones** See HARMONIC.

**oviduct** The tube that conveys an animal egg cell from the ovary to other parts of the reproductive system or to the outside. Eggs are passed along the oviduct by the action of muscles and cilia. See FALLOPIAN TUBE.

**oviparity** Reproduction in which fertilized eggs are laid or spawned by the mother and hatch outside her body. It occurs in most animals except marsupial and placental mammals. Compare OVOVIVIPARITY; VIVIPARITY.

**ovipositor** An organ at the hind end of the abdomen of female insects through which eggs are laid. It consists of a pair of modified appendages and is often long and piercing, so that eggs can be laid in otherwise inaccessible places. The sting of bees and wasps is a modified ovipositor.

**ovoviviparity** Reproduction in which fertilized eggs develop and hatch in the oviduct of the mother. It occurs in many invertebrates and in some fish and reptiles (e.g. the viper). Compare OVIPARITY; VIVIPARITY.

**ovulation** The release of an egg cell from the ovary, which in mammals is stimulated by \*luteinizing hormone. The developing egg cell within its follicle migrates to the ovary surface; when mature, it is released from the follicle (which

breaks open) into the body cavity, from where it passes into the oviduct. See also MENSTRUAL CYCLE.

**ovule** The part of the female reproductive organs of seed plants that consists of the \*nucellus, \*embryo sac, and \*integuments. The ovules of gymnosperms are situated on ovuliferous scales of the female cones while those of angiosperms are enclosed in the carpel. After fertilization, the ovule becomes the seed.

**ovuliferous scale** One of a group of large woody specialized leaves that form the female \*cone of conifers and related trees. It bears the ovules, which develop into seeds.

**ovum (egg cell)** (*pl. ova*) **1.** (in zoology) The mature reproductive cell (see GAMETE) of female animals, which is produced by the ovary (see OOGENESIS). It is spherical, has a nucleus, is covered with a vitelline membrane, and is not mobile. **2.** (in botany) The \*oosphere of plants.

**oxalate** A salt or ester of \*oxalic acid.

**oxalic acid (ethanedioic acid)** A crystalline solid,  $(\text{COOH})_2$ , that is slightly soluble in water. Oxalic acid is strongly acidic and very poisonous. It occurs in certain plants, e.g. sorrel and the leaf blades of rhubarb.

**oxaloacetic acid** A compound,  $\text{HO}_2\text{CCH}_2\text{COCO}_2\text{H}$ , that plays an integral role in the \*Krebs cycle. The anion, oxaloacetate, reacts with the acetyl group from acetyl coenzyme A to form citrate.

**oxbow lake** A crescent-shaped lake formed when a meander of a slow-flowing river is cut off from the main channel after the river, in flood, crosses the neck of land between two bends. Most oxbow lakes, or cutoffs, soon silt up.

**oxfuel** A liquid fuel containing added alcohols or ethers to act as an additional source of oxygen during combustion of the fuel. It has been claimed that such additives help to lower the concentration of carbon monoxide in engine emissions.

**oxidant** See OXIDIZING AGENT.

**oxidase** Any enzyme that catalyses \*oxidation-reduction reactions that involve

the transfer of electrons to molecular oxygen.

**oxidation** See OXIDATION-REDUCTION.

**oxidation number (oxidation state)** See OXIDATION-REDUCTION.

**oxidation-reduction (redox)** Originally, **oxidation** was simply regarded as a chemical reaction with oxygen. The reverse process – loss of oxygen – was called **reduction**. Reaction with hydrogen also came to be regarded as reduction. Later, a more general idea of oxidation and reduction was developed in which oxidation was loss of electrons and reduction was gain of electrons. This wider definition covered the original one. For example, in the reaction

the sodium atoms lose electrons to give  $\text{Na}^+$  ions and are oxidized. At the same time, the oxygen atoms gain electrons and are reduced. These definitions of oxidation and reduction also apply to reactions that do not involve oxygen. For instance in

the sodium is oxidized and the chlorine reduced. Oxidation and reduction also occurs at the electrodes in \*cells.

This definition of oxidation and reduction applies only to reactions in which electron transfer occurs – i.e. to reactions involving ions. It can be extended to reactions between covalent compounds by using the concept of **oxidation number (or state)**. This is a measure of the electron control that an atom has in a compound compared to the atom in the pure element. An oxidation number consists of two parts:

- (1) Its sign, which indicates whether the control has increased (negative) or decreased (positive).
- (2) Its value, which gives the number of electrons over which control has changed.

The change of electron control may be complete (in ionic compounds) or partial (in covalent compounds). For example, in  $\text{SO}_2$  the sulphur has an oxidation number +4, having gained partial control over 4 electrons compared to sulphur atoms in pure sulphur. The oxygen has an oxida-

tion number -2, each oxygen having lost partial control over 2 electrons compared to oxygen atoms in gaseous oxygen. Oxidation is a reaction involving an increase in oxidation number and reduction involves a decrease. Thus in

the hydrogen in water is +1 and the oxygen -2. The hydrogen is oxidized and the oxygen is reduced.

The oxidation number is used in naming inorganic compounds. Thus in  $\text{H}_2\text{SO}_4$ , sulphuric(VI) acid, the sulphur has an oxidation number of +6. Compounds that tend to undergo reduction readily are \*oxidizing agents; those that undergo oxidation are \*reducing agents.

**oxidative decarboxylation** The reaction in the \*Krebs cycle in which oxygen, derived from two water molecules, is used to oxidize two carbon atoms to two molecules of carbon dioxide. The two carbon atoms result from the \*decarboxylation reactions that occur during the Krebs cycle as the six-carbon compound citrate is converted to the four-carbon compound oxaloacetate.

**oxidative phosphorylation** A reaction occurring during the final stages of \*aerobic respiration, in which ATP is formed from ADP and phosphate coupled to electron transport in the \*electron transport chain. The reaction occurs in the mitochondria and is the cell's principal method of storing the energy released by the oxidation of food. See also PHOSPHORYLATION.

**oxides** Binary compounds formed between elements and oxygen. Oxides of nonmetals are covalent compounds having simple molecules (e.g.  $\text{CO}$ ,  $\text{CO}_2$ ,  $\text{SO}_2$ ) or giant molecular lattices (e.g.  $\text{SiO}_2$ ). They are typically acidic or neutral. Oxides of metals are ionic, containing the  $\text{O}^{2-}$  ion. They are generally basic or \*amphoteric. Various other types of ionic oxide exist (see OZONIDES; PEROXIDES; SUPEROXIDES).

**oxidizing acid** An acid that can act as a strong oxidizing agent as well as an acid. Nitric acid is a common example. It is able to attack metals, such as copper, that are below hydrogen in the electromotive series, by oxidizing the metal:

This is followed by reaction between the acid and the oxide:

**oxidizing agent (oxidant)** A substance that brings about oxidation in other substances. It achieves this by being itself reduced. Oxidizing agents contain atoms with high oxidation numbers; that is the atoms have suffered electron loss. In oxidizing other substances these atoms gain electrons.

**oxidoreductase** Any of a class of enzymes that catalyse \*oxidation-reduction reactions, i.e. they are involved in the transfer of hydrogen or electrons between molecules. They include the \*oxidases and \*dehydrogenases.

**oximes** Compounds containing the group C:NOH, formed by reaction of an aldehyde or ketone with hydroxylamine ( $\text{H}_2\text{NOH}$ ) (see illustration). Ethanal ( $\text{CH}_3\text{CHO}$ ), for example, forms the oxime  $\text{CH}_3\text{CH:NOH}$ .

**oxo-** Prefix indicating the presence of oxygen in a chemical compound.

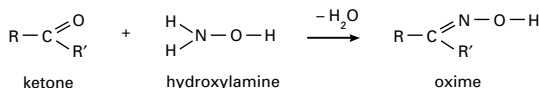

**oxoacid** An acid in which the acidic hydrogen is part of a hydroxyl group bound to an atom that is bound to an oxo group (=O). Sulphuric acid is an example. Compare HYDROXOACID.

### 3-oxobutanoic acid (acetoacetic acid)

A colourless syrupy liquid,  $\text{CH}_3\text{COCH}_2\text{COOH}$ . It is an unstable compound, decomposing into propanone and carbon dioxide. The acid can be prepared from its ester, \*ethyl 3-oxobutanoate.

**oxonium ion** An ion of the type  $\text{R}_3\text{O}^+$ , in which R indicates hydrogen or an organic group, especially the ion  $\text{H}_3\text{O}^+$ , which is formed when \*acids dissociate in water. This is also called the **hydroxonium ion** or the **hydronium ion**.

**oxo process** An industrial process for

**Oximes.** Formation of an oxime from a ketone; the same reaction occurs with an aldehyde ( $\text{R}' = \text{H}$ ).

making aldehydes by reaction between alkanes, carbon monoxide, and hydrogen (cobalt catalyst using high pressure and temperature).

**oxyacetylene burner** A welding or cutting torch that burns a mixture of oxygen and acetylene (ethyne) in a specially designed jet. The flame temperature of about  $3300^\circ\text{C}$  enables all ferrous metals to be welded. For cutting, the point at which the steel is to be cut is preheated with the oxyacetylene flame and a powerful jet of oxygen is then directed onto the steel. The oxygen reacts with the hot steel to form iron oxide and the heat of this reaction melts more iron, which is blown away by the force of the jet.

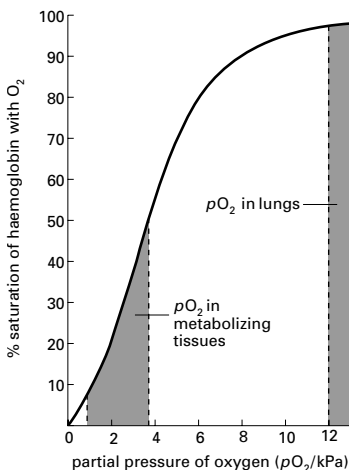

**oxygen** Symbol O. A colourless odourless gaseous element belonging to \*group 16 (formerly VIB) of the periodic table; a.n. 8; r.a.m. 15.9994; d.  $1.429 \text{ g dm}^{-3}$ ; m.p.  $-218.4^\circ\text{C}$ ; b.p.  $-183^\circ\text{C}$ . It is the most abundant element in the earth's crust (49.2% by weight) and is present in the atmosphere (28% by volume). Atmospheric oxygen is of vital importance for all organisms that carry out \*aerobic respiration. For industrial purposes it is obtained by fractional distillation of liquid air. It is used in metallurgical processes, in high-temperature flames (e.g. for welding), and in breathing apparatus. The common form is diatomic (**dioxygen**,  $\text{O}_2$ ); there is also a reactive allotrope \*ozone ( $\text{O}_3$ ). Chemically, oxygen reacts with most other elements forming \*oxides. The element was discovered by Joseph Priestley in 1774.

**oxygen cycle** The cycling of oxygen between the biotic and abiotic components of the environment (see BIOGEOCHEMICAL CYCLE). The oxygen cycle is closely linked to the \*carbon cycle and the water cycle (see HYDROLOGICAL CYCLE). In the process of respiration oxygen is taken in by living organisms and released into the atmosphere, combined with carbon, in the form of carbon dioxide. Carbon dioxide enters

the carbon cycle or is taken up by plants for \*photosynthesis. During photosynthesis oxygen is evolved by the chemical splitting of water and returned to the atmosphere. In the upper atmosphere, \*ozone is formed from oxygen and dissociates to release oxygen (see OZONE LAYER).

**oxygen debt** The physiological state that exists in a normally aerobic animal when insufficient oxygen is available for metabolic requirements (e.g. during a period of strenuous physical activity). To meet the body's increased demand for energy, pyruvate is converted anaerobically (i.e. in the absence of oxygen) to lactic acid, which requires oxygen for its breakdown and accumulates in the tissues. When oxygen is available again lactic acid is oxidized in the liver, thus repaying the debt.

**oxygen dissociation curve** The S-shaped curve produced when the percentage saturation of haemoglobin with oxygen (i.e. the percentage of binding sites of haemoglobin that are occupied by oxygen molecules) is plotted against the partial pressure of oxygen ( $pO_2$ ), which is a measure of the oxygen concentration in the surrounding medium. The steep rise of the curve indicates the high affinity of haemoglobin for oxygen: a small increase

Oxygen dissociation curve

in  $pO_2$  results in a relatively sharp increase in the percentage saturation of haemoglobin with oxygen. Therefore in the lungs, where the  $pO_2$  is high, the blood is rapidly saturated with oxygen. Conversely, a small drop in  $pO_2$  results in a large drop in percentage saturation of haemoglobin. Thus in tissues that utilize oxygen at a high rate, where the  $pO_2$  is low, oxygen readily dissociates from haemoglobin and is released for use by the tissues. See also BOHR EFFECT.

**oxyhaemoglobin** See HAEMOGLOBIN.

**oxyntic cell (parietal cell)** Any of the cells in the wall of the stomach that produce hydrochloric acid, which forms part of the \*gastric juice. Hydrochloric acid is required for the conversion of pepsinogen to pepsin in the lumen of the stomach and kills various microorganisms that enter with food. The oxyntic cells also produce intrinsic factor, which is involved in the absorption of vitamin  $B_{12}$  in the small intestine (see VITAMIN B COMPLEX).

**oxytocin** A hormone, produced by birds and mammals, that in mammals causes both contraction of smooth muscle in the uterus during birth and expulsion of milk from the mammary glands during suckling. Oxytocin is produced in the neurosecretory cells of the hypothalamus (see NEUROSECRETION) but is stored and secreted by the posterior pituitary gland.

**ozoneation** The formation of \*ozone ( $O_3$ ) in the earth's atmosphere. In the upper atmosphere (stratosphere) about 20–50 km above the surface of the earth, oxygen molecules ( $O_2$ ) dissociate into their constituent atoms under the influence of \*ultraviolet light of short wavelength (below about 240 nm). These atoms combine with oxygen molecules to form ozone (see OZONE LAYER). Ozone is also formed in the lower atmosphere from nitrogen oxides and other pollutants by photochemical reactions (see PHOTOCHEMICAL SMOG).

**ozone (trioxygen)** A colourless gas,  $O_3$ , soluble in cold water and in alkalis; m.p.  $-192.7^\circ\text{C}$ ; b.p.  $-111.9^\circ\text{C}$ . Liquid ozone is dark blue in colour and is diamagnetic (dioxygen,  $O_2$ , is paramagnetic). The gas is made by passing oxygen through a silent

electric discharge and is usually used in mixtures with oxygen. It is produced in the stratosphere by the action of high-energy ultraviolet radiation on oxygen (see OZONATION) and its presence there acts as a screen for ultraviolet radiation (see OZONE LAYER). Ozone is also one of the greenhouse gases (see GREENHOUSE EFFECT). It is a powerful oxidizing agent and is used to form ozonides by reaction with alkenes and subsequently by hydrolysis to carbonyl compounds.

**ozone hole** See OZONE LAYER.

**ozone layer (ozonosphere)** A layer of the earth's atmosphere in which most of the atmosphere's ozone is concentrated. It occurs 15–50 km above the earth's surface and is virtually synonymous with the \*stratosphere. In this layer most of the sun's ultraviolet radiation is absorbed by the ozone molecules, causing a rise in the temperature of the stratosphere and preventing vertical mixing so that the stratosphere forms a stable layer. By absorbing most of the solar ultraviolet radiation the ozone layer protects living organisms on earth. The fact that the ozone layer is thinnest at the equator is believed to account for the high equatorial incidence of skin cancer as a result of exposure to unabsorbed solar ultraviolet radiation. In the

1980s it was found that depletion of the ozone layer was occurring over both the poles, creating **ozone holes**. This is thought to have been caused by a series of complex photochemical reactions involving \*nitrogen oxides produced from aircraft and, more seriously, \*chlorofluorocarbons (CFCs) and halons. CFCs rise to the stratosphere, where they react with ultraviolet light to release chlorine atoms; these atoms, which are highly reactive, catalyse the destruction of ozone. Use of CFCs is now much reduced in an effort to reverse this human-induced damage to the ozone layer. See also AIR POLLUTION.

**ozonides** **1.** A group of compounds formed by reaction of ozone with alkali metal hydroxides and formally containing the ion  $O_3^-$ . **2.** Unstable compounds formed by the addition of ozone to the C=C double bond in alkenes. See OZONOLYSIS.

**ozonolysis** A reaction of alkenes with ozone to form an ozonide. It was once used to investigate the structure of alkenes by hydrolysing the ozonide to give aldehydes or ketones, for instance:

These could be identified, and the structure of the original alkene determined.

**P (parental generation)** The individuals that are selected to begin a breeding experiment, crosses between which yield the \*F<sub>1</sub> generation. Only pure-breeding (homozygous) individuals are selected for the P generation.

**pacemaker 1. (sinoatrial node)** A small mass of specialized muscle cells in the mammalian heart, found in the wall of the right atrium near the opening for the vena cava. The cells initiate and maintain the heart beat: by their rhythmic and spontaneous contractions they stimulate contraction of the atria (*see also* ATRIOVENTRICULAR NODE). The cells themselves are controlled by the autonomic nervous system, which determines the heart rate. Similar pacemakers occur in the hearts of other vertebrates. **2.** An electronic or nuclear battery-charged device that can be implanted surgically into the chest to produce and maintain the heart beat. These devices are used when the heart's own pacemaker is defective or diseased.

**pachytene** The period in the first prophase of \*meiosis when paired \*homologous chromosomes are fully contracted and twisted around each other.

**packing density 1.** The number of devices (such as \*logic circuits) or integrated circuits per unit area of a \*silicon chip. **2.** The quantity of information stored in a specified space of a storage system associated with a computer, e.g. \*bits per inch of magnetic tape.

**packing fraction** The algebraic difference between the relative atomic mass of an isotope and its mass number, divided by the mass number.

**paedogenesis** Reproduction by an animal that is still in the larval or pre-adult form. Paedogenesis is a form of \*neoteny and is particularly marked in the axolotl, a larval form of the salamander, which retains its larval features owing to a thyroid deficiency but can breed, producing

individuals like itself. If the thyroid hormone thyroxine is given, metamorphosis occurs.

**pahoehoe** *See* LAVA.

**pairing (synapsis)** The close association between \*homologous chromosomes that develops during the first prophase of \*meiosis. The two chromosomes move together and an exact pairing of corresponding points along their lengths occurs as they lie side by side. The resulting structure is called a **bivalent**.

**pair production** The creation of an electron and a positron from a photon in a strong electric field, such as that surrounding an atomic nucleus. The electron and the positron each have a mass of about  $9 \times 10^{-31}$  kg, which is equivalent on the basis of the mass-energy equation ( $E = mc^2$ ) to a total of  $16 \times 10^{-14}$  J. The frequency,  $\nu$ , associated with a photon of this energy (according to  $E = h\nu$ ) is  $2.5 \times 10^{20}$  Hz. Pair production thus requires photons of high quantum energy (Bremsstrahlung or gamma rays). Any excess energy is taken up as kinetic energy of the products.

**palaeobotany** The branch of \*palaeontology concerned with the study of plants through geological time, as revealed by their \*fossil remains (*see also* PALYNOLOGY). It overlaps with other aspects of plant study, including anatomy, ecology, evolution, and taxonomy.

**Palaeocene** The earliest geological epoch of the \*Tertiary period. It began about 65 million years ago, following the Cretaceous period, and extended for about 11.1 million years to the beginning of the \*Eocene (the Palaeocene is sometimes included in the Eocene). It was named by the palaeobotanist W. P. Schimper in 1874. A major floral and faunal discontinuity occurred between the end of the Cretaceous and the beginning of the Palaeocene: following the extinc-

tion of many reptiles the mammals became abundant on land. By the end of the epoch primates and rodents had evolved.

**palaeoclimatology** The study of climates of earlier geological periods. This is based largely on the study of sediments that were laid down during these periods and of fossils. The changes in the positions of the continents as a result of \*continental drift and \*plate tectonics complicate the study.

**palaeoecology** The study of the relationships of \*fossil organisms to each other and to their environments. It involves the study both of the fossils and of the surrounding rocks in which they are found. Trace fossils may provide information on the behaviour of the organism.

**Palaeolithic** The Old Stone Age, lasting in Europe from about 2.5 million to 9000 years ago, during which humans used primitive stone tools made by chipping stones and flints.

**palaeomagnetism** The study of magnetism in rocks, which provides information on variations in the direction and intensity of the earth's magnetic field with time. During the formation of an igneous or sedimentary rock containing magnetic minerals the polarity of the earth's magnetic field at that time becomes 'frozen' into the rock. Studies of this fossil magnetism in samples of rocks have enabled the former positions of magnetic poles at various geological times to be located. It has also revealed that periodic reversals in the geomagnetic field have taken place (i.e. the N-pole becomes the S-pole and vice versa). This information has been important in plate tectonics in establishing the movements of lithospheric plates over the earth's surface. The magnetic reversals provided crucial evidence for the sea-floor spreading hypothesis proposed in the early 1960s.

**palaeontology** The study of extinct organisms, including their structure, environment, evolution, and distribution, as revealed by their \*fossil remains. Palaeontological work also makes important contributions to geology in revealing stratigraphic relationships between rock strata and determining the physical ap-

pearance and climate of the earth during past geological ages. *See also* PALAEOBOTANY; PALAEOECOLOGY; PALAEOZOOLOGY.

**Palaeozoic** The first era of \*Phanerozoic time. It follows the \*Precambrian and is subdivided into the Lower Palaeozoic, comprising the \*Cambrian, \*Ordovician, and \*Silurian periods, and the Upper Palaeozoic, comprising the \*Devonian, \*Carboniferous, and \*Permian periods. It extended from about 590 million years ago to about 248 million years ago, when it was succeeded by the \*Mesozoic era.

**palaeozoology** The branch of \*palaeontology concerned with the study of animals throughout geological time, as revealed by their \*fossil remains.

**palate** The roof of the mouth cavity of vertebrates, which separates the \*buccal and nasal cavities. In mammals it is divided into two zones, the bony **hard palate** and the **soft palate**, and completely separates the buccal cavity from the air passage to enable simultaneous eating and breathing.

**palisade mesophyll** *See* MESOPHYLL.

**palladium** Symbol Pd. A soft white ductile \*transition element (*see also* PLATINUM METALS); a.n. 46; r.a.m. 106.4; r.d. 12.02; m.p. 1552°C; b.p. 3140±1°C. It occurs in some copper and nickel ores and is used in jewellery and as a catalyst for hydrogenation reactions. Chemically, it does not react with oxygen at normal temperatures. It dissolves slowly in hydrochloric acid. Palladium is capable of occluding 900 times its own volume of hydrogen. It forms few simple salts, most compounds being complexes of palladium(II) with some palladium(IV). It was discovered by William Woolaston (1766-1828) in 1803.

**pallium** *See* CEREBRAL CORTEX.

**palmitate (hexadecanoate)** A salt or ester of palmitic acid.

**palmitic acid (hexadecanoic acid)** A 16-carbon saturated fatty acid,  $\text{CH}_3(\text{CH}_2)_{14}\text{COOH}$ ; r.d. 0.85; m.p. 63°C; b.p. 390°C. Glycerides of palmitic acid occur widely in plant and animal oils and fats.

**palp** An elongated sensory organ, usually near the mouth, in many inverte-

brates. Examples are the tactile head appendages of polychaete worms, the ciliated flap of tissue that produces feeding currents in bivalve molluscs, the distal part of the \*mandibles of crustaceans, and the olfactory parts of the first and second \*maxillae of some insects.

**palynology (micropalaeontology)** The study of fossil pollen and spores (**pollen analysis**) and various other \*microfossils, such as coccoliths and dinoflagellates. Palynology is used in stratigraphy, palaeoclimatology, and archaeology. Pollen and spores are very resistant to decay and therefore their fossils are found in sedimentary rocks. They may be extracted by various methods, including boiling with potassium hydroxide solution, washing with strong oxidizing mixtures, and centrifuging repeatedly. Spores and pollen are classified according to shape, form of aperture, and both internal and external details of the exine (outer coat). They indicate the nature of the dominant flora, and therefore the climate and conditions of the period in which they lived.

**pancreas** A gland in vertebrates lying between the duodenum and the spleen. Under the influence of the hormone \*secretin it secretes **pancreatic juice** containing digestive enzymes or their precursors (mainly \*trypsin, \*chymotrypsin, \*amylase, and \*lipase) into the duodenum via the pancreatic duct. It also contains groups of cells - the \*islets of Langerhans - that function as an \*endocrine gland, producing the hormones \*insulin and \*glucagon, which regulate blood sugar levels.

**pancreozymin** See CHOLECYSTOKININ.

**panicle** A type of flowering shoot common in the grass family. The primary axis bears groups of \*racemes and is itself racemose, as the youngest groups of flowers are at the top (e.g. oat). The term may be used loosely for any form of branched \*racemose inflorescence; for example, the horse chestnut is a raceme of cymes. Both these arrangements are seen in the family Polygonaceae (docks and sorrels).

**pantothenic acid** A vitamin of the \*vitamin B complex. It is a constituent of \*coenzyme A, which performs a crucial

role in the oxidation of fats, carbohydrates, and certain amino acids. Deficiency rarely occurs because the vitamin occurs in many foods, especially cereal grains, peas, egg yolk, liver, and yeast.

**papain** A protein-digesting enzyme (see PROTEASE) occurring in the fruit of the West Indian papaya tree (*Carica papaya*). It is used as a digestant and in the manufacture of meat tenderizers.

**paper chromatography** A technique for analysing mixtures by \*chromatography, in which the stationary phase is absorbent paper. A spot of the mixture to be investigated is placed near one edge of the paper and the sheet is suspended vertically in a solvent, which rises through the paper by capillary action carrying the components with it. The components move at different rates, partly because they absorb to different extents on the cellulose and partly because of partition between the solvent and the moisture in the paper. The paper is removed and dried, and the different components form a line of spots along the paper. Colourless substances are detected by using ultraviolet radiation or by spraying with a substance that reacts to give a coloured spot (e.g. ninhydrin gives a blue coloration with amino acids). The components can be identified by the distance they move in a given time.

**papilla** Any cone-shaped protuberance projecting from the surface of an organ or organism. Papillae occur, for example, on the tongue, in the kidneys, and, in plants, on the surface of many petals.

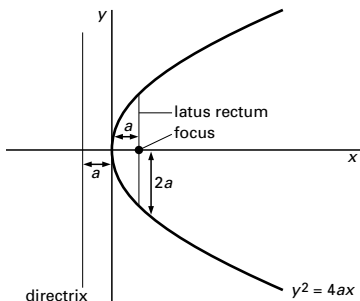

**papovavirus** One of a group of DNA-containing viruses that produce tumours in their hosts. **Papillomaviruses** produce nonmalignant tumours (such as warts) in all vertebrates; **polyomaviruses** produce malignant tumours in certain classes of vertebrates (not including humans).

**pappus** A group of modified \*sepals, often in the form of a ring of silky hairs. For example, when the fruit of the dandelion matures a pappus of hairs persists at the top of a thin stalk forming a parachute-like structure, which serves to disperse the fruit.

**para-** 1. Prefix designating a benzene

compound in which two substituents are in the 1,4 positions, i.e. directly opposite each other, on the benzene ring. The abbreviation *p*- is used; for example, *p*-xylene is 1,4-dimethylbenzene. *Compare* ORTHO-; META-. **2.** Prefix denoting the form of diatomic molecules in which the nuclei have opposite spins, e.g. parahydrogen. *Compare* ORTHO-.

**parabola** A \*conic with eccentricity  $e = 1$ . It is the locus of a point that moves so that its distance from the **focus** is equal to its perpendicular distance from the **directrix**. A chord through the focus, perpendicular to the axis, is called the **latus rectum**. For a parabola with its vertex at the origin, lying symmetrically about the  $x$ -axis, the equation is  $y^2 = 4ax$ , where  $a$  is the distance from the vertex to the focus. The directrix is the line  $x = -a$ , and the latus rectum is  $4a$ . See illustration.

A parabola

**parabolic reflector (paraboloidal reflector)** A reflector having a section that is a parabola. A concave parabolic reflector will reflect a parallel beam of radiation through its focus and, conversely, will produce a parallel beam if the source of the radiation is placed at its focus. Parabolic mirrors are used in reflecting optical \*telescopes to collect the light and in some light sources that require a parallel beam of light. In radio telescopes a dish aerial may also consist of a parabolic reflector.

**paraboloid** A solid formed by rotating a parabola about its axis of symmetry.

**paraffin** *See* PETROLEUM.

**paraffins** *See* ALKANES.

**paraffin wax** *See* PETROLEUM.

**paraformaldehyde** *See* METHANAL.

**parahydrogen** *See* HYDROGEN.

**paraldehyde** *See* ETHANAL.

**parallax 1.** An apparent displacement of a distant object (with respect to a more distant background) when viewed from two different positions. If such an object is viewed from two points at either end of a base line, the angle between the lines joining the object to the ends of the base line is the **angle of parallax**. If the base line is the distance between the two eyes of an observer the angle is called the **binocular parallax**. **2.** The angular displacement in the apparent position of a celestial body when observed from two different points. **Diurnal parallax** results from the earth's daily rotation, the celestial body being viewed from the surface of the earth rather than from its centre. **Annual parallax** is caused by the earth's motion round the sun, the celestial body being viewed from the earth rather than from the centre of the sun. **Secular parallax** is caused by the motion of the solar system relative to the fixed stars.

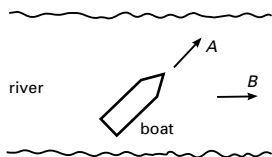

**parallel circuits** A circuit in which the circuit elements are connected so that the current divides between them. For resistors in parallel, the total resistance,  $R$ , is given by  $1/R = 1/r_1 + 1/r_2 + 1/r_3 \dots$ , where  $r_1$ ,  $r_2$ , and  $r_3$  are the resistances of the individual elements. For capacitors in parallel, the total capacitance,  $C$ , is given by  $C = C_1 + C_2 + C_3 \dots$

**parallelepiped (paralleloiped)** A solid with six faces, all of which are parallelograms.

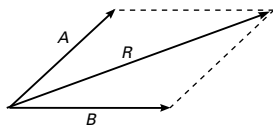

**parallel evolution** The development of related organisms along similar evolutionary paths due to strong selection pressures acting on all of them in the same way. It is debatable if the phenomenon really exists: many argue that all evolution is ultimately \*convergent or divergent (*see* ADAPTIVE RADIATION).

**parallelogram of forces** *See* PARALLELOGRAM OF VECTORS.

**parallelogram of vectors** A method

$A$  is the velocity of the boat with respect to the water;  $B$  is the velocity of the water with respect to the bank

$R$  is the resultant velocity of the boat with respect to the bank

#### Parallelogram of velocities

of determining the \*resultant of two \*vector quantities. The two vector quantities are represented by two adjacent sides of a parallelogram and the resultant is then the diagonal through their point of intersection. The magnitude and direction of the resultant is found by scale drawing or by trigonometry. The method is used for such vectors as forces (**parallelogram of forces**) and velocities (**parallelogram of velocities**). See illustration.

**parallelogram of velocities** See PARALLELOGRAM OF VECTORS.

**parallel processing** A technique that allows more than one process - stream of activity - to be running at any given moment in a computer system, hence processes can be executed in parallel. This means that two or more processors are active among a group of processes at any instant.

**parallel spins** Neighbouring spinning electrons in which the \*spins, and hence the magnetic moments, of the electrons are aligned in the same direction. The interaction between the magnetic moments of electrons in atoms is dominated by exchange interactions (see EXCHANGE FORCE). Under some circumstances the exchange interactions between magnetic moments favour parallel spins, while under other conditions they favour \*antiparallel spins. The case of ferromagnetism (see MAGNETISM) is an example of a system with parallel spins.

**paramagnetism** See MAGNETISM.

**parametric equation** An equation of a curve expressed in the form of the parameters that locate points on the curve. The parametric equations of a straight line are

$x = a + bt$ ,  $y = c + dt$ . For a circle, they are  $x = a \cos \theta$ ,  $y = a \sin \theta$ .

**paraphyletic** See MONOPHYLETIC.

**parapositronium** See POSITRONIUM.

**parasitic capture** The absorption of a neutron by a nuclide that does not result in either fission or a useful artificial element.

**parasitism** An association in which one organism (the **parasite**) lives on (**ectoparasitism**) or in (**endoparasitism**) the body of another (the \*host), from which it obtains its nutrients. Some parasites inflict comparatively little damage on their host, but many cause characteristic diseases (these are, however, never immediately fatal, as killing the host would destroy the parasite's source of food). Parasites are usually highly specialized for their way of life, which may involve one host or several (if the \*life cycle requires it). They typically produce vast numbers of eggs, very few of which survive to find their way to another suitable host. **Obligate parasites** can only survive and reproduce as parasites; **facultative parasites** can also live as \*saprotrophs. The parasites of humans include fleas and lice (which are ectoparasites), various bacteria, protozoans, and fungi (endoparasites causing characteristic diseases), and tapeworms (e.g. *Taenia solium*, which lives in the gut).

#### parasympathetic nervous system

Part of the \*autonomic nervous system. Its nerve endings release acetylcholine as a \*neurotransmitter and its actions tend to antagonize those of the \*sympathetic nervous system. For example, the parasympathetic nervous system increases salivary gland secretion, decreases heart rate, promotes digestion (by increasing

\*peristalsis), and dilates blood vessels, while the sympathetic nervous system has opposite effects.

**parathyroid glands** Two pairs of \*endocrine glands situated behind, or embedded within, the thyroid gland in higher vertebrates. They produce \*parathyroid hormone, which controls the amount of calcium in the blood. *See also* C CELL.

**parathyroid hormone (PTH; parathormone; parathyrin)** A peptide hormone secreted by the \*parathyroid gland in response to low levels of calcium in the blood. It acts to maintain normal blood levels of calcium by (1) increasing the number of osteoclasts, cells that break down the bone matrix and release calcium into the blood; (2) increasing the re-absorption of calcium and magnesium ions in the kidney tubules, so that their concentration is maintained in the blood; (3) converting \*vitamin D to its active form, which increases calcium absorption in the intestine. Parathyroid hormone acts in opposition to \*calcitonin.

**paraxial ray** A ray of light that falls on a reflecting or refracting surface close to and almost parallel to the axis. It is for such rays that simple lens theory can be developed, by means of making small angle approximations.

**parenchyma** **1.** A plant tissue consisting of roughly spherical relatively undifferentiated cells, frequently with air spaces between them. The cortex and pith are composed of parenchyma cells (*see* GROUND TISSUES). **2.** Loose \*connective tissue formed of large cells. Its function is to pack the spaces between organs in some simple acoelomate animals, such as flatworms (Platyhelminthes).

**parent** **1.** (in biology) **a.** Either male or female partner that together produce offspring in the process of sexual reproduction. *See also* P. **b.** Denoting an organism or cell that gives rise to new organisms or cells, as by asexual reproduction or cell division. **2.** (in physics) *See* DAUGHTER.

**parity** Symbol  $P$ . The property of a \*wave function that determines its behaviour when all its spatial coordinates are reversed in direction, i.e. when  $x, y, z$  are replaced by  $-x, -y, -z$ . If a wave function

$\psi$  satisfies the equation  $\psi(x, y, z) = \psi(-x, -y, -z)$  it is said to have even parity, if it satisfies  $\psi(x, y, z) = -\psi(-x, -y, -z)$  it has odd parity. In general,

$$\psi(x, y, z) = P\psi(-x, -y, -z),$$

where  $P$  is a quantum number called parity that can have the value +1 or -1. The principle of **conservation of parity** (or **space-reflection symmetry**) would hold if all physical laws could be stated in a coordinate system independent of left- or right-handedness. If parity was conserved there would therefore be no fundamental way of distinguishing between left and right. In electromagnetic and strong interactions, parity is, in fact, conserved. In 1956, however, it was shown that parity is not conserved in weak interactions. In the beta decay of cobalt-60, for example, the electrons from the decay are emitted preferentially in a direction opposite to that of the cobalt spin. This experiment provides a fundamental distinction between left and right.

**parsec** A unit of length used to express astronomical distance. The distance at which the mean radius of the earth's orbit subtends an angle of one second of arc. One parsec is equal to  $3.0857 \times 10^{16}$  metres or 3.2616 light years.

**parthenocarpy** The formation of fruit without prior fertilization of the flower by pollen. The resulting fruits are seedless and therefore do not contribute to the reproduction of the plant; examples are bananas and pineapples. Plant \*growth substances may have a role in this phenomenon, which can be induced by auxins in the commercial production of tomatoes and other fruits.

**parthenogenesis** The development of an organism from an unfertilized egg. This occurs sporadically in many plants (e.g. dandelions and hawkweeds) and in a few animals, but in some species it is the main and sometimes only method of reproduction. For example, in some species of aphid, males are absent or very rare. The eggs formed by the females contain the full (diploid) number of chromosomes and are genetically identical. Variation is consequently very limited in species that reproduce parthenogenetically.

**partial** A simple component of a complex tone. When a musical instrument produces a note, say, middle C, it will produce a complex tone in which the fundamental frequency is mixed with a number of partials. Some of these partials, for example, if the note is produced by bowing a taut string, will be \*harmonics, i.e. integral multiples of the fundamental. If the string is struck, however, some of the partials can be inexact multiples of the fundamental. Partial s are not therefore identical with harmonics.

**partial derivative** The infinitesimal change in a function consisting of two or more variables when one of the variable changes and the others remain constant. If  $z = f(x, y)$ ,  $\partial z/\partial x$  is the partial derivative of  $z$  with respect to  $x$ , while  $y$  remains unchanged. A **partial differential equation**, such as the \*Laplace equation, is an equation containing partial derivatives of a function.

**partial eclipse** See ECLIPSE.

**partial pressure** See DALTON'S LAW.

**particle 1.** (in physics) One of the fundamental components of matter. See ELEMENTARY PARTICLES. **2.** (in mechanics) A hypothetical body that has mass but no physical extension. As it is regarded as having no volume, a particle is incapable of rotation and therefore can only have translational motion. Thus a real body may often, for translational purposes, be regarded as a particle located at the body's centre of mass and having a mass equal to that of the whole body.

**particle physics** The study of \*elementary particles.

**particulate inheritance** The transmission from parent to offspring of separate units that determine characteristics. Gregor Mendel observed that \*recessive characteristics, absent in the offspring of a cross in which only one parent possessed them, reappeared repeatedly in the progeny of subsequent crosses. This led him to formulate his theory of inherited 'factors' (now called \*alleles) that retain their identity through succeeding generations (see MENDEL'S LAWS). Compare BLENDING INHERITANCE.

**partition** If a substance is in contact with two different phases then, in general, it will have a different affinity for each phase. Part of the substance will be absorbed or dissolved by one and part by the other, the relative amounts depending on the relative affinities. The substance is said to be **partitioned** between the two phases. For example, if two immiscible liquids are taken and a third compound is shaken up with them, then an equilibrium is reached in which the concentration in one solvent differs from that in the other. The ratio of the concentrations is the **partition coefficient** of the system. The **partition law** states that this ratio is a constant for given liquids.

**partition coefficient** See PARTITION.

**partition function** The quantity  $Z$  defined by  $Z = \sum \exp(-E_i/kT)$ , where the sum is taken over all states  $i$  of the system.  $E_i$  is the energy of the  $i$ th state,  $k$  is the \*Boltzmann constant, and  $T$  is the thermodynamic \*temperature.  $Z$  is a quantity of fundamental importance in equilibrium \*statistical mechanics. For a system in which there are non-trivial interactions, it is very difficult to calculate the partition function exactly. For such systems it is necessary to use \*approximation techniques and/or \*model systems. The partition function links results at the atomic level to \*thermodynamics, since  $Z$  is related to the Helmholtz \*free energy  $F$  by  $F = kT \ln Z$ .

**parton** A pointlike, almost free, particle postulated as a component of nucleons. The parton model enabled the results of very high-energy experiments on nucleons to be understood. See QUANTUM CHROMODYNAMICS.

**parturition** The act of giving birth to young at the end of the \*gestation period. Fetal hormones cause the process to start.

**pascal** The \*SI unit of pressure equal to one newton per square metre.

**Pascal, Blaise** (1623–62) French mathematician and physicist. An infant prodigy, he had already made a mechanical calculating machine by 1642. In physics he formulated \*Pascal's law concerning fluid pressure and the principle behind the hy-

draulic press. The SI unit of pressure is named after him.

**Pascal's law** In a confined fluid, externally applied pressure is transmitted uniformly in all directions. In a static fluid, force is transmitted at the speed of sound throughout the fluid and acts at right angles to any surface in or bounding the fluid. This principle is made use of in the hydraulic jack, the pneumatic tyre, and similar devices. The law was discovered in 1647 by Blaise Pascal.

**Pascal's triangle** A triangular array of numbers in which each number is the sum of the two numbers immediately above it (except for the 1s):

```

      1
     1 1
    1 2 1
   1 3 3 1
  1 4 6 4 1
 1 5 10 10 5 1
1 6 15 20 15 6 1
1 7 21 35 35 21 7 1

```

and so on. The numbers in each row are the coefficients of the expansion of the binomial  $(x + y)^n$  (see BINOMIAL THEOREM). It is named after Blaise Pascal.

**Paschen-Back effect** An effect in atomic line spectra that occurs when the atoms are placed in a strong magnetic field. Spectral lines that give the anomalous Zeeman effect when the atoms are placed in a weaker magnetic field have a different splitting pattern in a very strong magnetic field in which the spectral lines go back to the pattern of the normal Zeeman effect. The Paschen-Back effect is named after the German physicists Louis Paschen (1865-1947) and Ernest Back (1881-1959), who discovered it in 1912.

**Paschen series** See HYDROGEN SPECTRUM.

**passive** Describing a solid that has reacted with another substance to form a protective layer, so that further reaction stops. The solid is said to have been 'rendered passive'. For example, aluminium reacts spontaneously with oxygen in air to form a thin layer of aluminium oxide, which prevents further oxidation. Similarly, pure iron forms a protective oxide

layer with concentrated nitric acid and is not dissolved further.

**passive device** **1.** An electronic component, such as a capacitor or resistor, that is incapable of amplification. **2.** An artificial satellite that reflects an incoming signal without amplification. **3.** A solar-power device that makes use of an existing structure to collect and utilize solar energy without the use of pumps, fans, etc. **4.** A radar device that provides information for navigation, guidance, surveillance, etc., by receiving the microwave radiation. Such a passive device emits no microwave energy itself and therefore does not disclose its position. **5.** A system that detects an object by the radiation that it emits, rather than by reflecting radiation off it, as in a passive infrared detector (**PIT detector**). Compare ACTIVE DEVICE.

**passive immunity** See IMMUNITY.

**passive transport** See DIFFUSION.

**Pasteur, Louis** (1822-95) French chemist and microbiologist, who held appointments in Strasbourg (1849-54) and Lille (1854-57), before returning to Paris to the Ecole Normale and the Sorbonne. From 1888 to his death he was director of the Pasteur Institute. In 1848 he discovered optical activity, in 1860 relating it to molecular structure. In 1856 he began work on fermentation, and by 1862 was able to disprove the existence of spontaneous generation. He introduced pasteurization (originally for wine) in 1863. He went on to study disease and developed vaccines against cholera (1880), anthrax (1882), and rabies (1885).

**pasteurization** The treatment of milk to destroy disease-causing bacteria, such as those of tuberculosis, typhoid, and brucellosis. Milk is heated to 65°C for 30 minutes or to 72°C for 15 minutes followed by rapid cooling to below 10°C. The method was devised by the French microbiologist Louis Pasteur (1822-95).

**patella (kneecap)** A small rounded movable bone that is situated in a tendon in front of the knee joint in most mammals (including humans). The function of the patella is to protect the knee.

**path integral formulation** A formulation of quantum mechanics put forward by Richard Feynman in 1942 in which all the possible paths a particle in a quantum mechanical system can take, weighted by the probability of each path occurring, are added up. Path integrals have been used extensively, both in analysing the foundations of quantum mechanics and in solving certain types of problem.

**pathogen** Any disease-causing microorganism. Pathogens include viruses, rickettsiae, and many bacteria, fungi, and protozoans. *See* INFECTION.

**pathology** The study of the changes in organs and tissues that are caused by or give rise to disease. This involves the examination of tissue samples, X-ray photographs, or other evidence taken from living patients or from cadavers. **Clinical pathology** applies these findings to clinical cases, particularly in the development of diagnostic tests and treatments. In **experimental pathology**, disease processes are studied using experimental animals, cell cultures, or other means.

**patristic** Denoting similarity between organisms resulting from common ancestry. *Compare* HOMOPLASY.

**Pauli, Wolfgang Ernst** (1900–58) Austrian-born Swiss physicist. After studying with Niels \*Bohr and Max Born, he taught at Heidelberg and, finally Zurich. His formulation in 1925 of the \*Pauli exclusion principle explained the electronic make-up of atoms. For this work he was awarded the 1945 Nobel Prize for physics. In 1930 he predicted the existence of the \*neutrino, which was finally discovered in 1956 by Clyde Cowan (1919– ) and Fredrick Reines (1918– ).

**Pauli exclusion principle** The quantum-mechanical principle, applying to fermions but not to bosons, that no two identical particles in a system, such as electrons in an atom or quarks in a hadron, can possess an identical set of quantum numbers. It was first formulated by Wolfgang Pauli in 1925. The origin of the Pauli exclusion principle lies in the \*spin-statistics theorem of relativistic quantum field theory.

**Pauling, Linus Carl** (1901–94) US

chemist. After spending two years in Europe, he became a professor at the Californian Institute of Technology. His original work was on chemical bonding; in the mid-1930s he turned to the structure of proteins, for which he was awarded the 1954 Nobel Prize for chemistry. He was also an active campaigner against nuclear weapons and in 1962 was awarded the Nobel Peace Prize.

**Pavlov, Ivan Petrovich** (1849–1936) Russian physiologist, who became professor of physiology in St Petersburg in 1886. While working on the physiology of digestion he discovered that the mere sight of food stimulates the production of digestive juices. For this work he was awarded the 1904 Nobel Prize for physiology or medicine. Pavlov went on to demonstrate operant \*conditioning in dogs and other animals. *See also* LEARNING (Feature).

**p-block elements** The block of elements in the periodic table consisting of the main groups 13 (B to Tl), 14 (C to Pb), 15 (N to Bi), 16 (O to Po), 17 (F to At) and 18 (He to Rn). The outer electronic configurations of these elements all have the form  $ns^2np^x$  where  $x = 1$  to 6. Members at the top and on the right of the p-block are nonmetals (C, N, P, O, F, S, Cl, Br, I, At). Those on the left and at the bottom are metals (Al, Ga, In, Tl, Sn, Pb, Sb, Bi, Po). Between the two, from the top left to bottom right, lie an ill-defined group of metalloid elements (B, Si, Ge, As, Te).

**PC** *See* PERSONAL COMPUTER.

**PCB** *See* POLYCHLORINATED BIPHENYL.

**PCR** *See* POLYMERASE CHAIN REACTION.

**p.d. (potential difference)** *See* ELECTRIC POTENTIAL.

**PDGF** *See* GROWTH FACTOR.

**peacock ore** *See* BORNITE.

**pearl ash** *See* POTASSIUM CARBONATE.

**pearlite** *See* STEEL.

**peat** A mass of dark-brown or black fibrous plant debris produced by the partial disintegration of vegetation in wet places. It may accumulate in depressions. When subjected to burial and hence pressure and heat it may be converted to

\*coal. Peat is used to improve soil and as a fuel, especially in Ireland and Sweden.

**pebi-** See BINARY PREFIXES.

**peck order** See DOMINANT.

**pecten** Any of various comblike structures in animals. The pecten in the eyes of birds consists essentially of a network of blood vessels attached to the optic nerve and projecting into the vitreous humour. Its function is uncertain, but it may be involved in supplying the retina with nutrients and oxygen. A simple form of this structure is found in the eyes of reptiles.

**pectic substances** A group of polysaccharides made up primarily of sugar acids. They are important constituents of plant cell walls and the \*middle lamella between adjacent cell walls. Normally they are present in an insoluble form, but in ripening fruits and in tissues affected by certain diseases they change into a soluble form, which is evidenced by softening of the tissues.

**pectin** A type of \*pectic substance. It is used in making jam as it forms a gel with sucrose.

**pectoral fins** See FINS.

**pectoral girdle (shoulder girdle)** The bony or cartilaginous structure in vertebrates to which the anterior limbs (pectoral fins, forelegs, or arms) are attached. In mammals it consists of two dorsal \*scapulae (shoulder blades) attached to the backbone and two ventral \*clavicles (collar bones) attached to the sternum (breastbone).

**pedicel** The stalk attaching a flower to the main floral axis (see PEDUNCLE). Some flowers, described as **sessile**, do not have a pedicel and arise directly from the peduncle.

**pedology** The science of the study of soils, including their origin and characteristics and their utilization.

**peduncle** The main stalk of a plant that bears the flowers, which may be solitary or grouped in an \*inflorescence. Compare PEDICEL.

**pegmatite** Very coarse-grained igneous rock. Granite pegmatite, the commonest

type, consists chiefly of alkali feldspar and quartz; accessory minerals, such as mica, tourmaline, topaz, beryl, fluorite, cassiterite, and garnet, may also be present. Many pegmatites are thus economically important as sources of these minerals. The individual crystals may be extremely large; for example, mica and quartz crystals over 3 m in length have been found.

**pelagic** Describing organisms that swim or drift in a sea or a lake, as distinct from those that live on the bottom (see BENTHOS). Pelagic organisms are divided into \*plankton and \*nekton.

**Pelecypoda** See BIVALVIA.

**pellagra** A disease resulting from a deficiency of \*nicotinic acid, which is characterized by dermatitis and mental disorder.

**pellicle** The thin outer covering, composed of protein, that protects and maintains the shape of certain unicellular organisms, e.g. *Euglena*. It is transparent and in ciliated organisms, e.g. *Paramecium*, contains small pores through which the cilia emerge.

**Peltier effect** The change in temperature produced at a junction between two dissimilar metals or semiconductors when an electric current passes through the junction. The direction of the current determines whether the temperature rises or falls. The first metals to be investigated were bismuth and copper; if the current flows from bismuth to copper the temperature rises. If the current is reversed the temperature falls. The effect was discovered in 1834 by Jean Peltier (1785–1845) and has been used recently for small-scale refrigeration. Compare SEEBECK EFFECT.

**pelvic fins** See FINS.

**pelvic girdle (pelvis; hip girdle)** The bony or cartilaginous structure in vertebrates to which the posterior limbs (pelvic fins or legs) are attached. The pelvic girdle articulates dorsally with the backbone; it is made up of two halves, each produced by the fusion of the \*ilium, \*ischium, and \*pubis.

**pelvis** **1.** See PELVIC GIRDL. **2.** The lower part of the abdomen in the region of the pelvic girdle. **3.** A conical chamber in the \*kidney into which urine drains from the

kidney tubules before passing to the \*ureter.

**pen drive** See USB DRIVE.

**pendulum** Any rigid body that swings about a fixed point. The **ideal simple pendulum** consists of a bob of small mass oscillating back and forth through a small angle at the end of a string or wire of negligible mass. Such a device has a period  $2\pi\sqrt{l/g}$ , where  $l$  is the length of the string or wire and  $g$  is the \*acceleration of free fall. This type of pendulum moves with \*simple harmonic motion.

The **compound pendulum** consists of a rigid body swinging about a point within it. The period of such a pendulum is given by

$$T = 2\pi\sqrt{(h^2 + k^2)/hg},$$

where  $k$  is the radius of gyration about an axis through the centre of mass and  $h$  is the distance from the pivot to the centre of mass. See also KATER'S PENDULUM.

**penicillin** An \*antibiotic derived from the mould *Penicillium notatum*; specifically it is known as **penicillin G** (benzylpenicillin) and belongs to a class of similar substances called penicillins. They are all active against a wide variety of bacteria, producing their effects by disrupting synthesis of the bacterial cell wall, and are used to treat a variety of infections caused by these bacteria.

**penis** The male reproductive organ of mammals (and also of some birds and reptiles) used to introduce sperm into the female reproductive tract to ensure internal fertilization. It contains a duct (the \*urethra) through which the sperms pass. The penis becomes erect during precopulatory activity, either by filling with blood or haemolymph or by the action of muscles, and can be inserted into the vagina (or cloaca). In mammals the urine also leaves the body through the penis.

**Penrose, Sir Roger** See HAWKING, STEPHEN WILLIAM.

**Penrose process** A process by which the rotational energy of a rotating black hole can be extracted. An object close to the event horizon may split into two particles. One, with negative energy, falls into the black hole, causing the rotation

rate to decrease. The other, with positive rotation, moves away. The result is that energy is extracted at the expense of rotational energy of the black hole. This process was suggested by Sir Roger Penrose in 1969. See also BLANDFORD-ZNAJEK PROCESS.

**pentadactyl limb** A limb with five digits, characteristic of tetrapod vertebrates (amphibians, reptiles, birds, and mammals). It evolved from the paired fins of primitive fish as an adaptation to locomotion on land and is not found in modern fish. The limb has three parts (see illustration): the upper arm or thigh containing one long bone, the forearm or shank containing two long bones, and the hand or foot, which contains a number of small bones. This basic design is modified in many species, according to the function of the limb, particularly by the loss or fusion of the terminal bones.

**pentahydrate** A crystalline hydrate that has five moles of water per mole of compound.

**pentane** A straight-chain alkane hydrocarbon,  $C_5H_{12}$ ; r.d. 0.63; m.p.  $-129.7^\circ C$ ; b.p.  $36.1^\circ C$ . It is obtained by distillation of petroleum.

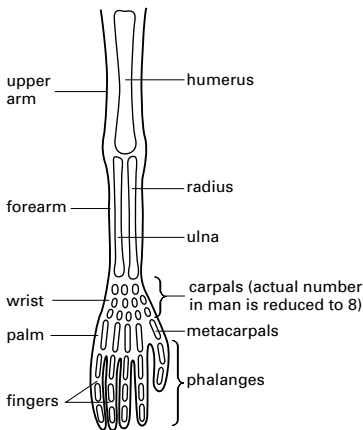

**pentanoic acid (valeric acid)** A colourless liquid \*carboxylic acid,  $CH_3(CH_2)_3COOH$ ; r.d. 0.9; m.p.  $-34^\circ C$ ; b.p.  $186.05^\circ C$ . It is used in the perfume industry.

**pentaquark** A long-lived particle consisting of five quarks with a mass of just over 1500 MeV, which has been predicted to exist. There is some evidence for the existence of this particle but, at present, this evidence is not conclusive.

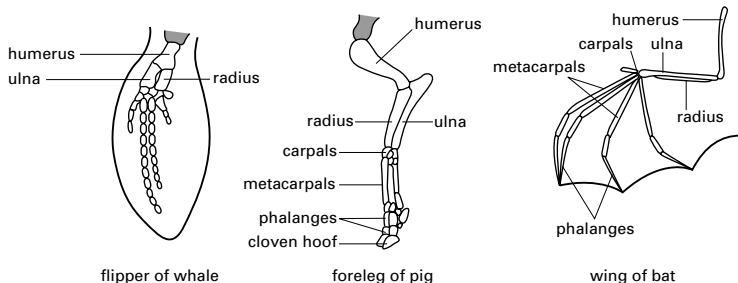

**pentavalent (quinquevalent)** Having a valency of five.

**pentlandite** A mineral consisting of a mixed iron-nickel sulphide,  $(Fe,Ni)_5S_8$ , crystallizing in the cubic system; the chief ore of nickel. It is yellowish-bronze in colour with a metallic lustre. The chief occurrence of the mineral is at Sudbury in Ontario, Canada.

**pentode** A \*thermionic valve with a **suppressor grid** between the anode and the screen grid of a tetrode. Its purpose is to suppress the loss of electrons from the

A basic pentadactyl forelimb, as exemplified by the human arm

The modified pentadactyl forelimb of various vertebrates

anode as a result of secondary emission. The suppressor grid is maintained at a negative potential relative to the anode and to the screen grid.

**pentose** A sugar that has five carbon atoms per molecule. See MONOSACCHARIDE.

**pentose phosphate pathway (pentose shunt)** A series of biochemical reactions that results in the conversion of glucose 6-phosphate to ribose 5-phosphate and generates NADPH, which provides reducing power for other metabolic reactions, such as synthesis of fatty acids. Ribose 5-phosphate and its derivatives are components of such molecules as ATP,

coenzyme A, NAD, FAD, DNA, and RNA. In plants the pentose phosphate pathway also plays a role in the synthesis of sugars from carbon dioxide. In animals the pathway occurs at various sites, including the liver and adipose tissue.

**pentyl group or radical** The organic group  $\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\cdot$ , derived from pentane.

**penumbra** See SHADOW.

**pepo** See BERRY.

**pepsin** An enzyme that catalyses the breakdown of proteins to polypeptides in the vertebrate stomach. It is secreted as an inactive precursor, \*pepsinogen.

**pepsinogen** The inactive precursor of the enzyme \*pepsin. Pepsinogen is secreted by the lining of the vertebrate stomach into the lumen, where it is converted to pepsin by hydrochloric acid and also by the action of pepsin itself.

**peptidase** See ENDOPEPTIDASE; EXOPEPTIDASE; PROTEASE.

**peptide** Any of a group of organic compounds comprising two or more amino acids linked by **peptide bonds**. These bonds are formed by the reaction between adjacent carboxyl ( $-\text{COOH}$ ) and amino ( $-\text{NH}_2$ ) groups with the elimination of water (see illustration). **Dipeptides** contain two amino acids, **tripeptides** three, and so on. \*Polypeptides contain more than ten and usually 100–300. Naturally occurring **oligopeptides** (of less than ten amino acids) include the tripeptide glutathione and the pituitary hormones antidiuretic hormone and oxytocin, which are octapeptides. Peptides also result from protein breakdown, e.g. during digestion.

**per-** Prefix indicating that a chemical compound contains an excess of an element, e.g. a peroxide.

**percentile** For a random variable in \*statistics, any of the 99 values that divide its distribution such that an integral percentage of the collection lies below that value. For example, the 85th percentile is the value of a variable that has 85% of the collection below that value. The 25th percentile is called the lower **quartile**, the 50th percentile is the **median**, and the 75th percentile is the upper quartile.

**perchlorate** See CHLORATES.

**perchloric acid** See CHLORIC(VII) ACID.

**perdisulphuric acid** See PEROXOSULPHURIC(VI) ACID.

**perennation** The survival of biennial or

perennial plants from one year to the next by vegetative means. In biennials and herbaceous perennials the aerial parts of the plant die down and the plants survive by means of underground storage roots (e.g. carrot), \*rhizomes (e.g. couch grass, Solomon's seal), \*tubers (e.g. dahlia), \*bulbs (e.g. daffodil, snowdrop), or \*corms (e.g. crocus, gladiolus). These **perennating organs** are also frequently responsible for \*vegetative propagation. Woody perennials survive the winter by reducing their metabolic activity (e.g. by leaf loss in deciduous trees and shrubs).

**perennial** A plant that lives for a number of years. Woody perennials (trees and shrubs) have a permanent aerial form, which continues to grow year after year. Herbaceous (i.e. nonwoody) perennials have aerial shoots that die down each autumn and are replaced in spring by new shoots from an underground structure (see PERENNATION). Lupin and rhubarb are examples of herbaceous perennials. Compare ANNUAL; BIENNIAL; EPHEMERAL.

**perfect gas** See IDEAL GAS; GAS.

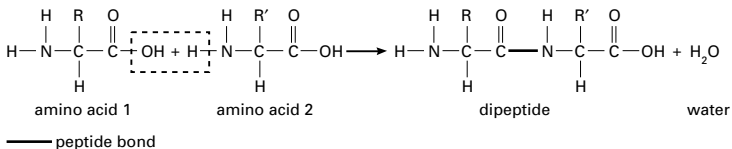

**perfect pitch** See ABSOLUTE PITCH.

**perfect solution** See RAOULT'S LAW.

**perianth** The part of a flower situated outside the stamens and carpels. In dicotyledons it consists of two distinct whorls, the outer of sepals (see CALYX) and the inner of petals (see COROLLA). In monocotyledons the two whorls are similar and often brightly coloured. In wind-pollinated flowers both whorls may be reduced or absent. In many horticultural varieties the number of perianth parts is multiplied, but the resulting 'double' flowers are often sterile.

**periastron** See APASTRON.

**pericardial cavity** The cavity in verte-

Formation of a peptide bond

brates that contains the heart and is bounded by a membrane (the \*pericardium). It is part of the \*coelom.

**pericardium (pericardial membrane)**

The membrane that encloses the pericardial cavity, containing the vertebrate heart. The pericardium holds the heart in position while allowing it to relax and contract. It consists of two main parts: a tough outer fibrous layer (**fibrous pericardium**) and the more delicate **serous pericardium**, which consists of a double layer of \*serous membrane, the inner layer being in close contact with the heart.

**pericarp (fruit wall)** The part of a fruit that develops from the ovary wall of a flower. The type of fruit that develops depends on whether the pericarp becomes dry and hard or soft and fleshy. The pericarp can be made up of three layers. The outer skin (**epicarp** or **exocarp**) may be tough and hard; the middle layer (**mesocarp**) may be succulent as in peach, hard as in almond, or fibrous as in coconut; and the inner layer (**endocarp**) may be hard and stony as in many \*drupes, membranous as in citrus fruits, or indistinguishable from the mesocarp, as in many \*berries.

**pericycle** A plant tissue comprising the outermost layer of the root vascular tissue, lying immediately beneath the \*endodermis. Lateral roots originate from the pericycle.

**pericynthion** The point in the orbit around the moon of a satellite launched from the earth that is nearest to the moon. For a satellite launched from the moon the equivalent point is the **perilune**. Compare APOCYNTHION.

**periderm** See CORK CAMBIUM.

**perigee** See APOGEE.

**perihelion** The point in the orbit of a planet, comet, or artificial satellite in solar orbit at which it is nearest to the sun. The earth is at perihelion on about 3 January. Compare APHELION.

**perilymph** The fluid of the \*inner ear that fills the space between the bony labyrinth and the membranous labyrinth. Compare ENDOLYMPH.

**period 1.** The time taken for one complete cycle of an oscillating system or wave. **2.** See PERIODIC TABLE. **3.** See MENSTRUAL CYCLE. **4.** See GEOLOGICAL TIME SCALE.

**period doubling** A mechanism for describing the transition to \*chaos in certain dynamical systems. If the force on a body produces a regular orbit with a specific \*period a sudden increase in the force can suddenly double the period of the orbit and the motion becomes more complex. The original simple motion is called a **one-cycle**, while the more complicated motion after the period doubling is called a **two-cycle**. The process of period doubling can continue until a motion called an **n-cycle** is produced. As  $n$  increases to infinity the motion becomes non-periodic. The period-doubling route to chaos occurs in many systems involving nonlinearity, including lasers and certain chaotic chemical reactions. The period-doubling route to chaos was postulated and investigated by the US physicist Mitchell Feigenbaum in the early 1980s. Routes to chaos other than period doubling also exist.

**periodic acid** See IODIC(VII) ACID.

**periodic law** The principle that the physical and chemical properties of elements are a periodic function of their proton number. The concept was first proposed in 1869 by Dimitri Mendeleev, using relative atomic mass rather than proton number, as a culmination of efforts to rationalize chemical properties by Johann Döbereiner (1817), John Newlands (1863), and Lothar Meyer (1864). One of the major successes of the periodic law was its ability to predict chemical and physical properties of undiscovered elements and unknown compounds that were later confirmed experimentally. See PERIODIC TABLE.

**periodic motion** Any motion of a system that is continuously and identically repeated. The time  $T$  that it takes to complete one cycle of an oscillation or wave motion is called the \*period, which is the reciprocal of the \*frequency. See PENDULUM; SIMPLE HARMONIC MOTION.

**periodic table** A table of elements ar-

ranged in order of increasing proton number to show the similarities of chemical elements with related electronic configurations. (The original form was proposed by Dimitri Mendeleev in 1869 using relative atomic masses.) In the modern **short form**, the \*lanthanoids and \*actinoids are not shown. The elements fall into vertical columns, known as **groups**. Going down a group, the atoms of the elements all have the same outer shell structure, but an increasing number of inner shells. Traditionally, the alkali metals were shown on the left of the table and the groups were numbered IA to VIIA, IB to VIIB, and 0 (for the noble gases). All the elements in the middle of the table are classified as \*transition elements and the nontransition elements are regarded as **main-group** elements. Because of confusion in the past regarding the numbering of groups and the designations of subgroups, modern practice is to number the groups across the table from 1 to 18 (see Appendix). Horizontal rows in the table are **periods**. The first three are called **short periods**; the next four (which include transition elements) are **long periods**. Within a period, the atoms of all the elements have the same number of shells, but with a steadily increasing number of electrons in the outer shell. The periodic table can also be divided into four **blocks** depending on the type of shell being filled: the \*s-block, the \*p-block, the \*d-block, and the \*f-block.

There are certain general features of chemical behaviour shown in the periodic table. In moving down a group, there is an increase in metallic character because of the increased size of the atom. In going across a period, there is a change from metallic (electropositive) behaviour to nonmetallic (electronegative) because of the increasing number of electrons in the outer shell. Consequently, metallic elements tend to be those on the left and towards the bottom of the table; non-metallic elements are towards the top and the right.

There is also a significant difference between the elements of the second short period (lithium to fluorine) and the other elements in their respective groups. This is because the atoms in the second period are smaller and their valence electrons are shielded by a small  $1s^2$  inner shell.

Atoms in the other periods have inner s- and p-electrons shielding the outer electrons from the nucleus. Moreover, those in the second period only have s- and p-orbitals available for bonding. Heavier atoms can also promote electrons to vacant d-orbitals in their outer shell and use these for bonding. See also DIAGONAL RELATIONSHIP; INERT-PAIR EFFECT.

**periodontal membrane** The membrane of connective tissue that surrounds the root of a \*tooth and anchors it to its socket in the jawbone. Fibres of the periodontal membrane pass into the \*cement covering the root, which provides a firm attachment.

**periosteum** The outer membrane that surrounds a bone. It contains connective tissue, capillaries, nerves, and a number of types of bone cell. The periosteum plays an important role in bone repair and growth.

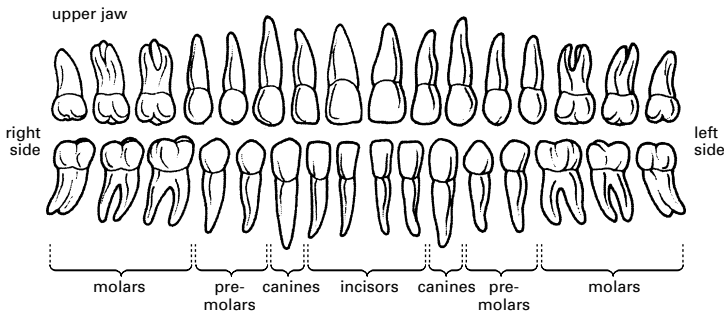

**peripheral device** Any device, such as an input or output device, connected to the central processing unit of a \*computer. Backing store is also usually regarded as a peripheral.

**peripheral nervous system** All parts of the nervous system excluding the \*central nervous system. It consists of all the \*cranial and \*spinal nerves and their branches, which link the \*receptors and \*effectors with the central nervous system. See also AUTONOMIC NERVOUS SYSTEM.

**periscope** An optical device that enables an observer to see over or around opaque objects. The simplest type consists of a long tube with mirrors at each end set at  $45^\circ$  to the direction to be viewed. A better type uses internally reflecting prisms instead of plane mirrors. Periscopes are used in tanks (to enable the observer to see over obstacles without being shot at) and in submarines (when the vessel is submerged). Such periscopes are usually quite complicated instruments and include telescopes.

**Perissodactyla** An order of mammals having hooved feet with an odd number of toes. They are all herbivores and include the tapirs, rhinoceros, and horse. The teeth are large and specialized for grinding. Cellulose digestion occurs in the

Permanent teeth of an adult human

caecum and large intestine. Fossils of the Eocene epoch, 60 million years ago, show that these animals were at that time already distinct from the cloven-hoofed \*Artiodactyla.

**peristalsis** Waves of involuntary muscular contraction and relaxation that pass along the alimentary canal, forcing food contents along. It is brought about by contraction of the circular muscles of the gut wall in sequence.

**peristome 1.** A ring of toothlike structures around the opening of a moss \*capsule. The teeth tend to bend and twist in dry weather, so opening the mouth of the capsule and allowing the spores to escape. In wet weather they close over the opening of the capsule. **2.** The area around the mouth in many invertebrates. It sometimes assists in food collecting. Examples are the spirally ciliated groove around the mouth of some ciliate protozoans and the first segment of the earthworm.

**peritoneum** The thin layer of tissue (see SEROUS MEMBRANE) that lines the abdominal cavity of vertebrates and covers the abdominal organs. *See also* MESENTERY.

**Perkin, Sir William Henry** (1838–1907) British chemist, who while still a student accidentally produced mauvine, the first aniline dye and the first dyestuff to be synthesized. Perkin built a factory to produce it, and made a fortune.

**permafrost** Permanently frozen soil and subsoil that occurs in arctic, subarc-

tic, and alpine regions. It ranges from 30 cm to over 1000 m thick and covers nearly a fifth of the land surface of the earth. In summer the top few centimetres may thaw, forming pools of meltwater (which cannot drain through the frozen soil beneath).

**Permalloys** A group of alloys of high magnetic permeability consisting of iron and nickel (usually 40–80%) often with small amounts of other elements (e.g. 3–5% molybdenum, copper, chromium, or tungsten). They are used in thin foils in electronic transformers, for magnetic shielding, and in computer memories.

**permanent gas** A gas, such as oxygen or nitrogen, that was formerly thought to be impossible to liquefy. A permanent gas is now regarded as one that cannot be liquefied by pressure alone at normal temperatures (i.e. a gas that has a critical temperature below room temperature).

**permanent hardness** *See* HARDNESS OF WATER.

**permanent magnet** *See* MAGNET.

**permanent teeth** The second and final set of teeth that mammals produce after shedding the \*deciduous teeth. An adult human normally has 32 permanent teeth, consisting of incisors, canines, molars, and premolars (see illustration). These usually appear between the ages of approximately 6 and 21 years. *See also* DENTAL FORMULA; DIPHODONT.

**permanganate** *See* MANGANATE(VII).

**permeability (magnetic permeability)**

Symbol  $\mu$ . The ratio of the magnetic flux density,  $B$ , in a substance to the external field strength,  $H$ ; i.e.  $\mu = B/H$ . The permeability of free space,  $\mu_0$ , is also called the **magnetic constant** and has the value  $4\pi \times 10^{-7} \text{ H m}^{-1}$  in \*SI units. The relative permeability of a substance,  $\mu_r$ , is given by  $\mu/\mu_0$  and is therefore dimensionless. See MAGNETISM.

**Permian** The last geological period in the Palaeozoic era. It extended from the end of the Carboniferous period, about 286 million years ago, to the beginning of the Mesozoic era, about 248 million years ago. It was named by the British geologist Roderick Murchison (1792–1871) in 1841 after the Perm province in Russia. In some areas continental conditions prevailed, which continued into the following period, the Triassic. These conditions resulted in the deposition of the New Red Sandstone. During the period a number of animal groups became extinct, including the trilobites, tabulate and rugose corals, and blastoids (see MASS EXTINCTION). Amphibians and reptiles continued to be the dominant land animals and gymnosperms replaced ferns, clubmosses, and horsetails as the dominant plants.

**permittivity** Symbol  $\epsilon$ . The ratio of the \*electric displacement in a medium to the intensity of the electric field producing it. It is important for electrical insulators used as \*dielectrics.

If two charges  $Q_1$  and  $Q_2$  are separated by a distance  $r$  in a vacuum, the force  $F$  between the charges is given by:

$$F = Q_1 Q_2 / r^2 4\pi\epsilon_0$$

In this statement of \*Coulomb's law using \*SI units,  $\epsilon_0$  is called the absolute permittivity of free space, which is now known as the **electric constant**. It has the value  $8.854 \times 10^{-12} \text{ F m}^{-1}$ .

If the medium between the charges is anything other than a vacuum the equation becomes:

$$F = Q_1 Q_2 / r^2 4\pi\epsilon$$

and the force between the charges is reduced.  $\epsilon$  is the **absolute permittivity** of the new medium. The **relative permittivity** ( $\epsilon_r$ ) of a medium, formerly called the **dielectric constant**, is given by  $\epsilon_r = \epsilon/\epsilon_0$ .

**permonosulphuric(VI) acid** See PEROXOSULPHURIC(VI) ACID.

**permutations and combinations** A combination is any subset of a particular set of objects, regardless of the order of selection. If the set consists of  $n$  objects,  $r$  objects can be selected giving  $n!/r!(n-r)!$  different combinations. This can be written  ${}_n C_r$ .

A permutation is an ordered subset (i.e. attention is paid to the order of selection or arrangement) of a particular set of objects. If the set consists of  $n$  objects,  $r$  such objects can be selected to give  $n!(n-r)!$  permutations. This is written  ${}_n P_r$ .

**Permutit** Trade name for a \*zeolite used for water softening.

**peroxides 1.** A group of inorganic compounds that contain the  $O_2^{2-}$  ion. They are notionally derived from hydrogen peroxide,  $H_2O_2$ , but these ions do not exist in aqueous solution due to extremely rapid hydrolysis to  $OH^-$ . **2.** A class of organic compounds that contain the  $-O-O-$  group. Organic peroxides tend to be unstable and some are explosive. They can be used to initiate free-radical reactions.

**peroxisome** An organelle, found in the cytoplasm of virtually all plant and animal cells, that contains several enzymes involved in oxidation processes. Peroxisomes are bound by a single membrane; the enzymes they contain include urate oxidase and catalase (which catalyses the breakdown of hydrogen peroxide, produced as a by-product of the activity of the other enzymes). Peroxisomes are active in the process of \*detoxification, being particularly abundant in the liver and in the \*proximal convoluted tubules of the kidney. In plant cells they are the main site of \*fatty-acid oxidation.

**peroxodisulphuric acid** See PEROXOSULPHURIC(VI) ACID.

**peroxomonosulphuric(VI) acid** See PEROXOSULPHURIC(VI) ACID.

**peroxosulphuric(VI) acid** The term commonly refers to **peroxomonosulphuric(VI) acid**,  $H_2SO_5$ , which is also called **permonosulphuric(VI) acid** and **Caro's acid**. It is a crystalline compound made by the action of hydrogen peroxide on concen-

trated sulphuric acid. It decomposes in water and the crystals decompose, with melting, above 45°C. The compound **peroxodisulphuric acid**,  $\text{H}_2\text{S}_2\text{O}_8$ , also exists (formerly called **perdisulphuric acid**). It is made by the high-current electrolysis of sulphate solutions. It decomposes at 65°C (with melting) and is hydrolysed in water to give the mono acid and sulphuric acid. Both peroxy acids are very powerful oxidizing agents. *See also* SULPHURIC ACID (for structural formulas).

**perpetual motion** **1.** Perpetual motion of the first kind. Motion in which a mechanism, once started, would continue indefinitely to perform useful work without being supplied with energy from an outside source. Such a device would contravene the first law of \*thermodynamics and is therefore not feasible. Many historical attempts, exercising great ingenuity, were constructed before the concept of energy and its conservation were understood. Some attempts have been made, since the first law of thermodynamics became generally accepted, by inventors seeking to establish loopholes in the laws of nature. **2.** Perpetual motion of the second kind. Motion in which a mechanism extracts heat from a source and converts all of it into some other form of energy. An example of such a mechanism would be a ship that utilized the internal energy of the oceans for propulsion. Such a device does not contravene the first law of thermodynamics but it does contravene the second law. In the case of the ship, the sea would have to be at a higher temperature than the ship to establish a useful flow of heat. This could not occur without an external energy source. **3.** Perpetual motion of the third kind. A form of motion that continues indefinitely but without doing any useful work. An example is the random molecular motion in a substance. This type postulates the complete elimination of friction. A mechanism consisting of frictionless bearings maintained in a vacuum could turn indefinitely, once started, without contravening the first or second laws of thermodynamics, provided it did no external work. Experience indicates that on the macroscopic scale such a condition cannot be achieved. On the microscopic scale,

however, a superconducting ring of wire will apparently sustain a perpetual current flow without the application of an external force. This could be considered a form of perpetual motion of the third kind, if the energy required to cool the wire to superconducting temperatures is ignored.

**personal computer** A general-purpose \*microcomputer designed for use by one person at a time. The original Personal Computer (or PC) was a highly successful product from IBM. An **IBM-compatible** computer is functionally identical to an IBM PC and able to accept all hardware and software intended for it. The abbreviation PC is now most often used to mean an IBM-compatible computer as opposed to other systems. Personal computers range widely in capability and cost. They may take the form of desktop computers or be portable versions, such as laptop, notebook, or subnotebook computers.

**Perspex** Trade name for a form of \*polymethylmethacrylate.

**perturbation** A departure by a celestial body from the trajectory or orbit it would follow if it moved only under the influence of a single central force. According to \*Kepler's law, for example, a single planet orbiting the sun would move in an elliptical orbit. In fact, planets are perturbed from elliptical orbits by the gravitational forces exerted on them by other planets. Similarly, the moon's orbit round the earth is perturbed by the gravitational effect of the sun and the trajectories of comets are perturbed when they pass close to planets.

**perturbation theory** A method used in calculations in both classical physics (e.g. planetary orbits) and quantum mechanics (e.g. atomic structure), in which the system is divided into a part that is exactly calculable and a small term, which prevents the whole system from being exactly calculable. The technique of perturbation theory enables the effects of the small term to be calculated by an infinite series (which in general is an asymptotic series). Each term in the series is a 'correction term' to the solutions of the exactly calculable system. In classical physics, perturbation theory can be used for calculat-

ing planetary orbits. In quantum mechanics, it can be used to calculate the energy levels in molecules. In the many-body problem in quantum mechanics and in relativistic quantum field theory, the terms in perturbation theory may be represented pictorially by Feynman diagrams (see QUANTUM ELECTRODYNAMICS).

**perversion** See LATERAL INVERSION.

**pest** Any of various organisms, such as fungi, insects, rodents, and plants, that harm crops or livestock or otherwise interfere with the wellbeing of human beings. **Weeds** are plant pests that grow where they are not wanted – often on cultivated land, where they compete with crop plants for space, light, nutrients, etc. Pests are controlled by the use of \*pesticides and \*biological control methods.

**pesticide** Any chemical compound used to kill pests that destroy agricultural production or are in some way harmful to humans. Pesticides include **herbicides** (such as \*2,4-D and Paraquat), which kill unwanted plants or weeds; **insecticides** (such as \*pyrethrum), which kill insect pests; **fungicides**, which kill fungi; and **rodenticides** (such as \*warfarin), which kill rodents. The problems associated with pesticides are that they are very often nonspecific and may therefore be toxic to organisms that are not pests; they may also be nonbiodegradable, so that they persist in the environment and may accumulate in living organisms (see BIOACCUMULATION). Organophosphorus insecticides, such as malathion and parathion, are biodegradable but can also damage the respiratory and nervous systems in humans as well as killing useful insects, such as bees. They act as \*anticholinesterases. Organochlorine insecticides, such as dieldrin, aldrin, and \*DDT, are very persistent and not easily biodegradable.

**peta-** Symbol P. A prefix used in the metric system to denote one thousand million million times. For example,  $10^{15}$  metres = 1 petametre (Pm).

**petal** One of the parts of the flower that make up the \*corolla. Petals of insect-pollinated plants are usually brightly coloured and often scented. Those of

wind-pollinated plants are usually reduced or absent. Petals are considered to be modified leaves but their structure is simpler. Epidermal hairs may be present and the cuticle is often covered by lines or dots known as **honey guides**, which direct insects to the \*nectar.

**Peters' projection** See MAP PROJECTIONS.

**petiole** The stalk that attaches a \*leaf blade to the stem. Leaves without petioles are described as **sessile**.

**Petri dish** A shallow circular flat-bottomed dish made of glass or plastic and having a fitting lid. It is used in laboratories chiefly for culturing bacteria and other microorganisms. It was invented by the German bacteriologist Julius Petri (1852–1921).

**petrification** See FOSSIL.

**petrochemicals** Organic chemicals obtained from petroleum or natural gas.

**petroleum** A naturally occurring oil that consists chiefly of hydrocarbons with some other elements, such as sulphur, oxygen, and nitrogen. In its unrefined form petroleum is known as **crude oil** (sometimes **rock oil**). Petroleum is believed to have been formed from the remains of living organisms that were deposited, together with rock particles and biochemical and chemical precipitates, in shallow depressions, chiefly in marine conditions. Under burial and compaction the organic matter went through a series of processes before being transformed into petroleum, which migrated from the source rock to become trapped in large underground reservoirs beneath a layer of impermeable rock. The petroleum often floats above a layer of water and is held under pressure beneath a layer of \*natural gas.

Petroleum reservoirs are discovered through geological exploration: commercially important oil reserves are detected by exploratory narrow-bore drilling. The major known reserves of petroleum are in Saudi Arabia, Russia, China, Kuwait, Iran, Iraq, Mexico, USA, United Arab Emirates, Libya, Venezuela, and beneath the North Sea. The oil is actually obtained by the sinking of an oil well. Before it can be used it is separated by fractional distilla-

tion in oil refineries. The main fractions obtained are:

- (1) **Refinery gas** A mixture of methane, ethane, butane, and propane used as a fuel and for making other organic chemicals.
- (2) **Gasoline** A mixture of hydrocarbons containing 5 to 8 carbon atoms, boiling in the range 40–180°C. It is used for motor fuels and for making other chemicals.
- (3) **Kerosine** (or **paraffin oil**) A mixture of hydrocarbons having 11 or 12 carbon atoms, boiling in the range 160–250°C. Kerosine is a fuel for jet aircraft and for oil-fired domestic heating. It is also cracked to produce smaller hydrocarbons for use in motor fuels.
- (4) **Diesel oil** (or **gas oil**) A mixture of hydrocarbons having 13 to 25 carbon atoms, boiling in the range 220–350°C. It is a fuel for diesel engines.

The residue is a mixture of higher hydrocarbons. The liquid components are obtained by vacuum distillation and used in lubricating oils. The solid components (**paraffin wax**) are obtained by solvent extraction. The final residue is a black tar containing free carbon (**asphalt** or **bitumen**).

**petroleum ether** A colourless volatile flammable mixture of hydrocarbons (not an ether), mainly pentane and hexane. It boils in the range 30–70°C and is used as a solvent.

**pewter** An alloy of lead and tin. It usually contains 63% tin; pewter tankards and food containers should have less than 35% of lead so that the lead remains in solid solution with the tin in the presence of weak acids in the food and drink. Copper is sometimes added to increase ductility and antimony is added if a hard alloy is required.

**Pfund series** See HYDROGEN SPECTRUM.

**PGD** See PREIMPLANTATION GENETIC DIAGNOSIS.

**pH** See PH SCALE.

**PHA** See PHYTOHAEMAGGLUTININ.

**Phaeophyta** (**brown algae**) A phylum of \*algae in which the green chlorophyll pigments are usually masked by the brown pigment fucoxanthin. Brown algae are

usually marine (being abundant in cold water) and many species, such as the wracks (*Fucus*), inhabit intertidal zones. They vary in size from small branched filaments to ribbon-like bodies (known as kelps) many metres long.

**phage** See BACTERIOPHAGE.

**phagocyte** A cell that is able to engulf and break down foreign particles, cell debris, and disease-producing microorganisms (see PHAGOCYTOSIS). Many protozoans and certain mammalian cells (e.g. \*macrophages and \*monocytes) are phagocytes. Phagocytes are important elements in the natural defence mechanism of most animals.

**phagocytosis** The process by which foreign particles invading the body or minute food particles are engulfed and broken down by certain animal cells (known as \*phagocytes). The plasma membrane of the phagocyte invaginates to capture the particle and then closes around it to form a sac or \*vacuole. The vacuole coalesces with a \*lysosome, which contains enzymes that break down the particle. See ENDOCYTOSIS. Compare PINOCYTOSIS.

**phalanges** The bones that make up the \*digits of the hand or foot in vertebrates. They articulate with the \*metacarpals of the hand or with the \*metatarsals of the foot. In the basic \*pentadactyl limb there are two phalanges for the first digit (the thumb or big toe in humans) and three for each of the others.

**Phanerozoic** The most recent eon of geological time, represented by rock strata containing clearly recognizable fossils. It comprises the \*Palaeozoic, \*Mesozoic, and \*Cenozoic eras and has extended for about 570 million years from the beginning of the Cambrian period. Compare PROTEROZOIC.

**pharmacogenomics** (**pharmacogenetics**) The study of how genes affect the actions of drugs. The enormous growth in knowledge about human genetics arising from the \*Human Genome Project, coupled with the rapid advance of computer systems to analyse the vast amounts of data, has revolutionized drug discovery and development. This approach, which

combines \*genomics and pharmacology, improves understanding of drug actions, suggests new potential drug molecules, and enables computer-based searches for likely drug targets. It also raises the prospect of drugs being tailor-made to suit the genetic make-up of particular patients or groups of patients. This more precise targeting of drugs should make drugs more effective, with less risk of adverse side effects.

**pharmacokinetics** The movement of foreign substances, particularly drugs, throughout the body of an animal. Processes that influence the pharmacokinetics of a compound include uptake, distribution throughout the body tissues, the length of time the compound remains in the body, and its rate of clearance (e.g. by metabolism or excretion).

**pharmacology** The study of the properties of drugs and their effects on living organisms. Clinical pharmacology is concerned with the effects of drugs in treating disease.

**pharynx 1.** The cavity in vertebrates between the mouth and the \*oesophagus and windpipe (\*trachea), which serves for the passage of both food and respiratory gases. The presence of food in the pharynx stimulates swallowing (see DEGLUTITION). In fish and aquatic amphibians the pharynx is perforated by \*gill slits. **2.** The corresponding region in invertebrates.

**phase 1.** A homogeneous part of a heterogeneous system that is separated from other parts by a distinguishable boundary. A mixture of ice and water is a two-phase system. A solution of salt in water is a single-phase system. **2.** A description of the stage that a periodic motion has reached, usually by comparison with another such motion of the same frequency. Two varying quantities are said to be **in phase** if their maximum and minimum values occur at the same instants; otherwise, there is said to be a **phase difference**. See also PHASE ANGLE. **3.** One of the circuits in an electrical system or device in which there are two or more alternating currents that are not in phase with each other. In a three-phase system the displacement between the currents is one

third of a period. **4.** See PHASES OF THE MOON.

**phase angle** The difference in \*phase between two sinusoidally varying quantities. The displacement  $x_1$  of one quantity at time  $t$  is given by  $x_1 = a \sin \omega t$ , where  $\omega$  is the angular frequency and  $a$  is the amplitude. The displacement  $x_2$  of a similar wave that reaches the end of its period  $T$ , a fraction  $\beta$  of the period before the first is said to **lead** the first quantity by a time  $\beta T$ ; if it reaches the end of its period, a fraction  $\beta$  of the period after the first quantity it **lags** by a time  $\beta T$ . The value of  $x_2$  is then given by  $x_2 = a \sin(\omega t + \phi)$ .  $\phi$  is called the phase angle and it is equal to  $2\pi\beta$ .

**phase-contrast microscope** A type of \*microscope that is widely used for examining such specimens as biological cells and tissues. It makes visible the changes in phase that occur when nonuniformly transparent specimens are illuminated. In passing through an object the light is slowed down and becomes out of phase with the original light. With transparent specimens having some structure \*diffraction occurs, causing a larger phase change in light outside the central maximum of the pattern. The phase-contrast microscope provides a means of combining this light with that of the central maximum by means of an annular diaphragm and a **phase-contrast plate**, which produces a matching phase change in the light of the central maximum only. This gives greater contrast to the final image, due to constructive interference between the two sets of light waves. This is **bright contrast**; in **dark contrast** a different phase-contrast plate is used to make the same structure appear dark, by destructive interference of the same waves.

**phase diagram** A graph showing the relationship between solid, liquid, and gaseous \*phases over a range of conditions (e.g. temperature and pressure). See STEEL.

**phase I metabolism** The first stage in the conversion of a foreign compound, such as a drug or toxin, into a form that can be eliminated by the body. Common reactions during this phase are oxidation, reduction, and hydrolysis; the resulting metabolites are chemically more reactive

than the parent compound, enabling them to undergo the reactions of the second stage (see PHASE II METABOLISM).

**phase II metabolism** The second stage in adapting foreign compounds for elimination from the body (compare PHASE I METABOLISM). Phase II metabolism involves the addition of chemical groups (e.g. glycine or acetate), which usually makes the compound less toxic to body tissues and easier to excrete.

**phase modulation** See MODULATION.

**phase rule** For any system at equilibrium,  $P + F = C + 2$ , where  $P$  is the number of distinct phases,  $C$  the number of components, and  $F$  the number of degrees of freedom of the system. The relationship, derived by Josiah Willard Gibbs in 1876, is often called the **Gibbs phase rule**.

**phases of the moon** The shapes of the illuminated surface of the moon as seen from the earth. The shape changes as a result of the relative positions of the earth, sun, and moon.

**New moon** occurs when the nearside is totally unilluminated by the sun. As the moon moves eastwards in its orbit the sunrise \*terminator crosses the nearside from east to west producing a **crepuscular moon**. The moon is half illuminated at **first quarter**. When it is more than half-phase but less than full phase it is said to be a **gibbous moon**. When the moon is at \*opposition the nearside is fully illuminated producing a **full moon**. The sunset terminator then follows to produce a waning gibbous moon, **last quarter**, a waning crescent moon, and eventually the next new moon.

**phase space** For a system with  $n$  degrees of freedom, the  $2n$ -dimensional space with coordinates  $(q_1, q_2, \dots, q_n, p_1, p_2, \dots, p_n)$ , where the  $q$ s describe the degrees of freedom of the system and the  $p$ s are the corresponding momenta. Each point represents a state of the system. In a gas of  $N$  point particles, each particle has three positional coordinates and three corresponding momentum coordinates, so that the phase space has  $6N$ -dimensions. If the particles have internal degrees of freedom, such as the vibrations and rotations of molecules, then these must be included

in the phase space, which is consequently of higher dimension than that for point particles. As the system changes with time the representative points trace out a curve in phase space known as a **trajectory**. See also ATTRACTOR; CONFIGURATION SPACE; STATISTICAL MECHANICS.

**phase speed (phase velocity)** Symbol  $V_p$ . The speed of propagation of a pure sine wave.  $V_p = \lambda f$ , where  $\lambda$  is the wavelength and  $f$  is the frequency. The value of the phase speed depends on the nature of the medium through which it is travelling and may also depend on the mode of propagation. For electromagnetic waves travelling through space the phase speed  $c$  is given by  $c^2 = 1/\epsilon_0\mu_0$ , where  $\epsilon_0$  and  $\mu_0$  are the electric constant and the \*magnetic constant respectively.

**phase transition** A change in a feature that characterizes a system. Examples of phase transitions are changes from solid to liquid, liquid to gas, and the reverse changes. Other examples of phase transitions include the transition from a paramagnet to a ferromagnet (see MAGNETISM) and the transition from a normally conducting metal to a superconductor. Phase transitions can occur by altering such variables as temperature and pressure.

Phase transitions can be classified by their **order**. If there is non-zero \*latent heat at the transition it is said to be a **first-order transition**. If the latent heat is zero it is said to be a **second-order transition**.

Some \*models describing phase transitions, particularly in \*low-dimensional systems, are amenable to exact mathematical solutions. An effective technique for understanding phase transitions is the \*renormalization group since it can deal with problems involving different length-scales, including the feature of **universality**, in which very different physical systems behave in the same way near a phase transition. See also ORDER PARAMETER; RENORMALIZATION GROUP; TRANSITION POINT; BROKEN SYMMETRY; EARLY UNIVERSE.

**phasor** A rotating \*vector that represents a sinusoidally varying quantity. Its length represents the amplitude of the quantity and it is imagined to rotate with

angular velocity equal to the angular frequency of the quantity, so that the instantaneous value of the quantity is represented by its projection upon a fixed axis. The concept is convenient for representing the \*phase angle between two quantities; it is shown on a diagram as the angle between their phasors.

**phellem** See CORK.

**phelloderm** See CORK CAMBIUM.

**phellogen** See CORK CAMBIUM.

**phenetic** Describing a system of \*classification of organisms based on similarities and differences in as many observable characteristics as possible. A phenetic system does not aim to reflect evolutionary descent, although it may well do so. Compare PHYLOGENETIC.

**phenol (carbolic acid)** A white crystalline solid,  $C_6H_5OH$ ; r.d. 1.1; m.p.  $43^\circ C$ ; b.p.  $182^\circ C$ . It is made by the \*cumene process or by the \*Raschig process and is used to make a variety of other organic chemicals. See also PHENOLS.

**phenolphthalein** A dye used as an acid-base \*indicator. It is colourless below pH 8 and red above pH 9.6. It is used in titrations involving weak acids and strong bases. It is also used as a laxative.

**phenols** Organic compounds that contain a hydroxyl group ( $-OH$ ) bound directly to a carbon atom in a benzene ring. Unlike normal alcohols, phenols are acidic because of the influence of the aromatic ring. Thus, phenol itself ( $C_6H_5OH$ ) ionizes in water:

Phenols are made by fusing a sulphonic acid salt with sodium hydroxide to form the sodium salt of the phenol. The free phenol is liberated by adding sulphuric acid.

**phenotype** The observable characteristics of an organism. These are determined by its genes (see GENOTYPE), the dominance relationships between the \*alleles, and by the interaction of the genes with the environment.

**phenylalanine** See AMINO ACID.

**phenylamine (aniline; aminobenzene)** A

colourless oily liquid aromatic \*amine,  $C_6H_5NH_2$ , with an 'earthy' smell; r.d. 1.0217; m.p.  $-6.3^\circ C$ ; b.p.  $184.1^\circ C$ . The compound turns brown on exposure to sunlight. It is basic, forming the **phenylammonium** (or **anilinium**) ion,  $C_6H_5NH_3^+$ , with strong acids. It is manufactured by the reduction of nitrobenzene or by the addition of ammonia to chlorobenzene using a copper(II) salt catalyst at  $200^\circ C$  and 55 atm. The compound is used extensively in the rubber industry and in the manufacture of drugs and dyes.

**phenylammonium ion** The ion  $C_6H_5NH_3^+$ , derived from \*phenylamine.

**N-phenylethanamide** See ACETANILIDE.

**phenylethene (styrene)** A liquid hydrocarbon,  $C_6H_5CH=CH_2$ ; r.d. 0.9; m.p.  $-31^\circ C$ ; b.p.  $145^\circ C$ . It can be made by dehydrogenating ethylbenzene and is used in making polystyrene.

**phenyl group** The organic group  $C_6H_5-$ , present in benzene.

**phenylhydrazine** A toxic colourless dense liquid,  $C_6H_8N_2$ , b.p.  $240^\circ C$ , which turns brown on exposure to air. It is a powerful reducing agent, made from \*diazonium salts of benzene. It is used to identify aldehydes and ketones, with which it forms condensation products called \*hydrazones. With glucose and similar sugars it forms osazones. For such tests, the nitro derivative 2,4-dinitrophenylhydrazine (DNP) is often preferred as this generally forms crystalline derivatives that can be identified by their melting points. Phenylhydrazine is also used to make dyes and derivatives of \*indole.

**phenylhydrazones** See HYDRAZONES.

**phenylketonuria** A genetic disorder in which there is disordered metabolism of the amino acid phenylalanine, leading to severe mental retardation of affected children. The disease is caused by the absence or deficiency of the enzyme phenylalanine hydroxylase, which results in the accumulation of phenylalanine in all body fluids. There are also high levels of the ketone phenylpyruvate in the urine, hence the name of the disease. The disease occurs in individuals who are homozygous for the defective recessive allele; both par-

ents of such individuals are thus heterozygous carriers of the allele. The advent of \*gene probes has greatly aided accurate diagnosis, of both phenylketonurics and carriers.

**phenylmethanol (benzyl alcohol)** A liquid aromatic alcohol,  $C_6H_5CH_2OH$ ; r.d. 1.04; m.p.  $-15.3^\circ C$ ; b.p.  $205.4^\circ C$ . It is used mainly as a solvent.

**phenylmethylaniline** See BENZYLAMINE.

**3-phenylpropenoic acid** See CINNAMIC ACID.

**pheromone (ectohormone)** A chemical substance emitted by an organism into the environment as a specific signal to another organism, usually of the same species. Pheromones play an important role in the social behaviour of certain animals, especially insects and mammals. They are used to attract mates, to mark trails, and to promote social cohesion and coordination in colonies. Pheromones are usually highly volatile organic acids or alcohols and can be effective at minute concentrations.

**Phillips process** A process for making high-density polyethylene by polymerizing ethene at high pressure (30 atmospheres) and  $150^\circ C$ . The catalyst is chromium(III) oxide supported on silica and alumina.

**phloem (bast)** A tissue that conducts food materials in vascular plants from regions where they are produced (notably the leaves) to regions, such as growing points, where they are needed. It consists of hollow tubes (sieve tubes) that run parallel to the long axis of the plant organ and are formed from elongated cells (\*sieve elements) joined end to end. The end walls of these cells are broken down to a greater or lesser extent to allow passage of materials. In young plants and in newly formed tissues of mature plants the phloem is formed by the activity of the \*apical meristem. In most plants secondary phloem is later differentiated by the vascular \*cambium and this replaces the earlier formed phloem in older regions. See also COMPANION CELL. Compare XYLEM.

**phlogiston theory** A former theory of combustion in which all flammable ob-

jects were supposed to contain a substance called **phlogiston**, which was released when the object burned. The existence of this hypothetical substance was proposed in 1669 by Johann Becher, who called it 'combustible earth' (*terra pinguis*: literally 'fat earth'). For example, according to Becher, the conversion of wood to ashes by burning was explained on the assumption that the original wood consisted of ash and *terra pinguis*, which was released on burning. In the early 18th century Georg Stahl renamed the substance phlogiston (from the Greek for 'burned') and extended the theory to include the calcination (and corrosion) of metals. Thus, metals were thought to be composed of **calx** (a powdery residue) and phlogiston; when a metal was heated, phlogiston was set free and the calx remained. The process could be reversed by heating the metal over charcoal (a substance believed to be rich in phlogiston, because combustion almost totally consumed it). The calx would absorb the phlogiston released by the burning charcoal and become metallic again.

The theory was finally demolished by Antoine Lavoisier, who showed by careful experiments with reactions in closed containers that there was no *absolute* gain in mass – the gain in mass of the substance was matched by a corresponding loss in mass of the air used in combustion. After experiments with Priestley's dephlogisticated air, Lavoisier realized that this gas, which he named oxygen, was taken up to form a calx (now called an oxide). The role of oxygen in the new theory was almost exactly the opposite of phlogiston's role in the old. In combustion and corrosion phlogiston was released; in the modern theory, oxygen is taken up to form an oxide.

**phloroglucinol** A red dye (usually acidified with hydrochloric acid) that stains lignin in plant cells red.

**phon** A unit of loudness of sound that measures the intensity of a sound relative to a reference tone of defined intensity and frequency. The reference tone usually used has a frequency of 1 kilohertz and a root-mean-square sound pressure of  $2 \times 10^{-5}$  pascal. The observer listens with both ears to the reference tone and the sound

to be measured alternately. The reference tone is then increased until the observer judges it to be of equal intensity to the sound to be measured. If the intensity of the reference tone has been increased by  $n$  \*decibels to achieve this, the sound being measured is said to have an intensity of  $n$  phons. The decibel and phon scales are not identical as the phon scale is subjective and relies on the sensitivity of the ear to detect changes of intensity with frequency.

**phonochemistry** See SONOCHEMISTRY.

**phonon** A quantum of \*crystal-lattice vibrational energy having a magnitude  $hf$ , where  $h$  is the \*Planck constant and  $f$  is the frequency of the vibration. Phonons are analogous to the quanta of light, i.e. \*photons. The concept of phonons is useful in the treatment of the thermal conductivity of nonmetallic solids and, through consideration of electron-phonon interactions, the temperature dependence of the electrical conductivity of metals.

**phosgene** See CARBONYL CHLORIDE.

**phosphagen** A compound in animal tissues that provides a reserve of chemical energy in the form of high-energy phosphate bonds. The most common phosphagens are \*creatine phosphate, occurring in vertebrate muscle and nerves, and arginine phosphate, found in most invertebrates. During tissue activity (e.g. in muscle contraction) phosphagens give up their phosphate groups, thereby generating \*ATP from ADP. The phosphagens are then reformed when ATP is available.

**phosphatase** An enzyme that catalyses the removal of a phosphate group from an organic compound.

**phosphates** Salts based formally on phosphorus(V) oxoacids and in particular salts of \*phosphoric(V) acid,  $H_3PO_4$ . A large number of polymeric phosphates also exist, containing P–O–P bridges. These are formed by heating the free acid and its salts under a variety of conditions; as well as linear polyphosphates, cyclic polyphosphates and cross-linked polyphosphates or ultraphosphates are known.

**phosphatide** See PHOSPHOLIPID.

**phosphatidylcholine** See LECITHIN.

**phosphide** A binary compound of phosphorus with a more electropositive element. Phosphides show a wide range of properties. Alkali and alkaline earth metals form ionic phosphides, such as  $Na_3P$  and  $Ca_3P_2$ , which are readily hydrolysed by water. The other transition-metal phosphides are inert metallic-looking solids with high melting points and electrical conductivities.

**phosphine** A colourless highly toxic gas,  $PH_3$ ; m.p.  $-133^\circ C$ ; b.p.  $-87.7^\circ C$ ; slightly soluble in water. Phosphine may be prepared by reacting water or dilute acids with calcium phosphide or by reaction between yellow phosphorus and concentrated alkali. Solutions of phosphine are neutral but phosphine does react with some acids to give phosphonium salts containing  $PH_4^+$  ions, analogous to the ammonium ions. Phosphine prepared in the laboratory is usually contaminated with diphosphine and is spontaneously flammable but the pure compound is not so. Phosphine can function as a ligand in binding to transition-metal ions. Dilute gas mixtures of very pure phosphine and the rare gases are used for doping semiconductors.

**phosphinic acid (hypophosphorus acid)** A white crystalline solid,  $H_3PO_2$ ; r.d. 1.493; m.p.  $26.5^\circ C$ ; decomposes above  $130^\circ C$ . It is soluble in water, ethanol, and ethoxyethane. Salts of phosphinic acid may be prepared by boiling white phosphorus with the hydroxides of group 1 or group 2 metals. The free acid is made by the oxidation of phosphine with iodine. It is a weak monobasic acid in which it is the  $-O-H$  group that is ionized to give the ion  $H_2PO_2^-$ . The acid and its salts are readily oxidized to the orthophosphate and consequently are good reducing agents.

**phosphite** See PHOSPHONIC ACID.

**phospholipid (phosphatide)** One of a group of lipids having both a phosphate group and one or more fatty acids. **Glycerophospholipids** (or **phosphoglycerides**) are based on \*glycerol; the three hydroxyl groups are esterified with two fatty acids and a phosphate group, which may itself

be bound to one of a variety of simple organic groups (e.g. in \*lecithin (phosphatidylcholine) it is choline).

**Sphingolipids** are based on the alcohol sphingosine and contain only one fatty acid linked to an amino group. With their hydrophilic polar phosphate groups and long hydrophobic hydrocarbon 'tails', sphingolipids readily form membrane-like structures in water. They are a major component of plasma membranes (see LIPID BILAYER).

**phosphonate** See PHOSPHONIC ACID.

**phosphonic acid (phosphorous acid; orthophosphorous acid)** A colourless to pale-yellow deliquescent crystalline solid,  $\text{H}_3\text{PO}_3$ ; r.d. 1.65; m.p.  $73.6^\circ\text{C}$ ; decomposes at  $200^\circ\text{C}$ ; very soluble in water and soluble in alcohol. Phosphonic acid may be crystallized from the solution obtained by adding ice-cold water to phosphorus(III) oxide or phosphorus trichloride. The structure of this material is unusual in that it contains one direct P-H bond and is more correctly written  $(\text{HO})_2\text{HPO}$ . The acid is dibasic, giving rise to the ions  $\text{H}_2\text{PO}_3^-$  and  $\text{HPO}_3^{2-}$  (**phosphonates**; formerly **phosphites**), and has moderate reducing properties. On heating it gives phosphine and phosphoric(V) acid.

**phosphonium ion** The ion  $\text{PH}_4^+$ , or the corresponding organic derivatives of the type  $\text{R}_3\text{PH}^+$ ,  $\text{RPH}_3^+$ . The phosphonium ion  $\text{PH}_4^+$  is formally analogous to the ammonium ion  $\text{NH}_4^+$  but  $\text{PH}_3$  has a much lower proton affinity than  $\text{NH}_3$  and reaction of  $\text{PH}_3$  with acids is necessary for the production of phosphonium salts.

**phosphor** A substance that is capable of \*luminescence (including phosphorescence). Phosphors that release their energy after a short delay of between  $10^{-10}$  and  $10^{-4}$  second are sometimes called **scintillators**.

**phosphor bronze** An alloy of copper containing 4% to 10% of tin and 0.05% to 1% of phosphorus as a deoxidizing agent. It is used particularly for marine purposes and where it is exposed to heavy wear, as in gear wheels. See also BRONZE.

**phosphorescence** See LUMINESCENCE.

**phosphoric(V) acid (orthophosphoric**

**acid)** A white rhombic solid,  $\text{H}_3\text{PO}_4$ ; r.d. 1.834; m.p.  $42.35^\circ\text{C}$ ; loses water at  $213^\circ\text{C}$ ; very soluble in water and soluble in ethanol. Phosphoric(V) acid is very deliquescent and is generally supplied as a concentrated aqueous solution. It is the most commercially important derivative of phosphorus, accounting for over 90% of the phosphate rock mined. It is manufactured by two methods; the **wet process**, in which the product contains some of the impurities originally present in the rock and applications are largely in the fertilizer industry, and the **thermal process**, which produces a much purer product suitable for the foodstuffs and detergent industries. In the wet process the phosphate rock,  $\text{Ca}_3(\text{PO}_4)_2$ , is treated with sulphuric acid and the calcium sulphate removed either as gypsum or the hemihydrate. In the thermal process, molten phosphorus is sprayed and burned in a mixture of air and steam. Phosphoric(V) acid is a weak tribasic acid, which is best visualized as  $(\text{HO})_3\text{PO}$ . Its full systematic name is **tetraoxo-phosphoric(V) acid**. It gives rise to three series of salts containing **phosphate(V)** ions based on the anions  $[(\text{HO})_2\text{PO}_2]^-$ ,  $[(\text{HO})\text{PO}_3]^{2-}$ , and  $\text{PO}_4^{3-}$ . These salts are acidic, neutral, and alkaline in character respectively and phosphate ions often feature in buffer systems. There is also a wide range of higher acids and acid anions in which there is some P-O-P chain formation. The simplest of these is **pyrophosphoric acid** (technically **hepta-oxodiphosphoric(V) acid**),  $\text{H}_4\text{P}_2\text{O}_7$ , produced by heating phosphoric(V) acid (solid) and phosphorus(III) chloride oxide. **Metaphosphoric acid** is a glassy polymeric solid  $(\text{HPO}_2)_x$ .

**phosphorous acid** See PHOSPHONIC ACID.

**phosphorus** Symbol P. A nonmetallic element belonging to \*group 15 (formerly VB) of the periodic table; a.n. 15; r.a.m. 30.9738; r.d. 1.82 (white), 2.34 (red); m.p.  $44.1^\circ\text{C}$  ( $\alpha$ -white); b.p.  $280^\circ\text{C}$  ( $\alpha$ -white). It occurs in various phosphate rocks, from which it is extracted by heating with carbon (coke) and silicon(IV) oxide in an electric furnace ( $1500^\circ\text{C}$ ). Calcium silicate and carbon monoxide are also produced. Phosphorus has a number of allotropic forms. The  $\alpha$ -white form consists of  $\text{P}_4$  tetrahedra

(there is also a  $\beta$ -white form stable below  $-77^\circ\text{C}$ ). If  $\alpha$ -white phosphorus is dissolved in lead and heated at  $500^\circ\text{C}$  a violet form is obtained. Red phosphorus, which is a combination of violet and white phosphorus, is obtained by heating  $\alpha$ -white phosphorus at  $250^\circ\text{C}$  with air excluded. There is also a black allotrope, which has a graphite-like structure, made by heating white phosphorus at  $300^\circ\text{C}$  with a mercury catalyst. The element is highly reactive. It forms metal \*phosphides and covalently bonded phosphorus(III) and phosphorus(V) compounds. Phosphorus is an \*essential element for living organisms. It is an important constituent of tissues (especially bones and teeth) and of cells, being required for the formation of nucleic acids and energy-carrying molecules (e.g. ATP) and also involved in various metabolic reactions. The element was discovered by Hennig Brand (c. 1630–92) in 1669.

**phosphorus(III) bromide (phosphorus tribromide)** A colourless fuming liquid,  $\text{PBr}_3$ ; r.d. 2.85; m.p.  $-40^\circ\text{C}$ ; b.p.  $173^\circ\text{C}$ . It is prepared by passing bromine vapour over phosphorus but avoiding an excess, which would lead to the phosphorus(V) bromide. Like the other phosphorus(III) halides,  $\text{PBr}_3$  is pyramidal in the gas phase. In the liquid phase the P–Br bonds are labile; for example,  $\text{PBr}_3$  will react with  $\text{PCl}_3$  to give a mixture of products in which the halogen atoms have been redistributed. Phosphorus(III) bromide is rapidly hydrolysed by water to give phosphonic acid and hydrogen bromide. It reacts readily with many organic hydroxyl groups and is used as a reagent for introducing bromine atoms into organic molecules.

**phosphorus(V) bromide (phosphorus pentabromide)** A yellow readily sublimable solid,  $\text{PBr}_5$ , which decomposes below  $100^\circ\text{C}$  and is soluble in benzene and carbon tetrachloride (tetrachloromethane). It may be prepared by the reaction of phosphorus(III) bromide with bromine or the direct reaction of phosphorus with excess bromine. It is very readily hydrolysed to give hydrogen bromide and phosphoric(V) acid. An interesting feature of this material is that in the solid state it has the structure

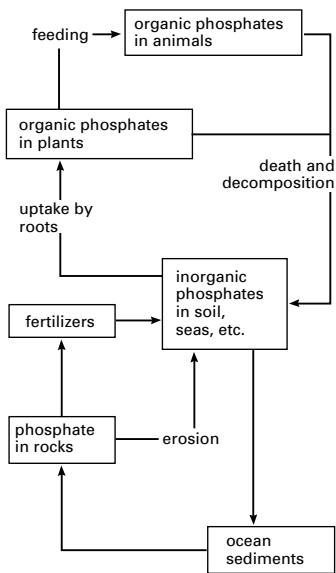

$[\text{PBr}_4]^+\text{Br}^-$ . It is used in organic chemistry as a brominating agent.

**phosphorus(III) chloride (phosphorus trichloride)** A colourless fuming liquid,  $\text{PCl}_3$ ; r.d. 1.57; m.p.  $-112^\circ\text{C}$ ; b.p.  $75.5^\circ\text{C}$ . It is soluble in ether and in carbon tetrachloride but reacts with water and with ethanol. It may be prepared by passing chlorine over excess phosphorus (excess chlorine contaminates the product with phosphorus(V) chloride). The molecule is pyramidal in the gas phase and possesses weak electron-pair donor properties. It is hydrolysed violently by water to phosphonic acid and hydrogen chloride. Phosphorus(III) chloride is an important starting point for the synthesis of a variety of inorganic and organic derivatives of phosphorus.

**phosphorus(V) chloride (phosphorus pentachloride)** A yellow-white rhombic solid,  $\text{PCl}_5$ , which fumes in air; r.d. 4.65; m.p.  $166.8^\circ\text{C}$  (under pressure); sublimes at  $160$ – $162^\circ\text{C}$ . It is decomposed by water to give hydrogen chloride and phosphoric(V) acid. It is soluble in organic solvents. The compound may be prepared by the reaction of chlorine with phosphorus(III) chloride. Phosphorus(V) chloride is structurally interesting in that in the gas phase it has the expected trigonal bipyramidal form but in the solid phase it consists of the ions  $[\text{PCl}_4]^+[\text{PCl}_6]^-$ . The same ions are detected when phosphorus(V) chloride is dissolved in polar solvents. It is used in organic chemistry as a chlorinating agent.

**phosphorus(III) chloride oxide (phosphorus oxychloride; phosphoryl chloride)** A colourless fuming liquid,  $\text{POCl}_3$ ; r.d. 1.67; m.p.  $2^\circ\text{C}$ ; b.p.  $105.3^\circ\text{C}$ . It may be prepared by the reaction of phosphorus(III) chloride with oxygen or by the reaction of phosphorus(V) oxide with phosphorus(V) chloride. Its reactions are very similar to those of phosphorus(III) chloride. Hydrolysis with water gives phosphoric(V) acid. Phosphorus(III) chloride oxide has a distorted tetrahedral shape and can act as a donor towards metal ions, thus giving rise to a series of complexes.

**phosphorus cycle** The cycling of \*phosphorus between the biotic and abiotic components of the environment (see BIOGEOCHEMICAL CYCLE). Inorganic phos-

The phosphorus cycle

phates ( $\text{PO}_4^{3-}$ ,  $\text{HPO}_4^{2-}$ , or  $\text{H}_2\text{PO}_4^-$ ) are absorbed by plants from the soil and bodies of water and eventually pass into animals through food chains. Within living organisms phosphates are built up into nucleic acids and other organic molecules. When plants and animals die, phosphates are released and returned to the abiotic environment through the action of bacteria. On a geological time scale, phosphates in aquatic environments eventually become incorporated into and form part of rocks; through a gradual process of erosion, these phosphates are returned to the soil, seas, rivers, and lakes. Phosphorus-containing rocks are mined for the manufacture of fertilizers, which provide an additional supply of inorganic phosphate to the abiotic environment.

**phosphorus(III) oxide (phosphorus trioxide)** A white or colourless waxy solid,  $\text{P}_4\text{O}_6$ ; r.d. 2.13; m.p.  $23.8^\circ\text{C}$ ; b.p.  $173.8^\circ\text{C}$ . It is soluble in ether, chloroform, and benzene but reacts with cold water to give phosphonic acid,  $\text{H}_3\text{PO}_3$ , and with hot water to give phosphine and phosphoric(V) acid. The compound is formed

when phosphorus is burned in an oxygen-deficient atmosphere (about 50% yield). As it is difficult to separate from white phosphorus by distillation, the mixture is irradiated with ultraviolet radiation to convert excess white phosphorus into the red form, after which the oxide can be separated by dissolution in organic solvents. Although called a trioxide for historical reasons, phosphorus(III) oxide consists of  $\text{P}_4\text{O}_6$  molecules of tetrahedral symmetry in which each phosphorus atom is linked to the three others by an oxygen bridge. The chemistry is very complex. Above  $210^\circ\text{C}$  it decomposes into red phosphorus and polymeric oxides. It reacts with chlorine and bromine to give oxo-halides and with alkalis to give phosphonates (see PHOSPHONIC ACID).

**phosphorus(V) oxide (phosphorus pentoxide; phosphoric anhydride)** A white powdery and extremely deliquescent solid,  $\text{P}_4\text{O}_{10}$ ; r.d. 2.39; m.p.  $580^\circ\text{C}$  (under pressure); sublimes at  $300^\circ\text{C}$ . It reacts violently with water to give phosphoric(V) acid. It is prepared by burning elemental phosphorus in a plentiful supply of oxygen, then purified by sublimation. The hexagonal crystalline form consists of  $\text{P}_4\text{O}_{10}$  molecular units; these have the phosphorus atoms arranged tetrahedrally, each P atom linked to three others by oxygen bridges and having in addition one terminal oxygen atom. The compound is used as a drying agent and as a dehydrating agent; for example, amides are converted into nitrites and sulphuric acid is converted to sulphur trioxide.

**phosphorus oxychloride** See PHOSPHORUS(III) CHLORIDE OXIDE.

**phosphorus pentabromide** See PHOSPHORUS(V) BROMIDE.

**phosphorus pentachloride** See PHOSPHORUS(V) CHLORIDE.

**phosphorus tribromide** See PHOSPHORUS(III) BROMIDE.

**phosphorus trichloride** See PHOSPHORUS(III) CHLORIDE.

**phosphorus trioxide** See PHOSPHORUS(III) OXIDE.

**phosphorylase** See PHOSPHORYLATION.

**phosphorylation** The introduction of a phosphate group ( $\text{PO}_4^{3-}$ ) to a biomolecule in a reaction that is normally controlled by a **phosphorylase** enzyme. Phosphate is able to combine easily with inert organic compounds, making them chemically active. The first stage in many biochemical reactions is phosphorylation. The conversion of AMP and ADP to \*ATP occurs by phosphorylation reactions in two main metabolic pathways, \*oxidative phosphorylation and \*photophosphorylation. The formation of nucleotides also involves a phosphorylation reaction. The activity of many enzymes is controlled by phosphorylation: certain enzymes are activated when they are phosphorylated (see KINASE), while others are deactivated. Phosphorylation of these enzymes is under the control of hormones and other messengers.

**phosphoryl chloride** See PHOSPHORUS(III) CHLORIDE OXIDE.

**phot** A unit of illuminance equal to  $10^4$  lux or one lumen per square centimetre.

**photic zone** The upper layer of a sea or a lake, in which there is sufficient light for photosynthesis. The limit of the photic zone varies from less than a metre to more than 200 metres, depending on the turbidity of the water.

**photino** See SUPERSYMMETRY.

**photoautotroph** An autotrophic organism, such as a green plant or a phototrophic bacterium, that synthesizes its organic materials using energy derived from the sun (solar energy) in the process of photosynthesis. See AUTOTROPHIC NUTRITION.

**photocathode** A \*cathode that emits electrons when light falls upon it, as a result of the \*photoelectric effect. See PHOTOELECTRIC CELL.

**photocell** See PHOTOELECTRIC CELL.

**photochemical reaction** A chemical reaction caused by light or ultraviolet radiation. The incident photons are absorbed by reactant molecules to give excited molecules or free radicals, which undergo further reaction.

**photochemical smog** A noxious smog

produced by the reaction of nitrogen oxides with hydrocarbons in the presence of ultraviolet light from the sun. The reaction is very complex and one of the products is ozone.

**photochemistry** The branch of chemistry concerned with \*photochemical reactions.

**photochromism** A change of colour occurring in certain substances when exposed to light. Photochromic materials are used in sunglasses that darken in bright sunlight.

**photoconductive effect** See PHOTOELECTRIC EFFECT.

**photodiode** A \*semiconductor diode used to detect the presence of light or to measure its intensity. It usually consists of a *p-n* junction device in a container that focuses any light in the environment close to the junction. The device is usually biased in reverse so that in the dark the current is small; when it is illuminated the current is proportional to the amount of light falling on it. See PHOTOELECTRIC EFFECT.

**photodisintegration** The decay of a nuclide as a result of the absorption of a gamma-ray photon.

**photoelasticity** An effect in which certain materials exhibit double refraction when subjected to stress. It is used in a technique for detecting strains in transparent materials (e.g. Perspex, celluloid, and glass). When polarized white light is passed through a stressed sample, the birefringence causes coloured patterns to be seen on the viewing screen of a suitable \*polarimeter. If monochromatic polarized light is used, a complex pattern of light and dark fringes is produced.

**photoelectric cell (photocell)** Any of several devices that produce an electric signal in response to exposure to electromagnetic radiation. The original photocells utilized photoemission from a photosensitive cathode (**photocathode**). The electrons emitted are attracted to an anode. A positive potential on the anode enables a current to flow through an external circuit, the current being proportional to the intensity of the illumination

on the cathode. The electrodes are enclosed in an evacuated glass tube (see also PHOTOMULTIPLIER).

More modern light-sensitive devices utilize the photoconductive effect and the photovoltaic effect (see PHOTOELECTRIC EFFECT; PHOTODIODE; PHOTOTRANSISTOR; SOLAR CELL).

**photoelectric effect** The liberation of electrons (see PHOTOELECTRON) from a substance exposed to electromagnetic radiation. The number of electrons emitted depends on the intensity of the radiation. The kinetic energy of the electrons emitted depends on the frequency of the radiation. The effect is a quantum process in which the radiation is regarded as a stream of \*photons, each having an energy  $hf$ , where  $h$  is the Planck constant and  $f$  is the frequency of the radiation. A photon can only eject an electron if the photon energy exceeds the \*work function,  $\phi$ , of the solid, i.e. if  $hf_0 = \phi$  an electron will be ejected;  $f_0$  is the minimum frequency (or **threshold frequency**) at which ejection will occur. For many solids the photoelectric effect occurs at ultraviolet frequencies or above, but for some materials (having low work functions) it occurs with light. The maximum kinetic energy,  $E_m$ , of the photoelectron is given by the \*Einstein equation:  $E_m = hf - \phi$  (see also PHOTOIONIZATION).

Apart from the liberation of electrons from atoms, other phenomena are also referred to as photoelectric effects. These are the **photoconductive effect** and the **photovoltaic effect**. In the photoconductive effect, an increase in the electrical conductivity of a semiconductor is caused by radiation as a result of the excitation of additional free charge carriers by the incident photons. **Photoconductive cells**, using such photosensitive materials as cadmium sulphide, are widely used as radiation detectors and light switches (e.g. to switch on street lighting).

In the photovoltaic effect, an e.m.f. is produced between two layers of different materials as a result of irradiation. The effect is made use of in **photovoltaic cells**, most of which consist of  $p$ - $n$  \*semiconductor junctions (see also PHOTODIODE; PHOTOTRANSISTOR). When photons are absorbed near a  $p$ - $n$  junction new free

charge carriers are produced (as in photoconductivity); however, in the photovoltaic effect the electric field in the junction region causes the new charge carriers to move, creating a flow of current in an external circuit without the need for a battery. See also PHOTOELECTRIC CELL.

**photoelectron** An electron emitted from a substance by irradiation as a result of the \*photoelectric effect or \*photoionization.

**photoelectron spectroscopy** A technique for determining the \*ionization potentials of molecules. The sample is a gas or vapour irradiated with a narrow beam of ultraviolet radiation (usually from a helium source at 58.4 nm, 21.21 eV photon energy). The photoelectrons produced in accordance with the \*Einstein equation are passed through a slit into a vacuum region, where they are deflected by magnetic or electrostatic fields to give an energy spectrum. The photoelectron spectrum obtained has peaks corresponding to the ionization potentials of the molecule (and hence the orbital energies). The technique also gives information on the vibrational energy levels of the ions formed. **ESCA** (electron spectroscopy for chemical analysis) is a similar analytical technique in which a beam of X-rays is used. In this case, the electrons ejected are from the inner shells of the atoms. Peaks in the electron spectrum for a particular element show characteristic chemical shifts, which depend on the presence of other atoms in the molecule.

**photoemission** The process in which electrons are emitted by a substance as a result of irradiation. See PHOTOELECTRIC EFFECT; PHOTOIONIZATION.

**photofission** A \*nuclear fission that is caused by a gamma-ray photon.

**photographic density** A measure of the opacity of a photographic emulsion (negative or transparency). See DENSITOMETER.

**photography** The process of forming a permanent record of an image on specially treated film or paper. In normal black-and-white photography a camera is used to expose a film or plate to a focused

image of the scene for a specified time. The film or plate is coated with an emulsion containing silver salts and the exposure to light causes the silver salts to break down into silver atoms; where the light is bright dark areas of silver are formed on the film after development (by a mild reducing agent) and fixing. The negative so formed is printed, either by a contact process or by projection. In either case light passing through the negative film falls on a sheet of paper also coated with emulsion. Where the negative is dark, less light passes through and the resulting positive is light in this area, corresponding with a light area in the original scene. As photographic emulsions are sensitive to ultraviolet and X-rays, they are widely used in studies involving these forms of electromagnetic radiation. *See also* COLOUR PHOTOGRAPHY.

**photoionization** The \*ionization of an atom or molecule as a result of irradiation by electromagnetic radiation. For a photoionization to occur the incident photon of the radiation must have an energy in excess of the \*ionization potential of the species being irradiated. The ejected photoelectron will have an energy,  $E$ , given by  $E = hf - I$ , where  $h$  is the Planck constant,  $f$  is the frequency of the incident radiation, and  $I$  is the ionization potential of the irradiated species.

**photolithography** A technique used in the manufacture of semiconductor components, integrated circuits, etc. It depends on the principle of masking selected areas of a surface and exposing the unmasked areas to such processes as the introduction of impurities, deposition of thin films, removal of material by etching, etc. The technique has been developed for use on tiny structures (typically measured in micrometres), which can only be examined by means of an electron microscope.

**photoluminescence** *See* LUMINESCENCE.

**photolysis** A chemical reaction produced by exposure to light or ultraviolet radiation. Photolytic reactions often involve free radicals, the first step being homolytic fission of a chemical bond. (*See* FLASH PHOTOLYSIS.) The photolysis of

water, using energy from sunlight absorbed by chlorophyll, produces gaseous oxygen, electrons, and hydrogen ions and is a key reaction in \*photosynthesis.

**photometer** An instrument used to measure \*luminous intensity, illumination, and other photometric quantities. The older types rely on visual techniques to compare a source of light with a standard source. More modern photometers use \*photoelectric cells, of the photoconductive, photoemissive, or photovoltaic types. The photovoltaic types do not require an external power source and are therefore very convenient to use but are relatively insensitive. The photoemissive type usually incorporates a \*photomultiplier, especially for use in astronomy and with other weak sources. Photoconductive units require only low-voltage supplies, which makes them convenient for commercial illumination meters and photographers' exposure meters.

**photometric brightness** *See* LUMINANCE.

**photometry** The study of visual radiation, especially the calculations and measurements of \*luminous intensity, \*luminous flux, etc. In some cases photometric calculations and measurements extend into the near infrared and the near ultraviolet.

In photometry, two types of measurement are used: those that measure **luminous** quantities rely on the use of the human eye (for example, to compare the illuminance of two surfaces); those called **radiant** quantities rely on the use of photoelectric devices to measure electromagnetic energy. *See also* PHOTOMETER.

**photomicrography** The use of photography to obtain a permanent record (a **photomicrograph**) of the image of an object as viewed through a microscope.

**photomorphogenesis** The development of plants under the influence of light. All the processes crucial to the growth and development of plants are triggered by light, including seed germination, stem elongation, chloroplast formation, and flowering. These light responses are mediated by various types of light-sensitive molecules, principally

\*phytochrome. It is thought that phytochrome brings about these responses by regulating gene transcription, although the precise mechanisms involved are unknown.

**photomultiplier** A sensitive type of \*photoelectric cell in which electrons emitted from a photocathode are accelerated to a second electrode where several electrons are liberated by each original photoelectron, as a result of \*secondary emission. The whole process is repeated as many times as necessary to produce a useful electric current by secondary emission from the last electrode. A photomultiplier is thus a photocathode with the output amplified by an electron multiplier. The initial photocurrent can be amplified by a factor of  $10^8$ . Photomultipliers are thus useful when it is necessary to detect low intensities of light, as in stellar photometry, star and planet tracking in guidance systems, and more mundanely in process control.

**photon** A particle with zero rest mass consisting of a \*quantum of electromagnetic radiation. The photon may also be regarded as a unit of energy equal to  $hf$ , where  $h$  is the \*Planck constant and  $f$  is the frequency of the radiation in hertz. Photons travel at the speed of light. They are required to explain the photoelectric effect and other phenomena that require light to have particle character.

**photonutron** A neutron emitted by an atomic nucleus undergoing a \*photonuclear reaction.

**photonuclear reaction** A \*nuclear reaction that is initiated by a (gamma-ray) photon.

**photoperiodism** The response of an organism to changes in day length (**photo-period**). Many plant responses are controlled by day length, the most notable being flowering in many species (see FLORIGEN; DAY-NEUTRAL PLANT; LONG-DAY PLANT; SHORT-DAY PLANT). In plants the internal \*biological clock and the pigment \*phytochrome are both thought to be involved in for the regulation of photoperiodic responses (see also DARK PERIOD). Activities in animals that are determined

by photoperiod include breeding, migration, and other seasonal events.

**photophosphorylation** The formation of ATP from ADP and inorganic phosphate using light energy in \*photosynthesis (compare OXIDATIVE PHOSPHORYLATION). There are two pathways: noncyclic photophosphorylation and cyclic photophosphorylation. In **noncyclic photophosphorylation** electrons derived from the \*photolysis of water pass from a complex of chlorophyll molecules along a series of carrier molecules to  $NADP^+$ . As they do so some of their energy is coupled to the formation of ATP from ADP and inorganic phosphate.  $NADP^+$  is reduced to NADPH, which provides reducing power for the light-independent reactions of photosynthesis. In **cyclic photophosphorylation** the electrons are recycled through the electron carrier system back to the chlorophyll complex, resulting in further ATP formation (but no NADPH).

**photopic vision** The type of vision that occurs when the cones in the eye are the principal receptors, i.e. when the level of illumination is high. Colours can be identified with photopic vision. Compare SCOTOPIC VISION.

**photoprotection** Protection of a plant's photosynthetic apparatus from the harmful effects of light. During periods of peak light intensity plants are able to utilize less than half the incoming energy. The surplus energy poses the risk of photooxidation, and the formation of highly reactive superoxide radicals that can destroy the cell's chlorophyll and many other cellular components. Much of the excess energy is trapped and dissipated as heat by \*carotenoids.

**photoreceptor** A sensory cell or group of cells that reacts to the presence of light. It usually contains a pigment that undergoes a chemical change when light is absorbed, thus stimulating a nerve. See EYE.

**photosensitive substance** **1.** Any substance that when exposed to electromagnetic radiation produces a photoconductive, photoelectric, or photovoltaic effect. **2.** Any substance, such as the emulsion of a photographic film, in which

electromagnetic radiation produces a chemical change.

**photosphere** The visible surface of the \*sun or other star and the source of its continuous spectrum. It is a gaseous layer several hundreds of kilometres thick with an average temperature of 5780 K. Where the photosphere merges with the \*chromosphere the temperature is 4000 K.

**photosynthesis** The chemical process by which green plants, algae, and certain bacteria synthesize organic compounds from carbon dioxide and water in the presence of sunlight. It occurs in the \*chloroplasts and there are two principal types of reaction. In the **light-dependent reactions**, which require the presence of light, energy from sunlight is absorbed by \*photosynthetic pigments (chiefly the green pigment \*chlorophyll) and used to bring about the \*photolysis of water:

The electrons released by this reaction pass along a series of electron carriers (see ELECTRON TRANSPORT CHAIN); as they do so they lose their energy, which is used to convert ADP to ATP in the process of \*photophosphorylation. The electrons

and protons produced by the photolysis of water are used to reduce NADP:

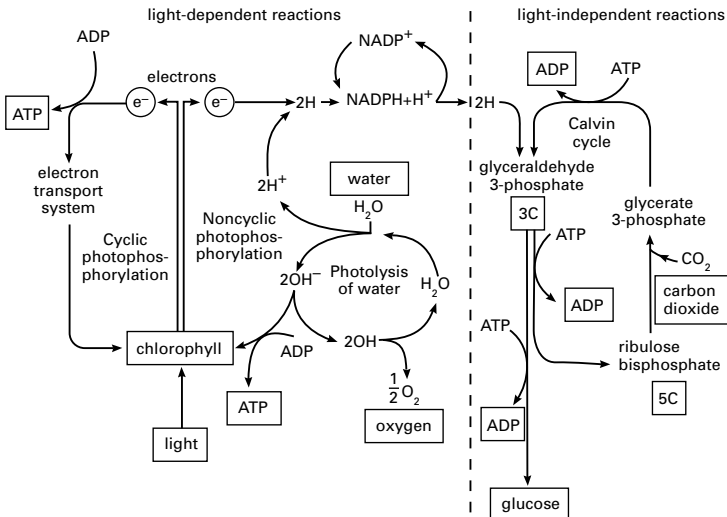

The ATP and NADPH produced during the light-dependent reactions provide energy and reducing power, respectively, for the ensuing **light-independent reactions** (formerly called the dark reaction), which do not require the presence of light. During these reactions carbon dioxide is reduced to carbohydrate in a metabolic pathway known as the \*Calvin cycle. Photosynthesis can be summarized by the equation:

Since virtually all other forms of life are directly or indirectly dependent on plants for food, photosynthesis is the basis for all life on earth. Furthermore virtually all the atmospheric oxygen has originated from oxygen released during photosynthesis.

**photosynthetic pigments** The pigments responsible for the capture of light energy during the light-dependent reactions of \*photosynthesis. In plants, algae, and cyanobacteria the green pigment \*chlorophyll *a* is the principal light receptor, absorbing blue and red light. However

\*carotenoids also absorb light energy and pass this on to the chlorophyll molecules.

**phototaxis** The movement of a cell (e.g. a gamete) or a unicellular organism in response to light. For example, certain algae (e.g. *Chlamydomonas*) can perceive light by means of a sensitive eyespot and move to regions of higher light concentration to enhance photosynthesis. See TAXIS.

**phototransistor** A junction \*transistor that is photosensitive. When radiation falls on the emitter-base junction, new free charge carriers are created in the base region and the collector current is increased. Phototransistors are similar to \*photodiodes except that the primary photoelectric current is amplified internally and it is therefore more sensitive to light than the photodiode. Some types can be used as switching or bistable devices, a small intensity of radiation switching them from a low to high current state.

**phototropism (heliotropism)** The growth of plant organs in response to light. Aerial shoots usually grow towards light, while some aerial roots grow away from light. The phototropic response is thought to be controlled by \*auxin, a plant growth substance. See TROPISM.

**photovoltaic effect** See PHOTOELECTRIC EFFECT.

**pH scale** A logarithmic scale for expressing the acidity or alkalinity of a solution. To a first approximation, the pH of a solution can be defined as  $-\log_{10}c$ , where  $c$  is the concentration of hydrogen ions in moles per cubic decimetre. A neutral solution at 25°C has a hydrogen-ion concentration of  $10^{-7}$  mol dm<sup>-3</sup>, so the pH is 7. A pH below 7 indicates an acid solution; one above 7 indicates an alkaline solution. More accurately, the pH depends not on the concentration of hydrogen ions but on their \*activity, which cannot be measured experimentally. For practical purposes, the pH scale is defined by using a hydrogen electrode in the solution of interest as one half of a cell, with a reference electrode (e.g. a calomel electrode) as the other half cell. The pH is then given by  $(E - E_R)/2.303RT$ , where  $E$  is the e.m.f. of the cell and  $E_R$  the standard electrode potential of the reference electrode, and  $F$

the Faraday constant. In practice, a glass electrode is more convenient than a hydrogen electrode.

pH stands for 'potential of hydrogen'. The scale was introduced by Søren Sørensen (1868–1939) in 1909.

**phthalic acid** A colourless crystalline dicarboxylic acid, C<sub>6</sub>H<sub>4</sub>(COOH)<sub>2</sub>; r.d. 1.6; m.p. 207°C. The two -COOH groups are substituted on adjacent carbon atoms of the ring, the technical name being **benzene-1,2-dicarboxylic acid**. The acid is made from **phthalic anhydride** (benzene-1,2-dicarboxylic anhydride, C<sub>8</sub>H<sub>4</sub>O<sub>3</sub>), which is made by the catalytic oxidation of naphthalene. The anhydride is used in making plasticizers and polyester resins.

**phthalic anhydride** See PHTHALIC ACID.

**phycomycetes** In older classification schemes, all primitive \*fungi, many of which are found in water (e.g. the water moulds, which may be parasitic on fish) or in damp areas. Many are unicellular but those that form mycelia generally have hyphae lacking cross walls, which distinguishes them from the \*Ascomycota and \*Basidiomycota. They include the \*Zygomycota.

**phyllotaxis (phyllotaxy)** The arrangement of leaves on a plant stem. The leaves may be inserted in whorls or pairs at each node or singly up the stem. When arranged in pairs the two leaves arise on opposite sides of the stem and are usually at right angles to the leaf pairs above and below them. Single leaves may be inserted alternately or in a spiral pattern up the stem. Phyllotaxis generally results in the minimum of shading of leaves by those above them.

**phylogenetic** Describing a system of \*classification of organisms that aims to show their evolutionary history. Compare PHENETIC.

**phylogeny** The evolutionary history of an organism or group of related organisms. Compare ONTOGENY.

**phylum** A category used in the \*classification of organisms that consists of one or several similar or closely related classes. Examples of phyla are the Rhodophyta, Ascomycota, Bryophyta, Annelida, and

Chordata. Phyla are grouped into kingdoms. In traditional plant classification schemes, the \*division was used instead of the phylum.

**physical chemistry** The branch of chemistry concerned with the effect of chemical structure on physical properties. It includes chemical thermodynamics and electrochemistry.

**physical map** (in genetics) Any map that shows the arrangement of the material (i.e. the nucleoprotein) making up a chromosome or segment of a genome (see CHROMOSOME MAP). The coarsest physical maps are ones depicting chromosome banding patterns, which are dark and light transverse bands obtained by staining entire chromosomes in mitosis. These **cytological maps** enable characterization of individual chromosomes and can reveal gross anomalies, such as missing or duplicated segments. On a much larger scale are **contig maps**; these show the order of cloned DNA segments taken from a \*DNA library and fitted together to form a series of overlapping, or contiguous, segments, called a **contig**. Such segments are roughly on a gene-length scale. Once a contig has been correctly aligned, the base sequence of each component segment can be determined (see DNA SEQUENCING), and hence the overall sequence of the chromosomal DNA can be pieced together. Compare LINKAGE MAP.

**physics** The study of the laws that determine the structure of the universe with reference to the matter and energy of which it consists. It is concerned not with chemical changes that occur but with the forces that exist between objects and the interrelationship between matter and energy. Traditionally, the study was divided into separate fields: heat, light, sound, electricity and magnetism, and mechanics (see CLASSICAL PHYSICS). Since the turn of the century, however, quantum mechanics and relativistic physics have become increasingly important; the growth of modern physics has been accompanied by the studies of atomic physics, nuclear physics, and particle physics. The physics of astronomical bodies and their interactions is known as **astrophysics**, the physics of the earth is known as **geo-**

**physics**, and the study of the physical aspects of biology is called **biophysics**. See also THEORETICAL PHYSICS.

**physiological saline** A liquid medium in which animal tissues may be kept alive for a few hours during experiments without pathological changes or distortion of the cells taking place. Such fluids are salt solutions that are isotonic with and have the same pH as the body fluids of the animal. A well-known example is **Ringer's solution**, formulated by the British physiologist S. Ringer (1835-1910), which is a mixture of sodium chloride, calcium chloride, sodium bicarbonate, and potassium chloride solutions.

**physiological specialization** The occurrence within a species of several forms that are identical in appearance but differ in physiology; these are termed **physiological races**. For example, many pathogenic fungi develop new physiological races in response to the strong selection pressure exerted when disease-resistant crop varieties are sown over large areas.

**physiology** The branch of biology concerned with the vital functions of plants and animals, such as nutrition, respiration, reproduction, and excretion.

**physisorption** See ADSORPTION.

**phyto-** Prefix denoting plants. For example, phytopathology is the study of plant diseases.

**phytochrome** A protein-based plant pigment present in small quantities in many plant organs. It exists in two interconvertible forms: a physiologically active form, which forms when the plant is illuminated with red light or normal daylight; and an inactive form, formed when the plant is exposed to far-red light or darkness. The active form regulates many plant processes, such as seed germination and the initiation of flowering.

**phytogeography** See PLANT GEOGRAPHY.

**phytohaemagglutinin (PHA)** Any of various plant-derived compounds that induce changes in lymphocytes normally associated with antigen challenge. These changes include cell enlargement, in-

creased RNA and DNA synthesis, and, finally, cell division. Response to PHAs is used to test for competence of cell-mediated \*immunity, for example in patients suffering chronic virus infections.

**phytohormone** See GROWTH SUBSTANCE.

**phytoplankton** The photosynthesizing organisms of \*plankton, consisting chiefly of microscopic algae, such as diatoms and dinoflagellates. Near the surface of the sea there may be many millions of such plants per cubic metre. Members of the phytoplankton are of great importance as they form the basis of food for all other forms of aquatic life, being the primary \*producers. Compare ZOOPLANKTON.

**pi** Symbol  $\pi$ . The ratio of the circumference of any circle to its diameter. It is a \*transcendental number with the value 3.141 592....

**pia mater** The innermost of the three membranes (\*meninges) that surround the brain and spinal cord of vertebrates. The pia mater lies immediately adjacent to the central nervous system, and the \*choroid plexus, which secretes cerebrospinal fluid, is an extension of it.

**piano stool** See SANDWICH COMPOUND.

**pi bond** See ORBITAL.

**pico-** Symbol p. A prefix used in the metric system to denote  $10^{-12}$ . For example,  $10^{-12}$  farad = 1 picofarad (pF).

**picornavirus** One of a group of small RNA-containing viruses (*pico* = small; hence pico-RNA-virus) commonly present in the alimentary and respiratory tracts of vertebrates. They cause mild infections of these tracts but the group also includes the polioviruses, which attack the central nervous system causing poliomyelitis; and the causal agent of foot and mouth disease in cattle, sheep, and pigs.

**picrate** A salt or ester of picric acid.

**picric acid (2,4,6-trinitrophenol)** A yellow highly explosive nitro compound,  $C_6H_2(NO_2)_3$ ; r.d. 1.8; m.p. 122°C.

**pie chart** A diagram in which percentages are shown as sectors of a circle. If x percent of the prey of a carnivore com-

prises species X, y percent species Y, and z percent species Z, a pie chart would show three sectors having central angles  $3.6x^\circ$ ,  $3.6y^\circ$ , and  $3.6z^\circ$ .

**pi electron** An electron in a pi orbital. See ORBITAL.

**piezoelectric effect** The generation of a potential difference across the opposite faces of certain nonconducting crystals (**piezoelectric crystals**) as a result of the application of a mechanical stress between these faces. The electric polarization produced is proportional to the stress and the direction of the polarization reverses if the stress changes from compression to tension. The **reverse piezoelectric effect** is the opposite phenomenon: if the opposite faces of a piezoelectric crystal are subjected to a potential difference, the crystal changes its shape. Rochelle salt and quartz are the most frequently used piezoelectric materials. While Rochelle salt produces the greater polarization for a given stress, quartz is more widely used as its crystals have greater strength and are stable at temperatures in excess of 100°C.

If a quartz plate is subjected to an alternating electric field, the reverse piezoelectric effect causes it to expand and contract at the field frequency. If this field frequency is made to coincide with the natural elastic frequency of the crystal, the plate resonates; the direct piezoelectric effect then augments the applied electric field. This is the basis of the \*crystal oscillator and the \*quartz clock. See also CRYSTAL MICROPHONE; CRYSTAL PICK-UP.

**pig iron** The impure form of iron produced by a blast furnace, which is cast into pigs (blocks) for converting at a later date into cast iron, steel, etc. The composition depends on the ores used, the smelting procedure, and the use to which the pigs will later be put.

**pigment** (in biology) A compound that gives colour to a tissue. Pigments perform a variety of functions. For example, \*haemoglobin in vertebrate erythrocytes gives blood its characteristic red colour and enables the transport of oxygen throughout the body. Other biological pigments include \*chlorophyll, a photosynthetic pigment in plants that is responsible for their green coloration; and

\*melanin, a brown pigment in animals that provides protection from ultraviolet light and can be used in camouflaging colorations.

**pileus** The umbrella-shaped cap of certain fungi, such as mushrooms. Spores are produced from \*gills or pores on the lower surface.

**piliferous layer** The part of the root epidermis that bears \*root hairs. It extends over a region about 4–10 mm behind the root tip. Beyond this the piliferous layer is sloughed off to reveal the hypodermis.

**pillow lava** See LAVA.

**Piltown man** Fossil remains, purported to have been found by Charles Dawson (1864–1916) at Piltown, Sussex, in 1912, that were named *Eoanthropus dawsoni* and described as a representative of the true ancestors of modern humans. The skull resembled that of a human but the jaw was apelike. In 1953 dating techniques showed the specimen to be a fraud.

**pi-meson** See PION.

**pinch effect** A magnetic attraction between parallel conductors carrying currents flowing in the same direction. The force was noticed in early induction furnaces. Since the late 1940s it has been widely studied as a means of confining the hot plasma in a \*thermonuclear reactor. In an experimental toroidal thermonuclear reactor a large electric current is induced in the plasma by electromagnetic induction; this current both heats the plasma and draws it away from the walls of the tube as a result of the pinch effect.

**pineal eye** See MEDIAN EYE.

**pineal gland** An outgrowth of the \*forebrain. In humans its functions are obscure, but in other vertebrates it acts as an endocrine gland, secreting the hormone \*melatonin.

**pinna (auricle)** The visible part of the \*outer ear, present in some mammals. It is made of cartilage and its function is to channel sound waves into the external auditory meatus. In some species the pinna

is movable and aids in detecting the direction from which a sound originates.

**pinocytosis** The process by which a living cell engulfs a minute droplet of liquid. It involves a mechanism similar to \*phagocytosis. See ENDOCYTOSIS.

**pion (pi-meson)** An \*elementary particle classified as a \*meson. It exists in three forms: neutral, positively charged, and negatively charged. The charged pions decay into muons and neutrinos; the neutral pion decays into two gamma-ray photons. Pions consist of a quark and an anti-quark.

**pi orbital** See ORBITAL.

**pipette** A graduated tube used for transferring measured volumes of liquid.

**Pirani gauge** An instrument used to measure low pressures (1–10<sup>-4</sup> torr; 100–0.01 Pa). It consists of an electrically heated filament, which is exposed to the gas whose pressure is to be measured. The extent to which heat is conducted away from the filament depends on the gas pressure, which thus controls its equilibrium temperature. Since the resistance of the filament is dependent on its temperature, the pressure is related to the resistance of the filament. The filament is arranged to be part of a \*Wheatstone bridge circuit and the pressure is read from a microammeter calibrated in pressure units. As the effect depends on the thermal conductivity of the gas, the calibration has to be made each time the pressure of a different gas is measured.

**PIR detector** See PASSIVE DEVICE.

**pirsonnite** A mineral consisting of a hydrated mixed carbonate of sodium and calcium, Na<sub>2</sub>CO<sub>3</sub>·CaCO<sub>3</sub>·2H<sub>2</sub>O.

**Pisces** In some classifications, a superclass of the \*Gnathostomata (jawed chordates) comprising the fishes (*compare* TETRAPODA). There are two classes of modern fish: \*Chondrichthyes (cartilaginous fishes) and \*Osteichthyes (bony fishes).

**pistil** The female part of a flower, consisting either of a single \*carpel (**simple pistil**) or a group of carpels (**compound pistil**).

**pitch 1.** (in chemistry) A black or dark-

brown residue resulting from the distillation of coal tar, wood tar, or petroleum (bitumen). The term is also sometimes used for the naturally occurring petroleum residue (asphalt). Pitch is used as a binding agent (e.g. in road tars), for waterproofing (e.g. in roofing felts), and as a fuel. **2.** (in physics) The property of a sound that characterizes its highness or lowness to an observer. It is related to, but not identical with, frequency. Below about 1000 Hz the pitch is slightly higher than the frequency and above 1000 the position is reversed. The loudness of a sound also affects the pitch. Up to 1000 Hz an increase in loudness causes a decrease in pitch. From about 1000 to 3000 Hz the pitch is independent of loudness, while above 3000 Hz an increase in loudness seems to cause a raising of pitch. Pitch is usually measured in mels; a note of 1000 Hz frequency with a loudness of 40 decibels above the absolute threshold of hearing has a pitch of 1000 mels. **3.** (in mechanics) See SCREW.

**pitchblende** See URANINITE.

**pitfall trap** A simple trap for small invertebrate animals consisting of a tin that is placed in the ground with its rim at ground level. The trap, which contains some kind of bait, can be covered by a tile suspended above ground level by stones so that rain does not enter the tin.

**pith 1. (medulla)** The cylinder of \*parenchyma tissue found in the centre of plant stems to the inside of the vascular tissue. It is light in weight and has been put to various commercial uses, notably the manufacture of pith helmets. **2.** (not in scientific usage) The white tissue below the rind of many citrus fruits. **3.** To destroy the central nervous system of an animal, especially a laboratory animal such as a frog, by severing its spinal cord.

**Pithecanthropus** See HOMO.

**Pitot tube** A device for measuring the speed of a fluid. It consists of two tubes, one with an opening facing the moving fluid and the other with an opening at 90° to the direction of the flow. The two tubes are connected to the opposite sides of a manometer so that the difference be-

tween the dynamic pressure in the first tube and the static pressure in the second tube can be measured. The speed  $v$  of the flow of an incompressible fluid is then given by:  $v^2 = 2(P_2 - P_1)/\rho$ , where  $P_2$  is the dynamic pressure,  $P_1$  is the static pressure, and  $\rho$  is the density of the fluid. The device has a wide variety of applications. It was devised by Henri Pitot (1695-1771).

**pituitary gland (pituitary body; hypophysis)** A pea-sized endocrine gland attached by a thin stalk to the \*hypothalamus at the base of the brain. It consists of two lobes: the anterior and the posterior. The **anterior pituitary** secretes such hormones as \*growth hormone, the \*gonadotrophins, \*prolactin, thyroid-stimulating hormone (see THYROID GLAND) and \*ACTH. Because these hormones regulate the growth and activity of several other endocrine glands, the anterior pituitary is often referred to as the **master endocrine gland**. Activity of the anterior pituitary itself is regulated by specific \*releasing hormones produced by the hypothalamus (see also NEUROENDOCRINE SYSTEM). The **posterior pituitary** secretes the hormones \*oxytocin and antidiuretic hormone.

**pixel** One of the tiny dots that make up an image on the screen of a computer's \*visual-display unit (VDU) or on some types of television receiver; it is short for picture element. Screen resolution is determined by the number of pixels (the more pixels, the better the resolution), and each pixel is given a brightness and colour. A typical high-resolution colour VDU screen has a 1024 × 768 array of pixels.

**pK value** A measure of the strength of an acid or base on a logarithmic scale. For an acid, the value, denoted  $pK_a$ , is given by  $\log_{10}(1/K_a)$ , where  $K_a$  is the acid dissociation constant. Similarly, for a base  $pK_b$  is given by  $\log_{10}(1/K_b)$ .  $pK_a$  values are often used to compare the strengths of different acids.

**placenta 1.** The organ in mammals and other viviparous animals by means of which the embryo is attached to the wall of the uterus. It is composed of embryonic and maternal tissues: extensions of the \*chorion and \*allantois grow into the

uterine wall so that materials (e.g. oxygen, nutrients) can pass between the blood of the embryo and its mother (there is, however, no direct connection between the maternal and embryonic blood). The placenta is eventually expelled as part of the \*afterbirth. **2.** A ridge of tissue on the ovary wall of flowering plants to which the ovules are attached. The arrangement of ovules on the placenta (**placentation**) is variable, depending on the number of carpels and whether they are free (see APOCARPY) or fused (see SYNCARPY).

**Placentalia** See EUTHERIA.

**placoid scale (denticle)** See SCALES.

**Placozoa** A phylum of simple aquatic animals containing just a single known species, *Trichoplax adhaerens*. This has a transparent round flattened body, between 0.2 and 3 mm in diameter, without head, tail, or appendages. It is covered in cilia, which it uses to crawl over surfaces, and it feeds by secreting enzymes from its ventral surface. An adult comprises a few thousand cells of just four types, whose DNA content is the smallest of any animal. The evolutionary relationships of placozoans with other animals, especially the sponges (\*Porifera), remain speculative. Molecular studies of ribosomal RNA sequences have indicated that the Placozoa may be secondarily simplified descendants of more complex ancestors and are not closely related to the sponges.

**plagiotropism** The tendency for a \*tropism (growth response of a plant) to be orientated at an angle to the line of action of the stimulus concerned. For example, the growth of lateral branches and lateral roots is at an oblique angle to the stimulus of gravity (**plagiogeotropism**). Compare ORTHOTROPISM.

**planarians** See TURBELLARIA.

**Planck, Max Carl Ernst Ludwig** (1858–1947) German physicist, who became a professor at Berlin University in 1892. Here he formulated the \*quantum theory, which had its basis in a paper of 1900. (See also \*Planck constant; \*Planck's radiation law). One of the most important scientific discoveries of the century, this theory earned him the 1918 Nobel Prize for physics.

**Planck constant** Symbol  $h$ . The fundamental constant equal to the ratio of the energy  $E$  of a quantum of energy to its frequency  $\nu$ :  $E = h\nu$ . It has the value  $6.626\ 176 \times 10^{-34}$  J s. It is named after Max Planck. In quantum-mechanical calculations (especially particle physics) the **rationalized Planck constant** (or **Dirac constant**)  $\hbar = h/2\pi = 1.054\ 589 \times 10^{-34}$  J s is frequently used.

**Planck length** The length scale at which a classical description of gravity ceases to be valid, and \*quantum mechanics must be taken into account. It is given by  $L_p = \sqrt{(G\hbar/c^3)}$ , where  $G$  is the gravitational constant,  $\hbar$  is the rationalized Planck constant, and  $c$  is the speed of light. The value of the Planck length is of order  $10^{-35}$  m (twenty orders of magnitude smaller than the size of a proton,  $10^{-15}$  m).

**Planck mass** The mass of a particle whose Compton wavelength is equal to the \*Planck length. It is given by  $m_p = \sqrt{(\hbar/G)}$ , where  $\hbar$  is the rationalized Planck constant,  $c$  is the speed of light, and  $G$  is the gravitational constant. The description of an elementary particle of this mass, or particles interacting with energies per particle equivalent to it (through  $E = mc^2$ ), requires a \*quantum theory of gravity. Since the Planck mass is of order  $10^{-8}$  kg (equivalent energy  $10^{19}$  GeV), and, for example, the proton mass is of order  $10^{-27}$  kg and the highest energies attainable in present-day particle accelerators are of order  $10^3$  GeV, quantum-gravitational effects do not arise in laboratory particle physics. However, energies equivalent to the Planck mass did occur in the early universe according to \*big-bang theory, and a quantum theory of gravity is important for discussing conditions there (see PLANCK TIME).

**Planck's radiation law** A law giving the distribution of energy radiated by a \*black body. It introduced into physics the novel concept of energy as a quantity that is radiated by a body in small discrete packets rather than as a continuous emission. These small packets became known as quanta and the law formed the basis of \*quantum theory. The **Planck formula** gives the energy radiated per unit time at

frequency  $\nu$  per unit frequency interval per unit solid angle into an infinitesimal cone from an element of the black-body surface that is of unit area in projection perpendicular to the cone's axis. The expression for this **monochromatic specific intensity**  $I_\nu$  is:

$$I_\nu = 2hc^{-2}\nu^3 / [\exp(h\nu/kT) - 1],$$

where  $h$  is the \*Planck constant,  $c$  is the \*speed of light,  $k$  is the \*Boltzmann constant, and  $T$  is the thermodynamic temperature of the black body.  $I_\nu$  has units of watts per square metre per steradian per hertz ( $\text{W m}^{-2} \text{sr}^{-1} \text{Hz}^{-1}$ ). The monochromatic specific intensity can also be expressed in terms of the energy radiated at wavelength  $\lambda$  per unit wavelength interval; it is then written as  $I_\lambda$ , and the Planck formula is:

$$I_\lambda = 2hc^2\lambda^{-5} / [\exp(hc/\lambda kT) - 1].$$

There are two important limiting cases of the Planck formula. For low frequencies  $\nu \ll kT/h$  (equivalently, long wavelengths  $\lambda \gg hc/kT$ ) the **Rayleigh-Jeans formula** is valid:

$$I_\nu = 2c^{-2}\nu^2 kT,$$

or

$$I_\lambda = 2c\lambda^{-4}kT.$$

Note that these expressions do not involve the Planck constant. They can be derived classically and do not apply at high frequencies, i.e. high energies, when the quantum nature of \*photons must be taken into account. The second limiting case is the **Wien formula**, which applies at high frequencies  $\nu \gg kT/h$  (equivalently, short wavelengths  $\lambda \ll hc/kT$ ):

$$I_\nu = 2hc^{-2}\nu^3 \exp(-h\nu/kT),$$

or

$$I_\lambda = 2hc^2\lambda^{-5} \exp(-hc/\lambda kT).$$

See also WIEN'S DISPLACEMENT LAW.

**Planck time** The time taken for a photon (travelling at the speed of light  $c$ ) to move through a distance equal to the \*Planck length. It is given by  $t_p = \sqrt{(G\hbar/c^5)}$ , where  $G$  is the gravitational constant and  $\hbar$  is the rationalized Planck constant. The value of the Planck time is of order  $10^{-43}$  s. In the \*big-bang theory, up until a time

$t_p$  after the initial instant, it is necessary to use a \*quantum theory of gravity to describe the evolution of the universe.

**Planck units** A system of \*units, used principally in discussions of \*quantum theories of gravity, in which length, mass, and time are expressed as multiples of the \*Planck length, mass, and time respectively. This is equivalent to setting the gravitational constant, the speed of light, and the reduced Planck constant all equal to unity. All quantities that ordinarily have dimensions involving length, mass, and time become dimensionless in Planck units. Since, in the subject area where Planck units are used, it is normal to employ \*Gaussian or \*Heaviside-Lorentz units for electromagnetic quantities, these then become dimensionless. See also GEOMETRIZED UNITS; NATURAL UNITS.

**plane** A flat surface defined by the condition that any two points in the plane are joined by a straight line that lies entirely in the surface.

**plane-polarized light** See POLARIZATION OF LIGHT.

**planet** A body that revolves around a central astronomical body, especially one of the nine bodies (Mercury; Venus; earth; Mars; Jupiter; Saturn; Uranus; Neptune; Pluto) that revolve in elliptical orbits around the sun. See SOLAR SYSTEM.

**planetesimal** One of the many small objects that underwent the process of \*accretion to form the planets of the solar system. Planetesimals probably ranged in size from about 1 millimetre to several kilometres across.

**planimeter** An instrument used to measure the area of a closed curve. The outline of the curve is followed by a pointer on the instrument and the area is given on a graduated disc.

**plankton** Minute \*pelagic organisms that drift or float passively with the current in a sea or lake. Plankton includes many microscopic organisms, such as algae, protozoans, various animal larvae, and some worms. It forms an important food source for many other members of the aquatic community and is divided into

\*zooplankton and \*phytoplankton. *Compare* NEKTON.

**plano-concave lens** *See* CONCAVE; LENS.

**plano-convex lens** *See* CONVEX; LENS.

**plant** Any living organism of the kingdom Plantae. Plants are distinguished from other multicellular organisms by their life cycles, in which a haploid generation (\*gametophyte) alternates with a diploid generation (\*sporophyte). (*See also* ALTERNATION OF GENERATIONS.) Most plants manufacture carbohydrates by \*photosynthesis, in which simple inorganic substances are built up into organic compounds. The radiant energy needed for this process is absorbed by \*chlorophyll, a complex pigment not found in animals. Plants also differ from animals in the possession of \*cell walls (usually composed of \*cellulose). Plants are immobile, as there is no necessity to search for food, and they respond slowly to external stimuli. For a classification of the plant kingdom, see Appendix.

**plant geography (phytogeography)**

The study of the distribution of vegetation around the world, with particular emphasis on the influence of the environmental factors that determine this distribution.

**plantigrade** Describing the gait of many mammals, including humans, in which the whole lower surface of the foot is on the ground. *Compare* DIGITIGRADE; UNGULIGRADE.

**planula** The ciliated free-swimming larva of many cnidarians, consisting of a solid mass of cells. It eventually settles on a suitable surface and develops into a \*polyp.

**plaque** **1.** A thin layer of organic material covering all or part of the exposed surface of a tooth. It contains dissolved food (mostly sugar) and bacteria. The bacteria in plaque metabolize the sugar and produce acid, which eats into the surface of the enamel of the tooth and eventually causes tooth decay (\*dental caries). **2.** A clear area in a bacterial culture grown on an agar plate due to \*lysis of the bacteria by a bacteriophage.

**plasma** **1.** (in physics) A highly ionized gas in which the number of free electrons

is approximately equal to the number of positive ions. Sometimes described as the fourth state of matter, plasmas occur in interstellar space, in the atmospheres of stars (including the sun), in discharge tubes, and in experimental thermonuclear reactors.

Because the particles in a plasma are charged, its behaviour differs in some respects from that of a gas. Plasmas can be created in the laboratory by heating a low-pressure gas until the mean kinetic energy of the gas particles is comparable to the \*ionization potential of the gas atoms or molecules. At very high temperatures, from about 50 000 K upwards, collisions between gas particles cause cascading ionization of the gas. However, in some cases, such as a fluorescent lamp, the temperature remains quite low as the plasma particles are continually colliding with the walls of the container, causing cooling and recombination. In such cases ionization is only partial and requires a large energy input. In \*thermonuclear reactors an enormous plasma temperature is maintained by confining the plasma away from the container walls using electromagnetic fields (*see* PINCH EFFECT). The study of plasmas is known as **plasma physics**.

**2.** (in physiology) *See* BLOOD PLASMA.

**plasma cells** Antibody-producing cells found in the epithelium of the lungs and gut and also in bone-forming tissue. They develop in the lymph nodes, spleen, and bone marrow when antigens stimulate lymphocytes to form the precursor cells that give rise to them (*see* B CELL).

**plasmagel** The specialized outer gel-like \*cytoplasm of living cells (such as *Amoeba*) that move by extruding part of the cell (known as a \*pseudopodium) in the direction of motion. A reversible conversion of plasmagel to the more fluid \*plasmalol is involved in the continuous flow forward of cytoplasm necessary for forming a pseudopodium. *See also* CYTOPLASMIC STREAMING.

**plasma membrane (plasmalemma; cell membrane)** The partially permeable membrane forming the boundary of a cell. It consists mostly of protein and lipid (*see* LIPID BILAYER) and plays various crucial roles in the cell's activities. A key task is

to regulate the flow of materials and signals into and out of the cell; this is accomplished, for example, by membrane proteins that act as \*ion channels or as \*receptors for signal molecules arriving at the cell surface. The plasma membrane is the site of junctions with neighbouring cells and forms attachments to the \*extracellular matrix, thus ensuring tissue integrity. In plants, fungi, bacteria, and many protoctists, it helps in assembling a cell wall or capsule on its outer surface.

**plasma protein** Any of the protein constituents of blood plasma. They comprise \*albumins, \*globulins, and \*fibrinogen.

**plasmasol** The specialized inner sol-like \*cytoplasm of living cells that move by producing \*pseudopodia. Compare PLASMAGEL.

**plasmid** A structure in bacterial cells consisting of DNA that can exist and replicate independently of the chromosome. Plasmids provide genetic instructions for certain cell activities (e.g. resistance to antibiotic drugs). They can be transferred from cell to cell in a bacterial colony. Plasmids are widely used as \*vectors to produce recombinant DNA for \*gene cloning. See also GENETICALLY MODIFIED ORGANISMS (Feature).

**plasmin (fibrinase; fibrinolysin)** An enzyme, present in blood plasma, that breaks down a blood clot by destroying the fibrin threads of the clot and by inactivating factors involved in blood clotting, such as prothrombin and the \*clotting factors. This occurs during \*fibrinolysis. Plasmin is derived from an inactive precursor, \*plasminogen.

**plasminogen** The inactive precursor of the enzyme \*plasmin. Plasminogen is incorporated into blood clots and is converted to plasmin during \*fibrinolysis.

**plasmodesmata** (*sing.* plasmodesma) Fine cytoplasmic strands that connect the \*protoplasts of adjacent plant cells by passing through their cell walls and thus permit the passage of substances between cells. Plasmodesmata are cylindrical in shape (about 20–40 nm in diameter) and are lined by the plasma membrane of the two adjacent cells. The endoplasmic reticula of the two adjacent cells are con-

nected by a narrower structure, the **desmotubule**, which runs through the centre of a plasmodesma.

**plasmolysis** The loss of water by \*osmosis from a plant cell to the extent that the cytoplasm shrinks away from the cell wall. This happens when the cell is placed in a solution that has a higher solute concentration than that of the cell sap, i.e. it has a lower (more negative) \*water potential, since water always moves from an area of high water potential to an area of low water potential. Compare TURGOR.

**plasmon** A \*collective excitation for quantized oscillations of the electrons in a metal.

**plaster of Paris** The hemihydrate of \*calcium sulphate,  $2\text{CaSO}_4 \cdot \text{H}_2\text{O}$ , prepared by heating the mineral gypsum. When ground to a fine powder and mixed with water, plaster of Paris sets hard, forming interlocking crystals of gypsum. The setting results in an increase in volume and so the plaster fits tightly into a mould. It is used in pottery making, as a cast for setting broken bones, and as a constituent of the plaster used in the building industry.

**plasticity** The property of solids that causes them to change permanently in size or shape as a result of the application of a stress in excess of a certain value, called the **yield point**.

**plasticizer** A substance added to a synthetic resin to make it flexible. See PLASTICS.

**plastics** Materials that can be shaped by applying heat or pressure. Most plastics are made from polymeric synthetic \*resins, although a few are based on natural substances (e.g. cellulose derivatives or shellac). They fall into two main classes. **Thermoplastic materials** can be repeatedly softened by heating and hardened again on cooling. **Thermosetting materials** are initially soft, but change irreversibly to a hard rigid form on heating. Plastics contain the synthetic resin mixed with such additives as pigments, plasticizers (to improve flexibility), antioxidants and other stabilizers, and fillers. See Chronology.

**plastid** An \*organelle within a plant cell, often occurring in large numbers. Apart from the nucleus, plastids are the

**PLASTICS**

- 1851 Scottish chemist Charles Macintosh (1766–1843) makes ebonite (from rubber).
- 1855 British chemist Alexander Parkes (1813–90) patents Parkesine, a plastic made from nitrocellulose, methanol, and wood pulp; it is later called ‘celluloid’.
- 1860 British chemist Charles Williams (1829–1910) prepares isoprene (synthetic rubber).
- 1868 US printer John Hyatt (1837–1920) develops commercial process for making celluloid.
- 1884 French chemist Hilaire de Chardonnet (1839–1924) develops process for making rayon.
- 1892 British chemists Edward Bevan (1856–1921) and Charles Cross (1855–1935) develop the viscose process for making rayon.
- 1899 British chemist Frederick Kipping (1863–1949) discovers silicone plastics.
- 1901 German chemists Krische and Spitteler make formaldehyde–casein plastic (Galalith).
- 1905 Belgian-born US chemist Leo Baekland (1863–1944) invents Bakelite.
- 1912 Swiss chemist Jacques Brandenberger produces Cellophane (viscose cellulose film).
- 1913 US Formica Insulation company markets plastic laminate made from formaldehyde resins.
- 1918 Hans John prepares urea–formaldehyde resin.
- 1926 German chemist Hermann Staudinger (1881–1965) discovers the polymeric nature of plastics.
- 1930 US chemist Waldo Semon develops PVC (polyvinyl chloride).
- 1930 Canadian chemist William Chalmers discovers polymethylmethacrylate (Perspex and Plexiglass).
- 1930 German chemists at IG Farbenindustrie produce polystyrene.
- 1931 Wallace Carothers invents nylon.
- 1938 US chemist Roy Plunkett produces polytetrafluoroethene (PTFE).
- 1939 British company ICI develops commercial process for making polyethene.
- 1941 British chemists John Whinfield (1901–66) and J. Dickson develop Terylene (Dacron).
- 1941 German company IG Farbenindustrie produces polyurethane.
- 1943 US Dow Corning company produces silicone plastics.
- 1947 British chemists produce acrylic fibres.
- 1953 German chemist Karl Ziegler (1896–1973) discovers catalyst for making high-density polyethene.
- 1954 Italian chemist Giulio Natta (1903–79) develops industrial process for making high-density polyethene (using Ziegler catalyst).
- 1989 Italian company Ferruzzi produces biodegradable plastic (based on starch).

largest solid inclusions in a plant cell. For convenience they are classified into those containing pigments (\*chromoplasts) and those that are colourless (\*leucoplasts), although changes from one to the other frequently occur. Plastids develop from **proplastids**, colourless bodies found in meristematic and immature cells; they also arise by division of existing plastids. See also CHLOROPLAST.

**plastoglobulus** (*pl. plastoglobuli*) A densely staining droplet found, often in large numbers, in plastids of plant cells. Plastoglobuli consist of lipid pigment and are especially prominent in coloured plastids (\*chromoplasts), for example in ripening fruits. Plastoglobuli also occur in chloroplasts, but are masked by the green chlorophyll. When the chlorophyll breaks down as the leaves start to die in autumn, the pigmented plastoglobuli become apparent as the red or yellow 'fall' colours.

**plastron** See CARAPACE.

**platelet (thrombocyte)** A minute disc-shaped cell fragment in mammalian blood. Platelets are formed as fragments of larger cells (**megakaryocytes**) found in red bone marrow; they have no nucleus. They play an important role in \*blood clotting, releasing thromboxane A<sub>2</sub> (see PROSTAGLANDIN), serotonin, and other chemicals in response to local tissue damage, which causes a chain of events leading to the formation of a plug at the site of the damage, thus preventing further blood loss. There are about 250 000 platelets per cubic millimetre of blood.

**platelet-derived growth factor** See GROWTH FACTOR.

**plate tectonics** The theory, developed in the early 1960s, that the surface of the earth is made of lithospheric plates, which have moved throughout geological time resulting in the present-day positions of the continents. The theory explains the locations of mountain building as well as earthquakes and volcanoes. The rigid lithospheric plates consist of continental and oceanic crust together with the upper mantle, which lie above the weaker plastic asthenosphere. These plates move relative to each other across the earth. Six major plates (Eurasian, American, African,

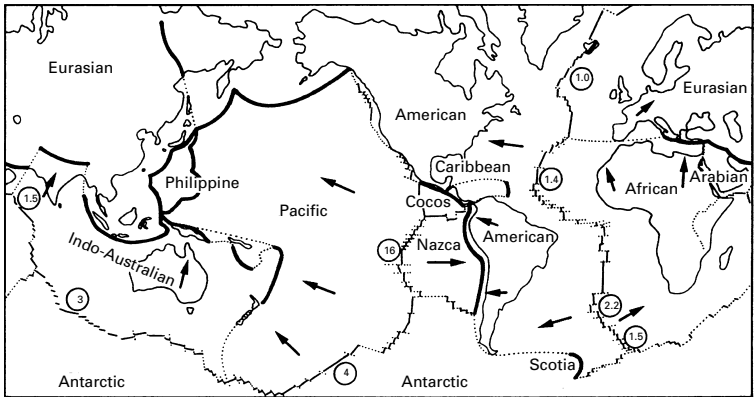

Pacific, Indian, and Antarctic) are recognized, together with a number of smaller ones. The plate margins (boundaries) coincide with zones of seismic and volcanic activity.

A **constructive** (or **divergent**) plate margin occurs when two plates move away from each other. It is marked by a mid-oceanic ridge where basaltic material wells up from the mantle to form new oceanic crust, in a process known as **sea-floor spreading**. The production of new crust at constructive plate margins is compensated for by the destruction of material along a **destructive** (or **convergent**) plate margin. Along these margins, which are also known as **subduction zones** and marked by an oceanic trench, one plate (usually oceanic) is forced to plunge down beneath the other (which may be continental or oceanic). The crust becomes partially melted and rises to form a chain of volcanoes in the upper plate parallel to the trench. When two continental plates collide the compression results in the formation of mountain chains (e.g. the Himalayas formed by the collision of the Indian and Eurasian plates). A third type of plate margin – the **transform plate margin** – occurs where two plates are slipping past each other.

**platinum** Symbol Pt. A silvery white metallic \*transition element (see ALTIMETAL); a.n. 78; r.a.m. 195.09; r.d. 21.45; m.p. 1772°C; b.p. 3827±100°C. It occurs in some nickel and copper ores and is also found native in some deposits. The main source is the anode sludge obtained in copper-nickel refining. The element is used in jewellery, laboratory apparatus (e.g. thermocouples, electrodes, etc.), electrical contacts, and in certain alloys (e.g. with iridium or rhodium). It is also a hydrogenation catalyst. The element does not oxidize nor dissolve in hydrochloric acid. Most of its compounds are platinum(II) or platinum(IV) complexes.

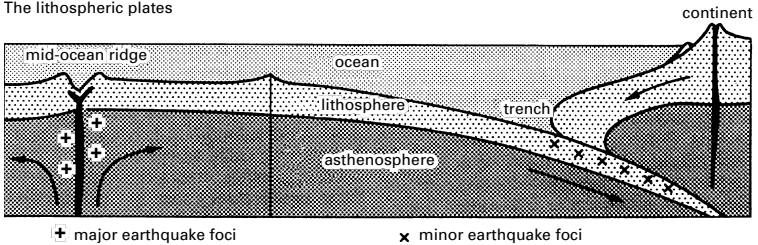

**platinum black** Black finely divided platinum metal produced by vacuum evaporation and used as an absorbent and a catalyst.

**platinum metals** The three members of the second and third transition series immediately preceding silver and gold:

- ← direction of plate movement  
 ..... transform faults  
 ——— destructive plate margins (subduction zones)
- constructive plate margins  
 (3) spreading rates (centimetres per year)

#### The lithospheric plates

Cross-section showing a constructive plate margin, where two plates are drawing apart along a mid-ocean ridge, and a destructive plate margin, where the oceanic plate is being subducted below the continental plate. Volcanic activity and earthquakes are associated with these margins

#### Plate tectonics

ruthenium (Ru), rhodium (Rh), and palladium (Pd); and osmium (Os), iridium (Ir), and platinum (Pt). These elements, together with iron, cobalt, and nickel, were formerly classed as group VIII of the periodic table. The platinum-group metals are relatively hard and resistant to corrosion and are used in jewellery and in some industrial applications (e.g. electrical contacts). They have certain chemical similarities that justify classifying them together. All are resistant to chemical attack. In solution they form a vast range of complex ions. They also form coordination compounds with carbon monoxide and other pi-bonding ligands. A number

of complexes can be made in which a hydrogen atom is linked directly to the metal. The metals and their organic compounds have considerable catalytic activity. *See also* TRANSITION ELEMENTS.

**Platyhelminthes** A phylum of invertebrates comprising the flatworms, characterized by a flattened unsegmented body. The simple nervous system shows some concentration of cells at the head end. The mouth leads to a simple branched gut without an anus. Flatworms are hermaphrodite but self-fertilization is unusual. Many species are parasitic. The phylum contains the classes \*Turbellaria (planari-

ans), \*Trematoda (flukes), and \*Cestoda (tapeworms).

**Playfair, John** See HUTTON, JAMES.

**pleiomorphism** The existence of distinctly different forms during the life cycle of an individual, e.g. the caterpillar, pupa, and winged adult of a butterfly.

**Pleistocene** The earlier epoch of the \*Quaternary period (compare HOLOCENE). It extended from the end of the Pliocene, about 2 million years ago, to the beginning of the Holocene, about 10 000 years ago. The Pleistocene is often known as the **Ice Age** as it was characterized by a series of glacials, in which ice margins advanced towards the equator, separated by interglacials when the ice retreated. See also ICE AGE.

**pleochroic** Denoting a crystal that appears to be of different colours, depending on the direction from which it is viewed. It is caused by polarization of light as it passes through an anisotropic medium.

**pleura (pleural membrane)** The double membrane that lines the thoracic cavity and covers the exterior surface of the lungs. It is a \*serous membrane forming a closed sac, with a small space (the **pleural cavity**) between the two layers.

**plexus** A compact branching network of nerves or blood vessels, such as the **brachial plexus** – a network of spinal nerves that supply branches to the forelimbs in vertebrates. See also CHOROID PLEXUS.

**Pliocene** The fifth and final epoch of the \*Tertiary period. Preceded by the Miocene and followed by the Pleistocene, it began about 5.1 million years ago and lasted for about 3 million years. Mammals similar to modern forms existed during the epoch and the australopithecines (see AUSTRALOPITHECUS), early forerunners of humans, appeared.

**plumbago** See CARBON.

**plumbane (lead(IV) hydride)** An extremely unstable gas,  $PbH_4$ , said to be formed by the action of acids on magnesium–lead alloys. It was first reported in 1924, although doubts have since been ex-

pressed about the existence of the compound. It demonstrates the declining stability of the hydrides in group 14. More stable organic derivatives are known; e.g. trimethyl plumbane,  $(CH_3)_3PbH$ .

**plumbate** A compound formed by reaction of lead oxides (or hydroxides) with alkali. The oxides of lead are amphoteric (weakly acidic) and react to give plumbate ions. With the lead(IV) oxide, reaction with molten alkali gives the plumbate(IV) ion

In fact, various ions are present in which the lead is bound to hydroxide groups, the principal one being the hexahydroxoplumbate(IV) ion  $Pb(OH)_6^{2-}$ . This is the negative ion present in crystalline 'trihydrates' of the type  $K_2PbO_3 \cdot 3H_2O$ . Lead(II) oxide gives the trihydroxoplumbate(II) ion in alkaline solutions

Plumbate(IV) compounds were formerly referred to as **orthoplumbates** ( $PbO_4^{4-}$ ) or **metaplumbates** ( $PbO_3^{2-}$ ). Plumbate(II) compounds were called **plumbites**.

**plumbic compounds** Compounds of lead in its higher (+4) oxidation state; e.g. plumbic oxide is lead(IV) oxide,  $PbO_2$ .

**plumbite** See PLUMBATE.

**plumbous compounds** Compounds of lead in its lower (+2) oxidation state; e.g. plumbous oxide is lead(II) oxide,  $PbO$ .

**plumule 1.** (in zoology) A \*down feather. **2.** (in botany) The part of a plant embryo that develops into the shoot system. It consists of the stem apex and first leaves. In seedlings showing \*epigeal germination the plumule grows above the soil surface together with the cotyledons; in seeds showing \*hypogeal germination, the plumule alone emerges. Compare RADICLE.

**pluripotent** See STEM CELL.

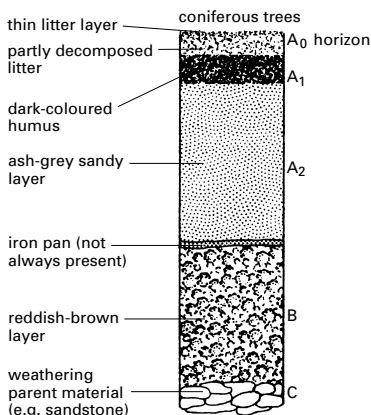

**Pluto** The outermost planet in the \*solar system and the one whose orbit has the highest eccentricity (0.2488) and inclination (17.14°). Its mean distance from the sun is  $5.9 \times 10^9$  km but at perihelion, owing to the high eccentricity of the

orbit, it is closer to the sun than Neptune at about  $4480 \times 10^6$  km. Its \*sidereal period is 248.02 years. Pluto was discovered in 1930 by Clyde Tombaugh (1906–97) although its presence had been previously predicted. In 1978 Pluto was discovered to have a close satellite, provisionally named Charon, and estimates of Pluto's diameter have been reduced from about 5900 km to about 2390 km. The diameter is still not well established. Pluto and Charon appear to be composed mostly of ice with a mean temperature of about 50 K.

**plutonium** Symbol Pu. A dense silvery radioactive metallic transuranic element belonging to the \*actinoids; a.n. 94; mass number of most stable isotope 244 (half-life  $7.6 \times 10^7$  years); r.d. 19.84; m.p.  $641^\circ\text{C}$ ; b.p.  $3232^\circ\text{C}$ . Thirteen isotopes are known, by far the most important being plutonium-239 (half-life  $2.44 \times 10^4$  years), which undergoes \*nuclear fission with slow neutrons and is therefore a vital power source for \*nuclear weapons and some \*nuclear reactors. About 20 tonnes of plutonium are produced annually by the world's nuclear reactors, a detailed inventory of every gram of which is kept in order to prevent its military misuse. The element was first produced by Seaborg, McMillan, Kennedy, and Wahl in 1940.

**pod** See LEGUME.

**podzol (podsol)** A type of soil that forms

Podzol soil profile

under cool humid conditions where the vegetation is coniferous or heath. It is characteristic of the taiga zones of Eurasia and North America. The soil has an ashen-coloured upper layer (the A horizon) overlying a layer (the B horizon) containing iron or humus that has been leached down from the A horizon and redeposited.

**poikilothermy** The passive variation in the internal body temperature of an animal, which depends on the temperature of the environment. All animals except birds and mammals exhibit poikilothermy and are described as \*ectotherms. Although unable to maintain a constant body temperature, they can respond to compensate for very low or very high temperatures. For example, the tissue composition (especially cell osmotic pressure) can change to regulate the blood flow to peripheral tissues (and thus increase heat loss or heat absorption), and the animals can actively seek sun or shade. Seasonal changes in metabolism are usually under hormonal control. In particularly hot climates, ectotherms may undergo \*aestivation to escape the heat. Compare HOMOIOOTHERMY.

**point-contact transistor** See TRANSISTOR.

**point defect** See CRYSTAL DEFECT.

**point discharge** See CORONA.

**point group** The group formed by all the symmetry operations applied to a pattern arranged around a fixed point. The symmetry operations of molecules form point groups. There are 32 point groups, called **crystallographic point groups**, that have symmetries that are also compatible with the translational symmetries of crystals.

**point mutation (gene mutation)** A change in the nucleotide sequence of the DNA within a gene; a gene in which such a change has occurred is known as a \*mutant gene or allele. The DNA sequence can be altered in several ways; for example by \*insertion, \*substitution, \*deletion, and \*inversion. Point mutations result in a misreading of the genetic code during the translation phase of protein synthesis and usually change the order of amino acids

making up a protein, which may or may not affect the function of that protein.

*Compare* CHROMOSOME MUTATION; SINGLE NUCLEOTIDE POLYMORPHISM. *See also* MUTATION.

**poise** A \*c.g.s. unit of viscosity equal to the tangential force in dynes per square centimetre required to maintain a difference in velocity of one centimetre per second between two parallel planes of a fluid separated by one centimetre. 1 poise is equal to  $10^{-1} \text{ N s m}^{-2}$ .

**Poiseuille's equation** An equation relating the volume flow rate,  $V$ , of a fluid through a cylindrical tube to the pressure difference,  $p$ , between the ends of the tube:  $V = \pi pr^4/8l\eta$ , where  $r$  is the radius and  $l$  the length of the tube;  $\eta$  is the viscosity of the fluid. It applies if the Reynolds number is less than 2000 and was first stated by Jean Louis Poiseuille (1799–1869).

**poison 1.** (in biology) Any substance that is injurious to the health of a living organism. **2.** (in chemistry) A substance that prevents the activity of a catalyst. **3.** (in physics) A substance that absorbs neutrons in a nuclear reactor and therefore slows down the reaction. It may be added intentionally for this purpose or may be formed as a fission product and need to be periodically removed.

**Poisson distribution** In \*statistics, a probability distribution that represents the number of events that occur randomly in a given time at an average rate  $\lambda$ , written as  $Po(\lambda)$ . The corresponding probabilities are given by  $P(k) = e^{-\lambda} \lambda^k / k!$  where  $k = 0, 1, 2, 3, \dots$  Such a distribution describes some natural events, such as radioactive decay; it is also used in analysing traffic flow in communication systems. When  $\lambda$  is large, the Poisson distribution approximates to a \*normal distribution. It was named after the French mathematician and physicist Siméon-Denis Poisson (1781–1840). *See also* NORMAL DISTRIBUTION; T-DISTRIBUTION.

**Poisson's ratio** The ratio of the lateral strain to the longitudinal strain in a stretched rod. If the original diameter of the rod is  $d$  and the contraction of the diameter under stress is  $\Delta d$ , the lateral

strain  $\Delta d/d = s_d$ ; if the original length is  $l$  and the extension under stress  $\Delta l$ , the longitudinal strain is  $\Delta l/l = s_l$ . Poisson's ratio is then  $s_d/s_l$ . For steels the value is between 0.28 and 0.30 and for aluminium alloys it is about 0.33. It was first introduced by Simeon Poisson (1781–1840).

**polar body** *See* OOGENESIS.

**polar compound** A compound that is either ionic (e.g. sodium chloride) or that has molecules with a large permanent dipole moment (e.g. water).

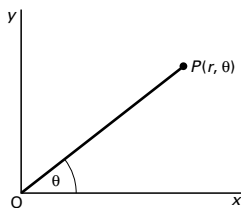

**polar coordinates** A system used in analytical geometry to locate a point  $P$ , with reference to two or three axes. The distance of  $P$  from the origin is  $r$ , and the angle between the  $x$ -axis and the **radius vector**  $OP$  is  $\theta$ , thus in two-dimensional polar coordinates the coordinates of  $P$  are  $(r, \theta)$ . If the \*Cartesian coordinates of  $P$  are  $(x, y)$  then,  $x = r \cos \theta$  and  $y = r \sin \theta$ .

In three dimensions the point  $P$  may be regarded as lying on the surface of a cylinder, giving **cylindrical polar coordinates**, or on the surface of a sphere, giving **spherical polar coordinates**. In the former the coordinates of  $P$  would be  $(r, \theta, z)$ ; in the latter they would be  $(r, \theta, \phi)$  (see illustration).

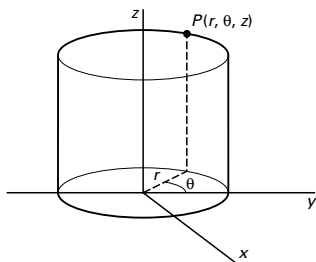

**polarimeter (polariscope)** An instrument used to determine the angle through which the plane of polarization of plane-polarized light is rotated on passing through an optically active substance. Essentially, a polarimeter consists of a light source, a **polarizer** (e.g. a sheet of Polaroid) for producing plane-polarized light, a transparent cell containing the sample, and an **analyser**. The analyser is a polarizing material that can be rotated. Light from the source is plane-polarized by the polarizer and passes through the sample, then through the analyser into the eye or onto a light-detector. The angle of polarization is determined by rotating the analyser until the maximum transmission of light occurs. The angle of rotation is read off a scale. Simple portable polarimeters are used for estimating the concentrations of sugar solutions in confectionary manufacture. *See also* PHOTOELASTICITY.

**polarity 1.** The property of a cell, tissue, or organism of being structurally and/or

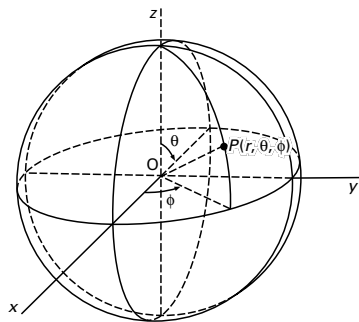

functionally different at opposite ends of its long axis. For example, plants consist of roots, which grow in the direction of the force of gravity, and stems, which grow away from the gravitational force (see GEOTROPISM). **2.** The property of molecules of having an uneven distribution of electrons, so that one part has a positive charge and the other a negative charge.

two-dimensional coordinates

cylindrical polar coordinates

spherical polar coordinates

Polar coordinates

**polarizability** Symbol  $\alpha$ . A measure of the response of a molecule to an external electric field. When a molecule is placed in an external electric field, the displacement of electric charge induces a dipole in the molecule (see ELECTRIC DISPLACEMENT). If the \*electric field strength is denoted  $E$  and the electrical dipole moment induced by this electric field  $p$ , the polarizability  $\alpha$  is defined by  $p = \alpha E$ . To calculate the polarizability from first principles it is necessary to use the quantum mechanics of molecules. However, if regarded as a parameter, the polarizability  $\alpha$  provides a link between microscopic and macroscopic theories as in the \*Clausius-Mossotti equation and the \*Lorentz-Lorenz equation.

**polarization 1.** The process of confining the vibrations of the vector constituting a transverse wave to one direction. In unpolarized radiation the vector oscillates in all directions perpendicular to the direction of propagation. See POLARIZATION OF LIGHT. **2.** The formation of products of the chemical reaction in a \*voltaic cell in the vicinity of the electrodes resulting in increased resistance to current flow and, frequently, to a reduction in the e.m.f. of the cell. See also DEPOLARIZATION. **3.** The partial separation of electric charges in an insulator subjected to an electric field. **4.** The separation of charge in a polar \*chemical bond.

**polarization of light** The process of confining the vibrations of the electric vector of light waves to one direction. In unpolarized light the electric field vibrates in all directions perpendicular to the direction of propagation. After reflection or transmission through certain substances (see POLAROID) the electric field is confined to one direction and the radiation is said to be **plane-polarized light**. The plane of plane-polarized light can be rotated when it passes through certain substances (see OPTICAL ACTIVITY).

In **circularly polarized light**, the tip of the electric vector describes a circular helix about the direction of propagation with a frequency equal to the frequency of the light. The magnitude of the vector remains constant. In **elliptically polarized light**, the vector also rotates about the direction of propagation but the amplitude

changes; a projection of the vector on a plane at right angles to the direction of propagation describes an ellipse. Circularly and elliptically polarized light are produced using a \*retardation plate.

**polarizer** A device used to plane-polarize light (see POLARIZATION OF LIGHT). \*Nicol prisms or \*Polaroid can be used as polarizers. If a polarizer is placed in front of a source of unpolarized light, the transmitted light is plane-polarized in a specific direction. As the human eye is unable to detect that light is polarized, it is necessary to use an \*analyser to detect the direction of polarization. **Crossing** a polarizer and analyser causes extinction of the light, i.e. if the plane of polarization of the polarizer and the plane of the analyser are perpendicular, no light is transmitted when the polarizer and analyser are combined. Both a polarizer and an analyser are components of a \*polarimeter.

**polarizing angle** See BREWSTER'S LAW.

**polar molecule** A molecule that has a dipole moment; i.e. one in which there is some separation of charge in the \*chemical bonds, so that one part of the molecule has a positive charge and the other a negative charge.

**polarography** An analytical technique having an electrochemical basis. A dropping-mercury electrode is used as the cathode along with a large nonpolarizable anode, and a dilute solution of the sample. The **dropping-mercury electrode (DME)** consists of a narrow tube through which mercury is slowly passed into the solution so as to form small drops at the end of the tube, which fall away. In this way the cathode can have a low surface area and be kept clean. A variable potential is applied to the cell and a plot of current against potential (a **polarogram**) made. As each chemical species is reduced at the cathode (in order of their electrode potentials) a step-wise increase in current is obtained. The height of each step is proportional to the concentration of the component. It is also possible to use an electrode formed from a small rotating disc in place of the dropping-mercury electrode. The technique is useful for de-

tecting trace amounts of metals and for the investigation of solvated complexes.

**Polaroid** Trade name for a doubly refracting material that plane-polarizes unpolarized light passed through it. It consists of a plastic sheet strained in a manner that makes it birefringent by aligning its molecules. Sunglasses incorporating a Polaroid material absorb light that is vibrating horizontally – produced by reflection from horizontal surfaces – and thus reduce glare.

**polaron** A coupled electron-ion system that arises when an electron is introduced into the conduction band of a perfect ionic crystal and induces lattice polarization around itself.

**polar solvent** See SOLVENT.

**polar vector** A \*vector that reverses its sign when the coordinate system is changed to a new system by a reflection in the origin (i.e.  $x'_i = -x_i$ ). Compare AXIAL VECTOR.

**pole 1.** See MAGNETIC POLES; MAGNETIC MONOPOLE. **2.** The \*optical centre of a curved mirror.

**pollen** The mass of grains containing the male gametes of seed plants, which are produced in large numbers in the \*pollen sacs. The pollen grains of insect-pollinated plants may be spiny or pitted and are usually larger than those of wind-pollinated plants, which are usually smooth and light. The pollen grain represents the male \*gametophyte generation; it contains two male gamete nuclei. The wall of the mature pollen grain consists of the tough outer wall (**exine**) and the more delicate narrower **intine**. The latter gives rise to the \*pollen tube. See also POLLINATION.

**pollen analysis** See PALYNOLOGY.

**pollen sac** The structure in seed plants in which pollen is produced. In angiosperms there are usually four pollen sacs in each \*anther. In gymnosperms variable numbers of pollen sacs are borne on the microsporophylls that make up the male \*cone.

**pollen tube** An outgrowth of a pollen grain, which transports the male gametes

to the ovule. It will only grow if the pollen grain is compatible with the female tissue. In angiosperms, the pollen grain is deposited on the stigma and the pollen tube grows down through the style and into the ovule. In some conifers, e.g. *Pinus* (pines), the pollen tube penetrates the \*nucellus but does not develop further until the following year, when the female part of the plant is mature. *See also* EMBRYO SAC; FERTILIZATION.

**pollex** The innermost digit on the forelimb of a tetrapod vertebrate. It contains two phalanges (*see* PENTADACTYL LIMB) and in humans and higher primates it is the thumb, which is opposable (i.e. capable of facing and touching the other digits) and gives the hand greater manipulating ability. In some mammals a pollex is absent. *Compare* HALLUX.

**pollination** The transfer of pollen from an anther (the male reproductive organ) to a stigma (the receptive part of the female reproductive organ), either of the same flower (**self-pollination**) or of a different flower of the same species (**cross-pollination**). Cross-pollination involves the action of a pollinating agent to effect transfer of the pollen (*see* ANEMOPHILY; ENTOMOPHILY; HYDROPHILY). *See also* FERTILIZATION; INCOMPATIBILITY.

**pollutant** Any substance, produced and released into the environment as a result of human activities, that has damaging effects on living organisms. Pollutants may be toxic substances (e.g. \*pesticides) or natural constituents of the atmosphere (e.g. carbon dioxide) that are present in excessive amounts. *See* POLLUTION.

**pollution** An undesirable change in the physical, chemical, or biological characteristics of the natural environment, brought about by human activities. It may be harmful to human or nonhuman life. Pollution may affect the soil, rivers, seas, or the atmosphere (*see* AIR POLLUTION). There are two main classes of \*pollutants: those that are **biodegradable** (e.g. sewage), i.e. can be rendered harmless by natural processes and need therefore cause no permanent harm if adequately dispersed or treated; and those that are **non-biodegradable** (e.g. \*heavy metals (such as lead) in industrial effluents and \*DDT and

other chlorinated hydrocarbons used as pesticides), which eventually accumulate in the environment and may be concentrated in food chains. Other forms of pollution in the environment include noise (e.g. from jet aircraft, traffic, and industrial processes) and thermal pollution (e.g. the release of excessive waste heat into lakes or rivers causing harm to wildlife). Recent pollution problems include the disposal of radioactive waste; \*acid rain; \*photochemical smog; increasing levels of human waste; high levels of carbon dioxide and other greenhouse gases in the atmosphere (*see* GREENHOUSE EFFECT); damage to the \*ozone layer by nitrogen oxides, \*chlorofluorocarbons (CFCs), and \*halons; and pollution of inland waters by agricultural \*fertilizers and \*sewage effluent, causing eutrophication (*see* EUTROPHIC). Attempts to contain or prevent pollution include strict regulations concerning factory emissions, the use of smokeless fuels, the banning of certain pesticides, the greater use of renewable energy sources, restrictions on the use of chlorofluorocarbons, and the introduction, in some countries, of catalytic converters to cut pollutants in car exhausts.

**polonium** Symbol Po. A rare radioactive metallic element of group 16 (formerly VIB) of the periodic table; a.n. 84; r.a.m. 210; r.d. 9.32; m.p. 254°C; b.p. 962°C. The element occurs in uranium ores to an extent of about 100 micrograms per 1000 kilograms. It has over 30 isotopes, more than any other element. The longest-lived isotope is polonium-209 (half-life 103 years). Polonium has attracted attention as a possible heat source for spacecraft as the energy released as it decays is  $1.4 \times 10^5 \text{ J kg}^{-1} \text{ s}^{-1}$ . It was discovered by Marie Curie in 1898 in a sample of pitchblende.

**poly-** Prefix indicating a polymer, e.g. polyethylene. Sometimes brackets are used in polymer names to indicate the repeated unit, e.g. poly(ethene).

**polyamide** A type of condensation polymer produced by the interaction of an amino group of one molecule and a carboxylic acid group of another molecule to give a protein-like structure. The polyamide chains are linked together by hydrogen bonding.

**polyatomic molecule** A molecule formed from several atoms (e.g. pyridine,  $C_5H_5N$ , or dinitrogen tetroxide,  $N_2O_4$ ), as distinguished from diatomic and monatomic molecules.

**polybasic acid** An acid with more than one replaceable hydrogen atom. Examples include the dibasic sulphuric acid ( $H_2SO_4$ ) and tribasic phosphoric(V) (orthophosphoric) acid ( $H_3PO_4$ ). Replacement of all the hydrogens by metal atoms forms normal salts. If not all the hydrogens are replaced, \*acid salts are formed.

**Polychaeta** A class of annelid worms in which each body segment has a pair of flattened fleshy lobes (**parapodia**) bearing numerous bristles (\*chaetae). All polychaetes are aquatic and most of them are marine. They include the fanworms (*Sabella*), which construct tubes of sand, etc., in which they live; and the lugworms (*Arenicola*) and ragworms (*Nereis*), which burrow in sand or mud.

**polychlorinated biphenyl (PCB)** Any of a number of derivatives of biphenyl ( $C_{12}H_{10}$ ) in which some of the hydrogen atoms on the benzene rings have been replaced by chlorine atoms. Polychlorinated biphenyls are used in the manufacture of certain polymers as electrical insulators. They are highly toxic and are suspected to be carcinogenic; their increasing use has caused concern because they have been shown to accumulate in the food chain.

**polychloroethene (PVC; polyvinyl chloride)** A tough white solid material, which softens with the application of a plasticizer, manufactured from chloroethene by heating in an inert solvent using benzoyl peroxide as an initiator, or by the free-radical mechanism initiated by heating chloroethene in water with potassium persulphate or hydrogen peroxide. The polymer is used in a variety of ways, being easy to colour and resistant to fire, chemicals, and weather.

**polychromatic radiation** Electromagnetic radiation that consists of a mixture of different wavelengths. This need not refer only to visible radiation. Compare MONOCHROMATIC RADIATION.

**polycyclic** Denoting a compound that

has two or more rings in its molecules. Polycyclic compounds may contain single rings (as in phenylbenzene,  $C_6H_5-C_6H_5$ ) or fused rings (as in naphthalene,  $C_{10}H_8$ ).

**polydioxoboric(III) acid** See BORIC ACID.

**polyembryony 1.** The formation of more than one embryo in a plant seed. Often one embryo develops from the fertilized egg cell, while the others have formed asexually from other tissues in the ovule. **2.** The formation of more than one embryo from a single animal zygote.

\*Identical twins are produced in this way.

**polyene** An unsaturated hydrocarbon that contains two or more double carbon-carbon bonds in its molecule.

**polyester** A condensation polymer formed by the interaction of polyhydric alcohols and polybasic acids. Linear polyesters are saturated thermoplastics and linked by dipole-dipole attraction as the carbonyl groups are polarized. They are extensively used as fibres (e.g. **Terylene**). Unsaturated polyesters readily copolymerize to give thermosetting products. They are used in the manufacture of glass-fibre products. See also ALKYD RESIN.

**polyethene (polyethylene; polythene)** A flexible waxy translucent polyalkene thermoplastic made in a variety of ways producing a polymer of varying characteristics. In the ICI process, ethene containing a trace of oxygen is subjected to a pressure in excess of 1500 atmospheres and a temperature of 200°C. Low-density polyethene (r.d. 0.92) has a formula weight between 50 000 and 300 000, softening at a temperature around 110°C, while the high-density polyethene (r.d. 0.945–0.96) has a formula weight up to 3 000 000, softening around 130°C. The low-density polymer is less crystalline, being more atactic. Polyethene is used as an insulator; it is acid resistant and is easily moulded and blown. See PHILLIPS PROCESS; ZIEGLER PROCESS.

**polyethylene** See POLYETHENE.

**polygene** Any of a group of genes influencing a quantitative characteristic, e.g. height in humans. See POLYGENIC INHERITANCE.

**polygenic inheritance (multifactorial inheritance; quantitative inheritance)** The determination of a particular characteristic, e.g. height or skin colour, by many genes (**polygenes**), each having a small effect individually. Characteristics controlled in this way show \*continuous variation.

**polygon** A plane figure with a number of sides. In a **regular polygon** all the sides and internal angles are equal. For such a polygon with  $n$  sides, the interior angle is  $(180 - 360/n)$  degrees and the sum of the interior angles is  $(180n - 360)$  degrees.

**polygon of forces** A polygon in which the sides represent, in magnitude and direction, all forces acting on a rigid body. The side required to close the polygon represents the resultant of a system of forces.

**polyhedron** A solid bounded by polygonal faces. In a **regular polyhedron** all the faces are congruent regular polygons. The cube is one of five possible regular polyhedrons. The others are the **tetrahedron** (four triangular faces), the **octahedron** (eight triangular faces), the **dodecahedron** (twelve pentagonal faces), and the **icosahedron** (twenty triangular faces).

**polyhydric alcohol** An \*alcohol that has several hydroxyl groups per molecule.

**polymer** A substance having large molecules consisting of repeated units (the monomers). See Feature.

**polymerase** Any enzyme that catalyses the elongation of a polymeric molecule. **RNA polymerases** catalyse the synthesis of RNA using as a template either an existing DNA strand (**DNA-dependent RNA polymerase**) or an RNA strand. **DNA polymerases** catalyse the elongation of a new DNA strand during DNA replication, using an existing DNA strand as template. **RNA-directed DNA polymerase** is more usually known as \*reverse transcriptase.

**polymerase chain reaction (PCR)** A technique used to replicate a fragment of DNA so as to produce many copies of a particular DNA sequence. PCR is commonly employed as an alternative to \*gene cloning as a means of amplifying genetic material for \*DNA sequencing.

The technique has also proved invaluable in forensic science, enabling amplification of minute traces of genetic material for \*DNA fingerprinting or for detecting microsatellite DNA (see REPETITIVE DNA). The two strands of the DNA are separated by heating and short sequences of a single DNA strand (**primers**) are added, together with a supply of free nucleotides and DNA \*polymerase obtained from a bacterium that can withstand extreme heat. In a series of heating and cooling cycles, the DNA sequence flanked by the primers doubles with each cycle and is thus rapidly amplified.

**polymerization** A chemical reaction in which molecules join together to form a polymer. If the reaction is an addition reaction, the process is **addition polymerization**; condensation reactions cause **condensation polymerization**, in which a small molecule is eliminated during the reaction. Polymers consisting of a single monomer are **homopolymers**; those formed from two different monomers are **copolymers**.

**polymethanal** A solid polymer of methanal, formed by evaporation of an aqueous solution of methanal.

**polymethylmethacrylate** A clear thermoplastic acrylic material made by polymerizing methyl methacrylate. The technical name is **poly(methyl 2-methylpropenoate)**. It is used in such materials as **Perspex**.

**polymorphism 1.** (in biology) The existence of two or more distinctly different forms (**morphs**) within a plant or animal species. An example is the \*caste system of social insects, in which there are workers, drones, and queens. This is an **environmental polymorphism**, i.e. the differences are caused by environmental rather than genetic factors, in this case by the larvae receiving different types of food. There are also **heritable** or **genetic polymorphisms**. An example is the occurrence of sickle-cell disease, a genetic disease that principally affects Black populations of central Africa and is characterized by an abnormal form of the blood pigment haemoglobin and sickle-shaped red blood cells. Three different types of individual occur in such popula-

## POLYMERS

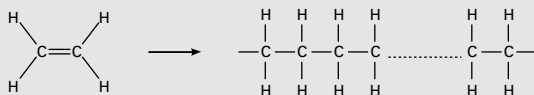

Polymers are substances that have \*macromolecules composed of many repeating units (known as 'mers'). A large number of naturally occurring substances are polymers including \*rubber and many substances based on glucose, such as the polysaccharides \*cellulose and \*starch (in plants) and \*glycogen (in animals). \*Proteins, nucleic acids, and inorganic macromolecular substances, such as \*silicates, are other examples.

### Synthetic polymers

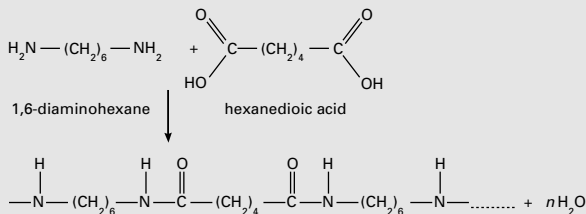

One of the unique features of the chemistry of carbon is its ability to form long chains of atoms. This property is the basis of an important area of industrial chemistry concerned with the manufacture of polymeric materials with a variety of properties (see PLASTICS). The molecules in these materials are essentially long chains of atoms of various lengths. In some polymers, cross-linkage occurs between the chains. Synthetic polymers are formed by chemical reactions in which individual molecules (monomers) join together to form larger units (see POLYMERIZATION). Two types of polymer, **homopolymers** and **heteropolymers**, can be distinguished

### Homopolymers

These are polymers formed from a single monomer. An example is \*polyethene (polyethylene), which is made by polymerization of ethene ( $\text{CH}_2\text{:CH}_2$ ). Typically such polymers are formed by \*addition reactions involving unsaturated molecules. Other similar examples are \*polypropene (polypropylene), polystyrene, and \*polytetrafluoroethene (PTFE).

Addition polymerization of ethene to form polyethene: a homopolymer

Condensation polymerization to form nylon: a heteropolymer

Formation of polymers

tions: those who have two genes (AA) for normal haemoglobin and therefore do not suffer from the disease; those with one normal and one abnormal gene (AS), who are described as having the **sickle-cell trait** and generally suffer no symptoms; and those with two abnormal genes (SS), who suffer a chronic and eventually fatal form of anaemia. Normally such a harmful gene would have been eliminated from the population by the process of natural selection, but it is maintained in this case because people with the sickle-cell trait are resistant to a severe form of malaria endemic in central Africa. *See also* RESTRICTION FRAGMENT LENGTH POLYMORPHISM; SINGLE NUCLEOTIDE POLYMORPHISM. **2.** (in chemistry) The existence of chemical substances in two (**dimorphism**) or more physical forms. *See* ALLOTROPY.

**polynomial** A mathematical expression containing three or more terms. It has the general form  $a_0x^n + a_1x^{n-1} + a_2x^{n-2} + \dots + a_n$ , where  $a_0, a_1, \dots$ , are constants and  $n$  is the highest power of the variable, called the **degree** of the polynomial.

**polynucleotide** *See* NUCLEOTIDE.

**polyp** The sedentary stage in the life cycle of the  $\text{Cnidaria}$ , consisting of a cylindrical body fixed at one end to a firm base and having a mouth surrounded by a ring of tentacles at the other. Some polyps (e.g. *Hydra*) are single; others (e.g. the corals and *Obelia*) form colonies. Polyps typically reproduce asexually by budding to form either new polyps or  $\text{medusae}$ . The latter reproduce sexually giving rise to new polyps. Sea anemones are solitary polyps that reproduce sexually to form new polyps.

**polypeptide** A  $\text{peptide}$  comprising ten or more amino acids. Polypeptides that constitute proteins usually contain 100–300 amino acids. Shorter ones include certain antibiotics, e.g. gramicidin, and some hormones, e.g.  $\text{ACTH}$ , which has 39 amino acids. The properties of a polypeptide are determined by the type and sequence of its constituent amino acids.

**polyphyletic** Denoting any group of organisms the members of which have originated from several different ancestors.

An example is the group including all insectivorous animals. Polyphyletic groups are not natural groups and do not have any place in natural classifications. *Compare* MONOPHYLETIC.

**polyphyodont** Describing a type of dentition in which the teeth are continuously shed and replaced during the lifetime of the animal. Sharks and frogs have a polyphyodont dentition. *Compare* DIPHYODONT; MONOPHYODONT.

**polyploid** Describing a nucleus that contains more than two sets of chromosomes (*see* DIPLOID) or a cell or organism containing such nuclei. For example,  $\text{triploid}$  plants have three sets of chromosomes and  $\text{tetraploid}$  plants have four. Polyploidy is far more common in plants than in animals; many crops, in particular, are polyploid (bread wheat, for example, is  $\text{hexaploid}$ , i.e.  $6n$ ). It can be induced chemically with  $\text{*colchicine}$ . *See also* ALLOPOLYPLOID; AUTOPOLYPLOID.

**polypropene (polypropylene)** An isotactic polymer existing in both low and high formula-weight forms. The lower-formula-weight polymer is made by passing propene at moderate pressure over a heated phosphoric acid catalyst spread on an inert material at  $200^\circ\text{C}$ . The reaction yields the trimer and tetramer. The higher-formula-weight polymer is produced by passing propene into an inert solvent, heptane, which contains a trialkyl aluminium and a titanium compound. The product is a mixture of isotactic and atactic polypropene, the former being the major constituent. Polypropene is used as a thermoplastic moulding material.

**polypropylene** *See* POLYPROPENE.

**polyribosome (polysome)** An aggregate of ribosomes in association with a single messenger RNA molecule during the  $\text{*translation}$  process of protein synthesis. In eukaryotes, polyribosomes are attached to the surface of the rough endoplasmic reticulum and the outer membrane of the nucleus; in bacteria they are found free in the cytoplasm.

**polysaccharide (glycan)** Any of a group of carbohydrates comprising long chains of monosaccharide (simple sugar) mol-

ecules. **Homopolysaccharides** consist of only one type of monosaccharide; **heteropolysaccharides** contain two or more different types. Polysaccharides may have molecular weights of up to several million and are often highly branched. Some important examples are starch, glycogen, and cellulose.

**polysome** See POLYRIBOSOME.

**polyspermy** The entry of several sperms into the egg during fertilization although only one sperm nucleus actually fuses with the egg nucleus. Polyspermy occurs in animals with yolky eggs (e.g. birds).

**polystyrene** A clear glasslike material manufactured by free-radical polymerization of phenylethene (styrene) using benzoyl peroxide as an initiator. It is used as both a thermal and electrical insulator and for packing and decorative purposes.

**polysulphides** See SULPHIDES.

**polytetrafluoroethene (PTFE)** A thermosetting plastic with a high softening point (327°C) prepared by the polymerization of tetrafluoroethene under pressure (45–50 atmospheres). The reaction requires an initiator, ammonium peroxosulphate. The polymer has a low coefficient of friction and its 'anti-stick' properties are probably due to its helical structure with the fluorine atoms on the surface of an inner ring of carbon atoms. It is used for coating cooking utensils and nonlubricated bearings.

**polythene** See POLYETHENE.

**polythionate** A salt of a polythionic acid.

**polythionic acids** Oxo acids of sulphur with the general formula  $\text{HO.SO}_2\text{S}_n\text{.SO}_2\text{.OH}$ , where  $n = 0-4$ . See also SULPHURIC ACID.

**polyurethane** A polymer containing the urethane group  $-\text{NH.CO.O}-$ , prepared by reacting di-isocyanates with appropriate diols or triols. A wide range of polyurethanes can be made, and they are used in adhesives, durable paints and varnishes, plastics, and rubbers. Addition of water to the polyurethane plastics turns them into foams.

**polyvinylacetate (PVA)** A thermoplastic polymer used in adhesives and coatings. It is made by polymerizing vinyl acetate ( $\text{CH}_2\text{:CHCOOCH}_3$ ).

**polyvinyl chloride** See POLYCHLORoETHENE.

**polyyne** An unsaturated hydrocarbon that contains two or more triple carbon-carbon bonds in its molecule.

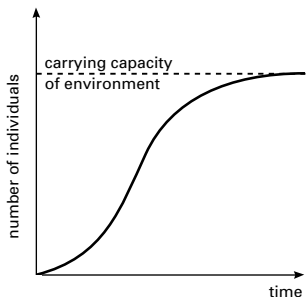

**pome** A type of fruit characteristic of apples and pears. The flesh of the fruit develops from the \*receptacle of the flower, which completely encloses the fused carpels. After fertilization the carpels form the 'core' of the fruit, which contains the seeds. See also PSEUDOCARP.

**pons (pons Varolii)** A thick tract of nerve fibres in the brain that links the medulla oblongata to the midbrain. Its function is to relay impulses between different parts of the brain. The pons is named after its discoverer, the Italian anatomist C. Varoli (1543–75).

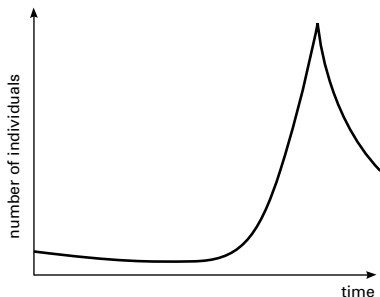

**population** (in ecology) **1.** A group of individuals of the same species within a \*community. The nature of a population is determined by such factors as density, \*sex ratio, birth and death rates, emigration, and immigration. **2.** The total number of individuals of a given species or other class of organisms in a defined area, e.g. the population of rodents in Britain.

**population dynamics** The study of the fluctuations that occur in the numbers of individuals in animal and plant populations and the factors controlling these fluctuations. An important distinction is maintained between those factors that are dependent on population density and have a stabilizing effect (e.g. food supply) and those that are independent of population density (e.g. catastrophes, such as flooding).

**population genetics** The study of the distribution of inherited \*variation among a group of organisms of the same species. The potential for change depends on the sum total of alleles that are available to the organisms (the **gene pool**), and estimates of changes in allele frequency in a population give an indication of its response to a changing condition.

sigmoid growth curve

J-shaped growth curve

Population growth curves

**population growth** The increase in a population that occurs when the \*birth rate is higher than the \*death rate, or when immigration exceeds emigration, or when a combination of these factors is present. A growth curve, obtained by plotting population size against time, is typically S-shaped (sigmoid) or J-shaped (see graphs). A sigmoid curve shows an initial phase of \*exponential growth. The curve levels off when the environment has reached its \*carrying capacity. A J-shaped growth curve shows an initial phase of exponential growth that ceases abruptly, with a sudden decrease in population numbers. This decrease may be caused by a number of factors, such as the end of the life cycle of the prey or any other factor contributing to \*environmental resistance that may suddenly take effect. See also BACTERIAL GROWTH CURVE.

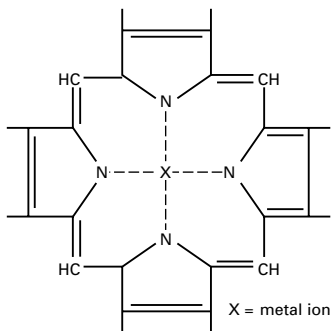

**population inversion** See LASER.

**population type** A method of classifying stars as either population I or population II bodies, devised in 1944 by Wilhelm Baade (1893–1960). Population I stars are the young metal-rich highly luminous stars found in the spiral arms of galaxies. Population II stars are older metal-deficient stars that occur in the centres of galaxies.

**Porifera** The phylum of marine and freshwater invertebrates that comprise the sponges, which live permanently attached to rocks or other surfaces. The body of a sponge is hollow and consists basically of an aggregation of cells be-

tween which there is little nervous coordination. The body is supported by an internal skeleton of spicules of chalk, silica, or fibrous protein (bath sponges have protein skeletons). Undulipodium-bearing cells (**choanocytes**) cause water to flow in through openings in the body wall and out through openings at the top; food particles are filtered from the water by the choanocytes.

**porphyrin** Any of a group of organic pigments characterized by the possession of a cyclic group of four linked nitrogen-containing rings (a **tetrapyrrole** nucleus), the nitrogen atoms of which are often coordinated to metal ions. Porphyrins differ in the nature of their side-chain groups. They include the \*chlorophylls, which contain magnesium; and \*haem, which contains iron and forms the \*prosthetic

Generalized structure of a porphyrin

group of haemoglobin, myoglobin, and the cytochromes.

**portal vein (portal circulation; portal system)** Any vein that collects blood from one network of capillaries and transports it directly to a second capillary network in another region of the body, without returning to the heart. *See* HEPATIC PORTAL SYSTEM.

**positive charge** *See* CHARGE.

**positive feedback** *See* FEEDBACK.

**positron** The antiparticle of the \*electron. *See also* ANNIHILATION; ELEMENTARY PARTICLES; PAIR PRODUCTION.

**positronium** A bound state consisting of an electron and a positron. There are two types of positronium: **orthopositronium**, in which the spins of the two constituents are parallel, and **parapositronium**, in which the spins are antiparallel. Both forms have brief existences, with orthopositronium decaying into three photons in about  $1.5 \times 10^{-7}$  s and parapositronium decaying into two photons in the even shorter time of about  $10^{-10}$  s. Positronium has a hydrogen-like spectrum, but with different values of the frequencies since a positron is much lighter than a proton.

**postcaval vein** *See* VENA CAVA.

**posterior 1.** Designating the part of an animal that is to the rear, i.e. that follows when the animal is moving. In humans and bipedal animals (e.g. kangaroos) the posterior surface is equivalent to the \*dorsal surface. **2.** Designating the side of a flower or axillary bud that faces towards the flower stalk or main stem, respectively. *Compare* ANTERIOR.

**postsynaptic membrane** The membrane at the end of a neuron that receives an impulse at a \*synapse.

**potash** Any of a number of potassium compounds, such as the carbonate or the hydroxide.

**potash alum** *See* ALUMINIUM POTASSIUM SULPHATE; ALUMS.

**potash mica** *See* MUSCOVITE.

**potassamide** *See* POTASSIUM MONOXIDE.

**potassium** Symbol K. A soft silvery

metallic element belonging to group 1 (formerly IA) of the periodic table (*see* ALKALI METALS); a.n. 19; r.a.m. 39.098; r.d. 0.86; m.p. 63.7°C; b.p. 774°C. The element occurs in seawater and in a number of minerals, such as sylvite (KCl), carnallite (KCl.MgCl<sub>2</sub>.6H<sub>2</sub>O), and kainite (MgSO<sub>4</sub>.KCl.3H<sub>2</sub>O). It is obtained by electrolysis. The metal has few uses but potassium salts are used for a wide range of applications. Potassium is an \*essential element for living organisms. The potassium ion, K<sup>+</sup>, is the most abundant cation in plant tissues, being absorbed through the roots and being used in such processes as protein synthesis. In animals the passage of potassium and sodium ions across the nerve-cell membrane is responsible for the changes of electrical potential that accompany the transmission of impulses. Chemically, it is highly reactive, resembling sodium in its behaviour and compounds. It also forms an orange-coloured superoxide, KO<sub>2</sub>, which contains the O<sub>2</sub><sup>-</sup> ion. Potassium was discovered by Sir Humphry Davy in 1807.

**potassium-argon dating** A \*dating technique for certain rocks that depends on the decay of the radioisotope potassium-40 to argon-40, a process with a half-life of about  $1.27 \times 10^{10}$  years. It assumes that all the argon-40 formed in the potassium-bearing mineral accumulates within it and that all the argon present is formed by the decay of potassium-40. The mass of argon-40 and potassium-40 in the sample is estimated and the sample is then dated from the equation:

$${}^{40}\text{Ar} = 0.1102 {}^{40}\text{K}(e^{\lambda t} - 1),$$

where  $\lambda$  is the decay constant and  $t$  is the time in years since the mineral cooled to about 300°C, when the <sup>40</sup>Ar became trapped in the crystal lattice. The method is effective for micas, feldspar, and some other minerals.

**potassium bicarbonate** *See* POTASSIUM HYDROGENCARBONATE.

**potassium bichromate** *See* POTASSIUM DICHROMATE.

**potassium bromide** A white or colourless crystalline solid, KBr, slightly hygroscopic and soluble in water and very slightly soluble in ethanol; cubic; r.d. 2.75;

m.p. 734°C; b.p. 1435°C. Potassium bromide may be prepared by the action of bromine on hot potassium hydroxide solution or by the action of iron(III) bromide or hydrogen bromide on potassium carbonate solution. It is used widely in the photographic industry and is also used as a sedative. Because of its range of transparency to infrared radiation, KBr is used both as a matrix for solid samples and as a prism material in infrared spectroscopy.

**potassium carbonate (pearl ash; potash)** A translucent (granular) or white (powder) deliquescent solid known in the anhydrous and hydrated forms.  $K_2CO_3$  (monoclinic; r.d. 2.4; m.p. 891°C) decomposes without boiling.  $2K_2CO_3 \cdot 3H_2O$  (monoclinic; r.d. 2.04) dehydrates to  $K_2CO_3 \cdot H_2O$  above 100°C and to  $K_2CO_3$  above 130°C. It is prepared by the Engel-Precht process in which potassium chloride and magnesium oxide react with carbon dioxide to give the compound **Engel's salt**,  $MgCO_3 \cdot KHCO_3 \cdot 4H_2O$ . This is decomposed in solution to give the hydrogen-carbonate, which can then be calcined to  $K_2CO_3$ . Potassium carbonate is soluble in water (insoluble in alcohol) with significant hydrolysis to produce basic solutions. Industrial uses include glasses and glazes, the manufacture of soft soaps, and in dyeing and wool finishing. It is used in the laboratory as a drying agent.

**potassium chlorate** A colourless crystalline compound,  $KClO_3$ , which is soluble in water and moderately soluble in ethanol; monoclinic; r.d. 2.32; m.p. 356°C; decomposes above 400°C giving off oxygen. The industrial route to potassium chlorate involves the fractional crystallization of a solution of potassium chloride and sodium chlorate but it may also be prepared by electrolysis of hot concentrated solutions of potassium chloride. It is a powerful oxidizing agent finding applications in weedkillers and disinfectants and, because of its ability to produce oxygen, it is used in explosives, pyrotechnics, and matches.

**potassium chloride** A white crystalline solid, KCl, which is soluble in water and very slightly soluble in ethanol; cubic; r.d. 1.98; m.p. 772°C; sublimes at 1500°C. Potassium chloride occurs natu-

rally as the mineral **sylvite** (KCl) and as **carnallite** ( $KCl \cdot MgCl_2 \cdot 6H_2O$ ); it is produced industrially by fractional crystallization of these deposits or of solutions from lake brines. It has the interesting property of being more soluble than sodium chloride in hot water but less soluble in cold. It is used as a fertilizer, in photography, and as a source of other potassium salts, such as the chlorate and the hydroxide. It has low toxicity.

**potassium chromate** A bright yellow crystalline solid,  $K_2CrO_4$ , soluble in water and insoluble in alcohol; rhombic; r.d. 2.73; m.p. 968.3°C; decomposes without boiling. It is produced industrially by roasting powdered chromite ore with potassium hydroxide and limestone and leaching the resulting cinder with hot potassium sulphate solution. Potassium chromate is used in leather finishing, as a textile mordant, and in enamels and pigments. In the laboratory it is used as an analytical reagent and as an indicator. Like other chromium(III) compounds it is toxic when ingested or inhaled.

**potassium chromium sulphate (chrome alum)** A violet or ruby-red crystalline solid,  $K_2SO_4 \cdot Cr_2(SO_4)_3 \cdot 24H_2O$ , that is soluble in water and insoluble in ethanol; cubic or octahedral; r.d. 1.826; m.p. 89°C; loses  $10H_2O$  at 100°C,  $12H_2O$  at 400°C. Six water molecules surround each of the chromium(III) ions and the remaining ones are hydrogen bonded to the sulphate ions. Like all alums, the compound may be prepared by mixing equimolar quantities of the constituent sulphates. See ALUMS.

**potassium cyanide (cyanide)** A white crystalline or granular deliquescent solid, KCN, soluble in water and in ethanol and having a faint characteristic odour of almonds (due to hydrolysis forming hydrogen cyanide at the surface); cubic; r.d. 1.52; m.p. 634°C. It is prepared industrially by the absorption of hydrogen cyanide in potassium hydroxide. The compound is used in the extraction of silver and gold, in some metal-finishing processes and electroplating, as an insecticide and fumigant (source of HCN), and in the preparation of cyanogen derivatives. In the laboratory it is used in analysis, as a

reducing agent, and as a stabilizing \*ligand for low oxidation states. The salt itself is highly toxic and aqueous solutions of potassium cyanide are strongly hydrolysed to give rise to the slow release of equally toxic hydrogen cyanide gas.

**potassium dichromate (potassium bichromate)** An orange-red crystalline solid,  $K_2Cr_2O_7$ , soluble in water and insoluble in alcohol; monoclinic or triclinic; r.d. 2.68; monoclinic changes to triclinic at 241.6°C; m.p. 396°C; decomposes above 500°C. It is prepared by acidification of crude potassium chromate solution (the addition of a base to solutions of potassium dichromate reverses this process). The compound is used industrially as an oxidizing agent in the chemical industry and in dyestuffs manufacture, in electroplating, pyrotechnics, glass manufacture, glues, tanning, photography and lithography, and in ceramic products. Laboratory uses include application as an analytical reagent and as an oxidizing agent. Potassium dichromate is toxic and considered a fire risk on account of its oxidizing properties.

**potassium dioxide** See POTASSIUM SUPEROXIDE.

**potassium hydride** A white or greyish white crystalline solid, KH; r.d. 1.43–1.47. It is prepared by passing hydrogen over heated potassium and marketed as a light grey powder dispersed in oil. The solid decomposes on heating and in contact with moisture and is an excellent reducing agent. Potassium hydride is a fire hazard because it produces hydrogen on reaction with water.

**potassium hydrogencarbonate (potassium bicarbonate)** A white crystalline solid,  $KHCO_3$ , soluble in water and insoluble in ethanol; r.d. 2.17; decomposes about 120°C. It occurs naturally as **calcinite** and is prepared by passing carbon dioxide into saturated potassium carbonate solution. It is used in baking, soft-drinks manufacture, and in  $CO_2$  fire extinguishers. Because of its buffering capacity, it is added to some detergents and also used as a laboratory reagent.

**potassium hydrogentartrate (cream of tartar)** A white crystalline acid salt,

$HOOC(CHOH)_2COOK$ . It is obtained from deposits on wine vats (argol) and used in baking powders.

**potassium hydroxide (caustic potash; lye)** A white deliquescent solid, KOH, often sold as pellets, flakes, or sticks, soluble in water and in ethanol and very slightly soluble in ether; rhombic; r.d. 2.044; m.p. 360.4°C; b.p. 1320°C. It is prepared industrially by the electrolysis of concentrated potassium chloride solution but it can also be made by heating potassium carbonate or sulphate with slaked lime,  $Ca(OH)_2$ . It closely resembles sodium hydroxide but is more soluble and is therefore preferred as an absorber for carbon dioxide and sulphur dioxide. It is also used in the manufacture of soft soap, other potassium salts, and in Ni-Fe and alkaline storage cells. Potassium hydroxide is extremely corrosive to body tissues and especially damaging to the eyes.

**potassium iodate** A white crystalline solid,  $KIO_3$ , soluble in water and insoluble in ethanol; monoclinic; r.d. 3.9; m.p. 560°C. It may be prepared by the reaction of iodine with hot concentrated potassium hydroxide or by careful electrolysis of potassium iodide solution. It is an oxidizing agent and is used as an analytical reagent. Some potassium iodate is used as a food additive.

**potassium iodide** A white crystalline solid, KI, with a strong bitter taste, soluble in water, ethanol, and acetone; cubic; r.d. 3.13; m.p. 681°C; b.p. 1330°C. It may be prepared by the reaction of iodine with hot potassium hydroxide solution followed by separation from the iodate (which is also formed) by fractional crystallization. In solution it has the interesting property of dissolving iodine to form the triiodide ion  $I_3^-$ , which is brown. Potassium iodide is widely used as an analytical reagent, in photography, and also as an additive to table salt to prevent goitre and other disorders due to iodine deficiency.

**potassium manganate(VII) (potassium permanganate)** A compound,  $KMnO_4$ , forming purple crystals with a metallic sheen, soluble in water (intense purple solution), acetone, and methanol, but decomposed by ethanol; r.d. 2.70; de-

composition begins slightly above 100°C and is complete at 240°C. The compound is prepared by fusing manganese(IV) oxide with potassium hydroxide to form the manganate and electrolyzing the manganate solution using iron electrodes at about 60°C. An alternative route employs production of sodium manganate by a similar fusion process, oxidation with chlorine and sulphuric acid, then treatment with potassium chloride to crystallize the required product.

Potassium manganate(VII) is widely used as an oxidizing agent and as a disinfectant in a variety of applications, and as an analytical reagent.

**potassium monoxide** A grey crystalline solid,  $K_2O$ ; cubic; r.d. 2.32; decomposition occurs at 350°C. It may be prepared by the oxidation of potassium metal with potassium nitrate. It reacts with ethanol to form potassium ethoxide ( $KOC_2H_5$ ), and with liquid ammonia to form potassium hydroxide and **potasamide** ( $KNH_2$ ).

**potassium nitrate (saltpetre)** A colourless rhombohedral or trigonal solid,  $KNO_3$ , soluble in water, insoluble in alcohol; r.d. 2.109; transition to trigonal form at 129°C; m.p. 334°C; decomposes at 400°C. It occurs naturally as **nitre** and may be prepared by the reaction of sodium nitrate with potassium chloride followed by fractional crystallization. It is a powerful oxidizing agent (releases oxygen on heating) and is used in gunpowder and fertilizers.

**potassium nitrite** A white or slightly yellow deliquescent solid,  $KNO_2$ , soluble in water and insoluble in ethanol; r.d. 1.91; m.p. 440°C; may explode at 600°C. Potassium nitrite is prepared by the reduction of potassium nitrate. It reacts with cold dilute mineral acids to give nitrous acid and is also able to behave as a reducing agent (if oxidized to the nitrate) or as an oxidizing agent (if reduced to nitrogen). It is used in organic synthesis because of its part in diazotization, and in detecting the presence of the amino groups in organic compounds.

**potassium permanganate** See POTASSIUM MANGANATE(VII).

**potassium sulphate** A white crystalline powder,  $K_2SO_4$ , soluble in water and insoluble in ethanol; rhombic or hexagonal; r.d. 2.66; m.p. 1069°C. It occurs naturally as **schönite** (Strassfurt deposits) and in lake brines, from which it is separated by fractional crystallization. It has also been produced by the **Hargreaves process**, which involves the oxidation of potassium chloride with sulphuric acid. In the laboratory it may be obtained by the reaction of either potassium hydroxide or potassium carbonate with sulphuric acid. Potassium sulphate is used in cements, in glass manufacture, as a food additive, and as a fertilizer (source of  $K^+$ ) for chloride-sensitive plants, such as tobacco and citrus.

**potassium sulphide** A yellow-red or brown-red deliquescent solid,  $K_2S$ , which is soluble in water and in ethanol but insoluble in diethyl ether; cubic; r.d. 1.80; m.p. 840°C. It is made industrially by reducing potassium sulphate with carbon at high temperatures in the absence of air. In the laboratory it may be prepared by the reaction of hydrogen sulphide with potassium hydroxide. The pentahydrate is obtained on crystallization. Solutions are strongly alkaline due to hydrolysis. It is used as an analytical reagent and as a depilatory. Potassium sulphide is generally regarded as a hazardous chemical with a fire risk; dusts of  $K_2S$  have been known to explode.

**potassium sulphite** A white crystalline solid,  $K_2SO_3$ , soluble in water and very sparingly soluble in ethanol; r.d. 1.51; decomposes on heating. It is a reducing agent and is used as such in photography and in the food and brewing industries, where it prevents oxidation.

**potassium superoxide (potassium dioxide)** A yellow paramagnetic solid,  $KO_2$ , produced by burning potassium in an excess of oxygen; it is very soluble (by reaction) in water, soluble in ethanol, and slightly soluble in diethyl ether; m.p. 380°C. When treated with cold water or dilute mineral acids, hydrogen peroxide is obtained. The compound is a powerful oxidizing agent and on strong heating releases oxygen with the formation of the monoxide,  $K_2O$ .

**potential barrier** A region containing a maximum of potential that prevents a particle on one side of it from passing to the other side. According to classical theory a particle must possess energy in excess of the height of the potential barrier to pass it. However, in quantum theory there is a finite probability that a particle with less energy will pass through the barrier (see TUNNEL EFFECT). A potential barrier surrounds the atomic nucleus and is important in nuclear physics; a similar but much lower barrier exists at the interface between <sup>\*</sup>semiconductors and metals and between differently doped semiconductors. These barriers are important in the design of electronic devices.

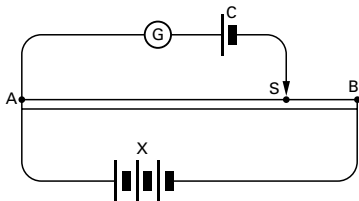

**potential difference** See ELECTRIC POTENTIAL.

**potential divider** See VOLTAGE DIVIDER.

**potential energy** See ENERGY.

**potentiometer 1.** See VOLTAGE DIVIDER.

**2.** An instrument for measuring, comparing, or dividing small potential differences. A typical example of its use is the measurement of the e.m.f. ( $E_1$ ) of a cell by comparing it with the e.m.f. ( $E_2$ ) of a standard cell. In this case a circuit is set up as illustrated, in which AB is a wire of uniform resistance and S is a sliding contact onto this wire. An accumulator X maintains a steady current through the wire. To measure the e.m.f. of a cell C, it is connected up as shown in the diagram and the sliding contact moved until the e.m.f. of C exactly balances the p.d. from the accumulator, as indicated by a zero reading on the galvanometer G. If the length AS is then  $l_1$ , the value of  $E_1$  is given by  $E_1/E_2 = l_1/l_2$ , where  $l_2$  is the length AS when the standard cell is used as the cell C.

Potentiometer

**potentiometric titration** A titration in which the end point is found by measuring the potential on an electrode immersed in the reaction mixture.

**potometer** An apparatus used to measure the rate of water loss from a shoot (see TRANSPIRATION) under natural or artificial conditions.

**pound** The unit of mass in the <sup>\*</sup>f.p.s. system of units defined as 0.453 592 37 kilogram. Before 1963 it was defined in terms of a platinum cylinder called the Imperial Standard Pound.

**poundal** The unit of force in the <sup>\*</sup>f.p.s. system of units equal to the force required to impart to a mass of one pound an acceleration of one foot per second per second.

**powder metallurgy** A process in which powdered metals or alloys are pressed into a variety of shapes at high temperatures. The process started with the pressing of powdered tungsten into incandescent lamp filaments in the first decade of this century and is now widely used for making self-lubricating bearings and cemented tungsten carbide cutting tools.

The powders are produced by atomization of molten metals, chemical decomposition of a compound of the metal, or crushing and grinding of the metal or alloy. The parts are pressed into moulds at pressures ranging from  $140 \times 10^6$  Pa to  $830 \times 10^6$  Pa after which they are heated in a controlled atmosphere to bond the particles together (see SINTERING).

**powder method** See DEBYE-SCHERRER METHOD.

**power 1.** (in physics) Symbol  $P$ . The rate at which work is done or energy is transferred. In SI units it is measured in watts (joules per second). See also HORSEPOWER.

**2.** (in mathematics) The number of times a quantity is multiplied; e.g.  $x^5$  is the fifth power of  $x$ . A **power series** is one in which the power of the variable increases with each term, e.g.  $a_0 + a_1x + a_2x^2 + a_3x^3 + \dots + a_nx^n$ .

**power factor** See ELECTRIC POWER.

**power reactor** A <sup>\*</sup>nuclear reactor designed to produce electrical power.

**poxvirus** One of a group of DNA-containing viruses, often enclosed in an outer membrane, that typically produce skin lesions in vertebrates. They include those viruses causing smallpox (variola), cowpox (vaccinia), and myxomatosis. Some poxviruses produce tumours.

**Poynting vector** Symbol  $S$ . A vector that gives a measure of the flow of energy in an electromagnetic field. It is given by the vector product  $S = E \times H$ , where  $E$  is the electric field strength and  $H$  is the magnetic field strength. It was discovered by the British physicist John Henry Poynting (1852–1914) in 1884.

**praseodymium** Symbol Pr. A soft silvery metallic element belonging to the \*lanthanoids; a.n. 59; r.a.m. 140.91; r.d. 6.773; m.p. 931°C; b.p. 3512°C. It occurs in bastnasite and monazite, from which it is recovered by an ion-exchange process. The only naturally occurring isotope is praseodymium-141, which is not radioactive; however, fourteen radioisotopes have been produced. It is used in mischmetal, a rare-earth alloy containing 5% praseodymium, for use in lighter flints. Another rare-earth mixture containing 30% praseodymium is used as a catalyst in cracking crude oil. The element was discovered by Carl von Welsbach (1856–1929) in 1885.

**preamplifier** An \*amplifier in a radio, record player, etc., providing a first stage of amplification. It is usually located close to the signal source (i.e. the aerial or pick-up) and the signal is then transmitted by cable to the main amplifier. Preamplification at this early stage improves the signal-to-noise ratio of the whole system.

**Precambrian** Describing the time from the formation of the earth, nearly 5 billion years ago, to the beginning of the Cambrian period, some 570 million years ago. The term 'Precambrian' is no longer used for a specific geological time interval but remains as a general adjective. Precambrian time is now divided into three eons: \*Hadean, \*Archaean, and \*Proterozoic. Fossils are rare, although \*stromatolites indicate that there were flourishing populations of bacteria. However, subsequent metamorphism of Precambrian rocks makes correlation of rocks and

events extremely difficult. The largest areas of exposed Precambrian rocks are the shield areas, such as the Canadian (Laurentian) Shield and the Baltic Shield.

**precaval vein** See VENA CAVA.

**precessional motion** A form of motion that occurs when a torque is applied to a rotating body in such a way that it tends to change the direction of its axis of rotation. It arises because the resultant of the angular velocity of rotation and the increment of angular velocity produced by the torque is an angular velocity about a new direction; this commonly changes the axis of the applied torque and leads to sustained rotation of the original axis of rotation.

A spinning top, the axis of which is not exactly vertical, has a torque acting on it as a result of gravity. Instead of falling over, the top precesses about a vertical line through the pivot. The earth also experiences a torque and undergoes a slow precession, primarily as a result of the gravitational attraction of the sun and the moon on its equatorial bulge (see PRECESSION OF THE EQUINOXES).

**precession of the equinoxes** The slow westward motion of the \*equinoxes about the ecliptic as a result of the earth's \*precessional motion. The equinoxes move round the ecliptic with a period of 25 800 years.

**precipitate** A suspension of small solid particles produced in a liquid by chemical reaction.

**precipitation 1.** All liquid and solid forms of water that are deposited from the atmosphere; it includes rain, drizzle, snow, hail, dew, and hoar frost. **2.** The formation of a precipitate.

**precipitin** Any \*antibody that combines with its specific soluble \*antigen to form a precipitate. The term is sometimes applied to the precipitate itself. See also AGGLUTINATION.

**precursor** A compound that leads to another compound in a series of chemical reactions.

**predation** An interaction between two populations of animals in which one (the predator) hunts, captures, and kills the

other (the **prey**) for food. Predator-prey relationships form important links in many food chains. They are also important in regulating population sizes of both predator and prey, especially when the predator relies on a single prey species. The term predation is also used, more loosely, for any feeding relationship in which an organism feeds on any other living organism (animal or plant).

**predator** An animal that obtains its food by \*predation. All predators are \*carnivores, although not all carnivores are predators.

**pregnancy** See GESTATION.

**preimplantation genetic diagnosis (PGD)** The screening of early embryos for disease-causing genes to enable the selection of 'healthy' embryos. The technique is used in conjunction with *in vitro* fertilization, which typically yields a number of embryos. A single cell is removed from an eight-stage embryo and subjected to genetic testing; for example, it may be tested for a specific disease allele. If the results are satisfactory, the embryo is implanted in the mother's uterus, and development proceeds. Removal of a single cell at this stage does not affect the embryo's subsequent development. PGD can help especially when couples who are being treated for fertility problems also have a history of genetic disease. However, use of PGD can be extended in non-therapeutic ways, such as choosing a baby's sex or selecting particular desired traits to produce so-called 'designer babies'. These highly controversial applications of PGD are prohibited in certain countries, including the UK.

**premolar** A broad ridged tooth in mammals that is situated behind the \*canine teeth (when present) and in front of the \*molars. Premolars are adapted for grinding and chewing food and are present in both the deciduous and permanent dentitions.

**premutation** A gene variant (allele) that produces a normal individual but is predisposed to become a full mutation in subsequent generations. Genetic analysis of human families has revealed the involvement of premutations in several ge-

netic diseases. For example, in the gene for Huntington's disease, normal individuals have a string of 6 to 39 CAG repeats near the start of the coding sequence. In individuals with the disease, this region extends to 36-180 CAG repeats. Individuals with CAG repeats in the low 30s have a premutation for Huntington's disease; this region of the gene is amplified during meiosis to become an abnormal allele, sufficient to produce the disease in that individual's offspring.

**preons** Hypothetical entities that are postulated as being 'building blocks' of quarks and leptons. There is no experimental evidence for preons but the idea has considerable theoretical appeal. It is expected that evidence for preons would only be obtained at much higher energies than are available from present accelerators.

**presbyopia** A loss of accommodation that normally develops in human eyes over the age of 45-50 years. Vision of distant objects remains unchanged but accommodation of the eye to near objects is reduced as a result of loss of elasticity in the lens of the eye. The defect is corrected by reading glasses using weak converging lenses.

**pressure** The force acting normally on unit area of a surface or the ratio of force to area. It is measured in \*pascals in SI units. **Absolute pressure** is pressure measured on a gauge that reads zero at zero pressure rather than at atmospheric pressure. **Gauge pressure** is measured on a gauge that reads zero at atmospheric pressure.

**pressure gauge** Any device used to measure pressure. Three basic types are in use: the liquid-column gauge (e.g. the mercury \*barometer and the \*manometer), the expanding-element gauge (e.g. the \*Bourdon gauge and the aneroid \*barometer), and the electrical transducer. In the last category the \*strain gauge is an example. Capacitor pressure gauges also come into this category. In these devices, the pressure to be measured displaces one plate of a capacitor and thus alters its capacitance.

**pressurized-water reactor** See NUCLEAR REACTOR.

**presumptive** Describing embryonic tissue that is not yet \*determined but which will eventually develop into a certain kind of tissue by virtue of its position in the embryo.

**presynaptic membrane** The membrane of a neuron that releases neurotransmitter into the synaptic cleft between nerve cells (see SYNAPSE).

**Prévost's theory of exchanges** A body emits and absorbs radiant energy at equal rates when it is in equilibrium with its surroundings. Its temperature then remains constant. If the body is not at the same temperature as its surroundings there is a net flow of energy between the surroundings and the body because of unequal emission and absorption. The theory was proposed by Pierre Prévost (1751–1839) in 1791.

**prey** An animal that is a source of food for a predator. See PREDATION.

**Pribnow box** A \*consensus sequence of nucleotides – TATAAT – occurring in the promoter region of prokaryote genes (see OPERON) about 10 nucleotides before the start of transcription. The predominance of adenine and thymine bases means that hydrogen bonding between the two DNA strands in this region is relatively weak, enabling the strands to be separated more easily to permit transcription by RNA polymerase. See also TATA BOX.

**prickle** A hard sharp protective outgrowth, many of which may cover the surface of a plant. It contains cortical and vascular tissue and is not regarded as an epidermal outgrowth. Compare SPINE; THORN.

**Priestley, Joseph** (1733–1804) British chemist, who in 1755 became a Presbyterian minister. In Leeds, in 1767, he experimented with carbon dioxide ('fixed air') from a nearby brewery; with it he invented soda water. He moved to a ministry in Birmingham in 1780, and in 1791 his revolutionary views caused a mob to burn his house, as a result of which he emigrated to the USA in 1794. In the early 1770s he experimented with combustion

and produced the gases hydrogen chloride, sulphur dioxide, and dinitrogen oxide (nitrous oxide). In 1774 he isolated oxygen (see also LAVOISIER, ANTOINE).

**primary alcohol** See ALCOHOLS.

**primary amine** See AMINES.

**primary cell** A \*voltaic cell in which the chemical reaction producing the e.m.f. is not satisfactorily reversible and the cell cannot therefore be recharged by the application of a charging current. See DANIELL CELL; LECLANCHÉ CELL; WESTON CELL; MERCURY CELL. Compare SECONDARY CELL.

**primary colour** Any one of a set of three coloured lights that can be mixed together to give the sensation of white light as well as approximating all the other colours of the spectrum. An infinite number of such sets exists, the condition being that none of the individual colours of a set should be able to be matched by mixing the other two; however, unless the colours are both intense and very different the range that they can match well will be limited. The set of primary colours most frequently used is red, green, and blue. See also COLOUR.

**primary consumer** See CONSUMER.

**primary growth** The increase in size of shoots and roots of plants that results from the activity of the \*apical (tip) meristems and subsequent expansion of the cells produced. The tissues thus produced are called **primary tissues** and the resultant plant parts constitute the **primary plant body**. Compare SECONDARY GROWTH.

**primary producer** See PRODUCER.

**primary structure** See PROTEIN.

**primary winding** The winding on the input side of a \*transformer or \*induction coil. Compare SECONDARY WINDING.

**Primates** An order of mammals that includes the monkeys, apes, and humans. Primates evolved from arboreal insectivores 130 million years ago. They are characterized by thumbs and big toes that are opposable (i.e. capable of facing and touching the other digits), which permits manual dexterity, and forward-facing eyes allowing \*binocular vision. The brain, par-

ticularly the cerebrum, is relatively large and well-developed, accounting for the intelligence and quick reactions of these mammals. The young are usually produced singly and undergo a long period of growth and development to the adult form.

**primordium** A group of cells that represents the initial stages in development of a plant organ. Root and shoot primordia are present in a young plant embryo while leaf primordia (or **leaf buttresses**) are seen as small bulges just below the shoot apex.

**principal axis** See OPTICAL AXIS.

**principal focus** A point through which rays close to and parallel to the axis of a lens or spherical mirror pass, or appear to pass, after refraction or reflection. A mirror has one principal focus, a lens has a principal focus on both sides.

**principal plane** The plane that is perpendicular to the optical axis of a lens and that passes through the optical centre. A thick lens has two principal planes, each passing through a \*principal point.

**principal point** Either of two points on the principal axis of a thick lens from which simply related distances can be measured, as from the optical centre of a thin lens.

**principle of superposition** The resultant displacement at any point in a region through which two waves of the same type pass is the algebraic sum of the displacements that the two would separately produce at that point. Both waves leave the region of superposition unaltered.

**printed circuit** An electronic circuit consisting of a conducting material deposited (printed) onto the surface of an insulating sheet. These devices are now common in all types of electronic equipment, facilitating batch production and eliminating the unreliability of the hand-soldered joint.

**printer** A device for producing a printed version of text (and, sometimes, pictures) from a computer. There are several types. **Impact printers** work on the same principle as a typewriter, in which a ribbon is hit by a surface embossed with the char-

acter. A **line printer** produces a whole line of text at a time. In this device the characters are held on a row of spinning cylinders. In a **daisywheel printer**, the characters are held on the ends of a series of arms radiating from the centre of a wheel. A **dot-matrix printer** forms the image of each character from a rectangular matrix of dots. An **inkjet printer** works by spraying fine jets of quick-drying ink onto the paper. A **laser printer** uses a xerographic technique in which a photosensitive plate is scanned by a low-power laser.

**prion** An abnormal form of a normal cell protein (PrP) found in the brain of mammals that is believed to be the agent responsible for the diseases scrapie in sheep, \*bovine spongiform encephalopathy (BSE) in cattle, and \*Creutzfeldt-Jakob disease in humans. Produced by mutation of the normal PrP gene, the abnormal prion protein interacts with normal protein, causing it to accumulate in the brain and progressively damage and destroy brain cells. It can be transmitted to other individuals of the same or closely related species, by injection or ingestion of infected tissue, and some forms appear to be transmissible between species that are not closely related (e.g. between cattle and humans).

**prism 1.** (in mathematics) A polyhedron with two parallel congruent polygons as bases and parallelograms for all other faces. A **triangular prism** has triangular bases. **2.** (in optics) A block of glass or other transparent material, usually having triangular bases. Prisms have several uses in optical systems: they can be used to deviate a ray, to disperse white light into the visible spectrum, or to erect an inverted image (see BINOCULARS). Prisms of other materials are used for different kinds of radiation. See also NICOL PRISM; WOLLASTON PRISM.

**probability** The likelihood of a particular event occurring. If there are  $n$  equally likely outcomes of some experiment, and  $a$  ways in which event E could occur, then the probability of event E is  $a/n$ . For instance, if a die is thrown there are 6 possible outcomes and 3 ways in which an odd number may occur. The probability of throwing an odd number is  $3/6 = 1/2$ .

**Proboscidea** The order of mammals that comprises the elephants. They are herbivorous, with a muscular trunk (\*proboscis) used for drinking, bathing, and collecting food. The tusks are continuously growing upper incisors and the enormous ridged molar teeth are produced in sequence to replace worn teeth throughout life. The order, which evolved in the Eocene epoch, was formerly much larger and more widespread than it is today and included the extinct mammoths. There are only two species of modern elephants: the African and Indian species.

**proboscis 1.** The trunk of an elephant: a muscular and very flexible elongation of the nose, which has a finger-like extremity and is capable of picking up and moving objects, taking in water, collecting food, etc. **2.** The elongated mouthparts of certain invertebrates, such as the two-winged flies (Diptera).

**procambium** A plant tissue formed by the \*apical meristems of shoots and roots. It consists of cells elongated parallel to the long axis of the plant. The procambium subsequently gives rise to the primary \*vascular tissue.

**procaryote** See PROKARYOTE.

**Proconsul** A genus of extinct apes known from fossil remains, 50 million years old, found mostly in Kenya and assigned to the species *P. africanus*. A find made in 1948 was the first discovery of a skull of Miocene ape. It is believed that *Proconsul* was similar and possibly closely related to the genus \**Dryopithecus*.

**producer** An organism considered as a source of energy for those above it in a \*food chain (i.e. at the next \*trophic level). Green plants, which convert energy from sunlight into chemical energy, are **primary producers**; herbivores are **secondary producers**, as they utilize energy from green plants and supply energy for carnivores. Compare CONSUMER.

**producer gas (air gas)** A mixture of carbon monoxide and nitrogen made by passing air over very hot carbon. Usually some steam is added to the air and the mixture contains hydrogen. The gas is used as a fuel in some industrial processes.

**product** See CHEMICAL REACTION.

**productivity (production)** (in ecology) The rate at which an organism, population, or community assimilates energy (**gross productivity**) or makes energy potentially available (as body tissue) to an animal that feeds on it (**net productivity**). The difference between these two rates is due to the rate at which energy is lost through excretion and respiration. Thus **gross primary productivity** is the rate at which plants (or other \*producers) assimilate light energy, and **net primary productivity** is the rate at which energy is incorporated as plant tissue. It is measured in kilojoules per square metre per year ( $\text{kJ m}^{-2} \text{y}^{-1}$ ). In terrestrial plants, much of the net productivity is not actually available to \*consumers, e.g. tree roots are not eaten by herbivores. See also ENERGY FLOW.

**profundal** Occurring in or designating the deep-water zone of an inland lake. Light intensity, oxygen concentration, and (during summer and autumn) temperature are markedly lower than in the surface layer. Compare LITTORAL; SUBLITTORAL.

**progeny** See OFFSPRING.

**progesterone** A hormone, produced primarily by the \*corpus luteum of the ovary but also by the placenta, that prepares the inner lining of the uterus for implantation of a fertilized egg cell. If implantation fails, the corpus luteum degenerates and progesterone production ceases accordingly. If implantation occurs, the corpus luteum continues to secrete progesterone, under the influence of \*luteinizing hormone and \*prolactin, for several months of pregnancy, by which time the placenta has taken over this function. During pregnancy, progesterone maintains the constitution of the uterus and prevents further release of eggs from the ovary. Small amounts of progesterone are produced by the testes. See also PROGESTOGEN.

**progestogen** One of a group of naturally occurring or synthetic hormones that maintain the normal course of pregnancy. The best known is \*progesterone. In high doses progestogens inhibit secretion of \*luteinizing hormone, thereby

preventing ovulation, and alter the consistency of mucus in the vagina so that conception tends not to occur. They are therefore used as major constituents of \*oral contraceptives.

**program** See COMPUTER.

**programmed cell death** See APOPTOSIS.

**progressive wave** See WAVE.

**projectile** Any body that is thrown or projected. If the projectile is discharged on the surface of the earth at an angle  $\theta$  to the horizontal it will describe a parabolic flight path (if  $\theta < 90^\circ$  and the initial velocity  $<$  the \*escape velocity). Neglecting air resistance, the maximum height of this flight path will be  $(v^2 \sin^2 \theta) / 2g$ , where  $v$  is the velocity of discharge and  $g$  is the acceleration of free fall. The horizontal distance covered will be  $(v^2 \sin 2\theta) / g$  and the time of the flight will be  $(2v \sin \theta) / g$ .

**projector** An optical device for throwing a large image of a two-dimensional object onto a screen. In an **episcope**, light is reflected from the surface of an opaque two-dimensional object (such as a diagram or photographic print) and an enlarged image is thrown onto a distant screen by means of a system of mirrors and lenses. The **diascope** passes light through the two-dimensional object (such as a photographic transparency, slide, or film) and uses a converging projection lens to form an enlarged image on a distant screen. An **epidiascope** is a device that can be used as both episcope and diascope. An **overhead projector** is a form of diascope that throws its image on a wall or screen behind and above the operator. In a **motion-picture projector** (or **ciné projector**) the film, consisting of a long sequence of transparent pictures, is driven by a motor past the light source in such a way that each picture comes to rest for a brief period in front of the light source. The illusion of motion is created as each image on the screen is replaced by the next; during the picture change the light is interrupted.

**prokaryote (procaryote)** Any organism belonging to the kingdom Prokaryotae (or Monera), in which the genetic material is not enclosed in a cell nucleus. Bacteria are

prokaryotes. It is believed that eukaryotic cells (see EUKARYOTE) probably evolved as symbiotic associations of prokaryotes. See CELL.

**Prokhorov, Aleksandr** See BASOV, NIKOLAI GENEDIYEVITCH.

**prolactin (lactogenic hormone; luteotrophic hormone; luteotrophin)** A hormone produced by the anterior pituitary gland. In mammals it stimulates the mammary glands to secrete milk (see LACTATION) and the corpus luteum of the ovary to secrete the hormone \*progesterone. Secretion of prolactin is increased by suckling. In birds prolactin stimulates secretion of crop milk by the crop glands.

**proline** See AMINO ACID.

**PROM** See ROM.

**promethium** Symbol Pm. A soft silvery metallic element belonging to the \*lanthanoids; a.n. 61; r.a.m. 145; r.d. 7.26 (20°C); m.p. 1080°C; b.p. 2460°C. The only naturally occurring isotope, promethium-147, has a half-life of only 2.52 years. Eighteen other radioisotopes have been produced, but they have very short half-lives. The only known source of the element is nuclear-waste material. Promethium-147 is of interest as a beta-decay power source but the promethium-146 and -148, which emit penetrating gamma radiation, must first be removed. It was discovered by J. A. Marinsky, L. E. Glendenin, and C. D. Coryell in 1947.

**prominence** A cloud of hot gas from the sun's chromosphere that rises into the lower corona. Cooler than its surroundings, it forms a bright luminous plume lasting for minutes or even for months, and is best seen at the edge of the sun against the blackness of space. Against the sun's disc it appears as a dark feature and is known as a filament. The plumes may be straight (surge and spray prominences), arched (arch prominences) or form a loop (loop prominences). They often form over sunspots, where they are supported by magnetic fields. See also SOLAR FLARE.

**promoter 1.** (in chemistry) A substance added to a catalyst to increase its activity. **2.** (in protein synthesis) The region of a DNA molecule that signals the start of

transcription. See OPERON; PRIBNOW BOX; TATA BOX.

**prompt neutrons** The neutrons emitted during a nuclear fission process within less than a microsecond of fission. Compare DELAYED NEUTRONS.

**pronation** Rotation of the lower forearm so that the hand faces backwards or downwards with the radius and ulna crossed. Compare SUPINATION.

**proof** A measure of the amount of alcohol (ethanol) in drinks. **Proof spirit** contains 49.28% ethanol by weight (about 57% by volume). Degrees of proof express the percentage of proof spirit present, so 70° proof spirit contains  $0.7 \times 57\%$  alcohol.

**1,2-propadiene (allene)** A colourless gas,  $\text{CH}_2\text{CCH}_2$ ; r.d. 1.79; m.p.  $-136^\circ\text{C}$ ; b.p.  $-34.5^\circ\text{C}$ . Propadiene may be prepared from 1,3-dibromopropane ( $\text{CH}_2\text{BrCHCH}_2\text{Br}$ ) by the action of zinc dust. See also ALLENES.

**propagation 1.** (in botany) See VEGETATIVE PROPAGATION. **2.** (in neurophysiology) The process whereby a nerve \*impulse travels along the axon of a neuron. Compare TRANSMISSION.

**propanal (propionaldehyde)** A colourless liquid \*aldehyde,  $\text{C}_2\text{H}_5\text{CHO}$ ; m.p.  $-81^\circ\text{C}$ ; b.p.  $48.8^\circ\text{C}$ .

**propane** A colourless gaseous hydrocarbon,  $\text{C}_3\text{H}_8$ ; m.p.  $-190^\circ\text{C}$ ; b.p.  $-42^\circ\text{C}$ . It is the third member of the \*alkane series and is obtained from petroleum. Its main use is as bottled gas for fuel.

**propanedioic acid (malonic acid)** A white crystalline dicarboxylic acid,  $\text{HOOCCH}_2\text{COOH}$ ; m.p.  $132^\circ\text{C}$ . It decomposes above its melting point to ethanoic acid. Propanedioic acid is used in the synthesis of other dicarboxylic acids.

**propanoic acid (propionic acid)** A colourless liquid \*carboxylic acid,  $\text{CH}_3\text{CH}_2\text{COOH}$ ; r.d. 0.99; m.p.  $-20.8^\circ\text{C}$ ; b.p.  $141^\circ\text{C}$ . It is used to make calcium propanate - an additive in bread.

**propanol** Either of two \*alcohols with the formula  $\text{C}_3\text{H}_7\text{OH}$ . Propan-1-ol is  $\text{CH}_3\text{CH}_2\text{CH}_2\text{OH}$  and propan-2-ol is  $\text{CH}_3\text{CH}(\text{OH})\text{CH}_3$ . Both are colourless

volatile liquids. Propan-2-ol is used in making propanone (acetone).

**propanone (acetone)** A colourless flammable volatile compound,  $\text{CH}_3\text{COCH}_3$ ; r.d. 0.79; m.p.  $-95.4^\circ\text{C}$ ; b.p.  $56.2^\circ\text{C}$ . The simplest \*ketone, propanone is miscible with water. It is made by oxidation of propan-2-ol (see PROPANOL) or is obtained as a by-product in the manufacture of phenol from cumene; it is used as a solvent and as a raw material for making plastics.

**propenal (acrolein)** A colourless pungent liquid unsaturated aldehyde,  $\text{CH}_2=\text{CHCHO}$ ; r.d. 0.84; m.p.  $-87^\circ\text{C}$ ; b.p.  $53^\circ\text{C}$ . It is made from propene and can be polymerized to give acrylate resins.

**propene (propylene)** A colourless gaseous hydrocarbon,  $\text{CH}_3\text{CH}=\text{CH}_2$ ; m.p.  $-185.25^\circ\text{C}$ ; b.p.  $-47.4^\circ\text{C}$ . It is an \*alkene obtained from petroleum by cracking alkanes. Its main use is in the manufacture of polypropene.

**propenoate (acrylate)** A salt or ester of \*propenoic acid.

**propenoic acid (acrylic acid)** An unsaturated liquid \*carboxylic acid,  $\text{CH}_2=\text{CHCOOH}$ ; m.p.  $13^\circ\text{C}$ ; b.p.  $141.6^\circ\text{C}$ . It readily polymerizes and it is used in the manufacture of \*acrylic resins.

**propenenitrile (acrylonitrile; vinyl cyanide)** A colourless liquid,  $\text{H}_2\text{C}=\text{CHCN}$ ; r.d. 0.81; m.p.  $-83.5^\circ\text{C}$ . It is an unsaturated nitrile, made from propene and used to make acrylic resins.

**propenyl group (allyl group)** The organic group  $\text{H}_2\text{C}=\text{CHCH}_2-$ .

**proper motion** The apparent angular motion of a star on the \*celestial sphere. This is motion in a direction that is perpendicular to the line of sight.

**prophage** The DNA of a temperate \*bacteriophage following its incorporation into the host bacterium. The process of incorporation of the viral DNA is known as **lysogeny**.

**prophase** The first stage of cell division, during which chromosomes contract and divide along their length (except for the centromeres) into chromatids. In \*mitosis, the chromosomes remain separate

from each other. In the first division of \*meiosis, homologous chromosomes become paired (see PAIRING). By the end of first prophase the two chromosomes begin to move apart.

**propionaldehyde** See PROPANAL.

**proplastid** See PLASTID.

**proportional counter** A type of detector for \*ionizing radiation in which the size of the output pulse is proportional to the number of ions formed in the initial ionizing event. It operates in a voltage region, called the **proportional region**, intermediate between that of an \*ionization chamber and a \*Geiger counter, avalanche ionization being limited to the immediate vicinity of the primary ionization rather than the entire length of the central wire electrode.

**proportional limit** See ELASTICITY.

**proprioceptor** Any \*receptor that is sensitive to movement, pressure, or stretching within the body. Proprioceptors occurring in muscles, tendons, and ligaments are important for the coordination of muscular activity and the maintenance of balance and posture. See also MUSCLE SPINDLE.

**prop root** Any of the modified roots that arise from the stem of certain plants and provide extra support. Such stems are usually tall and slender and the prop roots develop at successively higher levels as the stem elongates, as in the maize plant. **Buttress roots**, which develop at the base of the trunks of many tropical trees, are similar but tend to have a more flattened appearance. **Stilt roots** are stouter than prop roots. Those formed at the base of the mangrove tree provide firm anchorage in the soft mud of the swamps.

**propylene** See PROPENE.

**propyl group** The organic group  $\text{CH}_3\text{CH}_2\text{CH}_2-$ .

**prosencephalon** See FOREBRAIN.

**prostacyclin** See PROSTAGLANDIN.

**prostaglandin** Any of a group of organic compounds derived from \*essential fatty acids and causing a range of physiological effects in animals. Prostaglandins

have been detected in most body tissues. They act at very low concentrations to cause the contraction of smooth muscle; natural and synthetic prostaglandins are used to induce abortion or labour in humans and domestic animals. Two prostaglandin derivatives have antagonistic effects on blood circulation: **thromboxane A<sub>2</sub>** promotes blood clotting and causes constriction of blood vessels, while **prostacyclin** inhibits blood clotting and causes blood vessels to dilate. Prostaglandins are also involved in inflammation, being released from affected tissues. See also ASPIRIN.

**prostate gland** A gland in male mammals that surrounds and opens into the urethra where it leaves the bladder. During ejaculation it secretes a slightly alkaline fluid into the \*semen that activates the sperms and prevents them from sticking together.

**prosthetic group** A tightly bound non-peptide inorganic or organic component of a protein. Prosthetic groups may be lipids, carbohydrates, metal ions, phosphate groups, etc. Some \*coenzymes are more correctly regarded as prosthetic groups.

**protactinium** Symbol Pa. A radioactive metallic element belonging to the \*actinoids; a.n. 91; r.a.m. 231.036; r.d. 15.37 (calculated); m.p. <1600°C (estimated). The most stable isotope, protactinium-231, has a half-life of  $3.43 \times 10^4$  years; at least ten other radioisotopes are known. Protactinium-231 occurs in all uranium ores as it is derived from uranium-235. Protactinium has no practical applications; it was discovered by Lise Meitner and Otto Hahn in 1917.

**protamine** Any of a group of proteins of relatively low molecular weight found in association with the chromosomal \*DNA of vertebrate sperm cells. They contain a single polypeptide chain comprising about 67% arginine. Protamines serve in packaging the highly condensed DNA of the germ-cell chromosomes.

**protandry 1.** The condition in which the male reproductive organs (stamens) of a flower mature before the female ones (carpels), thereby ensuring that self-ferti-

zation does not occur. Examples of protandrous flowers are ivy and rosebay willowherb. *Compare* PROTOGYNY; HOMOGAMY. *See also* DICHOGAMY. **2.** The condition in some hermaphrodite or colonial invertebrates in which the male gonads or individuals are sexually mature before the female ones. *Compare* PROTOGYNY.

**protease (peptidase; proteinase; proteolytic enzyme)** Any enzyme that catalyses the hydrolysis of proteins into smaller \*peptide fractions and amino acids, a process known as **proteolysis**. Examples are \*pepsin and \*trypsin. Several proteases, acting sequentially, are normally required for the complete digestion of a protein to its constituent amino acids.

**protein** Any of a large group of organic compounds found in all living organisms. Proteins comprise carbon, hydrogen, oxygen, and nitrogen and most also contain sulphur; molecular weights range from 6000 to several million. Protein molecules consist of one or several long chains (\*polypeptides) of \*amino acids linked in a characteristic sequence. This sequence is called the **primary structure** of the protein. These polypeptides may undergo coiling or pleating, the nature and extent of which is described as the **secondary structure**. The three-dimensional shape of the coiled or pleated polypeptides is called the **tertiary structure**. **Quaternary structure** specifies the structural relationship of the component polypeptides.

Proteins may be broadly classified into globular proteins and fibrous proteins. **Globular proteins** have compact rounded molecules and are usually water-soluble. Of prime importance are the \*enzymes, proteins that catalyse biochemical reactions. Other globular proteins include the \*antibodies, which combine with foreign substances in the body; the carrier proteins, such as \*haemoglobin; the storage proteins (e.g. \*casein in milk and \*albumin in egg white), and certain hormones (e.g. \*insulin). **Fibrous proteins** are generally insoluble in water and consist of long coiled strands or flat sheets, which confer strength and elasticity. In this category are \*keratin and \*collagen. Actin and myosin are the principal fibrous proteins of muscle, the interaction of which brings

about muscle contraction. \*Blood clotting involves the fibrous protein called fibrin.

When heated over 50°C or subjected to strong acids or alkalis, proteins lose their specific tertiary structure and may form insoluble coagulates (e.g. egg white). This usually inactivates their biological properties.

**protein blotting** *See* WESTERN BLOTTING.

**protein engineering** The techniques used to alter the structure of proteins (especially enzymes) in order to improve their use to humans. This involves artificially modifying the DNA sequences that encode them so that, for example, new amino acids are inserted into existing proteins. Synthesized lengths of novel DNA can be used to produce new proteins by cells or other systems containing the necessary factors for \*transcription and \*translation. Alternatively, new proteins can be synthesized by **solid state synthesis**, in which polypeptide chains are assembled under the control of chemicals. One end of the chain is anchored to a solid support and the chemicals selectively determine which amino acids are added to the free end. The appropriate chemicals can be renewed during the process; when synthesized, the polypeptide is removed and purified. Protein engineering is used to synthesize enzymes (so-called 'designer enzymes') used in biotechnology. The three-dimensional tertiary structure of proteins is crucially important for their function, and this can be investigated using computer-aided modelling.

**proteinoid** A protein-like substance formed by polymerization of amino acids under inorganic conditions, such as heating to over 140°C. In the 1970s it was discovered that proteinoids could also be formed by relatively mild heating (70°C) in the presence of certain inorganic catalysts (e.g. phosphoric acid). In water, proteinoids aggregate to form small round bodies called **proteinoid microspheres**, or 'protocells'. These have certain attributes of living cells, such as a differentially permeable filmlike outer layer, the ability to swell and shrink due to osmotic movements of water, and the capability for

budding and binary fission. It has been proposed that such microspheres could have provided a suitable vehicle for the chemical components of life to evolve a primitive form of metabolism and pave the way for the emergence of the first living cells.

**protein sequencing** The process of determining the amino-acid sequence of a protein or its component polypeptides. The technique most commonly used is Edman degradation (devised by Pehr Edman), in which the terminal amino-acid residues are removed sequentially and identified chromatographically. Each step is automated and the whole process can now be performed by a single machine – the sequenator. Large polypeptides must be cleaved into smaller peptides before sequencing.

The results of this chemical sequencing can often be compared with the amino-acid sequence deduced by \*DNA sequencing. The gene coding for the protein under investigation may be found by screening a \*DNA library, for example by \*Western blotting. However, the base sequence of the gene gives only the amino-acid sequence of the nascent protein, i.e. before post-translational modification. The sequence of the functional protein can only be found by chemical analysis.

**protein synthesis** The process by which living cells manufacture proteins from their constituent amino acids, in accordance with the genetic information carried in the DNA of the chromosomes. This information is encoded in messenger \*RNA, which is transcribed from DNA in the nucleus of the cell (see GENETIC CODE; TRANSCRIPTION); the sequence of amino acids in a particular protein is determined by the sequence of nucleotides in messenger RNA. At the ribosomes the information carried by messenger RNA is translated into the sequence of amino acids of the protein in the process of \*translation.

**proteolysis** The enzymic splitting of proteins. See PROTEASE.

**proteolytic enzyme** See PROTEASE.

**proteome** The entire complement of proteins synthesized by a cell or organism

at a given time. This can be determined by analysing protein constituents of cell contents using such techniques as gel electrophoresis, high-throughput liquid chromatography, and mass spectroscopy, coupled with automated database searching to identify proteins. Unlike the genome, the proteome is constantly changing due to the influence of intracellular and extracellular factors. See PROTEOMICS.

**proteomics** The study of the proteins synthesized by a particular cell or organism (see PROTEOME). This vast and rapidly expanding field is of fundamental significance to many areas of biology and medicine. It endeavours to determine what proteins a cell makes, how and when it makes them and in what quantities, how different proteins function, where they function, and how they interact with other cell components, including other proteins. Moreover, proteomics seeks to discover the internal and external factors that influence the proteome, for example during development, disease, or ageing. See also TRANSCRIPTOMICS.

**Proterozoic** The eon of geological time extending from the end of the \*Archaean, about 2600 million years ago, to the start of the present eon (see PHANEROZOIC), about 570 million years ago. Life in the early Proterozoic was dominated by bacteria, which flourished in shallow seas and muds. They depended on a wide variety of metabolic strategies, including photosynthesis, which were crucial in determining the composition of the earth's atmosphere and oceans. The oldest eukaryotic fossils date from after the middle Proterozoic, about 1200 million years ago. These early protocists are thought to have arisen through symbiotic associations of various prokaryotes (see ENDOSYMBIONT THEORY), probably on several independent occasions.

**prothallus** A small flattened multicellular structure that represents the independent \*gametophyte generation of clubmosses, horsetails, and ferns. In some of these plants a single prothallus bears both male and female sex organs. In others there are separate male and female prothalli.

**prothrombin (Factor II)** One of the blood \*clotting factors. It is the precursor of the enzyme thrombin, which catalyses the formation of the fibrin matrix of the blood clot. Prothrombin synthesis occurs in the liver and is dependent on adequate supplies of vitamin K. *See also* BLOOD CLOTTING.

**Protista** In some classifications, a kingdom containing unicellular eukaryotes that cannot be classified as animals, plants, or fungi. Originally proposed by Ernst \*Haeckel in 1866 to include the algae, bacteria, fungi, and protozoa, it was later restricted first to unicellular organisms, and then to protozoa, unicellular algae, and organisms then regarded as simple fungi. In most modern classifications it has been replaced by the \*Protocista.

**Protoctista** A kingdom consisting of unicellular or simple multicellular organisms that possess nuclei and cannot be classified as animals, plants, or fungi. Protoctists include the \*protozoa, \*algae, and \*slime moulds. *See also* PROTISTA.

**protogyny 1.** The condition in which the female reproductive organs (carpels) of a flower mature before the male ones (stamens), thereby ensuring that self-fertilization does not occur. Examples of protogynous flowers are plantain and figwort. *Compare* PROTANDRY; HOMOGAMY. *See also* DICHOAMY. **2.** The condition in hermaphrodite or colonial invertebrates in which the female gonads or individuals are sexually mature before the male ones. *Compare* PROTANDRY.

**proton** An \*elementary particle that is stable, bears a positive charge equal in magnitude to that of the \*electron, and has a mass of  $1.672\ 614 \times 10^{-27}$  kg, which is 1836.12 times that of the electron. The proton occurs in all atomic nuclei (the hydrogen nucleus consists of a single proton).

**proton decay** A process of the type

where a proton decays into a positron and a pion, predicted to occur in \*grand unified theories (GUTs) because baryon number is no longer conserved. The life-

time depends on the theory used and is typically  $10^{35}$  years, but a combination of GUTs and \*supersymmetry gives a lifetime of about  $10^{45}$  years. Considerable experimental effort has been spent in looking for proton decay, so far with no success.

**protonic acid** An \*acid that forms positive hydrogen ions (or, strictly, oxonium ions) in aqueous solution. The term is used to distinguish 'traditional' acids from Lewis acids or from Lowry-Brønsted acids in nonaqueous solvents.

**proton number** *See* ATOMIC NUMBER.

**proto-oncogene** *See* ONCOGENE.

**protoplasm** The material comprising the living contents of a \*cell, i.e. all the substances in a cell except large vacuoles and material recently ingested or to be excreted. The term is no longer used; the material of the cell is now referred to as the \*nucleoplasm and the \*cytoplasm.

**protoplast (energid)** The living unit of a cell, consisting of the nucleus and cytoplasm bounded by the plasma membrane. Protoplasts of bacterial and plant cells can be prepared by removing the cell wall; they are used to study the processes involved in cell metabolism and reproduction.

**protostar** *See* STELLAR EVOLUTION.

**Prototheria** A subclass of mammals – the monotremes – that lay large yolky eggs. It contains only the duckbilled platypus and the spiny anteater. After hatching, the young feed on milk from simple mammary glands inside a maternal abdominal pouch. In the anteater the eggs are also incubated in this pouch, while the platypus builds an underground nest. Adult monotremes have no true teeth. Their skeleton resembles that of a reptile, and although they are warm-blooded the body temperature is somewhat variable. They are believed to have originated at least 150 million years ago.

**protozoa** A group of unicellular or acellular, usually microscopic, organisms now classified in various phyla of the kingdom \*Protocista. They were formerly regarded either as a phylum of simple animals or as members of the kingdom \*Protista. They

are very widely distributed in marine, freshwater, and moist terrestrial habitats; most protozoans are saprotrophs, but some are parasites, including the agents causing malaria (*Plasmodium*) and sleeping sickness (*Trypanosoma*), and a few contain chlorophyll and carry out photosynthesis, like plants. Protozoan cells may be flexible or rigid, with an outer \*pellicle or protective **test**. In some (such as *Paramecium* and *Trypanosoma*) cilia or flagella (see **UNDULIPODIUM**) are present for locomotion; others (such as \**Amoeba*) have \*pseudopodia for movement and food capture. \*Contractile vacuoles occur in freshwater protozoans. Reproduction is usually asexual, by binary \*fission, but some protozoans undergo a form of sexual reproduction (see **CONJUGATION**).

**Prout's hypothesis** The hypothesis put forward by the British chemist William Prout (1785–1850) in 1815 that all atomic weights are integer multiples of the atomic weight of hydrogen and hence that all atoms are made out of hydrogen. Subsequent work on atomic weights in the 19th century showed that this hypothesis is incorrect (with chlorine having an atomic weight of 35.5 being a glaring example of this). The understanding of atomic structure that emerged in the 20th century, with atomic number being the number of protons in an atom and non-integer atomic weights being due to mixtures of isotopes, has vindicated the spirit of Prout's hypothesis.

**proventriculus 1.** The anterior part of the stomach of a bird, where digestive enzymes are secreted. Food passes from the proventriculus to the \*gizzard. **2.** See **GASTRIC MILL**.

**provirus** The intermediate stage in the infection of a host cell by a virus, e.g. a \*retrovirus, in which the viral genome is integrated into the host cell DNA, where it can undergo successive replications before being transcribed to form new RNA viruses. A provirus, notably that of \*HIV, can remain dormant for long periods before being transcribed.

**proximal** Denoting the part of an organ that is nearest to the organ's point of attachment. For example, the knuckles are

at the proximal end of the fingers. *Compare* **DISTAL**.

**proximal convoluted tubule (first convoluted tubule)** The section of a \*nephron situated between Bowman's capsule and the loop of Henle in the vertebrate kidney. Reabsorption of salt, water, and glucose from the \*glomerular filtrate occurs in this tubule; at the same time certain substances, including uric acid and drug metabolites, are actively transferred from the blood capillaries into the tubule. Both activities are facilitated by finger-like projections (see **BRUSH BORDER**) on the inner surface of the tubule, which increase its effective surface area.

**prussic acid** See **HYDROGEN CYANIDE**.

**pseudoaromatic (antiaromatic)** A compound that has a ring of atoms containing alternating double and single bonds, yet does not have the characteristic properties of \*aromatic compounds. Such compounds do not obey the Hückel rule. Cyclooctatetraene ( $C_8H_8$ ), for instance, has a ring of eight carbon atoms with conjugated double bonds, but the ring is not planar and the compound acts like an alkene, undergoing addition reactions. See also **ANNULENES**.

**pseudocarp (false fruit)** A fruit that incorporates, in addition to the ovary wall, other parts of the flower, such as the \*receptacle. For example, the fleshy part of the strawberry is formed from the receptacle and the 'pips' on the surface are the true fruits. See also **COMPOSITE FRUIT**; **POME**; **SOROSIS**; **SYCONUS**.

**pseudogene** A sequence of nucleotides in DNA that resembles a functional gene but is not transcribed. Pseudogenes are thought to arise by duplication of an existing gene through unequal crossing-over during meiosis, with accompanying loss of the promoter or other flanking regions required for transcription. For example, the  $\alpha$ - and  $\beta$ -globin gene clusters in humans contain several pseudogenes.

**pseudohalogens** A group of compounds, including cyanogen ( $CN$ )<sub>2</sub> and thiocyanogen ( $SCN$ )<sub>2</sub>, that have some resemblance to the halogens. Thus, they form hydrogen acids (HCN and HSCN) and

ionic salts containing such ions as  $\text{CN}^-$  and  $\text{SCN}^-$ .

**pseudo order** An order of a chemical reaction that appears to be less than the true order because of the experimental conditions used. Pseudo orders occur when one reactant is present in large excess. For example, a reaction of substance A undergoing hydrolysis may appear to be proportional only to  $[\text{A}]$  because the amount of water present is so large.

**pseudoparenchyma** A tissue that superficially resembles plant parenchyma but is made up of an interwoven mass of hyphae (in fungi) or filaments (in algae). Examples of pseudoparenchymatous structures are the fruiting bodies (mushrooms, toadstools, etc.) of certain fungi and the thalli of certain red and brown algae.

**pseudopodium** A temporary outgrowth of the cell of some protozoans (e.g. *Amoeba*), which serves as a feeding and locomotory organ. Pseudopodia may be blunt or threadlike, form a branching network, or be stiffened with an internal supporting rod. Phagocytic white blood cells also form pseudopodia to engulf invading bacteria.

**pseudopregnancy** A state resembling pregnancy that may occur in some mammals (e.g. rabbits and rodents) in which many of the phenomena of pregnancy are present but there is no fetus developing in the uterus. It is caused by an extended dioestrus (see OESTROUS CYCLE) in the absence of fertilization.

**pseudo-scalar** A \*scalar quantity that changes sign when the coordinate system is changed to a new system by a reflection in the origin (i.e.  $x'_i = -x_i$ ). It is the \*scalar product of an \*axial vector and a \*polar vector.

**pseudo-vector** See AXIAL VECTOR.

**psi particle (J particle)** A \*meson discovered in 1974, which led to the extension of the quark model and the hypothesis that a fourth quark existed with the property of charm (see ELEMENTARY PARTICLES). The psi particle is believed to consist of a charmed quark and its antiquark.

**psychrometer** See HYGROMETER.

**Pteridophyta** In traditional classification systems, a division of the plant kingdom that included ferns, horsetails, and clubmosses, i.e. the nonseed-bearing tracheophytes. These are now classified as separate phyla: \*Filicinophyta (ferns), \*Sphenophyta (horsetails), and \*Lycophyta (clubmosses).

**Pteridospermales** See CYCADOFILICALES.

**pterodactyls** See PTEROSAURIA.

**Pterophyta** See FILICINOPHYTA.

**Pteropsida** In older classifications, a subdivision of tracheophytes that contained the ferns and seed plants, or a class of the \*Pteridophyta containing only the ferns.

**Pterosauria** An extinct order of flying reptiles – the pterodactyls – that lived in the Jurassic and Cretaceous periods (180–70 million years ago). Pterodactyls had beaked jaws and an elongated fourth finger that supported a membranous wing. They had long jointed tails, no feathers, and could probably only fly by soaring.

**PTFE** See POLYTETRAFLUOROETHENE.

**PTH** See PARATHYROID HORMONE.

**Ptolemaic astronomy** The system of astronomy originally proposed by Apollonius of Perga in the third century BC and completed by Claudius Ptolemaeus of Alexandria (100–178 AD). It assumed that the earth was at the centre of the universe and that each known planet, the moon, and the sun moved round it in a circular orbit, called the deferent. In addition to this motion the orbiting bodies also described epicycles, small circles about points on the deferent. The system gave moderately good predictions, but was completely replaced by the heliocentric astronomy of Copernicus in the 16th century. The Ptolemaic system was published by Ptolemaeus in the work known by its Arabic name, the *Almagest*.

**ptyalin** An enzyme that digests carbohydrates (see AMYLASE). It is present in mammalian \*saliva and is responsible for the initial stages of starch digestion.

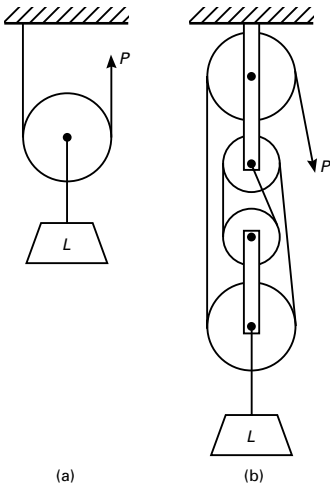

**p-type conductivity** See SEMICONDUCTOR; TRANSISTOR.

**puberty** See ADOLESCENCE.

**pubis** One of the three bones that make up each half of the \*pelvic girdle. It is the most anterior of the three pelvic bones. In mammals and many reptiles the pubes are united at a slightly movable joint, the **pubic symphysis**. See also ILIUM; ISCHIUM.

**pulley** A simple machine consisting of a wheel with a flat, crowned, or grooved rim to take a belt, rope, or chain with which a load can be raised.

In fig (a), assuming the system is frictionless, the force  $P$  in any part of the rope is constant, therefore  $2P = L$ , where  $L$  is the load. In general,  $nP = L$ , where  $n$  is the number of supporting ropes. In fig (b), the number of supporting ropes is 4. The mechanical advantage of a pulley system is the ratio of the load,  $L$ , to the effort applied to the free end of the rope,  $P$ , i.e. mechanical advantage =  $L/P = L(L/n)^{-1} = n$ . Thus in fig (b) the mechanical advantage is 4. A combination of ropes and pulleys as in fig (b) is called a **block and tackle**.

Pulleys

**pulmonary** Of or relating to the lungs.

**pulmonary artery** The artery that conveys deoxygenated blood from the right ventricle of the heart to the lungs, where it receives oxygen.

**pulmonary circulation** The part of the circulatory system of birds and mammals that transports deoxygenated blood from the right side of the heart to the lungs and returns oxygenated blood to the left side of the heart. Compare SYSTEMIC CIRCULATION. See DOUBLE CIRCULATION.

**pulmonary vein** The vein that conveys oxygenated blood from the lungs to the left atrium of the heart.

**pulp cavity** The central region of a tooth, which is connected by a narrow channel at the tip of the root with the surrounding tissues. The pulp cavity contains the **pulp** – connective tissue in which blood vessels and nerve fibres are embedded, and it is lined with \*odontoblasts, which produce the \*dentine.

**pulsar** A celestial source of radiation emitted in brief (0.03 second to 4 seconds) regular pulses. First discovered in 1968, pulsars are believed to be rotating \*neutron stars. The strong magnetic field of the neutron star concentrates charged particles in two regions and the radiation is emitted in two directional beams. The pulsing effect occurs as the beams rotate. Most pulsars are radio sources (emit electromagnetic radiation of radio frequencies) but a few that emit light or X-rays have been detected. Over 300 pulsars are now known in our Galaxy.

**pulsatance** See ANGULAR FREQUENCY.

**pulse 1.** (in physics) **a.** A brief variation in a quantity, usually for a finite time, especially in a quantity that is normally constant. **b.** A series of such variations having a regular waveform in which the variable quantity rises sharply from a base value to a maximum value and then falls back to the base value in a relatively short time.

**2.** (in physiology) A series of waves of dilation that pass along the arteries, caused by pressure of blood pumped from the heart through contractions of the left ventricle. In humans it can be felt easily where arteries pass close to the skin surface, e.g. at the wrist.

**pulse jet** A type of ramjet (see JET PROPULSION) in which a louvred valve at the front of the projectile is blown open by the ram effect of the moving projectile and remains open until pressure has built

up in the combustion chamber. Fuel is then admitted and the mixture exploded by spark ignition. This closes the louvred valve and produces thrust at the open rear end of the projectile. The German flying bombs of World War II were powered by pulse jets.

**pulse modulation** See MODULATION.

**pulvinus** A group of cells at the base of a leaf or leaflet in certain plants that, by rapidly losing water, brings about changes in the position of the leaves. In the sensitive plant (*Mimosa pudica*), the pulvinus is responsible for the folding of the leaves that occurs at nightfall or when the plant is touched or injured.

**pumice** A porous volcanic rock that is light and full of cavities due to expanding gases that were liberated from solution in \*lava while it solidified. Pumice is often light enough to float on water. It is usually acid (siliceous) in composition, and is used as an abrasive and for polishing.

**pump** A device that imparts energy to a fluid in order to move it from one place or level to another or to raise its pressure (compare VACUUM PUMP). **Centrifugal pumps** and \*turbines have rotating impellers, which increase the velocity of the fluid, part of the energy so acquired by the fluid then being converted to pressure energy. Displacement pumps act directly on the fluid, forcing it to flow against a pressure. They include piston, plunger, gear, screw, and cam pumps. See also ELECTROMAGNETIC PUMP.

**punctuated equilibrium** A controversial hypothesis, published in 1972 by N. Eldredge and Stephen J. Gould, proposing that in evolutionary history the development of new species occurs very rapidly in short bursts (lasting typically less than 100 000 years), which are separated by long periods in which little evolutionary change occurs. This hypothesis, which contradicted the orthodox Darwinian view of evolution as a gradual and continuous process, was based on studies of various fossil lineages (e.g. ammonite molluscs) in which forms intermediate between species are absent. Subsequent scrutiny of the evidence supports a pattern of punctuated equilibrium for some,

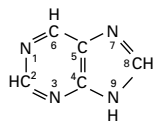

but not all, lineages, so it cannot be regarded as universal. For example, the rodent lineage shows as much morphological change between speciation events as during speciation.

**pupa** The third stage of development in the life cycle of some insects. During the pupal stage locomotion and feeding cease and \*metamorphosis from the larva to the adult form takes place. There are three types of pupa. The commonest is the **exarate** or free pupa, in which the wings and other appendages are visible and movable. In the **obtect** type the wings are stuck to the body and immovable, as in the **chrysalis** of a butterfly or moth; and in the **co-arctate** type an exarate pupa develops within a hard barrel-shaped **puparium**, as in the housefly and other Diptera.

**pupil** See IRIS.

**pure line** A population of plants or animals all having a particular feature that has been retained unchanged through many generations. The organisms are \*homozygous and are said to 'breed true' for the feature concerned.

**purine** An organic nitrogenous base (see formula), sparingly soluble in water, that gives rise to a group of biologically important derivatives, notably \*adenine and \*guanine, which occur in \*nucleotides and nucleic acids (DNA and RNA).

Purine

**Purkyne fibres (Purkinje fibres)** Modified fibres in the mammalian heart that originate in the \*bundle of His and spread out in a network over the ventricles. Action potentials generated in the sinoatrial node (the \*pacemaker of the heart) are conducted extremely rapidly through the ventricles, due to the extensive branching of the Purkyne fibres, causing both ventricles to contract almost simultaneously. They are named after the Czech physiologist Johannes Purkyne (1787–1869).

**putrefaction** The microbial decomposition of organic matter, especially the anaerobic breakdown of proteinaceous material with the production of foul-smelling amines.

**PVA** See POLYVINYLACETATE.

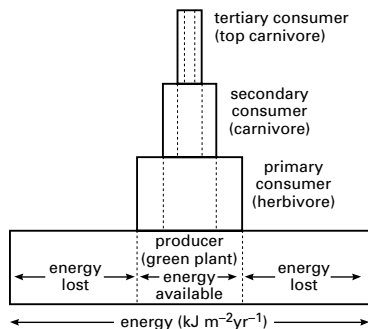

**PVC** See POLYCHLOROETHENE.

**pyloric sphincter** See SPHINCTER; STOMACH.

**pyramid** A solid having a polygonal base with  $n$  sides, each side forming the base of a triangle. The  $n$  triangles so formed have a common vertex. The **axis** of the pyramid is a line joining the vertex to the centre of symmetry of the base. If the axis is perpendicular to the base the solid is a **right pyramid**. A **square pyramid** has a square base and a **triangular pyramid** has a triangular base (see TETRAHEDRON). The volume of a pyramid is one third of the base area multiplied by the height.

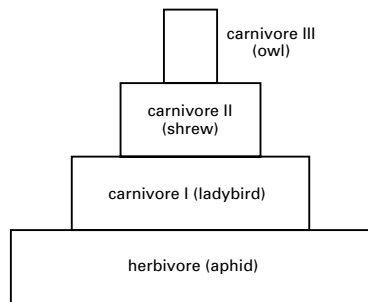

**pyramid of biomass** A diagrammatic representation of the amount of organic material (see BIOMASS), measured in grams of dry mass per square metre ( $\text{g m}^{-2}$ ), found in a particular habitat at ascending trophic levels of a food chain. Biomass decreases at each ascending level of the food chain. A pyramid of biomass is a more accurate representation of the flow of energy through a food chain than a pyramid of numbers, but seasonal variations in the rate of turnover of the organisms at a particular level may result in higher or lower values for the amount of biomass sampled at a particular time than the average amount over the whole year. The best representation of energy flow in a food chain is a pyramid of energy.

**pyramid of energy** A diagrammatic representation of the amount of energy, measured in kilojoules per square metre per year ( $\text{kJ m}^{-2} \text{yr}^{-1}$ ), available at ascending trophic levels of a food chain in a particular habitat. A pyramid of energy is the most accurate representation of the energy flow through a food chain as it indicates how much energy is lost at each trophic level (through respiration, etc.). Compare PYRAMID OF BIOMASS; PYRAMID OF NUMBERS.

Pyramid of energy

**pyramid of numbers** A diagrammatic representation of the numbers of animals found in an area at ascending trophic levels of a food chain (see illustration). Because only a small proportion of the energy taken in by an organism is converted to tissue and is thus available to consumers at the next trophic level, the number of organisms that can be supported at each level is generally much less than the number at the level that supplies its food (i.e. the level below). See also PYRAMID OF BIOMASS; PYRAMID OF ENERGY.

Pyramid of numbers for a woodland food chain

**pyranose** A sugar having a six-membered ring containing five carbon atoms and one oxygen atom.

**pyrenocarp** See DRUPE.

**pyrenoid** A spherical protein body found in the chloroplasts of many algae. Pyrenoids are associated with the storage

of starch: layers of starch are often found around them.

**pyrethrum** An insecticide (see PESTICIDE) prepared from the flowers of *Chrysanthemum cinerariifolium*. It penetrates the insect's cuticle and is fast-acting, nontoxic to other animals and to plants, and readily biodegradable.

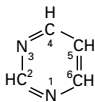

**pyridine** A colourless liquid with a strong unpleasant smell,  $C_5H_5N$  (see formula); r.d. 0.98; m.p.  $-42^\circ C$ ; b.p.  $115^\circ C$ . Pyridine is an aromatic heterocyclic compound present in coal tar. It is used in making other organic chemicals.

Pyridine

**pyridoxine** See VITAMIN B COMPLEX.

**pyrimidine** An organic nitrogenous base (see formula), sparingly soluble in water, that gives rise to a group of biologically important derivatives, notably \*uracil, \*thymine, and \*cytosine, which occur in \*nucleotides and nucleic acids (DNA and RNA).

Pyrimidine

**pyrite (iron pyrites)** A mineral form of iron(II) sulphide,  $FeS_2$ . Superficially it resembles gold in appearance, hence it is also known as **fool's gold**, but it is harder and more brittle than gold (which may be cut with a knife). Pyrite crystallizes in the cubic system, is brass yellow in colour, has a metallic lustre, and a hardness of 6–6.5 on the Mohs' scale. It is the most common and widespread of the sulphide minerals and is used as a source of sulphur for the production of sulphuric acid. Sources include the Rio Tinto mines in Spain.

**pyro-** Prefix denoting an oxo acid that could be obtained from a lower acid by dehydration of two molecules. For example, pyrosulphuric acid is  $H_2S_2O_7$  (i.e.  $2H_2SO_4$  minus  $H_2O$ ).

**pyroboric acid** See BORIC ACID.

**pyroelectricity** The property of certain crystals, such as tourmaline, of acquiring opposite electrical charges on opposite faces when heated. In tourmaline a rise in temperature of 1 K at room temperature produces a polarization of some  $10^{-5} C m^{-2}$ .

**pyrogallol** 1,2,3-trihydroxybenzene,  $C_6H_3(OH)_3$ , a white crystalline solid, m.p.  $132^\circ C$ . Alkaline solutions turn dark brown on exposure to air through reaction with oxygen. It is a powerful reducing agent, employed in photographic developers. It is also used in volumetric gas analysis as an absorber of oxygen.

**pyrolusite** A soft black mineral consisting mainly of manganese dioxide ( $MnO_2$ ); it is the most important ore of manganese. It is generally found as a secondary deposit of masses of fibrous or needle-shaped crystals. As well as an ore, it is used as a decolourizer and oxidizing agent.

**pyrolysis** Chemical decomposition occurring as a result of high temperature.

**pyrometric cones** See SEGER CONES.

**pyrometry** The measurement of high temperatures from the amount of radiation emitted, using a **pyrometer**. Modern **narrow-band** or **spectral** pyrometers use infrared-sensitive \*photoelectric cells behind filters that exclude visible light. In the **optical pyrometer** (or disappearing filament pyrometer) the image of the incandescent source is focused in the plane of a tungsten filament that is heated electrically. A variable resistor is used to adjust the current through the filament until it blends into the image of the source, when viewed through a red filter and an eyepiece. The temperature is then read from a calibrated ammeter or a calibrated dial on the variable resistor. In the **total-radiation pyrometer** radiation emitted by the source is focused by a concave mirror onto a blackened foil to which a ther-

mopile is attached. From the e.m.f. produced by the thermopile the temperature of the source can be calculated.

**pyrophoric** Igniting spontaneously in air. **Pyrophoric alloys** are alloys that give sparks when struck. See MISCH METAL.

**pyrophosphoric acid** See PHOSPHORIC(V) ACID.

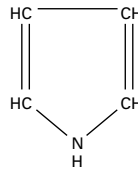

**pyrosilicate** See SILICATE.

**pyrosulphuric acid** See DISULPHURIC(VI) ACID.

**pyroxenes** A group of ferromagnesian rock-forming silicate minerals. They are common in basic igneous rocks but may also be developed by metamorphic processes in gneisses, schists, and marbles. Pyroxenes have a complex crystal chemistry; they are composed of continuous chains of silicon and oxygen atoms linked by a variety of other elements. They are related to the \*amphiboles, from which they differ in cleavage angles. The general formula is  $X_{1-p}Y_{1+p}Z_2O_6$ , where X = Ca, Na; Y = Mg, Fe<sup>2+</sup>, Mn, Li, Al, Fe<sup>3+</sup>, Ti; and Z = Si, Al.

Orthorhombic pyroxenes (**orthopyroxenes**), (Mg, Fe)<sub>2</sub>Si<sub>2</sub>O<sub>6</sub>, vary in composition between the end-members enstatite (Mg<sub>2</sub>Si<sub>2</sub>O<sub>6</sub>) and orthoferrosilite (Fe<sub>2</sub>Si<sub>2</sub>O<sub>6</sub>). Monoclinic pyroxenes (**clinopyroxenes**), the larger group, include: diopside, CaMgSi<sub>2</sub>O<sub>6</sub>; hedenbergite, CaFe<sup>2+</sup>Si<sub>2</sub>O<sub>6</sub>; johannsenite, CaMnSi<sub>2</sub>O<sub>6</sub>; augite, (Ca, Mg, Fe, Ti, Al)<sub>2</sub>(Si, Al)<sub>2</sub>O<sub>6</sub>; aegirine, NaFe<sup>3+</sup>Si<sub>2</sub>O<sub>6</sub>; jadeite (see JADE); pigeonite (Mg, Fe<sup>2+</sup>, Ca)(Mg, Fe<sup>2+</sup>)Si<sub>2</sub>O<sub>6</sub>.

**pyrrole** An organic nitrogen-containing compound (see formula) that forms part of the structure of \*porphyrins.

Pyrrole

**pyruvic acid (2-oxopropanoic acid)** A colourless liquid organic acid, CH<sub>3</sub>CO-COOH. Pyruvate is an important intermediate compound in metabolism, being produced during \*glycolysis and converted to acetyl coenzyme A, required for the \*Krebs cycle. Under anaerobic conditions pyruvate is converted to lactate or ethanol.

**Pythagoras of Samos** (c. 580–c. 500 BC) Greek philosopher and mathematician, who in about 520 BC went to Croton in Italy, where he founded an academy at which numbers and their mystical significance were studied. Pythagoras discovered \*irrational numbers and the celebrated \*Pythagoras' theorem.

**Pythagoras' theorem** For a right-angled triangle of lengths  $h$  (where  $h$  is the hypotenuse, the side opposite the right angle),  $a$ , and  $b$  (where  $a$  and  $b$  are the other two sides), the relationship

$$h^2 = a^2 + b^2.$$

**QCD** See QUANTUM CHROMODYNAMICS.

**QED** See QUANTUM ELECTRODYNAMICS.

**QFD** Quantum flavourdynamics. See ELECTROWEAK THEORY.

**QSG** See QUASARS.

**QSO** See QUASARS.

**QSS** See QUASARS.

**quadrat** An ecological sampling unit consisting of a small square area of ground within which all species of interest are noted or measurements taken. Quadrats may be spaced over a larger area to form an overall view when a total survey would be impracticable, or they may be used to sample along a \*transect.

**quadrate** A paired bone in the upper jaw of bony fishes, amphibians, reptiles, and birds that articulates with the lower jawbone. It is absent in mammals, being reduced to a small bone (the incus) in the middle ear (see EAR OSSICLES).

**quadratic equation** An equation of the second degree having the form  $ax^2 + bx + c = 0$ . Its roots are:

$$x = \frac{-b \pm \sqrt{(b^2 - 4ac)}}{2a}.$$

**quadrature** The position of the moon or an outer planet when the line joining it to the earth makes a right angle with a line joining the earth to the sun.

**quadrivalent** Having a valency of four.

**qualitative analysis** See ANALYSIS.

**qualitative variation** See DISCONTINUOUS VARIATION.

**quality of sound (timbre)** The quality a musical note has as a result of the presence of \*harmonics. A pure note consists only of the fundamental; however, a note from a musical instrument will have several harmonics present, depending on the type of instrument and the way in which it is played. For example, a plucked string

(as in a guitar) produces a series of harmonics of diminishing intensity, whereas a struck string (as in a piano) produces a series of harmonics of more nearly equal intensity.

**quantitative analysis** See ANALYSIS.

**quantitative inheritance** See POLYGENIC INHERITANCE.

**quantitative variation** See CONTINUOUS VARIATION.

**quantization** The process of constructing a quantum theory for a system, using the original classical theory as a basis. The starting point for such a process is to write the \*Lagrangian or \*Hamiltonian of the classical system. The formulation of the quantum theory for the system can be performed using a formalism such as \*matrix mechanics, or \*wave mechanics. The application of these methods leads to the conclusion that energy levels in systems, such as atoms, are discrete (**quantized**) rather than continuous. Before the discovery of quantum mechanics in the mid 1920s, quantization involved a series of ad hoc postulates for atomic systems, such as the \*Bohr theory and its extensions.

**quantum** (*pl. quanta*) The minimum amount by which certain properties, such as energy or angular momentum, of a system can change. Such properties do not, therefore, vary continuously, but in integral multiples of the relevant quantum, and are described as **quantized**. This concept forms the basis of the \*quantum theory. In waves and fields the quantum can be regarded as an excitation, giving a particle-like interpretation to the wave or field. Thus, the quantum of the electromagnetic field is the \*photon and the \*graviton is the quantum of the gravitational field. See QUANTUM MECHANICS.

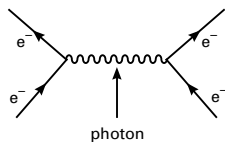

**quantum chaos** The \*quantum mechanics of systems for which the corresponding classical system can exhibit

\*chaos. This subject was initiated by Einstein in 1917, who showed that the quantization conditions associated with the \*Bohr theory need to be modified for systems that show chaos in classical mechanics. The subject of quantum chaos is an active field of research in which many basic issues still require clarification. It appears that systems exhibiting chaos in classical mechanics do not necessarily exhibit chaos in quantum mechanics.

**quantum chromodynamics (QCD)** A \*gauge theory that describes the strong interaction in terms of quarks and antiquarks and the exchange of massless gluons between them (*see also* ELEMENTARY PARTICLES). Quantum chromodynamics is similar to quantum electrodynamics (QED), with colour being analogous to electric charge and the gluon being the analogue of the photon. The gauge group of QCD is non-Abelian and the theory is much more complicated than quantum electrodynamics; the gauge symmetry in QCD is not a \*broken symmetry.

QCD has the important property of \*asymptotic freedom - that at very high energies (and, hence, short distances) the interactions between quarks tend to zero as the distance between them tends to zero. Because of asymptotic freedom, perturbation theory may be used to calculate the high energy aspects of strong interactions, such as those described by the \*parton model.

**quantum electrodynamics (QED)** The study of the properties of electromagnetic radiation and the way in which it interacts with charged matter in terms of \*quantum mechanics. The collision of a moving electron with a proton, in this theory, can be visualized by a space-time diagram (**Feynman diagram**) in which photons are exchanged (*see illustration*).

An example of a Feynman diagram for electron-electron scattering

\*Perturbation-theory calculations using Feynman diagrams enable an agreement between theory and experiment to a greater accuracy than one part in  $10^9$  to be obtained. Because of this, QED is the most accurate theory known in physical science. Although many of the effects calculated in QED are very small (about  $4 \times 10^{-6}$  eV), such as \*energy level splitting in the spectra of \*atoms, they are of great significance for demonstrating the physical reality of fluctuations and polarization in the vacuum state.

QED is a \*gauge theory for which the gauge \*group is Abelian.

**quantum electronics** The application of \*quantum optics and the specifically quantum-mechanical properties of electrons to the design of electronic devices.

**quantum entanglement** A phenomenon in quantum mechanics in which a particle or system does not have a definite state but exists as an intermediate form of two 'entangled' states. One of these states is realized when a 'measurement' is made. *See* BELL'S THEOREM.

**quantum field theory** A quantum-mechanical theory applied to systems that have an infinite number of degrees of freedom. In quantum field theories, particles are represented by fields that have quantized normal modes of oscillation. For instance, \*quantum electrodynamics is a quantum field theory in which the photon is emitted or absorbed by particles; the photon is the quantum of the electromagnetic field. **Relativistic quantum field theories** are used to describe fundamental interactions between elementary particles. They predict the existence of \*antiparticles and also show the connection between spin and statistics that leads to the Pauli exclusion principle (*see* SPIN-STATISTICS THEOREM). In spite of their success, it is not clear whether a quantum field theory can give a completely unified description of all interactions (including the gravitational interaction).

**quantum flavourdynamics (QFD)** *See* ELECTROWEAK THEORY.

**quantum gravity** An aspect of \*quantum theory that attempts to incorporate

the \*gravitational field as described by the general theory of \*relativity; no such theory has yet been accepted, however. Unlike the \*quantum field theories for the other three \*fundamental interactions, the procedure of \*renormalization does not work for quantum gravity, although there is some evidence that \*superstring theory can provide a quantum theory of gravity free of infinities. An approximation to quantum gravity is given by **quantum field theory in curved space-time**, in which the gravitational interactions are treated classically, while all other interactions are treated by \*quantum mechanics. An important aspect of quantum field theory in curved space-time is its description of Hawking radiation (see HAWKING PROCESS). It is necessary to consider quantum gravity in the very \*early universe, just after the \*big bang, and the singularities associated with \*black holes can also be interpreted as requiring a quantum theory of gravity.

**quantum Hall effect** A quantum mechanical version of the \*Hall effect found at very low temperatures, in which the Hall coefficient  $R_H$  is proportional to  $h/e^2$ , where  $h$  is the Planck constant and  $e$  is the charge of the electron. Thus, the Hall coefficient is quantized. There are two types of quantum Hall effect. The **integer quantum Hall effect** has  $R_H$  given as an integer with great precision. It can be used for precision measurements of constants such as  $e$  and  $h$ . In the **fractional quantum Hall effect**,  $R_H$  has fractional values.

The integer quantum Hall effect can be understood in terms of noninteracting electrons, whereas the fractional effect is thought to result from many-electron interactions in two-dimensional systems, and be an example of anyons (see QUANTUM STATISTICS).

**quantum jump** A change in a system (e.g. an atom or molecule) from one quantum state to another.

**quantum mechanics** A system of mechanics based on \*quantum theory, which arose out of the failure of classical mechanics and electromagnetic theory to provide a consistent explanation of both \*electromagnetic waves and atomic structure. Many phenomena at the atomic

level puzzled physicists at the beginning of the 20th century because there seemed to be no way of explaining them without making use of incompatible concepts. One such phenomenon was the emission of \*electrons from the surface of a metal illuminated by light. Einstein realized that the classical description of light as a wave on an electromagnetic field could not explain this \*photoelectric effect, as it is called. Experiments showed that electrons would be emitted only if the incident light was of a sufficiently short wavelength, while the intensity of the light appeared not to be relevant. It seemed not to make sense that small ripples of short wavelength could easily knock electrons out of the metal, but a huge tidal wave of long wavelength could not. In 1905 Einstein abandoned classical mechanics and sought an explanation of this photoelectric effect in Planck's work on thermal radiation (see PLANCK'S RADIATION LAW). In this work light energy is regarded as being imparted to matter in discrete packets rather than continuously, as one might expect from a wave. Einstein assumed that in the photoelectric effect, light behaves as a shower of particles, each with energy  $E$  given by Planck's expression:

$$E = hf,$$

where  $f$  is the light's frequency and  $h$  is the \*Planck constant. Each particle of light, which Einstein called a \*photon, would impart its energy to a single electron in the metal. The electron would be liberated only if the photon could impart at least the required amount of energy. However many photons were falling on the surface of the metal, no electrons would be liberated unless individual photons had the required energy ( $hf$ ) to break the attractive forces holding the electrons in the metal. This elegantly quantified reversion to Newton's corpuscular theory of light by Einstein was one of the milestones in the development of quantum mechanics.

Further verification that light could indeed behave as a shower of particles came from the \*Compton effect. In Compton scattering, X-radiation is scattered off an electron in a manner that resembles a particle collision. The momentum im-

parted to the electron can be predicted by assuming that the X-ray possesses the momentum of a photon. An expression for photon momentum is suggested by the classical theory of radiation pressure. It is known that if energy is transported by an electromagnetic wave at a rate  $W$  joules per unit area per second, the wave exerts a radiation pressure  $W/c$ , where  $c$  is the speed of light. Planck's expression for the energy of photons therefore led to an equivalent expression for the momentum  $p$  of these photons:

$$p = h/\lambda,$$

where  $\lambda$  is the wavelength of the light. Experimental studies of the Compton effect produce results in good agreement with this expression.

Both the photoelectric effect and the Compton effect imply that light imparts energy and momentum to matter in the form of packets. It is as if energy and momentum are fundamental 'currencies' of physical interaction, and that these currencies exist in denominations that are all multiples of the Planck constant. These quantities are said to be 'quantized' and a packet of energy or momentum is called a \*quantum. Quantum mechanics is essentially concerned with the exchange of these quanta of energy and momentum. For more than a century before the birth of quantum mechanics, experiments had indicated that light behaves as a wave. The successful explanation of the photoelectric and Compton effects demonstrated that in some situations light interacts with matter as if it is a shower of particles. The principle that two models are required to explain the nature of light was called by Niels Bohr \*complementarity. This principle was extended by the French aristocrat, Louis de Broglie, who suggested in 1923 that particles of matter might also behave as waves in certain circumstances.

Louis de Broglie received the Nobel Prize for this idea in 1929 after the successful measurement of the \*de Broglie wavelength of an electron in 1927 by Clinton Davisson and Lester Germer, who had observed the \*diffraction of electrons by single crystals of nickel. The behaviour of individual electrons seemed random and unpredictable, but when a large number

had passed through the crystal a typical diffraction pattern emerged. This provided proof that the electron, which until then had been thought of simply as a particle of matter, could under the right circumstances exhibit wavelike properties. Classical mechanics and electromagnetism were based on two kinds of entity: matter and fields. In classical physics, matter consists of particles and waves are oscillations on a field. Quantum mechanics blurs the distinction between matter and field. Modern physicists are forced to concede that the universe is made up of entities that exhibit a \*wave-particle duality.

A new representation of matter and field is needed to fully appreciate this wave-particle duality. In quantum mechanics, an electron is represented by a \*complex number called a \*wave function that depends on time and space coordinates. The wave function behaves like a classical wave displacement on a medium (e.g. on a string), exhibiting wave behaviour, interference, diffraction, etc. However, unlike a classical wave displacement, the wave function is essentially a complex quantity. Since an electron's observable properties do not involve complex numbers, it follows that an electron's wave function cannot itself be identified with a single physical property of the electron. The diffraction of electrons observed by Davisson and Germer revealed that, although the behaviour of the individual electrons is random and unpredictable, when a large number have passed through the apparatus, a diffraction pattern is formed whose intensity distribution is proportional to the intensity of the associated wave function. The intensity of the wave function,  $\Psi$ , is the square of its \*absolute value  $|\Psi|^2$ . Therefore, although an electron's wave function itself has no physical significance, the square of its absolute value at a point turns out to be proportional to the probability of finding an electron at that point.

The electron wave function must satisfy a wave equation based on the conservation of energy and momentum for the electron. There are two main ways of treating this wave equation: a classical or a relativistic treatment. The resulting wave equations are called **eigenvalue equations** because they have the same

form as equations in a branch of mathematics called **eigenvalue problems**, i.e.

$$\Omega\Psi = \omega\Psi,$$

where  $\Omega$  is some mathematical operation (multiplication by some number, differentiation, etc.) on the wave function  $\Psi$  and  $\omega$ , called the **eigenvalue** in quantum mechanics, is always a real number. In such an equation the wave function is often called the **eigenfunction**. This form of treatment of quantum mechanics is known as **wave mechanics** (see also SCHRÖDINGER EQUATION).

The energy  $E$  and momentum  $p$  of an electron are associated with the frequency  $f$  and wavelength  $\lambda$  of the electron's wave using the expressions  $E = hf$  and  $p = h/\lambda$ . While the wave equation expresses the behaviour of the wavelike properties of a particle, it does not define the physical attributes it has as a particle. As a particle, the electron has an easily defined spatial and temporal position, not possessed by an oscillation of some kind of field, whose influence extends over a region of space and time. The incompatibility of these two views of the electron leads to the Heisenberg \*uncertainty principle. Heisenberg recognized that if matter had wavelike properties, the physical attributes normally associated with matter (position, momentum, kinetic energy, etc.) would have to be expressed in a statistical, rather than a deterministic, manner. This is illustrated by the electron diffraction patterns of Davisson and Germer. Individual electrons somehow fell onto the apparatus to form a pattern statistically consistent with the intensity of a wave function. It is as if the final wave function were made up of a superposition of all the possible positions that the electrons could fall onto, the waves of electrons constructively and destructively interfering to form the final diffraction pattern.

It is known that a clever superposition of waves of different wavelengths can lead to a construction of a wave packet of finite extension (see FOURIER ANALYSIS). However, to produce a packet that exists at a point of zero width requires an infinite number of waves to superimpose. Heisenberg realized that these packets of waves must account for the way in which

matter particles, such as electrons, could retain some semblance of their particle-like qualities. However, this must also mean that there is an inherent uncertainty in position and momentum associated with electrons and indeed all particles of matter (see UNCERTAINTY PRINCIPLE). Since waves of different wavelength correspond to different possible momentum values of an electron, a superposition of such waves to form a particle at a point would correspond to an infinite uncertainty in the momentum of the electron. Therefore the more one knows about the position of an electron the less one will know about its momentum and vice versa. A similar uncertainty between the energy of the electron and its temporal position also exists. Quantities that are related by such an uncertainty principle are said to be **incompatible**.

An alternative to the wave mechanical treatment of quantum mechanics is an equivalent formalism called \*matrix mechanics, which is based on mathematical operators. See also HIDDEN-VARIABLES THEORY; BELL'S THEOREM.

**quantum number** See ATOM; SPIN.

**quantum optics** The study of those aspects of light that rely on \*quantum mechanics. Quantum optics makes use of the \*quantum theory of radiation to describe photons, \*coherent radiation, and the interaction of photons and atoms. The study of \*lasers is an important branch of quantum optics; other applications include photonics and \*quantum electronics.

**quantum simulation** The mathematical modelling of systems of large numbers of atoms or molecules by computer studies of relatively small clusters. It is possible to obtain information about solids and liquids in this way and to study surface properties and reactions.

**quantum state** The state of a quantized system as described by its quantum numbers. For instance, the state of a hydrogen \*atom is described by the four quantum numbers  $n$ ,  $l$ ,  $m_l$ ,  $m_s$ . In the ground state they have values 1, 0, 0, and  $\frac{1}{2}$  respectively.

**quantum statistics** A statistical de-

scription of a system of particles that obeys the rules of \*quantum mechanics rather than classical mechanics. In quantum statistics, energy states are considered to be quantized. **Bose-Einstein statistics** apply if any number of particles can occupy a given quantum state. Such particles are called **bosons**. Bosons have an angular momentum  $n\hbar/2\pi$ , where  $n$  is zero or an integer and  $\hbar$  is the Planck constant. For identical bosons the \*wave function is always symmetric. If only one particle may occupy each quantum state, **Fermi-Dirac statistics** apply and the particles are called **fermions**. Fermions have a total angular momentum  $(n + 1/2)\hbar$  and any wave function that involves identical fermions is always antisymmetric.

The relation between the spin and statistics of particles is given by the \*spin-statistics theorem.

In two-space dimensions, it is possible that there are particles (or \*quasiparticles) that have statistics intermediate between bosons and fermions. These particles are known as **anyons**; for identical anyons the wave function is not symmetric (a phase sign of +1) or antisymmetric (a phase sign of -1), but interpolates continuously between +1 and -1. Anyons may be involved in the fractional \*quantum Hall effect.

**quantum theory** The theory devised by Max Planck in 1900 to account for the emission of the black-body radiation from hot bodies. According to this theory energy is emitted in quanta (see QUANTUM), each of which has an energy equal to  $h\nu$ , where  $h$  is the \*Planck constant and  $\nu$  is the frequency of the radiation. This theory led to the modern theory of the interaction between matter and radiation known as \*quantum mechanics, which generalizes and replaces classical mechanics and Maxwell's electromagnetic theory. In **nonrelativistic quantum theory** particles are assumed to be neither created nor destroyed, to move slowly relative to the speed of light, and to have a mass that does not change with velocity. These assumptions apply to atomic and molecular phenomena and to some aspects of nuclear physics. **Relativistic quantum theory** applies to particles that travel at or near the speed of light.

**quantum theory of radiation** The

study of the emission and absorption of \*photons of electromagnetic radiation by atomic systems using \*quantum mechanics. Photons are emitted by atoms when a transition occurs from an excited state to the ground state. If an atom is exposed to external electromagnetic radiation a transition can occur from the ground state to an excited state by absorption of a photon. An excited atom can lose the energy it has gained by \*stimulated emission. However, an atom can also emit a photon in the absence of external electromagnetic radiation, a process called \*spontaneous emission. The quantum theory of radiation was initiated by Einstein in 1916-17, as an extension of \*Planck's radiation law. The theory is quantified by the \*Einstein coefficients. The quantum theory of radiation is the basis of the theory behind the operation of \*lasers and \*masers.

**quarantine** A period of isolation imposed on an animal that moves from an area where particular diseases are prevalent to an area where those diseases are not prevalent. In the UK domestic animals or livestock entering the country are quarantined for the necessary incubation period (see INFECTION) in order to prevent the spread of a particular disease.

**quark** See ELEMENTARY PARTICLES.

**quark confinement** The hypothesis that free quarks can never be seen in isolation. It is a result of \*quantum chromodynamics, in which the property of \*asymptotic freedom means that the interactions between quarks get weaker as the distance between them gets smaller, and tends to zero as the distance between them tends to zero. Conversely, the attractive interactions between quarks get stronger as the distance between them gets greater, and the quark-confinement hypothesis is that the quarks cannot escape from one another. It is possible that at very high temperatures, such as those in the \*early universe, quarks may become free. The temperature at which this occurs is called the **deconfinement temperature**. The hypothesis of quark confinement has not been proved theoretically in a conclusive way, although there is a lot of evidence for it.

**quark-gluon plasma** A state of matter in which quarks and gluons are not confined into baryons and mesons but exist as a hot plasma. It is thought that this state existed in the early universe until there was a phase transition about  $10^{-5}$  s after the big bang when the universe cooled to a sufficiently low temperature that \*quark confinement into hadrons occurred.

**quart** A unit of capacity equal to one quarter of a \*gallon.

**quarter-wave plate** See RETARDATION PLATE.

**quartile** See PERCENTILE.

**quartz** The most abundant and common mineral, consisting of crystalline silica (silicon dioxide,  $\text{SiO}_2$ ), crystallizing in the trigonal system. It has a hardness of 7 on the Mohs' scale. Well-formed crystals of quartz are six-sided prisms terminating in six-sided pyramids. Quartz is ordinarily colourless and transparent, in which form it is known as **rock crystal**. Coloured varieties, a number of which are used as gemstones, include \*amethyst, citrine quartz (yellow), rose quartz (pink), milk quartz (white), smoky quartz (grey-brown), \*chalcidony, \*agate, and \*jasper. Quartz occurs in many rocks, especially igneous rocks such as granite and quartzite (of which it is the chief constituent), metamorphic rocks such as gneisses and schists, and sedimentary rocks such as sandstone and limestone. The mineral has the property of being piezoelectric and hence is used to make oscillators for clocks (see QUARTZ CLOCK), radios, and radar instruments. It is also used in optical instruments and in glass, glaze, and abrasives.

**quartz clock** A clock based on a piezoelectric crystal of quartz. Each quartz crystal has a natural frequency of vibration, which depends on its size and shape. If such a crystal is introduced into an oscillating electronic circuit that resonates at a frequency very close to that of the natural frequency of the crystal, the whole circuit (including the crystal) will oscillate at the crystal's natural frequency and the frequency will remain constant over considerable periods (a good crystal will

maintain oscillation for a year with an accumulated error of less than 0.1 second). In a quartz clock or watch the alternating current from the oscillating circuit containing such a crystal is amplified and the frequency subdivided until it is suitable to drive a synchronous motor, which in turn drives a gear train to operate hands. Alternatively it is used to activate a digital display.

**quasars** A class of astronomical objects that appear on optical photographs as starlike but have large \*redshifts quite unlike those of stars. They were first observed in 1961 when it was found that strong radio emission was emanating from many of these starlike bodies. Over 600 such objects are now known and their redshifts can be as high as 4. The redshifts are characteristic of the \*expansion of the universe. This **cosmological redshift** is the explanation of the high observed redshifts of quasars favoured by most astronomers. (A few, however, maintain that the redshift could be a local Doppler effect, characteristic of movement relative to the earth and sun of nearby objects in the Galaxy, or a gravitational effect.) If the redshifts are cosmological, quasars are the most distant objects in the universe, some being up to  $10^{10}$  light-years away. The exact nature of quasars is unknown but it is believed that they are the nuclei of galaxies in which there is violent activity. The luminosity of the nucleus is so much greater than that of the rest of the galaxy that the source appears pointlike. It has been proposed that the power source in a quasar is a supermassive \*black hole accreting material from the stars and gas in the surrounding galaxy.

The name 'quasar' is a contraction of quasistellar object (QSO) or quasistellar galaxy (QSG). Quasars that are also radio sources are sometimes called quasistellar radio sources (QSS).

**quasicrystal** A type of solid structure in which there is long-range order but in which the symmetry of the structure is not allowed in crystallography. AlMn is an example of a substance that forms quasicrystals.

**quasiparticle** A long-lived single-

particle \*excitation in the quantum theory of many-body systems, in which the excitations of the individual particles are modified by their interactions with the surrounding medium.

**Quaternary** The second period of the Cenozoic era, which began about 2 million years ago, following the \*Tertiary period, and includes the present. It is subdivided into two epochs – the \*Pleistocene and \*Holocene. The beginning of the Quaternary is usually based on the onset of a worldwide cooling. During the period four principal glacial phases occurred in Europe and North America, in which ice advanced towards the equator, separated by interglacials during which conditions became warmer and the ice sheets and glaciers retreated. The last glacial ended about 10 000 years ago. Humans became the dominant terrestrial species during the Quaternary. Among the fauna adapted to the cold conditions were the mammoth and the woolly rhinoceros.

**quaternary ammonium compounds**

See AMINE SALTS.

**quaternary structure** See PROTEIN.

**quenching 1.** (in metallurgy) The rapid cooling of a metal by immersing it in a bath of liquid in order to improve its properties. Steels are quenched to make them harder but some nonferrous metals are quenched for other reasons (copper,

for example, is made softer by quenching). **2.** (in physics) The process of inhibiting a continuous discharge in a \*Geiger counter so that the incidence of further ionizing radiation can cause a new discharge. This is achieved by introducing a quenching vapour, such as methane mixed with argon or with neon, into the tube.

**quicklime** See CALCIUM OXIDE.

**quinhydrone electrode** A \*half cell consisting of a platinum electrode in an equimolar solution of quinone (cyclohexadiene-1,4-dione) and hydroquinone (benzene-1,4-diol). It depends on the oxidation-reduction reaction

**quinine** A white solid,  $\text{C}_{20}\text{H}_{24}\text{N}_2\text{O}_2 \cdot 3\text{H}_2\text{O}$ , m.p. 57°C. It is a poisonous alkaloid occurring in the bark of the South American cinchona tree, although it is now usually produced synthetically. It forms salts and is toxic to the malarial parasite, and so quinine and its salts are used to treat malaria; in small doses it may be prescribed for colds and influenza. In dilute solutions it has a pleasant astringent taste and is added to some types of tonic water.

**quinol** See BENZENE-1,4-DIOL.

**quinone 1.** See CYCLOHEXADIENE-1,4-DIONE. **2.** Any similar compound containing C=O groups in an unsaturated ring.

# R

**race 1.** (in biology) A category used in the \*classification of organisms that consists of a group of individuals within a species that are geographically, ecologically, physiologically, or chromosomally distinct from other members of the species. The term is frequently used in the same sense as \*subspecies. **Physiological races**, for example, are identical in appearance but differ in function. They

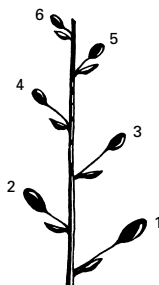

include strains of fungi adapted to infect different varieties of the same crop species. **2.** (in anthropology) A distinct human type possessing several characteristics that are genetically inherited. The major races are Mongoloid, Caucasian, Negroid, and Australoid.

**racemate** See RACEMIC MIXTURE.

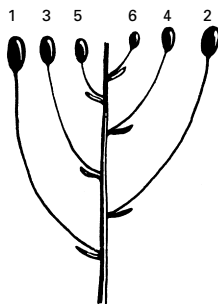

**raceme** A type of \*racemose inflores-

spike  
(e.g. plantain)

raceme  
(e.g. lupin)

corymb  
(e.g. candytuft)

umbel  
(e.g. hogweed)

capitulum  
(e.g. daisy)

1 = oldest flower

Types of racemose inflorescence

cence in which the main flower stalk is elongated and bears stalked flowers. An example is the lupin. *See also* PANICLE.

**racemic mixture (racemate)** A mixture of equal quantities of the (+) or *d*- and (-) or *l*- forms of an optically active compound. Racemic mixtures are denoted by the prefix ( $\pm$ ) or *dl*-. A racemic mixture shows no \*optical activity.

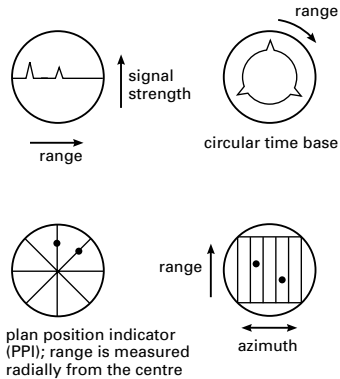

**racemization** A chemical reaction in which an optically active compound is converted into a \*racemic mixture.

**racemose inflorescence (indefinite inflorescence)** A type of flowering shoot (*see* INFLORESCENCE) in which the growing region at the tip of the flower stalk continues to produce new flower buds during growth. As a result, the youngest flowers are at the top and the oldest flowers are at the base of the stalk. In a flattened inflorescence, the youngest flowers are in the centre and the oldest flowers are on the outside. Types of racemose inflorescence include the \*capitulum, \*catkin, \*corymb, \*raceme, \*spadix, \*spike, and \*umbel (*see* illustration). *Compare* CYMOSE INFLORESCENCE.

**rachis (rhachis) 1.** The main axis of a compound leaf or an inflorescence. **2.** The shaft of a \*feather. **3.** The backbone.

**rad** *See* RADIATION UNITS.

**radar (radio detection and ranging)** A method of detecting the presence, position, and direction of motion of distant objects (such as ships and aircraft) by means of their ability to reflect a beam of electromagnetic radiation of centimetric wavelengths. It is also used for navigation and guidance. It consists of a transmitter producing radio-frequency radiation, often pulsed, which is fed to a movable aerial from which it is transmitted as a beam. If the beam is interrupted by a solid object, a part of the energy of the radiation is reflected back to the aerial. Signals received by the aerial are passed to the receiver, where they are amplified and detected. An echo from a reflection of a solid object is indicated by a sudden rise in the detector output. The time taken for a pulse to reach the object and be reflected back (*t*) enables the distance

Types of cathode-ray tube radar display

away (*d*) of the target to be calculated from the equation  $d = ct/2$ , where *c* is the speed of light. In some systems the speed of the object can be measured using the \*Doppler effect. The output of the detector is usually displayed on a cathode-ray tube in a variety of different formats (*see* illustration).

**radial symmetry** The arrangement of parts in an organ or organism such that cutting through the centre of the structure in any direction produces two halves that are mirror images of each other. The stems and roots of plants usually show radial symmetry, while all animals belonging to the Cnidaria (e.g. jellyfish) and Echinodermata (e.g. starfish) are radially symmetrical – and typically sessile – in their adult form. The term **actinomorphy** is used to describe radial symmetry in flowers (e.g. a buttercup flower). *Compare* BILATERAL SYMMETRY.

**radial velocity** *See* LINE-OF-SIGHT VELOCITY.

**radian** *See* CIRCULAR MEASURE.

**radiance** Symbol  $I_e$ . The radiant intensity per unit transverse area, in a given direction, of a source of radiation. It is measured in  $W\ sr^{-1}\ m^{-2}$ .

**radiant energy** Energy transmitted as electromagnetic radiation.

**radiant exitance** *See* EXITANCE.

**radiant flux** Symbol  $\Phi_e$ . The total power emitted, received, or passing in the form of electromagnetic radiation. It is measured in watts.

**radiant intensity** Symbol  $I_e$ . The \*radiant flux per unit solid angle emitted by a point source. It is measured in watts per steradian.

**radiation 1.** Energy travelling in the form of electromagnetic waves or photons. **2.** A stream of particles, especially alpha- or beta-particles from a radioactive source or neutrons from a nuclear reactor. **3.** See ADAPTIVE RADIATION.

**radiation belts** See VAN ALLEN BELTS.

**radiation damage** Harmful changes that occur to inanimate materials and living organisms as a result of exposure to energetic electrons, nucleons, fission fragments, or high-energy electromagnetic radiation. In inanimate materials the damage may be caused by electronic excitation, ionization, transmutation, or displacement of atoms. In organisms, these mechanisms can cause changes to cells that alter their genetic structure, interfere with their division, or kill them. In humans, these changes can lead to **radiation sickness**, **radiation burns** (from large doses of radiation), or to long-term damage of several kinds, the most serious of which result in various forms of cancer (especially leukaemia).

**radiationless decay** Decay of an atom or molecule from an excited state to a lower energy state without the emission of electromagnetic radiation. A common example of a radiationless process is the \*Auger effect, in which an electron rather than a photon is emitted as a result of decay.

**radiation pressure** The pressure exerted on a surface by electromagnetic radiation. As radiation carries momentum as well as energy it exerts a force when it meets a surface, i.e. the \*photons transfer momentum when they strike the surface. The pressure is usually negligible on large bodies, for example, the pressure of radiation from the sun on the surface of the earth is of the order of  $10^{-5}$  pascal, but on small bodies it can have a considerable effect, driving them away from the radia-

tion source. Radiation pressure is also important in the interiors of stars of very high mass.

**radiation temperature** The surface temperature of a celestial body as calculated by \*Stefan's law, assuming that the body behaves as a \*black body. The radiation temperature is usually measured over a narrow portion of the electromagnetic spectrum, such as the visible range (which gives the **optical temperature**).

**radiation units** Units of measurement used to express the \*activity of a radionuclide and the \*dose of ionizing radiation. The units **curie**, **roentgen**, **rad**, and **rem** are not coherent with SI units but their temporary use with SI units has been approved while the derived SI units **becquerel**, **gray**, and **sievert** become familiar.

The becquerel (Bq), the SI unit of activity, is the activity of a radionuclide decaying at a rate, on average, of one spontaneous nuclear transition per second. Thus  $1 \text{ Bq} = 1 \text{ s}^{-1}$ . The former unit, the curie (Ci), is equal to  $3.7 \times 10^{10}$  Bq. The curie was originally chosen to approximate the activity of 1 gram of radium-226.

The gray (Gy), the SI unit of absorbed dose, is the absorbed dose when the energy per unit mass imparted to matter by ionizing radiation is 1 joule per kilogram. The former unit, the rad (rd), is equal to  $10^{-2}$  Gy.

The sievert (Sv), the SI unit of dose equivalent, is the dose equivalent when the absorbed dose of ionizing radiation multiplied by the stipulated dimensionless factors is  $1 \text{ J kg}^{-1}$ . As different types of radiation cause different effects in biological tissue a weighted absorbed dose, called the **dose equivalent**, is used in which the absorbed dose is modified by multiplying it by dimensionless factors stipulated by the International Commission on Radiological Protection. The former unit of dose equivalent, the rem (originally an acronym for *roentgen equivalent man*), is equal to  $10^{-2}$  Sv.

In SI units, exposure to ionizing radiation is expressed in coulombs per kilogram, the quantity of X- or gamma-radiation that produces ion pairs carrying 1 coulomb of charge in 1 kilogram of pure dry air. The former unit, the roentgen (R), is equal to  $2.58 \times 10^{-4} \text{ C kg}^{-1}$ .

**radiative collision** A collision between charged particles in which part of the kinetic energy is radiated in the form of photons.

**radical** **1.** (in chemistry) A group of atoms, either in a compound or existing alone. See FREE RADICAL; FUNCTIONAL GROUP. **2.** (in mathematics) A root of a number or a quantity. The symbol  $\sqrt{\quad}$  is called the **radical sign**.

**radicle** The part of a plant embryo that develops into the root system. The tip of the radicle is protected by a root cap and points towards the micropyle. On germination it breaks through the testa and grows down into the soil. Compare PLUMULE.

**radio** A means of transmitting information in which the transmission medium consists of electromagnetic radiation. Information is transmitted by means of the \*modulation of a \*carrier wave in a transmitter; the modulated carrier wave is fed to a transmitting aerial from which it is broadcast through the atmosphere or through space. A receiving aerial forms part of a \*resonant circuit, which can be tuned to the frequency of the carrier wave, enabling the receiver that it feeds selectively to amplify and then to demodulate the transmitted signal. A replica of the original information is thus produced by the receiver. See also RADIO TRANSMISSION.

**radioactive age** The age of an archaeological or geological specimen as determined by a process that depends on a radioactive decay. See CARBON DATING; FISSION-TRACK DATING; POTASSIUM-ARGON DATING; RUBIDIUM-STRONTIUM DATING; URANIUM-LEAD DATING.

**radioactive series** A series of radioactive nuclides in which each member of the series is formed by the decay of the nuclide before it. The series ends with a stable nuclide. Three radioactive series occur naturally, those headed by thorium-232 (**thorium series**), uranium-235 (**actinium series**), and uranium-238 (**uranium series**). All three series end with an isotope of lead. The neptunium series starts with the artificial isotope pluto-

nium-241, which decays to neptunium-237, and ends with bismuth-209.

**radioactive tracing** See LABELLING.

**radioactive waste (nuclear waste)** Any solid, liquid, or gaseous waste material that contains \*radionuclides. These wastes are produced in the mining and processing of radioactive ores, the normal running of nuclear power stations and other reactors, the manufacture of nuclear weapons, and in hospitals and research laboratories. Because high-level radioactive wastes can be extremely dangerous to all living matter and because they may contain radionuclides having half-lives of many thousands of years, their disposal has to be controlled with great stringency. High-level waste (e.g. spent nuclear fuel) requires to be cooled artificially and is therefore stored for several decades by its producers before it can be disposed of. Intermediate-level waste (e.g. processing plant sludge and reactor components) is solidified, mixed with concrete, packed in steel drums, and stored in special sites at power stations before being buried in concrete chambers in deep mines or below the seabed. Low-level waste (e.g. solids or liquids lightly contaminated by radioactive substances) is disposed of in steel drums in special sites in concrete-lined trenches. In the UK, a company (Nirex Ltd) was set up by the nuclear industry and the government in 1988 to handle the disposal of low-level nuclear waste, which is disposed of at an underground site at Driggs in Cumbria. There are also nuclear reprocessing plants at Dounreay (Scotland) and Sellafield in Cumbria. Formerly, low- and intermediate-level wastes were disposed of in the Atlantic deeps, in steel drums cast in concrete, but this practice was banned by international agreement in 1983.

**radioactivity** The spontaneous disintegration of certain atomic nuclei accompanied by the emission of alpha particles (helium nuclei), beta particles (electrons or positrons), or gamma radiation (short-wavelength electromagnetic waves).

**Natural radioactivity** is the result of the spontaneous disintegration of naturally occurring radioisotopes. Many radioisotopes can be arranged in three \*radio-

active series. The rate of disintegration is uninfluenced by chemical changes or any normal changes in their environment. However, radioactivity can be induced in many nuclides by bombarding them with neutrons or other particles. *See also* DECAY; IONIZING RADIATION; RADIATION UNITS.

**radio astronomy** The study of the radio-frequency radiation emitted by celestial bodies. This branch of astronomy began in 1932 when a US engineer, Karl Jansky (1905–40), first detected radio waves from outside the earth's atmosphere. *See* RADIO SOURCE; RADIO TELESCOPE; RADIO WINDOW.

**radiobiology** The branch of biology concerned with the effects of radioactive substances on living organisms and the use of radioactive tracers to study metabolic processes (*see* LABELLING).

**radiocarbon dating** *See* CARBON DATING.

**radiochemistry** The branch of chemistry concerned with radioactive compounds and with ionization. It includes the study of compounds of radioactive elements and the preparation and use of compounds containing radioactive atoms. *See* LABELLING; RADIOLYSIS.

**radio frequencies** The range of frequencies, between about 3 kilohertz and 300 gigahertz, over which electromagnetic radiation is used in radio transmission. It is subdivided into eight equal bands: \*very low frequency, \*low frequency, \*medium frequency, \*high frequency, \*very high frequency, \*ultra-high frequency, \*super high frequency, and \*extremely high frequency.

**radio galaxies** A \*radio source outside the Galaxy that has been identified with an optically visible galaxy. These radio galaxies are distinguished from normal galaxies by having a radio power output some  $10^6$  times greater (i.e. up to  $10^{38}$  watts rather than  $10^{32}$  W). The source of the radio-frequency energy is associated with violent activity, involving the ejection of relativistic jets of particles from the nucleus of the galaxy. It has been suggested that the radio sources are powered by supermassive \*black holes in the nucleus.

**radiogenic** Resulting from radioactive decay.

**radiography** The process or technique of producing images of an opaque object on photographic film or on a fluorescent screen by means of radiation (either particles or electromagnetic waves of short wavelength, such as X-rays and gamma-rays). The photograph produced is called a **radiograph**. The process is widely used in diagnostic \*radiology, using X-rays, and in flaw detection in industrial products, using high-energy X-rays, gamma-radiation, neutron beams, and (more recently) beams of charged particles. *See also* AUTORADIOGRAPHY.

**radio interferometry** *See* RADIO TELESCOPE.

**radioisotope (radioactive isotope)** An isotope of an element that is radioactive. *See* LABELLING.

**radiolocation** The location of distant objects by means of \*radar.

**radiology** The study and use of X-rays, radioactive materials, and other ionizing radiations for medical purposes, especially for diagnosis (**diagnostic radiology**) and the treatment of cancer and allied diseases (**therapeutic radiology** or **radiotherapy**).

**radiolysis** The use of ionizing radiation to produce chemical reactions. The radiation used includes alpha particles, electrons, neutrons, X-rays, and gamma rays from radioactive materials or from accelerators. Energy transfer produces ions and excited species, which undergo further reaction. A particular feature of radiolysis is the formation of short-lived solvated electrons in water and other polar solvents.

**radiometric dating (radioactive dating)** *See* DATING TECHNIQUES; RADIOACTIVE AGE.

**radionuclide (radioactive nuclide)** A \*nuclide that is radioactive.

**radiopaque (radio-opaque)** Describing a medium that is opaque to X-rays and gamma rays. Examples are barium salts, used in diagnostic radiology of the digestive tract. *See also* OPACITY.

**radiosonde** A meteorological instrument that measures temperature, pres-

sure, humidity, and winds in the upper atmosphere. It consists of a package of instruments and a radio transmitter attached to a balloon. The data is relayed back to earth by the transmitter. The position of the balloon can be found by radar and from its changes in position the wind velocities can be calculated.

**radio source** An astronomical object that has been observed with a \*radio telescope to emit radio-frequency electromagnetic radiation. Radio sources within the Galaxy include Jupiter, the sun, pulsars, and background radiation arising from \*synchrotron radiation. Sources outside the Galaxy include spiral galaxies, \*radio galaxies, and \*quasars. Radio sources were formerly known as **radio stars**.

**radio star** See RADIO SOURCE.

**radio telescope** An instrument for detecting and measuring electromagnetic radiation of radio frequencies that have passed through the \*radio window in the earth's atmosphere and reached the surface of the earth. There are a great diversity of \*radio sources within the universe and radio telescopes are required to detect both continuous emissions and specific spectral lines. They therefore require the highest possible angular resolution so that the details of radio sources can be studied and they should be able to pick up weak signals. The simplest radio telescope consists of a paraboloidal steerable-dish aerial together with ancillary amplifiers. The paraboloidal reflecting dish surface reflects the incoming signal to the principal focus of the reflector. At this point the radio-frequency signals are amplified up to 1000 times and converted to a lower, intermediate, frequency before transmission by cable to the control building. Here the intermediate frequency is amplified again and passed to the detector and display unit. As the radio waves arriving from the surface of the reflector at the focus must be in phase, the surface of the dish must be very accurately constructed; for example, a 100-metre-diameter dish must be accurate to the nearest millimetre, when receiving radiation of 1 cm wavelength. To overcome the problem of constructing large dishes to such a high accuracy, the technique of **radio interfer-**

**ometry** has been developed. In this technique an array of small aerials connected by cable is used to simulate a large dish aerial. In earth-rotation **aperture synthesis**, the individual positions and displacements of an array of only a few such small aerials can be made to simulate an enormous dish aerial as the earth rotates. All but the smallest steerable dishes are constructed from metal mesh so that wind can pass through them. A few very large fixed dishes have been built into the earth's surface.

**radiotherapy** See RADIOLOGY.

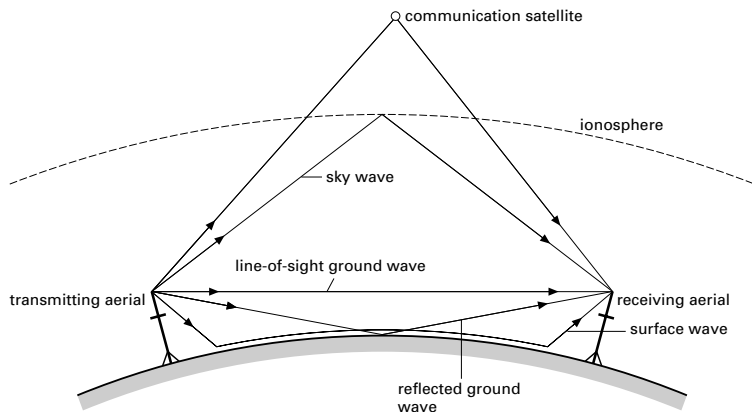

**radio transmission** The transmission of radio waves from a transmitting aerial to a receiving aerial. The radiation may take several paths (see illustration). The sum of the line-of-sight ground wave, the reflected ground wave, and the surface wave is called the **ground wave** (or **tropospheric wave**). **Sky waves** (or **ionospheric waves**) are reflected by the ionosphere and enable long-distance transmissions to be made. The ionization of atoms and molecules in the ionosphere is caused largely by solar ultraviolet and X-radiation and therefore conditions differ between night and day. Ionization in the lower E-region of the ionosphere falls off at night in the absence of sunlight and ions and electrons tend to recombine. However, in the less dense (higher) F-region there are fewer collisions between ions and electrons and therefore fewer recombinations at night. The F-region is therefore a more effective reflector at night.

The UHF and VHF waves used in television broadcasting penetrate the ionosphere with little reflection. Therefore TV broadcasts can only be made over long distances by means of artificial satellites. See also RADIO.

**radiotransparent** Transparent to radiation, especially to X-rays and gamma-rays.

**radio window** A region of the electromagnetic spectrum in the radio-frequency band within which radio waves can be transmitted through the earth's atmosphere without significant reflection or attenuation by constituents of the atmosphere. It extends from about 10 megahertz to 100 gigahertz and enables radiation in this range from celestial radio

### Radio transmission

sources to be picked up by \*radio telescopes on the earth's surface. Below 100 MHz incoming radio waves are reflected by the ionosphere and those above 100 GHz are increasingly affected by molecular absorption.

**radium** Symbol Ra. A radioactive metallic element belonging to \*group 2 (formerly IIA) of the periodic table; a.n. 88; r.a.m. 226.0254; r.d. -5; m.p. 700°C; b.p. 1140°C. It occurs in uranium ores (e.g. pitchblende). The most stable isotope is radium-226 (half-life 1602 years), which decays to radon. It is used as a radioactive source in research and, to some extent, in radiotherapy. The element was isolated from pitchblende in 1898 by Marie and Pierre Curie.

**radius 1.** (in anatomy) The smaller of the two bones in the lower section of the forelimb of a tetrapod vertebrate (*compare* ULNA). The radius articulates with some carpal bones and the ulna at the wrist and with the \*humerus at the elbow. This sophisticated articulation of the radius enables humans (and some other animals) to twist the forearm (*see* PRONATION; SUPINATION). **2.** (in mathematics) *See* CIRCLE.

**radius of curvature** *See* CENTRE OF CURVATURE.

**radius of gyration** Symbol  $k$ . The square root of the ratio of the \*moment of inertia of a rigid body about an axis to

the body's mass, i.e.  $k^2 = I/m$ , where  $I$  is the body's moment of inertia and  $m$  is its mass. If a rigid body has a moment of inertia  $I$  about an axis and mass  $m$  it behaves as if all its mass is rotating at a distance  $k$  from the axis.

**radius vector** *See* POLAR COORDINATES.

**radon** Symbol Rn. A colourless radioactive gaseous element belonging to group 18 of the periodic table (the \*noble gases); a.n. 86; r.a.m. 222; d. 9.73 g dm<sup>-3</sup>; m.p. -71°C; b.p. -61.8°C. At least 20 isotopes are known, the most stable being radon-222 (half-life 3.8 days). It is formed by decay of radium-226 and undergoes alpha decay. It is used in radiotherapy. Radon occurs naturally, particularly in areas underlain by granite, where it is thought to be a health hazard. As a noble gas, radon is practically inert, although a few compounds, e.g. radon fluoride, can be made. It was first isolated by William Ramsey and Robert Whytlaw-Gray (1877-1958) in 1908.

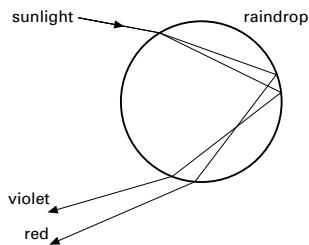

**radula** A tongue-like organ of molluscs, consisting of a horny strip whose surface is studded with rows of horny teeth for rasping food. In some species it is modified for scraping or boring.

**raffinate** A liquid purified by solvent extraction.

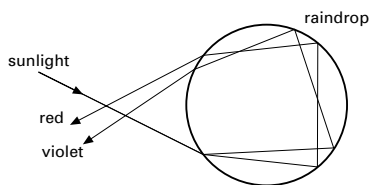

**raffinose** A white solid carbohydrate,

$C_{18}H_{32}O_{16}$ , m.p.  $80^{\circ}\text{C}$ . It is a trisaccharide (a type of \*sugar) consisting of fructose, galactose and glucose. It occurs naturally in sugar-beet and cotton-seed residues.

**rainbow** An optical phenomenon that appears as an arc of the colours of the spectrum across the sky when falling water droplets are illuminated by sunlight from behind the observer. The colours are produced by the refraction and internal reflection of the sunlight by the water drops. Two bows may be visible, the inner ring being known as the primary bow and the outer, in which the colours are reversed, as the secondary bow (see illustration).

Primary rainbow (one internal reflection)

Secondary rainbow (two internal reflections)

**rainfall** See PRECIPITATION.

**rainforest** Any major terrestrial \*biome in which trees form the dominant plants and annual rainfall is high (over 200 cm). Tropical rainforest is restricted to equatorial regions, such as the Amazon basin, central west Africa, and SE Asia. It is dominated by broadleaved evergreens and shows a very rich species diversity (see BIODIVERSITY). The leafy crowns of the trees typically form three layers of canopy, since the trees grow to different heights, which prevents much sunlight from

reaching ground level. This limits the number of herbaceous plants and small shrubs that grow on the forest floor, but \*epiphytes, vines, and creepers are abundant. The average temperature is about  $27^{\circ}\text{C}$ , which – together with the high humidity – encourages rapid decomposition of leaf litter, releasing minerals that replace those leached from the soil by the heavy rain. If the forest canopy is removed, the soil is destroyed rapidly due to leaching by rain. The soil of a rainforest, known as **latosol**, is acidic and typically red, due to the oxidation of iron oxide ( $\text{Fe}_2\text{O}_3$ ) in the topsoil. Rainforests are thought to contain many undiscovered plant species that could be of benefit in the fields of medicine and biotechnology. The continued destruction of rainforest in many parts of the world, particularly in South America and SE Asia (see DEFORESTATION), will not only result in the loss of these and other species but also contributes to the \*greenhouse effect.

**RAM** Random-access memory. The main memory of a computer, fabricated from \*integrated circuits, in which data can only be stored temporarily – until the power supply is turned off. RAM consists of arrays of 'cells', each capable of holding one \*bit of data. Cells are completely independent so that the access time to any location is fixed (and extremely rapid) hence the term random access.

**r.a.m.** See RELATIVE ATOMIC MASS.

**Raman effect** A type of inelastic \*scattering of light and ultraviolet radiation discovered in 1928 by Chandrasekara Raman (1880–1970). If a beam of monochromatic light is passed through a transparent substance some of the radiation will be scattered. Although most of the scattered radiation will be the same as the incident frequency, some will have frequencies above (anti-Stokes radiation) and below (Stokes radiation) that of the incident beam. This effect is known as **Raman scattering** and is due to inelastic collisions between photons and molecules leading to changes in the vibrational and rotational energy levels of the molecules. An increase in frequency represents a loss in molecular energy; a decrease represents a gain in molecular energy.

This effect is used in **Raman spectroscopy** for investigating the vibrational and rotational energy levels of molecules. Because the scattering intensity is low, a laser source is used.

**Ramapithecus** A genus of extinct primates that lived about 12–14 million years ago. Fossil remains of ramapithecines have been found in India and Pakistan, the Near East, and East Africa. Early discoveries of jaw fragments suggested that they chewed from side to side and had fairly short muzzles, both of which are humanoid features. However, subsequent finds, including a complete jaw, were not hominoid, and ramapithecines are now regarded by many authorities as ancestral to the Asian great apes (e.g. orang-utans), not the hominids. See also DRYOPITHECUS; AUSTRALOPITHECUS.

**ramjet** See JET PROPULSION.

**Ramón y Cajal, Santiago** See GOLGI, CAMILLO.

**Ramsay, Sir William** (1852–1916) British chemist, born in Glasgow. After working under Robert \*Bunsen, he returned to Glasgow before taking up professorships at Bristol (1880–87) and London (1887–1912). In the early 1890s he worked with Lord \*Rayleigh on the gases in air and in 1894 they discovered \*argon. In 1898, with Morris Travers (1872–1961), he discovered \*neon, \*krypton, and \*xenon. Six years later he discovered the last of the noble gases, \*radon. He was awarded the Nobel Prize for chemistry in 1904, the year in which Rayleigh received the physics prize.

**Ramsden eyepiece** An eyepiece for optical instruments consisting of two identical plano-convex lenses with their convex faces pointing towards each other. They are separated by a distance of two thirds of the focal length of either lens.

**random alloy** See DISORDERED SOLID.

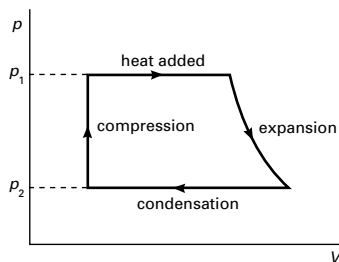

**random walk** The problem of determining the distance from a starting position made by a walker, who can either move forward (toward +x) or backwards (toward -x) with the choice being made randomly (e.g. by tossing a coin). The progress of the walker is characterized by

the net distance  $D_N$  travelled in  $N$  steps. After  $N$  steps the \*root mean square value  $D_{rms}$ , which is the average distance away from the starting position, is given by  $D_{rms} = \sqrt{N}$ . Physical applications of the random walk include diffusion and the related problem of Brownian motion as well as problems involving the structures of polymers and disordered solids.

**Raney nickel** A spongy form of nickel made by the action of sodium hydroxide on a nickel–aluminium alloy. The sodium hydroxide dissolves the aluminium leaving a highly active form of nickel with a large surface area. The material is a black pyrophoric powder saturated with hydrogen. It is an extremely efficient catalyst, especially for hydrogenation reactions at room temperature. It was discovered in 1927 by the American chemist M. Raney.

**rank (category)** (in biology) The position or status of a \*taxon in a \*classification hierarchy. Examples of ranks are the family, genus, and species.

**Rankine cycle** A cycle of operations in a heat engine. The Rankine cycle more closely approximates to the cycle of a real steam engine that does the \*Carnot cycle. It therefore predicts a lower ideal thermal efficiency than the Carnot cycle. In the Rankine cycle (see illustration), heat is added at constant pressure  $p_1$ , at which water is converted in a boiler to superheated steam; the steam expands at constant entropy to a pressure  $p_2$  in the cylinder; heat is rejected at constant pressure  $p_2$  in a condenser; the water so formed is compressed at constant entropy to pressure  $p_1$  by a feed pump. The cycle

Rankine cycle

was devised by William Rankine (1820–70).

**Rankine temperature scale** An absolute temperature scale based on the Fahrenheit scale. Absolute zero on this scale, 0°R, is equivalent to -459.67°F and the melting point of ice (32°F) is therefore (459.67 + 32 = 491.67)°R. The scale was devised by William Rankine.

**ranksite** A mineral consisting of a mixed sodium carbonate, sodium sulphate, and potassium chloride,  $2\text{Na}_2\text{CO}_3 \cdot 9\text{Na}_2\text{SO}_4 \cdot \text{KCl}$ .

**Raoult's law** The partial vapour pressure of a solvent is proportional to its mole fraction. If  $p$  is the vapour pressure of the solvent (with a substance dissolved in it) and  $X$  the mole fraction of solvent (number of moles of solvent divided by total number of moles) then  $p = p_0X$ , where  $p_0$  is the vapour pressure of the pure solvent. A solution that obeys Raoult's law is said to be an **ideal solution**. In general the law holds only for dilute solutions, although some mixtures of liquids obey it over a whole range of concentrations. Such solutions are **perfect solutions** and occur when the intermolecular forces between molecules of the pure substances are similar to the forces between molecules of one and molecules of the other. Deviations in Raoult's law for mixtures of liquids cause the formation of \***azeotropes**. The law was discovered by the French chemist François Raoult (1830–1901).

**rapeseed methyl ester** See **BIOFUEL**.

**rare-earth elements** See **LANTHANOIDS**.

**rarefaction** A reduction in the pressure of a fluid and therefore of its density.

**rare gases** See **NOBLE GASES**.

**Raschig process** An industrial process for making chlorobenzene (and phenol) by a gas-phase reaction between benzene vapour, hydrogen chloride, and oxygen (air) at 230°C

The catalyst is copper(II) chloride. The chlorobenzene is mainly used for making phenol by the reaction

This reaction proceeds at 430°C with a silicon catalyst. The process was invented by the German chemist Fritz Raschig (1863–1928).

**Raschig synthesis** See **HYDRAZINE**.

**raster** The pattern of scanning lines on the screen of the cathode-ray tube in a television receiver or other device that provides a visual display.

**rate constant (velocity constant)** Symbol  $k$ . The constant in an expression for the rate of a chemical reaction in terms of concentrations (or activities). For instance, in a simple unimolecular reaction

the rate is proportional to the concentration of A, i.e.

$$\text{rate} = k[\text{A}]$$

where  $k$  is the rate constant, which depends on the temperature. The equation is the **rate equation** of the reaction, and its form depends on the reaction mechanism.

**rate-determining step** The slowest step in a chemical reaction that involves a number of steps. In such reactions, there is often a single step that is appreciably slower than the other steps, and the rate of this determines the overall rate of the reaction.

**rationalized Planck constant** See **PLANCK CONSTANT**.

**rationalized units** A system of units in which the defining equations have been made to conform to the geometry of the system in a logical way. Thus equations that involve circular symmetry contain the factor  $2\pi$ , while those involving spherical symmetry contain the factor  $4\pi$ . \*SI and \*Heaviside-Lorentz units are rationalized; \*Gaussian units are unrationalized.

**rational number** Any number that can be expressed as the ratio of two integers. For example, 0.3333... is rational because it can be written as  $1/3$ .  $\sqrt{2}$ , however, is \*irrational.

**Ratitae (Palaeognathae)** A group comprising the flightless birds, including the

ostrich, kiwi, and emu. They have long legs, heavy bones, small wings, a flat breastbone, and curly feathers. These birds are thought to have descended from a variety of flying birds and are not representatives of a single homologous group.

**ray 1.** (in optics) A narrow beam of radiation or an idealized representation of such a beam on a **ray diagram**, which can be used to indicate the positions of the object and image in a system of lenses or mirrors. **2.** (in botany) See MEDULLARY RAY.

**Rayleigh, Baron** (John William Strutt; 1842–1919) British physicist, who built a private laboratory after working at Cambridge University. His work in this laboratory included the discovery of Rayleigh \*scattering. He also worked in acoustics, electricity, and optics, as well as collaborating with William \*Ramsay on the discovery of \*argon. He was awarded the 1904 Nobel Prize for physics.

**Rayleigh criterion** See RESOLVING POWER.

**Rayleigh–Jeans formula** See PLANCK'S RADIATION LAW.

**Rayleigh scattering** See SCATTERING OF ELECTROMAGNETIC RADIATION.

**rayon** A textile made from cellulose. There are two types, both made from wood pulp. In the viscose process, the pulp is dissolved in carbon disulphide and sodium hydroxide to give a thick brown liquid containing cellulose xanthate. The liquid is then forced through fine nozzles into acid, where the xanthate is decomposed and a cellulose filament is produced. The product is **viscose rayon**. In the acetate process cellulose acetate is made and dissolved in a solvent. The solution is forced through nozzles into air, where the solvent quickly evaporates leaving a filament of **acetate rayon**.

**reactance** Symbol  $X$ . A property of a circuit containing inductance or capacitance that together with any resistance makes up its \*impedance. The impedance  $Z$  is given by  $Z^2 = R^2 + X^2$ , where  $R$  is the resistance. For a pure capacitance  $C$ , the reactance is given by  $X_C = 1/2\pi fC$ , where  $f$  is the frequency of the \*alternating current; for a pure inductance  $L$ ,  $X_L = 2\pi fL$ . If the

resistance, inductance, and capacitance are in series the impedance  $Z = \sqrt{R^2 + (X_L - X_C)^2}$ . Reactance is measured in ohms.

**reactant** See CHEMICAL REACTION.

**reaction 1.** A force that is equal in magnitude but opposite in direction to some other force, in accordance with Newton's third law of motion. If a body A exerts a force on body B, then B exerts an equal and opposite force on A. Thus, every force could be described as 'a reaction', and the term is better avoided, although it is still used in such terms as 'reaction propulsion'. **2.** See CHEMICAL REACTION.

**reaction propulsion** See JET PROPULSION.

**reaction time (latent period)** The period of time between the detection of a stimulus at a sensory receptor and the performance of the appropriate response by the effector organ. This delay is caused by the time taken for the impulse to travel across the synapses of adjacent neurons. The reaction time for a \*reflex response, involving only a single linking synapse, is very short.

**reactive dye** See DYES.

**reactor 1.** See NUCLEAR REACTOR. **2.** Any device, such as an inductor or capacitor, that introduces \*reactance into an electrical circuit.

**reading frame** A sequence of bases in messenger RNA (or deduced from DNA) that encodes for a polypeptide. Since each coding unit (\*codon) of the genetic code consists of three consecutive bases, the reading frame is established according to precisely where translation starts. The hallmark of a functional gene is that it is transcribed to produce an **open reading frame (ORF)**, consisting of a \*start codon to pinpoint where translation should start, a \*stop codon to signal termination of translation, and typically a long sequence of codons that specify the constituent amino acids of the polypeptide (as well as \*introns in most eukaryote genes).

**reagent** A substance reacting with another substance. Laboratory reagents are compounds, such as sulphuric acid, hydrochloric acid, sodium hydroxide, etc., used in chemical analysis or experiments.

**realgar** A red mineral form of arsenic(III) sulphide,  $As_2S_2$ .

**real gas** A gas that does not have the properties assigned to an \*ideal gas. Its molecules have a finite size and there are forces between them (see EQUATION OF STATE).

**real image** See IMAGE.

**real-is-positive convention (real-positive convention)** A convention used in optical formulae relating to lenses and mirrors. In this convention, distances from optical components to real objects, images, and foci are taken as positive, whereas distances to virtual points are taken as negative.

**rearrangement** A type of chemical reaction in which the atoms in a molecule rearrange to form a new molecule.

**Réaumur temperature scale** A temperature scale in which the melting point of ice is taken as  $0^\circ R$  and the boiling point of water as  $80^\circ R$ . It was devised by René Antoine Réaumur (1683-1757).

**recalescence** A phenomenon that occurs during the cooling of iron and other ferromagnetic metals (see MAGNETISM) after they have been heated. When iron is heated to white heat and then allowed to cool, it abruptly evolves heat at a certain temperature. This evolution of heat, which slows down the cooling process and can lead to a brief reheating, is caused by an \*exothermic reaction when the structure of the crystal changes. The temperature at which this occurs is called the **recalescence point**. For pure iron there are two recalescence points: at  $780^\circ C$  and  $880^\circ C$ . A reverse phenomenon causing cooling, called **decalescence**, occurs when ferromagnetic metals are heated.

**Recent** See HOLOCENE.

**receptacle 1. (thalamus or torus)** The tip of a flower stalk, which bears the petals, sepals, stamens, and carpels. The way the receptacle develops determines the position of the flower parts. It can be dilated and dome-shaped, saucer-shaped, or hollow and enclosing the gynoecium. In some plants it may become part of the fruit (see PSEUDOCARP). **2.** A swollen part of the thallus of some algae, e.g. *Fucus*,

that bears the conceptacles in which the sex organs are situated.

**receptor (in biology) 1.** A cell or group of cells specialized to detect a particular stimulus and to initiate the transmission of impulses via the sensory nerves. The eyes, ears, nose, skin, and other sense organs all contain specific receptors responding to external stimuli (see EXTEROCEPTOR); other receptors are sensitive to changes within the body (see INTEROCEPTOR). See also BARORECEPTOR; CHEMORECEPTOR; MECHANORECEPTOR; OSMORECEPTOR; PROPRIOCEPTOR. **2.** An area of a plasma membrane, consisting of a specially adapted membrane protein, that can bind with a specific hormone, neurotransmitter, drug, or other chemical, thereby initiating a change within the cell. For example, the binding of protein hormones to receptors of target cells initiates the synthesis of a \*second messenger inside the cell.

**recessive** The \*allele that is not expressed in the \*phenotype when two different alleles are present in the cells of an organism. The aspect of a characteristic controlled by a recessive allele only appears when two such alleles are present, i.e. in the **double recessive** condition. Compare DOMINANT.

**recipient** An individual who receives tissues or organs of the body from another (the \*donor).

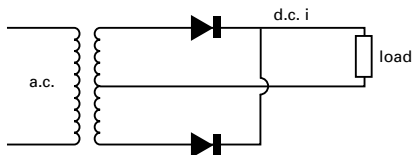

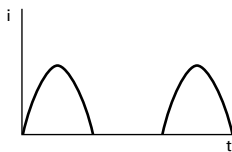

**reciprocal cross** A \*cross reversing the roles of males and females to confirm the results obtained from an earlier cross. For example, if the pollen (male) from tall plants is transferred to the stigmas (female) of dwarf plants in one cross, the reciprocal cross would use the pollen of dwarf plants to pollinate the stigmas of tall plants.

**reciprocal proportions** See CHEMICAL COMBINATION.

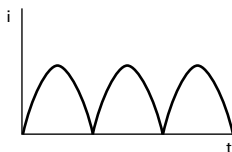

**recombinant DNA** DNA that contains genes from different sources that have been combined by the techniques of \*genetic engineering rather than by breeding experiments. Genetic engineering is therefore also known as **recombinant DNA technology**. Recombinant DNA is formed

Half-wave rectification

Full-wave rectification

during \*gene cloning and in the creation of \*genetically modified organisms.

**recombination** The rearrangement of genes that occurs when reproductive cells (gametes) are formed. It results from the \*independent assortment of parental sets of chromosomes and exchange of chromosomal material (see CROSSING OVER) that occur during \*meiosis. Recombination results in offspring that have a combination of characteristics different from that of their parents. Recombination can also be induced artificially by \*genetic engineering techniques.

**recombination era** The period after the big bang when the universe was sufficiently cool for electrons and nuclei to form atoms for the first time. The recombination occurred about 300 000 years after the big bang. Up to this time, photons in the universe were scattered by free electrons and it is sometimes said that the universe was 'opaque'. With recombination, photons were able to travel without impediment, and the universe became 'transparent'. See also MICROWAVE BACKGROUND RADIATION.

**recombination process** The process in which a neutral atom or molecule is formed by the combination of a positive ion and a negative ion or electron; i.e. a process of the type:

or

In recombination, the neutral species formed is usually in an excited state, from which it can decay with emission of light or other electromagnetic radiation.

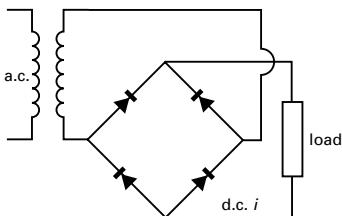

**recrystallization** A process of repeated crystallization in order to purify a substance or to obtain more regular crystals of a purified substance.

**rectification 1.** (in physics) The process of obtaining a direct current from an alternating electrical supply. See RECTIFIER.

**2.** (in chemistry) The process of purifying a liquid by \*distillation. See FRACTIONAL DISTILLATION.

**rectified spirit** A constant-boiling mixture of \*ethanol (95.6°) and water; it is obtained by distillation.

**rectifier** An electrical device that allows more current to flow in one direction than the other, thus enabling alternating e.m.f.s to drive only direct current. The device most commonly used for rectification is the semiconductor \*diode. In **half-wave rectification**, achieved with one

Bridge rectifier

diode, a pulsating current is produced. In **full-wave rectification** two diodes are used, one pair conducting during the first half cycle and the other conducting during the second half (see illustration). The full-wave rectified signal can be smoothed using a capacitor or an inductor. The **bridge rectifier** illustrated also gives full-wave rectification.

**rectum** The portion of the \*alimentary canal between the \*colon and the \*anus. Its main function is the storage of \*faeces prior to elimination.

**recycling 1.** The recovery and processing of materials after they have been used, which enables them to be reused. For example, used paper, cans, and glass can be broken down into their constituents, which form the raw materials for the manufacture of new products.

**2.** The continual movement of \*essential elements between the biotic (living) and abiotic (nonliving) components of the environment. See CARBON CYCLE; NITROGEN CYCLE; OXYGEN CYCLE; PHOSPHORUS CYCLE; SULPHUR CYCLE.

**red algae** See RHODOPHYTA.

**red blood cell** See ERYTHROCYTE.

**red dwarf** A \*dwarf star on the main sequence (see HERTZSPRUNG-RUSSELL DIAGRAM) that is much cooler, smaller, and less massive than the sun. These stars display a number of magnetic phenomena. See also FLARE STAR.

**red giant** A \*giant star thought to be in the later stages of \*stellar evolution. It has a surface temperature in the range 2000–3000 K and a diameter 10–100 times that of the sun. See also HERTZSPRUNG-RUSSELL DIAGRAM.

**red lead** See DILEAD(II) LEAD(IV) OXIDE.

**redox** See OXIDATION-REDUCTION.

**redshift 1. (Doppler redshift)** A displacement of the lines in the spectra of certain galaxies towards the red end of the visible spectrum (i.e. towards longer wavelengths). It is usually interpreted as a \*Doppler effect resulting from the recession of the galaxies along the line of sight (see EXPANSION OF THE UNIVERSE). The redshift is usually expressed as  $\Delta\lambda/\lambda$ , where

$\Delta\lambda$  is the shift in wavelength of radiation of wavelength  $\lambda$ . For relatively low velocities of recession this is equivalent to  $v/c$ , where  $v$  is the relative velocity of recession and  $c$  is the speed of light. If very high velocities of recession are involved, a relativistic version of  $v/c$  is required (see RELATIVISTIC SPEED). The redshift of spectral lines occurs in all regions of the electromagnetic spectrum; ultraviolet can be shifted into the visible region and visible radiation can be shifted into the infrared region. **2. (gravitational or Einstein redshift)** A similar displacement of spectral lines towards the red caused not by a Doppler effect but by a high gravitational field. This type of redshift was predicted by Einstein and some astronomers believe that this is the cause of the large redshifts of \*quasars, which can be as high as 3.35.

**reducing agent (reductant)** A substance that brings about reduction in other substances. It achieves this by being itself oxidized. Reducing agents contain atoms with low oxidation numbers; that is the atoms have gained electrons. In reducing other substances, these atoms lose electrons.

**reducing sugar** A monosaccharide or disaccharide sugar that can donate electrons to other molecules and can therefore act as a reducing agent. The possession of a free ketone ( $-CO-$ ) or aldehyde ( $-CHO$ ) group enables most monosaccharides and disaccharides to act as reducing sugars. Reducing sugars can be detected by \*Benedict's test. Compare NONREDUCING SUGAR.

**reductant** See REDUCING AGENT.

**reduction** See OXIDATION-REDUCTION.

**reduction division** See MEIOSIS.

**reef** An outcrop of rock that projects above the surface in shallow seas, particularly one constructed by calcareous animals, such as \*corals, shellfish, and some algae. Reefs may be mounds or ridges, often with very steep sides, or even a chain of islands. A fringing reef is attached to the coast and acts as a breakwater; a barrier reef runs parallel to the coast, usually with a deeper lagoon on the landward side. Reefs provide rich habitats for fish and invertebrates. See also ATOLL.

**refinery gas** See PETROLEUM.

**refining** The process of purifying substances or extracting substances from mixtures.

**reflectance** The ratio of the radiant flux reflected by a surface to that falling on it. This quantity is also known as the **radiant reflectance**. The radiant reflectance measured for a specified wavelength of the incident radiant flux is called the **spectral reflectance**.

**reflecting telescope (reflector)** See TELESCOPE.

**reflection** The return of all or part of a beam of particles or waves when it encounters the boundary between two media. The **laws of reflection** state: (1) that the incident ray, the reflected ray, and the normal to the reflecting interface at the point of incidence are all in the same plane; (2) that the angle of incidence equals the angle of reflection. See also MIRROR; REFLECTANCE; TOTAL INTERNAL REFLECTION.

**reflex** An automatic and innate response to a particular stimulus. A reflex response is extremely rapid. This is because it is mediated by a simple nervous circuit called a **reflex arc**, which at its simplest involves only a receptor linked to a sensory neuron, which synapses with a motor neuron (supplying the effector) in the spinal cord. Such reflexes are known as **spinal reflexes**; examples are the **withdrawal reflex** of the hand from a painful stimulus (such as fire) and the **stretch reflex**. **Cranial reflexes** are mediated by pathways in the cranial nerves and brain; examples are the blinking and swallowing reflexes. See also CONDITIONING.

**refluxing** A laboratory technique in which a liquid is boiled in a container attached to a condenser (**reflux condenser**), so that the liquid continuously flows back into the container. It is used for carrying out reactions over long periods in organic synthesis.

**reforestation** The replanting of trees on areas of land where forests have been cleared by felling or burning (see DEFOR-ESTATION) or by natural means. Reforestation is particularly important in countries,

such as Brazil, where large areas of forest have been destroyed by deforestation, although planted forest has much less species diversity (see BIODIVERSITY) than the original forest. It also helps to counteract global emissions of carbon dioxide, by fixing the gas as plant material. Hence reforestation can play a part in slowing **\*global warming**.

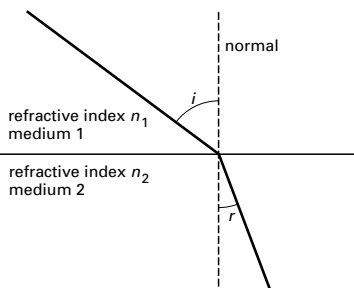

**reforming** The conversion of straight-chain alkanes into branched-chain alkanes by **\*cracking** or by catalytic reaction. It is used in petroleum refining to produce hydrocarbons suitable for use in gasoline. Benzene is also manufactured from alkane hydrocarbons by catalytic reforming. **Steam reforming** is a process used to convert methane (from natural gas) into a mixture of carbon monoxide and hydrogen, which is used to synthesize organic chemicals. The reaction

occurs at about 900°C using a nickel catalyst.

**refracting telescope (refractor)** See TELESCOPE.

**refraction** The change of direction suffered by wavefront as it passes obliquely from one medium to another in which its speed of propagation is altered. The phenomenon occurs with all types of waves, but is most familiar with light waves. In optics the direction is changed in accordance with **Snell's law**, i.e.  $n_1 \sin i = n_2 \sin r$ , where  $i$  and  $r$  are the angles made by the incident beam of radiation and the refracted beam to the normal (an imaginary line perpendicular to the interface be-

Refraction

tween the two media);  $n_1$  and  $n_2$  are the \*refractive indices of the two media. This law is also known as one of the **laws of refraction**. The other law of refraction is that the incident ray, the refracted ray, and the normal at the point of incidence lie in the same plane. The change of direction results from a change in the speed of propagation and the consequent change in wavelength (see illustration).

**refractive index (refractive constant)**

Symbol  $n$ . The **absolute refractive index** of a medium is the ratio of the speed of electromagnetic radiation in free space to the speed of the radiation in that medium. As the refractive index varies with wavelength, the wavelength should be specified. It is usually given for yellow light (sodium D-lines; wavelength 589.3 nm). The **relative refractive index** is the ratio of the speed of light in one medium to that in an adjacent medium. See also REFRACTION.

**refractivity** A measure of the extent to which a medium will deviate a ray of light entering its surface. In some contexts it is equal to  $(n - 1)$ , where  $n$  is the \*refractive index.

**refractometer** Any of various instruments for measuring the \*refractive index of a substance or medium. An example is the **Pulfrich refractometer**, which is a glass block with a polished top, with a small cell on top of the block for liquid samples. A telescope rotating on a vertical circular scale is used to find the angle ( $\alpha$ ) between the top of the block and the direction in which the limiting ray (from incident light parallel to the top face) leaves the side of the block. If the refractive index of the block ( $n_g$ ) is known, that of the liquid can be calculated using  $n = \sqrt{(n_g^2 - \sin^2 \alpha)}$ .

**refractory 1.** Having a high melting point. Metal oxides, carbides, and silicides tend to be refractory, and are extensively used for lining furnaces. **2.** A refractory material.

**refractory period** The period after the transmission of an impulse in a nerve or muscle in which the membrane of the axon or muscle fibre regains its ability to transmit impulses (see ACTION POTENTIAL). This period lasts approximately 3 millise-

conds and is divided into an **absolute refractory period**, during which a second impulse may not be generated; and a **relative refractory period**, during which it is possible to generate an impulse only if there is an abnormally strong stimulus.

**refrigerant** See REFRIGERATION.

**refrigeration** The process of cooling a substance and of maintaining it at a temperature below that of its surroundings. See Feature.

**regeneration** The growth of new tissues or organs to replace those lost or damaged by injury. Many plants can regenerate a complete plant from a shoot segment or a single leaf, this being the basis of many horticultural propagation methods (see CUTTING). The capacity for regeneration in animals is less marked. Some planarians and sponges can regenerate whole organisms from small pieces, and crustaceans (e.g. crabs), echinoderms (e.g. brittlestars), and some reptiles and amphibians can grow new limbs or tails (see AUTOTOMY), but in mammals regeneration is largely restricted to wound healing.

**regma** A dry fruit that is characteristic of the geranium family. It is similar to the \*carcerulus but breaks up into one-seeded parts, each of which splits open to release a seed.

**Regnault's method** A technique for measuring gas density by evacuating and weighing a glass bulb of known volume, admitting gas at known pressure, and reweighing. The determination must be carried out at constant known temperature and the result corrected to standard temperature and pressure. The method is named after the French chemist Henri Victor Regnault (1810–78).

**regolith** A layer of weathered rock fragments that lies below the soil and above the bedrock below. In the tropics it may be up to 60 m thick. Fine regolith differs from soil in that it has no organic content (humus) and cannot therefore support plant life, although the roots of trees and other plants may penetrate it for water.

**regulator gene** See OPERON.

**regulatory genes** Genes that control development by regulating the expression

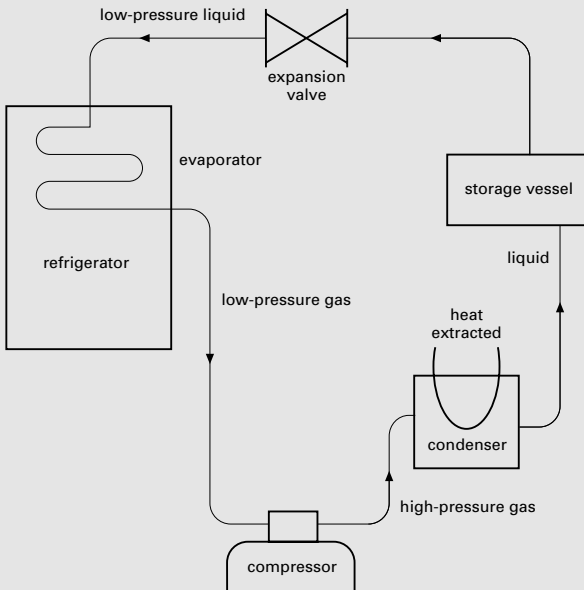

## REFRIGERATION

In the domestic refrigerator a cycle of operations equivalent to those of a \*heat pump is used.

### The vapour-compression cycle

In this cycle (see illustration) a volatile liquid refrigerant, such as a fluorocarbon, is pumped through the cooling coils of the evaporator to the ice-making compartment of the refrigerator. Inside these coils the refrigerant evaporates, taking the latent heat required to effect the change of state from the inside of the ice-making compartment, causing the temperature in this compartment to fall. The vapour is then passed to an electrically driven compressor before entering the condenser, where the high-pressure gas is converted back to a liquid. The heat produced by this second change of state is given out, usually at the back of the refrigerator. The liquid refrigerant then enters a storage vessel before finally passing through an expansion valve to reduce its pressure prior to beginning the cycle again in the evaporator.

This cycle is repeated over and over again until the temperature reaches the desired level (about 1–2°C in the food chamber of a domestic refrigerator and minus 15–18°C in the deep-freeze compartment). The compressor is then switched off, and on again later, by a thermostat to maintain a steady temperature. In order to transfer heat from the cold interior to the warm surroundings without contravening the second law of thermodynamics, energy has to be supplied to the cycle by the electric current that drives the compressor.

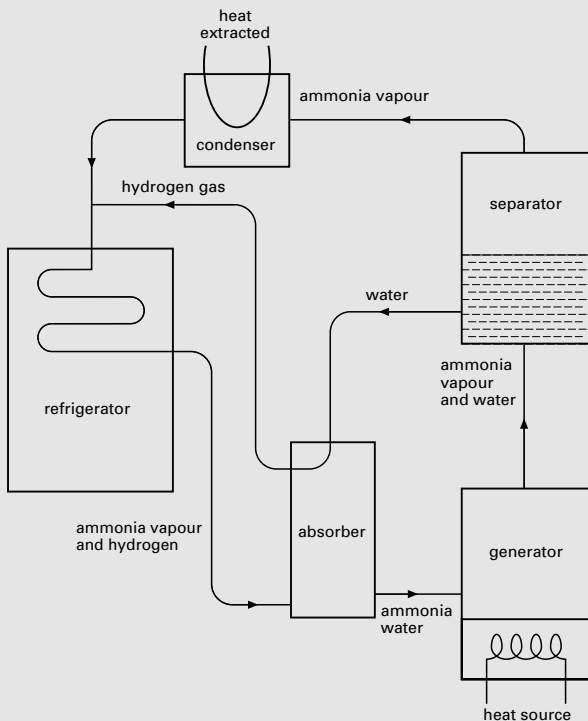

Vapour-compression cycle

### The vapour-absorption cycle

In this cycle there are no moving parts and energy is supplied as heat either by an electric heater or a gas burner. The refrigerant is usually ammonia, which is liberated from a water solution and moved through the evaporator by a stream of hydrogen gas under pressure. Heat is applied to the generator, raising the ammonia and water vapour to the separator; the ammonia separates from the water and passes to the condenser, where it cools and liquefies, giving off its latent heat to the surroundings. The liquid ammonia is then mixed with hydrogen gas, which carries it through the evaporator and helps in the process of evaporation. Subsequently the hydrogen and ammonia vapour enter the absorber, where the water returned from the separator dissolves the ammonia before returning to the generator.

### Small-scale refrigerator

These two systems account for all domestic and industrial refrigerators including those on in ships, trains, and refrigerated lorries. However, small-scale refrigeration is sometimes achieved by means of the \*Peltier effect at junctions for *n*-type and *p*-type semiconductors.

Vapour-absorption cycle

of structural genes responsible for the formation of body components. They encode \*transcription factors, which interact with regulatory sites of other genes causing activation or repression of developmental pathways. Much of development in quite different organisms, such as mammals and insects, is controlled by genes that are structurally very similar, thought to descended from genes in ancient common ancestors. Prime examples are the \*homeotic genes.

**Reines, Frederick** See PAULI, WOLFGANG ERNST.

**reinforcement** (in animal behaviour) Increasing (or decreasing) the frequency of a particular behaviour through \*conditioning, by arranging for some biologically important event (the **reinforcer**) always to follow another event. In instrumental conditioning an **appetitive reinforcer**, or **reward** (e.g. food), given after a response made by the animal, increases that response; an **aversive reinforcer**, or **punishment** (e.g. an electric shock) decreases the response.

**relative aperture** See APERTURE.

**relative atomic mass (atomic weight; r.a.m.)** Symbol  $A_r$ . The ratio of the average mass per atom of the naturally occurring form of an element to 1/12 of the mass of a carbon-12 atom.

**relative density (r.d.)** The ratio of the \*density of a substance to the density of some reference substance. For liquids or solids it is the ratio of the density (usually at 20°C) to the density of water (at its maximum density). This quantity was formerly called **specific gravity**. Sometimes relative densities of gases are used; for example, relative to dry air, both gases being at s.t.p.

**relative humidity** See HUMIDITY.

**relative molecular mass (molecular weight)** Symbol  $M_r$ . The ratio of the average mass per molecule of the naturally occurring form of an element or compound to 1/12 of the mass of a carbon-12 atom. It is equal to the sum of the relative atomic masses of all the atoms that comprise a molecule.

**relative permeability** See PERMEABILITY.

**relative permittivity** See PERMITTIVITY.

**relativistic mass** The mass of a moving body as measured by an observer in the same frame of reference as the body. According to the special theory of \*relativity the mass  $m$  of a body moving at speed  $v$  is given by  $m = m_0/\sqrt{1 - v^2/c^2}$ , where  $m_0$  is its \*rest mass and  $c$  is the speed of light. The relativistic mass therefore only differs significantly from the rest mass if its speed is a substantial fraction of the speed of light. If  $v = c/2$ , for example, the relativistic mass is 15% greater than the rest mass.

**relativistic mechanics** An extension of Newtonian mechanics that takes into account the theory of \*relativity.

**relativistic quantum theory** See QUANTUM THEORY; QUANTUM FIELD THEORY.

**relativistic speed** A speed that is sufficiently large to make the mass of a body significantly greater than its \*rest mass. It is usually expressed as a proportion of the speed of light. See RELATIVITY; RELATIVISTIC MASS.

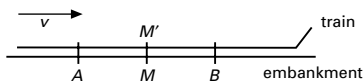

**relativity** Two widely accepted theories proposed by Albert \*Einstein to account for departures from Newtonian mechanics. The special theory, of 1905, refers to non-accelerated frames of reference, while the general theory, of 1915, extends to accelerated systems.

**The special theory.** For Galileo and Newton, all uniformly moving frames of reference (Galilean frames) are equivalent for describing the dynamics of moving bodies. There is no experiment in dynamics that can distinguish between a stationary laboratory and a laboratory that is moving at uniform velocity. Einstein's special theory of relativity takes this notion of equivalent frames one step further: he required all physical phenomena, not only those of dynamics, to be independent of the uniform motion of the laboratory.

When Einstein published his special theory, he realized that it could explain the apparent lack of experimental evidence for an ether, which was supposed to be the medium required for the propagation of electromagnetic waves (see

MICHELSON-MORLEY EXPERIMENT). Einstein recognized that the existence of an ether would render invalid any equivalent relativity principle for electromagnetic phenomena; i.e. uniform movement of the laboratory through the ether would lead to measurable differences in the propagation of electromagnetic waves *in vacuo*. Since no experimental evidence of the ether was forthcoming, Einstein was encouraged to continue his search for a relativity principle that encompassed all physical phenomena. Since light is a physical phenomenon, its propagation *in vacuo* could not be used to distinguish between uniformly moving frames of reference. Therefore in all such frames the measured speed of light *in vacuo* must be the same.

This conclusion has some important consequences for the nature of space and time. In his popular exposition of 1916, Einstein illustrated these consequences with thought experiments. In one such experiment, he invites the reader to imagine a very long train travelling along an embankment with a constant velocity  $v$  in a given direction (see diagram).

Einstein's thought experiment

Observers on the train use it as a rigid reference body, regarding all events with reference to the train. Einstein posed a simple question: Are two events, which are simultaneous relative to the railway embankment, also simultaneous relative to the observer on the train? For example, two lightning strokes strike the embankment at points  $A$  and  $B$  simultaneously with respect to the embankment, so that an observer at  $M$  (the mid-point of the line  $AB$ ) will record no time lapse between them. However, the events  $A$  and  $B$  also correspond to positions  $A$  and  $B$  on the train.  $M'$  is the mid-point of the distance  $AB$  on the moving train. When the flashes occur, from the point of view of the embankment,  $M'$  coincides with  $M$ . However,  $M$  moves with speed  $v$  towards the right and therefore hastens towards the beam of light coming from  $B$ , while moving on ahead of the beam from  $A$ . The observer

at  $M'$  would not agree with the observer at  $M$  on the simultaneity of the events  $A$  and  $B$  because the beam of light from  $B$  will be seen to be emitted before the beam of light at  $A$ .

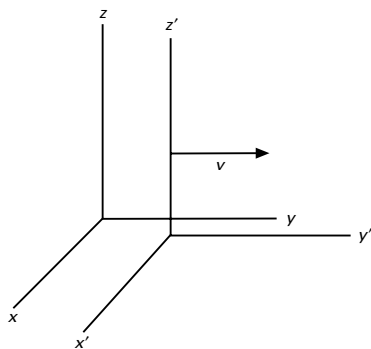

At first sight there may seem to be a problem here. If the observer at  $M'$  is 'hastening towards the beam of light from  $B'$ ', is this not equivalent to saying that the beam of light is travelling towards  $M'$  at a combined speed of  $v + c$ , where  $c$  is the speed of light *in vacuo*?

The resolution of this problem is the basis of special relativity. According to Einstein, the moving observer at  $M'$  must measure the speed of light *in vacuo* to be  $c$ , since there can be no experiment that distinguishes the train's moving frame from any other Galilean frame. It is therefore the concept of time measurement that requires revision; that is, the time required for a particular event to occur with respect to the train cannot have the same duration as the same event when judged from the embankment.

This remarkable result also has implications for the measurement of spatial intervals. The measurement of a spatial interval requires the time coincidence of two points along a measuring rod. The relativity of simultaneity means that one cannot contend that an observer who traverses a distance  $x$  m per second in the train, traverses the same distance  $x$  m also with respect to the embankment in each second. In trying to include the law of propagation of light into a relativity principle, Einstein questioned the way in which measurements of space and time in different Galilean frames are compared. Place and time measurements in two different Galilean frames must be related by a transformation preserving the relativity principle that every ray of light has a velocity of transmission  $c$  relative to observers in both frames.

Transformations that preserve the relativity principle are called \*Lorentz transformations. The form of these looks complicated at first (see diagram). However, they arise from the simple requirement that there can be no experiment in dynamics or electromagnetism that will distinguish between two different Galilean frames of reference.

These transformations suggest that ob-

Lorentz transformations

servers in the two frames will not agree on measurements of length made in the  $y$ -direction. Indeed, the duration of intervals of time cannot be agreed upon in the two frames. This is exactly what was suggested in Einstein's thought experiment on the train. Simple manipulations lead to the following formulae, which relate lengths and time intervals in the  $x', y', z'$  frame to their equivalent quantities in the  $x, y, z$  frame:

$$\Delta l = \Delta l' (1 - v^2/c^2)^{1/2} \text{ and}$$

$$\Delta t = \Delta t' (1 - v^2/c^2)^{-1/2},$$

where  $\Delta l$  and  $\Delta t$  are respectively intervals in space and time. Motion therefore leads to a length contraction of the  $x', y', z'$  lengths with respect to the  $x, y, z$  lengths. Similarly, the equation relating the time intervals in the two frames leads to a time dilation in the  $x', y', z'$  system compared to the  $x, y, z$  system. From these expressions it is clear that the velocity  $c$  plays the part of a limiting velocity, which can neither be reached nor exceeded by any material body.

The velocity  $c$  is often said to be the limiting velocity for the transfer of information in the universe. Faster-than-light signals violate \*causality when taken to their logical conclusions. The universe, therefore, according to the special theory, updates itself at the maximum speed of light  $c$ : any local changes in the properties within a region of space are not communicated to the rest of the universe instantaneously. Rather, the universe is updated

The frame  $(x', y', z')$  is moving uniformly with respect to  $(x, y, z)$  at a velocity  $v$  in the  $y$  direction.

Coordinates in the two frames are related as follows by the Lorentz transformations

$$y' = \frac{y - vt}{\sqrt{1 - \frac{v^2}{c^2}}}$$

$$t' = \frac{t - vy/c^2}{\sqrt{1 - \frac{v^2}{c^2}}}$$

$$x' = x \\ z' = z$$

through a wave of reality, which emanates at speed  $c$  from the region in which the change took place.

**The general theory.** In his special theory, Einstein updated the Galilean principle of relativity by including electromagnetic phenomena. Galileo, and later Newton, were well aware that no experiment in the dynamics of moving bodies could distinguish between frames of reference moving relative to each other at constant velocity (Galilean frames). If two Galilean frames move with respect to each other at uniform velocity, no experiment could determine which frame was in absolute motion and which frame was at absolute rest.

This is the basic principle of Einstein's special theory of relativity. However, Einstein was not content with the apparent absolute status conferred to accelerating frames by the behaviour of bodies within them. Einstein sought a general principle of relativity that would require all frames of reference, whatever their relative state of motion, to be equivalent for the formulation of the general laws of nature. In his popular exposition of 1916, Einstein explains this by describing the experiences of an observer within a railway carriage that is decelerating. In his own words: "At all events it is clear that the Galilean law does not hold with respect to the non-uniformly moving carriage. Because of this, we feel compelled at the present juncture to grant a kind of absolute physical reality to non-uniform motion, in op-

position to the general principle of relativity.”

Once again it was one of Galileo's observations that provided the starting point for the formulation of Einstein's ideas. Galileo observed that bodies moving under the sole influence of a \*gravitational field acquire an acceleration that does not depend upon the material or the physical state of the body. Einstein realized that this property of gravitational fields implied equivalence between gravity and accelerating frames of reference. This equivalence, which became the basis of his general theory of relativity, is well illustrated by one of Einstein's thought experiments. Imagine an elevator, so far removed from stars and other large masses that there is no appreciable gravitational field. An observer inside the elevator is equipped with the appropriate apparatus and uses the elevator as a reference frame. Initially, if the elevator is a Galilean frame, the observer would feel weightless with only inferences from decorations inside the elevator to distinguish between 'up' and 'down'. However, if a rope attached to the top of the elevator were to be pulled with a constant acceleration of  $9.81 \text{ m s}^{-2}$ , the observer would detect this acceleration as a force reaction on the floor of the elevator. The experiences of the observer in the elevator are equivalent to the experiences of an observer in an elevator in the earth's gravitational field of strength  $9.81 \text{ N kg}^{-1}$ . Moreover, the force reaction at the feet of the observer in the accelerating frame is due to the observer's inertial \*mass (the mass that represents the reluctance of the observer's body to accelerate under the influence of a force).

An observer in the earth-bound elevator would feel the same force reaction at the floor of the elevator, but for this observer the force is due to the influence of the earth's gravitational field on the observer's gravitational mass. Guided by this example, Einstein realized that his extension of the principle of relativity to include accelerations implies the equality of inertial and gravitational mass, which had been established experimentally by Roland Eötvös (1848–1919) in 1888.

These considerations have significant implications for the nature of space and

time under the influence of a gravitational field. Another of Einstein's thought experiments illustrates these implications.

Imagine a Galilean frame of reference  $K$  from which an observer  $A$  takes measurements of a non-Galilean frame  $K'$ , which is a rotating disc inhabited by an observer  $B$ .  $A$  notes that  $B$  is in circular motion and experiences a centrifugal acceleration. This acceleration is produced by a force, which may be interpreted as an effect of  $B$ 's inertial mass. However, on the basis of the general principle of relativity,  $B$  may contend that he is actually at rest but under the influence of a radially directed gravitational field.

A comparison of time-measuring devices placed at the centre and edge of the rotating disc would show a remarkable result. For although the devices would both be at rest with respect to  $K'$ , the motion of the disc with respect to  $K$  would lead to a \*time dilation at the edge with respect to measured time at the centre. It follows that the clock at the disc's periphery runs at a permanently slower rate than that at the centre, i.e. as observed from  $K$ . The same effect would be noted by an observer who is sitting next to the clock at the centre of the disc. Thus, on the disc, or indeed in any gravitational field, a timing device will run at different rates depending on where it is situated.

The measurement of spatial intervals on the rotating disc will also incur a similar lack of definition. Standard measuring rods placed tangentially around the circumference  $C$  of the disc will all be contracted in length due to relativistic length contraction with respect to  $K$ . However, measuring rods will not experience shortening in length, as judged from  $K$ , if they are applied across a diameter  $D$ . Dividing the circumference by the diameter would produce a surprising result from  $K$ 's point of view. Normally such a quotient would have the value  $\pi = 3.14159\dots$ , but in this situation the quotient is larger. Euclidean geometry does not seem to hold in an accelerating frame, or indeed by the principle of relativity, within a gravitational field. Spaces in which the propositions of Euclid are not valid are sometimes called curved spaces. For example, the sum of the internal angles of a triangle drawn on a flat sheet of paper will be  $180^\circ$ ; how-

ever, a triangle drawn on the curved surface of a sphere will not follow this Euclidean rule.

Einstein fully expected to see this effect in gravitational fields, such was his belief in the general principle of relativity. In fact, it was the effect gravitational fields have on the propagation of light that was heralded as the major verification of his general relativity. Einstein realized that rays of light would be perceived as curving in an accelerating frame. This led him to conclude that, in general, rays of light are propagated curvilinearly in gravitational fields. By means of photographs taken of stars during the solar eclipse of 29 May 1919, the existence of the deflection of starlight around the sun's mass was confirmed.

The mathematics required to describe the curvature of space in the presence of gravitational fields existed before Einstein had need for it, but it was essentially re-discovered by Einstein to solve his general relativistic problems. In general relativity, material bodies follow lines of shortest distance, called **geodesics**. The line formed by stretching an elastic band over a curved surface would be a geodesic on the curved surface. Light follows geodesics called **null-geodesics**. The motions of material bodies are therefore determined by the curvature of the space in the region through which they pass. However, it is the mass of the bodies that causes the curvature of the space in the first place, which demonstrates the elegant self-consistency of Einstein's general theory.

**relaxation oscillator** See OSCILLATOR.

**relay** An electrical or electronic device in which a variation in the current in one circuit controls the current in a second circuit. These devices are used in an enormous number of different applications in which electrical control is required. The simplest is the electromechanical relay in which the first circuit energizes an electromagnet, which operates a switch in a second circuit. The \*thyatron gas-filled relay found many uses in the past but has now been largely replaced by the \*thyristor solid-state relay.

**releaser** See SIGN STIMULUS.

**releasing hormone (releasing factor)** A

hormone that is produced by the hypothalamus and stimulates the release of a hormone from the anterior \*pituitary gland into the bloodstream. Each hormone has a specific releasing hormone; for example, thyrotrophin-releasing hormone stimulates the release of \*thyroid-stimulating hormone.

**reluctance** Symbol  $R$ . The ratio of the magnetomotive force to the total magnetic flux in a magnetic circuit or component. It is measured in henries.

**reluctivity** The reciprocal of magnetic \*permeability.

**rem** See RADIATION UNITS.

**remanence (retentivity)** The magnetic flux density remaining in a ferromagnetic substance when the saturating field is reduced to zero. See HYSTERESIS.

**remote sensing** The gathering and recording of information concerning the earth's surface by techniques that do not involve actual contact with the object or area under study. These techniques include photography (e.g. aerial photography), multispectral imagery, infrared imagery, and radar. Remote sensing is generally carried out from aircraft and, increasingly, satellites. The techniques are used, for example, in cartography (map making).

**renal** Of or relating to the \*kidney. For example, the **renal artery** and **renal vein** convey blood towards and away from the kidney, respectively.

**renal capsule** See BOWMAN'S CAPSULE.

**renewable energy sources** Sources of energy that do not use up the earth's finite mineral resources. **Nonrenewable energy sources** are \*fossil fuels and fission fuels (see NUCLEAR FISSION). Various renewable energy sources are being used or investigated. See GEOTHERMAL ENERGY; HYDROELECTRIC POWER; NUCLEAR FUSION; SOLAR ENERGY; TIDES; WIND POWER; WAVE POWER.

**renin** A proteolytic enzyme (see PROTEASE) that is involved in the formation of the hormone \*angiotensin, which raises blood pressure. Renin is secreted into the blood by cells of the kidney

glomeruli under the control of the sympathetic nervous system; its release also occurs in response to a fall in blood-sodium levels and to falling blood pressure. Renin catalyses cleavage of circulating  $\alpha_2$ -globulin to produce angiotensin I, precursor of the active hormone.

**rennin (chymosin)** An enzyme secreted by cells lining the stomach in mammals that is responsible for clotting milk. It acts on a soluble milk protein (**caseinogen**), which it converts to the insoluble form \*casein. This ensures that milk remains in the stomach long enough to be acted on by protein-digesting enzymes.

**renormalization** A procedure used in relativistic \*quantum field theory to deal with the fact that in \*perturbation theory calculations give rise to infinities beyond the first term. Renormalization was first used in \*quantum electrodynamics, where the infinities were removed by taking the observed mass and charge of the electron as 'renormalized' parameters rather than the 'bare' mass and charge.

Theories for which finite results for all perturbation-theory calculations exist, by taking a finite number of parameters from experiment and using renormalization, are called **renormalizable**. Only certain types of quantum field theories are renormalizable. Theories that need an infinite number of parameters are said to be **nonrenormalizable** and are regarded as incomplete physical theories. The \*gauge theories that describe the strong, weak, and electromagnetic interactions are renormalizable. The quantum theory of gravitational interactions is a nonrenormalizable theory, indicating that gravity needs to be unified with other fundamental interactions before one can have a consistent quantum theory of gravity.

**renormalization group** A technique used to understand systems in which many length-scales are involved. Such systems include phase transitions, turbulence, polymers, many-electron systems, and the localization of electrons in disordered systems. The renormalization group has its origin in \*quantum field theory, in which it is used to calculate how \*coupling constants change with energy. The way in which this change with energy

takes place involves a \*group and the procedure of \*renormalization.

**repetitive DNA** DNA whose base sequence is repeated many times throughout the genome of an organism. It is common in eukaryotes, accounting for about half of the total DNA in mammals, for example, and can be divided into various types. Some serves a useful purpose, but a significant proportion is of uncertain function, and may be 'junk', or \*selfish DNA. One important type consists of multiple copies of particular genes or gene sequences, which may be duplicates of genes encoding histones or ribosomal RNAs. **Satellite DNA** - repeats of short DNA sequences (typically less than 10 bp) flanking the centromeres of each chromosome and stretching for hundreds of kilobases along either arm of the chromosome - and telomeric DNA (see **TELOMERE**) are important for maintaining chromosome structure. Other distinct types of repetitive DNA dispersed throughout the genome, both in noncoding introns within genes and between genes, include **minisatellite DNA** (variable number tandem repeats) - sequences of 15-100 bp repeated hundreds or thousands of times - and **microsatellite DNA**, repeats of shorter sequences (2-10 bp). Both these types are of value as \*molecular markers in DNA fingerprinting.

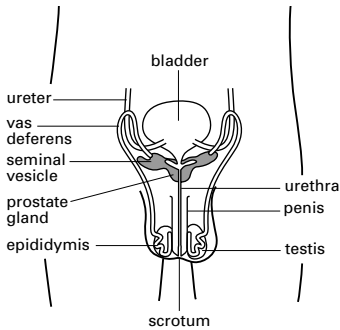

**replacing bone** See **CARTILAGE BONE**.

**replicon** A DNA sequence that is replicated as a unit from a single initiation site (origin of replication). The genome of a bacterium or a virus comprises a single replicon; eukaryotes contain a number of replicons on each chromosome.

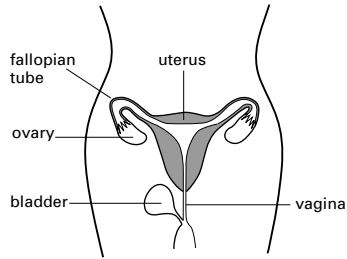

**repolarization** The restoration of the \*resting potential in neurons or muscle fibres following the passage of a nerve impulse. Repolarization is brought about by diffusion of potassium ions out of the neuron and by active elimination of sodium ions (see **SODIUM PUMP**).

**repressor** A protein that can prevent the expression of a gene. See **OPERON**.

**reproduction** The production of new individuals more or less similar in form to the parent organisms. This may be achieved by a number of means (see **SEX-**

Human male reproductive system

Human female reproductive system

UAL REPRODUCTION; ASEXUAL REPRODUCTION) and serves to perpetuate or increase a species.

**reproductive system** The organs that are involved in the process of \*sexual reproduction in an organism. The reproductive system of a flowering plant is found in the \*flower and consists of the stamens (male organs) and carpels (female organs). In mammals the reproductive system consists of the testes, epididymis, sperm duct, and penis in the male and the ovaries, fallopian tubes, and uterus in the female.

**Reptilia** The class that contains the first entirely terrestrial vertebrates, which can live in dry terrestrial habitats as their skin is covered by a layer of horny scales, preventing water loss. They breathe atmospheric oxygen by means of lungs assisted by respiratory movements principally involving the ribs (there is no diaphragm). Reptiles are cold-blooded (see POIKILO- THERMY) but behavioural patterns make it possible for them to maintain a fairly even body temperature throughout the day. Fertilization is internal and the majority of reptiles lay eggs on land. These eggs have a porous shell to provide protection from desiccation and allow gas exchange. In some reptiles the eggs are retained within the body of the mother until the young are ready to hatch, thereby greatly reducing juvenile mortality (see OVOVIVIPARITY).

The class includes the modern crocodiles, lizards and snakes (see SQUAMATA), and tortoises and turtles, as well as many

extinct forms, such as the \*dinosaurs and \*Pterosauria.

**residual volume** The amount of air remaining in the lungs after maximum expiration, which cannot be expelled from the lungs voluntarily. An average human has a residual volume of about 1 litre. See also VITAL CAPACITY.

**resin** A synthetic or naturally occurring \*polymer. Synthetic resins are used in making \*plastics. Natural resins are acidic chemicals secreted by many trees (especially conifers) into ducts or canals. They are found either as brittle glassy substances or dissolved in essential oils. Their functions are probably similar to those of gums and mucilages, i.e. protective.

**resistance** **1.** (in physics) Symbol *R*. The ratio of the potential difference across an electrical component to the current passing through it. It is thus a measure of the component's opposition to the flow of electric charge. In general, the resistance of a metallic conductor increases with temperature, whereas the resistance of a \*semiconductor decreases with temperature. **2.** (in microbiology) The degree to which pathogenic microorganisms remain unaffected by antibiotics and other drugs. Genes for antibiotic resistance are often carried on \*plasmids or \*transposons, which can spread across species barriers. **3.** (in ecology) **a.** The degree to which a \*pest can withstand the effects of a pesticide. It depends on the selection and spread within a pest population of genes that confer the ability to destroy, or

minimize the effects of, a pesticide. **b.** See ENVIRONMENTAL RESISTANCE. **4.** (in immunology) The degree of \*immunity to infection that an animal possesses.

**resistance thermometer (resistance pyrometer)** A \*thermometer that relies on the increase of electrical resistance of a metal wire with rising temperature, according to the approximate relationship

$$R = R_0(1 + aT + bT^2),$$

where  $R$  is the resistance of the wire at temperature  $T$  and  $R_0$  is the resistance of the wire at a reference temperature, usually  $0^\circ\text{C}$ ;  $a$  and  $b$  are constants characteristic of the metal of the wire. The metal most frequently used is platinum and the platinum resistance coil is usually incorporated into one arm of a \*Wheatstone bridge. The effect of the temperature change on the leads carrying current to the platinum coil is compensated by including a pair of dummy leads within the casing carrying the coil. See also THERMISTOR.

**resistivity** Symbol  $\rho$ . A measure of a material's ability to oppose the flow of an electric current. It is given by  $RA/l$ , where  $R$  is the resistance of a uniform specimen of the material, having a length  $l$  and a cross-sectional area  $A$ . It is usually given at  $0^\circ\text{C}$  or  $20^\circ\text{C}$  and is measured in ohm metres. It was formerly known as **specific resistance**.

**resistor** A component in an electrical or electronic circuit that is present because of its electrical resistance. For electronic purposes many resistors are either wire-wound or consist of carbon particles in a ceramic binder. The ceramic coating carries a number or colour code indicating the value of the resistance. Some resistors can be varied manually by means of a sliding contact; others are markedly dependent on temperature or illumination.

**resolution 1.** (in chemistry) The process of separating a racemic mixture into its optically active constituents. In some cases the crystals of the two forms have a different appearance, and the separation can be done by hand. In general, however, physical methods (distillation, crystallization, etc.) cannot be used because the optical isomers have identical physical

properties. The most common technique is to react the mixture with a compound that is itself optically active, and then separate the two. For instance, a racemic mixture of (-)-A and (+)-A reacted with (-)-B, gives two compounds AB that are not optical isomers but diastereoisomers and can be separated and reconverted into the pure (-)-A and (+)-A. Biological techniques using bacteria that convert one form but not the other can also be used. **2.** (in mathematics) The separation of a vector quantity into two components, which are usually at right angles to each other. Thus, a force  $F$  acting on a body in a vertical plane at an angle  $\theta$  to the horizontal can be resolved into a horizontal component  $F\cos\theta$  and a vertical component  $F\sin\theta$ , both in the same plane as the original force. **3.** (in optics) See RESOLVING POWER.

**resolving power** A measure of the ability of an optical instrument to form separable images of close objects or to separate close wavelengths of radiation. The **chromatic resolving power** for any spectroscopic instrument is equal to  $\lambda/\delta\lambda$ , where  $\delta\lambda$  is the difference in wavelength of two equally strong spectral lines that can barely be separated by the instrument and  $\lambda$  is the average wavelength of these two lines. For a telescope forming images of stars the **angular resolving power** is the smallest angular separation of the images; the **linear resolving power** is the linear separation of the images in the focal plane. In a telescope forming images of two stars, as a result of diffraction by the lens aperture each image consists of a bright central blob surrounded by light and dark rings. According to the **Rayleigh criterion** for resolution, the central ring of one image should fall on the first dark ring of the other. The angular resolving power in radians is then  $1.22\lambda/d$ , where  $d$  is the diameter of the objective lens in centimetres and  $\lambda$  is the wavelength of the light (usually taken as 560 nanometres). For microscopes, the resolving power is usually taken as the minimum distance between two points that can be separated. In both cases, the smaller the resolving power, the better the resolution; to avoid this apparent paradox the resolv-

ing power is now sometimes taken as the reciprocals of the quantities stated above.

**resonance 1.** (in physics) An oscillation of a system at its natural frequency of vibration, as determined by the physical parameters of the system. It has the characteristic that large amplitude vibrations will ultimately result from low-power driving of the system. Resonance can occur in atoms and molecules, mechanical systems, and electrical circuits (see RESONANT CIRCUIT; RESONANT CAVITY).

**2.** (in particle physics) A very short-lived \*elementary particle that can be regarded as an excited state of a more stable particle. Resonances decay by the strong interaction (see FUNDAMENTAL INTERACTIONS) in  $10^{-24}$  second. **3.** (in chemistry) The representation of the structure of a molecule by two or more conventional formulae.

For example, the formula of methanal can be represented by a covalent structure  $\text{H}_2\text{C}=\text{O}$ , in which there is a double bond in the carbonyl group. It is known that in such compounds the oxygen has some negative charge and the carbon some positive charge. The true bonding in the molecule is somewhere between  $\text{H}_2\text{C}=\text{O}$  and the ionic compound  $\text{H}_2\text{C}^+\text{O}^-$ . It is said to be a **resonance hybrid** of the two, indicated by

The two possible structures are called **canonical forms**, and they need not contribute equally to the actual form. The double-headed arrow does not imply that the two forms are in equilibrium.

**resonant cavity (cavity resonator)** A closed space within a conductor in which an electromagnetic field can be made to oscillate at frequencies above those at which a \*resonant circuit will operate. The resonant frequency of the oscillation will depend on the dimensions and the shape of the cavity. The device is used to produce microwaves (see KLYSTRON; MAGNETRON).

**resonant circuit** A reactive circuit (see REACTANCE) so arranged that it is capable of \*resonance. In a **series resonant circuit** a resistor, inductor, and capacitor are arranged in series. Resonance occurs when the \*impedance ( $Z$ ) is a minimum and the

current amplitude therefore a maximum. In a **parallel resonant circuit** the inductance and capacitance are in parallel and resonance (with minimal current amplitude) occurs at maximum impedance. The frequency at which resonance occurs is called the **resonant frequency**. In a series resonant circuit

$$Z = R + i[\omega L - 1/\omega C],$$

where  $\omega = 2\pi f$  and  $f$  is the frequency,  $R$  is the resistance,  $L$  is the inductance, and  $C$  is the capacitance. At resonance,  $Z$  is a minimum and  $\omega L = 1/\omega C$ , i.e. the circuit behaves as if it is purely resistive. In the parallel circuit, resonance occurs when  $R^2 + \omega^2 L^2 = 1/C$ , which in most cases also approximates to  $\omega L = 1/\omega C$ . Resonant circuits are widely used in \*radio to select one signal frequency in preference to others.

**respiration** The metabolic process in animals and plants in which organic substances are broken down to simpler products with the release of energy, which is incorporated into special energy-carrying molecules (see ATP) and subsequently used for other metabolic processes. In most plants and animals respiration requires oxygen, and carbon dioxide is an end product. The exchange of oxygen and carbon dioxide between the body tissues and the environment is called **external respiration** (see VENTILATION). In many animals the exchange of gases takes place at \*respiratory organs (e.g. \*lungs in air-breathing vertebrates) and is assisted by \*respiratory movements (e.g. breathing). In plants oxygen enters through pores on the plant surface and diffuses through the tissues via intercellular spaces or dissolved in tissue fluids.

Respiration at the cellular level is known as **internal (or tissue) respiration** and can be divided into two stages. In the first, \*glycolysis, glucose is broken down to pyruvate. This does not require oxygen and is a form of \*anaerobic respiration. In the second stage, the \*Krebs cycle, pyruvate is broken down by a cyclic series of reactions to carbon dioxide and water. This is the main energy-yielding stage and requires oxygen. The processes of glycolysis and the Krebs cycle are common to all plants and animals that respire aerobically (see AEROBIC RESPIRATION).

**respiratory chain** See ELECTRON TRANSPORT CHAIN.

**respiratory movement** The muscular movement that enables the passage of air to and from the lungs or other \*respiratory organs of an animal. The mechanism of the movement varies with the species. In insects abdominal muscles relax and contract rhythmically to encourage the flow of air through the \*tracheae. In amphibians air is drawn into the lungs by a pumping action of the muscles in the floor of the mouth. **Breathing** in mammals involves the muscle of the \*diaphragm and the \*intercostal muscles between the ribs. Contraction of these muscles lowers the diaphragm and raises the ribs, so that the lungs expand and air is drawn in (see INSPIRATION). Relaxation has the opposite effect and forces air out during \*expiration.

**respiratory organ** Any animal organ across which exchange of carbon dioxide and oxygen takes place. The surface membranes of such organs are always moist, thin, and well supplied with blood. Examples are the \*lungs of air-breathing vertebrates, the \*gills of fish, and the \*tracheae of insects.

**respiratory pigment** A coloured compound that is capable of reversibly binding with oxygen at high oxygen concentrations and releasing it at low oxygen concentrations. Such pigments are present in the blood, transporting oxygen within the circulatory system from the \*respiratory organs to the tissues of the body. In vertebrates the respiratory pigment is \*haemoglobin, contained in the erythrocytes (red blood cells). See also HAEMOCYANIN.

**respiratory quotient (RQ)** The ratio of the volume of carbon dioxide produced by an organism during respiration to the volume of oxygen consumed. The RQ is usually about 0.8.

**respirometer** Any device that measures an organism's oxygen uptake. Simple respirometers consist of a chamber (in which the organism is placed) connected to a \*manometer. Carbon dioxide is chemically removed from the chamber so that only oxygen uptake is measured.

Human oxygen consumption is generally measured by a device known as a **spirometer**, which can also be used to measure depth and frequency of breathing.

**response** The physiological, muscular, or behavioural activity that can be elicited by a \*stimulus.

**rest energy** The \*rest mass of a body expressed in energy terms according to the relationship  $E_0 = m_0c^2$ , where  $m_0$  is the rest mass of the body and  $c$  is the speed of light.

**resting potential** The difference in electrical potential that exists across the membrane of a nerve cell that is not in the process of transmitting a nerve impulse. The resting potential is maintained by means of the \*sodium pump. Compare ACTION POTENTIAL.

**restitution coefficient** Symbol  $e$ . A measure of the elasticity of colliding bodies. For two spheres moving in the same straight line,

$$e = (v_2 - v_1)/(u_1 - u_2),$$

where  $u_1$  and  $u_2$  are the velocities of bodies 1 and 2 before collision ( $u_1 > u_2$ ) and  $v_1$  and  $v_2$  are the velocities of 1 and 2 after impact ( $v_2 > v_1$ ). If the collision is perfectly elastic  $e = 1$  and the kinetic energy is conserved; for an inelastic collision  $e < 1$ .

**rest mass** The mass of a body at rest when measured by an observer who is at rest in the same frame of reference. Compare RELATIVISTIC MASS.

**restriction enzyme (restriction endonuclease)** A type of enzyme that can cleave molecules of foreign DNA at a particular site. Restriction enzymes are produced by many bacteria and protect the cell by cleaving (and therefore destroying) the DNA of invading viruses. The bacterial cell is protected from attack by its own restriction enzymes by modifying the bases of its DNA during replication. Restriction enzymes are widely used in the techniques of genetic engineering (see DNA FINGER-PRINTING; DNA LIBRARY; DNA SEQUENCING; GENE CLONING; RESTRICTION MAPPING).

**restriction fragment length polymorphism (RFLP)** The occurrence of different cleavage sites for \*restriction

enzymes in the DNA of different individuals of the same species. Cleavage of DNA from different individuals with restriction enzymes thus produces differing sets of restriction fragments. The deletion of existing restriction sites or the creation of new ones is the result of random base changes in the noncoding stretches of DNA (\*introns) between genes. RFLPs have provided geneticists with a powerful set of genetic markers for mapping the genome (see RESTRICTION MAPPING) and for identifying particular genes (see GENE TRACKING).

**restriction mapping** A technique for determining the sites at which a length of DNA (e.g. from a chromosome) is cleaved by \*restriction enzymes. By cleaving the DNA with various such enzymes, both individually and in combination, and analysing the resultant number and size of fragments by electrophoresis, a **restriction map**, indicating the order of restriction sites in the original DNA, can be deduced (see also LINKAGE MAP). Restriction mapping is routinely applied to organisms undergoing genetic investigation. Gene deletions or rearrangements that alter the restriction sites can be detected as changes in the pattern of fragments obtained. This may be used, for instance, to diagnose certain genetic abnormalities in the fetus. The fragments are separated by gel electrophoresis and identified using specific \*gene probes, as in the \*Southern blotting technique. The absence of a certain fragment in a fetal DNA digest can be diagnostic of a pathological change in the fetal gene containing the corresponding restriction site.

**resultant** A \*vector quantity that has the same effect as two or more other vector quantities of the same kind. See PARALLELOGRAM OF VECTORS.

**retardation (deceleration)** The rate of reduction of speed, velocity, or rate of change.

**retardation plate** A transparent plate of a birefringent material, such as quartz, cut parallel to the optic axis. Light falling on the plate at 90° to the optic axis is split into an ordinary ray and an extraordinary ray (see DOUBLE REFRACTION), which travel through the plate at different speeds. By

cutting the plate to different thicknesses a specific phase difference can be introduced between the transmitted rays. In the **half-wave plate** a phase difference of  $\pi$  radians, equivalent to a path difference of half a wavelength, is introduced. In the **quarter-wave plate** the waves are out of step by one quarter of a wavelength.

**reticular formation** See BRAINSTEM.

**reticulum** The first of four chambers that form the stomach of ruminants. See RUMINANTIA.

**retina** The light-sensitive membrane that lines the interior of the eye. The retina consists of two layers. The inner layer contains nerve cells, blood vessels, and two types of light-sensitive cells (\*rods and \*cones). The outer layer is pigmented, which prevents the back reflection of light and consequent decrease in visual acuity. Light passing through the lens stimulates individual rods and cones, which generates nerve impulses that are transmitted through the optic nerve to the brain, where the visual image is formed.

**retinal** See RHODOPSIN; VITAMIN A.

**retinol** See VITAMIN A.

**retort** **1.** A laboratory apparatus consisting of a glass bulb with a long neck. **2.** A vessel used for reaction or distillation in industrial chemical processes.

**retrograde motion** **1.** The apparent motion of a planet from east to west as seen from the earth against the background of the stars. **2.** The clockwise rotation of a planet, as seen from its north pole. Compare DIRECT MOTION.

**retorocket** A small rocket motor that produces thrust in the opposite direction to a \*rocket's main motor or motors in order to decelerate it.

**retrotransposon** A type of \*transposon found in the DNA of various organisms, including yeast, *Drosophila*, and mammals, that forms copies of itself using a mechanism similar to that of retroviruses. It undergoes transcription to RNA, then creates a DNA copy of the transcript with the aid of the enzyme \*reverse transcriptase.

This DNA copy can then reintegrate into the cell's genome.

**retrovirus** An RNA-containing virus that converts its RNA into DNA by means of the enzyme \*reverse transcriptase; this enables it to become integrated into its host's DNA. Some retroviruses can cause cancer in animals: they contain \*oncogenes, which are activated when the virus enters its host cell and starts to replicate. Retroviruses are useful as \*vectors for inserting genetic material into eukaryotic cells. The best-known retrovirus is \*HIV, responsible for AIDS in humans. *See also* PROVIRUS.

**reverberation time** The time taken for the energy density of a sound to fall to the threshold of audibility from a value  $10^6$  times as great; i.e. a fall of 60 decibels. It is an important characteristic of an auditorium. The optimum value is proportional to the linear dimensions of the auditorium.

**reverberatory furnace** A metallurgical furnace in which the charge to be heated is kept separate from the fuel. It consists of a shallow hearth on which the charge is heated by flames that pass over it and by radiation reflected onto it from a low roof.

**reverse genetics** Any approach to genetic investigation that aims to find the function for some known protein or gene. It contrasts with the more traditional \*forward genetics approach. For example, analysis of gene sequences reveals open reading frames, which are the hallmarks of functional genes (*see* READING FRAME). Reverse genetics methods can be used to discover the function of such genes, which can be cloned, subjected to mutation, and then reinserted into the organism (e.g. a bacterium or yeast cell) to see what effect the mutations have on function. A similar approach can be taken starting with a protein of unknown function. The amino-acid sequence can be back-translated into genetic code, a DNA probe constructed for part of the DNA sequence, and the relevant gene selected from a \*DNA library of the organism.

**reverse osmosis** A method of obtaining pure water from water containing a

salt, as in \*desalination. Pure water and the salt water are separated by a semipermeable membrane and the pressure of the salt water is raised above the osmotic pressure, causing water from the brine to pass through the membrane into the pure water. This process requires a pressure of some 25 atmospheres, which makes it difficult to apply on a large scale.

**reverse transcriptase** An enzyme, occurring in \*retroviruses, that catalyses the formation of double-stranded DNA using the single RNA strand of the viral genome as template. This enables the viral genome to be inserted into the host's DNA and replicated by the host. Reverse transcriptase is thus an RNA-directed DNA \*polymerase. The enzyme is used in genetic engineering for producing \*complementary DNA from messenger RNA.

**reversible process** Any process in which the variables that define the state of the system can be made to change in such a way that they pass through the same values in the reverse order when the process is reversed. It is also a condition of a reversible process that any exchanges of energy, work, or matter with the surroundings should be reversed in direction and order when the process is reversed. Any process that does not comply with these conditions when it is reversed is said to be an **irreversible process**. All natural processes are irreversible, although some processes can be made to approach closely to a reversible process.

**Reynolds number** Symbol  $Re$ . A dimensionless number used in fluid dynamics to determine the type of flow of a fluid through a pipe, to design prototypes from small-scale models, etc. It is the ratio  $v\rho l/\eta$ , where  $v$  is the flow velocity,  $\rho$  is the fluid density,  $l$  is a characteristic linear dimension, such as the diameter of a pipe, and  $\eta$  is the fluid viscosity. In a smooth straight uniform pipe, laminar flow usually occurs if  $Re < 2000$  and turbulent flow is established if  $Re > 3000$ . It is named after Osborne Reynolds (1842–1912).

**RFLP** *See* RESTRICTION FRAGMENT LENGTH POLYMORPHISM.

**$R_F$  value** (in chromatography) The distance travelled by a given component di-

vided by the distance travelled by the solvent front. For a given system at a known temperature, it is a characteristic of the component and can be used to identify components.

**Rh** See RHESUS FACTOR.

**rhachis** See RACHIS.

**rhe** A unit of fluidity equal to the reciprocal of the \*poise.

**rhodium** Symbol Re. A silvery-white metallic \*transition element; a.n. 75; r.a.m. 186.2; r.d. 20.53; m.p. 3180°C; b.p. 5627 (estimated)°C. The element is obtained as a by-product in refining molybdenum, and is used in certain alloys (e.g. rhodium-molybdenum alloys are superconducting). It forms a number of complexes with oxidation states in the range 1-7. It was discovered by Walter Noddack (1893-1960) and Ida Tacke in 1925.

**rheology** The study of the deformation and flow of matter.

**rheopexy** The process by which certain thixotropic substances set more rapidly when they are stirred, shaken, or tapped. Gypsum in water is such a **rheoplectic substance**.

**rheostat** A variable \*resistor, the value of which can be changed without interrupting the current flow. In the common wire-wound rheostat, a sliding contact moves along the length of the coil of wire.

**rhesus factor (Rh factor)** An \*antigen whose presence or absence on the surface of red blood cells forms the basis of the rhesus \*blood group system. (The factor was first recognized in rhesus monkeys.) Most people possess the Rh factor, i.e. they are rhesus positive (Rh+). People who lack the factor are Rh-. If Rh+ blood is given to an Rh- patient, the latter develops anti-Rh antibodies. Subsequent transfusion of Rh+ blood results in \*agglutination, with serious consequences. Similarly, an Rh- pregnant woman carrying an Rh+ fetus may develop anti-Rh antibodies in her blood; these will react with the blood of a subsequent Rh+ fetus, causing anaemia in the newborn baby.

**rhizoid** One of a group of delicate and often colourless hairlike outgrowths

found in certain algae and the gametophyte generation of bryophytes and ferns. They anchor the plant to the substrate and absorb water and mineral salts.

**rhizome** A horizontal underground stem. It enables the plant to survive from one growing season to the next and in some species it also serves to propagate the plant vegetatively. It may be thin and wiry, as in couch grass, or fleshy and swollen, as in *Iris*. Compact upright underground stems, as in rhubarb, strawberry, and primrose, are often called **rootstocks**.

**rhodium** Symbol Rh. A silvery-white metallic \*transition element; a.n. 45; r.a.m. 102.9; r.d. 12.4; m.p. 1966°C; b.p. 3727°C. It occurs with platinum and is used in certain platinum alloys (e.g. for thermocouples) and in plating jewellery and optical reflectors. Chemically, it is not attacked by acids (dissolves only slowly in aqua regia) and reacts with nonmetals (e.g. oxygen and chlorine) at red heat. Its main oxidation state is +3 although it also forms complexes in the +4 state. The element was discovered in 1803 by William Wollaston (1766-1828).

**Rhodophyta (red algae)** A phylum of \*algae that are often pink or red in colour due to the presence of the pigments phycoyanin and phycoerythrin. Members of the Rhodophyta may be unicellular or multicellular; the latter form branched flattened thalli or filaments. They are commonly found along the coasts of tropical areas.

**rhodopsin (visual purple)** The light-sensitive pigment found in the \*rods of the vertebrate retina. It consists of a protein component, **opsin**, linked to a non-protein part, **retinal** (a derivative of \*vitamin A). Light falling on the rod is absorbed by the retinal, which changes its form and separates from the opsin component; this initiates the transmission of a nerve impulse to the brain. The great sensitivity of rhodopsin allows vision in dim light (night vision).

**rhombencephalon** See HINDBRAIN.

**rhombus** A parallelogram in which all the sides are of equal length.

**rhumb line (loxodrome)** (in navigation) A line of constant compass direction that cuts across all lines of longitude at the same angle. The rhumb line is not the shortest distance between two points unless the two points are on the same meridian or on the equator. On the Mercator map projection a rhumb line is represented by a straight line.

**rhyolite** An igneous rock, the volcanic equivalent of granite. It is usually glassy or cryptocrystalline and consists of quartz, feldspars, and mica or amphibole. It may contain larger crystals (phenocrysts) set in a much finer-grained matrix.

**rhytidome** See BARK.

**rib** One of a series of slender curved bones that form a cage to enclose, support, and protect the heart and lungs (see THORAX). Ribs occur in pairs, articulating with the \*thoracic vertebrae of the spinal column at the back and (in reptiles, birds, and mammals) with the \*sternum (breastbone) in front. Movements of the rib cage, controlled by **intercostal muscles** between the ribs, are important in breathing (see RESPIRATORY MOVEMENT).

**riboflavin** See VITAMIN B COMPLEX.

**ribonuclease** See RNASE.

**ribonucleic acid** See RNA.

**ribonucleoprotein (RNP)** Any complex of protein and RNA that forms during the synthesis of RNA in eukaryotes; the protein is involved in the packaging and condensation of the RNA. Certain RNPs are restricted to the nucleus whereas others are found in both the nucleus and the cytoplasm. The most common RNP occurring in the nucleus is **heterogeneous nuclear RNP (hnRNP)**, which consists of protein bound to the primary transcript of DNA (see TRANSCRIPTION). It may be associated with **small nuclear RNP (snRNP)**, which is involved in the removal of intron sequences from the primary transcript to form messenger RNA, which eventually leaves the nucleus (see GENE SPLICING).

**ribose** A \*monosaccharide,  $C_5H_{10}O_5$ , rarely occurring free in nature but important as a component of \*RNA (ribonucleic acid). Its derivative **deoxyribose**,  $C_5H_{10}O_4$ , is equally important as a constituent of

\*DNA (deoxyribonucleic acid), which carries the genetic code in chromosomes.

**ribosomal RNA** See RIBOSOME; RNA.

**ribosome** A small spherical body within a living cell that is the site of \*protein synthesis. Ribosomes consist of two subunits, one large and one small, each of which comprises a type of RNA (called **ribosomal RNA**) and protein. Usually there are many ribosomes in a cell, either attached to the \*endoplasmic reticulum or free in the cytoplasm. During protein synthesis they are associated with messenger RNA as \*polyribosomes in the process of \*translation.

**ribozyme (catalytic RNA)** Any RNA molecule that can catalyse changes to its own molecular structure. Self-splicing introns (see GENE SPLICING) are examples of ribozymes.

**ribulose** A ketopentose sugar (see MONOSACCHARIDE),  $C_5H_{11}O_5$ , that is involved in carbon dioxide fixation in photosynthesis as a component of \*ribulose biphosphate.

**ribulose biphosphate (RuBP)** A five-carbon sugar that is combined with carbon dioxide to form two three-carbon intermediates in the first stage of the light-independent reactions of \*photosynthesis (see CALVIN CYCLE). The enzyme that mediates the carboxylation of ribulose biphosphate is **ribulose biphosphate carboxylase/oxygenase (rubisco)**.

**Richardson equation (Richardson-Dushman equation)** See THERMIONIC EMISSION.

**Richter scale** A logarithmic scale devised in 1935 by Charles Richter (1900–85) to compare the magnitude of earthquakes. The scale ranges from 0 to 10 and the Richter scale value is related to the logarithm of the amplitude of the ground motion divided by the period of the dominant wave, subject to certain corrections. On this scale a value of 2 can just be felt as a tremor and damage to buildings occurs for values in excess of 6. The largest shock recorded had a magnitude of 9.5.

**rickets** A childhood condition caused by decalcification of bone, resulting in deformed bones. Rickets is associated with

chronic deficiency of \*vitamin D or calcium and with disorders that cause poor phosphate reabsorption from the kidney \*nephrons.

**rickettsia** A very small spherical or rod-shaped Gram-negative bacterium belonging to the phylum Proteobacteria. Most rickettsias are obligate parasites, being unable to reproduce outside the cells of their hosts. Rickettsias can infect such arthropods as ticks, fleas, lice, and mites, through which they can be transmitted to vertebrates, including humans. The group includes the causal agents of trench fever, Rocky Mountain spotted fever, and forms of typhus.

**rift valley** A steep-sided depression that occurs in regions in which there is \*plate tectonic activity. Upwelling of magma causes a part of a plate to dome up and stretch. Subsequently a pair of long normal faults form, and the valley collapses between them; it is in effect a large \*graben. The valleys may be extremely large, e.g. the East African Rift Valley extends for more than 4000 km, with cliff-like edges 2–3 km tall.

**right ascension** A coordinate for locating an object on the \*celestial sphere, equivalent to longitude in the earth's latitude and longitude system; the other coordinate is the declination. The 360° around the celestial equator are divided into 24 hours (1 hour = 15°); the ecliptic crosses the equator at 0 hours.

**rigidity modulus** See ELASTIC MODULUS.

**ring** A closed chain of atoms in a molecule. In compounds, such as naphthalene, in which two rings share a common side, the rings are **fused rings**. **Ring closures** are chemical reactions in which one part of a chain reacts with another to form a ring, as in the formation of \*lactams and \*lactones.

**Ringer's solution** See PHYSIOLOGICAL SALINE.

**R-isomer** See ABSOLUTE CONFIGURATION.

**ritualization** An evolutionary process in which the form or context of an action is altered because it comes to play a role in social communication. For example, many \*courtship and greeting ceremonies

in animals include ritual food presentation (though the quantities of food may be negligible), derived from the action of feeding the young.

**RME** See BIOFUEL.

**RMS value** See ROOT-MEAN-SQUARE VALUE.

**RNA (ribonucleic acid)** A complex organic compound (a nucleic acid) in living cells that is concerned with \*protein synthesis. In some viruses, RNA is also the hereditary material. Most RNA is synthesized in the nucleus and then distributed to various parts of the cytoplasm. An RNA molecule consists of a long chain of \*nucleotides in which the sugar is \*ribose and the bases are adenine, cytosine, guanine, and uracil (see illustration; *compare* DNA). **Messenger RNA (mRNA)** is responsible for carrying the \*genetic code transcribed from DNA to specialized sites within the cell (known as \*ribosomes), where the information is translated into protein composition (see TRANSCRIPTION; TRANSLATION). **Ribosomal RNA (rRNA)** is present in ribosomes; it is single-stranded but helical regions are formed by \*base pairing within the strand. **Transfer RNA (tRNA, soluble RNA, sRNA)** is involved in the assembly of amino acids in a protein chain being synthesized at a ribosome. Each tRNA is specific for an amino acid and bears a triplet of bases complementary with a triplet on mRNA (see CODON). See also ANTISENSE RNA; RIBONUCLEOPROTEIN.

**RNAase** See RNASE.

**RNA polymerase** See POLYMERASE.

**RNase (ribonuclease; RNAase)** Any enzyme that catalyses the cleavage of nucleotides in RNA. Each RNase has a specificity for a different cleavage site. For example, RNase A is a digestive enzyme secreted by the pancreas that hydrolyses phosphodiester bonds in the nucleotide chain. Other RNases are active at the cellular level, for instance in modifying transfer RNA and ribosomal RNA after transcription.

**roasting** The heating of a finely ground ore, especially a sulphide, in air prior to \*smelting. The roasting process expels

**rocking-chair cell** See INTERCALATION CELL.

**rock salt** See HALITE.

**rod** A type of light-sensitive receptor cell present in the retinas of vertebrates. Rods contain the pigment \*rhodopsin and are essential for vision in dim light. They are not evenly distributed on the retina, being absent in the \*fovea and occupying all of the retinal margin. Compare CONE.

**Rodentia** An order of mammals characterized by a single pair of long curved incisors in each jaw. These teeth are specialized for gnawing; they continue growing throughout life and have enamel only on the front so that they wear to a chisel-shaped cutting edge. Rodents often breed throughout the year and produce large numbers of quickly maturing young. The order includes the squirrels, beavers, rats, mice, and porcupines.

**roentgen** The former unit of dose equivalent (see RADIATION UNITS). It is named after W. K. Roentgen.

**Roentgen, William Konrad** (1845–1923) German physicist, who made many contributions to physics, the best known being his discovery of X-rays in 1895. For this work he was awarded the first Nobel Prize for physics in 1901.

**roentgenium** Symbol Rg. A radioactive transactinide; a.n. 111. It was made by fusion of  $^{209}\text{Bi}$  with  $^{64}\text{Ni}$ . Only a few atoms have been detected.

**rolling friction** \*Friction between a rolling wheel and the plane surface on which it is rotating. As a result of any small distortions of the two surfaces, there is a frictional force with a component,  $F_1$ , that opposes the motion. If  $N$  is the normal force,  $F_r = N\mu_r$ , where  $\mu_r$  is called the **coefficient of rolling friction**.

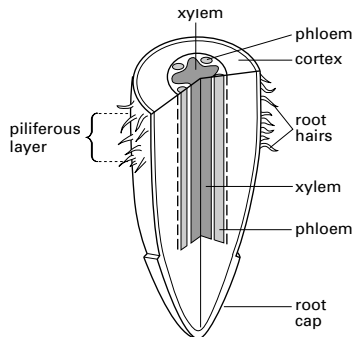

**ROM** Read-only memory. A form of computer memory, fabricated from \*integrated circuits, whose contents are permanently recorded at the time of manufacture. It is thus used to store data that never require modification. (The contents of **programmable ROM** (or **PROM**) are recorded in a separate process after manufacture.) Like \*RAM it consists of an

array of 'cells' to which there is direct and extremely rapid access.

**root 1.** (in botany) The part of a vascular plant that grows beneath the soil surface in response to gravity and water. It anchors the plant in the soil and absorbs water and mineral salts. Unlike the stem, it never produces leaves, buds, or flowers and never contains chlorophyll. The \*radicle (embryonic root) may give rise either to a **tap root system** with a single main **tap root** from which lateral roots develop, or a **fibrous root system**, with many roots of equal size. The \*apical meristem at the root tip gives rise to a protective sheath, the \*root cap, and to the primary tissues of the root. The vascular tissues usually form a central core (see illustration). This distinguishes roots from stems, in which the vascular tissue often forms a ring. A short distance behind the root tip **root hairs** develop from the epidermis and greatly increase the surface area for absorption of water and minerals. Beyond this, lateral roots develop.

Roots may be modified in various ways. Some are swollen with food to survive the winter, as in the carrot. Certain plants, such as orchids, have absorptive aerial roots; others, such as ivy, have short clasping roots for climbing. The roots of leguminous plants, such as beans and peas, contain \*root nodules, which have an important role in nitrogen fixation. Other modifications include \*prop roots, stilt roots, and buttress roots, which support the plant.

**2.** (in dentistry) The portion of a \*tooth

Section through the tip of a plant root

that is not covered with enamel and is embedded in a socket in the jawbone. Incisors, canines, and premolars have single roots; molars normally have several roots.

**3.** (in anatomy) The point of origin of a nerve in the central nervous system.

There are two roots for every \*spinal nerve (see DORSAL ROOT; VENTRAL ROOT).

**4.** (in mathematics) **a.** One of the equal factors of a number or quantity, e.g. the cube root of 8 is 2. In general, the  $n$ th root of a number or quantity  $a$  is a number or quantity  $x$  that satisfies the equation  $x^n = a$ . **b.** The value or values of an independent variable in an equation that satisfies that equation.

**root cap (calyptra)** A cone-shaped structure that covers the root tip and develops as a result of cell division by a meristem at the root apex (see CALYPTROGEN). It protects the root tip as it grows between the soil particles. The cells are constantly worn away by friction and are replaced by the meristem.

**root hair** See ROOT.

**root-mean-square value (RMS value)**

**1.** (in statistics) A typical value of a number ( $n$ ) of values of a quantity ( $x_1, x_2, x_3, \dots$ ) equal to the square root of the sum of the squares of the values divided by  $n$ , i.e.

$$\text{RMS value} = \sqrt{(x_1^2 + x_2^2 + x_3^2 \dots)/n}$$

**2.** (in physics) A typical value of a continuously varying quantity, such as an alternating electric current, obtained similarly from many samples taken at regular time intervals during a cycle. Theoretically this can be shown to be the **effective value**, i.e. the value of the equivalent direct current that would produce the same power dissipation in a given resistor. For a sinusoidal current this is equal to  $I_m/\sqrt{2}$ , where  $I_m$  is the maximum value of the current.

**root nodule** A swelling on the roots of certain plants, especially those of the family Fabaceae (Leguminosae), that contains bacteria (notably *Rhizobium*) capable of fixing atmospheric nitrogen into ammonia, which is subsequently converted to nitrates and amino acids (see NITROGEN FIXATION). Plants that possess root nodules increase soil fertility by increasing the nitrate content of the soil. The practice of

\*crop rotation will normally include the cultivation of a leguminous species.

**root pressure** The pressure that forces water, absorbed from the soil, to move through the roots and up the stem of a plant. This pressure can be demonstrated by cutting a stem, from which water will exude. A \*manometer can be attached to a plant stem to measure the root pressure. Root pressure is believed to be due to both the osmosis of water, from the soil into the root cells, and the active pumping of salts into the \*xylem tissue, which maintains a concentration gradient along which the water will move. See also TRANSPIRATION.

**rootstock** See RHIZOME.

**Rose's metal** An alloy of low melting point (about 100°C) consisting of 50% bismuth, 25–28% lead, and 22–25% tin.

**rot** (in mathematics) See CURL.

**rotary converter** A device for converting direct current to alternating current or one d.c. voltage to another. It consists of an electric motor coupled to a generator.

**rotational motion** The laws relating to the rotation of a body about an axis are analogous to those describing linear motion. The **angular displacement** ( $\theta$ ) of a body is the angle in radians through which a point or line has been rotated in a specified sense about a specified axis. The **angular velocity** ( $\omega$ ) is the rate of change of angular displacement with time, i.e.  $\omega = d\theta/dt$ , and the **angular acceleration** ( $\alpha$ ) is the rate of change of angular velocity, i.e.  $\alpha = d\omega/dt = d^2\theta/dt^2$ .

The equations of linear motion have analogous rotational equivalents, e.g.:

$$\omega_2 = \omega_1 + \alpha t$$

$$\theta = \omega_1 t + \alpha t^2/2$$

$$\omega_2^2 = \omega_1^2 + 2\theta\alpha$$

The counterpart of Newton's second law of motion is  $T = I\alpha$ , where  $T$  is the \*torque causing the angular acceleration and  $I$  is the \*moment of inertia of the rotating body.

**rotor** The rotating part of an electric

motor, electric generator, turbine, etc.  
*Compare* STATOR.

**roughage** *See* (DIETARY) FIBRE.

**rounding error** The difference between the exact value of a number and its approximate value that results from considering only a fixed number of decimal places or \*significant figures (by rounding up or down). Because only a finite number of \*bytes are available to stand for a number in a computer system, computer calculations are subject to rounding errors.

**round window (fenestra rotunda)** A membrane-covered opening between the middle ear and the inner ear (*see* EAR), situated below the \*oval window. Pressure waves transmitted through the perilymph in the \*cochlea are released into the middle ear through the round window.

**roundworms** *See* NEMATODA.

**r-process** *See* ORIGIN OF THE ELEMENTS.

**RQ** *See* RESPIRATORY QUOTIENT.

**RR Lyrae variable star** A type of short-period pulsating \*variable star that occurs in globular clusters and in the galactic nucleus. RR Lyrae variables are old population II stars (*see* POPULATION TYPE), typically giant stars whose brightness varies widely every few hours.

**rRNA** *See* RNA.

**R-S convention** *See* ABSOLUTE CONFIGURATION.

**r selection** A type of selection that favours organisms with a high rate of reproduction (*r* value). Organisms that are *r* selected (*r* strategists) are able to colonize a habitat rapidly, utilizing the food and other resources before other organisms are established and begin to compete. They tend to be relatively small with short life spans (e.g. bacteria) and often live in unstable environments; characteristically their survival depends on their ability to produce large numbers of offspring rather than on their ability to compete. *Compare* K SELECTION.

**rubber** A polymeric substance obtained from the sap of the tree *Hevea brasiliensis*. Crude natural rubber is obtained by coagulating and drying the sap (latex), and is

then modified by \*vulcanization and compounding with fillers. It is a polymer of \*isoprene containing the unit  $-\text{CH}_2\text{C}(\text{CH}_3)\text{CHCH}_2-$ . Various synthetic rubbers can also be made. *See* NEOPRENE; NITRILE RUBBER; SILICONES.

**rubidium** Symbol Rb. A soft silvery-white metallic element belonging to \*group 1 (formerly IA) of the periodic table; a.n. 37; r.a.m. 85.47; r.d. 1.53; m.p. 38.89°C; b.p. 688°C. It is found in a number of minerals (e.g. lepidolite) and in certain brines. The metal is obtained by electrolysis of molten rubidium chloride. The naturally occurring isotope rubidium-87 is radioactive (*see* RUBIDIUM-STRONTIUM DATING). The metal is highly reactive, igniting spontaneously in air. It was discovered spectroscopically by Robert Bunsen and Gustav Kirchhoff in 1861.

**rubidium-strontium dating** A method of dating geological specimens based on the decay of the radioisotope rubidium-87 into the stable isotope strontium-87. Natural rubidium contains 27.85% of rubidium-87, which has a half-life of  $4.7 \times 10^{10}$  years. The ratio  $^{87}\text{Rb}/^{87}\text{Sr}$  in a specimen gives an estimate of its age (up to several thousand million years).

**rubisco** *See* RIBULOSE BISPHTHOSPHATE.

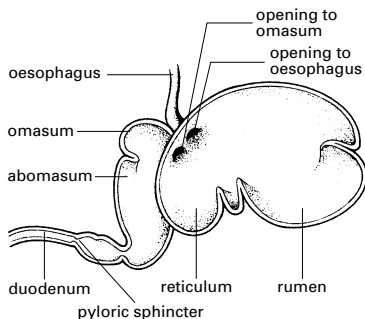

**ruby** The transparent red variety of the mineral \*corundum, the colour being due to the presence of traces of chromium. It is a valuable gemstone, more precious than diamonds. The finest rubies are obtained from Mogok in Burma, where they occur in metamorphic limestones; Sri Lanka and Thailand are the only other important sources. Rubies have been produced synthetically by the Verneuil flame-fusion process. Industrial rubies are used in lasers, watches, and other precision instruments.

**rumen** The second of four chambers that form the stomach of ruminants. *See* RUMINANTIA.

**Rumford, Count** (Benjamin Thompson; 1753–1814) American-born British physicist, who acted as an English spy during the American Revolution. As a result he was forced to flee in 1775, first to England and then to Munich. There he observed the boring of cannon barrels, which led

him to his best-known proposition, that \*friction produces heat. While in Munich he was made a count of the Holy Roman Empire. Returning to England in 1795, he helped to demolish the \*caloric theory.

**Ruminantia** A suborder of hooved mammals (see ARTIODACTYLA) comprising the sheep, cattle, goats, deer, and antelopes. They are characterized by a four-chambered stomach (see illustration). Swallowed food passes from the first chamber, the **reticulum**, to the **rumen**, where food is digested by \*cellulase and other enzymes secreted by symbiotic anaerobic microorganisms that live in the rumen. Some products of digestion are absorbed in the rumen; the remaining partly digested food is regurgitated and chewed to a pulp – the process known as ‘chewing the cud’. This food mass is then swallowed and passes from the reticulum to the third chamber, the **omasum**, where water and some nutrients are absorbed; and finally to the **abomasum**, in which further digestion takes place.

Section of the stomach of a ruminant

**runner** A stem that grows horizontally along the soil surface and gives rise to new plants from axillary or terminal buds. Runners are seen in the creeping buttercup and the strawberry. **Offsets**, e.g. those of the houseleek, are short runners.

**Russell-Saunders coupling (L-S coupling)** A type of coupling in systems involving many \*fermions. These systems include electrons in atoms and nucleons in nuclei, in which the energies associated with electrostatic repulsion are much

greater than the energies associated with \*spin-orbit coupling. \*Multiplets of many-electron atoms with a low \*atomic number are characterized by Russell-Saunders coupling. It is named after the US physicists Henry Norris Russell (1877–1957) and F. A. Saunders, who postulated this type of coupling to explain the spectra of many-electron atoms with low atomic number in 1925. The multiplets of heavy atoms and nuclei are better described by \*j-j coupling or **intermediate coupling**, i.e. a coupling in which the energies of electrostatic repulsion and spin-orbit coupling are similar in size.

**rusting** Corrosion of iron (or steel) to form a hydrated iron(III) oxide  $\text{Fe}_2\text{O}_3 \cdot x\text{H}_2\text{O}$ . Rusting occurs only in the presence of both water and oxygen. It is an electrochemical process in which different parts of the iron surface act as electrodes in a cell reaction. At the anode, iron atoms dissolve as  $\text{Fe}^{2+}$  ions:

At the cathode, hydroxide ions are formed:

The  $\text{Fe(OH)}_2$  in solution is oxidized to  $\text{Fe}_2\text{O}_3$ . Rusting is accelerated by impurities in the iron and by the presence of acids or other electrolytes in the water.

**rusts** A group of parasitic fungi of the phylum \*Basidiomycota. Many of these species attack the leaves and stems of cereal crops: characteristic rust-coloured streaks of spores appear on infected plants. The life cycles of some rusts may be complex; many form a number of different types of spore and some require two different host plants. *Compare* SMUTS.

**ruthenium** Symbol Ru. A hard white metallic \*transition element; a.n. 44; r.a.m. 101.07; r.d. 12.3; m.p. 2310°C; b.p. 3900°C. It is found associated with platinum and is used as a catalyst and in certain platinum alloys. Chemically, it dissolves in fused alkalis but is not attacked by acids. It reacts with oxygen and halogens at high temperatures. It also forms complexes with a range of oxidation states. The element was isolated by K. K. Klaus in 1844.

**Rutherford, Ernest, Baron** (1871–1937) New Zealand-born British physicist, who worked under Sir J. J. \*Thomson at Cambridge University (1895–98). He then took up a professorship at McGill University, Canada, and collaborated with Frederick \*Soddy in studying radioactivity. In 1899 he discovered \*alpha particles and beta particles, followed by the discovery of \*gamma radiation the following year. In 1905, with Soddy, he announced that radioactive \*decay involves a series of transformations. In 1907 he moved to Manchester University, where he directed the \*Rutherford scattering experiments that led to the discovery of the atomic \*nucleus. After moving to Cambridge in 1919 he achieved the artificial splitting of light atoms. In 1908 he was awarded the Nobel Prize for chemistry.

**rutherfordium** Symbol Rf. A radioactive \*transactinide element; a.n. 104. It was first reported in 1964 at Dubna, near Moscow, and in 1969 it was detected by A. Ghiorso and a team at Berkeley, California. It can be made by bombarding californium-249 nuclei with carbon-12 nuclei.

**Rutherford scattering** The scattering of \*alpha particles by thin films of heavy metals, notably gold. The experiments, performed in 1909 by Geiger and Marsden under Rutherford's direction, provided evidence for the existence of an atomic \*nucleus. A narrow beam of alpha particles from a radon source was directed onto a thin metal foil. A glass screen coated with zinc sulphide (which scintillates on absorbing alpha particles) was placed at the end of a travelling microscope and was used to detect scattered alpha particles. The travelling microscope could be rotated about the metal foil; by counting the number of scintillations produced in various positions during equal intervals, the angular dependence of the scattering was determined. Since the range of alpha particles in air is limited, the central chamber of the apparatus was evacuated. Most alpha particles suffered only small angles of deflection. However, a very small number, about 1 in 8000, were deviated by more than an angle  $\theta = 90^\circ$ .

Rutherford concluded that alpha parti-

cles deflected by angles greater than  $90^\circ$  had encountered a small intense positive charge of high inertia. In 1911 he proposed that an atom has a positively charged nucleus, which contains most of the mass of the atom and is surrounded by orbiting electrons (see BOHR THEORY). Since very few alpha particles were scattered through large angles, it follows that the probability of a head-on collision with the nucleus is small. The nucleus therefore occupies a very small part of the atomic volume. It is of the order of  $10^{-15}$  m across, whereas the atomic radius is of the order of  $10^{-10}$  m.

**rutile** A mineral form of titanium(IV) oxide,  $\text{TiO}_2$ .

**Rydberg constant** Symbol  $R$ . A constant that occurs in the formulae for atomic spectra and is related to the binding energy between an electron and a nucleon. It is connected to other constants by the relationship  $R = \mu_0^2 m e^4 c^3 / 8 h^3$ , where  $\mu_0$  is the magnetic constant (see PERMEABILITY),  $m$  and  $e$  are the mass and charge of an electron,  $c$  is the speed of light, and  $h$  is the \*Planck constant. It has the value  $1.097 \times 10^7 \text{ m}^{-1}$ . It is named after the Swedish physicist Johannes Robert Rydberg (1854–1919), who developed a formula for the spectrum of hydrogen.

**Rydberg spectrum** An absorption spectrum of a gas in the ultraviolet region, consisting of a series of lines that become closer together towards shorter wavelengths, merging into a continuous absorption region. The absorption lines correspond to electronic transitions to successively higher energy levels. The onset of the continuum corresponds to photoionization of the atom or molecule, and can thus be used to determine the ionization potential.

**Ryle, Sir Martin** (1918–84) British radio astronomer, who became professor of radio astronomy at Cambridge University in 1959. He organized three surveys of celestial radio sources and developed the technique of aperture synthesis (see RADIO TELESCOPE). In 1974 he shared the Nobel Prize for physics with Antony Hewish (1924– ), who discovered pulsars.

**Sabatier–Senderens process** A method of organic synthesis employing hydrogenation and a heated nickel catalyst. It is employed commercially for hydrogenating unsaturated vegetable oils to make margarine. It is named after Paul Sabatier (1854–1941) and Jean-Baptiste Senderens (1856–1937).

**saccharide** See SUGAR.

**saccharin** A white crystalline solid,  $C_7H_5NO_3S$ , m.p.  $224^{\circ}C$ . It is made from a compound of toluene, derived from petroleum or coal tar. It is a well-known artificial sweetener, being some 500 times as sweet as sugar (sucrose), and is usually marketed as its sodium salt. Because of an association with cancer in laboratory animals, its use is restricted in some countries.

**Saccharomyces** An industrially important genus of yeasts. *S. cerevisiae*, of which there are at least 1000 strains, is used in baking (see BAKER'S YEAST), brewing, and wine making; it is also used in the production of \*single-cell protein and ergosterol, a steroid. The other main yeast used in the production of beer is *S. uvarum* (or *carlsbergensis*); it is distinguished from *S. cerevisiae* by its ability to ferment the disaccharide melibiose using  $\alpha$ -galactosidase, an enzyme not produced by *S. cerevisiae*.

**saccharose** See SUCROSE.

**sacculus (saccul)** A chamber of the \*inner ear from which the \*cochlea arises in reptiles, birds, and mammals. It bears patches of sensory epithelium concerned with balance (see MACULA).

**Sachse reaction** A reaction of methane at high temperature to produce ethyne:

The reaction occurs at about  $1500^{\circ}C$ , the high temperature being obtained by burning part of the methane in air.

**Sachs–Wolfe effect** A phenomenon, predicted in 1967 by R. K. Sachs and A. M. Wolfe, in which density fluctuations associated with quantum-mechanical effects in the early universe caused 'ripples' in the cosmic microwave background radiation. It was first observed by the \*COBE satellite and analysed in detail by \*WMAP.

**sacral vertebrae** The vertebrae that lie between the lumbar and the caudal vertebrae in the \*vertebral column. The function of the sacral vertebrae is to articulate securely with the \*pelvic girdle, and they are usually fused to form a single bone (the **sacrum**) to provide a firm support. The number of sacral vertebrae varies from animal to animal. Amphibians have a single sacral vertebra, reptiles have two, and mammals have three or more.

**sacrificial protection (cathodic protection)** The protection of iron or steel against corrosion (see RUSTING) by using a more reactive metal. A common form is galvanizing (see GALVANIZED IRON), in which the iron surface is coated with a layer of zinc. Even if the zinc layer is scratched, the iron does not rust because zinc ions are formed in solution in preference to iron ions. Pieces of magnesium alloy are similarly used in protecting pipelines, etc.

**saddle point** For a three-dimensional surface, a point that is a minimum in one planar cross-section and a maximum in another plane. At this point, the surface is saddle-shaped.

**safranin** A stain used in optical microscopy that colours lignified tissues, cutinized tissues, and nuclei red and chloroplasts pink. It is used mainly for plant tissues, in conjunction with a green or blue counterstain.

**sal ammoniac** See AMMONIUM CHLORIDE.

**salicylic acid (1-hydroxybenzoic acid)** A naturally occurring carboxylic acid,  $\text{HOC}_6\text{H}_4\text{COOH}$ , found in certain plants; r.d. 1.44; m.p. 159°C; sublimes at 211°C. It is used in making aspirin and in the food-stuffs and dyestuffs industries.

**saline** Describing a chemical compound that is a salt, or a solution containing a salt. *See also* PHYSIOLOGICAL SALINE.

**salinometer** An instrument for measuring the salinity of a solution. There are two main types: one is a type of \*hydrometer to measure density; the other is an apparatus for measuring the electrical conductivity of the solution.

**saliva** A watery fluid secreted by the \*salivary glands in the mouth. Production of saliva is stimulated by the presence of food in the mouth and also by the smell or thought of food. Saliva contains mucin, which lubricates food and eases its passage into the oesophagus, and in some animals salivary \*amylase (or ptyalin), which begins the digestion of starch. The saliva of insects is rich in digestive enzymes, and that of bloodsucking animals contains an anticoagulant.

**salivary glands** Glands in many terrestrial animals that secrete \*saliva into the mouth. In humans there are three pairs: the sublingual, submandibular, and the submaxillary glands. The salivary gland cells of some insect larvae produce giant (polytene) chromosomes, which are widely used in the study of genetics and protein synthesis.

**Salmonella** A genus of rod-shaped Gram-negative bacteria that inhabit the intestine and cause disease (salmonellosis) in humans and animals. They are aerobic or facultatively anaerobic, and most are motile. Salmonellae can exist for long periods outside their host, and may be found, for example, in sewage and surface water. Humans may become infected by consuming contaminated water or food, especially animal products, such as eggs, meat, and milk, or vegetables that have been fertilized with contaminated manure. The bacteria can also be transmitted from human or animal carriers by unhygienic food preparation. Various species of *Salmonella* cause gastroenteritis and septi-

caemia; typhoid fever and paratyphoid fever are caused by *S. typhi* and *S. paratyphi*, respectively.

**sal soda** Anhydrous \*sodium carbonate,  $\text{Na}_2\text{CO}_3$ .

**salt** A compound formed by reaction of an acid with a base, in which the hydrogen of the acid has been replaced by metal or other positive ions. Typically, salts are crystalline ionic compounds such as  $\text{Na}^+\text{Cl}^-$  and  $\text{NH}_4^+\text{NO}_3^-$ . Covalent metal compounds, such as  $\text{TiCl}_4$ , are also often regarded as salts.

**saltation** A mechanism by which the moving water in a river carries sedimentary material. The particles bound along the river bed in a series of small leaps. A similar process occurs on land, when wind acts on grains of material.

**salt bridge** An electrical connection made between two half cells. It usually consists of a glass U-tube filled with agar jelly containing a salt, such as potassium chloride. A strip of filter paper soaked in the salt solution can also be used.

**salt cake** Industrial \*sodium sulphate.

**saltling in** *See* SALTING OUT.

**saltling out** The effect in which the solubility of a substance in a certain solvent is reduced by the presence of a second solute dissolved in the solvent. For example, certain substances dissolved in water can be precipitated (or evolved as a gas) by addition of an ionic salt. The substance is more soluble in pure water than in the salt solution. The opposite effect involving an increase in solubility may occur. This is known as **saltling in**.

**saltpetre** *See* NITRE.

**samara** A dry single-seeded indehiscent fruit in which the fruit wall hardens and extends to form a long membranous winglike structure that aids dispersal. Examples are ash and elm fruits. The sycamore fruit is a double samara and technically a \*schizocarp. *See also* ACHENE.

**samarium** Symbol Sm. A soft silvery metallic element belonging to the \*lanthanoids; a.n. 62; r.a.m. 150.35; r.d. 7.52 (20°C); m.p. 1077°C; b.p. 1791°C. It occurs in monazite and bastnatite. There are

seven naturally occurring isotopes, all of which are stable except samarium-147, which is weakly radioactive (half-life  $2.5 \times 10^{11}$  years). The metal is used in special alloys for making nuclear-reactor parts as it is a neutron absorber. Samarium oxide ( $\text{Sm}_2\text{O}_3$ ) is used in small quantities in special optical glasses. The largest use of the element is in the ferromagnetic alloy  $\text{SmCo}_5$ , which produces permanent magnets five times stronger than any other material. The element was discovered by François Lecoq de Boisbaudran in 1879.

**sampling** The selection of small groups of entities to represent a large number of entities in \*statistics. In **random sampling** each individual of a population has an equal chance of being selected as part of the sample. In **stratified random sampling**, the population is divided into strata, each of which is randomly sampled and the samples from the different strata are pooled. In **systematic sampling**, individuals are chosen at fixed intervals; for example, every tenth animal in a population. In **sampling with replacement**, each individual chosen is replaced before the next selection is made.

**sand** Particles of rock with diameters in the range 0.06–2.00 mm. Most sands are composed chiefly of particles of quartz, which are derived from the weathering of quartz-bearing rocks.

**Sandmeyer reaction** A reaction of diazonium salts used to prepare chloro- or bromo-substituted aromatic compounds. The method is to diazotize an aromatic amide at low temperature and add an equimolar solution of the halogen acid and copper(I) halide. A complex of the diazonium salt and copper halide forms, which decomposes when the temperature is raised. The copper halide acts as a catalyst in the reaction of the halide ions from the acid, for example

The reaction was discovered in 1884 by the German chemist Traugott Sandmeyer (1854–1922). See also GATTERMANN REACTION.

**sandstone** A common sedimentary rock composed of grains of sand. The sand

accumulated originally underwater in shallow seas or lakes, or on the ground along shorelines or in desert regions. The rounded quartz grains are 0.06–2 mm across. They may be consolidated by pressure, but more often they are cemented together by calcite (calcareous sandstone), clay, or iron oxide (ferruginous sandstone), which determines the colour of the rock.

**sandwich compound** A transition-metal complex in which a metal atom or ion is 'sandwiched' between two rings of atoms. \*Ferrocene was the first such compound to be prepared, having two parallel cyclopentadienyl rings with an iron ion between them. In such compounds (also known as **metallocenes**) the metal coordinates to the pi electron system of the ring, rather than to individual atoms. A wide variety of these compounds are known, having five-, six-, seven-, or eight-membered rings and involving such metals as Cr, Mn, Co, Ni, and Fe. Other similar compounds are known. A **multidecker sandwich** has three or more parallel rings with metal atoms between them. In a **bent sandwich**, the rings are not parallel. A **half sandwich** (or **piano stool**) has one ring, with single ligands on the other side of the metal.

**Sanger's reagent** 2,4-dinitrofluorobenzene,  $\text{C}_6\text{H}_3\text{F}(\text{NO}_2)_2$ , used to identify the end \*amino acid in a protein chain. It is named after Frederick Sanger (1918– ).

**sap 1.** The sugary fluid that is found in the phloem tissue of plants. Sap is the medium in which carbohydrates, produced in photosynthesis, and other organic molecules are transported and stored in plants. **2. (cell sap)** The fluid that is contained in the \*vacuoles of plant cells. It is a solution of organic and inorganic compounds, including sugars, amino acids, salts, pigments, and waste products.

**saponification** The reaction of esters with alkalis to give alcohols and salts of carboxylic acids:

See ESTERIFICATION; SOAP.

**sapphire** Any of the gem varieties of

\*corundum except ruby, especially the blue variety, but other colours of sapphire include yellow, brown, green, pink, orange, and purple. Sapphires are obtained from igneous and metamorphic rocks and from alluvial deposits. The chief sources are Sri Lanka, Kashmir, Burma, Thailand, East Africa, the USA, and Australia. Sapphires are used as gemstones and in record-player styluses and some types of laser. They are synthesized by the Verneuil flame-fusion process.

**saprotroph** (*saprobe*; *saprobiont*) Any organism that feeds by absorbing dead organic matter. Most saprotrophs are bacteria and fungi. Saprotrophs are important in \*food chains as they bring about decay and release nutrients for plant growth. *Compare* PARASITISM.

**sapwood** (*alburnum*) The outer wood of a tree trunk or branch. It consists of living \*xylem cells, which both conduct water and provide structural support. *Compare* HEARTWOOD.

**sarcoma** *See* CANCER.

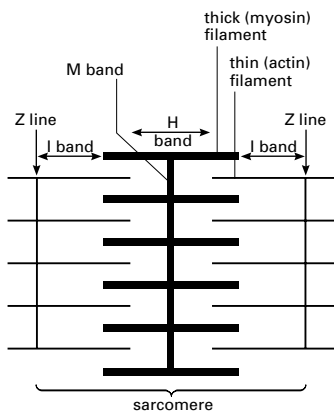

**sarcomere** Any of the functional units that make up the myofibrils of \*voluntary muscle. Each sarcomere is bounded by two membranes (**Z lines**), which provide the points of attachment of \*actin filaments; another membrane (the **M band** or **line**) is the point of attachment of the \*myosin filaments. The sarcomere is di-

vided into various bands reflecting the arrangement of the filaments (see illustration). During muscle contraction the actin and myosin filaments slide over each other and the length of the sarcomere shortens: the Z lines are drawn closer together and the I and H bands become narrower.

**satellite 1. (natural satellite)** A relatively small natural body that orbits a planet. For example, the earth's only natural satellite is the moon. **2. (artificial satellite)** A man-made spacecraft that orbits the earth, moon, sun, or a planet. Artificial satellites are used for a variety of purposes. **Communication satellites** are used for relaying telephone, radio, and television signals round the curved surface of the earth (*see* SYNCHRONOUS ORBIT). They are of two types: **passive satellites** reflect signals from one point on the earth's surface to another; **active satellites** are able to amplify and retransmit the signals that they pick up. **Astronomical satellites** are equipped to gather and transmit to earth astronomical information from space, including conditions in the earth's atmosphere, which is of great value in weather forecasting.

**satellite DNA** *See* REPETITIVE DNA.

**saturated 1.** (of a solution) Containing the maximum equilibrium amount of solute at a given temperature. In a saturated solution the dissolved substance is in equilibrium with undissolved substance; i.e. the rate at which solute particles leave the solution is exactly balanced by the rate at which they dissolve. A solution containing less than the equilibrium amount is said to be **unsaturated**. One containing more than the equilibrium amount is **supersaturated**. Supersaturated solutions can be made by slowly cooling a saturated solution. Such solutions are metastable; if a small crystal seed is added the excess solute crystallizes out of solution. **2.** (of a vapour) *See* VAPOUR PRESSURE. **3.** (of a ferromagnetic material) Unable to be magnetized more strongly as all the domains are orientated in the direction of the field. **4.** (of a compound) Consisting of molecules that have only single bonds (i.e. no double or triple bonds). Saturated compounds can un-

Structure of a sarcomere

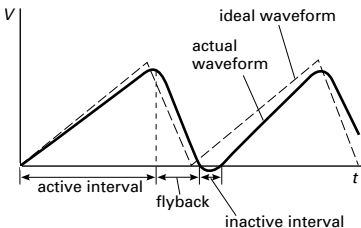

dergo substitution reactions but not addition reactions. *Compare* UNSATURATED.

**saturation 1.** See COLOUR. **2.** See SUPER-SATURATION.

**Saturn** A planet having its orbit between those of Jupiter and Uranus. Its mean distance from the sun is  $1426.72 \times 10^6$  km and its equatorial diameter 120 536 km; it has a sidereal period of 29.42 years. Although it is the second largest planet its mean density is lower than any other, its relative density being 0.7. It has at least 34 satellites, of which the largest, Titan, is the only planetary satellite to have a dense atmosphere. Saturn is believed to consist of a dense rocky core, surrounded by hydrogen compressed to such an extent that it behaves like a metal; this layer merges with an atmosphere of hydrogen. The planet is best known for the system of rings that surrounds it in an equatorial plane; the rings have an overall diameter of about 273 000 km. They are believed to consist of millions of particles of ice (possibly with a rock core) with diameters between <1 mm and 10 m. Saturn was given a preliminary examination by the satellite Pioneer II in 1979 and more detailed studies by Voyager I in 1980 and Voyager II in 1981.

**savanna** See GRASSLAND.

**sawtooth waveform** A waveform in which the variable increases uniformly with time for a fixed period, drops sharply to its initial value, and then repeats the sequence periodically. The illustration shows the ideal waveform and the waveform generated by practical electrical circuits. Sawtooth generators are frequently used to provide a time base for electronic

Sawtooth waveform

circuits, as in the \*cathode-ray oscilloscope.

**s-block elements** The elements of the first two groups of the \*periodic table; i.e. groups 1 (Li, Na, K, Rb, Cs, Fr) and 2 (Be, Mg, Ca, Sr, Ba, Ra). The outer electronic configurations of these elements all have inert-gas structures plus outer  $ns^1$  (group 1) or  $ns^2$  (group 2) electrons. The term thus excludes elements with incomplete inner  $d$ -levels (transition metals) or with incomplete inner  $f$ -levels (lanthanoids and actinoids) even though these often have outer  $ns^2$  or occasionally  $ns^1$  configurations. Typically, the  $s$ -block elements are reactive metals forming stable ionic compounds containing  $M^+$  or  $M^{2+}$  ions. See ALKALI METALS; ALKALINE-EARTH METALS.

**scalar product (dot product)** The product of two vectors  $\mathbf{U}$  and  $\mathbf{V}$ , with components  $U_1, U_2, U_3$  and  $V_1, V_2, V_3$ , respectively, given by:

$$\mathbf{U} \cdot \mathbf{V} = U_1V_1 + U_2V_2 + U_3V_3.$$

It can also be written as  $UV\cos\theta$ , where  $U$  and  $V$  are the lengths of  $\mathbf{U}$  and  $\mathbf{V}$ , respectively, and  $\theta$  is the angle between them. *Compare* VECTOR PRODUCT.

**scalar quantity** A quantity in which direction is either not applicable (as in temperature) or not specified (as in speed). *Compare* VECTOR.

**scalar triple product** See TRIPLE PRODUCT.

**scalene** Denoting a triangle having three unequal sides.

**scaler (scaling circuit)** An electronic counting circuit that provides an output when it has been activated by a prescribed number of input pulses. A **decade scaler** produces an output pulse when it has received ten or a multiple of ten input pulses; a **binary scaler** produces its output after two input pulses.

**scales** The small bony or horny plates forming the body covering of fish and reptiles. The wings of some insects, notably the Lepidoptera (butterflies and moths), are covered with tiny scales that are modified cuticular hairs.

In fish there are three types of scales.

**Placoid scales (denticles)**, characteristic of

cartilaginous fish, are small and toothlike, with a projecting spine and a flattened base embedded in the skin. They are made of \*dentine, have a pulp cavity, and the spine is covered with a layer of enamel. Teeth are probably modified placoid scales. **Cosmoid scales**, characteristic of lungfish and coelacanths, have an outer layer of hard **cosmin** (similar to dentine) covered by modified enamel (**ganoine**) and inner layers of bone. The scale grows by adding to the inner layer only. In modern lungfish the scales are reduced to large bony plates. **Ganoid scales** are characteristic of primitive ray-finned fishes, such as sturgeons. They are similar to cosmoid scales but have a much thicker layer of ganoine and grow by the addition of material all round. The scales of modern teleost fish are reduced to thin bony plates.

In reptiles there are two types of scales: horny epidermal **corneoscutes** sometimes fused with underlying bony dermal **osteoscutes**.

**scandium** Symbol Sc. A rare soft silvery metallic element belonging to group 3 (formerly IIIA) of the periodic table; a.n. 21; r.a.m. 44.956; r.d. 2.989 (alpha form), 3.19 (beta form); m.p. 1541°C; b.p. 2831°C. Scandium often occurs in \*lanthanoid ores, from which it can be separated on account of the greater solubility of its thiocyanate in ether. The only natural isotope, which is not radioactive, is scandium-45, and there are nine radioactive isotopes, all with relatively short half-lives. Because of the metal's high reactivity and high cost no substantial uses have been found for either the metal or its compounds. Predicted in 1869 by Dmitri Mendeleev, and then called **ekaboron**, the oxide (called **scandia**) was isolated by Lars Nilson (1840-99) in 1879.

**scanning** The process of repeatedly crossing a surface or volume with a beam, aerial, or moving detector in order to bring about some change to the surface or volume, to measure some activity, or to detect some object. The fluorescent screen of a television picture tube is scanned by an electron beam in order to produce the picture; an area of the sky may be scanned by the movable dish aerial of a

radio telescope in order to detect celestial bodies, etc.

**scanning electron microscope** *See* ELECTRON MICROSCOPE.

**scanning tunnelling microscope (STM)** A type of microscope in which a fine conducting probe is held close to the surface of a sample. Electrons tunnel between the sample and the probe, producing an electrical signal. The probe is slowly moved across the surface and raised and lowered so as to keep the signal constant. A profile of the surface is produced, and a computer-generated contour map of the surface is produced. The technique is capable of resolving individual atoms, but works better with conducting materials. *See also* ATOMIC FORCE MICROSCOPE.

**scapula (shoulder blade)** The largest of the bones that make up each half of the \*pectoral (shoulder) girdle. It is a flat triangular bone, providing anchorage for the muscles of the forelimb and an articulation for the \*humerus at the \*glenoid cavity. It is joined to the \*clavicle (collar bone) in front.

**scattering of electromagnetic radiation** The process in which electromagnetic radiation is deflected by particles in the matter through which it passes. In **elastic scattering** the photons of the radiation are reflected; i.e. they bounce off the atoms and molecules without any change of energy. In this type of scattering, known as **Rayleigh scattering** (after Lord Rayleigh; 1842-1919), there is a change of phase but no frequency change. In **inelastic scattering** and **superelastic scattering**, there is interchange of energy between the photons and the particles. Consequently, the scattered photons have a different wavelength as well as a different phase. Examples include the \*Raman effect and the \*Compton effect. *See also* TYN-DALL EFFECT.

**scavenger** An animal that feeds on dead organic matter. Scavengers (such as hyenas) may feed on animals killed by predators or they may be \*detritivores.

**Scheele, Karl Wilhelm** (1742-86) Swedish chemist, who became an apothecary and in 1775 set up his own pharmacy

at Köping. He made many chemical discoveries. In 1772 he prepared oxygen (see also LAVOISIER, ANTOINE; PRIESTLEY, JOSEPH) and in 1774 he isolated chlorine. He also discovered manganese, glycerol, hydrocyanic (prussic) acid, citric acid, and many other substances.

**scheelite** A mineral form of calcium tungstate,  $\text{CaWO}_4$ , used as an ore of tungsten. It occurs in contact metamorphosed deposits and vein deposits as colourless or white tetragonal crystals.

### Schiaparelli, Giovanni Virginio

(1835–1910) Italian astronomer, who became director of the Milan Observatory in 1860. There he studied asteroids, meteors, and planets. In 1877 he described *canali* among the surface features of \*Mars. The Italian word (which means 'channels') was mistranslated as 'canals', establishing a long controversy about the possibility of intelligent life on Mars.

**Schiff's base** A compound formed by a condensation reaction between an aromatic amine and an aldehyde or ketone, for example

The compounds are often crystalline and are used in organic chemistry for characterizing aromatic amines (by preparing the Schiff's base and measuring the melting point). They are named after the German chemist Hugo Schiff (1834–1915).

**Schiff's reagent** A reagent used for testing for aldehydes and ketones; it consists of a solution of fuchsin dye that has been decolorized by sulphur dioxide. Aliphatic aldehydes restore the pink immediately, whereas aromatic ketones have no effect on the reagent. Aromatic aldehydes and aliphatic ketones restore the colour slowly.

**schist** A group of coarse-grained metamorphic rocks characterized by the presence of platy minerals (e.g. micas, chlorite, talc, hornblende, and graphite) that show parallel alignment at right angles to the direction of stress. The original bedding of the rock is absent. Schists readily split into layers along schistosity planes, parallel to the alignment of the minerals.

**schizocarp** A dry indehiscent fruit formed from carpels that develop into separate one-seeded fragments called **mericarps**, which may be dehiscent, as in the \*regma, or indehiscent, as in the \*cremocarp and \*carcerulus.

**schizogeny** The localized separation of plant cells to form a cavity (surrounded by the intact cells) in which secretions accumulate. Examples are the resin canals of some conifers and the oil ducts of caraway and aniseed fruits. Compare LYSIGENY.

**Schleiden, Matthias Jakob** See CELL THEORY; SCHWANN, THEODOR.

**schlieren photography** A technique that enables density differences in a moving fluid to be photographed. In the turbulent flow of a fluid, for example, short-lived localized differences in density create differences of refractive index, which show up on photographs taken by short flashes of light as streaks (German: *Schliere*). Schlieren photography is used in wind-tunnel studies to show the density gradients created by turbulence and the shock waves around a stationary model.

**Schmidt camera** See TELESCOPE.

**schönite** A mineral form of potassium sulphate,  $\text{K}_2\text{SO}_4$ .

**Schottky defect** See CRYSTAL DEFECT.

**Schottky effect** A reduction in the \*work function of a substance when an external accelerating electric field is applied to its surface in a vacuum. The field reduces the potential energy of electrons outside the substance, distorting the potential barrier at the surface and causing \*field emission. A similar effect occurs when a metal surface is in contact with a \*semiconductor rather than a vacuum, when it is known as a **Schottky barrier**. The effect was discovered by the German physicist Walter Schottky (1886–1976).

**Schrieffer, John** See BARDEEN, JOHN.

**Schrödinger, Erwin** (1887–1961) Austrian physicist, who became professor of physics at Berlin University in 1927. He left for Oxford to escape the Nazis in 1933, returned to Graz in Austria in 1936, and then left again in 1938 for Dublin's

Institute of Advanced Studies. He finally returned to Austria in 1956. He is best known for the development of \*wave mechanics and the \*Schrödinger equation, work that earned him a share of the 1933 Nobel Prize for physics with Paul Dirac (1902–84).

**Schrödinger equation** An equation used in wave mechanics (see QUANTUM MECHANICS) for the wave function of a particle. The time-independent Schrödinger equation is:

$$\nabla^2\psi + 8\pi^2m(E - U)\psi/h^2 = 0$$

where  $\psi$  is the wave function,  $\nabla^2$  the Laplace operator (see LAPLACE EQUATION),  $h$  the Planck constant,  $m$  the particle's mass,  $E$  its total energy, and  $U$  its potential energy. The equation can be solved exactly for simple systems, such as the harmonic oscillator and the hydrogen atom. It was devised by Erwin Schrödinger, who was mainly responsible for wave mechanics.

**Schrödinger's cat** A thought experiment introduced by Erwin Schrödinger in 1935 to illustrate the paradox in \*quantum mechanics regarding the probability of finding, say, a subatomic particle at a specific point in space. According to Niels Bohr, the position of such a particle remains indeterminate until it has been observed. Schrödinger postulated a sealed vessel containing a live cat and a device triggered by a quantum event, such as the radioactive decay of a nucleus. If the quantum event occurs, cyanide is released and the cat dies; if the event does not occur the cat lives. Schrödinger argued that Bohr's interpretation of events in quantum mechanics means that the cat could only be said to be alive or dead when the vessel has been opened and the situation inside it had been observed.

**Wigner's friend** is a variation of the Schrödinger's cat paradox in which a friend of the physicist Eugene Wigner is the first to look inside the vessel. The friend will either find a live or dead cat. However, if Professor Wigner has both the vessel with the cat and the friend in a closed room, the state of mind of the friend (happy if there is a live cat but sad if there is a dead cat) cannot be determined in Bohr's interpretation of quantum mechanics until the professor has

looked into the room although the friend has looked at the cat. This paradox has been extensively discussed since its introduction with many proposals made to resolve it. It is thought that the explanation depends on \*decoherence.

**Schwann, Theodor** (1810–82) German physiologist, who trained in medicine. After working in Berlin, he moved to Belgium. In 1838 the German botanist Matthias Schleiden (1804–81) had stated that plant tissues were composed of cells. Schwann demonstrated the same fact for animal tissues, and in 1839 concluded that all tissues are made up of cells: this laid the foundations for the \*cell theory. Schwann also worked on fermentation and discovered the enzyme \*pepsin. \*Schwann cells are named after him.

**Schwann cell** A cell that forms the \*myelin sheath of nerve fibres (axons). Each cell is responsible for a given length of a particular axon (called an **internode**); adjacent internodes are separated by small gaps (**nodes of Ranvier**) where the axon is bare. During its development the cell wraps itself around the fibre, so the sheath consists of concentric layers of Schwann cell membrane. These cells are named after Theodor Schwann.

**Schwarzschild radius** A critical radius of a body of given mass that must be exceeded if light is to escape from that body. It equals  $2GM/c^2$ , where  $G$  is the gravitational constant,  $c$  is the speed of light, and  $M$  is the mass of the body. If the body collapses to such an extent that its radius is less than the Schwarzschild radius the escape velocity becomes equal to the speed of light and the object becomes a \*black hole. The Schwarzschild radius is then the radius of the hole's event horizon. It is named after Karl Schwarzschild (1873–1916).

**Schweizer's reagent** A solution made by dissolving copper(II) hydroxide in concentrated ammonia solution. It has a deep blue colour and is used as a solvent for cellulose in the cuprammonium process for making rayon. When the cellulose solution is forced through spinnarets into an acid bath, fibres of cellulose are reformed.

**scientific notation** See STANDARD FORM.

**scintillation counter** A type of particle or radiation counter that makes use of the flash of light (scintillation) emitted by an excited atom falling back to its ground state after having been excited by a passing photon or particle. The scintillating medium is usually either solid or liquid and is used in connection with a \*photo-multiplier, which produces a pulse of current for each scintillation. The pulses are counted with a \*scaler. In certain cases, a pulse-height analyser can be used to give an energy spectrum of the incident radiation.

**scintillator** See PHOSPHOR.

**scion** See GRAFT.

**sclera** See SCLEROTIC.

**sclerenchyma** A plant tissue whose cell walls have become impregnated with lignin. Due to the added strength that this confers, sclerenchyma plays an important role in support; it is found in the stems and also in the midribs of leaves. Mature sclerenchyma cells are dead, since the lignin makes the cell wall impermeable to water and gases. The presence of \*plasmodesmata prevents lignin being deposited in areas of the cell wall called **pits**; these form shallow depressions enabling the exchange of substances between adjacent cells. Compare COLLENCYMA (see GROUND TISSUES); PARENCHYMA.

**sclerometer** A device for measuring the hardness of a material by determining the pressure on a standard point that is required to scratch it or by determining the height to which a standard ball will rebound from it when dropped from a fixed height. The rebound type is sometimes called a **scleroscope**.

**scleroprotein** Any of a group of proteins found in the exoskeletons of some invertebrates, notably insects. Scleroproteins are formed by conversion of the relatively soft elastic larval protein by a natural tanning process (**sclerotization**) involving orthoquinones. These are secreted and form cross linkages between polypeptides of the proteins, producing a hard rigid covering.

**sclerotic (sclera)** The tough external layer of the vertebrate eye. At the front of the eye, the sclera is modified to form the \*cornea.

**scorpions** See ARACHNIDA.

**scotopic vision** The type of vision that occurs when the \*rods in the eye are the principal receptors, i.e. when the level of illumination is low. With scotopic vision colours cannot be identified. Compare PHOTOPIC VISION.

**SCP** See SINGLE-CELL PROTEIN.

**screen grid** A wire grid in a tetrode or pentode \*thermionic valve, placed between the anode and the \*control grid to reduce the grid-anode capacitance. See also SUPPRESSOR GRID.

**screw 1.** A simple \*machine effectively consisting of an inclined plane wrapped around a cylinder. The mechanical advantage of a screw is  $2\pi r/p$ , where  $r$  is the radius of the thread and  $p$  is the **pitch**, i.e. the distance between adjacent threads of the screw measured parallel to its axis.

**2.** A symmetry element in a crystal lattice that consists of a combination of a rotation and a translation. See also GLIDE.

**scrotum** The sac of skin and tissue that contains and supports the \*testes in most mammals. It is situated outside the body cavity and allows sperm to develop at the optimum temperature, which is slightly lower than body temperature.

**scurvy** A disease caused by deficiency of \*vitamin C, which results in poor collagen formation. Symptoms include anaemia, skin discoloration, and tooth loss. Scurvy was a common disease among sailors in the 16th–18th centuries, when no fresh food was available on long sea voyages.

**S-drop** See STRANGE MATTER.

**seaborgium** Symbol Sg. A radioactive \*transactinide element; a.n. 106. It was first detected in 1974 by Albert Ghiorso and a team in California. It can be produced by bombarding californium-249 nuclei with oxygen-18 nuclei. It is named after the US physicist Glenn Seaborg (1912–99).

**seamount** An isolated steep-sided hill

up to 1000 m tall on the sea floor. Most are conical in shape and volcanic in origin, with summits 1000–2000 m below the sea surface. *See also* GUYOT.

**search coil** A small coil in which a current can be induced to detect and measure a magnetic field. It is used in conjunction with a \*fluxmeter.

**Searle's bar** An apparatus for determining the thermal conductivity of a bar of material. The bar is lagged and one end is heated while the other end is cooled, by steam and cold water respectively. At two points *d* apart along the length of the bar the temperature is measured using a thermometer or thermocouple. The conductivity can then be calculated from the measured temperature gradient.

**seaweeds** Large multicellular \*algae living in the sea or in the intertidal zone. They are commonly species of the \*Chlorophyta, \*Phaeophyta, and \*Rhodophyta.

**sebaceous gland** A small gland occurring in mammalian \*skin. Its duct opens into a hair follicle, through which it discharges \*sebum onto the skin surface.

**sebum** The substance secreted by \*sebaceous glands onto the surface of the \*skin. It is a fatty mildly antiseptic material that protects, lubricates, and waterproofs the skin and hair and helps prevent desiccation.

**secant 1.** *See* TRIGONOMETRIC FUNCTIONS.

**2.** A line that cuts a circle or other curve.

**sech** *See* HYPERBOLIC FUNCTIONS.

**second 1.** Symbol *s*. The SI unit of time equal to the duration of 9 192 631 770 periods of the radiation corresponding to the transition between two hyperfine levels of the ground state of the caesium-133 atom. **2.** Symbol *''*. A unit of angle equal to 1/3600 of a degree or 1/60 of a minute.

**secondary alcohol** *See* ALCOHOLS.

**secondary amine** *See* AMINES.

**secondary cell** A \*voltaic cell in which the chemical reaction producing the e.m.f. is reversible and the cell can therefore be charged by passing a current

through it. *See* ACCUMULATOR; INTERCALATION CELL. *Compare* PRIMARY CELL.

**secondary colour** Any colour that can be obtained by mixing two \*primary colours. For example, if beams of red light and green light are made to overlap, the secondary colour, yellow, will be formed. Secondary colours of light are sometimes referred to as the pigmentary primary colours. For example, if transparent yellow and magenta pigments are overlapped in white light, red will be observed. In this case the red is a pigmentary secondary although it is a primary colour of light.

**secondary consumer** *See* CONSUMER.

**secondary emission** The emission of electrons from a surface as a result of the impact of other charged particles, especially as a result of bombardment with (primary) electrons. As the number of secondary electrons can exceed the number of primary electrons, the process is important in \*photomultipliers. *See also* AUGER EFFECT.

**secondary growth (secondary thickening)** The increase in thickness of plant shoots and roots through the activities of the vascular \*cambium and \*cork cambium. It is seen in most dicotyledons and gymnosperms but not in monocotyledons. The tissues produced by secondary growth are called **secondary tissues** and the resultant plant or plant part is the **secondary plant body**. *Compare* PRIMARY GROWTH.

**secondary sexual characteristics** External features of a sexually mature animal that, although not directly involved in copulation, are significant in reproductive behaviour. The development of such features is controlled by sex hormones (androgens or oestrogens); they may be seasonal (e.g. the antlers of male deer or the body colour of male sticklebacks) or permanent (e.g. breasts in women or facial hair in men). In humans they develop during \*adolescence.

**secondary structure** *See* PROTEIN.

**secondary thickening** *See* SECONDARY GROWTH.

**secondary winding** The winding on

the output side of a \*transformer or \*induction coil. *Compare* PRIMARY WINDING.

**second convoluted tubule** *See* DISTAL CONVOLUTED TUBULE.

**second messenger** A chemical within a cell that is responsible for initiating the response to a signal from a chemical messenger (such as a hormone, neurotransmitter, or growth factor) that cannot enter the target cell itself, for example because it is not lipid-soluble and is therefore unable to cross the plasma membrane. A common second messenger is \*cyclic AMP; the signal for its formation within the cell is transmitted from hormone receptors on the cell surface by \*G protein.

**second-order reaction** *See* ORDER.

**secretin** A hormone produced by the anterior part of the small intestine (the \*duodenum and \*jejunum) in response to the presence of hydrochloric acid from the stomach. It causes the pancreas to secrete alkaline pancreatic juice and stimulates bile production in the liver. Secretin, whose function was first demonstrated in 1902, was the first substance to be described as a hormone.

**secretion 1.** The manufacture and discharge of specific substances into the external medium by cells in living organisms. (The substance secreted is also called the secretion.) Secretory cells are often specialized and organized in groups to form \*glands. The substances produced may be released directly into the blood (**endocrine secretion**; *see* ENDOCRINE GLAND) or through a duct (**exocrine secretion**; *see* EXOCRINE GLAND). Secretions can be classified according to the manner of their discharge. **Merocrine (eccrine) secretion** occurs without the secretory cells sustaining any permanent change; in **apocrine secretion** the cells release a secretory vesicle incorporating part of the secretory cell membrane; and **holocrine secretion** involves the disruption of the entire cell to release its accumulated secretory vesicles. **2.** The process by which a substance is pumped out of a cell against a concentration gradient. Secretion has an important role in adjusting

the composition of urine as it passes through the \*nephrons of the kidney.

**secular magnetic variation** *See* GEOMAGNETISM.

**sedimentary rocks** A group of rocks formed as a result of the accumulation and consolidation of sediments. Sedimentary rocks are one of the three major rock groups forming the earth's crust (*see also* IGNEOUS ROCKS; METAMORPHIC ROCKS). Most sedimentary rocks are formed from pre-existing rocks that have been broken down through mechanical processes into small particles, which have then been transported and redeposited; these form the clastic sedimentary rocks. The clastic rocks are subdivided according to the size of the dominant constituent particles: arenaceous being composed largely of sand-grade particles (e.g. sandstone, grit), argillaceous of silt- or clay-grade (e.g. mud, mudstone, clay, shale), and rudaceous of gravel-grade or larger particles (e.g. conglomerate). Chemical sedimentary rocks form the second large division of sedimentary rocks and originate as chemical precipitates at the site of deposition. These include the evaporites and sedimentary iron ores, and the organic sedimentary rocks, which are derived largely from the remains of plants and animals and include coal and many limestones.

**sedimentation** The settling of the solid particles through a liquid either to produce a concentrated slurry from a dilute suspension or to clarify a liquid containing solid particles. Usually this relies on the force of gravity, but if the particles are too small or the difference in density between the solid and liquid phases is too small, a \*centrifuge may be used. In the simplest case the rate of sedimentation is determined by \*Stokes' law, but in practice the predicted rate is rarely reached. Measurement of the rate of sedimentation in an \*ultracentrifuge can be used to estimate the size of macromolecules.

**Seebeck effect (thermoelectric effect)** The generation of an e.m.f. in a circuit containing two different metals or semiconductors, when the junctions between the two are maintained at different temperatures. The magnitude of the e.m.f. depends on the nature of the metals and the

difference in temperature. The Seebeck effect is the basis of the \*thermocouple. It was named after Thomas Seebeck (1770–1831), who actually found that a magnetic field surrounded a circuit consisting of two metal conductors only if the junctions between the metals were maintained at different temperatures. He wrongly assumed that the conductors were magnetized directly by the temperature difference. *Compare* PELTIER EFFECT.

**seed 1.** (in botany) The structure in angiosperms and gymnosperms that develops from the ovule after fertilization. Occasionally seeds may develop without fertilization taking place (see *APOMIXIS*). The seed contains the \*embryo and nutritive tissue, either as \*endosperm or food stored in the \*cotyledons. Angiosperm seeds are contained within a \*fruit that develops from the ovary wall. Gymnosperm seeds lack an enclosing fruit and are thus termed **naked**. The seed is covered by a protective layer, the \*testa. During development of the testa the seed dries out and enters a resting phase (dormancy) until conditions are suitable for germination.

Annual plants survive the winter or dry season as seeds. The evolution of the seed habit enabled plants to colonize the land, since seed plants do not depend on water for fertilization (unlike the lower plants).

**2.** (in chemistry) A crystal used to induce other crystals to form from a gas, liquid, or solution.

**seed coat** See *TESTA*.

**seed ferns** See *CYCADOFILICALES*.

**seed leaf** See *COTYLEDON*.

**seed plant** Any plant that produces seeds. Most seed plants belong to the phyla \*Anthophyta (flowering plants) or \*Coniferophyta (conifers).

**Seeger cones (pyrometric cones)** A series of cones used to indicate the temperature inside a furnace or kiln. The cones are made from different mixtures of clay, limestone, feldspars, etc., and each one softens at a different temperature. The drooping of the vertex is an indication that the known softening temperature has been reached and thus the furnace temperature can be estimated.

**segmentation 1.** See *METAMERIC SEGMENTATION*. **2.** See *CLEAVAGE*.

**segregation** The separation of pairs of \*alleles during the formation of reproductive cells so that they contain one allele only of each pair. Segregation is the result of the separation of \*homologous chromosomes during \*meiosis. *See also* MENDEL'S LAWS.

**Segrè plot** A plot of \*neutron number ( $N$ ) against \*proton number ( $Z$ ) for all stable nuclides. The stability of nuclei can be understood qualitatively on the basis of the nature of the strong interaction (see *FUNDAMENTAL INTERACTIONS*) and the competition between this attractive force and the repulsive electrical force. The strong interaction is independent of electric charge, i.e. at any given separation the strong force between two neutrons is the same as that between two protons or between a proton and a neutron. Therefore, in the absence of the electrical repulsion between protons, the most stable nuclei would be those having equal numbers of neutrons and protons. The electrical repulsion shifts the balance to favour a greater number of neutrons, but a nucleus with too many neutrons is unstable, because not enough of them are paired with protons.

As the number of nucleons increases, the total energy of the electrical interaction increases faster than that of the nuclear interaction. The (positive, repulsive) electric potential energy of the nucleus increases approximately as  $Z^2$ , while the (negative, attractive) nuclear potential energy increases approximately as  $N + Z$  with corrections for pairing effects. For large  $N + Z$  values, the electrical potential energy per nucleon grows much faster than the nuclear potential energy per nucleon, until a point is reached where the formation of a stable nucleus is impossible. The competition between the electric and nuclear forces therefore accounts for the increase with  $Z$  of the neutron-proton ratio in stable nuclei as well as the existence of maximum values for  $N + Z$  for stability. The plot is named after Emilio Segrè (1905–89). *See* *BINDING ENERGY*; *LIQUID-DROP MODEL*; *DECAY*.

**seif dune** See *DUNE*.

**seismic waves** A vibration propagated within the earth or along its surface as a result of an \*earthquake or explosion. Earthquakes generate two types of body waves that travel within the earth and two types of surface wave. The body waves consist of primary (or longitudinal) waves that impart a back-and-forth motion to rock particles along their path. They travel at speeds between 6 km per second in surface rock and 10.4 km per second near the earth's core. Secondary (or transverse or shear) waves cause rock particles to move back and forth perpendicularly to their direction of propagation. They travel at between 3.4 km per second in surface rock and 7.2 km per second near the core.

The surface waves consist of Rayleigh waves (after Lord Rayleigh, who predicted them) and Love waves (after A. E. Love). The Love waves displace particles perpendicularly to the direction of propagation and have no longitudinal or vertical components. They travel in the surface layer above a solid layer of rock with different elastic characteristics. Rayleigh waves travel over the surface of an elastic solid giving an elliptical motion to rock particles. It is these Rayleigh waves that have the strongest effect on distant seismographs.

**seismograph** An instrument that records ground oscillations, e.g. those caused by earthquakes, volcanic activity, and explosions. Most modern seismographs are based on the inertia of a delicately suspended mass and depend on the measurement of the displacement between the mass and a point fixed to the earth. Others measure the relative displacement between two points on earth. The record made by a seismograph is known as a **seismogram**.

**seismology** The branch of geology concerned with the study of earthquakes.

**Selachii** The major subclass of the Chondrichthyes (cartilaginous fishes), containing the sharks, rays, skates, and similar but extinct forms. Their sharp teeth develop from the toothlike placoid \*scales (denticles) and are rapidly replaced as they wear out.

**selection** (in biology) The process by

which one or more factors acting on a population produce differential mortality and favour the transmission of specific characteristics to subsequent generations. See ARTIFICIAL SELECTION; NATURAL SELECTION; SEXUAL SELECTION.

**selection pressure** The extent to which organisms possessing a particular characteristic are either eliminated or favoured by environmental demands. It indicates the degree of intensity of \*natural selection.

**selection rules** Rules that determine which transitions between different energy levels are possible in a system, such as an elementary particle, nucleus, atom, molecule, or crystal, described by quantum mechanics. Transitions cannot take place between any two energy levels.

\*Group theory, associated with the \*symmetry of the system, determines which transitions, called **allowed transitions**, can take place and which transitions, called \*forbidden transitions, cannot take place. Selection rules determined in this way are very useful in analysing the \*spectra of quantum-mechanical systems.

**selective breeding** See BREEDING.

**selectron** See SUPERSYMMETRY.

**selenides** Binary compounds of selenium with other more electropositive elements. Selenides of nonmetals are covalent (e.g. H<sub>2</sub>Se). Most metal selenides can be prepared by direct combination of the elements. Some are well-defined ionic compounds (containing Se<sup>2-</sup>), while others are nonstoichiometric interstitial compounds (e.g. Pd<sub>4</sub>Se, PdSe<sub>2</sub>).

**selenium** Symbol Se. A metalloid element belonging to group 16 (formerly VIB) of the periodic table; a.n. 34; r.a.m. 78.96; r.d. 4.81 (grey); m.p. 217°C (grey); b.p. 684.9°C. There are a number of allotropic forms, including grey, red, and black selenium. It occurs in sulphide ores of other metals and is obtained as a by-product (e.g. from the anode sludge in electrolytic refining). The element is a semiconductor; the grey allotrope is light-sensitive and is used in photocells, xerography, and similar applications. Chemically, it resembles sulphur, and forms compounds with selenium in the

+2, +4, and +6 oxidation states. Selenium was discovered in 1817 by Jöns Berzelius.

**selenium cell** Either of two types of \*photoelectric cell; one type relies on the photoconductive effect, the other on the photovoltaic effect (see PHOTOELECTRIC EFFECT). In the photoconductive selenium cell an external e.m.f. must be applied; as the selenium changes its resistance on exposure to light, the current produced is a measure of the light energy falling on the selenium. In the photovoltaic selenium cell, the e.m.f. is generated within the cell. In this type of cell, a thin film of vitreous or metallic selenium is applied to a metal surface, a transparent film of another metal, usually gold or platinum, being placed over the selenium. Both types of cell are used as light meters in photography.

**selenology** The branch of astronomy concerned with the scientific study of the \*moon.

**self-assembly** See SELF-ORGANIZATION.

**self-exciting generator** A type of electrical generator in which the field electromagnets are excited by current from the generator output.

**self-fertilization** See FERTILIZATION.

**self-inductance** See INDUCTANCE.

**selfish DNA** Regions of DNA that apparently have no function (they are also known as 'junk' DNA) and exist between those regions of DNA that represent the genes. \*Transposons are good examples. Certain types of \*repetitive DNA also have 'selfish' characteristics. This DNA is said to be 'selfish' as it seemingly exists only to pass copies of itself from one generation to another; it does so by using the organism in which it is contained as a survival machine. This is known as the **selfish DNA theory**. The greatest amounts of selfish DNA are found in vertebrates and higher plants. The presence of selfish DNA may be due to an unrecognizable function that it performs or because the cell has no way of halting its increase in the genome.

**self-organization** The spontaneous order arising in a system when certain parameters of the system reach critical values. Self-organization occurs in many

systems in physics, chemistry, and biology. An example in physics is the \*Bénard cell. In chemistry, **self-assembly** is one of the features of \*supramolecular chemistry. Self-organization can occur when a system is driven far from thermal \*equilibrium. Since a self-organizing system is open to its environment, the second law of \*thermodynamics is not violated by the formation of an ordered phase, as entropy can be transferred to the environment. Self-organization is related to the concepts of \*broken symmetry, \*complexity, nonlinearity, and \*non-equilibrium statistical mechanics. Many systems that undergo transitions to self-organization can also undergo transitions to \*chaos.

**self-pollination** See POLLINATION.

**self-sterility** The condition found in many hermaphrodite organisms in which male and female reproductive cells produced by the same individual will not fuse to form a zygote, or if they do, the zygote is unable to develop into an embryo. In plants this is usually termed **self-incompatibility** (see INCOMPATIBILITY).

**Seliwanoff's test** A biochemical test to identify the presence of ketonic sugars, such as fructose, in solution. It was devised by the Russian chemist F. F. Seliwanoff. A few drops of the reagent, consisting of resorcinol crystals dissolved in equal amounts of water and hydrochloric acid, are heated with the test solution and the formation of a red precipitate indicates a positive result.

**semen** A slightly alkaline fluid (pH 7.2-7.6) containing sperm and various secretions that is produced by a male mammal during copulation and is introduced into the body of the female by \*ejaculation. Spermatozoa are produced by the \*testes and the secretions by the \*prostate gland, \*seminal vesicles, and \*Cowper's glands. Semen also contains enzymes that activate the sperm after ejaculation.

**semicarbazones** Organic compounds containing the unsaturated group =C:N.NH.CO.NH<sub>2</sub>. They are formed when aldehydes or ketones react with a semicarbazide (H<sub>2</sub>N.NH.CO.NH<sub>2</sub>). Semicarbazones are crystalline compounds with

relatively high melting points. They are used to identify aldehydes and ketones in quantitative analysis: the semicarbazone derivative is made and identified by its melting point. Semicarbazones are also used in separating ketones from reaction mixtures: the derivative is crystallized out and hydrolysed to give the ketone.

**semicircular canals** The sense organ in vertebrates that is concerned with the maintenance of physical equilibrium (sense of balance). It occurs in the \*inner ear and consists of three looped canals set at right angles to each other and attached to the \*utricle. The canals contain a fluid (**endolymph**) that flows in response to movements of the head and body. A swelling (\*ampulla) at one attachment point of each canal contains sensory cells that respond to movement of the endolymph in any of the three planes. These sensory cells initiate nervous impulses to the brain.

**semiclassical approximation** An approximation technique used to calculate quantities in quantum mechanics. This technique is called the semiclassical approximation because the \*wave function is written as an asymptotic series with ascending powers of the Planck constant  $h$ , with the first term being purely classical. The semiclassical approximation is also known as the **Wentzel-Kramers-Brillouin (WKB) approximation**, named after its inventors Gregor Wentzel (1898–1978), Hendrik Anton Kramers (1894–1952), and Léon Brillouin (1889–1969), who invented it independently in 1926. The semiclassical approximation is particularly successful for calculations involving the \*tunnel effect, such as \*field emission and radioactive decay producing \*alpha particles.

**semiconductor** A crystalline solid with an electrical conductivity (typically  $10^5$ – $10^7$  siemens per metre) intermediate between that of a conductor (up to  $10^9$  S  $m^{-1}$ ) and an insulator (as low as  $10^{-15}$  S  $m^{-1}$ ). Semiconducting properties are a feature of \*metalloid elements, such as silicon and germanium. As the atoms in a crystalline solid are close together, the orbitals of their electrons overlap and their individual \*energy levels are spread out into \*energy bands. Conduction occurs in

semiconductors as the result of a net movement, under the influence of an electric field, of electrons in the conduction band and empty states, called **holes**, in the valence band. A hole behaves as if it was an electron with a positive charge. Electrons and holes are known as the **charge carriers** in a semiconductor. The type of charge carrier that predominates in a particular region or material is called the **majority carrier** and that with the lower concentration is the **minority carrier**. An **intrinsic semiconductor** is one in which the concentration of charge carriers is a characteristic of the material itself; electrons jump to the conduction band from the valence band as a result of thermal excitation, each electron that makes the jump leaving behind a hole in the valence band. Therefore, in an intrinsic semiconductor the charge carriers are equally divided between electrons and holes. In **extrinsic semiconductors** the type of conduction that predominates depends on the number and valence of the impurity atoms present. Germanium and silicon atoms have a valence of four. If impurity atoms with a valence of five, such as arsenic, antimony, or phosphorus, are added to the lattice, there will be an extra electron per atom available for conduction, i.e. one that is not required to pair with the four valence electrons of the germanium or silicon. Thus extrinsic semiconductors doped with atoms of valence five give rise to crystals with electrons as majority carriers, the so-called **n-type conductors**. Similarly, if the impurity atoms have a valence of three, such as boron, aluminium, indium, or gallium, one hole per atom is created by an unsatisfied bond. The majority carriers are therefore holes, i.e. **p-type conductors**.

Semiconductor devices have virtually replaced thermionic devices, because they are several orders of magnitude smaller, cheaper in energy consumption, and more reliable. The basic structure for electronic semiconductor devices is the **semiconductor diode** (see also TRANSISTOR). This consists of a silicon crystal doped in such a way that half is *p*-type and half is *n*-type. At the junction between the two halves there is a depletion layer in which electrons from the *n*-type have filled holes from the *p*-type. This sets up a potential

barrier, which tends to keep the remaining electrons in the *n*-region and the remaining holes in the *p*-region. However, if the *p*-region is biased with a positive potential, the height of the barrier is reduced; the diode is said to be forward biased, because the majority holes in the *p*-region can then flow to the *n*-region and majority electrons in the *n*-region flow to the *p*-region. When forward biased there is a good current flow across the barrier. On the other hand if the *p*-region is negatively biased, the height of the potential barrier is increased and there is only a small leakage current of minority electrons from the *p*-region able to flow to the *n*-region. Thus the *p-n* junction acts as an efficient rectifier, for which purpose it is widely used.

**semiconductor diode** See DIODE; SEMICONDUCTOR.

**semiconservative replication** The generally accepted method of \*DNA replication, in which the two strands of the DNA helix separate and free nucleotides pair with the exposed bases on the single chains to form two new DNA molecules, each containing one original and one newly synthesized strand of DNA.

**semimetal** See METALLOID.

**seminal receptacle** See SPERMATHECA.

**seminal vesicle** **1.** A pouch or sac in many male invertebrates and lower vertebrates that is used for storing sperm.

**2.** One of a pair of glands in male mammals that secrete a liquid component of \*semen into the vas deferens. This secretion is alkaline, which neutralizes the acidic conditions in the female genital tract, and contains fructose, used by the sperm as a source of energy.

**seminiferous tubules** See TESTIS.

**semipermeable membrane** A membrane that is permeable to molecules of the solvent but not the solute in \*osmosis. Semipermeable membranes can be made by supporting a film of material (e.g. cellulose) on a wire gauze or porous pot.

**semipolar bond** See CHEMICAL BOND.

**Semtex** A nitrogen-based stable odourless plastic \*explosive.

**senescence** The changes that occur in an organism (or a part of an organism) between maturity and death, i.e. ageing. Characteristically there is a deterioration in functioning as the cells become less efficient in maintaining and replacing vital cell components. In animals this results in a decline in physical ability and, in humans, there is also often a reduction in mental ability. Not all the parts of the body necessarily become senescent at the same time or age at the same rate. For example, in deciduous trees the shedding of senescent leaves in the autumn is a normal physiological process.

**sense organ** A part of the body of an animal that contains or consists of a concentration of \*receptors that are sensitive to specific stimuli (e.g. sound, light, pressure, heat). Stimulation of these receptors initiates the transmission of nervous impulses to the brain, where sensory information is analysed and interpreted. Examples of sense organs are the \*eye, \*ear, \*nose, and \*taste bud.

**senses** The faculties that enable animals to perceive information about their external environment or about the state of their bodies in relation to this environment (see SENSE ORGAN; VISION; HEARING; BALANCE; OLFACTION (SMELL); TASTE; TOUCH). Specific \*receptors are sensitive to pain, temperature, chemicals, etc.

**sensitivity (irritability)** One of the fundamental properties of all organisms: the capacity to detect, interpret, and respond to changes in the environment (e.g. the stimuli of light, touch, chemicals, etc.). Multicellular animals have specialized \*sense organs and \*effector organs for this purpose; in unicellular organisms, which lack a nervous system, the reception of, and response to, a stimulus occur in the same cell.

**sensitization** **1.** (of a cell) The alteration of the integrity of a plasma membrane resulting from the reaction of specific \*antibodies with \*antigens on the surface of the cell. In the presence of \*complement, the cell ruptures. **2.** (of an individual) Initial exposure to a specific antigen such that re-exposure to the same antigen causes a severe immune response (see ANAPHYLAXIS).

**sensory cell** See RECEPTOR.

**sensory neuron** A nerve cell (see NEURON) that transmits information about changes in the internal and external environment to the central nervous system. Sensory neurons are of two types. **Somatic sensory neurons** occur in peripheral nerves in the skin, skeletal muscle, joints, and bones. **Visceral sensory neurons** are located in sympathetic and parasympathetic nerves in the heart, lungs, and other organs.

**sepal** One of the parts of a flower making up the \*calyx. Sepals are considered to be modified leaves with a simpler structure. They are usually green and often hairy but in some plants, e.g. monk's hood, they may be brightly coloured.

**septivalent (heptavalent)** Having a valency of seven.

**septum** Any dividing wall in a plant or animal. Examples are the septa that separate the chambers of the heart.

**sequestration** The process of forming coordination complexes of an ion in solution. Sequestration often involves the formation of chelate complexes, and is used to prevent the chemical effect of an ion without removing it from the solution (e.g. the sequestration of  $\text{Ca}^{2+}$  ions in water softening). It is also a way of supplying ions in a protected form, e.g. sequestered iron solutions for plants in regions having alkaline soil.

**seré** A complete \*succession of plant communities, which results in the climax community. A seré is composed of a series of different plant communities that change with time. These communities are known as **seral stages** or **seral communities**.

**series** A sequence of terms each of which can be written in a form that is an algebraic function of its position in the series. For example, the \*exponential series  $1 + x + x^2/2! + x^3/3!$  has an  $n$ th term  $x^n/n!$ . The sum of all the terms from  $n = 0$  to  $n = \infty$  is written:

$$\sum_{n=0}^{\infty} x^n/n!$$

This series has an infinite number of terms and is therefore called an **infinite**

**series**. A **finite series** has a fixed number of terms. See also ASYMPTOTIC SERIES; CONVERGENT SERIES.

**series circuits** Circuits in which the circuit elements are arranged in sequence so that the same current flows through each of them in turn. For resistances in series, the total resistance is the sum of the individual resistances. For capacitors in series, the total capacitance,  $C$ , is given by  $1/C = 1/C_1 + 1/C_2 + 1/C_3 \dots$

**series-wound machine** See SHUNT.

**serine** See AMINO ACID.

**serology** The laboratory study of blood serum and its constituents, particularly \*antibodies and \*complement, which play a part in the \*immune response.

**serotonin (5-hydroxytryptamine; 5-HT)** A compound, derived from the amino acid tryptophan, that affects the diameter of blood vessels and also functions as a \*neurotransmitter. It is released by \*mast cells, \*basophils, and \*platelets and acts as a mediator of inflammation and allergic reactions. In the brain it is thought to influence mood: the **SSRIs** (selective serotonin reuptake inhibitors) are a class of antidepressant drugs that increase the levels of serotonin in the brain by blocking its resorption by the nerve endings there. See also LYSERGIC ACID DIETHYLAMIDE.

**serous membrane (serosa)** A tissue consisting of a layer of \*mesothelium attached to a surface by a thin layer of connective tissue. Serous membrane lines body cavities that do not open to the exterior; the \*peritoneum, \*pleura, and serous \*pericardium are examples.

**serpentine** Any of a group of hydrous magnesium silicate minerals with the general composition  $\text{Mg}_3\text{Si}_2\text{O}_5(\text{OH})_4$ . Serpentine is monoclinic and occurs in two main forms: **chrysotile**, which is fibrous and the chief source of \*asbestos; and **antigorite**, which occurs as platy masses. It is generally green or white with a mottled appearance, sometimes resembling a snakeskin – hence the name. It is formed through the metamorphic alteration of ultrabasic rocks rich in olivine, pyroxene, and amphibole. **Serpentinite** is a rock con-

sisting mainly of serpentine; it is used as an ornamental stone.

**Sertoli cells (sustentacular cells)** Cells that line the seminiferous tubules in the \*testis, named after the Italian histologist Enrico Sertoli (1842–1910). Sertoli cells protect the spermatids (developing germ cells) and convey nutrients to both the developing and mature spermatozoa. They also produce a hormone, **inhibin**, which can inhibit \*follicle-stimulating hormone and thereby regulate production of spermatozoa.

**serum** See BLOOD SERUM.

**sesqui-** Prefix indicating a ratio of 2:3 in a chemical compound. For example, a sesquioxide has the formula  $M_2O_3$ .

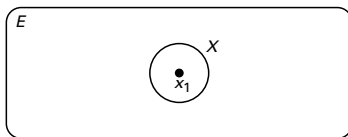

**sesquiterpene** See TERPENES.

**sessile 1.** Describing animals that live permanently attached to a surface, i.e. sedentary animals. Many marine animals, e.g. sea anemones and limpets, are sessile.

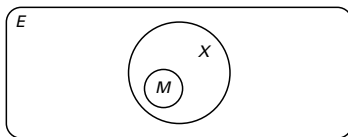

**2.** Describing any organ that does not possess a stalk where one might be expected. For example, the leaves of the oak (*Quercus robur*) are attached directly to the twigs.

**seta 1.** A bristle or hair in many invertebrates. Setae are produced by the epidermis and consist either of a hollow projection of cuticle containing all or part of an epidermal cell (as in insects) or are composed of chitin (as in the \*chaetae of annelid worms). **2.** See SPOROGENIUM.

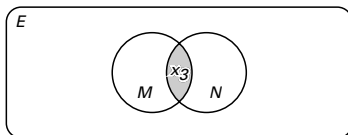

**sets** Collections of objects or elements that have at least one characteristic in common. For example, the set  $X$  may consist of all the elements  $x_1, x_2, x_3$ , etc. This is written  $\{x_1, x_2, x_3, \dots\} = X$ . A specific element in a set is characterized by  $x_1 \in X$ , meaning  $x_1$  is a member of set  $X$ . A **subset** of set  $X$ , say  $M$ , would be written  $M \subset X$ , i.e.  $M$  is contained in  $X$ . If  $x_3$  is a member of both subsets  $M$  and  $N$ , then  $x_3 \in (M \cap N)$ , i.e.  $x_3$  belongs to the **intersection** of  $M$  and  $N$ .  $M \cup N$  means the **union** of  $M$  and  $N$ . For example, if  $M$  consists of  $\{1, 4, 5, 8\}$  and  $N$  consists of  $\{2, 3, 4, 5\}$  then  $M \cap N = \{4, 5\}$  and  $M \cup N = \{1, 2, 3, 4, 5, 8\}$ . In the diagram, the rectangle represents the universal set  $E$ , circles represent sets or subsets. These diagrams are called **Venn diagrams**,

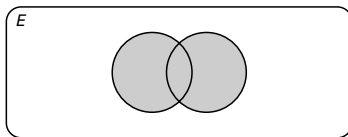

$$x_1 \in X$$

$$M \subset X$$

$$x_3 \in (M \cap N)$$

$$M \cup N$$

Sets

after John Venn (1834–1923), who invented them.

**sewage** Waste matter from industrial and domestic sources that is dissolved or suspended in water. Raw (untreated) sewage is a pollutant. It has a high content of organic matter (notably faeces and nitrogenous waste) and therefore provides a rich source of food for many decomposers (bacteria, fungi) and \*detritivores, some of which are pathogenic to humans. The release of raw (untreated) sewage into a river causes eutrophication (see EUTROPHIC); there is a sudden increase in the \*biochemical oxygen demand (BOD), as the organisms that feed on sewage proliferate and use up the available dissolved oxygen in the river. Oxygen-sensitive organisms, such as fish, will die. Certain organisms can proliferate in particular

concentrations of sewage, depending on their tolerance, and can be used as markers of the extent to which a river is polluted by sewage. For example, *Tubifex* worms are able to tolerate high concentrations of sewage.

Sewage can be treated before release. This involves a number of stages, including filtration, sedimentation, and microbial degradation (notably by \*methanogens). When most of the solid waste has been removed, the remaining liquid (**effluent**) is discharged into rivers, etc. During sedimentation, particulate organic matter accumulates at the bottom of large tanks. This material, known as **sludge**, is periodically removed, further decomposed by microorganisms, and then sold as fertilizer or dumped.

**sex chromosome** A chromosome that operates in the sex-determining mechanism of a species. In many animals there are two kinds of sex chromosomes; for example, in mammals there is a large **X chromosome** and a much smaller **Y chromosome**. A combination of two X chromosomes occurs in a female while one X and one Y chromosome is found in males. Sex chromosomes carry genes governing the development of sex organs and secondary sexual characteristics (see TESTIS-DETERMINING FACTOR). They also carry other genes unrelated to sex (see SEX LINKAGE). See also SEX DETERMINATION.

**sex determination** The method by which the distinction between males and females is established in a species. It is usually under genetic control. Equal numbers of males and females are produced when sex is determined by \*sex chromosomes or by a contrasting pair of alleles. In some species (e.g. bees) females develop from fertilized eggs and males from unfertilized eggs. This does not produce equal numbers. Environmental factors (e.g. temperature) can also play a role in determining the sex of developing individuals.

**sex hormones** Steroid hormones that control sexual development. The most important are the \*androgens and \*oestrogens.

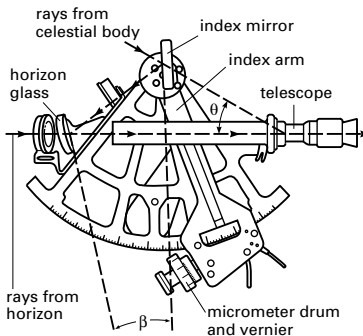

**sexivalent (hexavalent)** Having a valency of six.

**sex linkage** The tendency for certain inherited characteristics to occur far more frequently in one sex than the other. For example, red-green colour blindness and \*haemophilia affect men more often than women. This is because the genes governing normal colour vision and blood clotting occur on the X \*sex chromosome.

Women have two X chromosomes. If one carries an abnormal allele it is likely that its effects will be masked by a normal allele on the other X chromosome. However, men only have one X chromosome and any abnormal alleles therefore will not be masked. See also CARRIER.

**sex ratio** The ratio of the number of females to the number of males in a \*population. Because the mortality rates in the two sexes may be different, the sex ratios in different age classes may differ.

**sextant** An instrument used in navigation to measure the altitude of a celestial body. Originally it had an arc of  $60^\circ$  (one sixth of a circle, hence its name) but modern instruments have various angles. The sextant uses two mirrors: the horizon glass, in which only the lower half is silvered, and the index mirror, which can be rotated about an axis perpendicular to the plane of the instrument (see illustration). An arm attached to the index glass sweeps round the calibrated arc, from which angles are read. The instrument is aimed at the horizon and the index mirror rotated until the celestial object can also be seen through the telescope. After careful adjustment to make the image of

A sextant

the celestial body just touch the horizon, the angle is read off the graduated scale.

**sexual intercourse (coitus; copulation; mating)** The process by which spermatozoa from a male are deposited in the body of a female during \*sexual reproduction. In mammals the penis of the male becomes erect and stiff as its tissues become filled with blood, enabling it to be inserted into the vagina of the female. Thrusting movements of the penis result in \*ejaculation, in which \*semen, containing spermatozoa, is deposited in the vagina.

**sexually transmitted disease (STD)** Any disease that is passed from one individual to another during sexual intercourse or other types of sexual activity. These diseases have been traditionally referred to as **venereal diseases**. They include gonorrhoea, caused by the bacterium *Neisseria gonorrhoeae*; syphilis, due to infection by the bacterium *Treponema pallidum*; genital herpes, which is caused by a herpesvirus; and \*AIDS, resulting from infection with \*HIV, a retrovirus. The transmission of sexually transmitted diseases can be reduced by limiting the number of sexual partners and by the use of condoms (see BIRTH CONTROL), which reduces the risk of contact with body fluids that harbour the microorganisms that cause these diseases.

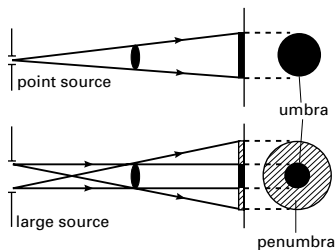

**sexual reproduction** A form of reproduction that involves the fusion of two reproductive cells (\*gametes) in the process of \*fertilization. Normally, especially in animals, it requires two parents, one male and the other female. However, most plants bear both male and female reproductive organs and self-fertilization may occur, as it does in hermaphrodite animals. Gametes are formed by \*meiosis, a special kind of cell division in the parent reproductive organs that both reassorts the genetic material and halves the chromosome number. Meiosis thus ensures genetic variability in the gametes and therefore in the offspring resulting from their subsequent fusion. Sexual reproduction, unlike \*asexual reproduction, therefore generates variability within a species. However, it depends on there being reliable means of bringing together male and

female gametes, and many elaborate mechanisms have evolved to ensure this.

**sexual selection** The means by which it is assumed that certain \*secondary sexual characteristics, particularly of male animals, have evolved. Females presumably choose to mate with the male that gives the best courtship display and therefore has the brightest coloration, etc.: these features would be inherited by its male offspring and would thus tend to become exaggerated down the generations.

**Seyfert galaxy** A type of galaxy, typically a spiral or barred spiral, with an active \*galactic nucleus. The nucleus is brighter than the spiral arms, too bright to derive its radiation only from stars. It is thought that there is probably a low-power \*quasar-like object at the centre. It is named after Carl Keenan Seyfert (1911–60).

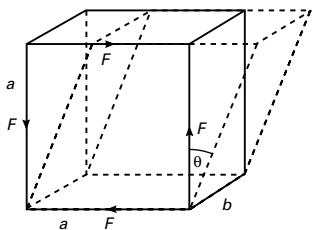

**shadow** An area of darkness formed on a surface when an object intercepts the light falling on the surface from a source. In the case of a point source the shadow has a sharply defined outline. If the source has an appreciable size the shadow has two distinct regions; one of full-shadow, called the **umbra**, the other of half-shadow, called the **penumbra** (see illustration).

Shadows

**shale** A form of \*clay that occurs in thin layers. Shales are very common \*sedimentary rocks. See also OIL SHALE.

**shearing force** A force that acts parallel to a plane rather than perpendicularly, as with a tensile or compressive force. A **shear stress** requires a combination of four forces acting over (most simply) four

Shearing force

sides of a plane and produces two equal and opposite couples. It is measured as the ratio of one shearing force to the area over which it acts,  $F/(ab)$  in the diagram. The shear strain is the angular deformation,  $\theta$ , in circular measure. The **shear modulus** is the ratio of the shear stress to the shear strain (see also ELASTIC MODULUS).

**shear modulus** See ELASTIC MODULUS; SHEARING FORCE.

**shell** See ATOM.

**shell model** **1.** See ATOM. **2.** A model of the atomic nucleus in which nucleons are assumed to move under the influence of a central field in shells that are analogous to atomic electron shells. The model provides a good explanation of the stability of nuclei that have \*magic numbers and is successful in predicting other properties of many nuclei.

**sherardizing** The process of coating iron or steel with a zinc corrosion-resistant layer by heating the iron or steel in contact with zinc dust to a temperature slightly below the melting point of zinc. At a temperature of about 371°C the two metals amalgamate to form internal layers of zinc-iron alloys and an external layer of pure zinc. The process was invented by Sherard Cowper-Coles (d. 1935).

**Sherrington, Sir Charles Scott** (1857–1952) British physiologist, who became professor of physiology at Oxford University in 1913. After early work on antitoxins he began studying human reflex reactions. Like \*Pavlov in Russia, he discovered conditioned reflexes. His subsequent research concerned the functioning of neurons, for which he shared the 1932

Nobel Prize for physiology or medicine with Sir Edgar \*Adrian.

**shielding** **1.** A barrier surrounding a region to exclude it from the influence of an energy field. For example, to protect a region from an electric field an earthed barrier is required; to protect it from a magnetic field a shield of high magnetic permeability is needed. **2.** A barrier used to surround a source of harmful or unwanted radiations. For example, the core of a \*nuclear reactor is surrounded by a cement or lead shield to absorb neutrons and other dangerous radiation. **3.** (in atoms) the barrier provided by inner electron shells to the influence of nuclear charge on outer electrons. Shielding has an effect on ionic radius, as in the \*lanthanoids.

**shivering** See THERMOGENESIS.

**SHM** See SIMPLE HARMONIC MOTION.

**Shockley, William** See BARDEEN, JOHN.

**shock wave** A very narrow region of high pressure and temperature formed in a fluid when the fluid flows supersonically over a stationary object or a projectile flying supersonically passes through a stationary fluid. A shock wave may also be generated by violent disturbances in a fluid, such as a lightning stroke or a bomb blast.

**shoot** The aerial part of a vascular plant. It develops from the \*plumule and consists of a stem supporting leaves, buds, and flowers.

**short-day plant** A plant in which flowering can be induced or enhanced by short days, usually of less than 12 hours of daylight. Examples are strawberry and chrysanthemum. See PHOTOPERIODISM. Compare DAY-NEUTRAL PLANT; LONG-DAY PLANT.

**short period** See PERIODIC TABLE.

**short-sightedness** See MYOPIA.

**shoulder girdle** See PECTORAL GIRDLE.

**shower** See COSMIC RADIATION.

**shunt** An electrical resistor or other element connected in parallel with some other circuit or device, to take part of the current passing through it. For example, a

shunt is used across the terminals of a galvanometer to increase the current that can pass through the system. A **shunt-wound** electric generator or motor is one in which the field winding is in parallel with the armature circuit. In a **series-wound** electrical machine the field coils and the armature circuit are in series.

**sial** The rocks that form the earth's continental crust. These are granite rock types rich in silica ( $\text{SiO}_2$ ) and aluminium (Al), hence the name. *Compare* SIMA.

**siblings** Individuals that have both parents in common.

**sickle-cell disease** *See* POLYMORPHISM.

**sideband** The band of frequencies above or below the frequency of the carrier wave in a telecommunications system within which the frequency components of the wave produced by \*modulation fall. For example, if a carrier wave of frequency  $f$  is modulated by a signal of frequency  $x$ , the **upper sideband** will have a frequency  $f + x$  and the **lower sideband** a frequency  $f - x$ .

**side chain** *See* CHAIN.

**side reaction** A chemical reaction that occurs at the same time as a main reaction but to a lesser extent, thus leading to other products mixed with the main products.

**sidereal day** *See* DAY.

**sidereal period** The time taken for a planet or satellite to complete one revolution of its orbit measured with reference to the background of the stars. *See also* DAY; SYNODIC PERIOD; YEAR.

**siderite** A brown or grey-green mineral form of iron(II) carbonate,  $\text{FeCO}_3$ , often with magnesium and manganese substituting for the iron. It occurs in sedimentary deposits or in hydrothermal veins and is an important iron ore. It is found in England, Greenland, Spain, N Africa, and the USA.

**siemens** Symbol S. The SI unit of electrical conductance equal to the conductance of a circuit or element that has a resistance of 1 ohm.  $1 \text{ S} = 10^{-1} \Omega$ . The unit was formerly called the mho or reciprocal

ohm. It is named after Ernst Werner von Siemens (1816–92).

**sieve element** A type of plant cell occurring within the \*phloem. Sieve elements combine to form a series of tubes (**sieve tubes**) connecting the leaves, shoots, and roots in a fine network. Food materials are transported from one element to another via perforations termed **sieve areas** or **sieve plates**. Sieve elements contain little cytoplasm and no nucleus. Their metabolic activities are supplemented by \*companion cells in angiosperms and by albuminous cells in gymnosperms.

**sievert** The SI unit of dose equivalent (*see* RADIATION UNITS). It is named after the Swedish physicist Rolf Sievert (1896–1966).

**sieve tube** A tube within the \*phloem tissue of a plant, composed of joined \*sieve elements.

**sigma bond** *See* ORBITAL.

**sigma electron** An electron in a sigma orbital. *See* ORBITAL.

**sigma particle** A type of spin  $\frac{1}{2}$  \*baryon. There are three types of sigma particles, denoted  $\Sigma^-$ ,  $\Sigma^0$ ,  $\Sigma^+$ , for the negatively charged, electrically neutral, and positively charged forms, respectively. The quark content of the sigma particles are  $\Sigma^-$  (dds),  $\Sigma^0$  (dus),  $\Sigma^+$  (uus), where d, u, and s denote down, up, and strange, respectively. The masses of the sigma particles are 1189.36 MeV ( $\Sigma^+$ ), 1192.46 MeV ( $\Sigma^0$ ), 1197.34 MeV ( $\Sigma^-$ ); their average lifetimes are  $0.8 \times 10^{-10}$  s ( $\Sigma^+$ ),  $5.8 \times 10^{-20}$  s ( $\Sigma^0$ ), and  $1.5 \times 10^{-10}$  s ( $\Sigma^-$ ).

**signal** The variable parameter that contains information and by which information is transmitted in an electronic system or circuit. The signal is often a voltage source in which the amplitude, frequency, and waveform can be varied.

**signal molecule** A molecule of a hormone, neurotransmitter, growth factor, or other chemical that binds specifically with a cell-surface \*receptor and thereby initiates a sequence of activities that triggers a response inside the cell. *See also* SECOND MESSENGER; G PROTEIN.

**sign convention** A set of rules determined by convention for giving plus or minus signs to distances in the formulae involving lenses and mirrors. The \*real-is-positive is the convention now usually adopted. The **New Cartesian convention** is now not widely used. In this convention distances to the right of the pole are treated as positive, those to the left as negative. This system has the advantage of conforming to the sign convention used with Cartesian coordinates in mathematics and is therefore preferred by some for the more complicated calculations.

**significant figures** The number of digits used in a number to specify its accuracy. The number 6.532 is a value taken to be accurate to four significant figures. The number  $7.3 \times 10^3$  is accurate only to three significant figures. Similarly 0.0732 is also only accurate to three significant figures. In these cases the zeros only indicate the order of magnitude of the number, whereas 7.065 is accurate to four significant figures as the zero in this case is significant in expressing the value of the number.

**sign stimulus (releaser)** The essential feature of a stimulus, which is necessary to elicit a response. For example, a red belly (characteristic of courting male sticklebacks) is the sign stimulus necessary to provoke an attack from a rival male; even a very crude model fish is attacked if it has a red undersurface.

**silane (silicane)** **1.** A colourless gas,  $\text{SiH}_4$ , which is insoluble in water; d.  $1.44 \text{ g dm}^{-3}$ ; r.d. 0.68 (liquid); m.p.  $-185^\circ\text{C}$ ; b.p.  $-112^\circ\text{C}$ . Silane is produced by reduction of silicon with lithium tetrahydridoaluminate(III). It is also formed by the reaction of magnesium silicide ( $\text{Mg}_2\text{Si}$ ) with acids, although other silicon hydrides are also produced at the same time. Silane itself is stable in the absence of air but is spontaneously flammable, even at low temperatures. It is a reducing agent and has been used for the removal of corrosion in inaccessible plants (e.g. pipes in nuclear reactors). **2. (silicon hydride)** Any of a class of compounds of silicon and hydrogen. They have the general formula  $\text{Si}_n\text{H}_{2n+2}$ . The first three in the series are silane itself ( $\text{SiH}_4$ ), **disilane** ( $\text{Si}_2\text{H}_6$ ), and **trisilane** ( $\text{Si}_3\text{H}_8$ ).

The compounds are analogous to the alkanes but are much less stable and only the lower members of the series can be prepared in any quantity (up to  $\text{Si}_6\text{H}_{14}$ ). No silicon hydrides containing double or triple bonds exist (i.e. there are no analogues of the alkenes and alkynes).

**silica** See SILICON(IV) OXIDE.

**silica gel** A rigid gel made by coagulating a sol of sodium silicate and heating to drive off water. It is used as a support for catalysts and also as a drying agent because it readily absorbs moisture from the air. The gel itself is colourless but, when used in desiccators, etc., a blue cobalt salt is added. As moisture is taken up, the salt turns pink, indicating that the gel needs to be regenerated (by heating).

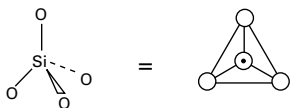

**silicane** See SILANE.

**silicate** Any of a group of substances containing negative ions composed of silicon and oxygen. The silicates are a very extensive group and natural silicates form the major component of most rocks (see SILICATE MINERALS). The basic structural unit is the tetrahedral  $\text{SiO}_4$  group. This may occur as a simple discrete  $\text{SiO}_4^{4-}$  anion as in the **orthosilicates**, e.g. **phenacite** ( $\text{Be}_2\text{SiO}_4$ ) and **willemitte** ( $\text{Zn}_2\text{SiO}_4$ ). Many larger silicate species are also found (see illustration). These are composed of  $\text{SiO}_4$  tetrahedra linked by sharing oxygen atoms as in the **pyrosilicates**,  $\text{Si}_2\text{O}_7^{6-}$ , e.g.  $\text{Sc}_2\text{Si}_2\text{O}_7$ . The linking can extend to such forms as bentonite,  $\text{BaTiSi}_3\text{O}_9$ , or alternatively infinite chain anions, which are single strand (\*pyroxenes) or double strand (\*amphiboles). Spodumene,  $\text{LiAl}(\text{SiO}_3)_2$ , is a pyroxene and the asbestos minerals are amphiboles. Large two-dimensional sheets are also possible, as in the various \*micas (see illustration), and the linking can extend to full three-dimensional framework structures, often with substituted trivalent atoms in the lattice. The \*zeolites are examples of this.

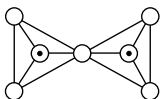

**silicate minerals** A group of rock-forming minerals that make up the bulk of the earth's outer crust (about 90%) and constitute one-third of all minerals. All silicate minerals are based on a fundamental structural unit – the  $\text{SiO}_4$  tetrahedron (see SILICATE). They consist of a

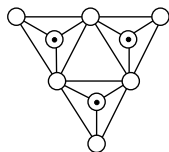

metal (e.g. calcium, magnesium, aluminium) combined with silicon and oxygen. The silicate minerals are classified on a structural basis according to how the tetrahedra are linked together. The six groups are: nesosilicates (e.g. olivine and \*garnet); sorosilicates (e.g. hemimorphite); cyclosilicates (e.g. axinite, \*beryl, and \*tourmaline); inosilicates (e.g. \*amphiboles and \*pyroxenes); phyllosilicates (e.g. \*micas, \*clay minerals, and \*talc); and tectosilicates (e.g. \*feldspars and

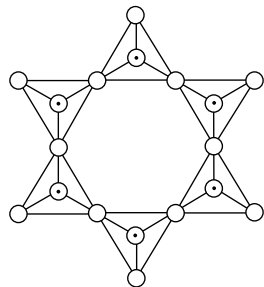

$\text{SiO}_4^{4-}$  as in  $\text{Be}_2\text{SiO}_4$  (phenacite)

$\text{Si}_2\text{O}_5^{2-}$  as in  $\text{Sc}_2\text{Si}_2\text{O}_7$  (thortveitite)

$\text{Si}_3\text{O}_9^{6-}$  as in  $\text{BaTiSi}_3\text{O}_9$  (bentonite)

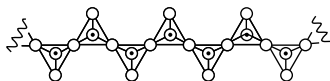

$\text{Si}_6\text{O}_{18}^{12-}$  as in  $\text{Be}_3\text{Al}_2\text{Si}_6\text{O}_{18}$  (beryl)

Structure of some discrete silicon ions

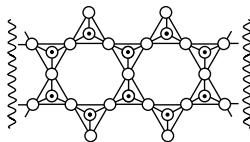

\*feldspathoids). Many silicate minerals are of economic importance.

**silicide** A compound of silicon with a more electropositive element. The silicides are structurally similar to the interstitial carbides but the range encountered is more diverse. They react with mineral acids to form a range of \*silanes.

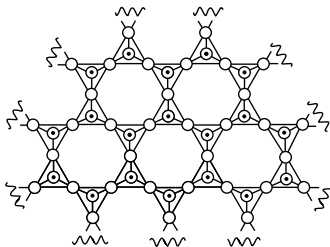

**silicon** Symbol Si. A metalloid element belonging to \*group 14 (formerly IVB) of the periodic table; a.n. 14; r.a.m. 28.086; r.d. 2.33; m.p. 1410°C; b.p. 2355°C. Silicon is the second most abundant element in the earth's crust (25.7% by weight) occurring in various forms of silicon(IV) oxide (e.g. \*quartz) and in \*silicate minerals. The element is extracted by reducing the oxide with carbon in an electric furnace and is used extensively for its semiconductor properties. It has a diamond-like crystal structure; an amorphous form also

single chain : pyroxenes

double chain : amphiboles

sheet : micas

Structure of some polymeric silicate ions

exists. Chemically, silicon is less reactive than carbon. The element combines with oxygen at red heat and is also dissolved by molten alkali. There is a large number of organosilicon compounds (e.g. \*siloxanes) although silicon does not form the range of silicon-hydrogen compounds and derivatives that carbon does (see SILANE). The element was identified by Antoine Lavoisier in 1787 and first isolated in 1823 by Jöns Berzelius.

**silicon carbide (carborundum)** A black solid compound, SiC, insoluble in water and soluble in molten alkali; r.d. 3.217; m.p. c. 2700°C. Silicon carbide is made by heating silicon(IV) oxide with carbon in an electric furnace (depending on the grade required sand and coke may be used). It is extremely hard and is widely used as an abrasive. The solid exists in both zinc blende and wurtzite structures.

**silicon chip** A single crystal of a semi-conducting silicon material, typically having millimetre dimensions, fabricated in such a way that it can perform a large number of independent electronic functions (see INTEGRATED CIRCUIT).

**silicon dioxide** See SILICON(IV) OXIDE.

**silicones** Polymeric compounds containing chains of silicon atoms alternating with oxygen atoms, with the silicon atoms linked to organic groups. A variety of silicone materials exist, including oils, waxes, and rubbers. They tend to be more resistant to temperature and chemical attack than their carbon analogues.

**silicon hydride** See SILANE.

**silicon(IV) oxide (silicon dioxide; silica)** A colourless or white vitreous solid, SiO<sub>2</sub>, insoluble in water and soluble (by reaction) in hydrofluoric acid and in strong alkali; m.p. 1713°C; b.p. 2230°C. The following forms occur naturally: **crystalite** (cubic or tetragonal crystals; r.d. 2.32); **tridymite** (rhombic; r.d. 2.26); \*quartz (hexagonal; r.d. 2.63-2.66); **lechatelierite** (r.d. 2.19). Quartz has two modifications: α-quartz below 575°C and β-quartz above 575°C; above 870°C β-quartz is slowly transformed to tridymite and above 1470°C this is slowly converted to cristobalite. Various forms of silicon(IV) oxide occur widely in the earth's crust;

yellow sand for example is quartz with iron(III) oxide impurities and flint is essentially amorphous silica. The gemstones amethyst, opal, and rock crystal are also forms of quartz.

Silica is an important commercial material in the form of **silica brick**, a highly refractive furnace lining, which is also resistant to abrasion and to corrosion. Silicon(IV) oxide is also the basis of both clear and opaque silica glass, which is used on account of its transparency to ultraviolet radiation and its resistance to both thermal and mechanical shock. A certain proportion of silicon(IV) oxide is also used in ordinary glass and in some glazes and enamels. It also finds many applications as a drying agent in the form of \*silica gel.

**silicula** A type of \*capsule formed from a bicarpellary ovary. It is longitudinally flattened and divided lengthwise into two cavities (**loculi**). It is broader than a \*siliqua. Examples include the fruits of *Alyssum* and candytuft.

**siliqua** A type of \*capsule formed from a bicarpellary ovary. It resembles a \*silicula but is longer than it is broad; an example is the fruit of the wallflower. See also LOMENTUM.

**siloxanes** A group of compounds containing silicon atoms bound to oxygen atoms, with organic groups linked to the silicon atoms, e.g. R<sub>3</sub>SiOSiR<sub>3</sub>, where R is an organic group. \*Silicones are polymers of siloxanes.

**Silurian** A geological period of the Palaeozoic era following the Ordovician period and extending until the beginning of the Devonian period. It began about 438 million years ago and lasted for about 30 million years. The Silurian was named by Roderick Murchison (1792-1871) after an ancient British tribe that inhabited South Wales, where he observed rocks of this period. The majority of Silurian life was marine but during the later part of the period primitive plants began to make their appearance on land. Trilobites and graptolites became less common, brachiopods were numerous and varied, crinoids became common for the first time, and corals also increased. The only known vertebrates during the Silurian were primitive fish; the first jawed fish ap-

peared later in the period. The Caledonian orogeny (mountain-building period) reached its peak towards the end of the Silurian.

**silver** Symbol Ag. A white lustrous soft metallic \*transition element; a.n. 47; r.a.m. 107.87; r.d. 10.5; m.p. 961.93°C; b.p. 2212°C. It occurs as the element and as the minerals argentite ( $\text{Ag}_2\text{S}$ ) and horn silver ( $\text{AgCl}$ ). It is also present in ores of lead and copper, and is extracted as a by-product of smelting and refining these metals. The element is used in jewellery, tableware, etc., and silver compounds are used in photography. Chemically, silver is less reactive than copper. A dark silver sulphide forms when silver tarnishes in air because of the presence of sulphur compounds. Silver(I) ionic salts exist (e.g.  $\text{AgNO}_3$ ,  $\text{AgCl}$ ) and there are a number of silver(II) complexes.

**silver(I) bromide** A yellowish solid compound,  $\text{AgBr}$ ; r.d. 6.5; m.p. 432°C. It can be precipitated from silver(I) nitrate solution by adding a solution containing bromide ions. It dissolves in concentrated ammonia solutions (but, unlike the chloride, does not dissolve in dilute ammonia). The compound is used in photographic emulsions.

**silver(I) chloride** A white solid compound,  $\text{AgCl}$ ; r.d. 5.6; m.p. 455°C; b.p. 1550°C. It can be precipitated from silver(I) nitrate solution by adding a solution of chloride ions. It dissolves in ammonia solution (due to formation of the complex ion  $[\text{Ag}(\text{NH}_3)_2]^+$ ). The compound is used in photographic emulsions.

**silver(I) iodide** A yellow solid compound,  $\text{AgI}$ ; r.d. 6.01; m.p. 558°C; b.p. 1506°C. It can be precipitated from silver(I) nitrate solutions by adding a solution of iodide ions. Unlike the chloride and bromide, it does not dissolve in ammonia solutions.

**silver-mirror test** See TOLLENS REAGENT.

**silver(I) nitrate** A colourless solid,  $\text{AgNO}_3$ ; r.d. 4.3; m.p. 212°C. It is an important silver salt because it is water-soluble. It is used in photography. In the laboratory, it is used as a test for chloride, bromide, and iodide ions and in volumetric

analysis of chlorides using an \*absorption indicator.

**silver(I) oxide** A brown slightly water-soluble amorphous powder,  $\text{Ag}_2\text{O}$ ; r.d. 7.14. It can be made by adding sodium hydroxide solution to silver(I) nitrate solution. Silver(I) oxide is strongly basic and is also an oxidizing agent. It is used in certain reactions in preparative organic chemistry; for example, moist silver(I) oxide converts haloalkanes into alcohols; dry silver oxide converts haloalkanes into ethers. The compound decomposes to the elements at 300°C and can be reduced by hydrogen to silver. With ozone it gives the oxide  $\text{AgO}$  (which is diamagnetic and probably  $\text{Ag}^+\text{Ag}^{\text{III}}\text{O}_2$ ).

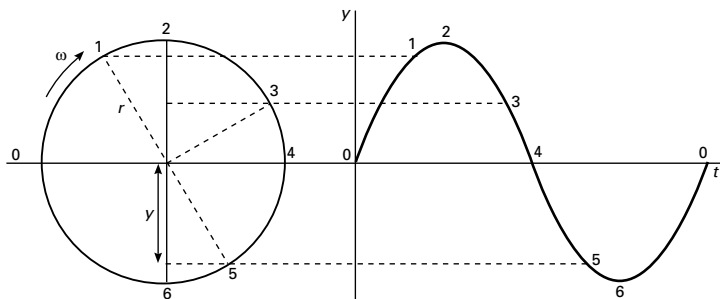

**sima** The rocks that form the earth's oceanic crust and underlie the upper crust. These are basaltic rock types rich in silica ( $\text{SiO}_2$ ) and magnesium (Mg), hence the name. The sima is denser and more plastic than the \*sial that forms the continental crust.

**simple harmonic motion (SHM)** A form of periodic motion in which a point or body oscillates along a line about a central point in such a way that it ranges an equal distance on either side of the central point and that its acceleration towards the central point is always proportional to its distance from it. One way of visualizing SHM is to imagine a point rotating around a circle of radius  $r$  at a constant angular velocity  $\omega$ . If the distance from the centre of the circle to the projection of this point on a vertical diameter is  $y$  at time  $t$ , this projection of the point will move about the centre of the circle with simple harmonic motion. A graph of  $y$  against  $t$  will be a sine wave, whose equation is  $y = r \sin \omega t$  (see diagram). See also PENDULUM.

**simulation** See MONTE CARLO SIMULATION.

**simultaneous equations** A set of equations that jointly specify the values of the variables they contain. If the number of variables is equal to the number of equations, each variable has a unique value, i.e. the equations can be solved.

**sine** See TRIGONOMETRIC FUNCTIONS.

Simple harmonic motion

**sine wave (sinusoidal wave)** Any waveform that has an equation in which one variable is proportional to the sine of the other. Such a waveform can be generated by an oscillator that executes \*simple harmonic motion.

**single bond** See CHEMICAL BOND.

**single-cell protein (SCP)** Protein produced by microorganisms, such as bacteria, yeasts, and unicellular algae, that is extracted for use as a component of human and animal foods.

**single circulation** The type of circulatory system that occurs in fishes, in which the blood passes only once through the heart in each complete circuit of the body. Compare DOUBLE CIRCULATION.

**single nucleotide polymorphism (SNP)** A variation in the base sequence occurring at any given single position in the genome (for example A instead of C) that is found in more than 1% of the population. It thus differs from a \*point mutation only in its greater frequency. SNPs can be found in all parts of the genome, including structural genes, regulatory regions, and noncoding 'junk' DNA. In the human genome overall, many millions of SNPs are thought to occur, making them exceptionally useful as \*molecular markers. Some are known to be linked to disease-causing alleles.

**single-sideband modulation** See AMPLITUDE MODULATION.

**singularity** An infinitely dense point located at the centre of a \*black hole, where the laws of physics no longer

apply. It is surrounded by the event horizon and so cannot be seen (because no light can escape from it).

**sinh** See HYPERBOLIC FUNCTIONS.

**sink hole (pot-hole)** A saucer-shaped or funnel-shaped depression in a limestone landscape formed when the rock is dissolved away by standing water. If a stream or river flows into the depression and disappears underground, it is called a swallow hole. Some sink holes are formed when the roof of a cave collapses.

**sinoatrial node** See PACEMAKER.

**sintered glass** Porous glass made by sintering powdered glass, used for filtration of precipitates in gravimetric analysis.

**sintering** The process of heating and compacting a powdered material at a temperature below its melting point in order to weld the particles together into a single rigid shape. Materials commonly sintered include metals and alloys, glass, and ceramic oxides. Sintered magnetic materials, cooled in a magnetic field, make especially retentive permanent magnets.

**sinus** A saclike cavity or organ in an animal, e.g. the **sinus venosus** in the heart of lower vertebrates.

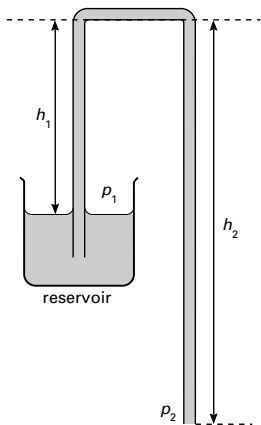

**sinusoid** A tiny blood vessel or blood-filled space in an organ. Sinusoids replace capillaries in certain organs, notably the liver; they allow more direct contact between the blood and the tissue it is supplying.

**sinusoidal oscillator** See OSCILLATOR.

**sinusoidal wave** See SINE WAVE.

**siphon** An inverted U-tube with one limb longer than the other. Liquid will be transferred from a reservoir at the base of the shorter limb to the end of the longer limb, provided that the U-tube is filled with liquid (see illustration). The device is useful for emptying an inaccessible container, such as a car's petrol tank.

The pressure ( $p_1$ ) on the liquid at the base of the short limb (length  $h_1$ ) is  $p - h_1k$ , where  $p$  is the atmospheric pressure and  $k$  is a constant equal to the product of the density of the liquid and the acceleration of free fall. The pressure ( $p_2$ ) on the liquid at the base of the long limb (length  $h_2$ ) is  $p - h_2k$ . Thus for fluid flow to occur through the tube, from short limb to long limb,  $p_1 > p_2$ , and for this to occur  $h_2 > h_1$ . Thus if the limbs are of equal length no flow will occur; it will only occur if the limb dipping into the reservoir is shorter than the delivering limb.

Siphon

**Siphonaptera** An order of wingless insects comprising the fleas. The body of a flea is laterally compressed and bears numerous backward-directed spines. Fleas live as blood-sucking ectoparasites of mammals and birds, having mouthparts adapted to piercing their host, injecting saliva to prevent clotting, and sucking up the blood. The long bristly legs can transmit energy stored in the elastic body wall

to leap relatively long distances (over 300 mm horizontally). Apart from causing irritation, fleas can transmit disease organisms, most notably bubonic plague bacteria, which can be carried from rats to humans by the rat flea (*Xenopsylla cheopis*). The whitish wormlike legless larvae feed on organic matter. After two moults the larva spins a cocoon and undergoes metamorphosis into the adult.

**Siphunculata (Anoplura)** An order of wingless insects comprising the sucking lice: blood-sucking ectoparasites of mammals, with piercing and sucking mouthparts forming a snoutlike proboscis. They constitute an irritating pest to humans and domestic animals and can transmit diseases, including typhoid. The human louse (*Pediculus humanus*) exists in two forms: the head louse (*P. humanus capitis*) and the body louse (*P. humanus corporis*).

**s-isomer** See ABSOLUTE CONFIGURATION.

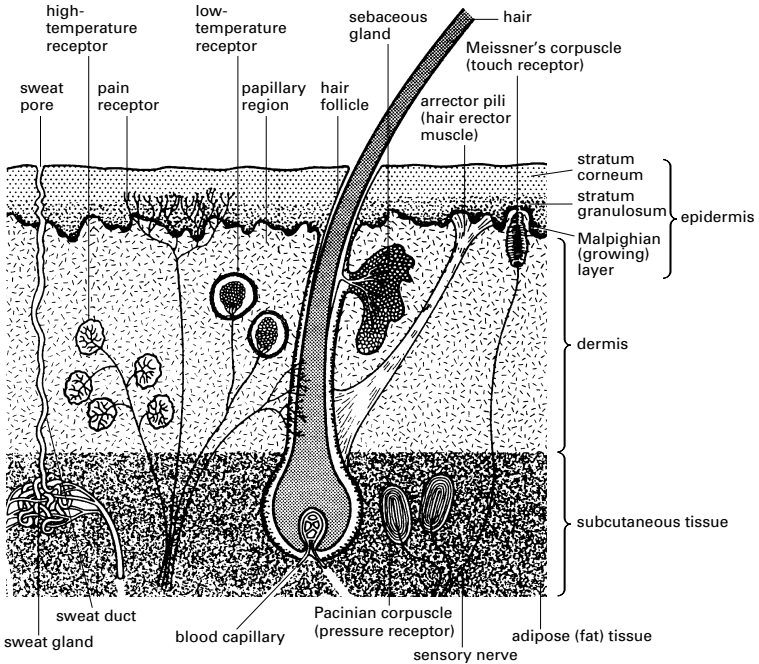

**Sisyphus effect** See LASER COOLING.

**Site of Special Scientific Interest** See SSSI.

**SI units** *Système International d'Unités*: the international system of units now recommended for all scientific purposes. A coherent and rationalized system of units derived from the \*m.k.s. units, SI units have now replaced \*c.g.s. units and \*Imperial units. The system has seven **base units** and two **dimensionless** (formerly called **supplementary**) units (see Appendix), all other units being derived from these nine units. There are 18 derived units with special names. Each unit has an agreed symbol (a capital letter or an initial capital letter if it is named after a scientist, otherwise the symbol consists of one or two lower-case letters). Decimal multiples of the units are indicated by a set of prefixes; whenever possible a prefix representing 10 raised to a power that is a multiple of three should be used.

**skeletal muscle** See VOLUNTARY MUSCLE.

**skeleton** The structure in an animal that provides mechanical support for the body, protection for internal organs, and a framework for anchoring the muscles. The skeleton may be external (see EXO-

Structure of mammalian skin

SKELETON) or internal (see ENDOSKELETON). Both types require \*joints to allow locomotion. The skeleton of higher vertebrates consists of a system of \*bones (see APPENDICULAR SKELETON; AXIAL SKELETON). Soft-bodied animals have a \*hydrostatic skeleton.

**skin** The outer layer of the body of a vertebrate (see illustration). It is composed of two layers, the \*epidermis and \*dermis, with a complex nervous and blood supply. The skin may bear a variety of specialized structures, including \*hair, \*scales, and \*feathers. This skin has an important role in protecting the body from mechanical injury, water loss, and the entry of harmful agents (e.g. disease-causing bacteria). It is also a sense organ, containing receptors sensitive to pain, temperature, and pressure. In warm-blooded animals it helps regulate body temperature by means of hair, fur, or feathers and \*sweat glands.

**skip distance** The minimum distance from the transmitter of a radio wave at which reception is possible by means of a sky wave (see RADIO TRANSMISSION). If a radio wave strikes the ionosphere at a small angle of incidence the wave passes through it and is not reflected. There is therefore a minimum angle of incidence at which reflection occurs for a given frequency. This leads to a region around a transmitter in which sky waves cannot be received. As the frequency of the transmission increases the minimum angle of incidence at which ionospheric reflection occurs becomes greater. Above about 4 megahertz there may be a region of several hundred kilometres around a transmitter, which is within the skip distance and in which ground waves are too attenuated to be effectively received. In this region no reception is possible.

**skull** The skeleton of the head. In mammals it consists of a \*cranium enclosing

the brain and the bones of the face and jaw. All the joints between the individual bones of the skull are immovable (*see* SUTURE) except for the joint between the mandible (lower jaw) and the rest of the skull. There is a large opening (**foramen magnum**) at the base of the skull through which the spinal cord passes from the brain.

**sky wave** *See* RADIO TRANSMISSION.

**slag** Material produced during the \*smelting or refining of metals by reaction of the flux with impurities (e.g. calcium silicate formed by reaction of calcium oxide flux with silicon dioxide impurities). The liquid slag can be separated from the liquid metal because it floats on the surface. *See also* BASIC SLAG.

**slaked lime** *See* CALCIUM HYDROXIDE.

**slate** A blue to grey fine-grained metamorphic rock characterized by the ease with which it cleaves into large thin sheets. It is formed mainly by the metamorphosis of mudstone or shale, in which platy minerals become aligned in parallel planes. Slate is traditionally used as a roofing material.

**sleep** A readily reversible state of reduced awareness and metabolic activity that occurs periodically in many animals. Usually accompanied by physical relaxation, the onset of sleep in humans and other mammals is marked by a change in the electrical activity of the brain, which is recorded by an \*electroencephalogram as waves of low frequency and high amplitude (**slow-wave sleep**). This is interspersed by short bouts of high-frequency low-amplitude waves (similar to wave patterns produced when awake) associated with restlessness, dreaming, and rapid eye movement (REM); this is called **REM** (or **paradoxical sleep**). Several regions of the brain are involved in sleep, especially the reticular formation of the \*brainstem.

**sleep movements** *See* NYCTINASTY.

**septon** *See* SUPERSYMMETRY.

**slime moulds** Small simple organisms widely distributed in damp habitats on land. They exist either as free cells (**myxamoebas**) or as multinucleate aggregates of cells (**plasmodia**), depending on the

stage of the life cycle. In the **plasmodial** (or **true**) **slime moulds** the nuclei of the plasmodium are not separated by plasma membranes; in **cellular slime moulds** the myxamoebas retain their plasma membranes after aggregating to form a 'pseudoplasmodium'. Cell walls are generally absent. Slime moulds show \*amoeboid movement and feed by ingesting small particles of food. They reproduce by means of spores. Slime moulds were formerly classified as fungi. They are now usually classified in two phyla, Myxomycota (plasmodial slime moulds) and Rhizopoda (amoebas and cellular slime moulds), of the kingdom Protocista.

**slow neutron** A neutron with a kinetic energy of less than  $10^2$  eV ( $10^{-17}$  joule). *See also* FAST NEUTRON; THERMALIZATION.

**sludge** *See* SEWAGE.

**slug 1.** (in physics) An f.p.s. unit of mass equal to the mass that will acquire an acceleration of  $1 \text{ ft sec}^{-2}$  when acted on by a force of one pound-force. **2.** (in zoology) *See* GASTROPODA.

**slurry** A paste consisting of a suspension of a solid in a liquid.

**small intestine** The portion of the \*alimentary canal between the stomach and the large intestine. It is subdivided into the \*duodenum, \*jejunum, and \*ileum. It plays an essential role in the final digestion and absorption of food.

**smectic** *See* LIQUID CRYSTAL.

**smell** *See* OLFACTION.

**smelting** The process of separating a metal from its ore by heating the ore to a high temperature in a suitable furnace in the presence of a reducing agent, such as carbon, and a fluxing agent, such as limestone. Iron ore is smelted in this way so that the metal melts and, being denser than the molten \*slag, sinks below the slag, enabling it to be removed from the furnace separately.

**smoke** A fine suspension of solid particles in a gas.

**smoker** An active hydrothermal vent on the sea floor that emits mineral-containing fluids at high pressure. Minerals precipitating out of solution as they rise in

the water give the appearance of smoke rising in the air. Dark sulphur compounds released from mid-ocean ridges form **black smokers**; the light-coloured emissions containing barytes or silica are **white smokers**. Sometimes deposits build up to form a tube-shaped chimney round the vent.

**smooth muscle** See INVOLUNTARY MUSCLE.

**smuts** A group of parasitic fungi of the phylum \*Basidiomycota. Many of these species attack the ears of cereal crops, replacing the grain by a mass of dark spores. Compare RUSTS.

**S<sub>N</sub>1** reaction See NUCLEOPHILIC SUBSTITUTION.

**S<sub>N</sub>2** reaction See NUCLEOPHILIC SUBSTITUTION.

**snakes** See SQUAMATA.

**Snell's law** See REFRACTION.

**SNG** Substitute (or synthetic) natural gas; a mixture of gaseous hydrocarbons produced from coal, petroleum, etc., and suitable for use as a fuel. Before the discovery of natural gas \*coal gas was widely used as a domestic and industrial fuel. This gave way to natural gas in the early part of this century in the US and other countries where natural gas was plentiful. The replacement of coal gas occurred somewhat later in the UK and other parts of Europe. More recently, interest has developed in ways of manufacturing hydrocarbon gas fuels. The main sources are coal and the naphtha fraction of petroleum. In the case of coal three methods have been used: (1) pyrolysis - i.e. more efficient forms of destructive distillation, often with further hydrogenation of the hydrocarbon products; (2) heating the coal with hydrogen and catalysts to give hydrocarbons - a process known as **hydroliquefaction** (see also BERGIUS PROCESS); (3) producing carbon monoxide and hydrogen and obtaining hydrocarbons by the \*Fischer-Tropsch process. SNG from naphtha is made by steam \*reforming.

**SNP** See SINGLE NUCLEOTIDE POLYMORPHISM.

**snRNP** See RIBONUCLEOPROTEIN.

**soap** A substance made by boiling animal fats with sodium hydroxide. The reaction involves the hydrolysis of \*glyceride esters of fatty acids to glycerol and sodium salts of the acids present (mainly the stearate, oleate, and palmitate), giving a soft semisolid with \*detergent action. Potassium hydroxide gives a more liquid product (**soft soap**). By extension, other metal salts of long-chain fatty acids are also called soaps. See also SAPONIFICATION.

**social behaviour** Any behaviour exhibited by a group of animals that interact with each other. Social behaviour ranges from moving as a herd in order to minimize the effects of predators to performing designated roles in highly organized societies. For example, within a colony of bees specific tasks, including tending the larvae, foraging for food, and controlling the temperature within the colony by wing fanning, are performed by different individuals.

**soda** Any of a number of sodium compounds, such as caustic soda (NaOH) or, especially, washing soda (Na<sub>2</sub>CO<sub>3</sub>·10H<sub>2</sub>O).

**soda ash** Anhydrous \*sodium carbonate, Na<sub>2</sub>CO<sub>3</sub>.

**soda lime** A mixed hydroxide of sodium and calcium made by slaking lime with caustic soda solution (to give NaOH + Ca(OH)<sub>2</sub>) and recovering greyish white granules by evaporation. The material is produced largely for industrial adsorption of carbon dioxide and water, but also finds some applications in pollution and effluent control. It is also used as a laboratory drying agent.

**sodamide** See SODIUM AMIDE.

**Soddy, Frederick** (1877-1956) British chemist, who worked with Ernest \*Rutherford in Canada and William \*Ramsay in London before finally settling in Oxford in 1919. His announcement in 1913 of the existence of \*isotopes won him the 1921 Nobel Prize for physics.

**sodium** Symbol Na. A soft silvery reactive element belonging to group 1 (formerly IA) of the periodic table (see ALKALI METALS); a.n. 11; r.a.m. 22.9898; r.d. 0.97; m.p. 97.8°C; b.p. 882-889°C. Sodium occurs as the chloride in sea water and in

the mineral halite. It is extracted by electrolysis in a \*Downs cell. The metal is used as a reducing agent in certain reactions and liquid sodium is also a coolant in nuclear reactors. Chemically, it is highly reactive, oxidizing in air and reacting violently with water (it is kept under oil). It dissolves in liquid ammonia to form blue solutions containing solvated electrons. Sodium is a major \*essential element required by animals. It is important in maintaining the \*acid-base balance and in controlling the volume of extracellular fluid and functions in the transmission of nerve impulses (see SODIUM PUMP). The element was first isolated by Humphry Davy in 1807.

**sodium acetate** See SODIUM ETHANOATE.

**sodium aluminate** A white solid,  $\text{NaAlO}_2$  or  $\text{Na}_2\text{Al}_2\text{O}_4$ , which is insoluble in ethanol and soluble in water giving strongly alkaline solutions; m.p. 1800°C. It is manufactured by heating bauxite with sodium carbonate and extracting the residue with water, or it may be prepared in the laboratory by adding excess aluminium to hot concentrated sodium hydroxide. In solution the ion  $\text{Al}(\text{OH})_4^-$  predominates. Sodium aluminate is used as a mordant, in the production of zeolites, in effluent treatment, in glass manufacture, and in cleansing compounds.

**sodium amide (sodamide)** A white crystalline powder,  $\text{NaNH}_2$ , which decomposes in water and in warm ethanol, and has an odour of ammonia; m.p. 210°C; b.p. 400°C. It is produced by passing dry ammonia over metallic sodium at 350°C. It reacts with red-hot carbon to give sodium cyanide and with nitrogen(I) oxide to give sodium azide.

**sodium azide** A white or colourless crystalline solid,  $\text{NaN}_3$ , soluble in water and slightly soluble in alcohol; hexagonal; r.d. 1.846; decomposes on heating. It is made by the action of nitrogen(I) oxide on hot sodamide ( $\text{NaNH}_2$ ) and is used as an organic reagent and in the manufacture of detonators.

**sodium benzenecarboxylate (sodium benzoate)** An either colourless crystalline or white amorphous powder,

$\text{C}_6\text{H}_5\text{COONa}$ , soluble in water and slightly soluble in ethanol. It is made by the reaction of sodium hydroxide with benzoic acid and is used in the dyestuffs industry and as a food preservative. It was formerly used as an antiseptic.

**sodium benzoate** See SODIUM BENZENECARBOXYLATE.

**sodium bicarbonate** See SODIUM HYDROGENCARBONATE.

**sodium bisulphate** See SODIUM HYDROGENSULPHATE.

**sodium bisulphite** See SODIUM HYDROGENSULPHITE.

**sodium bromide** A white crystalline solid,  $\text{NaBr}$ , known chiefly as the dihydrate (monoclinic; r.d. 2.17), and as the anhydrous salt (cubic; r.d. 3.20; m.p. 747°C; b.p. 1390°C). The dihydrate loses water at about 52°C and is very slightly soluble in alcohol. Sodium bromide is prepared by the reaction of bromine on hot sodium hydroxide solution or of hydrogen bromide on sodium carbonate solution. It is used in photographic processing and in analytical chemistry.

**sodium carbonate** Anhydrous sodium carbonate (**soda ash**, **sal soda**) is a white powder, which cakes and aggregates on exposure to air due to the formation of hydrates. The monohydrate,  $\text{Na}_2\text{CO}_3 \cdot \text{H}_2\text{O}$ , is a white crystalline material, which is soluble in water and insoluble in alcohol; r.d. 2.532; loses water at 109°C; m.p. 851°C.

The decahydrate,  $\text{Na}_2\text{CO}_3 \cdot 10\text{H}_2\text{O}$  (**washing soda**), is a translucent efflorescent crystalline solid; r.d. 1.44; loses water at 32–34°C to give the monohydrate; m.p. 851°C. Sodium carbonate may be manufactured by the \*Solvay process or by suitable crystallization procedures from any one of a number of natural deposits, such as:

**trona** ( $\text{Na}_2\text{CO}_3 \cdot \text{NaHCO}_3 \cdot 2\text{H}_2\text{O}$ ),  
**natron** ( $\text{Na}_2\text{CO}_3 \cdot 10\text{H}_2\text{O}$ ),  
**ranksite** ( $2\text{Na}_2\text{CO}_3 \cdot 9\text{Na}_2\text{SO}_4 \cdot \text{KCl}$ ),  
**pirsonnite** ( $\text{Na}_2\text{CO}_3 \cdot \text{CaCO}_3 \cdot 2\text{H}_2\text{O}$ ),  
**gaylussite** ( $\text{Na}_2\text{CO}_3 \cdot \text{CaCO}_3 \cdot 5\text{H}_2\text{O}$ ).

The method of extraction is very sensitive to the relative energy costs and transport costs in the region involved. Sodium carbonate is used in photography, in clean-

ing, in pH control of water, in textile treatment, glasses and glazes, and as a food additive and volumetric reagent. See also SODIUM SESQUICARBONATE.

**sodium chlorate(V)** A white crystalline solid,  $\text{NaClO}_3$ ; cubic; r.d. 2.49; m.p.  $250^\circ\text{C}$ . It decomposes above its melting point to give oxygen and sodium chloride. The compound is soluble in water and in ethanol and is prepared by the reaction of chlorine on hot concentrated sodium hydroxide. Sodium chlorate is a powerful oxidizing agent and is used in the manufacture of matches and soft explosives, in calico printing, and as a garden weed-killer.

**sodium chloride (common salt)** A colourless crystalline solid,  $\text{NaCl}$ , soluble in water and very slightly soluble in ethanol; cubic; r.d. 2.17; m.p.  $801^\circ\text{C}$ ; b.p.  $1413^\circ\text{C}$ . It occurs as the mineral \*halite (rock salt) and in natural brines and sea water. It has the interesting property of a solubility in water that changes very little with temperature. It is used industrially as the starting point for a range of sodium-based products (e.g. Solvay process for  $\text{Na}_2\text{CO}_3$ , Castner-Kellner process for  $\text{NaOH}$ ), and is known universally as a preservative and seasoner of foods. Sodium chloride has a key role in biological systems in maintaining electrolyte balances.

**sodium cyanide** A white or colourless crystalline solid,  $\text{NaCN}$ , deliquescent, soluble in water and in liquid ammonia, and slightly soluble in ethanol; cubic; m.p.  $564^\circ\text{C}$ ; b.p.  $1496^\circ\text{C}$ . Sodium cyanide is now made by absorbing hydrogen cyanide in sodium hydroxide or sodium carbonate solution. The compound is extremely poisonous because it reacts with the iron in haemoglobin in the blood, so preventing oxygen reaching the tissues of the body. It is used in the extraction of precious metals and in electroplating industries. Aqueous solutions are alkaline due to salt hydrolysis.

**sodium dichromate** A red crystalline solid,  $\text{Na}_2\text{Cr}_2\text{O}_7 \cdot 2\text{H}_2\text{O}$ , soluble in water and insoluble in ethanol. It is usually known as the dihydrate (r.d. 2.52), which starts to lose water above  $100^\circ\text{C}$ ; the compound decomposes above  $400^\circ\text{C}$ . It is

made by melting chrome iron ore with lime and soda ash and acidification of the chromate thus formed. Sodium dichromate is cheaper than the corresponding potassium compound but has the disadvantage of being hygroscopic. It is used as a mordant in dyeing, as an oxidizing agent in organic chemistry, and in analytical chemistry.

**sodium dihydrogenorthophosphate**  
See SODIUM DIHYDROGENPHOSPHATE(V).

**sodium dihydrogenphosphate(V) (sodium dihydrogenorthophosphate)** A colourless crystalline solid,  $\text{NaH}_2\text{PO}_4$ , which is soluble in water and insoluble in alcohol, known as the monohydrate (r.d. 2.04) and the dihydrate (r.d. 1.91). The dihydrate loses one water molecule at  $60^\circ\text{C}$  and the second molecule of water at  $100^\circ\text{C}$ , followed by decomposition at  $204^\circ\text{C}$ . The compound may be prepared by treating sodium carbonate with an equimolar quantity of phosphoric acid or by neutralizing phosphoric acid with sodium hydroxide. It is used in the preparation of sodium phosphate ( $\text{Na}_3\text{PO}_4$ ), in baking powders, as a food additive, and as a constituent of buffering systems. Both sodium dihydrogenphosphate and trisodium phosphate enriched in  $^{32}\text{P}$  have been used to study phosphate participation in metabolic processes.

**sodium dioxide** See SODIUM SUPEROXIDE.

**sodium ethanoate (sodium acetate)** A colourless crystalline compound,  $\text{CH}_3\text{COONa}$ , which is known as the anhydrous salt (r.d. 1.52; m.p.  $324^\circ\text{C}$ ) or the trihydrate (r.d. 1.45; loses water at  $58^\circ\text{C}$ ). Both forms are soluble in water and in ethoxyethane, and slightly soluble in ethanol. The compound may be prepared by the reaction of ethanoic acid (acetic acid) with sodium carbonate or with sodium hydroxide. Because it is a salt of a strong base and a weak acid, sodium ethanoate is used in buffers for pH control in many laboratory applications, in foodstuffs, and in electroplating. It is also used in dyeing, soaps, pharmaceuticals, and in photography.

**sodium fluoride** A crystalline compound,  $\text{NaF}$ , soluble in water and very

slightly soluble in ethanol; cubic; r.d. 2.56; m.p. 993°C; b.p. 1695°C. It occurs naturally as villiumite and may be prepared by the reaction of sodium hydroxide or of sodium carbonate with hydrogen fluoride. The reaction of sodium fluoride with concentrated sulphuric acid may be used as a source of hydrogen fluoride. The compound is used in ceramic enamels and as a preservative agent for fermentation. It is highly toxic but in very dilute solution (less than 1 part per million) it is used in the fluoridation of water for the prevention of tooth decay on account of its ability to replace OH groups with F atoms in the material of dental enamel.

**sodium formate** See SODIUM METHANOATE.

**sodium hexafluoraluminate** A colourless monoclinic solid,  $\text{Na}_3\text{AlF}_6$ , very slightly soluble in water; r.d. 2.9; m.p. 1000°C. It changes to a cubic form at 580°C. The compound occurs naturally as the mineral \*cryolite but a considerable amount is manufactured by the reaction of aluminium fluoride with alumina and sodium hydroxide or directly with sodium aluminate. Its most important use is in the manufacture of aluminium in the \*Hall-Heroult cell. It is also used in the manufacture of enamels, opaque glasses, and ceramic glazes.

**sodium hydride** A white crystalline solid, NaH; cubic; r.d. 0.92; decomposes above 300°C (slow); completely decomposed at 800°C. Sodium hydride is prepared by the reaction of pure dry hydrogen with sodium at 350°C. Electrolysis of sodium hydride in molten LiCl/KCl leads to the evolution of hydrogen; this is taken as evidence for the ionic nature of NaH and the presence of the hydride ion ( $\text{H}^-$ ). It reacts violently with water to give sodium hydroxide and hydrogen, with halogens to give the halide and appropriate hydrogen halide, and ignites spontaneously with oxygen at 230°C. It is a powerful reducing agent with several laboratory applications.

**sodium hydrogencarbonate (bicarbonate of soda; sodium bicarbonate)** A white crystalline solid,  $\text{NaHCO}_3$ , soluble in water and slightly soluble in ethanol; monoclinic; r.d. 2.159; loses carbon diox-

ide above 270°C. It is manufactured in the \*Solvay process and may be prepared in the laboratory by passing carbon dioxide through sodium carbonate or sodium hydroxide solution. Sodium hydrogencarbonate reacts with acids to give carbon dioxide and, as it does not have strongly corrosive or strongly basic properties itself, it is employed in bulk for the treatment of acid spillage and in medicinal applications as an antacid. Sodium hydrogencarbonate is also used in baking powders (and is known as **baking soda**), dry-powder fire extinguishers, and in the textiles, tanning, paper, and ceramics industries. The hydrogencarbonate ion has an important biological role as an intermediate between atmospheric  $\text{CO}_2/\text{H}_2\text{CO}_3$  and the carbonate ion  $\text{CO}_3^{2-}$ . For water-living organisms this is the most important and in some cases the only source of carbon.

**sodium hydrogensulphate (sodium bisulphate)** A colourless solid,  $\text{NaHSO}_4$ , known in anhydrous and monohydrate forms. The anhydrous solid is triclinic (r.d. 2.435; m.p. >315°C). The monohydrate is monoclinic and deliquescent (r.d. 2.103; m.p. 59°C). Both forms are soluble in water and slightly soluble in alcohol. Sodium hydrogensulphate was originally made by the reaction between sodium nitrate and sulphuric acid, hence its old name of **nitre cake**. It may be manufactured by the reaction of sodium hydroxide with sulphuric acid, or by heating equimolar proportions of sodium chloride and concentrated sulphuric acid. Solutions of sodium hydrogensulphate are acidic. On heating the compound decomposes (via  $\text{Na}_2\text{S}_2\text{O}_7$ ) to give sulphur trioxide. It is used in paper making, glass making, and textile finishing.

**sodium hydrogensulphite (sodium bisulphite)** A white solid,  $\text{NaHSO}_3$ , which is very soluble in water (yellow in solution) and slightly soluble in ethanol; monoclinic; r.d. 1.48. It decomposes on heating to give sodium sulphate, sulphur dioxide, and sulphur. It is formed by saturating a solution of sodium carbonate with sulphur dioxide. The compound is used in the brewing industry and in the sterilization of wine casks. It is a general

antiseptic and bleaching agent. *See also*

ALDEHYDES.

**sodium hydroxide (caustic soda)** A white translucent deliquescent solid, NaOH, soluble in water and ethanol but insoluble in ether; r.d. 2.13; m.p. 318°C; b.p. 1390°C. Hydrates containing 7, 5, 4, 3.5, 3, 2, and 1 molecule of water are known.

Sodium hydroxide was formerly made by the treatment of sodium carbonate with lime but its main source today is from the electrolysis of brine using mercury cells or any of a variety of diaphragm cells. The principal product demanded from these cells is chlorine (for use in plastics) and sodium hydroxide is almost reduced to the status of a by-product. It is strongly alkaline and finds many applications in the chemical industry, particularly in the production of soaps and paper. It is also used to adsorb acidic gases, such as carbon dioxide and sulphur dioxide, and is used in the treatment of effluent for the removal of heavy metals (as hydroxides) and of acidity. Sodium hydroxide solutions are extremely corrosive to body tissue and are particularly hazardous to the eyes.

**sodium iodide** A white crystalline solid, NaI, very soluble in water and soluble in both ethanol and ethanoic acid. It is known in both the anhydrous form (cubic; r.d. 3.67; m.p. 661°C; b.p. 1304°C) and as the dihydrate (monoclinic; r.d. 2.45). It is prepared by the reaction of hydrogen iodide with sodium carbonate or sodium hydroxide in solution. Like potassium iodide, sodium iodide in aqueous solution dissolves iodine to form a brown solution containing the  $I_3^-$  ion. It finds applications in photography and is also used in medicine as an expectorant and in the administration of radioactive iodine for studies of thyroid function and for treatment of diseases of the thyroid.

**sodium methanoate (sodium formate)** A colourless deliquescent solid, HCOONa, soluble in water and slightly soluble in ethanol; monoclinic; r.d. 1.92; m.p. 253°C; decomposes on further heating. The monohydrate is also known. The compound may be produced by the reaction of carbon monoxide with solid sodium hy-

droxide at 200°C and 10 atmospheres pressure; in the laboratory it can be conveniently prepared by the reaction of methanoic acid and sodium hydroxide. Its uses are in the production of oxalic acid (ethanedioic acid) and methanoic acid and in the laboratory it is a convenient source of carbon monoxide.

**sodium monoxide** A whitish-grey deliquescent solid,  $Na_2O$ ; r.d. 2.27; sublimes at 1275°C. It is manufactured by oxidation of the metal in a limited supply of oxygen and purified by sublimation. Reaction with water produces sodium hydroxide. Its commercial applications are similar to those of sodium hydroxide.

**sodium nitrate (Chile saltpetre)** A white solid,  $NaNO_3$ , soluble in water and in ethanol; trigonal; r.d. 2.261; m.p. 306°C; decomposes at 380°C. A rhombohedral form is also known. It is obtained from deposits of caliche or may be prepared by the reaction of nitric acid with sodium hydroxide or sodium carbonate. It was previously used for the manufacture of nitric acid by heating with concentrated sulphuric acid. Its main use is in nitrate fertilizers.

**sodium nitrite** A yellow hygroscopic crystalline compound,  $NaNO_2$ , soluble in water, slightly soluble in ether and in ethanol; rhombohedral; r.d. 2.17; m.p. 271°C; decomposes above 320°C. It is formed by the thermal decomposition of sodium nitrate and is used in the preparation of nitrous acid (reaction with cold dilute hydrochloric acid). Sodium nitrite is used in organic \*diazotization and as a corrosion inhibitor.

**sodium orthophosphate** *See* TRISODIUM PHOSPHATE(V).

**sodium peroxide** A whitish solid (yellow when hot),  $Na_2O_2$ , soluble in ice-water and decomposed in warm water or alcohol; r.d. 2.80; decomposes at 460°C. A crystalline octahydrate (hexagonal) is obtained by crystallization from ice-water. The compound is formed by the combustion of sodium metal in excess oxygen. At normal temperatures it reacts with water to give sodium hydroxide and hydrogen peroxide. It is a powerful oxidizing agent reacting with iodine vapour to give the io-

date and periodate, with carbon at 300°C to give the carbonate, and with nitrogen(II) oxide to give the nitrate. It is used as a bleaching agent in wool and yarn processing, in the refining of oils and fats, and in the production of wood pulp.

**sodium pump** A mechanism by which sodium ions are transported out of a eukaryotic cell across the plasma membrane. The process requires energy in the form of ATP, being a form of \*active transport. It maintains the differential concentrations of sodium and potassium ions on either side of the plasma membrane, which is necessary, for example, for establishing the \*resting potential of a neuron.

**sodium sesquicarbonate** A white crystalline hydrated double salt,  $\text{Na}_2\text{CO}_3 \cdot \text{NaHCO}_3 \cdot 2\text{H}_2\text{O}$ , soluble in water but less alkaline than sodium carbonate; r.d. 2.12; decomposes on heating. It may be prepared by crystallizing equimolar quantities of the constituent materials; it also occurs naturally as **trona** and in Searles Lake brines. It is widely used as a detergent and soap builder and, because of its mild alkaline properties, as a water-softening agent and bath-salt base. See also SODIUM CARBONATE.

**sodium sulphate** A white crystalline compound,  $\text{Na}_2\text{SO}_4$ , usually known as the anhydrous compound (orthorhombic; r.d. 2.67; m.p. 888°C) or the decahydrate (monoclinic; r.d. 1.46; which loses water at 100°C). The decahydrate is known as **Glauber's salt**. A metastable heptahydrate ( $\text{Na}_2\text{SO}_4 \cdot 7\text{H}_2\text{O}$ ) also exists. All forms are soluble in water, dissolving to give a neutral solution. The compound occurs naturally as

**mirabilite** ( $\text{Na}_2\text{SO}_4 \cdot 10\text{H}_2\text{O}$ ),

**threnardite** ( $\text{Na}_2\text{SO}_4$ ), and

**glauuberite** ( $\text{Na}_2\text{SO}_4 \cdot \text{CaSO}_4$ ).

Sodium sulphate may be produced industrially by the reaction of magnesium sulphate with sodium chloride in solution followed by crystallization, or by the reaction of concentrated sulphuric acid with solid sodium chloride. The latter method was used in the \*Leblanc process for the production of alkali and has given the name **salt cake** to impure industrial sodium sulphate. Sodium sulphate is used

in the manufacture of glass and soft glazes and in dyeing to promote an even finish. It also finds medicinal application as a purgative and in commercial aperient salts.

**sodium sulphide** A yellow-red solid,  $\text{Na}_2\text{S}$ , formed by the reduction of sodium sulphate with carbon (coke) at elevated temperatures. It is a corrosive and readily oxidized material of variable composition and usually contains polysulphides of the type  $\text{Na}_2\text{S}_2$ ,  $\text{Na}_2\text{S}_3$ , and  $\text{Na}_2\text{S}_4$ , which cause the variety of colours. It is known in an anhydrous form (r.d. 1.85; m.p. 1180°C) and as a nonahydrate,  $\text{Na}_2\text{S} \cdot 9\text{H}_2\text{O}$  (r.d. 1.43; decomposes at 920°C). Other hydrates of sodium sulphide have been reported. The compound is deliquescent, soluble in water with extensive hydrolysis, and slightly soluble in alcohol. It is used in wood pulping, dyestuffs manufacture, and metallurgy on account of its reducing properties. It has also been used for the production of sodium thiosulphate (for the photographic industry) and as a depilatory agent in leather preparation. It is a strong skin irritant.

**sodium sulphite** A white solid,  $\text{Na}_2\text{SO}_3$ , existing in an anhydrous form (r.d. 2.63) and as a heptahydrate (r.d. 1.59). Sodium sulphite is soluble in water and because it is readily oxidized it is widely used as a convenient reducing agent. It is prepared by reacting sulphur dioxide with either sodium carbonate or sodium hydroxide. Dilute mineral acids reverse this process and release sulphur dioxide. Sodium sulphite is used as a bleaching agent in textiles and in paper manufacture. Its use as an antioxidant in some canned foodstuffs gives rise to a slightly sulphurous smell immediately on opening, but its use is prohibited in meats or foods that contain vitamin B<sub>1</sub>. Sodium sulphite solutions are occasionally used as biological preservatives.

**sodium-sulphur cell** A type of \*secondary cell that has molten electrodes of sodium and sulphur separated by a solid electrolyte consisting of beta alumina (a crystalline form of aluminium oxide). When the cell is producing current, sodium ions flow through the alumina to the sulphur, where they form sodium

polysulphide. Electrons from the sodium flow in the external circuit. The opposite process takes place during charging of the cell. Sodium-sulphur batteries have been considered for use in electric vehicles because of their high peak power levels and relatively low weight. However, some of the output has to be used to maintain the operating temperature (about 370°C) and the cost of sodium is high.

**sodium superoxide (sodium dioxide)** A whitish-yellow solid,  $\text{NaO}_2$ , formed by the reaction of sodium peroxide with excess oxygen at elevated temperatures and pressures. It reacts with water to form hydrogen peroxide and oxygen.

**sodium thiosulphate (hypo)** A colourless efflorescent solid,  $\text{Na}_2\text{S}_2\text{O}_3$ , soluble in water but insoluble in ethanol, commonly encountered as the pentahydrate (monoclinic; r.d. 1.73; m.p. 42°C), which loses water at 100°C to give the anhydrous form (r.d. 1.66). It is prepared by the reaction of sulphur dioxide with a suspension of sulphur in boiling sodium hydroxide solution. Aqueous solutions of sodium thiosulphate are readily oxidized in the presence of air to sodium tetrathionate and sodium sulphate. The reaction with dilute acids gives sulphur and sulphur dioxide. It is used in the photographic industry and in analytical chemistry.

**sodium-vapour lamp** A form of \*electric lighting that gives a yellow light as a result of the luminous discharge obtained by the passage of a stream of electrons between tungsten electrodes in a tube containing sodium vapour. To facilitate starting, the tube also contains some neon; for this reason, until the lamp is warm the neon emits a characteristic pink glow. As the sodium vaporizes, the yellow light predominates. Sodium-vapour lamps are widely used as street lights because of their high luminous efficiency and because the yellow light is less absorbed than white light by fog and mist. Low-pressure sodium lamps emit a characteristic yellow light; in high-pressure lamps the atoms are sufficiently close to each other to interact and broaden the spectral lines into the orange and green regions.

**soft iron** A form of iron that contains

little carbon, has high relative permeability, is easily magnetized and demagnetized, and has a small hysteresis loss. Soft iron and other **soft ferromagnetic materials**, such as silicon steel, are used in making parts exposed to rapid changes of magnetic flux, such as the cores of electromagnets, motors, generators, and transformers.

By comparison, **hard ferromagnetic materials**, such as cobalt steel and various alloys of nickel, aluminium, and cobalt, have low relative permeability, are difficult to magnetize, and have a high hysteresis loss. They are used in making permanent magnets.

**soft matter** A general name given to non-crystalline condensed matter. This includes liquids, disordered solids (including glasses), liquid crystals, and random networks of polymers.

**soft radiation** Ionizing radiation of low penetrating power, usually used with reference to X-rays of long wavelength. *Compare* HARD RADIATION.

**soft soap** *See* SOAP.

**software** *See* COMPUTER.

**soft water** *See* HARDNESS OF WATER.

**softwood** *See* WOOD.

**soil** The layer of unconsolidated particles derived from weathered rock, organic material (\*humus), water, and air that forms the upper surface over much of the earth and supports plant growth. The formation of soil depends on the parent material (i.e. the original material from which the soil is derived), the climate and topography of the area, the organisms present in the soil, and the time over which the soil has been developing. Soils are often classified in terms of their structure and texture. The structure of a soil is the way in which the individual soil particles are bound together to form aggregates or peds. The structure types include platy, blocky, granular, and crumbly. The texture of a soil denotes the proportion of the various particle sizes that it contains. The four main texture classes are sand, silt, clay, and \*loam, of which loams are generally the best agricultural soils as they contain a mixture of all particle sizes. A number

of distinct horizontal layers can often be distinguished in a vertical section (profile) of soil – these are known as **soil horizons**. Four basic horizons are common to most soils: an uppermost A horizon (or **topsoil**) containing the organic matter; an underlying B horizon (or **subsoil**), which contains little organic material and is strongly leached; a C horizon consisting of weathered rock; and a D horizon comprising the bedrock. *See also* BROWN EARTH; CHERNOZEM; PODZOL.

**soil erosion** The removal and thinning of the soil layer due to climatic and physical processes, such as high rainfall, which is greatly accelerated by certain human activities, such as \*deforestation. Soil erosion can lead to a loss of agricultural land and if unchecked, eventually results in \*desertification.

**sol** A \*colloid in which small solid particles are dispersed in a liquid continuous phase.

**solar cell** An electric cell that uses the sun's radiation to produce usable electric current. Most solar cells consist of a single-crystal silicon *p-n* junction. When photons of light energy from the sun fall on or near the \*semiconductor junction the electron-hole pairs created are forced by the electric field at the junction to separate so that the holes pass to the *p*-region and the electrons pass to the *n*-region. This displacement of free charge creates an electric current when a load is connected across the terminals of the device (see illustration). Individual silicon solar cells cannot be made with a surface area

much in excess of 4000 mm<sup>2</sup> and the maximum power delivered by such a cell is approximately 0.6 W at about 0.5 V in full sun. The efficiency of such devices is about 15%. For practical use, therefore, solar cells have to be assembled in arrays. Panels of solar cells have been the exclusive source of power for satellites and space capsules. Their use on earth has been largely limited by their high cost, a reduction in the cost by a factor of 10 being required to make them competitive with other energy sources at present.

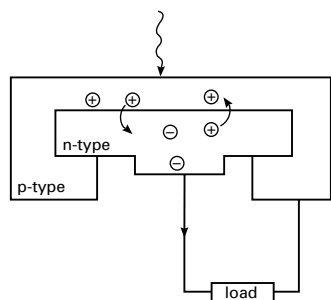

**solar constant** The rate at which solar energy is received per unit area at the outer limit of the earth's atmosphere at the mean distance between the earth and the sun. The value is 1.353 kW m<sup>-2</sup>.

**solar cycle** The 11-year period over which the sun's activity varies. The principal variable is in the number and disposition of sunspots. At the solar minimum, at the beginning of the cycle, there are no sunspots. Several weeks later they begin to appear at middle latitudes, then gradually drift towards the equator. This behaviour continues for about five years, accompanied by a general increase in the number of sunspots. The number decreases over the next six years until they disappear altogether. All activity within the sun can be associated with the cycle.

**solar day** *See* DAY.

**solar energy** The electromagnetic energy radiated from the sun. The tiny proportion (about  $5 \times 10^{-10}$  of the total) that falls on the earth is indicated by the \*solar constant. The total quantity of solar energy falling on the earth in one year is about  $4 \times 10^{18}$  J, whereas the total annual energy consumption of the earth's inhabitants is only some  $3 \times 10^{14}$  J. The sun, therefore, could provide all the energy needed. The direct ways of making use of solar energy can be divided into thermal methods (*see* SOLAR HEATING) and nonthermal methods (*see* SOLAR CELL).

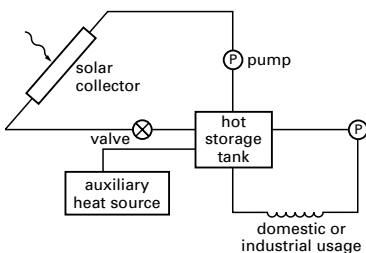

**solar flare** A sudden explosive release of particles and energy from the sun's chromosphere. It characteristically takes a few minutes to reach maximum brightness, and then fades during the next hour. When charged particles reach the earth,

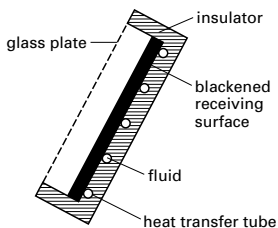

Silicon *p-n* junction

they cause radio interference, magnetic storms, and aurorae.

**solar heating** A form of domestic or industrial heating that relies on the direct use of solar energy. The basic form of **solar heater** is a thermal device in which a fluid is heated by the sun's rays in a collector (see illustrations) and pumped or allowed to flow round a circuit that provides some form of heat storage and some form of auxiliary heat source for use when the sun is not shining. More complicated systems are combined heating-and-cooling devices, providing heat in the winter and air-conditioning in the summer. The simplest form of solar collector is the flat-plate collector, in which a blackened receiving surface is covered by one or more glass plates that acts like a greenhouse (see GREENHOUSE EFFECT) and traps the maximum amount of solar energy. Tubes attached to the receiving surface carry air, water, or some other fluid to which the absorbed heat is transferred. The whole panel is insulated at the back and can thus form part of the roof of a building. More sophisticated collectors

Typical solar heating system

Flat-plate solar collector

focus the sun's rays using reflectors. See also SOLAR CELL.

**solar parallax** The angle subtended by the earth's equatorial radius at the centre of the sun at the mean distance between the earth and the sun (i.e. at 1 astronomical unit). It has the value 8.794 148 arc seconds.

**solar prominence** A cloud of gas that forms temporarily in the upper \*chromosphere or inner \*corona of the sun. It has a lower temperature but higher density than its surroundings and is observed as a bright projection.

**solar system** The sun, the nine major planets (Mercury, Venus, the earth, Mars, Jupiter, Saturn, Uranus, Neptune, and Pluto) and their natural satellites, the asteroids, the comets, and meteoroids. See Feature.

**solar units** Units based on the physical properties of the sun used to describe other celestial objects. Examples include solar luminosity (symbol  $L_{\odot}$ ), solar mass ( $M_{\odot}$ ), and solar radius ( $R_{\odot}$ ).

**solar wind** A continuous outward flow of charged particles, mostly protons and electrons, from the sun's \*corona into interplanetary space. The particles are controlled by the sun's magnetic field and are able to escape from the sun's gravitational field because of their high thermal energy. The average velocity of the particles in the vicinity of the earth is about  $450 \text{ km s}^{-1}$  and their density at this range is about  $8 \times 10^6$  protons per cubic metre.

**solar year** See YEAR.

**solder** An alloy used to join metal surfaces. A **soft solder** melts at a temperature in the range  $200\text{--}300^{\circ}\text{C}$  and consists of a tin-lead alloy. The tin content varies between 80% for the lower end of the melting range and 31% for the higher end.

**Hard solders** contain substantial quantities of silver in the alloy. **Brazing solders** are usually alloys of copper and zinc, which melt at over  $800^{\circ}\text{C}$ .

**solenoid** A coil of wire wound on a cylindrical former in which the length of the former is greater than its diameter. When a current is passed through the coil a magnetic field is produced inside the

## SOLAR SYSTEM

The solar system is dominated by a star, the \*sun. The sun's mass makes up more than 99% of the solar system's mass, and it is the gravitational attraction of the sun that holds the planets, asteroids, comets, and meteoroids in their orbits around it. Only the planetary satellites (such as the earth's moon) owe more allegiance to their parent planets, although the satellites too have to accompany the planets in their endless journey around the sun. The solar system itself also moves, rotating about the centre of the Milky Way galaxy about once every  $2.2 \times 10^8$  years.

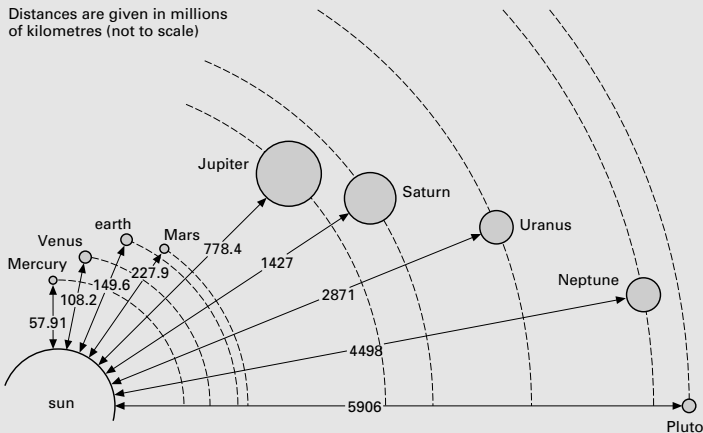

The solar system had its origin in a cloud of interstellar dust and gas that condensed around the proto-sun. The planets continued to grow by {accretion}, and by about 4.6 billion years ago the earth had formed. The inner, or terrestrial, planets - Mercury, Venus, earth, and Mars - are comparatively small. They are composed of rock and metal, with the metallic part forming a dense central core. Only the earth and Mars have natural satellites.

The outer, or giant, planets - Jupiter, Saturn, Uranus, and Neptune - have a rock-metal core surrounded by layers of solid, liquid, and gaseous hydrogen and helium. They are much farther from the sun and therefore much cooler than the inner planets, and have been able to retain gases of such low density. They have many satellites; Jupiter has at least 63, Saturn 34, Uranus 27, and Neptune 13. Pluto, the outermost planet, is small with one huge satellite.

The space between the orbits of Mars and Jupiter is occupied by thousands of \*asteroids, or minor planets. Most of these are small, often irregularly-shaped chunks of rock, with perhaps only 150 of them more than 100 km across. Even smaller are hundreds of thousands of meteoroids, some no larger than grains of dust. Those that enter the earth's atmosphere and burn up as trails of light (shooting stars) are termed \*meteors. The largest ones that reach the ground are called meteorites.

The last important members of the solar system are \*comets. Often described as 'dirty snowballs', they consist of a nucleus of dust and ice a kilometre or two across, surrounded by a gaseous coma and with a tail that appears as the comet nears the sun. A dusty tail behind the comet is the source of many meteoroids.

Distances are given in millions of kilometres (not to scale)

coil parallel to its axis. This field can be made to operate a plunger inside the former so that the solenoid can be used to operate a circuit breaker, valve, or other electromechanical device.

**solid** A state of matter in which there is a three-dimensional regularity of structure, resulting from the proximity of the component atoms, ions, or molecules and the strength of the forces between them. True solids are crystalline (*see also* AMORPHOUS). If a crystalline solid is heated, the kinetic energy of the components increases. At a specific temperature, called the **melting point**, the forces between the components become unable to contain them within the crystal structure. At this temperature, the lattice breaks down and the solid becomes a liquid.

**solid angle** Symbol  $\Omega$ . The three-dimensional 'angle' formed by the vertex of a cone. When this vertex is the centre of a sphere of radius  $r$  and the base of the cone cuts out an area  $s$  on the surface of the sphere, the solid angle in steradians is defined as  $s/r^2$ .

**solid solution** A crystalline material that is a mixture of two or more components, with ions, atoms, or molecules of one component replacing some of the ions, atoms, or molecules of the other component in its normal crystal lattice. Solid solutions are found in certain alloys. For example, gold and copper form solid solutions in which some of the copper atoms in the lattice are replaced by gold atoms. In general, the gold atoms are distributed at random, and a range of gold-copper compositions is possible. At a certain composition, the gold and copper atoms can each form regular individual lattices (referred to as **superlattices**). Mixed crystals of double salts (such as alums) are also examples of solid solutions. Compounds can form solid solutions if they are isomorphous (*see* ISOMORPHISM).

**solid-state detector** *See* JUNCTION DETECTOR.

**solid-state physics** The study of the physical properties of solids, with special emphasis on the electrical properties of semiconducting materials in relation to

their electronic structure. **Solid-state devices** are electronic components consisting entirely of solids (e.g. semiconductors, transistors, etc.) without heating elements, as in thermionic valves.

Recently the term **condensed-matter physics** has been introduced to include the study of crystalline solids, amorphous solids, and liquids.

**soliton** A stable particle-like solitary wave state that is a solution of certain equations for propagation. Solitons are thought to occur in many areas of physics and applied mathematics, such as plasmas, fluid mechanics, lasers, optics, solid-state physics, and elementary-particle physics.

**solstice** **1.** Either of the two points on the \*ecliptic midway between the \*equinoxes, at which the sun is at its greatest angular distance north (**summer solstice**) or south (**winter solstice**) of the celestial equator. **2.** The time at which the sun reaches either of these points. The summer solstice occurs on June 21 and the winter solstice on December 21 in the northern hemisphere; the dates are reversed in the southern hemisphere.

**solubility** The quantity of solute that dissolves in a given quantity of solvent to form a saturated solution. Solubility is measured in kilograms per metre cubed, moles per kilogram of solvent, etc. The solubility of a substance in a given solvent depends on the temperature. Generally, for a solid in a liquid, solubility increases with temperature; for a gas, solubility decreases. *See also* CONCENTRATION.

**solubility product** Symbol  $K_s$ . The product of the concentrations of ions in a saturated solution. For instance, if a compound  $A_xB_y$  is in equilibrium with its solution

the equilibrium constant is

$$K_c = [A^+]^x[B^-]^y/[A_xB_y]$$

Since the concentration of the undissolved solid can be put equal to 1, the solubility product is given by

$$K_s = [A^+]^x[B^-]^y$$

The expression is only true for sparingly

soluble salts. If the product of ionic concentrations in a solution exceeds the solubility product, then precipitation occurs.

**solute** The substance dissolved in a solvent in forming a \*solution.

**solution** A homogeneous mixture of a liquid (the \*solvent) with a gas or solid (the **solute**). In a solution, the molecules of the solute are discrete and mixed with the molecules of solvent. There is usually some interaction between the solvent and solute molecules (see SOLVATION). Two liquids that can mix on the molecular level are said to be **miscible**. In this case, the solvent is the major component and the solute the minor component. See also SOLID SOLUTION.

**solvation** The interaction of ions of a solute with the molecules of solvent. For instance, when sodium chloride is dissolved in water the sodium ions attract polar water molecules, with the negative oxygen atoms pointing towards the positive  $\text{Na}^+$  ion. Solvation of transition-metal ions can also occur by formation of coordinate bonds, as in the hexaquocopper(II) ion  $[\text{Cu}(\text{H}_2\text{O})_6]^{2+}$ . Solvation is the process that causes ionic solids to dissolve, because the energy released compensates for the energy necessary to break down the crystal lattice. It occurs only with polar solvents. Solvation in which the solvent is water is called **hydration**.

#### **Solvay process (ammonia–soda process)**

An industrial method of making sodium carbonate from calcium carbonate and sodium chloride. The calcium carbonate is first heated to give calcium oxide and carbon dioxide, which is bubbled into a solution of sodium chloride in ammonia. Sodium hydrogencarbonate is precipitated:

The sodium hydrogencarbonate is heated to give sodium carbonate and carbon dioxide. The ammonium chloride is heated with calcium oxide (from the first stage) to regenerate the ammonia. The process was patented in 1861 by the Belgian chemist Ernest Solvay (1838–1922).

**solvent** A liquid that dissolves another

substance or substances to form a \*solution. **Polar solvents** are compounds such as water and liquid ammonia, which have dipole moments and consequently high dielectric constants. These solvents are capable of dissolving ionic compounds or covalent compounds that ionize (see SOLVATION). **Nonpolar solvents** are compounds such as ethoxyethane and benzene, which do not have permanent dipole moments. These do not dissolve ionic compounds but will dissolve nonpolar covalent compounds. Solvents can be further categorized according to their proton-donating and accepting properties. **Amphiprotic solvents** self-ionize and can therefore act both as proton donors and acceptors. A typical example is water:

**Aprotic solvents** neither accept nor donate protons; tetrachloromethane (carbon tetrachloride) is an example.

**solvent extraction** The process of separating one constituent from a mixture by dissolving it in a solvent in which it is soluble but in which the other constituents of the mixture are not. The process is usually carried out in the liquid phase, in which case it is also known as **liquid–liquid extraction**. In liquid–liquid extraction, the solution containing the desired constituent must be immiscible with the rest of the mixture. The process is widely used in extracting oil from oil-bearing materials.

**solvolysis** A reaction between a compound and its solvent. See HYDROLYSIS.

**somatic** **1.** Relating to all the cells of an animal or plant other than the reproductive cells. Thus a somatic \*mutation is one that is not heritable. **2.** Relating to organs and tissues of the body other than the gut and its associated structures. The term is applied especially to voluntary muscles, the sense organs, and the nervous system. Compare VISCERAL.

**somatostatin (growth hormone inhibiting hormone; GHIH)** A hormone, secreted by the hypothalamus, that inhibits the release of \*growth hormone from the anterior pituitary gland. The secretion of somatostatin is stimulated by various factors, including very high blood glucose

levels, which result from the effect that growth hormone has on glucose metabolism. It is also produced by the delta (or D) cells of the  $\alpha$  islets of Langerhans in the pancreas and can inhibit the release of glucagon and insulin from the islets.

**somatotrophin** See GROWTH HORMONE.

**sonar** See ECHO.

**sonic boom** A strong  $\alpha$  shock wave generated by an aircraft when it is flying in the earth's atmosphere at supersonic speeds. This shock wave is radiated from the aircraft and where it intercepts the surface of the earth a loud booming sound is heard. The loudness depends on the speed and altitude of the aircraft and is lower in level flight than when the aircraft is undertaking a manoeuvre. The maximum increase of pressure in the shock wave during a transoceanic flight of a commercial supersonic transport (SST) is 120 Pa, equivalent to 136 decibels.

**sonochemistry** The study of chemical reactions in liquids subjected to high-intensity sound or ultrasound. This causes the formation, growth, and collapse of tiny bubbles within the liquid, generating localized centres of very high temperature and pressure, with extremely rapid cooling rates. Such conditions are suitable for studying novel reactions, decomposing polymers, and producing amorphous materials.

**sonometer** A device consisting essentially of a hollow sounding box with two bridges attached to its top. The string, fixed to the box at one end, is stretched between the two bridges so that the free end can run over a pulley and support a measured load. When the string is plucked the frequency of the note can be matched with that of another sound source, such as a tuning fork. It can be used to verify that the frequency ( $f$ ) of a stretched string is given by  $f = (1/2l)\sqrt{T/m}$ , where  $l$  is the length of the string,  $m$  is its mass per unit length, and  $T$  is its tension.

Originally called the **monochord**, the sonometer was widely used as a tuning aid, but is now used only in teaching laboratories.

**sorosis** A type of  $\alpha$  composite fruit

formed from an entire inflorescence spike. Mulberry and pineapple fruits are examples.

**sorption**  $\alpha$  Absorption of a gas by a solid.

**sorption pump** A type of vacuum pump in which gas is removed from a system by absorption on a solid (e.g. activated charcoal or a zeolite) at low temperature.

**sorus 1.** Any of the spore-producing structures on the undersurface of a fern frond, visible as rows of small brown dots.

**2.** A reproductive area on the thallus of some algae, e.g. *Laminaria*. **3.** Any of various spore-producing structures in certain fungi.

**sound** A vibration in an elastic medium at a frequency and intensity that is capable of being heard by the human ear. The frequency of sounds lie in the range 20–20 000 Hz, but the ability to hear sounds in the upper part of the frequency range declines with age (see also PITCH). Vibrations that have a lower frequency than sound are called **infrasounds** and those with a higher frequency are called **ultrasounds**.

Sound is propagated through an elastic fluid as a longitudinal **sound wave**, in which a region of high pressure travels through the fluid at the  $\alpha$  speed of sound in that medium. At a frequency of about 10 kilohertz the maximum excess pressure of a sound wave in air lies between  $10^{-4}$  Pa and  $10^3$  Pa. Sound travels through solids as either longitudinal or transverse waves.

**source 1.** The electrode in a field-effect  $\alpha$  transistor from which electrons or holes enter the interelectrode space. **2.** See MASS FLOW.

**Southern blotting** A chromatographic technique for isolating and identifying specific fragments of DNA, such as the fragments formed as a result of DNA cleavage by  $\alpha$  restriction enzymes. The mixture of fragments is subjected to electrophoresis through an agarose gel, followed by denaturation to form single-stranded fragments. These are transferred, or 'blotted', onto a nitrocellulose filter where they are immobilized in their relative positions. Specific  $\alpha$  gene probes

labelled with a radioisotope are then added. These hybridize with any complementary fragments on the filter, which are subsequently revealed by autoradiography. The technique was devised by E. M. Southern. A similar technique for detecting RNA fragments is called **Northern blotting**, by analogy. *See also* WESTERN BLOTING.

**space 1.** A property of the universe that enables physical phenomena to be extended into three mutually perpendicular directions. In Newtonian physics, space, time, and matter are treated as quite separate entities. In Einsteinian physics, space and time are combined into a four-dimensional continuum (*see* SPACE-TIME) and in the general theory of \*relativity matter is regarded as having an effect on space, causing it to curve. **2. (outer space)** The part of the universe that lies outside the earth's atmosphere.

**space group** A \*group formed by the set of all symmetry operations of a crystal lattice. This set consists of translations, rotations, and reflections and their combinations, such as \*glide and \*screw. It was discovered in the late 19th century that there are 230 possible space groups for a lattice in three dimensions. Space groups are used in the quantum theory of solids and in structure analysis in crystallography.

**space probe** An unmanned spacecraft that investigates features within the solar system. A **planetary probe** examines the conditions on or in the vicinity of one or more planets and a **lunar probe** is designed to obtain information about the moon. Probes are propelled by rocket motors and once out of the earth's gravitational field use their propulsion systems for course changes. Many are powered by panels of \*solar cells, for both internal operation and radio communications.

**space-reflection symmetry** *See* PARITY.

**space-time (space-time continuum)** A geometry that includes the three dimensions and a **fourth dimension** of time. In Newtonian physics, space and time are considered as separate entities and whether or not events are simultaneous is

a matter that is regarded as obvious to any competent observer. In Einstein's concept of the physical universe, based on a system of geometry devised by H. Minkowski (1864–1909), space and time are regarded as entwined, so that two observers in relative motion could disagree regarding the simultaneity of distant events. In Minkowski's geometry, an event is identified by a **world point** in a four-dimensional continuum.

**spadix** A flowering shoot (a type of \*spike) with a large fleshy floral axis bearing small, usually unisexual, flowers. It is protected by a large petal-like bract, the **spathe**, and is characteristic of plants of the family Araceae (e.g. calla lily).

**spallation** A type of nuclear reaction in which the interacting nuclei disintegrate into a large number of protons, neutrons, and other light particles, rather than exchanging nucleons between them.

**spark** *See* ELECTRIC SPARK.

**spark chamber** A device for detecting charged particles. It consists of a chamber, filled with helium and neon at atmospheric pressure, in which a stack of 20 to 100 plates are placed; the plates are connected alternately to the positive and negative terminals of a source of high potential (10 000 V or more). An incoming particle creates ion pairs in its track, causing the gas to become conducting and sparks to jump between the plates. The light from the sparks is focused to obtain stereoscopic photographs of the particles' tracks. It can also function as a counter (called a **spark counter**) when connected to suitable counting circuits. Some versions use crossed sets of parallel wires rather than plates; simple patterns may have a single wire near a plate, in the open atmosphere.

**spark counter** *See* SPARK CHAMBER.

**spathe** *See* SPADIX.

**special creation** The belief, in accordance with the Book of Genesis, that every species was individually created by God in the form in which it exists today and is not capable of undergoing any change. It was the generally accepted explanation of the origin of life until the ad-

vent of \*Darwinism. The idea has recently enjoyed a revival, especially among members of the fundamentalist movement in the USA, partly because there still remain problems that cannot be explained entirely by Darwinian theory. However, special creation is contradicted by fossil evidence and genetic studies, and the pseudoscientific arguments of **creation science** cannot stand up to logical examination.

**specialization 1.** Increasing \*adaptation of an organism to a particular environment. **2.** See PHYSIOLOGICAL SPECIALIZATION.

**special theory of relativity** See RELATIVITY.

**speciation** The development of one or more species from an existing species. It occurs when \*sympatric or \*allopatric populations diverge so much from the parent population that interbreeding can no longer occur between them.

**species 1.** (in biology) A category used in the \*classification of organisms. Similar species are grouped into a genus and a single species may be subdivided into \*subspecies or \*races (see also BINOMIAL NOMENCLATURE). According to the biological species concept, a species comprises a group of individuals that can usually breed among themselves and produce fertile offspring. Typically, a species consists of numerous local populations distributed over a geographical range. Within a species, groups of individuals become reproductively isolated because of geographical or behavioural factors (see ISOLATING MECHANISM), and over time may evolve different characteristics and form new and distinct species. **2.** (in chemistry) A chemical entity, such as a particular atom, ion, or molecule.

**species diversity** See BIODIVERSITY.

**specific 1.** (in physics) **a.** Denoting that an extensive physical quantity so described is expressed per unit mass. For example, the **specific latent heat** of a body is its latent heat per unit mass. When the extensive physical quantity is denoted by a capital letter (e.g. *L* for latent heat), the specific quantity is denoted by the corresponding lower-case letter (e.g. *l* for

specific latent heat). **b.** In some older physical quantities the adjective 'specific' was added for other reasons (e.g. specific gravity, specific resistance). These names are now no longer used. **2.** (in biology) Relating to a species.

**specific activity** See ACTIVITY.

**specific charge** The ratio of the charge of an \*elementary particle or other charged body to its mass.

**specific gravity** See RELATIVE DENSITY; SPECIFIC.

**specific heat capacity** See HEAT CAPACITY.

**specific humidity** See HUMIDITY.

**specific impulse** A measure of the thrust available from a rocket propellant. It is the ratio of the thrust produced to the fuel consumption.

**specific intensity** See PLANCK'S RADIATION LAW.

**specific latent heat** See LATENT HEAT.

**specific resistance** See RESISTIVITY; SPECIFIC.

**specific surface** The surface area of a particular substance per unit mass, expressed in  $\text{m}^2 \text{kg}^{-1}$ . It provides a measure of the surface area available for a process, such as adsorption, for a given mass of a powder or porous substance.

**specific volume** The volume of a substance per unit mass. The reciprocal of density, it has the units  $\text{m}^3 \text{kg}^{-1}$ .

**speckle interferometer** An instrument that improves the resolving power of an astronomical telescope by reducing the distortion produced by atmospheric turbulence (which greatly mars long-exposure photographs). Many short-exposure photographs are taken, one after the other, effectively 'freezing' the turbulence effects and producing a series of point images free from distortion. The overall image is obtained by combining these images.

**spectral class (spectral type)** A form of classification used for stars, based on their spectra. The **Harvard classification**, introduced in 1890 and modified in the 1920s,

is based on the seven star types known as O, B, A, F, G, K, M:

O hottest blue stars; ionized helium lines dominant

B hot blue stars; neutral helium lines dominant, no ionized helium

A blue blue-white stars; hydrogen lines dominant

F white stars; metallic lines strengthen, hydrogen lines weaken

G yellow stars; ionized calcium lines dominant

K orange-red stars; neutral metallic lines dominant, some molecular bands

M coolest red stars; molecular bands dominant

**spectrochemical series** A series of ligands arranged in the order in which they cause splitting of the energy levels of d orbitals in metal complexes (see CRYSTAL-FIELD THEORY). The series for some common ligands has the form:

**spectrograph** See SPECTROSCOPE.

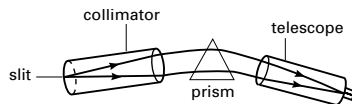

**spectroheliogram** A photograph of the sun's chromosphere taken at a particular wavelength of light with the aid of a high-dispersion \*spectroscope. Various levels of the chromosphere can be studied by varying the wavelength slightly.

**spectrometer** Any of various instruments for producing a spectrum and measuring the wavelengths, energies, etc., involved. A simple type, for visible radiation, is a spectroscope equipped with a calibrated scale allowing wavelengths to be read off or calculated. In the X-ray to infrared region of the electromagnetic spectrum, the spectrum is produced by dispersing the radiation with a prism or diffraction grating (or crystal, in the case of hard X-rays). Some form of photoelectric detector is used, and the spectrum can be obtained as a graphical plot, which shows how the intensity of the radiation varies with wavelength. Such instruments are also called **spectrophotometers**. Spectrometers also exist for investigating the gamma-ray region and the microwave and radio-wave regions of the spectrum (see ELECTRON-SPIN RESONANCE; NUCLEAR MAGNETIC RESONANCE). Instruments for ob-

taining spectra of particle beams are also called spectrometers (see SPECTRUM; PHOTOELECTRON SPECTROSCOPY).

**spectrophotometer** See SPECTROMETER.

**spectroscope** An optical instrument that produces a \*spectrum for visual observation. The first such instrument was made by R. W. Bunsen; in its simplest form it consists of a hollow tube with a slit at one end by which the light enters and a collimating lens at the other end to produce a parallel beam, a prism to disperse the light, and a telescope for viewing the spectrum (see illustration). In the **spectrograph**, the spectroscope is provided with a camera to record the spectrum. For a broad range of spectroscopic work, from the ultraviolet to the infrared, a diffraction grating is used instead of a prism. See also SPECTROMETER.

Spectroscope

**spectroscopic binary** See BINARY STARS.

**spectroscopy** The study of methods of producing and analysing \*spectra using \*spectroscopes, \*spectrometers, spectrographs, and spectrophotometers. The interpretations of the spectra so produced can be used for chemical analysis, examining atomic and molecular energy levels and molecular structures, and for determining the composition and motions of celestial bodies (see REDSHIFT).

**spectrum** (*pl.* spectra) **1.** A distribution of entities or properties arrayed in order of increasing or decreasing magnitude. For example, a beam of ions passed through a mass spectrograph, in which they are deflected according to their charge-to-mass ratios, will have a range of masses called a **mass spectrum**. A **sound spectrum** is the distribution of energy over a range of frequencies of a particular source. **2.** A range of electromagnetic energies arrayed in order of increasing or decreasing wavelength or frequency (see ELECTROMAGNETIC SPECTRUM). The **emis-**

**sion spectrum** of a body or substance is the characteristic range of radiations it emits when it is heated, bombarded by electron or ions, or absorbs photons. The **absorption spectrum** of a substance is produced by examining, through the substance and through a spectroscope, a continuous spectrum of radiation. The energies removed from the continuous spectrum by the absorbing medium show up as black lines or bands. With a substance capable of emitting a spectrum, these are in exactly the same positions in the spectrum as some of the lines and bands in the emission spectrum.

Emission and absorption spectra may show a **continuous spectrum**, a **line spectrum**, or a **band spectrum**. A continuous spectrum contains an unbroken sequence of frequencies over a relatively wide range; it is produced by incandescent solids, liquids, and compressed gases. Line spectra are discontinuous lines produced by excited atoms and ions as they fall back to a lower energy level. Band spectra (closely grouped bands of lines) are characteristic of molecular gases or chemical compounds. See also ACTION SPECTRUM; SPECTROSCOPY.

**speculum** An alloy of copper and tin formerly used in reflecting telescopes to make the main mirror as it could be cast, ground, and polished to make a highly reflective surface. It has now been largely replaced by silvered glass for this purpose.

**speed** The ratio of a distance covered by a body to the time taken. Speed is a \*scalar quantity, i.e. no direction is given. Velocity is a \*vector quantity, i.e. both the rate of travel and the direction are specified.

**speed of light** Symbol  $c$ . The speed at which electromagnetic radiation travels. The speed of light in a vacuum is  $2.997\,924\,58 \times 10^8 \text{ m s}^{-1}$ . When light passes through any material medium its speed is reduced (see REFRACTIVE INDEX). The speed of light in a vacuum is the highest speed attainable in the universe (see RELATIVITY; CERENKOV RADIATION). It is a universal constant and is independent of the speed of the observer. Since October 1983 it has formed the basis of the definition of the \*metre.

**speed of sound** Symbol  $c$  or  $c_s$ . The speed at which sound waves are propagated through a material medium. In air at  $20^\circ\text{C}$  sound travels at  $344 \text{ m s}^{-1}$ , in water at  $20^\circ\text{C}$  it travels at  $1461 \text{ m s}^{-1}$ , and in steel at  $20^\circ\text{C}$  at  $5000 \text{ m s}^{-1}$ . The speed of sound in a medium depends on the medium's modulus of elasticity ( $E$ ) and its density ( $\rho$ ) according to the relationship  $c = \sqrt{E/\rho}$ . For longitudinal waves in a narrow solid specimen,  $E$  is the Young modulus; for a liquid  $E$  is the bulk modulus (see ELASTIC MODULUS); and for a gas  $E = \gamma p$ , where  $\gamma$  is the ratio of the principal specific \*heat capacities and  $p$  is the pressure of the gas. For an ideal gas the relationship takes the form  $c = \sqrt{\gamma r T}$ , where  $r$  is the gas constant per unit mass and  $T$  is the thermodynamic temperature. This equation shows how the speed of sound in a gas is related to its temperature. This relationship can be written  $c = c_0 \sqrt{1 + t/273}$ , where  $c_0$  is the speed of sound in a particular gas at  $0^\circ\text{C}$  and  $t$  is the temperature in  $^\circ\text{C}$ .

**sperm 1.** A single \*spermatozoon.

**2.** Spermatozoa, collectively.

**spermatheca (seminal receptacle)** A sac or receptacle in some female or hermaphrodite animals (e.g. earthworms) in which sperm from the mate is stored until the eggs are ready to be fertilized.

**spermatid** A nonmotile cell, produced during \*spermatogenesis, that subsequently differentiates into a mature spermatozoon. Four spermatids are formed after two meiotic divisions of a primary spermatocyte and therefore contain the \*haploid number of chromosomes.

**spermatogenesis** The series of cell divisions in the testis that results in the production of spermatozoa. Within the seminiferous tubules of the testis germ cells grow and divide by mitosis to produce **spermatogonia**. These divide by mitosis to produce **spermatocytes**, which divide by meiosis to produce \*spermatids. The spermatids, which thus have half the number of chromosomes of the original germ cells, then develop into spermatozoa.

**Spermatophyta** In traditional classifications, a division of the plant kingdom

containing plants that reproduce by means of \*seeds. In modern systems seed plants are grouped into separate phyla, the most important of which are the \*Anthophyta and \*Coniferophyta.

**spermatozoid** See ANTHEROZOID.

**spermatozoon (sperm)** The mature mobile reproductive cell (see GAMETE) of male animals, which is produced by the testis (see SPERMATOGENESIS). It consists of a head section containing a \*haploid nucleus and an **acrosome**, a membranous sac that releases enzymes allowing the sperm to penetrate the egg at fertilization; a middle section containing \*mitochondria to provide the energy for movement; and a tail section, which lashes to drive the sperm forward.

**sperm competition** Competition between sperm from different males to reach and fertilize the egg cell of a single female. Sperm competition can occur among rodents in which a male mates a number of times with the same female, with a rest period between successive matings during which the sperm journeys towards the egg. If a second male mates with the female during a rest period its own sperm may disrupt the movement of sperm from the first male and succeed in fertilizing the egg cell. Certain animals in which sperm competition is possible have evolved features to minimize this interference. For example, in moths and butterflies the male cements the opening of the female genitalia after mating, thereby preventing further matings with other males. An ingenious mechanism operates in the fly *Johannseniella nitida*, in which the female eats a copulating male except for his genitalia, which remain in the body of the female and prevent further mating.

**sphalerite (zinc blende)** A mineral form of zinc sulphide,  $ZnS$ , crystallizing in the cubic system; the principal ore of zinc. It is usually yellow-brown to brownish-black in colour and occurs, often with galena, in metasomatic deposits and also in hydrothermal veins and replacement deposits. Sphalerite is mined on every continent, the chief sources including the USA, Canada, Mexico, Australia, Peru, and Poland.

**Sphenophyta (Arthropphyta)** A phylum of \*tracheophyte plants, the only living members of which are the horsetails (*Equisetum*). Horsetails have a perennial creeping rhizome supporting erect jointed stems bearing whorls of thin leaves. Spores are produced by terminal conelike structures. The group has a fossil record extending back to the Palaeozoic with its greatest development in the Carboniferous period, when giant tree forms were the dominant vegetation with the \*Lycopphyta.

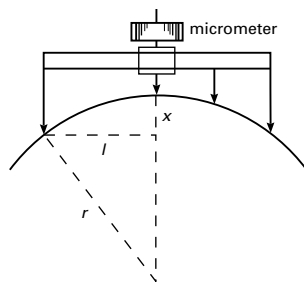

**sphere** The figure generated when a circle is rotated about a diameter. The volume of a sphere is  $4\pi r^3/3$  and its surface area is  $4\pi r^2$ , where  $r$  is its radius. In Cartesian coordinates the equation of a sphere centred at the origin is  $x^2 + y^2 + z^2 = r^2$ .

**spherical aberration** See ABERRATION.

**spherical mirror** See MIRROR.

**spherical polar coordinates** See POLAR COORDINATES.

**spherometer** An instrument for measuring the curvature of a surface. The usual instrument for this purpose consists of a tripod, the pointed legs of which rest on the spherical surface at the corners of an equilateral triangle. In the centre of this triangle is a fourth point, the height of which is adjusted by means of a micrometer screw (see illustration). If the distance between each leg and the axis through the micrometer screw is  $l$ ,  $r^2$  and the height of the micrometer point above (or below) a flat surface is  $x$ , the radius ( $r$ ) of the sphere is given by  $r = (l^2 + x^2)/2x$ .

Spherometer

**sphincter** A specialized muscle encircling an opening or orifice. Contraction of the sphincter tends to close the orifice. Examples are the **anal sphincter** (round the opening of the anus) and the **pyloric sphincter** (at the lower opening of the \*stomach).

**sphingolipid** See PHOSPHOLIPID.

**spiders** See ARACHNIDA.

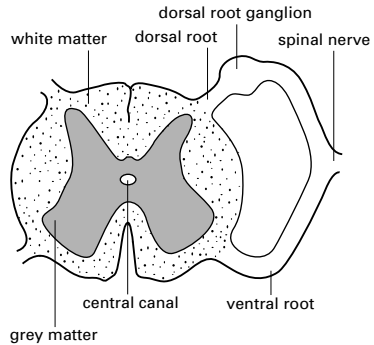

**spiegel (spiegeleisen)** A form of \*pig iron containing 15–30% of manganese and 4–5% of carbon. It is added to steel in a Bessemer converter as a deoxidizing agent and to raise the manganese content of steel.

**spike** A type of \*racemose inflorescence in which stalkless flowers arise from an undivided floral axis, as in plantain and *Orchis*. In the family Gramineae (Poaceae; sedges and grasses) the flowers are grouped in clusters called **spikelets**, which may be arranged to form a compound spike (as in wheat).

**spin (intrinsic angular momentum)** Symbol  $s$ . The part of the total angular momentum of a particle, atom, nucleus, etc., that can continue to exist even when the particle is apparently at rest, i.e. when its translational motion is zero and therefore its orbital angular momentum is zero. A molecule, atom, or nucleus in a specified energy level, or a particular elementary particle, has a particular spin, just as it has a particular charge or mass. According to \*quantum theory, this is quantized and is restricted to multiples of  $h/2\pi$ , where  $h$  is the \*Planck constant. Spin is characterized by a quantum number  $s$  (or  $m_s$ ). For example, for an electron  $s = \pm 1/2$ , implying a spin of  $+h/4\pi$  when it is spinning in one direction and  $-h/4\pi$  when it is spinning in the other. Because of their spin, particles also have their own intrinsic \*magnetic moments and in a magnetic field the spin of the particles lines up at an angle to the direction of the field, precessing around this direction. See also ELECTRON SPIN RESONANCE; NUCLEAR MAGNETIC RESONANCE.

**spinal column** See VERTEBRAL COLUMN.

**spinal cord** The part of the vertebrate central nervous system that is posterior to the brain and enclosed within the \*vert-

Transverse section of the spinal cord

ebra column. It consists of a hollow core of \*grey matter (H-shaped in cross section) surrounded by an outer layer of \*white matter; the central cavity contains \*cerebrospinal fluid. The white matter contains numerous longitudinal nerve fibres organized into distinct tracts: **ascending tracts** consist of sensory neurons, conducting impulses towards the brain; **descending tracts** consist of motor neurons, transmitting impulses from the brain. Paired \*spinal nerves arise from the spinal cord.

**spinal nerves** Pairs of nerves that arise from the \*spinal cord (compare CRANIAL NERVES). In humans there are 31 pairs (one from each of the vertebrae). Each nerve arises from a \*dorsal root and a \*ventral root and contains both motor and sensory fibres (i.e. they are mixed nerves). The spinal nerves form an important part of the \*peripheral nervous system.

**spinal reflex** See REFLEX.

**spindle 1.** A structure formed from \*microtubules in the cytoplasm during cell division that moves chromatids (see MITOSIS) or chromosomes (see MEIOSIS) diametrically apart and gathers them in two clusters at opposite ends (poles) of the cell. Broadest in the middle (the **spindle equator**) and narrowing to a point at either pole, its construction is directed by the \*centrosome. The spindle becomes fully formed by metaphase, when the chromatids are attached to spindle fibres

via their \*centromeres and lie at the spindle equator. During anaphase this set of fibres shortens and hauls the attached chromatids towards the corresponding pole of the cell. Also, the overlapping fibres at the equator actively engage and slide past each other to elongate the entire spindle. **2.** See MUSCLE SPINDLE.

**spindle attachment** See CENTROMERE.

**spine** **1.** See VERTEBRAL COLUMN. **2.** A hard pointed protective structure on a plant that is formed through modification of a leaf, part of a leaf, or a stipule. The edge of the holly leaf is drawn out into spines, but in cacti the whole leaf is modified as a spine. Compare PRICKLE; THORN.

**spinel** A group of oxide minerals with the general formula  $F^{2+}R_2^{3+}O_4$ , where  $F^{2+} = Mg, Fe, Zn, Mn, \text{ or } Ni$  and  $R^{3+} = Al, Fe, \text{ or } Cr$ , crystallizing in the cubic system. The spinels are divided into three series: spinel ( $MgAl_2O_4$ ), \*magnetite, and \*chromite. They occur in high-temperature igneous or metamorphic rocks.

**spin glass** An alloy of a small amount of a magnetic metal (0.1–10%) with a non-magnetic metal, in which the atoms of the magnetic element are randomly distributed through the crystal lattice of the nonmagnetic element. Examples are AuFe and CuMn. Theories of the magnetic and other properties of spin glasses are complicated by the random distribution of the magnetic atoms.

**spinneret** A small tubular appendage from which silk is produced in spiders and some insects. Spiders have four to six spinnerets on the hind part of the abdomen, into which numerous silk glands open. The silk is secreted as a fluid and hardens on contact with the air. It is composed of  $\alpha$ -keratin crystals embedded in a matrix of amino-acid chains, giving the material its flexibility and strength. Various types of silk are produced depending on its use (e.g. for webs, egg cocoons, etc.). The spinnerets that produce the cocoons of insects are not homologous with those of spiders. For example, the spinneret of the silkworm is in the pharynx and the silk is produced by modified salivary glands.

**spin-orbit coupling** An interaction between the orbital angular momentum and the spin angular momentum of an individual particle, such as an electron. For light atoms, spin-orbit coupling is small so that \*multiplets of many-electron atoms are described by \*Russell-Saunders coupling. For heavy atoms, spin-orbit coupling is large so that multiplets of many-electron atoms are described by \*j-j coupling. For medium-sized atoms the sizes of the energies associated with spin-orbit coupling are comparable to the sizes of energies associated with electrostatic repulsion between the electrons, the multiplets in this case being described as having **intermediate coupling**. Spin-orbit coupling is large in many nuclei, particularly heavy nuclei.

**spin-statistics theorem** A fundamental theorem of relativistic \*quantum field theory that states that half-integer \*spins can only be quantized consistently if they obey Fermi-Dirac statistics and even-integer spins can only be quantized consistently if they obey Bose-Einstein statistics (see QUANTUM STATISTICS). This theorem enables one to understand the result of quantum statistics that wave functions for bosons are symmetric and wave functions for fermions are antisymmetric. It also provides the foundation for the \*Pauli exclusion principle. It was first proved by Wolfgang Pauli in 1940.

**spin wave (magnon)** A \*collective excitation associated with magnetic systems. Spin waves occur in both ferromagnetic and antiferromagnetic systems (see MAGNETISM).

**spiracle** **1.** A small paired opening that occurs on each side of the head in cartilaginous fish. It is the reduced first \*gill slit, its small size resulting from adaptations of the skeleton for the firm attachment of the jaws. In modern teleosts (bony fish) the spiracle is closed up. In tetrapods the first gill slit develops into the middle ear cavity. **2.** Any of the external openings of the \*tracheae along the side of the body of an insect.

**spiral galaxy** See GALAXY.

**spirillum** Any rigid spiral-shaped bacterium. Generally, spirilla are Gram-

negative (see GRAM'S STAIN), aerobic, and highly motile, bearing flagella either singly or in tufts. They occur in soil and water, feeding on organic matter.

**spirits of salt** A name formerly given to hydrogen chloride because this compound can be made by adding sulphuric acid to common salt (sodium chloride).

**spirochaete** Any nonrigid corkscrew-shaped bacterium that moves by means of flexions of the cell. Most spirochaetes are Gram-negative (see GRAM'S STAIN), anaerobic, and feed on dead organic matter. They are very common in sewage-polluted waters. Some, however, can cause disease; *Treponema*, the agent of syphilis, is an example.

**spirometer** See RESPIROMETER.

**spleen** A vertebrate organ, lying behind the stomach, that is basically a collection of \*lymphoid tissue. Its functions include producing lymphocytes and destroying foreign particles. It acts as a reservoir for erythrocytes and can regulate the number in circulation. It is also the site for the breakdown of worn-out erythrocytes and it stores the iron they contain.

**splicing** See GENE SPLICING.

**sponges** See PORIFERA.

**spongy bone** See BONE.

**spongy mesophyll** See MESOPHYLL.

**spontaneous combustion** Combustion in which a substance produces sufficient heat within itself, usually by a slow oxidation process, for ignition to take place without the need for an external high-temperature energy source.

**spontaneous emission** The emission of a photon by an atom as it makes a transition from an excited state to the ground state. Spontaneous emission occurs independently of any external electromagnetic radiation; the transition is caused by interactions between atoms and vacuum fluctuations (see VACUUM STATE) of the quantized electromagnetic field. The process of spontaneous emission, which cannot be described by non-relativistic \*quantum mechanics, as given by formulations such as the \*Schrödinger equation, is responsible for the limited lifetime of

an excited state of an atom before it emits a photon. See also QUANTUM THEORY OF RADIATION; STIMULATED EMISSION; EINSTEIN COEFFICIENTS; LASER.

**spontaneous generation** The discredited belief that living organisms can somehow be produced by nonliving matter. For example, it was once thought that microorganisms arose by the process of decay and even that vermin spontaneously developed from household rubbish. Controlled experiments using sterilized media by Pasteur and others finally disproved these notions. Compare BIOGENESIS. See also BIOPOIESIS.

**sporangium** A reproductive structure in plants that produces asexual spores. See SPOROPHYLL.

**spore** A reproductive cell that can develop into an individual without first fusing with another reproductive cell (compare GAMETE). Spores are produced by plants, fungi, bacteria, and some protozoa. A spore may develop into an organism resembling the parent or into another stage in the life cycle, either immediately or after a period of dormancy. In plants showing \*alternation of generations, spores are formed by the \*sporophyte generation and give rise to the \*gametophyte generation. In ferns, the rows of brown reproductive structures on the undersurface of the fronds are spore-producing bodies.

**spore mother cell (sporocyte)** A diploid cell that gives rise to four haploid spores by meiosis.

**sporocyte** See SPORE MOTHER CELL.

**sporogonium** The \*sporophyte generation in mosses and liverworts. It is made up of an absorptive **foot**, a stalk (**seta**), and a spore-producing **capsule**. It may be completely or partially dependent on the \*gametophyte.

**sporophore (fructification)** The aerial spore-producing part of certain fungi; for example, the stalk and cap of a mushroom.

**sporophyll** A leaf that bears **sporangia** (spore-producing structures). In ferns the sporophylls are the normal foliage leaves, but in other plants the sporophylls are

modified and arise in specialized structures such as the strobilus (cone) of clubmosses, horsetails, and gymnosperms and the flower of angiosperms. Most plants produce spores of two different sizes (small **microspores** and large **megaspores**). The sporophylls bearing these are called **microsporophylls** and **megasporophylls** respectively.

**sporophyte** The generation in the life cycle of a plant that produces spores. The sporophyte is \*diploid but its spores are \*haploid. It is either completely or partially dependent on the \*gametophyte generation in mosses and liverworts but is the dominant plant in the life cycle of clubmosses, horsetails, ferns, and seed plants. See also ALTERNATION OF GENERATIONS.

**spreadsheet** A \*computer program that enables a user to make mathematical calculations on rows and columns of figures. If figures are interrelated, changing (updating) one figure also automatically changes all the others that are dependent on it. The user can also enter formulae for manipulating selected figures or groups of figures in a particular way.

**spring balance** A simple form of \*balance in which a force is measured by the extension it produces in a helical spring. The extension, which is read off a scale, is directly proportional to the force, provided that the spring is not overstretched. The device is often used to measure the weight of a body approximately.

**s-process** See ORIGIN OF THE ELEMENTS.

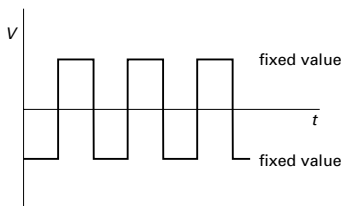

**sputtering** The process by which some of the atoms of an electrode (usually a cathode) are ejected as a result of bombardment by heavy positive ions. Although the process is generally unwanted, it can be used to produce a clean surface or to deposit a uniform film of a metal on an object in an evacuated enclosure.

**Squamata** An order of reptiles comprising the lizards and snakes. They appeared at the end of the Triassic period, about 170 million years ago, and have invaded a wide variety of habitats. Most lizards have four legs and a long tail, eardrums, and movable eyelids. Snakes are limbless rep-

tiles that lack eardrums; the eyes are covered by transparent immovable eyelids and the articulation of the jaws is very loose, enabling a wide gape to facilitate swallowing prey whole.

**square-planar** Describing a coordination compound in which four ligands positioned at the corners of a square coordinate to a metal ion at the centre of the square. See COMPLEX.

**square wave** A train of rectangular voltage pulses that alternate between two fixed values for equal lengths of time. The time of transition between each fixed value is negligible compared to the duration of the fixed value. See diagram.

Square wave

**squark** See SUPERSYMMETRY.

**SSB** See AMPLITUDE MODULATION.

**SSSI (Site of Special Scientific Interest)**

The legal designation for an area of land in England, Scotland, or Wales that has been identified by English Nature, Scottish National Heritage, or the Countryside Council for Wales as being of special interest because of its flora, fauna, or geological or physiographical features. Such sites are protected from development activities and funds are available for their conservation and management. There are over 6000 SSSIs in Britain; similar sites in Northern Ireland are designated **Areas of Special Scientific Interest (ASSIs)**.

**stability of matter** The conclusion that matter consisting of a very large number of protons and electrons described by non-relativistic \*quantum mechanics is stable. An essential element in the proof of this conclusion, which was established by several authors in the 1960s, is the \*Pauli exclusion principle.

**stabilization energy** The amount by which the energy of a delocalized chemical structure is less than the theoretical energy of a structure with localized bonds. It is obtained by subtracting the experimental heat of formation of the compound (in  $\text{kJ mol}^{-1}$ ) from that calculated on the basis of a classical structure with localized bonds.

**stabilizer 1.** A substance used to inhibit a chemical reaction, i.e. a negative catalyst. **2.** A substance used to prevent a colloid from coagulating.

**stable equilibrium** See EQUILIBRIUM.

**staggered conformation** See CONFORMATION.

**staining** A technique in which cells or thin sections of biological tissue that are normally transparent are immersed in one or more coloured dyes (**stains**) to make them more clearly visible through a microscope. Staining heightens the contrast between the various cell or tissue components. Stains are usually organic salts with a positive and negative ion. If the colour comes from the negative ion (organic anion), the stain is described as **acidic**, e.g. \*eosin. If the colour comes from the positive ion (organic cation), the stain is described as **basic**, e.g. \*haematoxylin. **Neutral stains** have a coloured cation and a coloured anion; an example is \*Leishman's stain. Cell constituents are described as being **acidophilic** if they are stained with acidic dyes, **basophilic** if receptive to basic dyes, and **neutrophilic** if receptive to neutral dyes. **Vital stains** are used to colour the constituents of living cells without harming them (see VITAL STAINING); **nonvital stains** are used for dead tissue.

**Counterstaining** involves the use of two or more stains in succession, each of which colours different cell or tissue constituents. **Temporary staining** is used for immediate microscopical observation of material, but the colour soon fades and the tissue is subsequently damaged. **Permanent staining** does not distort the cells and is used for tissue that is to be preserved for a considerable period of time.

**Electron stains**, used in the preparation of material for electron microscopy, are described as **electron-dense** as they inter-

fere with the transmission of electrons. Examples are lead citrate, phosphotungstic acid (PTA), and uranyl acetate (UA).

**stainless steel** A form of \*steel containing at least 11–12% of chromium, a low percentage of carbon, and often some other elements, notably nickel and molybdenum. Stainless steel does not rust or stain and therefore has a wide variety of uses in industrial, chemical, and domestic environments. A particularly successful alloy is the steel known as 18–8, which contains 18% Cr, 8% Ni, and 0.08% C.

**stalactites and stalagmites** Accretions of calcium carbonate in limestone caves. Stalactites are tapering cones or pendants that hang down from the roofs of caves; stalagmites are upward projections from the cave floor and tend to be broader at their bases than stalactites. Both are formed from drips of water containing calcium hydrogencarbonate in solution and may take thousands of years to grow.

**stamen** One of the male reproductive parts of a flower. It consists of an upper fertile part (the \*anther) on a thin sterile stalk (the **filament**).

**staminode** A sterile stamen.

**standard cell** A \*voltaic cell, such as a \*Clark cell, or \*Weston cell, used as a standard of e.m.f.

**standard deviation** A measure of the dispersion of data in statistics. For a set of values  $a_1, a_2, a_3, \dots, a_n$ , the mean  $m$  is given by  $(a_1 + a_2 + \dots + a_n)/n$ . The **deviation** of each value is the absolute value of the difference from the mean:  $|m - a_1|$ , etc. The standard deviation is the square root of the mean of the squares of these values, i.e.

$$\sqrt{(|m - a_1|^2 + \dots + |m - a_n|^2)/n}$$

When the data is continuous the sum is replaced by an integral.

**standard electrode** An electrode (a half cell) used in measuring electrode potential. See HYDROGEN HALF CELL.

**standard electrode potential** See ELECTRODE POTENTIAL.

**standard form (scientific notation)** A way of writing a number, especially a large or small number, in which only one integer appears before the decimal point, the value being adjusted by multiplying by the appropriate power of 10. For example, 236,214 would be written in the standard form as  $2.36214 \times 10^5$ ; likewise 0.006821047 would be written  $6.821047 \times 10^{-3}$ . Note that in the standard form, commas are not used, the digits are grouped into threes and a space is left between groups.

**standard model** See ELEMENTARY PARTICLES.

**standard solution** A solution of known concentration for use in volumetric analysis.

**standard state** A state of a system used as a reference value in thermodynamic measurements. Standard states involve a reference value of pressure (usually one atmosphere, 101.325 kPa) or concentration (usually 1 M). Thermodynamic functions are designated as 'standard' when they refer to changes in which reactants and products are all in their standard and their normal physical state. For example, the standard molar enthalpy of formation of water at 298 K is the enthalpy change for the reaction

Note that the superscript  $\ominus$  is used to denote standard state and the temperature should be indicated.

**standard temperature and pressure** See S.T.P.

**standing biomass** See STANDING CROP.

**standing crop** The total amount of living material in a specified population at a particular time, expressed as \*biomass (**standing biomass**) or its equivalent in terms of energy. The standing crop may vary at different times of the year; for example, in a population of deciduous trees between summer and winter.

**standing wave** See STATIONARY WAVE.

**stannane** See TIN(IV) HYDRIDE.

**stannate** A compound formed by reac-

tion of tin oxides (or hydroxides) with alkali. Tin oxides are amphoteric (weakly acidic) and react to give stannate ions. Tin(IV) oxide with molten alkali gives the stannate(IV) ion:

In fact, there are various ions present in which the tin is bound to hydroxide groups, the main one being the hexahydroxostannate(IV) ion,  $\text{Sn}(\text{OH})_6^{2-}$ . This is the negative ion present in crystalline 'trihydrates' of the type  $\text{K}_2\text{Sn}_2\text{O}_3 \cdot 3\text{H}_2\text{O}$ . Tin(II) oxide gives the trihydroxostannate(II) ion in alkaline solutions

Stannate(IV) compounds were formerly referred to as **orthostannates** ( $\text{SnO}_4^{4-}$ ) or **metastannates** ( $\text{SnO}_3^{2-}$ ). Stannate(II) compounds were called **stannites**.

**stannic compounds** Compounds of tin in its higher (+4) oxidation state; e.g. stannic chloride is tin(IV) chloride.

**stannite** See STANNATE.

**stannous compounds** Compounds of tin in its lower (+2) oxidation state; e.g. stannous chloride is tin(II) chloride.

**stapes (stirrup)** The third of the three \*ear ossicles of the mammalian middle ear.

**Staphylococcus** A genus of spherical nonmotile Gram-positive bacteria that occur widely as saprotrophs or parasites. The cells occur in grapelike clusters. Many species inhabit the skin and mucous membranes, and some cause disease in humans and animals. *S. aureus* infection can lead to boils and abscesses in humans; this species also produces \*toxins that irritate the gastrointestinal tract and result in staphylococcal food poisoning. Certain strains are resistant to antibiotics, and infection with these is very difficult to treat. For example, some strains of methicillin-resistant *S. aureus* (**MRSA**) are now resistant to nearly all antibiotics and pose a grave threat, both to patients in hospitals and to individuals in the wider community.

**star** A self-luminous celestial body, such as the \*sun, that generates nuclear energy within its core. Stars are not distributed

uniformly throughout the universe, but are collected together in \*galaxies. The age and lifetime of a star are related to its mass (see STELLAR EVOLUTION; HERTZSPRUNG-RUSSELL DIAGRAM).

**starch** A \*polysaccharide consisting of various proportions of two glucose polymers, \*amylose and \*amylopectin. It occurs widely in plants, especially in roots, tubers, seeds, and fruits, as a carbohydrate energy store. Starch is therefore a major energy source for animals. When digested it ultimately yields glucose. Starch granules are insoluble in cold water but disrupt if heated to form a gelatinous solution. This gives an intense blue colour with iodine solutions and starch is used as an \*indicator in certain titrations.

**star cluster** A group of stars that are sufficiently close to each other for them to be physically associated. Stars belonging to the cluster are formed together from the same cloud of interstellar gas and have approximately the same age and initial chemical composition. Because of this, and since the stars in a given cluster are at roughly the same distance from earth, observations of star clusters are of great importance in studies of stellar evolution.

There are two types of star cluster.

**Open** (or **galactic**) **clusters** are fairly loose systems of between a few hundred and a few thousand members. The stars in open clusters are quite young by astronomical standards (some as young as a few million years) and have relatively high abundances of heavy elements. **Globular clusters** are approximately spherical collections of between ten thousand and a million stars. These are very old (of order  $10^{10}$  years) and have low heavy-element abundances.

**Stark effect** The splitting of lines in the \*spectra of atoms due to the presence of a strong electric field. It is named after the German physicist Johannes Stark (1874–1957), who discovered it in 1913. Like the normal \*Zeeman effect, the Stark effect can be understood in terms of the classical electron theory of Lorentz. The Stark effect for hydrogen atoms was also described by the \*Bohr theory of the atom. In terms of \*quantum mechanics, the

Stark effect is described by regarding the electric field as a \*perturbation on the quantum states and energy levels of an atom in the absence of an electric field. This application of perturbation theory was its first use in quantum mechanics.

**start codon (initiation codon)** The triplet of nucleotides on a messenger \*RNA molecule (see CODON) at which the process of \*translation is initiated. In eukaryotes the start codon is AUG (see GENETIC CODE), which codes for the amino acid methionine; in bacteria the start codon can be either AUG, coding for *N*-formyl methionine, or GUG, coding for valine. Compare STOP CODON.

**stat-** A prefix attached to the name of a practical electrical unit to provide a name for a unit in the electrostatic system of units, e.g. statcoulomb, statvolt. Compare AB-. In modern practice both absolute and electrostatic units have been replaced by \*SI units.

**state of matter** One of the three physical states in which matter can exist, i.e. \*solid, \*liquid, or \*gas. \*Plasma is sometimes regarded as the fourth state of matter.

**static electricity** The effects produced by electric charges at rest, including the forces between charged bodies (see COULOMB'S LAW) and the field they produce (see ELECTRIC FIELD).

**statics** The branch of mechanics concerned with bodies that are acted upon by balanced forces and couples so that they remain at rest or in unaccelerated motion. Compare DYNAMICS.

**stationary orbit** See SYNCHRONOUS ORBIT.

**stationary phase 1.** See CHROMATOGRAPHY. **2.** See BACTERIAL GROWTH CURVE.

**stationary state** A state of a system when it has an energy level permitted by \*quantum mechanics. Transitions from one stationary state to another can occur by the emission or absorption of an appropriate quanta of energy (e.g. in the form of photons).

**stationary wave (standing wave)** A form of \*wave in which the profile of the

wave does not move through the medium but remains stationary. This is in contrast to a **travelling (or progressive) wave**, in which the profile moves through the medium at the speed of the wave. A stationary wave results when a travelling wave is reflected back along its own path. In a stationary wave there are points at which the displacement is zero; these are called **nodes**. Points of maximum displacement are called **antinodes**. The distance between a node and its neighbouring antinode is one quarter of a wavelength. In a stationary wave all the points along the wave have different amplitudes and the points between successive nodes are in phase; in a travelling wave every point vibrates with the same amplitude and the phase of vibration changes for different points along its path.

**statistical mechanics** The branch of physics in which statistical methods are applied to the microscopic constituents of a system in order to predict its macroscopic properties. The earliest application of this method was Boltzmann's attempt to explain the thermodynamic properties of gases on the basis of the statistical properties of large assemblies of molecules.

In classical statistical mechanics, each particle is regarded as occupying a point in *\*phase space*, i.e. to have an exact position and momentum at any particular instant. The probability that this point will occupy any small volume of the phase space is taken to be proportional to the volume. The Maxwell-Boltzmann law gives the most probable distribution of the particles in phase space.

With the advent of quantum theory, the exactness of these premises was disturbed (by the Heisenberg uncertainty principle). In the *\*quantum statistics* that evolved as a result, the phase space is divided into cells, each having a volume  $h^f$ , where  $h$  is the Planck constant and  $f$  is the number of degrees of freedom of the particles. This new concept led to Bose-Einstein statistics, and for particles obeying the Pauli exclusion principle, to Fermi-Dirac statistics.

**statistics** The branch of mathematics concerned with the inferences that can be drawn from numerical data on the basis

of probability. A **statistical inference** is a conclusion drawn about a population as a result of an analysis of a representative sample. See SAMPLING.

**statocyst (otocyst)** A balancing organ found in many invertebrates. It consists of a fluid-filled sac lined with sensory hairs and contains granules of calcium carbonate, sand, etc. (**statoliths**). As the animal moves the statoliths stimulate different hairs, giving a sense of the position of the body or part of it. The *\*semicircular canals* in the ears of vertebrates act on the same principle and have a similar function.

**stator** The stationary electromagnetic structure of an electric motor or electric generator. Compare ROTOR.

**steady-state theory** The cosmological theory that the universe has always existed in a steady state, that it had no beginning, will have no end, and has a constant mean density. To compensate for the observed *\*expansion of the universe* this theory postulates that matter is created throughout the universe at a rate of about  $10^{-10}$  nucleon per metre cubed per year as a property of space. Because it has failed to account for the *\*microwave background radiation* or the evidence of evolution in the universe it has lost favour to the *\*big-bang theory*. It was first proposed by Hermann Bondi (1919– ), Thomas Gold (1920–2004), and Fred Hoyle in 1948.

**steam distillation** A method of distilling liquids that are immiscible with water by bubbling steam through them. It depends on the fact that the vapour pressure (and hence the boiling point) of a mixture of two immiscible liquids is lower than the vapour pressure of either pure liquid.

**steam engine** A *\*heat engine* in which the thermal energy of steam is converted into mechanical energy. It consists of a cylinder fitted with a piston and valve gear to enable the high-pressure steam to be admitted to the cylinder when the piston is near the top of its stroke. The steam forces the piston to the bottom of its stroke and is then exhausted from the cylinder usually into a condenser. The re-

ciprocating motion of the piston is converted to rotary motion of the flywheel by means of a connecting rod, crosshead, and crank. The steam engine reached its zenith at the end of the 19th century, since when it has been replaced by the steam turbine and the internal-combustion engine. *See also* RANKINE CYCLE.

**steam point** The temperature at which the maximum vapour pressure of water is equal to the standard atmospheric pressure (101 325 Pa). On the Celsius scale it has the value 100°C.

**stearate (octadecanoate)** A salt or ester of stearic acid.

**stearic acid (octadecanoic acid)** A solid saturated \*fatty acid,  $\text{CH}_3(\text{CH}_2)_{16}\text{COOH}$ ; r.d. 0.94; m.p. 71.5–72°C; b.p. 360°C (with decomposition). It occurs widely (as \*glycerides) in animal and vegetable fats.

**steel** Any of a number of alloys consisting predominantly of iron with varying proportions of carbon (up to 1.7%) and, in some cases, small quantities of other elements (**alloy steels**), such as manganese, silicon, chromium, molybdenum, and nickel. Steels containing over 11–12% of chromium are known as \*stainless steels.

Carbon steels exist in three stable crystalline phases: **ferrite** has a body-centred cubic crystal, **austenite** has a face-centred cubic crystal, and **cementite** has an orthorhombic crystal. **Pearlite** is a mixture of

ferrite and cementite arranged in parallel plates. The phase diagram shows how the phases form at different temperatures and compositions.

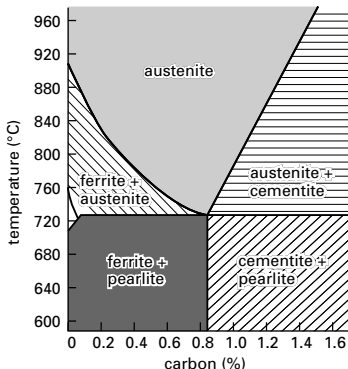

Steels are manufactured by the \*basic-oxygen process (L–D process), which has largely replaced the \*Bessemer process and the \*open-hearth process, or in electrical furnaces.

### Stefan's law (Stefan–Boltzmann law)

The total energy radiated per unit surface area of a \*black body in unit time is proportional to the fourth power of its thermodynamic temperature. The constant of proportionality, the **Stefan constant** (or **Stefan–Boltzmann constant**) has the value  $5.6697 \times 10^{-8} \text{ J s}^{-1} \text{ m}^{-2} \text{ K}^{-4}$ . The law was discovered by Joseph Stefan (1853–93) and theoretically derived by Ludwig Boltzmann.

**stele** The vascular tissue (i.e. \*xylem and \*phloem) of \*tracheophyte plants, together with the endodermis and pericycle (when present). The arrangement of stelar tissues is very variable. In roots the stele often forms a solid core, which better enables the root to withstand tension and compression. In stems it is often a hollow cylinder separating the cortex and pith. This arrangement makes the stem more resistant to bending stresses. Monocotyledons and dicotyledons can usually be distinguished by the pattern of their stelar tissue. In monocotyledons the vascular bundles are scattered throughout the stem whereas in dicotyledons (and gymnosperms) they are arranged in a circle around the pith.

**stellar evolution** The changes that occur to a \*star during its lifetime, from birth to final extinction. A star is believed to form from a condensation of interstellar matter, which collects either by chance or for unexplained reasons, and grows by attracting other matter towards itself as a result of its gravitational field. This initial cloud of cold contracting matter, called a **protostar**, builds up an internal pressure as a result of its gravitational contraction. The pressure raises the temperature until it reaches  $5\text{--}10 \times 10^6 \text{ K}$ , at which temperature the thermonuclear conversion of hydrogen to helium begins. In our \*sun, a typical star, hydrogen is

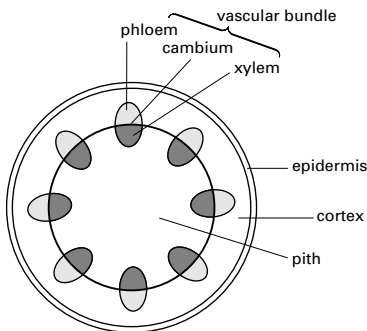

Phase diagram for steel

converted at a rate of some  $10^{11} \text{ kg s}^{-1}$  with the evolution of some  $6 \times 10^{23} \text{ J s}^{-1}$  of energy. It is estimated that the sun contains sufficient hydrogen to burn at this rate for  $10^{10}$  years and that it still has half its life to live as a main-sequence star (see HERTZSPRUNG-RUSSELL DIAGRAM). Eventually, however, this period of stability comes to an end, because the thermonuclear energy generated in the interior is no longer sufficient to counterbalance the gravitational contraction. The core, which is now mostly helium, collapses until a sufficiently high temperature is reached in a shell of unburnt hydrogen round the core to start a new phase of thermonuclear reaction. This burning of the shell causes the star's outer envelope to expand and cool, the temperature drop changes the colour from white to red and the star becomes a **red giant** or a **supergiant** if the original star was very large. The core now contracts, reaching a temperature of  $10^8 \text{ K}$ , and the helium in the core acts as the thermonuclear energy source. This reaction produces carbon, but a star of low mass relatively soon runs out of helium and the core collapses into a \*white dwarf, while the outer regions drift away into space, possibly forming a **planetary nebula**. Larger stars (several times larger than the sun) have sufficient helium for the process to continue so that heavier elements, up to iron, are formed. But iron is the heaviest element that can be formed with the production of energy and when the helium has all been consumed there is a catastrophic collapse of the core, resulting in a \*supernova explosion, blowing the outer layers away. The current theory suggests that thereafter the collapsed core becomes a \*neutron star or a \*black hole depending on its mass.

**stem** The part of a plant that usually grows vertically upwards towards the light and supports the leaves, buds, and reproductive structures (see illustration). The leaves develop at the \*nodes and side or branch stems develop from buds at the nodes. The stems of certain species are modified as bulbs, corms, rhizomes, and tubers. Some species have twining stems; others have horizontal stems, such as \*runners. Another modification is the \*cladode. Erect stems may be cylindrical

or angular; they may be covered with hairs, prickles, or spines and many exhibit secondary growth and become woody (see GROWTH RING). In addition to its supportive function, the stem contains \*vascular tissue that conducts food, water, and mineral salts between the roots and leaves. It may also contain chloroplasts and carry out photosynthesis.

Transverse section through a herbaceous stem

**stem cell** A cell that is not differentiated itself but can undergo unlimited division to form other cells, which either remain as stem cells or differentiate to form specialized cells. For example, **haemopoietic stem cells** in the bone marrow divide to produce daughter cells that differentiate into various types of blood cell (see HAEMOPOIETIC TISSUE). **Embryonic stem cells**, such as those taken from an early human embryo, are capable of differentiating into many or all of the various tissue cells found in a fully developed individual – they are described as **pluripotent**. Cultures of such cells have the potential to provide replacement tissues and organs for medical use, including transplantation. However, ethical concerns have led to tight controls on research using human embryonic stem cells in many countries, including the USA and UK.

**step** A single stage in a chemical reaction. For example, the addition of hydrogen chloride to ethene involves three steps:

**steradian** Symbol sr. The dimensionless \*SI unit of solid angle equal to the solid angle that encloses a surface on a sphere equal to the square of the radius of the sphere.

**stere** A unit of volume equal to  $1 \text{ m}^3$ . It is not now used for scientific purposes.

**stereochemistry** The branch of chemistry concerned with the structure of molecules and the way the arrangement of atoms and groups affects the chemical properties.

**stereographic projection** A type of azimuthal projection used for making maps (see MAP PROJECTIONS) and for specifying the structures of crystals (see CRYSTAL). A point  $p$  on a sphere (called a pole of the projection) is projected onto a plane that is a tangent to the sphere at a point diametrically opposite  $p$ . The sizes and sense of angles between lines or curves are preserved in this projection.

**stereoisomerism** See ISOMERISM.

**stereoregular** Describing a \*polymer that has a regular pattern of side groups along its chain.

**stereospecific** Describing chemical reactions that give products with a particular arrangement of atoms in space. An example of a stereospecific reaction is the \*Ziegler process for making polyethylene.

**steric effect** An effect in which the rate or path of a chemical reaction depends on the size or arrangement of groups in a molecule.

**steric hindrance** An effect in which a chemical reaction is slowed down or prevented because large groups on a reactant molecule hinder the approach of another reactant molecule.

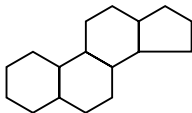

**sterile** **1.** (of living organisms) Unable to produce offspring. See also HYBRID; INCOMPATIBILITY; SELF-STERILITY; STERILIZATION. **2.** Free from contaminating microorganisms. See STERILIZATION.

**sterilization** **1.** The process of destroying microorganisms that contaminate

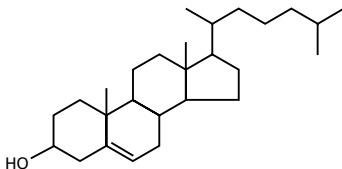

food, wounds, surgical instruments, etc. Common methods of sterilization include heat treatment (see AUTOCLAVE; PASTEURIZATION) and the use of \*disinfectants and \*antiseptics. **2.** The operation of making an animal or human incapable of producing offspring. Men are usually sterilized by tying and then cutting the \*vas deferens (**vasectomy**); in women the operation often involves permanently blocking the fallopian tubes by means of clips (**tubal occlusion**). See also BIRTH CONTROL.

**sternum (breastbone)** **1.** A shield-shaped or rod-shaped bone in terrestrial vertebrates, on the ventral side of the thorax, that articulates with the \*clavicle (collar bone) of the pectoral girdle and with most of the ribs. It is absent in fish, and in birds it bears a \*keel. **2.** The ventral portion of each segment of the exoskeleton of arthropods.

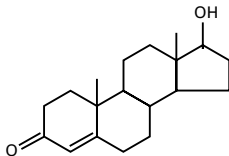

**steroid** Any of a group of lipids derived

steroid nucleus

cholesterol (a sterol)

testosterone (an androgen)

Steroid structure

from a saturated compound called cyclopentanoperhydrophenanthrene, which has a nucleus of four rings (see formulae). Some of the most important steroid derivatives are the steroid alcohols, or \*sterols. Other steroids include the \*bile acids, which aid digestion of fats in the intestine; the sex hormones (\*androgens and \*oestrogens); and the \*corticosteroid hormones, produced by the adrenal cortex. \*Vitamin D is also based on the steroid structure.

**sterol** Any of a group of \*steroid-based alcohols having a hydrocarbon side-chain of 8–10 carbon atoms. Sterols exist either as free sterols or as esters of fatty acids. Animal sterols (**zoosterols**) include \*cholesterol and lanosterol. The major plant sterol (**phytosterol**) is beta-sitosterol, while fungal sterols (**mycoosterols**) include \*ergosterol.

**stibnite** A mineral form of antimony(III) sulphide,  $Sb_2S_3$ , the chief ore of antimony. It is a steel-grey crystalline solid, often containing extractable amounts of lead, mercury, and silver in addition to the antimony.

**sticky end** A single unpaired strand of nucleotides protruding from the end of a double-stranded DNA molecule. It is able to join with a complementary single strand, e.g. the sticky end of another DNA molecule, thus forming a single large double-stranded molecule. Sticky ends provide a means of annealing segments of DNA in genetic engineering, e.g. in the packaging of \*vectors.

**stigma** **1.** The glandular sticky surface at the tip of a carpel of a flower, which receives the pollen. In insect-pollinated plants the stigmas are held within the flower, whereas in wind-pollinated species they hang outside it. **2.** See EYESPOT.

**stilt root** See PROP ROOT.

**stimulated emission** See INDUCED EMISSION; LASER.

**stimulus** Any change in the external or internal environment of an organism that provokes a physiological or behavioural response in the organism. In an animal specific \*receptors are sensitive to stimuli.

**stipe** **1.** The stalk that forms the lower

portion of the fruiting body of certain fungi, such as mushrooms, and supports the umbrella-shaped cap. **2.** The stalk between the holdfast and blade (**lamina**) of certain brown algae, notably kelps.

**stipule** An outgrowth from the petiole or leaf base of certain plants. Those of the garden pea are leaflike photosynthetic organs. The stipules of the lime tree are scalelike and protect the winter buds, whereas those of the false acacia (*Robinia*) are modified as spines.

**Stirling engine** A heat engine consisting of a hot cylinder and a cold cylinder separated by a regenerator acting as a heat exchanger. The cylinders enclose oscillating pistons. Heat is applied externally to the hot cylinder, causing the working fluid within it to expand and drive the piston. The fluid is cooled in the regenerator before entering the cold cylinder, where it is compressed by the piston and driven back to be heated in the regenerator before entering the hot cylinder again. Stirling engines, which were invented by Robert Stirling (1790–1878) in 1816, are silent and efficient but costly to produce. They have found limited use; interest in them revived in the 1960s.

**STM** See SCANNING TUNNELLING MICROSCOPE.

**stochastic process** Any process in which there is a random variable.

**stock** See GRAFT.

**stoichiometric** Describing chemical reactions in which the reactants combine in simple whole-number ratios.

**stoichiometric coefficient** See CHEMICAL EQUATION.

**stoichiometric compound** A compound in which atoms are combined in exact whole-number ratios. Compare NON-STOICHIOMETRIC COMPOUND.

**stoichiometric mixture** A mixture of substances that can react to give products with no excess reactant.

**stoichiometric sum** See CHEMICAL EQUATION.

**stoichiometry** The relative proportions

in which elements form compounds or in which substances react.

**stokes** Symbol St. A c.g.s. unit of kinematic viscosity equal to the ratio of the viscosity of a fluid in poises to its density in grams per cubic centimetre. 1 stokes =  $10^{-4} \text{ m}^2 \text{ s}^{-1}$ . It is named after Sir George Stokes.

**Stokes, Sir George Gabriel** (1819–1903) British physicist and mathematician, born in Ireland, who worked at Cambridge University all his life. He is best known for \*Stokes' law, concerning the movement of objects in a fluid. The \*stokes is named after him.

**Stokes' law** A law that predicts the frictional force  $F$  on a spherical ball moving through a viscous medium. According to this law  $F = 6\pi\eta rv$ , where  $r$  is the radius of the ball,  $v$  is its velocity, and  $\eta$  is the viscosity of the medium. The sphere accelerates until it reaches a steady terminal speed. For a falling ball,  $F$  is equal to the gravitational force on the sphere, less any upthrust. The law was discovered by Sir George Stokes.

**Stokes theorem** A theorem that is the analogue of the \*divergence theorem for the \*curl of a vector. Stokes theorem states that if a surface  $S$ , which is smooth and simply connected (i.e. any closed curve on the surface can be contracted continuously into a point without leaving the surface), is bounded by a line  $L$  the vector  $\mathbf{F}$  defined in  $S$  satisfies

$$\int_S \text{curl} \mathbf{F} \cdot d\mathbf{S} = \int_L \mathbf{F} \cdot d\mathbf{l}$$

where  $\mathbf{l}$  is distance. Stokes theorem was stated by Sir George Stokes as a Cambridge examination question, having been raised by Lord Kelvin in a letter to Stokes in 1850.

**stolon** A long aerial side stem that gives rise to a new daughter plant when the bud at its apex touches the soil. Plants that multiply in this way include blackberry and currant bushes. Gardeners often pin down stolons to the soil to aid the propagation of such plants. This process is termed **layering**.

**stoma** (*pl.* **stomata**) A pore, large numbers of which are present in the epidermis of leaves (especially on the

undersurface) and young shoots. Stomata function in gas exchange between the plant and the atmosphere. Each stoma is bordered by two semicircular **guard cells** (specialized epidermal cells), whose movements (due to changes in water content) control the size of the aperture. The term stoma is also used to mean both the pore and its associated guard cells.

**stomach** The portion of the vertebrate \*alimentary canal between the oesophagus and the small intestine. It is a muscular organ, capable of dramatic changes in size and shape, in which ingested food is stored and undergoes preliminary digestion. Cells lining the stomach produce \*gastric juice, which is thoroughly mixed with the food by muscular contractions of the stomach. The resultant acidic partly digested food mass (\*chyme) is discharged into the \*duodenum through the pyloric \*sphincter for final digestion and absorption. Some herbivorous animals (the Ruminantia) have multichambered stomachs from which food is regurgitated, rechewed, and swallowed again.

**stomium** A region of thin-walled cells in certain spore-producing structures that ruptures to release the spores. For example, in the sporangium of the fern *Dryopteris* the stomium ruptures when the annulus dries out.

**stop** A circular aperture that limits the effective size of a lens in an optical system. It may be adjustable, as the iris diaphragm in a camera, or have a fixed diameter, as the disc used in some telescopes.

**stop codon** The triplet of nucleotides on a messenger \*RNA molecule (see CODON) at which the process of \*translation ends. It is recognized by proteins called release factors, which attach to the binding site for an aminoacyl tRNA molecule. This effectively stops the formation of a polypeptide chain at that point. The three stop codons are UGA, UAA, and UAG (see GENETIC CODE). Compare START CODON.

**stopping power** A measure of the ability of matter to reduce the kinetic energy of a particle passing through it. The **linear stopping power**,  $-dE/dx$ , is energy loss of a particle per unit distance. The **mass stop-**

**ping power**,  $(1/\rho)dE/dx$ , is the linear stopping power divided by the density ( $\rho$ ) of the substance. The **atomic stopping power**,  $(1/m)dE/dx = (A/\rho N)dE/dx$ , is the energy loss per atom per unit area perpendicular to the particle's motion, i.e.  $n$  is the number of atoms in unit volume of the substance,  $N$  is the Avogadro number, and  $A$  is the relative atomic mass of the substance. The relative stopping power is the ratio of the stopping power of a substance to that of a standard substance, usually aluminium, oxygen, or air.

**storage compound** See FOOD RESERVES.

**storage ring** A large evacuated toroidal ring forming a part of some particle accelerators. The rings are designed like \*synchrotrons, except that they do not accelerate the particles circling within them but supply just sufficient energy to make up for losses (mainly \*synchrotron radiation). The storage rings are usually built tangentially to the associated accelerator so that particles can be transferred accurately between them. At \*CERN in Geneva, two interlaced storage rings are used, containing protons rotating in opposite directions. At the intersections very high collision energies (up to 1700 GeV) can be achieved.

**s.t.p.** Standard temperature and pressure, formerly known as **N.T.P.** (normal temperature and pressure). The standard conditions used as a basis for calculations involving quantities that vary with temperature and pressure. These conditions are used when comparing the properties of gases. They are 273.15 K (or 0°C) and 101 325 Pa (or 760.0 mmHg).

**straight chain** See CHAIN.

**strain** A measure of the extent to which a body is deformed when it is subjected to a \*stress. The **linear strain** or **tensile strain** is the ratio of the change in length to the original length. The **bulk strain** or **volume strain** is the ratio of the change in volume to the original volume. The **shear strain** is the angular distortion in radians of a body subjected to a \*shearing force. See also ELASTICITY; ELASTIC MODULUS.

**strain gauge** A device used to measure a small mechanical deformation in a body (see STRAIN). The most widely used devices

are metal wires or foils or semiconductor materials, such as a single silicon crystal, which are attached to structural members; when the members are stretched under tensile \*stress the resistance of the metal or semiconductor element increases. By making the resistance a component in a \*Wheatstone-bridge circuit an estimate of the strain can be made by noting the change in resistance. Other types of strain gauge rely on changes of capacitance or the magnetic induction between two coils, one of which is attached to the stressed member.

**strain hardening (work hardening)** An increase in the resistance to the further plastic deformation of a body as a result of a rearrangement of its internal structure when it is strained, particularly by repeated stress. See also ELASTICITY.

**strange attractor** See ATTRACTOR.

**strange matter** Matter composed of up, down, and strange quarks (rather than the up and down quarks found in normal nucleons). It has been suggested that strange matter may have been formed in the \*early universe, and that pieces of this matter (called **S-drops**) may still exist.

**strangeness** Symbol  $s$ . A property of certain elementary particles called hadrons (K-mesons and hyperons) that decay more slowly than would have been expected from the large amount of energy released in the process. These particles were assigned the quantum number  $s$  to account for this behaviour. For nucleons and other nonstrange particles  $s = 0$ ; for strange particles  $s$  does not equal zero but has an integral value. In quark theory (see ELEMENTARY PARTICLES) hadrons with the property of strangeness contain a strange quark or its antiquark.

**stratification** **1.** The arrangement of the components of an entity in layers (**strata**). Stratification is a feature of sedimentary rocks and \*soils. Thermal stratification can occur in some lakes (see THERMOCLINE). **2.** The practice of placing certain seeds between layers of peat or sand and then exposing them to low temperatures for a period, which is required before they will germinate. See VERNALIZATION.

**stratigraphy** The branch of geology concerned with the origin, composition, sequence, and correlation of rock strata. It forms the basis of historical geology and has also found practical application in mineral exploration, especially that of petroleum.

**stratosphere** See EARTH'S ATMOSPHERE.

**stratum corneum** The layer of dead keratinized cells that forms the outermost layer of mammalian \*epidermis. It provides a water-resistant barrier between the external environment and the living cells of the \*skin.

**streamline flow** A type of fluid flow in which no \*turbulence occurs and the particles of the fluid follow continuous paths, either at constant velocity or at a velocity that alters in a predictable and regular way (see also LAMINAR FLOW).

**Streptococcus** A genus of spherical Gram-positive bacteria occurring widely in nature, typically as chains or pairs of cells. Many are saprotrophic and exist as usually harmless commensals inhabiting the skin, mucous membranes, and intestine of humans and animals. Others are parasites, some of which cause diseases, including scarlet fever (*S. pyogenes*; group A streptococci), endocarditis (*S. viridans*), and pneumonia (*S. pneumoniae*).

**streptomycin** See ACTINOBACTERIA; ANTIBIOTICS.

**stress** The force per unit area on a body that tends to cause it to deform (see STRAIN). It is a measure of the internal forces in a body between particles of the material of which it consists as they resist separation, compression, or sliding in response to externally applied forces. **Tensile stress** and **compressive stress** are axial forces per unit area applied to a body that tend either to extend it or compress it linearly. **Shear stress** is a tangential force per unit area that tends to shear a body. See also ELASTICITY; ELASTIC MODULUS.

**stress protein** See HEAT-SHOCK PROTEIN.

**stretch reflex (myotatic reflex)** The \*reflex initiated when a muscle is stretched; an example is the **knee-jerk reflex**. Stretching of a muscle causes impulses to be generated in the \*muscle

spindles. These impulses are transmitted by sensory neurons to the spinal cord, where the sensory neurons synapse with motor neurons; these initiate contraction of the same muscle so that it returns to its original length. Since the reflex action involves the transmission of impulses across only one set of synapses, the response is rapid and described as **monosynaptic**.

**striated muscle** See VOLUNTARY MUSCLE.

**stridulation** The production of sounds by insects rubbing one part of the body against another. The parts of the body involved vary from species to species. Stridulation is typical of the Orthoptera (grasshoppers, crickets, cicadas), in which the purpose of the sounds is usually to bring the sexes together, although they are also used in territorial behaviour, warning, etc.

**string** A one-dimensional object used in theories of elementary particles and in cosmology (**cosmic string**). **String theory** replaces the idea of a pointlike elementary particle (used in quantum field theory) by a line or loop (a closed string). States of a particle may be produced by standing waves along this string. The combination of string theory with supersymmetry leads to \*superstring theory.

**strobilus 1.** A type of \*composite fruit that is formed from a complete inflorescence. It produces \*achenes enclosed in bracts and when mature becomes cone-shaped. The hop fruit is an example.

**2.** See CONE.

**stroboscope** A device for making a moving body intermittently visible in order to make it appear stationary. It may consist of a lamp flashing at regular intervals or a shutter that enables it to be seen intermittently. **Stroboscopic photography** is the taking of very short-exposure pictures of moving objects using an electronically controlled flash lamp.

**stroma** Tissue that forms the framework of an organ; for example, the tissue of the ovary that surrounds the reproductive cells, or the gel-like matrix of \*chloroplasts that surrounds the grana.

**stromatolite** A rocky cushion-like mass

formed by the unchecked growth of millions of lime-secreting cyanobacteria. Stromatolites are found only in areas where other organisms that would normally keep down the bacterial numbers cannot survive, such as extremely salty bays. Such bacteria were abundant during the \*Proterozoic and \*Archaean eons, perhaps from as early as 3900 million years ago. The white rings of fossilized microorganisms found in rocks of this age are the remains of stromatolites.

**strong acid** An \*acid that is completely dissociated in aqueous solution.

**strong electrolyte** An \*electrolyte that is completely dissociated into its component ions in aqueous solution (as opposed to a weak electrolyte, which is incompletely dissociated).

**strong interaction** See FUNDAMENTAL INTERACTIONS.

**strontia** See STRONTIUM OXIDE.

**strontianite** A mineral form of \*strontium carbonate,  $\text{SrCO}_3$ .

**strontium** Symbol Sr. A soft yellowish metallic element belonging to group 2 (formerly IIA) of the periodic table (see ALKALINE-EARTH METALS); a.n. 38; r.a.m. 87.62; r.d. 2.6; m.p. 769°C; b.p. 1384°C. The element is found in the minerals strontianite ( $\text{SrCO}_3$ ) and celestine ( $\text{SrSO}_4$ ). It can be obtained by roasting the ore to give the oxide, followed by reduction with aluminium (i.e. the \*Goldschmidt process). The element, which is highly reactive, is used in certain alloys and as a vacuum getter. The isotope strontium-90 is present in radioactive fallout (half-life 28 years), and can be metabolized with calcium so that it collects in bone. Strontium was discovered by Martin Klaproth (1743–1817) and Thomas Hope (1766–1844) in 1798 and isolated by Humphry Davy in 1808.

**strontium bicarbonate** See STRONTIUM HYDROGENCARBONATE.

**strontium carbonate** A white solid,  $\text{SrCO}_3$ ; orthorhombic; r.d. 3.7; decomposes at 1340°C. It occurs naturally as the mineral **strontianite** and is prepared industrially by boiling celestine (strontium sulphate) with ammonium carbonate. It

can also be prepared by passing carbon dioxide over strontium oxide or hydroxide or by passing the gas through a solution of strontium salt. It is a phosphor, used to coat the glass of cathode-ray screens, and is also used in the refining of sugar, as a slagging agent in certain metal furnaces, and to provide a red flame in fireworks.

**strontium chloride** A white compound,  $\text{SrCl}_2$ . The anhydrous salt (cubic; r.d. 3.05; m.p. 872°C; b.p. 1250°C) can be prepared by passing chlorine over heated strontium. It is deliquescent and readily forms the hexahydrate,  $\text{SrCl}_2 \cdot 6\text{H}_2\text{O}$  (r.d. 2.67). This can be made by neutralizing hydrochloric acid with strontium carbonate, oxide, or hydroxide. Strontium chloride is used for military flares.

**strontium hydrogencarbonate (strontium bicarbonate)** A compound,  $\text{Sr}(\text{HCO}_3)_2$ , which is stable only in solution. It is formed by the action of carbon dioxide on a suspension of strontium carbonate in water. On heating, this process is reversed.

**strontium oxide (strontia)** A white compound, SrO; r.d. 4.7; m.p. 2430°C, b.p. 3000°C. It can be prepared by the decomposition of heated strontium carbonate, hydroxide, or nitrate, and is used in the manufacture of other strontium salts, in pigments, soaps and greases, and as a drying agent.

**strontium sulphate** A white solid,  $\text{SrSO}_4$ ; r.d. 3.96; m.p. 1605°C. It can be made by dissolving strontium oxide, hydroxide, or carbonate in sulphuric acid. It is used as a pigment in paints and ceramic glazes and to provide a red colour in fireworks.

**structural formula** See FORMULA.

**structural gene** See OPERON.

**structural isomerism** See ISOMERISM.

**structure formation** The process by which \*large-scale structure, such as galaxies, forms in the universe. It is thought that quantum fluctuations in the early universe and the \*Jeans instability in an expanding universe are the key factors in understanding structure formation. A complete quantitative theory of

structure formation does not exist at present.

**strychnine** A colourless poisonous crystalline alkaloid found in certain plants.

**style** The stalk of a carpel, between the stigma and the ovary. In many plants it is elongated to aid pollination.

**styrene** See PHENYLETHENE.

**subarachnoid space** The space between the \*arachnoid membrane and the \*pia mater, two of the membranes (\*meninges) that surround the brain and spinal cord. It is filled with \*cerebrospinal fluid.

**subatomic particle** See ELEMENTARY PARTICLES.

**subclavian artery** A paired artery that passes beneath the collar bone (clavicle) and branches to supply blood to the arm. The left subclavian artery arises from the aorta; the right from the innominate artery.

**subcritical** See CRITICAL MASS; CRITICAL REACTION; MULTIPLICATION FACTOR.

**subcutaneous tissue** The tissue that lies immediately beneath the \*dermis (see SKIN). It is made up of loose fibrous \*connective tissue, muscle, and fat (see ADIPOSE TISSUE), which in some animals (e.g. whales and hibernating mammals) forms an insulating layer or an important food store.

**suberin** A mixture of waxy substances, similar to \*cutin, present in the thickened cell walls of many trees and shrubs, particularly in corky tissues. The deposition of suberin (**suberization**) provides a protective water-impermeable layer.

**sublimate** A solid formed by sublimation.

**sublimation** A direct change of state from solid to gas.

**sublittoral 1.** Designating or occurring in the shallow-water zone of a sea, over the continental shelf and below the low tide mark. **2.** Designating or occurring in the zone of a lake below the littoral zone, to a depth of 6–10 metres.

**subshell** See ATOM.

**subsoil** See SOIL.

**subsonic speed** A speed that is less than \*Mach 1.

**subspecies** A group of individuals within a \*species that breed more freely among themselves than with other members of the species and resemble each other in more characteristics. Reproductive isolation of a subspecies may become so extreme that a new species is formed (see SPECIATION). Subspecies are sometimes given a third Latin name, e.g. the mountain gorilla, *Gorilla gorilla beringei* (see also BINOMIAL NOMENCLATURE).

**substantive dye** See DYES.

**substantivity** The affinity of a dye for its substrate.

**substituent 1.** An atom or group that replaces another in a substitution reaction. **2.** An atom or group regarded as having replaced a hydrogen atom in a chemical derivative. For example, dibromobenzene ( $C_6H_4Br_2$ ) is a derivative of benzene with bromine substituents.

**substitution** (in genetics) A \*point mutation in which one base pair in the DNA sequence is replaced by another. Most substitutions tend to alter one amino acid in a protein chain, which may or may not affect the functioning of that protein. Sickle-cell anaemia is an example of a substitution mutation in which thymine is replaced by adenine in the triplet coding for the sixth amino acid in the  $\beta$ -chain of haemoglobin.

**substitution reaction (displacement reaction)** A reaction in which one atom or molecule is replaced by another atom or molecule. See ELECTROPHILIC SUBSTITUTION; NUCLEOPHILIC SUBSTITUTION.

**substrate 1.** The substance that is affected by the action of a catalyst; for example, the substance upon which an \*enzyme acts in a biochemical reaction.

**2.** The substance on which some other substance is adsorbed or in which it is absorbed. Examples include the material to which a dye is attached, the porous solid absorbing a gas, and the \*matrix trapping isolated atoms, radicals, etc. **3.** (in biology) The material on which a sedentary organism (such as a barnacle or a plant)

lives or grows. The substrate may provide nutrients for the organism or it may simply act as a support.

**subtractive process** See COLOUR.

**succession** (in ecology) The sequence of communities that develops in an area from the initial stages of colonization until a stable mature **climax community** is achieved. Many factors, including climate and changes brought about by the colonizing organisms, influence the nature of a succession; for example, after many years shrubs produce soil deep enough to support trees, which then shade out the shrubs. See also SERE.

**succinate** A salt of succinic acid (\*butanedioic acid), a four-carbon fatty acid. Succinate occurs in living organisms as an intermediate in metabolism, especially in the \*Krebs cycle.

**succulent** A plant that conserves water by storing it in fleshy leaves or stems. Succulents are found either in dry regions or in areas where there is sufficient water but it is not easily obtained, as in salt marshes. Such plants are often modified to reduce water loss by transpiration. For example, the leaves of cacti are reduced to spines.

**succus entericus** See INTESTINAL JUICE.

**sucker (turion)** A shoot that arises from an underground root or stem and grows at the expense of the parent plant. Suckers can be dug up with a portion of root attached and used to propagate a plant. If, however, a plant is grafted onto a different rootstock, as many roses are, any suckers will be of the wild rootstock, rather than the ornamental scion, and must be removed.

**sucrase** A carbohydrate-digesting enzyme, produced in the brush border of the small intestine, that breaks down the disaccharide sucrose into the monosaccharides glucose and fructose.

**sucrose (cane sugar; beet sugar; saccharose)** A sugar comprising one molecule of glucose linked to a fructose molecule. It occurs widely in plants and is particularly abundant in sugar cane and sugar beet (15–20%), from which it is extracted and

refined for table sugar. If heated to 200°C, sucrose becomes caramel.

**sugar (saccharide)** Any of a group of water-soluble \*carbohydrates of relatively low molecular weight and typically having a sweet taste. The simple sugars are called \*monosaccharides. More complex sugars comprise between two and ten monosaccharides linked together: \*disaccharides contain two, trisaccharides three, and so on. The name is often used to refer specifically to \*sucrose (cane or beet sugar).

**sugar of lead** See LEAD(II) ETHANOATE.

**sulpha drugs** See SULPHONAMIDES.

**sulphamic acid** A colourless crystalline solid,  $\text{NH}_2\text{SO}_2\text{OH}$ , which is extremely soluble in water and normally exists as the \*zwitterion  $\text{H}_3\text{N}^+\text{SO}_3^-$ . It is a strong acid, readily forming sulphamate salts. It is used in electroplating, hard-water scale removers, herbicides, and artificial sweeteners.

**sulphanes** Compounds of hydrogen and sulphur containing chains of sulphur atoms. They have the general formula  $\text{H}_2\text{S}_n$ . The simplest is hydrogen sulphide,  $\text{H}_2\text{S}$ ; other members of the series are  $\text{H}_2\text{S}_2$ ,  $\text{H}_2\text{S}_3$ ,  $\text{H}_2\text{S}_4$ , etc. See SULPHIDES.

**sulphanilic acid (4-aminobenzene sulphonic acid)** A colourless crystalline solid,  $\text{H}_2\text{NC}_6\text{H}_4\text{SO}_2\text{OH}$ , made by prolonged heating of \*phenylamine (aniline) sulphate. It readily forms \*diazo compounds and is used to make dyes and sulpha drugs.

**sulphate** A salt or ester of sulphuric(VI) acid. Organic sulphates have the formula  $\text{R}_2\text{SO}_4$ , where R is an organic group. Sulphate salts contain the ion  $\text{SO}_4^{2-}$ .

**sulphides 1.** Inorganic compounds of sulphur with more electropositive elements. Compounds of sulphur with non-metals are covalent compounds, e.g. hydrogen sulphide ( $\text{H}_2\text{S}$ ). Metals form ionic sulphides containing the  $\text{S}^{2-}$  ion; these are salts of hydrogen sulphide. **Poly-sulphides** can also be produced containing the polymeric ion  $\text{S}_x^{2-}$ . **2. (thio ethers)** Organic compounds that contain the group  $-\text{S}-$  linked to two hydrocarbon groups. Organic sulphides are named from the linking groups, e.g. dimethyl sul-

phide ( $\text{CH}_3\text{SCH}_3$ ), ethyl methyl sulphide ( $\text{C}_2\text{H}_5\text{SCH}_3$ ). They are analogues of ethers in which the oxygen is replaced by sulphur (hence the alternative name) but are generally more reactive than ethers. Thus they react with halogen compounds to form \*sulphonium compounds and can be oxidized to \*sulphoxides.

**sulphinat** (**dithionite**; **hyposulphite**) A salt that contains the negative ion  $\text{S}_2\text{O}_4^{2-}$ , usually formed by the reduction of sulphites with excess  $\text{SO}_2$ . Solutions are not very stable and decompose to give thiosulphate and hydrogensulphite ions. The structure is  $\text{O}_2\text{S}-\text{SO}_2^-$ .

**sulphinic acid** (**dithionous acid**; **hyposulphurous acid**) An unstable acid,  $\text{H}_2\text{S}_2\text{O}_4$ , known in the form of its salts (sulphinates). See also SULPHURIC ACID.

**sulphite** A salt or ester derived from sulphurous acid. The salts contain the trioxosulphate(IV) ion  $\text{SO}_3^{2-}$ . The sulphites generally have reducing properties.

**sulphonamides** Organic compounds containing the group  $-\text{SO}_2\text{NH}_2$ . The sulphonamides are amides of sulphonic acids. Many have antibacterial action and are also known as **sulpha drugs**, including sulphadiazine,  $\text{NH}_2\text{C}_6\text{H}_4\text{SO}_2\text{NHC}_4\text{H}_3\text{N}_2$ , and several others. They act by preventing bacteria from reproducing and are used to treat a variety of bacterial infections, especially of the gut and urinary system.

**sulphonate** A salt or ester of a sulphonic acid.

**sulphonation** A type of chemical reaction in which a  $-\text{SO}_2\text{H}$  group is substituted on a benzene ring to form a \*sulphonic acid. The reaction is carried out by refluxing with concentrated sulphuric(VI) acid for a long period. It can also occur with cold disulphuric(VI) acid ( $\text{H}_2\text{S}_2\text{O}_7$ ). Sulphonation is an example of electrophilic substitution in which the electrophile is a sulphur trioxide molecule,  $\text{SO}_3$ .

**sulphonic acids** Organic compounds containing the  $-\text{SO}_2\text{OH}$  group. Sulphonic acids are formed by reaction of aromatic hydrocarbons with concentrated sulphuric acid. They are strong acids, ioniz-

ing completely in solution to form the sulphonate ion,  $-\text{SO}_2\text{O}^-$ .

**sulphonium compounds** Compounds containing the ion  $\text{R}_3\text{S}^+$  (sulphonium ion), where R is any organic group. Sulphonium compounds can be formed by reaction of organic sulphides with halogen compounds. For example, diethyl sulphide,  $\text{C}_2\text{H}_5\text{SC}_2\text{H}_5$ , reacts with chloromethane,  $\text{CH}_3\text{Cl}$ , to give diethylmethylsulphonium chloride,  $(\text{C}_2\text{H}_5)_2\text{CH}_3\text{S}^+\text{Cl}^-$ .

$\text{R}-\text{S}-\text{R}$  sulphide (thio ether)

$\begin{array}{c} \text{R} \\ | \\ \text{S}^+ \\ | \\ \text{R} \end{array}$  sulphonium ion

$\text{R}-\text{S}-\text{H}$  thiol (mercaptan)

$\begin{array}{c} \text{R} \\ \diagdown \\ \text{S}=\text{O} \\ \diagup \\ \text{R} \end{array}$  sulphoxide

$\begin{array}{c} \text{O} \\ || \\ \text{R}-\text{S}-\text{OH} \\ || \\ \text{O} \end{array}$  sulphonic acid

$\begin{array}{c} \text{O} \\ || \\ \text{R}-\text{S}-\text{O}^- \\ || \\ \text{O} \end{array}$  sulphonate ion

$\begin{array}{c} \text{O} \\ || \\ \text{R}-\text{S}-\text{NH}_2 \\ || \\ \text{O} \end{array}$  sulphonamide

Examples of organic sulphur compounds

**sulphoxides** Organic compounds containing the group  $=\text{S}=\text{O}$  (**sulphoxide group**) linked to two other groups, e.g. dimethyl sulphoxide,  $(\text{CH}_3)_2\text{SO}$ .

**sulphur** Symbol S. A yellow nonmetallic element belonging to \*group 16 (formerly VI B) of the periodic table; a.n. 16; r.a.m. 32.06; r.d. 2.07 (rhombic); m.p. 112.8°C; b.p. 444.674°C. The element occurs in many sulphide and sulphate minerals and native sulphur is also found in Sicily and

the USA (obtained by the \*Frasch process). It can also be obtained from hydrogen sulphide by the \*Claus process.

Sulphur has various allotropic forms. Below 95.6°C the stable crystal form is rhombic; above this temperature the element transforms into a triclinic form. These crystalline forms both contain cyclic  $S_8$  molecules. At temperatures just above its melting point, molten sulphur is a yellow liquid containing  $S_8$  rings (as in the solid form). At about 160°C, the sulphur atoms form chains and the liquid becomes more viscous and dark brown. If the molten sulphur is cooled quickly from this temperature (e.g. by pouring into cold water) a reddish-brown solid known as **plastic sulphur** is obtained. Above 200°C the viscosity decreases. Sulphur vapour contains a mixture of  $S_2$ ,  $S_4$ ,  $S_6$ , and  $S_8$  molecules. **Flowers of sulphur** is a yellow powder obtained by subliming the vapour. It is used as a plant fungicide. The element is also used to produce sulphuric acid and other sulphur compounds.

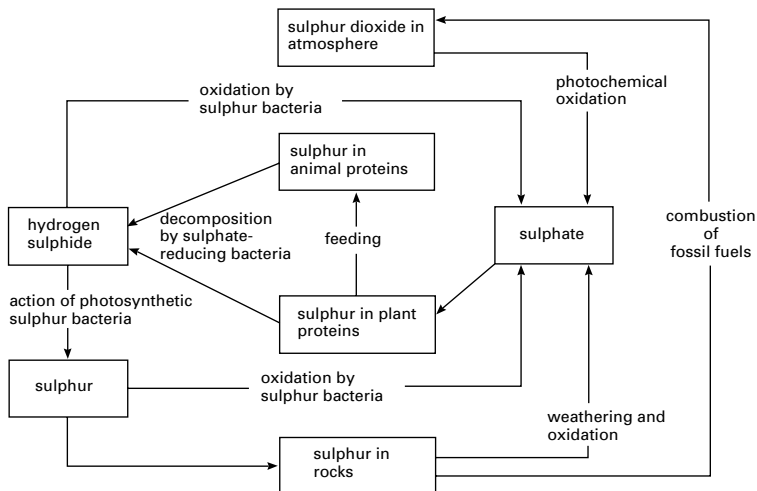

Sulphur is an \*essential element in living organisms, occurring in the amino acids cysteine and methionine and therefore in many proteins. It is also a constituent of various cell metabolites, e.g.

coenzyme A. Sulphur is absorbed by plants from the soil as the sulphate ion ( $SO_4^{2-}$ ). See SULPHUR CYCLE.

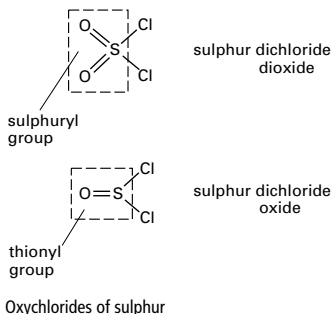

**sulphur bridge** See DISULPHIDE BRIDGE.

**sulphur cycle** The cycling of sulphur between the biotic (living) and abiotic (nonliving) components of the environment (see BIOGEOCHEMICAL CYCLE). Most of the sulphur in the abiotic environment is found in rocks, although a small amount is present in the atmosphere as sulphur dioxide ( $SO_2$ ), produced by combustion of fossil fuels. Sulphate ( $SO_4^{2-}$ ), derived from the weathering and oxidation of rocks, is taken up by plants and incorporated into sulphur-containing proteins. In this form sulphur is passed along food chains to animals. Decomposition of dead organic matter and faeces by anaerobic sulphate-reducing bacteria returns sulphur to the abiotic environment in the form of hydrogen sulphide ( $H_2S$ ). Hydrogen sulphide can be converted back to sulphate or to elemental sulphur by the action of photosynthetic and sulphide-oxidizing bacteria. Elemental sulphur becomes incorporated into rocks.

**sulphur dichloride** See DISULPHUR DICHLORIDE.

The sulphur cycle

### sulphur dichloride dioxide (sulphuryl chloride)

A colourless liquid,  $\text{SO}_2\text{Cl}_2$ ; r.d. 1.67; m.p.  $-54.1^\circ\text{C}$ ; b.p.  $69^\circ\text{C}$ . It decomposes in water but is soluble in benzene. The compound is formed by the action of chlorine on sulphur dioxide in the presence of an iron(III) chloride catalyst or sunlight. It is used as a chlorinating agent and a source of the related fluoride,  $\text{SO}_2\text{F}_2$ .

### sulphur dichloride oxide (thionyl chloride)

A colourless fuming liquid,  $\text{SOCl}_2$ ; m.p.  $-105^\circ\text{C}$ ; b.p.  $78.8^\circ\text{C}$ . It hydrolyses rapidly in water but is soluble in benzene. It may be prepared by the direct action of sulphur on chlorine monoxide or, more commonly, by the reaction of phosphorus(V) chloride with sulphur dioxide. It is used as a chlorinating agent in synthetic organic chemistry (replacing  $-\text{OH}$  groups with  $\text{Cl}$ ).

**sulphur dioxide (sulphur(IV) oxide)** A colourless liquid or pungent gas,  $\text{SO}_2$ , formed by sulphur burning in air; r.d. 1.43 (liquid); m.p.  $-72.7^\circ\text{C}$ ; b.p.  $-10^\circ\text{C}$ . It can be made by heating iron sulphide (pyrites) in air. The compound is a reducing agent and is used in bleaching and as a fumigant and food preservative. Large quantities are also used in the \*contact process for manufacturing sulphuric acid. It dissolves in water to give a mixture of sulphuric and sulphurous acids. *See also* ACID RAIN.

**sulphuretted hydrogen** *See* HYDROGEN SULPHIDE.

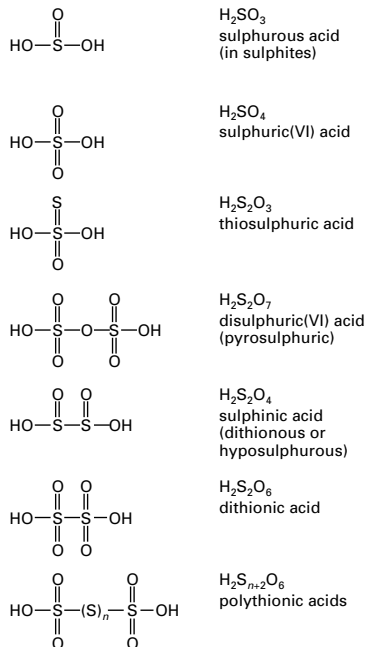

**sulphuric acid (oil of vitriol)** A colourless oily liquid,  $\text{H}_2\text{SO}_4$ ; r.d. 1.84; m.p.  $10.36^\circ\text{C}$ ; b.p.  $338^\circ\text{C}$ . The pure acid is rarely used; it is commonly available as a

96–98% solution (m.p.  $3.0^\circ\text{C}$ ). The compound also forms a range of hydrates:  $\text{H}_2\text{SO}_4 \cdot \text{H}_2\text{O}$  (m.p.  $8.62^\circ\text{C}$ );  $\text{H}_2\text{SO}_4 \cdot 2\text{H}_2\text{O}$  (m.p.  $-38/39^\circ\text{C}$ );  $\text{H}_2\text{SO}_4 \cdot 6\text{H}_2\text{O}$  (m.p.  $-54^\circ\text{C}$ );  $\text{H}_2\text{SO}_4 \cdot 8\text{H}_2\text{O}$  (m.p.  $-62^\circ\text{C}$ ).

Its full systematic name is **tetraoxosulphur(VI) acid**.

Until the 1930s, sulphuric acid was manufactured by the \*lead-chamber process, but this has now been replaced by the \*contact process (catalytic oxidation of sulphur dioxide). It is extensively used in industry, the main applications being fertilizers (32%), chemicals (16%), paints and pigments (15%), detergents (11%), and fibres (9%).

In concentrated sulphuric acid there is extensive hydrogen bonding and several competing equilibria, to give species such as  $\text{H}_3\text{O}^+$ ,  $\text{HSO}_4^-$ ,  $\text{H}_3\text{SO}_4^+$ , and  $\text{H}_2\text{S}_2\text{O}_7$ . Apart from being a powerful protonating agent (it protonates chlorides and nitrates producing hydrogen chloride and nitric acid),

Structures of some oxo acids of sulphur

the compound is a moderately strong oxidizing agent. Thus, it will dissolve copper:

It is also a powerful dehydrating agent, capable of removing H<sub>2</sub>O from many organic compounds (as in the production of acid \*anhydrides). In dilute solution it is a strong dibasic acid forming two series of salts, the sulphates and the hydrogensulphates.

**sulphuric(IV) acid** See SULPHUROUS ACID.

**sulphur monochloride** See DISULPHUR DICHLORIDE.

**sulphurous acid (sulphuric(IV) acid)** A weak dibasic acid, H<sub>2</sub>SO<sub>3</sub>, known in the form of its salts: the sulphites and hydrogensulphites. It is considered to be formed (along with sulphuric acid) when sulphur dioxide is dissolved in water. It is probable, however, that the molecule H<sub>2</sub>SO<sub>3</sub> is not present and that the solution contains hydrated SO<sub>2</sub>. It is a reducing agent. The systematic name is **trioxosulphuric(IV) acid**. See also SULPHURIC ACID.

**sulphur(IV) oxide** See SULPHUR DIOXIDE.

**sulphur(VI) oxide** See SULPHUR TRIOXIDE.

**sulphur trioxide (sulphur(VI) oxide)** A colourless fuming solid, SO<sub>3</sub>, which has three crystalline modifications. In decreasing order of stability these are:  $\alpha$ , r.d. 1.97; m.p. 16.83°C; b.p. 44.8°C;  $\beta$ , m.p. 16.24°C; sublimates at 50°C; r.d. 2.29;  $\gamma$ , m.p. 16.8°C; b.p. 44.8°C. All are polymeric, with linked SO<sub>4</sub> tetrahedra: the  $\gamma$ -form has an icelike structure and is obtained by rapid quenching of the vapour; the  $\beta$ -form has infinite helical chains; and the  $\alpha$ -form has infinite chains with some cross-linking of the SO<sub>4</sub> tetrahedra. Even in the vapour, there are polymeric species, and not discrete sulphur trioxide molecules (hence the compound is more correctly called by its systematic name **sulphur(VI) oxide**).

Sulphur trioxide is prepared by the oxidation of sulphur dioxide with oxygen in the presence of a vanadium(V) oxide cata-

lyst. It may be prepared in the laboratory by distilling a mixture of concentrated sulphuric acid and phosphorus(V) oxide. It reacts violently with water to give sulphuric(VI) acid and is an important intermediate in the preparation of sulphuric acid and oleum.

**sulphuryl chloride** See SULPHUR DICHLORIDE DIOXIDE.

**sulphuryl group** The group =SO<sub>2</sub>, as in \*sulphur dichloride oxide.

**sulphydryl group** See THIOLS.

**summation 1.** (in neurophysiology) The combined effect of the changes in electric potential elicited in one or more postsynaptic membranes by the transmission of impulses at \*synapses that is sufficient to trigger an action potential in the postsynaptic neuron. Summation occurs when one or a few postsynaptic potentials alone are insufficient to elicit a response in the postsynaptic neuron; it may consist of the effect of two or more potentials evoked simultaneously at different synapses on the same neuron (**spatial summation**) or in rapid succession at the same synapse (**temporal summation**). **2.** See SYNERGISM.

**sun** The \*star at the centre of the \*solar system. A typical main-sequence dwarf star (see HERTZSPRUNG-RUSSELL DIAGRAM; STELLAR EVOLUTION), the sun is some 149 600 000 km from earth. It has a diameter of about 1 392 000 km and a mass of  $1.9 \times 10^{30}$  kg. Hydrogen and helium are the primary constituents (about 75% hydrogen, 25% helium), with less than 1% of heavier elements. In the central core, some 400 000 km in diameter, hydrogen is converted into helium by thermonuclear reactions, which generate vast quantities of energy. This energy is radiated into space and provides the earth with all the light and heat necessary to have created and maintained life (see SOLAR CONSTANT). The surface of the sun, the \*photosphere, forms the boundary between its opaque interior and its transparent atmosphere. It is here that \*sunspots occur. Above the photosphere is the \*chromosphere and above this the \*corona, which extends tenuously into interplanetary space. See also SOLAR WIND.

**sunspot** A dark patch in the sun's

\*photosphere resulting from a localized fall in temperature to about 4000 K. Most spots have a central very dark umbra surrounded by a lighter penumbra. Sunspots tend to occur in clusters and to last about two weeks. The number of sunspots visible fluctuates over an eleven-year cycle – often called the **sunspot cycle**. The cause is thought to be the presence of intense localized magnetic fields, which suppress the convection currents that bring hot gases to the photosphere.

**supercluster** See GALAXY CLUSTER.

**supercomputer** An extremely high-power computer that has a large amount of main \*memory and very fast processors, capable of several billion operations per second. Often the processors run in parallel (see PARALLEL PROCESSING). Examples include the Cray computers, which are used for weather forecasting and other applications that need rapid real-time processing of large amounts of data.

**superconductivity** The absence of measurable electrical resistance in certain substances at temperatures close to 0 K. First discovered in 1911 in mercury, superconductivity is now known to occur in some 26 metallic elements and many compounds and alloys. The temperature below which a substance becomes superconducting is called the **transition temperature** (or **critical temperature**). Compounds are now known that show superconductivity at liquid-nitrogen temperatures.

The theoretical explanation of the phenomenon was given by John Bardeen, Leon Cooper (1930– ), and John Schrieffer (1931– ) in 1957 and is known as the **BCS theory**. According to this theory an electron moving through an elastic crystal lattice creates a slight distortion of the lattice as a result of Coulomb forces between the positively charged lattice and the negatively charged electron. If this distortion persists for a finite time it can affect a second passing electron. In 1956 Cooper showed that the effect of this phenomenon is for the current to be carried in superconductors not by individual electrons but by bound pairs of electrons, the **Cooper pairs**. The BCS theory is based on a \*wave function in which all the electrons are paired. Because the total momentum

of a Cooper pair is unchanged by the interaction between one of its electrons and the lattice, the flow of electrons continues indefinitely.

Superconducting coils in which large currents can circulate indefinitely can be used to create powerful magnetic fields and are used for this purpose in some particle accelerators and in other devices.

Superconductivity can also occur by a slightly more complicated mechanism than BCS theory in \*heavy-fermion systems. In 1986, Georg Bednorz (1950– ) and Karl Müller (1927– ) found an apparently completely different type of superconductivity. This is called **high-temperature superconductivity**, since the critical temperature is very much higher than for BCS superconductors; some high-temperature superconductors have critical temperatures greater than 100 K. A typical high-temperature superconductor is  $\text{YBa}_2\text{Cu}_3\text{O}_{1-7}$ .

At the present time a theory of high-temperature superconductivity has not yet been established.

**supercooling 1.** The cooling of a liquid to below its freezing point without a change from the liquid to solid state taking place. In this metastable state the particles of the liquid lose energy but do not fall into place in the lattice of the solid crystal. If the liquid is seeded with a small crystal, crystallization usually takes place and the temperature returns to the freezing point. Crystallization can also be induced by the presence of particles of dust, by mechanical vibration, or by rough surfaces. This is a common occurrence in the atmosphere where water droplets frequently remain unfrozen at temperatures well below 0°C until disturbed, following which they rapidly freeze. The supercooled droplets, for example, rapidly freeze on passing aircraft forming ‘icing’, which can be a hazard. **2.** The analogous cooling of a vapour to make it supersaturated until a disturbance causes condensation to occur, as in the Wilson \*cloud chamber.

**supercritical** See CRITICAL MASS; CRITICAL REACTION; MULTIPLICATION FACTOR.

**superficial expansivity** See EXPANSIVITY.

**superfluidity** The property of liquid helium at very low temperatures that enables it to flow without friction. Both helium isotopes possess this property, but  $^4\text{He}$  becomes superfluid at 2.172 K, whereas  $^3\text{He}$  does not become superfluid until a temperature of 0.00093 K is reached. There is a basic connection between superfluidity and \*superconductivity, so that sometimes a superconductor is called a charged superfluid. The temperature at which superfluidity occurs is called the **lambda point**.

**supergiant** The largest and most luminous type of star. They are formed from the most massive stars and are therefore very rare. They lie above the giants on the \*Hertzsprung–Russell diagram. *See also* STELLAR EVOLUTION.

**supergravity** A \*unified-field theory for all the known fundamental interactions that involves \*supersymmetry. Supergravity is most naturally formulated as a \*Kaluza–Klein theory in eleven dimensions. The theory contains particles of spin 2, spin 3/2, spin 1, spin 1/2, and spin 0. Although supersymmetry means that the infinities in the calculations are less severe than in other attempts to construct a quantum theory of gravity, it is probable that supergravity still contains infinities that cannot be removed by the process of \*renormalization. It is thought by many physicists that to obtain a consistent quantum theory of gravity one has to abandon \*quantum field theories, since they deal with point objects, and move to theories based on extended objects, such as \*superstrings and \*supermembranes, and therefore that supergravity is not a complete theory of the fundamental interactions.

**superheating** The heating of a liquid to above its normal boiling point by increasing the pressure.

**superheterodyne receiver** A widely used type of radio receiver in which the incoming radio-frequency signal is mixed with an internally generated signal from a local oscillator. The output of the mixer has a carrier frequency equal to the difference between the transmitted frequency and the locally generated frequency, still retains the transmitted modulation, and is

called the **intermediate frequency** (IF). The IF signal is amplified and demodulated before being passed to the audio-frequency amplifier. This system enables the IF signal to be amplified with less distortion, greater gain, better selectivity, and easier elimination of noise than can be achieved by amplifying the radio-frequency signal.

**super high frequency (SHF)** A radio frequency in the range 3–30 gigahertz.

**superionic conductor** An ionic solid in which the electrical conductivity due to the motion of ions is similar to that of a molten salt, i.e. a much higher conductivity than is usually observed in ionic solids.

**superior** Describing a structure that is positioned above or higher than another structure in the body. For example, in flowering plants the ovary is described as superior when located above the other organs of the flower. *Compare* INFERIOR.

**superlattice** *See* SOLID SOLUTION.

**supermembrane theory** A unified theory of the \*fundamental interactions involving \*supersymmetry, in which the basic entities are two-dimensional extended objects (**supermembranes**). They are thought to have about the same length scale as \*superstrings, i.e.  $10^{-35}$  m. At the present time there is no experimental evidence for supermembranes.

**supernatant liquid** The clear liquid remaining when a precipitate has settled.

**supernova** An explosive brightening of a star in which the energy radiated by it increases by a factor of  $10^{10}$ . It takes several years to fade and while it lasts dominates the whole galaxy in which it lies. It is estimated that there could be a supernova explosion in the Milky Way every 30 years, although only six have actually been observed in the last 1000 years. A supernova explosion occurs when a star has burnt up all its available nuclear fuel and the core collapses catastrophically (*see* STELLAR EVOLUTION). *Compare* NOVA.

**superoxides** A group of inorganic compounds that contain the  $\text{O}_2^-$  ion. They are formed in significant quantities only for sodium, potassium, rubidium, and caesium. They are very powerful oxidizing agents and react vigorously with water to

give oxygen gas and OH<sup>-</sup> ions. The superoxide ion has an unpaired electron and is paramagnetic and coloured (orange).

**superphosphate** A commercial phosphate mixture consisting mainly of mono-calcium phosphate. It is made by treating phosphate rock with sulphuric acid; the product contains 16–20% 'available' P<sub>2</sub>O<sub>5</sub>:

Triple-superphosphate is made by using phosphoric(V) acid in place of sulphuric acid; the product contains 45–50% 'available' P<sub>2</sub>O<sub>5</sub>:

**superplasticity** The ability of some metals and alloys to stretch uniformly by several thousand percent at high temperatures, unlike normal alloys, which fail after being stretched 100% or less. Since 1962, when this property was discovered in an alloy of zinc and aluminium (22%), many alloys and ceramics have been shown to possess this property. For superplasticity to occur, the metal grain must be small and rounded and the alloy must have a slow rate of deformation.

**supersaturated solution** See SATURATED.

**supersaturation** **1.** The state of the atmosphere in which the relative humidity is over 100%. This occurs in pure air where no condensation nuclei are available. Supersaturation is usually prevented in the atmosphere by the abundance of condensation nuclei (e.g. dust, sea salt, and smoke particles). **2.** The state of any vapour whose pressure exceeds that at which condensation usually occurs (at the prevailing temperature).

**supersonic** See MACH NUMBER.

**superstring theory** A unified theory of the \*fundamental interactions involving supersymmetry, in which the basic objects are one-dimensional objects (**superstrings**). Superstrings are thought to have a length scale of about 10<sup>-35</sup> m and, since very short distances are associated with very high energies, they should have energy scales of about 10<sup>19</sup> GeV, which is far

beyond the energy of any accelerator that can be envisaged.

Strings associated with bosons are only consistent as quantum theories in a 26-dimensional \*space-time; those associated with fermions are only consistent as quantum theories in 10-dimensional space-time. It is thought that four macroscopic dimensions arise by a Kaluza-Klein mechanism, with the remaining dimensions being 'curled up' to become very small.

One of the most attractive features of the theory of superstrings is that it leads to spin 2 particles, which are identified as \*gravitons. Thus, a superstring theory automatically contains a quantum theory of the gravitational interaction. It is thought that superstrings are free of the infinities that cannot be removed by \*renormalization, which plague attempts to construct a quantum field theory incorporating gravity. There is some evidence that superstring theory is free of infinities but not a complete proof yet.

**supersymmetry** A \*symmetry that can be applied to elementary particles so as to include both bosons and fermions. In the simplest supersymmetry theories, every boson has a corresponding fermion partner and every fermion has a corresponding boson partner. The boson partners of existing fermions have names formed by adding 's' to the beginning of the name of the fermion, e.g. **selectron**, **squark**, and **slepton**. The fermion partners of existing bosons have names formed by replacing '-on' at the end of the boson's name by '-ino' or by adding '-ino', e.g. **gluino**, **photino**, **wino**, and **zino**.

If supersymmetry is relevant to observed elementary particles then it must be a \*broken symmetry, although there is no convincing evidence at present to show at what energy it would be broken. There is, in fact, no experimental evidence for the theory, although it is thought that the idea of strings with supersymmetry may be the best approach to unifying the four fundamental interactions (see SUPERSTRING THEORY).

**supervolcano** See VOLCANO.

**supination** Rotation of the lower forearm so that the hand faces forwards or

upwards with the radius and ulna parallel.  
*Compare* PRONATION.

**supplementary units** *See* SI UNITS.

**suppressed-carrier transmission** *See* TRANSMITTER.

**suppressor grid** A wire grid in a pen-tode \*thermionic valve placed between the \*screen grid and the anode to prevent electrons produced by \*secondary emission from the anode from reaching the screen grid.

**supramolecular chemistry** A field of chemical research concerned with the formation and properties of large assemblies of molecules held together by intramolecular forces (hydrogen bonds, van der Waals' forces, etc.). One feature of supramolecular chemistry is that of **self-assembly** (*see* SELF-ORGANIZATION), in which the structure forms spontaneously as a consequence of the nature of the molecules. The molecular units are sometimes known as **synthons**. Another aspect is the study of very large molecules able to be used in complex chemical reactions in a fashion similar to, for example, the actions of the naturally occurring haemoglobin and nucleic acid molecules. Typical examples are the \*helicate and \*texaphyrin molecules and \*dendrimers. Such molecules have great potential in such areas as medicine, electronics, and optics. The field also includes **host-guest chemistry**, which is concerned with molecules specifically designed to accept other molecules. Examples include \*crown ethers, \*cryptands, and \*calixarenes.

**suprarenal glands** *See* ADRENAL GLANDS.

**surd** A quantity that cannot be expressed as a \*rational number. It consists of the root of an arithmetic member (e.g.  $\sqrt{3}$ ), which cannot be exactly determined, or the sum or difference of such roots.

**surface tension** Symbol  $\gamma$ . The property of a liquid that makes it behave as if its surface is enclosed in an elastic skin. The property results from intermolecular forces: a molecule in the interior of a liquid experiences a force of attraction from other molecules equally from all sides, whereas a molecule at the surface is only

attracted by molecules below it in the liquid. The surface tension is defined as the force acting over the surface per unit length of surface perpendicular to the force. It is measured in newtons per metre. It can equally be defined as the energy required to increase the surface area by one square metre, i.e. it can be measured in joules per metre squared (which is equivalent to  $\text{N m}^{-1}$ ).

The surface tension of water is very strong, due to the intermolecular hydrogen bonding, and is responsible for the formation of drops, bubbles, and meniscuses, as well as the rise of water in a capillary tube (**capillarity**), the absorption of liquids by porous substances, and the ability of liquids to wet a surface. Capillarity is very important in plants as it is largely responsible for the transport of water, against gravity, within the plant.

**surfactant (surface active agent)** A substance, such as a \*detergent, added to a liquid to increase its wetting properties by reducing its \*surface tension.

**surveying** The practice of accurately measuring and recording the relative altitudes, angles, and distances of features on, above, or below the land surface from which maps and plans can be plotted. Surveying is necessary to locate and measure property lines; to lay out buildings, bridges, roads, dams, and other constructions; and to obtain topographic information for mapping and charting. A number of methods are used depending on the degree of precision that is required. The chief methods include triangulation, trilateration, levelling (*see* LEVEL), plane tabling, and traversing.

**susceptance** Symbol  $B$ . The reciprocal of the \*reactance of a circuit and thus the imaginary part of its \*admittance. It is measured in siemens.

**susceptibility 1. (magnetic susceptibility)** Symbol  $\chi_m$ . The dimensionless quantity describing the contribution made by a substance when subjected to a magnetic field to the total magnetic flux density present. It is equal to  $\mu_r - 1$ , where  $\mu_r$  is the relative \*permeability of the material. Diamagnetic materials have a low negative susceptibility, paramagnetic materials have a low positive susceptibility, and fer-

romagnetic materials have a high positive value. **2. (electric susceptibility)** Symbol  $\chi_e$ . The dimensionless quantity referring to a \*dielectric equal to  $P/\epsilon_0 E$ , where  $P$  is the electric polarization,  $E$  is the electric intensity producing it, and  $\epsilon_0$  is the electric constant. The electric susceptibility is also equal to  $\epsilon_r - 1$ , where  $\epsilon_r$  is the relative \*permittivity of the dielectric.

**suspension** A mixture in which small solid or liquid particles are suspended in a liquid or gas.

**suture** The line marking the junction of two body structures. Examples are the immovable joints between the bones of the skull and, in plants, the seam along the edge of a pea or bean pod.

**swallowing** See DEGLUTITION.

**swash** A surge of turbulent seawater that rushes up the shore after a wave breaks; it runs back down the slope as a backwash. The swash can carry materials, such as driftwood, seashells, and seaweed, which are often left on the beach as a line marking the extent of high tide. On a falling tide the backwash may form a series of channels.

**sweat** The salty fluid secreted by the \*sweat glands onto the surface of the skin. Excess body heat is used to evaporate sweat, thereby resulting in cooling of the skin surface. Small amounts of urea are excreted in sweat.

**sweat gland** A small gland in mammalian skin that secretes \*sweat. The distribution of sweat glands on the body surface varies between species: they occur over most of the body surface in humans and higher primates but have a more restricted distribution in other mammals.

**swim bladder (air bladder)** An air-filled sac lying above the alimentary canal in bony fish that regulates the buoyancy of the animal. Air enters or leaves the bladder either via a pneumatic duct opening into the oesophagus or stomach or via capillary blood vessels, so that the specific gravity of the fish always matches the depth at which it is swimming. This makes the fish weightless, so less energy is required for locomotion. In lungfish it also has a respiratory function. The lungs

of tetrapods are homologous with the swim bladder, which has developed its hydrostatic function by specialization.

**syconus** A type of \*composite fruit formed from a hollow fleshy inflorescence stalk inside which tiny flowers develop. Small \*drupes, the 'pips', are produced by the female flowers. An example is the fig.

**sylvite (sylvine)** A mineral form of \*potassium chloride, KCl.

**symbiont** An organism that is a partner in a symbiotic relationship (see SYMBIOSIS).

**symbiosis** An interaction between individuals of different species (**symbionts**). The term symbiosis is usually restricted to interactions in which both species benefit (see MUTUALISM), but it may be used for other close associations, such as \*commensalism. Many symbioses are obligatory (i.e. the participants cannot survive without the interaction); for example, a lichen is an obligatory symbiotic relationship between an alga or a cyanobacterium and a fungus.

**symmetry 1.** (in physics) The set of invariances of a system. Upon application of a symmetry operation on a system, the system is unchanged. Symmetry is studied mathematically using \*group theory. Some of the symmetries are directly physical. Examples include reflections and rotation for molecules and translation in crystal lattices. Symmetries can be **discrete** (i.e. have a finite number), such as the set of rotations for an octahedral molecule, or **continuous** (i.e. do not have a finite number), such as the set of rotations for atoms or nuclei. More general and abstract symmetries can occur, as in the symmetries associated with \*gauge theories. See also BROKEN SYMMETRY; SUPERSYMMETRY. **2.** (in biology) See BILATERAL SYMMETRY; RADIAL SYMMETRY.

**sympathetic nervous system** Part of the \*autonomic nervous system. Its nerve endings release noradrenaline or adrenaline as a neurotransmitter and its actions tend to antagonize those of the \*parasympathetic nervous system, thus achieving a balance in the organs they serve. For example, the sympathetic nervous system decreases salivary gland secretion, increases heart rate, and

constricts blood vessels, while the parasympathetic nervous system has opposite effects.

**sympatric** Describing groups of similar organisms that, although in close proximity and theoretically capable of interbreeding, do not interbreed because of differences in behaviour, flowering time, etc. See ISOLATING MECHANISM. Compare ALLOPATRIC.

**symphysis** A \*joint that is only slightly movable; examples are the joints between the vertebrae of the vertebral column and that between the two pubic bones in the pelvic girdle. The bones at a symphysis articulate by means of smooth layers of cartilage and strong fibres.

**symplast** The system of \*protoplasts in plants, which are interconnected by \*plasmodesmata. This forms a continuous system of cytoplasm bounded by the plasma membranes of the cells. The movement of water through the symplast is known as the **symplast pathway**. It is the only means by which water crosses the \*endodermis. Compare APOPLAST.

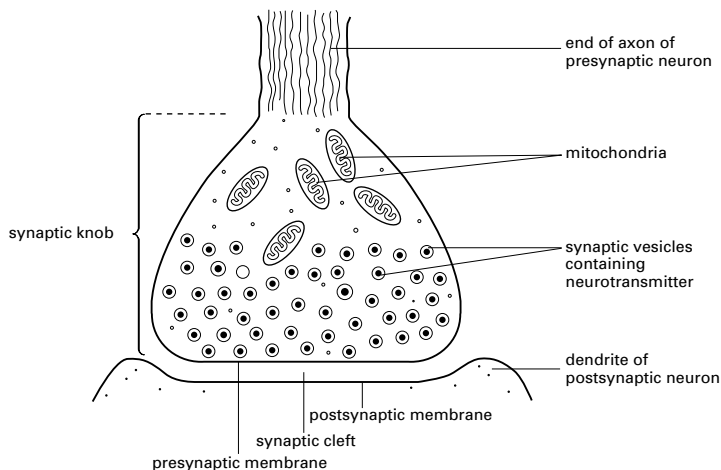

**sympodium** The composite primary axis of growth in such plants as lime and horse chestnut. After each season's growth the shoot tip of the main stem

stops growing (sometimes terminating in a flower spike); growth is continued by the tip of one or more of the lateral buds. Compare MONOPODIUM.

**synapse** The junction between two adjacent neurons (nerve cells), i.e. between the axon ending of one (the **presynaptic neuron**) and the dendrites of the next (the **postsynaptic neuron**). The swollen tip of the axon of the presynaptic neuron, called the **synaptic knob**, contains vesicles of \*neurotransmitter substance. At a synapse, the membranes of the two cells (the **pre- and postsynaptic membranes**) are in close contact, with only a minute gap (the **synaptic cleft**) between them. A nerve \*impulse is transmitted across the synapse by the release from the presynaptic membrane of neurotransmitter, which diffuses across the synaptic cleft to the postsynaptic membrane. This triggers the propagation of the impulse from the dendrite along the length of the postsynaptic neuron. Most neurons have more than one synapse. See also EXCITATORY POSTSYNAPTIC POTENTIAL.

**synapsis** (in genetics) See PAIRING.

**syncarpy** The condition in which the female reproductive organs (\*carpels) of a flower are joined to each other. It occurs,

Structure of a synapse

for example, in the primrose. *Compare* APOCARPY.

**synchrocyclotron** A form of \*cyclotron in which the frequency of the accelerating potential is synchronized with the increasing period of revolution of a group of the accelerated particles, resulting from their relativistic increase in mass as they reach \*relativistic speeds. The accelerator is used with protons, deuterons, and alpha particles.

**synchronous motor** *See* ELECTRIC MOTOR.

**synchronous orbit (geosynchronous orbit)** An orbit of the earth made by an artificial \*satellite with a period exactly equal to the earth's period of rotation on its axis, i.e. 23 hours 56 minutes 4.1 seconds. If the orbit is inclined to the equatorial plane the satellite will appear from the earth to trace out a figure-of-eight track once every 24 hours. If the orbit lies in the equatorial plane and is circular, the satellite will appear to be stationary. This is called a **stationary orbit** (or **geostationary orbit**) and it occurs at an altitude of 35 900 km. Most communication satellites are in stationary orbits, with three or more spaced round the orbit to give worldwide coverage.

**synchronous rotation** The rotation of a natural satellite in which the period of rotation is equal to its orbital period. The moon, for example, is in synchronous rotation about the earth and therefore always presents the same face to the earth.

**synchrotron** A particle accelerator used to impart energy to electrons and protons in order to carry out experiments in particle physics and in some cases to make use of the \*synchrotron radiation produced. The particles are accelerated in closed orbits (often circular) by radio-frequency fields. Magnets are spaced round the orbit to bend the trajectory of the particles and separate focusing magnets are used to keep the particles in a narrow beam. The radio-frequency accelerating cavities are interspersed between the magnets. The motion of the particles is automatically synchronized with the rising magnetic field, as the field strength has to increase as the particle energy increases; the fre-

quency of the accelerating field also has to increase synchronously.

**synchrotron radiation (magneto-bremsstrahlung)** Electromagnetic radiation that is emitted by charged particles moving at relativistic speeds in circular orbits in a magnetic field. The rate of emission is inversely proportional to the product of the radius of curvature of the orbit and the fourth power of the mass of the particles. For this reason, synchrotron radiation is not a problem in the design of proton \*synchrotrons but it is significant in electron synchrotrons. The greater the circumference of a synchrotron, the less important is the loss of energy by synchrotron radiation. In \*storage rings, synchrotron radiation is the principal cause of energy loss.

However, since the 1950s it has been realized that synchrotron radiation is itself a very useful tool and many accelerator laboratories have research projects making use of the radiation on a secondary basis to the main high-energy research. The radiation used for these purposes is primarily in the ultraviolet and X-ray frequencies.

Much of the microwave radiation from celestial radio sources outside the Galaxy is believed to originate from electrons moving in curved paths in celestial magnetic fields; it is also called synchrotron radiation as it is analogous to the radiation occurring in a synchrotron.

**syncline** *See* FOLD.

**syncytium** A group of animal cells in which cytoplasmic continuity is maintained. For example, the cells of striated muscle form a syncytium. In some syncytia the cells remain discrete but are joined together by cytoplasmic bridges.

**syndiotactic** *See* POLYMER.

**synecology** The study of ecology at the level of the \*community. A synecological study aims to investigate the relationships between different species that form a community and their interactions with the surrounding environment. Synecology involves both \*biotic and \*abiotic factors. *Compare* AUTECOLOGY.

**synergism (summation) 1.** The phenomenon in which the combined action

of two substances (e.g. drugs or hormones) produces a greater effect than would be expected from adding the individual effects of each substance. **2.** The combined action of one muscle (the **synergist**) with another (the **agonist**) in producing movement. *Compare* ANTAGONISM.

**syngamy** *See* FERTILIZATION.

**synodic month (lunation)** The interval between new \*moons. It is equal to 29 days, 12 hours, and 44 minutes.

**synodic period** The mean time taken by any object in the solar system to move between successive returns to the same position, relative to the sun as seen from the earth. Since a planet is best observed at opposition the synodic period of a planet,  $S$ , is easier to measure than its \*sidereal period,  $P$ . For inferior planets  $1/S = 1/P - 1/E$ ; for superior planets  $1/S = 1/E - 1/P$ , where  $E$  is the sidereal period of the earth.

**synoptic chart** *See* SYNOPTIC METEOROLOGY.

**synoptic meteorology** The branch of meteorology concerned with the study and analysis of weather information that is obtained simultaneously over a large area. It is based on the analysis of the **synoptic chart**, which is built up from simultaneous observations at weather stations of such elements as wind speed and direction, air temperature, cloud cover, and air pressure over an area at a particular time. Synoptic meteorology is applied chiefly to weather forecasting.

**synovial membrane** The membrane that lines the ligament surrounding a freely movable joint (such as that at the hip or elbow). It secretes a fluid (**synovial fluid**) that lubricates the layers of cartilage forming the articulating surfaces of the joint.

**synthesis** The formation of chemical compounds from more simple compounds.

**synthesis gas** A mixture of two parts hydrogen and one part carbon monoxide

made from methane and steam heated under pressure. It is used in the manufacture of various organic chemicals, including hydrocarbons, methanol, and other alcohols. *See also* HABER PROCESS.

**synthetic** Describing a substance that has been made artificially; i.e. one that does not come from a natural source.

**synthon** *See* SUPRAMOLECULAR CHEMISTRY.

**syrix** The sound-producing organ of a bird, situated at the lower end of the trachea where it splits into the bronchi. It has a complex structure with a number of vibrating membranes.

**systematics** The study of the diversity of organisms and their natural relationships. It is sometimes used as a synonym for \*taxonomy. The term **biosystematics** describes the experimental study of diversity, especially at the species level. Biosystematic methods include breeding experiments, biochemical work (known as **chemosystematics**), and cytotoxonomy. *See also* MOLECULAR SYSTEMATICS.

**Système International d'Unités** *See* SI UNITS.

**systemic circulation** The part of the circulatory system of birds and mammals that transports oxygenated blood from the left ventricle of the heart to the tissues in the body and returns deoxygenated blood from the tissues to the right atrium of the heart. *Compare* PULMONARY CIRCULATION. *See* DOUBLE CIRCULATION.

**systems software** *See* APPLICATIONS SOFTWARE.

**ystole** The phase of the heart beat during which the ventricles of the heart contract to force blood into the arteries. *Compare* DIASTOLE. *See* BLOOD PRESSURE.

**zygy** The situation that occurs when the sun, the moon (or a planet), and the earth are in a straight line. This occurs when the moon (or planet) is at \*conjunction or \*opposition.

**2,4,5-T** 2,4,5-trichlorophenoxyacetic acid (2,4,5-trichlorophenoxyethanoic acid): a synthetic \*auxin formerly widely used as a herbicide and defoliant. It is now banned in many countries as it tends to become contaminated with the toxic chemical \*dioxin.

**tachometer** An instrument for measuring angular speed, especially the number of revolutions made by a rotating shaft in unit time. Various types of instrument are used, including mechanical, electrical, and electronic devices. The widely used electrical-generator tachometer consists of a small generator in which the output voltage is a measure of the rate of rotation of the shaft that drives it.

**tachyon** A hypothetical particle that has a speed in excess of the \*speed of light. According to electromagnetic theory, a charged particle travelling through a medium at a speed in excess of the speed of light in that medium emits \*Cerenkov radiation. A charged tachyon would emit Cerenkov radiation even in a vacuum. No such particle has yet been detected. According to the special theory of \*relativity, it is impossible to accelerate a particle up to the speed of light because its energy  $E$ , given by  $E = mc^2/\sqrt{1 - v^2/c^2}$ , would have to become infinite. The theory, however, does not forbid the existence of particles with  $v > c$  (where  $c$  is the speed of light). In such cases the expression in the brackets becomes negative and the energy would be imaginary.

**tactic movement** See TAXIS.

**tactic polymer** See POLYMER.

**taiga** A terrestrial \*biome consisting mainly of evergreen coniferous forests (mainly pine, fir, and spruce), which occurs across subarctic North America and Eurasia. In certain parts, such as north-eastern Siberia, deciduous conifers and broadleaved trees, such as larch and birch, are dominant. Over most of the

taiga the ground is permanently frozen within about one metre of the surface, which prevents water from filtering down to deeper levels in the soil. This means that bogs may form in depressions. For at least six months of the year temperatures are below freezing but there is a short growing season lasting 3–5 months. The soil in taiga areas is acidic and infertile. Compare TUNDRA.

**talc** A white or pale-green mineral form of magnesium silicate,  $Mg_3Si_4O_{10}(OH)_2$ , crystallizing in the triclinic system. It forms as a secondary mineral by alteration of magnesium-rich olivines, pyroxenes, and amphiboles of ultrabasic rocks. It is soaplike to touch and very soft, having a hardness of 1 on the Mohs' scale. Massive fine-grained talc is known as **soapstone** or **steatite**. Talc in powdered form is used as a lubricant, as a filler in paper, paints, and rubber, and in cosmetics, ceramics, and French chalk. It occurs chiefly in the USA, Russia, France, and Japan.

**Tamm, Igor** See CERENKOV, PAVEL.

**tandem generator** A type of particle generator, essentially consisting of a \*Van de Graaff generator that maintains one electrode at a high positive potential; this electrode is placed between two earthed electrodes. Negative ions are accelerated from earth potential to the positively charged electrode, where surplus electrons are stripped from the ions to produce positive ions, which are accelerated again from the positive electrode back to earth. Thus the ions are accelerated twice over by a single high potential. This tandem arrangement enables energies up to 30 MeV to be achieved.

**tangent 1.** A line that touches a curve or a plane that touches a surface. **2.** See TRIGONOMETRIC FUNCTIONS.

**tangent galvanometer** A type of galvanometer, now rarely used, in which a

small magnetic needle is pivoted horizontally at the centre of a vertical coil that is adjusted to be parallel to the horizontal component of the earth's magnetic field. When a current  $I$  is passed through the coil, the needle is deflected so that it makes an angle  $\theta$  with its equilibrium position parallel to the earth's field. The value of  $I$  is given by  $I = (2Hr \tan \theta) / n$ , where  $H$  is the strength of the earth's horizontal component of magnetizing force,  $r$  is the radius of the coil, and  $n$  is the number of turns in the coil. Although not now used for measuring current, the instrument provides a means of measuring the earth's magnetizing force.

**tanh** See HYPERBOLIC FUNCTIONS.

**tannic acid** A yellowish complex organic compound present in certain plants. It is used in dyeing as a mordant.

**tannin** One of a group of complex organic chemicals commonly found in leaves, unripe fruits, and the bark of trees. Their function is uncertain though the unpleasant taste may discourage grazing animals. Some tannins have commercial uses, notably in the production of leather and ink.

**tantalum** Symbol Ta. A heavy blue-grey metallic \*transition element; a.n. 73; r.a.m. 180.948; r.d. 16.63; m.p. 2996°C; b.p. 5427°C. It is found with niobium in the ore columbite-tantalite (Fe,Mn)-(Ta,Nb)<sub>2</sub>O<sub>6</sub>. It is extracted by dissolving in hydrofluoric acid, separating the tantalum and niobium fluorides to give K<sub>2</sub>TaF<sub>7</sub>, and reduction of this with sodium. The element contains the stable isotope tantalum-181 and the long-lived radioactive isotope tantalum-180 (0.012%; half-life >10<sup>7</sup> years). There are several other short-lived isotopes. The element is used in certain alloys and in electronic components. Tantalum parts are also used in surgery because of the unreactive nature of the metal (e.g. in pins to join bones). Chemically, the metal forms a passive oxide layer in air. It forms complexes in the +2, +3, +4, and +5 oxidation states. Tantalum was identified in 1802 by Anders Ekeberg (1767–1813) and first isolated in 1820 by Jöns Berzelius.

**tapetum** A reflecting layer, containing

crystals of guanine, in the \*choroid of the eye of many nocturnal vertebrates. It reflects light back onto the retina, thus improving vision and causing the eyes to shine in the dark.

**tapeworms** See CESTODA.

**tap root** See ROOT.

**tar** Any of various black semisolid mixtures of hydrocarbons and free carbon, produced by destructive distillation of \*coal or by \*petroleum refining.

**tarsal (tarsal bone)** One of the bones that form the ankle (see TARSUS) in terrestrial vertebrates.

**tar sand** See OIL SAND.

**tarsus** The ankle (or corresponding part of the hindlimb) in terrestrial vertebrates, consisting of a number of small bones (**tarsals**). The number of tarsal bones varies with the species: humans, for example, have seven.

**tartaric acid** A white crystalline naturally occurring carboxylic acid, (CHOH)<sub>2</sub>(COOH)<sub>2</sub>; r.d. 1.8; m.p. 171–174°C. It can be obtained from tartar (potassium hydrogen tartrate) deposits from wine vats, and is used in baking powders and as a foodstuffs additive. The compound is optically active (see OPTICAL ACTIVITY). The systematic name is **2,3-dihydroxybutanedioic acid**.

**tartrate** A salt or ester of \*tartaric acid.

**tartrazine** A food additive (E102) that gives foods a yellow colour. Tartrazine can cause a toxic response in the immune system and is banned in some countries.

**taste 1.** The sense that enables the flavour of different substances to be distinguished (see TASTE BUD). **2.** The flavour of a substance.

**taste bud** A small sense organ in most vertebrates, specialized for the detection of taste. In terrestrial animals taste buds are concentrated on the upper surface of the \*tongue. They are sensitive to four types of taste: sweet, salt, bitter, or sour. The taste bud transmits information about a particular type of taste to the brain via nerve fibres. The four types of

taste bud show distinct distribution patterns on the surface of the human tongue.

In fishes, taste buds are distributed over the entire surface of the body and provide information about the surrounding water.

**TATA box (Hogness box)** A sequence of nucleotides that serves as the main recognition site for the attachment of RNA polymerase in the \*promoter of eukaryotic genes. Located at around 25 nucleotides before the start of transcription, it consists of the seven-base \*consensus sequence TATAAAA, and is analogous to the \*Pribnow box in prokaryotic promoters.

**Tatum, Edward** See BEADLE, GEORGE WELLS.

**tau particle** See ELEMENTARY PARTICLES; LEPTON.

**tautomerism** A type of \*isomerism in which the two isomers (**tautomers**) are in equilibrium. See KETO-ENOL TAUTOMERISM.

**taxis (taxic response; tactic movement)** The movement of a cell (e.g. a gamete) or a microorganism in response to an external stimulus. Certain microorganisms have a light-sensitive region that enables them to move towards or away from high light intensities (positive and negative \*phototaxis respectively). Many bacteria move in response to chemical stimuli (**chemotaxis**); a specific example is **aerotaxis**, in which atmospheric oxygen is the stimulus. Taxic responses are restricted to cells that possess cilia, flagella, or some other means of locomotion. The term is usually not applied to the movements of higher animals. Compare KINESIS; TROPISM.

**taxon** (*pl.* taxa) Any named taxonomic group of any \*rank in the hierarchical \*classification of organisms. Thus the taxa Papilionidae, Lepidoptera, Hexapoda, and Uniramia are named examples of a family, order, class, and phylum, respectively.

**taxonomy** The study of the theory, practice, and rules of \*classification of living and extinct organisms. The naming, description, and classification of a given organism draws on evidence from a number of fields. **Classical taxonomy** is based on morphology and anatomy. **Cytotaxonomy** compares the size, shape, and number of chromosomes of different or-

ganisms. **Numerical taxonomy** uses mathematical procedures to assess similarities and differences and establish taxonomic groups. See also SYSTEMATICS.

**Taylor series** The infinite power series of derivatives into which a function  $f(x)$  can be expanded, for a fixed value of the variable  $x = a$ :

$$f(x) = f(a) + f'(a)(x - a) + f''(a)(x - a)^2/2! + \dots$$

When  $a = 0$ , the series formed is known as **Maclaurin's series**:

$$f(x) = f(0) + f'(0)x + f''(0)x^2/2! + \dots$$

The series was discovered by Brook Taylor (1685-1731) and the special case was named after Colin Maclaurin (1698-1746).

**TCA cycle** See KREBS CYCLE.

**T cell (T lymphocyte)** Any of a population of \*lymphocytes that are the principal agents of cell-mediated \*immunity. T cells are derived from the bone marrow but migrate to the thymus to mature (hence T cell). Subpopulations of T cells play different roles in the immune response and can be characterized by their surface antigens (see CD). **Helper T cells** recognize foreign antigens provided these are presented by inducer cells (such as macrophages and B lymphocytes) bearing class II \*histocompatibility antigens. The helper T cell carries **T-cell receptors**, which recognize the class II antigens on the inducer cell. Interleukin-1 released by inducer cells stimulates helper T cells to release interleukin-2, which in turn triggers the release of other cytokines (see INTERLEUKIN). Consequently there is a proliferation of B lymphocytes and the generation of **effector T cells**, i.e. cytotoxic T cells, delayed hypersensitivity T cells, and suppressor T cells.

**Cytotoxic T cells** recognize foreign antigen on the surface of virus-infected cells and destroy the cell by releasing cytolytic proteins. **Suppressor T cells** are important in regulating the activity of other lymphocytes and are crucial in maintaining tolerance to self tissues. **Delayed hypersensitivity T cells** mediate delayed hypersensitivity by releasing various \*lymphokines.

**t-distribution** In \*statistics, a probability distribution made up of the means (see

AVERAGE) of random samples from a collection of samples that have a \*normal distribution of unknown \*variance. See also NORMAL DISTRIBUTION; POISSON DISTRIBUTION.

**tebi-** See BINARY PREFIXES.

**technetium** Symbol Tc. A radioactive metallic \*transition element; a.n. 43; m.p. 2172°C; b.p. 4877°C. The element can be detected in certain stars and is present in the fission products of uranium. It was first made by Carlo Perrier and Emilio Segrè (1905–89) by bombarding molybdenum with deuterons to give technetium-97. The most stable isotope is technetium-99 (half-life  $2.6 \times 10^6$  years); this is used to some extent in labelling for medical diagnosis. There are sixteen known isotopes. Chemically, the metal has properties intermediate between manganese and rhenium.

**technicolour theory** See HIGGS FIELD.

**teeth** See DECIDUOUS TEETH; PERMANENT TEETH; DENTITION; TOOTH.

**Teflon** Trade name for a form of \*polytetrafluoroethene.

**tektite** A small black, greenish, or yellowish glassy object found in groups on the earth's surface and consisting of a siliceous material unrelated to the geological formations in which it is found. Tektites are believed to have formed on earth as a result of the impact of meteorites.

**telecommunications** The study and application of means of transmitting information, either by wires or by electromagnetic radiation.

**Teleostei** The major superorder of the \*Osteichthyes (bony fish), containing about 20 000 species. Teleosts have colonized an extensive variety of habitats and show great diversity of form. The group includes the eel, seahorse, plaice, and salmon. They have been the dominant fish since the Cretaceous period (about 70 million years ago).

**telescope** An instrument that collects radiation from a distant object in order to produce an image of it or enable the radiation to be analysed. See Feature.

**television** The transmission and reception of moving images by means of radio waves or cable. The scene to be transmitted is focused onto a photoelectric screen in the television \*camera. This screen is scanned by an electron beam. The camera produces an electric current, the instantaneous magnitude of which is proportional to the brightness of the portion of the screen being scanned. In Europe the screen is scanned by 625 lines and 25 such frames are produced every second. In the USA 525 lines and 30 frames per second are used. The picture signal so produced is used to modulate a VHF or UHF carrier wave and is transmitted with an independent sound signal, but with colour information (if any) incorporated into the brief gaps between the picture lines. The signals received by the receiving aerial are demodulated in the receiver; the demodulated picture signal controls the electron beam in a cathode-ray tube, on the screen of which the picture is reconstructed. See also COLOUR TELEVISION.

**television tube** See CATHODE RAYS.

**tellurides** Binary compounds of tellurium with other more electropositive elements. Compounds of tellurium with nonmetals are covalent (e.g.  $H_2Te$ ). Metal tellurides can be made by direct combination of the elements and are ionic (containing  $Te^{2-}$ ) or nonstoichiometric interstitial compounds (e.g.  $Pd_4Te$ ,  $PdTe_2$ ).

**tellurium** Symbol Te. A silvery metalloid element belonging to \*group 16 (formerly VIB) of the periodic table; a.n. 52; r.a.m. 127.60; r.d. 6.24 (crystalline); m.p. 449.5°C; b.p. 989.8°C. It occurs mainly as \*tellurides in ores of gold, silver, copper, and nickel and it is obtained as a by-product in copper refining. There are eight natural isotopes and nine radioactive isotopes. The element is used in semiconductors and small amounts are added to certain steels. Tellurium is also added in small quantities to lead. Its chemistry is similar to that of sulphur. It was discovered by Franz Müller (1740–1825) in 1782.

**telomere** The end of a chromosome, which consists of tandemly repeated short sequences of DNA that perform the function of ensuring that each cycle of \*DNA replication has been completed.

## OPTICAL ASTRONOMICAL TELESCOPES

Optical astronomical telescopes fall into two main classes: **refracting telescopes** (or **refractors**), which use lenses to form the primary image, and **reflecting telescopes** (or **reflectors**), which use mirrors.

### Refracting telescopes

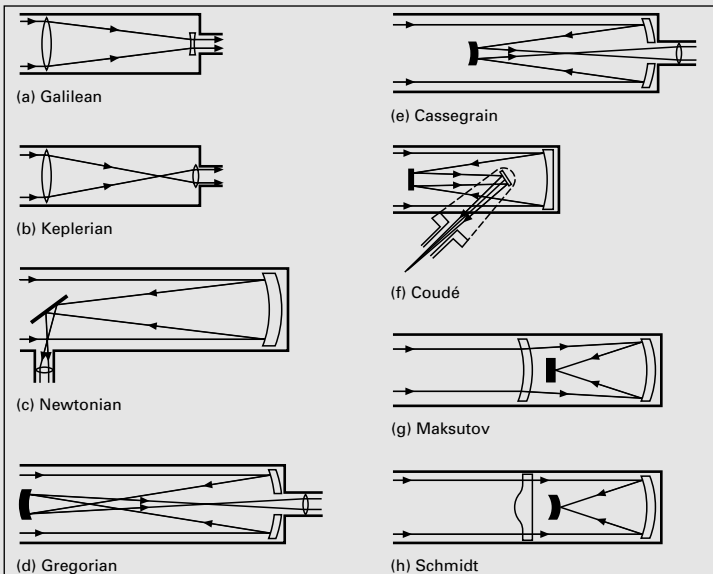

The refracting telescopes use a converging lens to collect the light and the resulting image is magnified by the eyepiece. This type of instrument was first constructed in 1608 by Hans Lippershey (1587–1619) in Holland and developed in the following year as an astronomical instrument by Galileo, who used a diverging lens as eyepiece. The **Galilean telescope** was later improved by Johannes Kepler (1571–1630), who substituted a converging eyepiece lens. This form is still in use for small astronomical telescopes (the **Keplerian telescope**).

### Reflecting telescopes

The first reflecting telescope was produced by Newton in 1668. This used a concave mirror to collect and focus the light and a small secondary mirror at an angle of  $45^\circ$  to the main beam to reflect the light into the magnifying eyepiece. This design is known as the **Newtonian telescope**. The **Gregorian telescope**, designed by James Gregory (1638–75), and the **Cassegrainian telescope**, designed by N. Cassegrain (*fl.* 1670s), use different secondary optical systems. The **coudé telescope** (French: angled) is sometimes used with larger instruments as it increases their focal lengths.

### Catadioptric telescopes

**Catadioptric telescopes** use both lenses and mirrors. The most widely used astronomical instruments in this class are the **Maksutov telescope** and the **Schmidt camera**.

**telophase** A stage of cell division. In \*mitosis the chromatids that separated from each other at \*anaphase collect at the poles of the spindle. A nuclear membrane forms around each group, producing two daughter nuclei with the same number and kind of chromosomes as the original cell nucleus. In the first telophase of \*meiosis, complete chromosomes from the pairs that separated at first anaphase form the daughter nuclei. The number of chromosomes in these nuclei is therefore half the number in the original one. In the second telophase, daughter nuclei are formed from chromatids (as in mitosis).

**temperament** The way in which the intervals between notes on keyboard instruments are distributed throughout the scale to ensure that music in all keys sounds in tune. The problem can be illustrated by a piano keyboard. Taking a low C and a high C seven octaves above, the interval should be  $2^7 = 128$ . However, in passing through the cycle of 12 keys, each using as its fundamental the fifth of its predecessor, the interval between Cs becomes  $(3/2)^{12} = 129.75$ . The difference between 129.75 and 128 is known as the **comma of Pythagoras**. The **equal-temperament scale**, which has been in use since the time of J. S. Bach, distributes the comma of Pythagoras equally between the 12 intervals of the scale over seven octaves. Thus each fifth becomes  $(128)^{1/12} = 1.4983$ . All forms of temperament involve a measure of compromise; this system is now regarded as the best.

**temperature** The property of a body or region of space that determines whether or not there will be a net flow of heat into it or out of it from a neighbouring body or region and in which direction (if any) the heat will flow. If there is no heat flow the bodies or regions are said to be in **thermodynamic equilibrium** and at the same temperature. If there is a flow of heat, the direction of the flow is from the body or region of higher temperature. Broadly, there are two methods of quantifying this property. The empirical method is to take two or more reproducible temperature-dependent events and assign **fixed points** on a scale of values to these events. For example, the Celsius temperature scale uses the freezing point and boiling point

of water as the two fixed points, assigns the values 0 and 100 to them, respectively, and divides the scale between them into 100 degrees. This method is serviceable for many practical purposes (see TEMPERATURE SCALES), but lacking a theoretical basis it is awkward to use in many scientific contexts. In the 19th century, Lord Kelvin proposed a thermodynamic method to specify temperature, based on the measurement of the quantity of heat flowing between bodies at different temperatures. This concept relies on an absolute scale of temperature with an \*absolute zero of temperature, at which no body can give up heat. He also used Sadi Carnot's concept of an ideal frictionless perfectly efficient heat engine (see CARNOT CYCLE). This Carnot engine takes in a quantity of heat  $q_1$  at a temperature  $T_1$ , and exhausts heat  $q_2$  at  $T_2$ , so that  $T_1/T_2 = q_1/q_2$ . If  $T_2$  has a value fixed by definition, a Carnot engine can be run between this fixed temperature and any unknown temperature  $T_1$ , enabling  $T_1$  to be calculated by measuring the values of  $q_1$  and  $q_2$ . This concept remains the basis for defining **thermodynamic temperature**, quite independently of the nature of the working substance. The unit in which thermodynamic temperature is now expressed is the \*kelvin. In practice thermodynamic temperatures cannot be measured directly; they are usually inferred from measurements with a gas thermometer containing a nearly ideal gas. This is possible because another aspect of thermodynamic temperature is its relationship to the \*internal energy of a given amount of substance. This can be shown most simply in the case of an ideal monatomic gas, in which the internal energy per mole ( $U$ ) is equal to the total kinetic energy of translation of the atoms in one mole of the gas (a monatomic gas has no rotational or vibrational energy). According to \*kinetic theory, the thermodynamic temperature of such a gas is given by  $T = 2U/3R$ , where  $R$  is the universal \*gas constant.

**temperature coefficient** A coefficient that determines the rate of change of some physical property with change in temperature. For example, the dependence of the resistance ( $R$ ) of a material on the Celsius temperature  $t$ , is given by  $R =$

$R_0 + \alpha t + \beta t^2$ , where  $R_0$  is the resistance at  $0^\circ\text{C}$  and  $\alpha$  and  $\beta$  are constants. If  $\beta$  is negligible, then  $\alpha$  is the **temperature coefficient of resistance**.

**temperature inversion** An abnormal increase in air temperature that occurs in the troposphere, the lowest level of the earth's atmosphere. This can lead to pollutants becoming trapped in the troposphere (see AIR POLLUTION).

**temperature scales** A number of empirical scales of \*temperature have been in use: the \*Celsius scale is widely used for many purposes and in certain countries the \*Fahrenheit scale is still used. These scales both rely on the use of **fixed points**, such as the freezing point and the boiling point of water, and the division of the **fundamental interval** between these two points into units of temperature (100 degrees in the case of the Celsius scale and 180 degrees in the Fahrenheit scale).

However, for scientific purposes the scale in use is the **International Practical Temperature Scale (IPTS)**, which is designed to conform as closely as possible to thermodynamic temperature and is expressed in the unit of thermodynamic temperature, the \*kelvin. The 1968 version of the table (known as IPTS-68) had 11 fixed points defined by both Celsius and thermodynamic temperatures. The most recent version (IPTS-90), introduced in 1990, has 16 fixed points with temperatures expressed in kelvins:

Triple point of hydrogen: 13.8033

Boiling point of hydrogen (33 321.3 Pa): 17.035

Boiling point of hydrogen (101 292 Pa): 20.27

Triple point of neon: 24.5561

Triple point of oxygen: 54.3584

Triple point of argon: 83.8058

Triple point of mercury: 234.3156

Triple point of water: 273.16 (0.01°C)

Melting point of gallium: 302.9146

Freezing point of indium: 429.7485

Freezing point of tin: 505.078

Freezing point of zinc: 692.677

Freezing point of aluminium: 933.473

Freezing point of silver: 1234.93

Freezing point of gold: 1337.33

Freezing point of copper: 1357.77

Methods for measuring intermediate temperatures between these fixed points

are specified; for example, at low temperatures (0–5 K) they are measured by means of vapour-pressure determinations of  $^3\text{He}$  and  $^4\text{He}$ ; at high temperatures (above 1234.93 K) a radiation pyrometer is used.

**tempering** The process of increasing the toughness of an alloy, such as steel, by heating it to a predetermined temperature, maintaining it at this temperature for a predetermined time, and cooling it to room temperature at a predetermined rate. In steel, the purpose of the process is to heat the alloy to a temperature that will enable the excess carbide to precipitate out of the supersaturated solid solution of \*martensite and then to cool the saturated solution fast enough to prevent further precipitation or grain growth. For this reason steel is quenched rapidly by dipping into cold water.

**template** Any molecule that acts as a pattern for the synthesis of a new molecule. For example, the two nucleotide chains of a DNA molecule can separate and each acts as a template for the synthesis of the missing chain (see DNA REPLICATION).

**temporary hardness** See HARDNESS OF WATER.

**temporary magnetism** Magnetism in a body that is present when the body is in a magnetic field but that largely disappears when it is removed from the field.

**tendon** A thick strand or sheet of tissue that attaches a muscle to a bone. Tendons consist of \*collagen fibres and are therefore inelastic: they ensure that the force exerted by muscular contraction is transmitted to the relevant part of the body to be moved.

**tendrils** A slender branched or unbranched structure found in many climbing plants. It may be a modified stem, leaf, leaflet, or petiole. Tendrils respond to contact with solid objects by twining around them (see THIGMOTROPISM). The cells that touch the object lose water and decrease in volume in comparison to the outer cells, thus causing the tendril to curve.

**tensile strength** A measure of the resistance that a material offers to tensile

\*stress. It is defined as the stress, expressed as the force per unit cross-sectional area, required to break it.

**tensimeter** A form of differential manometer with two sealed bulbs attached to the limbs. It is used to measure the difference in vapour pressure between liquids sealed into the bulbs. If one liquid has a known vapour pressure (often water is used) that of the other can be determined.

**tensiometer** Any apparatus for measuring \*surface tension.

**tentacle** Any of the soft flexible appendages in aquatic invertebrate animals that are used principally for feeding. Water flows over the tentacles, which are able to capture food and direct it to the oral aperture. Tentacles are possessed by many cnidarians, some echinoderms (including sea cucumbers), and by cephalopod molluscs, in which the tentacles bear rows of suckers.

**tera-** Symbol T. A prefix used in the metric system to denote one million million times. For example,  $10^{12}$  volts = 1 teravolt (TV).

**teratogen** Any environmental factor that acts on a fetus to cause congenital abnormality. Examples include ionizing radiation (e.g. X-rays), nutritional deficiencies, drugs (e.g. thalidomide), toxic chemicals, and virus infections (e.g. rubella).

**terbium** Symbol Tb. A silvery metallic element belonging to the \*lanthanoids; a.n. 65; r.a.m. 158.92; r.d. 8.23 (20°C); m.p. 1356°C; b.p. 3123°C. It occurs in apatite and xenotime, from which it is obtained by an ion-exchange process. There is only one natural isotope, terbium-159, which is stable. Seventeen artificial isotopes have been identified. It is used as a dopant in semiconducting devices. It was discovered by Carl Mosander (1797-1858) in 1843.

**terephthalic acid (1,4-benzenedicarboxylic acid)** A colourless crystalline solid,  $C_6H_4(COOH)_2$ , m.p. 300°C. It is made by oxidizing *p*-xylene (1,4-dimethylbenzene) and used for making polyesters, such as Terylene.

**terminal 1.** The point at which electri-

cal connection is made to a device or system. **2.** A device at which data is put into a \*computer or taken from it.

**terminal speed** The constant speed finally attained by a body moving through a fluid under gravity when there is a zero resultant force acting on it. See STOKES' LAW.

**terminator** The boundary, on the surface of the moon or a planet, between the sunlit area and the dark area.

**ternary compound** A chemical compound containing three different elements.

**terpenes** A group of unsaturated hydrocarbons present in plants (see ESSENTIAL OIL). Terpenes consist of isoprene units,  $CH_2:C(CH_3)CH:CH_2$ . Monoterpenes have two units,  $C_{10}H_{16}$ , sesquiterpenes three units,  $C_{15}H_{24}$ , diterpenes four units,  $C_{20}H_{32}$ , etc. **Terpenoids**, which are derivatives of terpenes, include abscisic acid and gibberellin (plant \*growth substances) and the \*carotenoid and \*chlorophyll pigments.

**terrestrial magnetism** See GEOMAGNETISM.

**territory** A fixed area that an animal or group of animals defends against intrusion from others of its species by various types of **territorial behaviour**. Outside the territory (which may contain food sources, hiding places, and nesting sites) others are not threatened. Many mammals indicate their territory boundaries with scent markings, while birds sing territorial songs that repel would-be intruders. Animals in neighbouring territories normally respect each other's boundaries, which reduces overt \*aggression. Some animals are territorial only at certain times of the year, usually the breeding season (see COURTSHIP).

**Tertiary** The older geological period of the Cenozoic era (compare QUATERNARY). It began about 65 million years ago, following the Cretaceous period, and extended to the beginning of the Quaternary, about 2 million years ago. It is subdivided into the Palaeocene, Eocene, Oligocene, Miocene, and Pliocene epochs in ascending order. The Tertiary period was charac-

terized by the rise of the modern mammals and the development of shrubs, grasses, and other flowering plants.

**tertiary alcohol** See ALCOHOLS.

**tertiary amine** See AMINES.

**tertiary colour** A colour obtained by mixing two \*secondary colours.

**tertiary consumer** See CONSUMER.

**tertiary structure** See PROTEIN.

**tervalent (trivalent)** Having a valency of three.

**Terylene** Trade name for a type of \*polyester used in synthetic fibres.

**tesla** Symbol T. The SI unit of magnetic flux density equal to one weber of magnetic flux per square metre, i.e.  $1 \text{ T} = 1 \text{ Wb m}^{-2}$ . It is named after Nikola Tesla (1870–1943), Croatian-born US electrical engineer.

**Tesla coil** A device for producing a high-frequency high-voltage current. It consists of a \*transformer with a high turns ratio, the primary circuit of which includes a spark gap and a fixed capacitor; the secondary circuit is tuned by means of a variable capacitor to resonate with the primary. It was devised by Nikola Tesla. Tesla coils are commonly used to excite luminous discharges in glass vacuum apparatus, in order to detect leaks.

**testa (seed coat)** The lignified or fibrous protective covering of a seed that develops from the integuments of the ovule after fertilization. See also HILUM; MICRO-PYLE.

**test cross** A mating (cross) made to identify hidden \*recessive alleles in an individual of unknown genotype. This individual is crossed with one that is \*homozygous for the allele being investigated (i.e. a homozygous recessive). The homozygous recessive individual may be the parent of the individual being investigated (see BACK CROSS).

**testis (testicle)** The reproductive organ in male animals in which spermatozoa are produced. In vertebrates there are two testes; as well as sperm, they produce steroid hormones (see ANDROGEN). In most animals the testes are within the body

cavity but in mammals, although they develop within the body near the kidneys, they come to hang outside the body cavity in a \*scrotum. Most of the vertebrate testis is made up of a mass of **seminiferous tubules**, in which the sperms develop. It is connected to the outside by means of the \*vas deferens. See REPRODUCTIVE SYSTEM.

**testis-determining factor (TDF; SRY protein)** A protein that plays a crucial role in sex determination in mammals. It is encoded by the SRY (sex reversal on Y) gene on the Y chromosome, and switches embryonic development from the default female pathway to the male pathway, by driving testis formation. Male development is then consolidated by secretion of the male sex hormone testosterone by the testes.

**testosterone** The principal male sex hormone. See ANDROGEN.

**tetrachloroethene** A colourless nonflammable volatile liquid,  $\text{CCl}_2\text{CCl}_2$ ; r.d. 1.6; m.p.  $-22^\circ\text{C}$ ; b.p.  $121^\circ\text{C}$ . It is used as a solvent.

**tetrachloromethane (carbon tetrachloride)** A colourless volatile liquid with a characteristic odour, virtually insoluble in water but miscible with many organic liquids, such as ethanol and benzene; r.d. 1.586; m.p.  $-23^\circ\text{C}$ ; b.p.  $76.54^\circ\text{C}$ . It is made by the chlorination of methane (previously by chlorination of carbon disulphide). The compound is a good solvent for waxes, lacquers, and rubbers and the main industrial use is as a solvent, but safer substances (e.g. 1,1,1-trichloroethane) are increasingly being used. Moist carbon tetrachloride is partly decomposed to phosgene and hydrogen chloride and this provides a further restriction on its use.

**tetrad** A group of four \*haploid cells formed at the end of the second division of \*meiosis.

**tetraethyl lead** See LEAD(IV) TETRAETHYL.

**tetragonal** See CRYSTAL SYSTEM.

**tetrahedral angle** **1.** (in geometry) The solid angle bounded by three faces of a tetrahedron. **2.** (in chemistry) The angle

between the bonds in a \*tetrahedral compound (approximately  $109^\circ$  for a regular tetrahedron).

**tetrahedral compound** A compound in which four atoms or groups situated at the corners of a tetrahedron are linked (by covalent or coordinate bonds) to an atom at the centre of the tetrahedron. *See also* COMPLEX.

**tetrahedron** A polyhedron with four triangular faces. In a **regular tetrahedron** all four triangles are congruent equilateral triangles. It constitutes a regular triangular \*pyramid.

**tetrahydrate** A crystalline hydrate containing four moles of water per mole of compound.

**tetrahydrofuran (THF)** A colourless volatile liquid,  $C_4H_8O$ ; r.d. 0.89; m.p.  $-65^\circ C$ ; b.p.  $67^\circ C$ . It is made by the acid hydrolysis of polysaccharides in oat husks, and is widely used as a solvent.

**tetrahydroxomoxodiboric(III) acid** *See* BORIC ACID.

**tetraoxophosphoric(V) acid** *See* PHOSPHORIC(V) ACID.

**tetraoxosulphuric(VI) acid** *See* SULPHURIC ACID.

**tetraploid** Describing a nucleus, cell, or organism that has four times ( $4n$ ) the haploid number ( $n$ ) of chromosomes. *See also* POLYPLOID.

**Tetrapoda** In some classifications, a superclass of jawed chordates (\*Gnathostomata) comprising all vertebrate animals with four limbs, i.e. the amphibians, reptiles, birds, and mammals. The skeleton of the limbs of all tetrapods is based on the same five-digit pattern (*see* PENTADACTYL LIMB).

**tetravalent (quadrivalent)** Having a valency of four.

**tetrode** A \*thermionic valve with a screen grid placed between the anode and the control grid of a \*triode to reduce the capacitance between these two electrodes and so improve the valve's performance as an amplifier or oscillator at high frequencies. The screen grid is maintained at a fixed potential.

**texaphyrin** A synthetic molecule similar to a porphyrin but containing five central nitrogen atoms rather than four, thus increasing the size of the central 'hole' and enabling larger cations, such as cadmium, to be bound stably. *See also* SUPRAMOLECULAR CHEMISTRY.

**thalamus 1.** (in anatomy) Part of the vertebrate \*forebrain that lies above the hypothalamus. It relays sensory information to the cerebral cortex and is also concerned with the translation of impulses into conscious sensations. **2.** (in botany) *See* RECEPTACLE.

**thallium** Symbol Tl. A greyish metallic element belonging to \*group 13 (formerly IIIB) of the periodic table; a.n. 81; r.a.m. 204.39; r.d. 11.85 ( $20^\circ C$ ); m.p.  $303.5^\circ C$ ; b.p.  $1457\pm 10^\circ C$ . It occurs in zinc blende and some iron ores and is recovered in small quantities from lead and zinc concentrates. The naturally occurring isotopes are thallium-203 and thallium-205; eleven radioisotopes have been identified. It has few uses - experimental alloys for special purposes and some minor uses in electronics. The sulphate has been used as a rodenticide. Thallium(I) compounds resemble those of the alkali metals. Thallium(III) compounds are easily reduced to the thallium(I) state and are therefore strong oxidizing agents. The element was discovered by Sir William Crookes in 1861.

**Thallophyta** A former division of the plant kingdom containing relatively simple plants, i.e. those with no leaves, stems, or roots. It included the \*algae, \*bacteria, \*fungi, and \*lichens.

**thallus** A relatively undifferentiated vegetative body with no true roots, stems, leaves, or vascular system. It is found in the algae, fungi, mosses, and liverworts and in the gametophyte generation of clubmosses, horsetails, and ferns.

**theca** *See* CAPSULE.

**theodolite** An optical surveying instrument for measuring horizontal and vertical angles. It consists of a sighting telescope, with crosshairs in the eyepiece for focusing on the target, which can be rotated in both the horizontal and vertical planes. It is mounted on a tripod and a

spirit level is used to indicate when the instrument is horizontal. The angles are read off graduated circles seen through a second eyepiece in the instrument.

**theoretical physics** The study of physics by formulating and analysing theories that describe natural processes. Theoretical physics is complementary to the study of physics by experiment, which is called **experimental physics**. A large part of theoretical physics consists of analysing the results of experiments to see whether or not they obey particular theories. The branch of theoretical physics concerned with the mathematical aspects of theories in physics is called **mathematical physics**.

**theory** See LAWS, THEORIES, AND HYPOTHESES.

**theory of everything** A theory that provides a unified description of all known types of elementary particles, all known forces in the universe, and the evolution of the universe. Some believe that \*superstring theory is potentially a theory of everything. Others believe that it is impossible to formulate a theory of everything and that any such theory could only claim to be a theory for all forces, particles, and observations concerning the evolution of the universe known at the time. It is thought that a \*quantum field theory or a \*unified-field theory cannot be a theory of everything. A theory of everything should explain the number of dimensions in the universe and why the number of observable dimensions is four.

**therapeutic half-life** (in pharmacology) The time taken for half the dose of a drug to be excreted: used to calculate the most effective and nontoxic dosing intervals. It can be determined by administering a therapeutic dose of the drug labelled with a radioisotope (see LABELLING) and measuring the time for half of it to be excreted in the urine.

**therm** A practical unit of energy defined as  $10^5$  British thermal units. 1 therm is equal to  $1.055 \times 10^8$  joules.

**thermal analysis** A technique for chemical analysis and the investigation of the products formed by heating a substance. In **differential thermal analysis**

(DTA) a sample is heated, usually in an inert atmosphere, and a plot of weight against temperature made. In **differential scanning calorimetry (DSC)** heat is added to or removed from a sample electrically as the temperature is increased, thus allowing the enthalpy changes due to thermal decomposition to be studied.

**thermal capacity** See HEAT CAPACITY.

**thermal conductivity** See CONDUCTIVITY.

**thermal diffusion** The diffusion that takes place in a fluid as a result of a temperature gradient. If a column of gas is maintained so that the lower end is cooler than the upper end, the heavier molecules in the gas will tend to remain at the lower-temperature end and the lighter molecules will diffuse to the higher-temperature end. This property has been used in the separation of gaseous isotopes (see CLUSIUS COLUMN).

**thermal equilibrium** See EQUILIBRIUM.

**thermal expansion** See EXPANSIVITY.

**thermalization** The reduction of the kinetic energy of neutrons in a thermal \*nuclear reactor by means of a \*moderator; the process of producing thermal neutrons.

**thermal neutrons** See MODERATOR; NUCLEAR REACTOR; THERMALIZATION.

**thermal reactor** See NUCLEAR REACTOR.

**thermionic emission** The emission of electrons, usually into a vacuum, from a heated conductor. The emitted current density,  $J$ , is given by the **Richardson (or Richardson-Dushman) equation**, i.e.  $J = AT^2 \exp(-W/kT)$ , where  $T$  is the thermodynamic temperature of the emitter,  $W$  is its \*work function,  $k$  is the Boltzmann constant, and  $A$  is a constant. Thermionic emission is the basis of the \*thermionic valve and the \*electron gun in cathode-ray tubes.

**thermionics** The branch of electronics concerned with the study and design of devices based on the emission of electrons from metal or metal-oxide surfaces as a result of high temperatures. The primary concern of thermionics is the design of

\*thermionic valves and the electron guns of cathode-ray tubes and other devices.

**thermionic valve** An electronic valve based on \*thermionic emission. In such valves the cathode is either directly heated by passing a current through it or indirectly heated by placing it close to a heated filament. Directly heated cathodes are usually made of tungsten wire, whereas indirectly heated cathodes are usually coated with barium and strontium oxides. Most electronic valves are thermionic vacuum devices, although a few have cold cathodes and some are gas-filled (see THYRATRON). See DIODE; TRIODE; TETRODE; PENTODE.

**thermistor** An electronic device the resistance of which decreases as its temperature increases. It consists of a bead, rod, or disc of various oxides of manganese, nickel, cobalt, copper, iron, or other metals. Thermistors are used as thermometers, often forming one element in a resistance bridge. They are used for this purpose in such applications as bearings, cylinder heads, and transformer cores. They are also used to compensate for the increased resistance of ordinary resistors when hot, and in vacuum gauges, time-delay switches, and voltage regulators.

**thermite** A stoichiometric powdered mixture of iron(III) oxide and aluminium for the reaction:

The reaction is highly exothermic and the increase in temperature is sufficient to melt the iron produced. It has been used for localized welding of steel objects (e.g. railway lines) in the **Thermit process**. Thermit is also used in incendiary bombs.

**thermochemistry** The branch of physical chemistry concerned with heats of chemical reaction, heats of formation of chemical compounds, etc.

**thermocline** A steep temperature gradient that exists in the middle zone (the **metalimnion**) of a lake and gives rise to thermally induced vertical stratification of the water. The metalimnion lies between the relatively warm **epilimnion** above and the cold **hypolimnion** below. The thermocline may represent a temperature change

of 1°C for every incremental depth of 1 metre of water. It may be short-lived, especially in shallow lakes where wind action can mix the water from different levels. However, it can exist for most of the summer period in temperate lakes and sometimes nearly all year in tropical lakes. A thermocline can speed up the process of eutrophication by preventing the diffusion of oxygen from the epilimnion to the hypolimnion (see EUTROPHIC).

**thermocouple** A device consisting of two dissimilar metal wires or semiconducting rods welded together at their ends. A thermoelectric e.m.f. is generated in the device when the ends are maintained at different temperatures, the magnitude of the e.m.f. being related to the temperature difference. This enables a thermocouple to be used as a thermometer over a limited temperature range. One of the two junctions, called the **hot or measuring junction**, is exposed to the temperature to be measured. The other, the **cold or reference junction**, is maintained at a known reference temperature. The e.m.f. generated is measured by a suitable millivoltmeter or potentiometer incorporated into the circuit. See SEEBECK EFFECT; THERMOPILE.

**thermodynamics** The study of the laws that govern the conversion of energy from one form to another, the direction in which heat will flow, and the availability of energy to do work. It is based on the concept that in an isolated system anywhere in the universe there is a measurable quantity of energy called the \*internal energy ( $U$ ) of the system. This is the total kinetic and potential energy of the atoms and molecules of the system of all kinds that can be transferred directly as heat; it therefore excludes chemical and nuclear energy. The value of  $U$  can only be changed if the system ceases to be isolated. In these circumstances  $U$  can change by the transfer of mass to or from the system, the transfer of heat ( $Q$ ) to or from the system, or by the work ( $W$ ) being done on or by the system. For an adiabatic ( $Q = 0$ ) system of constant mass,  $\Delta U = W$ . By convention,  $W$  is taken to be positive if work is done on the system and negative if work is done by the system.

For nonadiabatic systems of constant mass,  $\Delta U = Q + W$ . This statement, which is equivalent to the law of conservation of energy, is known as the **first law of thermodynamics**.

All natural processes conform to this law, but not all processes conforming to it can occur in nature. Most natural processes are irreversible, i.e. they will only proceed in one direction (see REVERSIBLE PROCESS). The direction that a natural process can take is the subject of the **second law of thermodynamics**, which can be stated in a variety of ways. R. Clausius (1822–88) stated the law in two ways: "heat cannot be transferred from one body to a second body at a higher temperature without producing some other effect" and "the entropy of a closed system increases with time". These statements introduce the thermodynamic concepts of \*temperature ( $T$ ) and \*entropy ( $S$ ), both of which are parameters determining the direction in which an irreversible process can go. The temperature of a body or system determines whether heat will flow into it or out of it; its entropy is a measure of the unavailability of its energy to do work. Thus  $T$  and  $S$  determine the relationship between  $Q$  and  $W$  in the statement of the first law. This is usually presented by stating the second law in the form  $\Delta U = T\Delta S - W$ .

The second law is concerned with changes in entropy ( $\Delta S$ ). The **third law of thermodynamics** provides an absolute scale of values for entropy by stating that for changes involving only perfect crystalline solids at \*absolute zero, the change of the total entropy is zero. This law enables absolute values to be stated for entropies.

One other law is used in thermodynamics. Because it is fundamental to, and assumed by, the other laws of thermodynamics it is usually known as the **zeroth law of thermodynamics**. This states that if two bodies are each in thermal equilibrium with a third body, then all three bodies are in thermal equilibrium with each other. See also ENTHALPY; FREE ENERGY.

**thermodynamic temperature** See TEMPERATURE.

**thermoelectricity** An electric current

generated by temperature difference. See SEEBECK EFFECT. The converse effects, the \*Peltier effect and the \*Thomson effect, are also sometimes known as thermoelectric effects.

**thermogenesis** The production of heat within tissues to raise body temperature. It occurs especially in birds and mammals, animals that maintain their temperature within a narrow range (i.e. \*endotherms), but is also found in some 'cold-blooded' vertebrates and invertebrates. There are two types of thermogenesis. **Shivering** involves repeated rapid contractions of antagonistic sets of skeletal muscles, which produce little net movement so that most of the chemical energy (in the form of ATP) is converted to heat rather than mechanical work.

**Nonshivering thermogenesis** takes place in \*fat cells (adipose tissue) and involves the breakdown of stored fat to generate heat in situ instead of its being transported to the liver for conversion to ATP. This process is activated by the sympathetic nervous system. Certain mammals have deposits of a special adipose tissue called \*brown fat that is adapted to provide the body with bursts of intense heat. Stimulation of brown fat oxidation enables rapid warming during the arousal of hibernating animals, for example. Brown fat deposits are also present in human babies and other neonate mammals, to help protect them against hypothermia.

**thermograph 1.** A recording thermometer used in meteorology to obtain a continuous record of temperature changes over a period on a graph. **2.** A record so obtained. **3. (thermogram)** A record obtained by the technique of \*thermography.

**thermography** A medical technique that makes use of the infrared radiation from the human skin to detect an area of elevated skin temperature that could be associated with an underlying cancer. The heat radiated from the body varies according to the local blood flow, thus an area of poor circulation produces less radiation. A tumour, on the other hand, has an abnormally increased blood supply and is revealed on the **thermogram** (or **thermograph**) as a 'hot spot'. The technique can

be used in mammography, the examination of the infrared radiation emitted by human breasts in order to detect breast cancer.

**thermoluminescence** \*Luminescence produced in a solid when its temperature is raised. It arises when free electrons and \*holes, trapped in a solid as a result of exposure to ionizing radiation, unite and emit photons of light. The process is made use of in **thermoluminescent dating**, which assumes that the number of electrons and holes trapped in a sample of pottery is related to the length of time that has elapsed since the pottery was fired. By comparing the luminescence produced by heating a piece of pottery of unknown age with the luminescence produced by heating similar materials of known age, a fairly accurate estimate of the age of an object can be made.

**thermoluminescent dating** See THERMOLUMINESCENCE.

**thermolysis (pyrolysis)** The chemical decomposition of a substance by heat. It is an important process in chemical manufacture, such as the thermal \*cracking of hydrocarbons in the petroleum industry.

**thermometer** An instrument used for measuring the \*temperature of a substance. A number of techniques and forms are used in thermometers depending on such factors as the degree of accuracy required and the range of temperatures to be measured, but they all measure temperature by making use of some property of a substance that varies with temperature. For example, **liquid-in-glass thermometers** depend on the expansion of a liquid, usually mercury or alcohol coloured with dye. These consist of a liquid-filled glass bulb attached to a partially filled capillary tube. In the **bimetallic thermometer** the unequal expansion of two dissimilar metals that have been bonded together into a narrow strip and coiled is used to move a pointer round a dial. The **gas thermometer**, which is more accurate than the liquid-in-glass thermometer, measures the variation in the pressure of a gas kept at constant volume. The **resistance thermometer** is based on the change in resistance of conductors or semiconductors with temperature change. Plat-

inum, nickel, and copper are the metals most commonly used in resistance thermometers. See also PYROMETRY; THERMISTOR; THERMOCOUPLE.

**thermonuclear reaction** See NUCLEAR FUSION; THERMONUCLEAR REACTOR.

**thermonuclear reactor (fusion reactor)** A reactor in which \*nuclear fusion takes place with the controlled release of energy. Although thermonuclear reactors do not yet exist, intense research in many parts of the world is being carried out with a view to achieving such a machine. There are two central problems in the creation of a self-sustaining thermonuclear reactor: heating the reacting nuclides to the enormous \*ignition temperature (about  $40 \times 10^6$  K for a deuterium-tritium reaction) and containing the reacting nuclides for long enough for the fusion energy released to exceed the energy required to achieve the ignition temperature (see LAWSON CRITERION). The two methods being explored are **magnetic containment** and **pellet fusion**.

In the closed magnetic-containment device the fusion \*plasma is contained in a toroidal-shaped reactor, called a **tokamak**, in which strong magnetic fields guide the charged plasma particles round the toroid without allowing them to contact the container walls. In open-ended magnetic systems the plasma is trapped between magnetic mirrors (strong magnetic fields) at the two ends of a straight containment vessel.

In pellet fusion the objective is to heat and compress a tiny pellet of the nuclear fuels, by means of a laser or an electron beam, so rapidly that fusion is achieved before the pellet flies apart. Results with this type of equipment have been comparable to those achieved by magnetic confinement.

**thermonuclear weapon** See NUCLEAR WEAPONS.

**thermophilic** Describing an organism that lives and grows optimally at extremely high temperatures, typically over 40°C. The majority are prokaryotes, such as the archaeobacteria found in hot springs and in undersea hydrothermal vents. See EXTREMOPHILE.

**thermopile** A device used to detect and measure the intensity of radiant energy. It consists of a number of \*thermocouples connected together in series to achieve greater sensitivity. The hot junctions of the thermocouples are blackened and exposed to the radiation to be detected or measured, while the cold junctions are shielded from the radiation. The thermoelectric e.m.f. generated enables the hot junction excess temperature to be calculated and the radiant intensity to be deduced. They are used in various applications, from a safety device that ceases to produce an electric current if a pilot light blows out to an instrument to measure the heat radiation received from the sun.

**thermoplastic** See PLASTICS.

**thermoregulation** Regulation of body temperature by any means, whether physiological or behavioural. Some animals, particularly mammals and birds, can maintain a fairly constant internal body temperature (see HOMIOOTHERMY), whereas in others the body temperature varies with the temperature of the environment (see POIKILOOTHERMY). See also THERMOGENESIS.

**thermosetting** See PLASTICS.

**thermostat** A device that controls the heating or cooling of a substance in order to maintain it at a constant temperature. It consists of a temperature-sensing instrument connected to a switching device. When the temperature reaches a predetermined level the sensor switches the heating or cooling source on or off according to a predetermined program. The sensing thermometer is often a \*bimetallic strip that triggers a simple electrical switch. Thermostats are used for space-heating controls, in water heaters and refrigerators, and to maintain the environment of a scientific experiment at a constant temperature.

**THF** See TETRAHYDROFURAN.

**thiamin(e)** See VITAMIN B COMPLEX.

**thigmotropism (haptotropism)** The growth of an aerial plant organ in response to localized physical contact. For example, when a tendril of sweet pea

touches a supporting structure, it curves in the direction of the support and coils around it. See TROPISM.

**thin-layer chromatography** A technique for the analysis of liquid mixtures using \*chromatography. The stationary phase is a thin layer of an absorbing solid (e.g. alumina) prepared by spreading a slurry of the solid on a plate (usually glass) and drying it in an oven. A spot of the mixture to be analysed is placed near one edge and the plate is stood upright in a solvent. The solvent rises through the layer by capillary action carrying the components up the plate at different rates (depending on the extent to which they are absorbed by the solid). After a given time, the plate is dried and the location of spots noted. It is possible to identify constituents of the mixture by the distance moved in a given time. The technique needs careful control of the thickness of the layer and of the temperature. See also  $R_f$  VALUE.

**thiocyanate** A salt or ester of thiocyanic acid.

**thiocyanic acid** An unstable gas, HSCN.

**thio ethers** See SULPHIDES.

**thiol group** See THIOLS.

**thiols (mercaptans; thio alcohols)** Organic compounds that contain the group -SH (called the **thiol group**, **mercapto group**, or **sulphydryl group**). Thiols are analogues of alcohols in which the oxygen atom is replaced by a sulphur atom. They are named according to the parent hydrocarbon; e.g. ethane thiol ( $C_2H_5SH$ ). A characteristic property is their strong disagreeable odour. For example the odour of garlic is produced by ethane thiol. Unlike alcohols they are acidic, reacting with alkalis and certain metals to form saltlike compounds. The older name, mercaptan, comes from their ability to react with ('seize') mercury.

**thionyl chloride** See SULPHUR DICHLORIDE OXIDE.

**thionyl group** The group =SO, as in \*sulphur dichloride oxide.

**thiophene** A colourless liquid,  $C_4H_4S$ , b.p.  $84^\circ C$ . It is a cyclic aromatic compound

with a ring containing four carbon atoms and one sulphur atom. It is made from butane and sulphur and occurs as an impurity in commercial benzene. Thienyl compounds are formed by substituting various groups in the ring. Thiophene has a smell resembling benzene and is used as a solvent.

**thiosulphate** A salt containing the ion  $S_2O_3^{2-}$  formally derived from thiosulphuric acid. Thiosulphates readily decompose in acid solution to give elemental sulphur and hydrogensulphite ( $HSO_3^-$ ) ions.

**thiosulphuric acid** An unstable acid,  $H_2S_2O_3$ , formed by the reaction of sulphur trioxide with hydrogen sulphide. *See also* SULPHURIC ACID.

**thiourea** A white crystalline solid,  $(NH_2)_2CS$ ; r.d. 1.4; m.p. 182°C. It is used as a fixer in photography.

**thixotropy** *See* NEWTONIAN FLUID.

**Thompson, Benjamin** *See* RUMFORD, COUNT.

**Thomson, Sir Joseph John** (1856–1940) British physicist, who became a professor at Cambridge University in 1884. He is best known for his work on \*cathode rays, which led to his discovery of the \*electron in 1897. He went on to study the conduction of electricity through gases, and it is for this work that he was awarded the Nobel Prize for physics in 1906.

**Thomson, William** *See* KELVIN, BARON.

**Thomson effect (Kelvin effect)** When an electric current flows through a conductor, the ends of which are maintained at different temperatures, heat is evolved at a rate approximately proportional to the product of the current and the temperature gradient. If either the current or the temperature gradient is reversed heat is absorbed rather than being evolved. It is named after Sir William Thomson (later Lord Kelvin).

**Thomson scattering** The scattering of electromagnetic radiation by free charged particles, especially electrons, when the photon energy is small compared with the energy equivalent to the \*rest mass of

the charged particles. The energy lost by the radiation is accounted for by classical theory as a result of the radiation emitted by the charged particles when they are accelerated in the transverse electric field of the radiation. It is named after Sir J. J. Thomson.

**thoracic cavity** The space within the \*thorax, which in vertebrates contains the heart, lungs, and rib cage.

**thoracic duct** The main collecting vessel of the \*lymphatic system, running longitudinally in front of the backbone. The thoracic duct drains its lymph into the superior vena cava.

**thoracic vertebrae** The \*vertebrae of the upper back, which articulate with the \*ribs. They lie between the \*cervical vertebrae and the \*lumbar vertebrae and are distinguished by a number of articulating facets for attachment of the ribs. In humans there are 12 thoracic vertebrae.

**thorax** The anterior region of the body trunk of animals. In vertebrates it contains the heart and lungs within the rib cage. It is particularly well-defined in mammals, being separated from the \*abdomen by the \*diaphragm. In insects the thorax is divided into an anterior **prothorax**, a middle **mesothorax**, and a posterior **metathorax**, each of which bears a pair of legs; the hindmost two segments also both carry a pair of wings. In other arthropods, especially crustaceans and arachnids, the thorax is fused with the head to form a **cephalothorax**.

**thoria** *See* THORIUM.

**thorium** Symbol Th. A grey radioactive metallic element belonging to the \*actinoids; a.n. 90; r.a.m. 232.038; r.d. 11.5–11.9 (17°C); m.p. 1740–1760°C; b.p. 4780–4800°C. It occurs in monazite sand in Brazil, India, and USA. The isotopes of thorium have mass numbers from 223 to 234 inclusive; the most stable isotope, thorium-232, has a half-life of  $1.39 \times 10^{10}$  years. It has an oxidation state of (+4) and its chemistry resembles that of the other actinoids. It can be used as a nuclear fuel for breeder reactors as thorium-232 captures slow neutrons to breed uranium-233. Thorium dioxide (**thoria**,  $ThO_2$ ) is used on gas mantles and in special refrac-

tories. The element was discovered by J. J. Berzelius in 1829.

**thorium series** See RADIOACTIVE SERIES.

**thorn** A hard side stem with a sharp point at the tip, replacing the growing point. In some plants the development of thorns and subsequent suppression of the growing points may be a response to dry conditions. Examples are the thorns of gorse and hawthorn. Compare PRICKLE; SPINE.

**thread cell (nematoblast; cnidoblast)** A specialized cell found only in the ectoderm of the \*Cnidaria. It contains a **nematocyst**, a fluid-filled sac within which lies a long hollow coiled thread. When a small sensory projection (**cnidocil**) on the surface of the thread cell is touched, e.g. by prey, the thread is shot out and adheres to the prey, coils round it, or injects poison into it. Numerous thread cells on the tentacles of jellyfish produce their sting.

**three-body problem** See MANY-BODY PROBLEM.

**threanardite** A mineral form of \*sodium sulphate,  $\text{Na}_2\text{SO}_4$ .

**threonine** See AMINO ACID.

**threshold 1.** (in physics) The minimum value of a parameter or variable that will produce a specified effect. **2.** (in physiology) The minimum intensity of a stimulus that is necessary to initiate a response.

**threshold frequency** See PHOTOELECTRIC EFFECT.

**thrombin** An enzyme that catalyses the conversion of fibrinogen to fibrin. See BLOOD CLOTTING; PROTHROMBIN.

**thrombocyte** See PLATELET.

**thromboplastin** A glycoprotein, released from damaged tissues at the site of a wound, that initiates the cascade of reactions leading to the formation of a blood clot. See BLOOD CLOTTING.

**thrombosis** The obstruction of a blood vessel by a mass of blood cells and fibrin (**thrombus**), which can result from excessive \*blood clotting.

**thromboxane A<sub>2</sub>** See PROSTAGLANDIN.

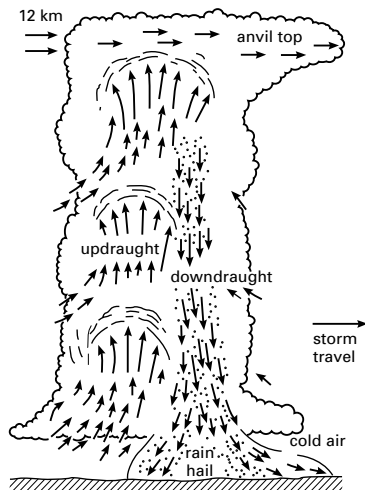

**thrust** The propelling force generated by

an aircraft engine or rocket. It is usually calculated as the product of the rate of mass discharge and the velocity of the exhaust gases relative to the vehicle.

**thulium** Symbol Tm. A soft grey metallic element belonging to the \*lanthanoids; a.n. 69; r.a.m. 168.934; r.d. 9.321 (20°C); m.p. 1545°C; b.p. 1947°C. It occurs in apatite and xenotime. There is one natural isotope, thulium-169, and seventeen artificial isotopes have been produced. There are no uses for the element, which was discovered by Per Cleve (1840-1905) in 1879.

**thumb drive** See USB DRIVE.

**thunderstorm** A convective storm accompanied by \*lightning and thunder and a variety of weather conditions, especially heavy rain or hail, high winds, and sudden temperature changes. Thunderstorms originate when intense heating causes a parcel of moist air to rise, leading to instability and the development of cumulonimbus cloud - a towering cloud with a characteristic anvil-shaped top (see illustration). The exact mechanisms of thunderstorms are not fully understood. They occur most frequently in the tropics but are also common in the mid-latitudes.

Cross section through a thunderstorm cell

**thymidine** A nucleoside consisting of one thymine molecule linked to a D-deoxyribose sugar molecule.

**thymine** A \*pyrimidine derivative and one of the major component bases of \*nucleotides and the nucleic acid \*DNA.

**thymus** An organ, present only in vertebrates, that is concerned with development of \*lymphoid tissue, particularly the white blood cells involved in cell-mediated \*immune responses (see T CELL). In mammals it is a bilobed organ in the region of the lower neck, above and in front of the heart. In humans it undergoes progressive shrinkage throughout life, starting after the first 12 months of age.

**thyatron** A thermionic valve (usually a triode) that functions as a gas-filled relay. A positive pulse fed to a correctly biased thyatron causes a discharge to start and to continue until the anode voltage has been reduced. It has now been replaced by its solid-state counterpart, the silicon-controlled rectifier.

**thyristor** A silicon-controlled rectifier whose anode-cathode current is controlled by a signal applied to a third electrode (the gate) in much the same way as in a thyatron valve. It consists usually of a four-layer chip comprising three *p-n* junctions.

**thyrocalcitonin** See CALCITONIN.

**thyroglobulin (TGB)** A glycoprotein, made in the thyroid gland, that consists of about 5000 amino acids, some of which are tyrosine residues. TGB is the precursor of the thyroid hormones, thyroxine and triiodothyronine. Iodine binds to the tyrosine residues in thyroglobulin, which is then hydrolysed into **iodotyrosines** that combine to form triiodothyronine ( $T_3$ ) or thyroxine (tetraiodothyronine or  $T_4$ ).

**thyroid gland** A bilobed endocrine gland in vertebrates, situated in the base of the neck. It secretes two iodine-containing **thyroid hormones**, **thyroxine ( $T_4$ )** and **triiodothyronine ( $T_3$ )**, which are formed in the gland from \*thyroglobulin; they control the rate of all metabolic processes in the body and influence physical development and activity of the nervous system. Growth and activity of the thyroid is con-

trolled by \*thyroid-stimulating hormone, secreted by the anterior \*pituitary gland.

**thyroid-stimulating hormone (TSH; thyrotrophin)** A hormone, secreted by the anterior pituitary gland, that controls the synthesis and secretion of the two thyroid hormones, thyroxine and triiodothyronine, in the \*thyroid gland. The secretion of thyroid-stimulating hormone is controlled by **thyrotrophin-releasing hormone (TRH)** from the hypothalamus. The release of TRH depends on many factors, including the levels of TSH, glucose, and thyroxine in the blood and the rate of metabolism in the body.

**thyrotrophin-releasing hormone (TRH)** See THYROID-STIMULATING HORMONE.

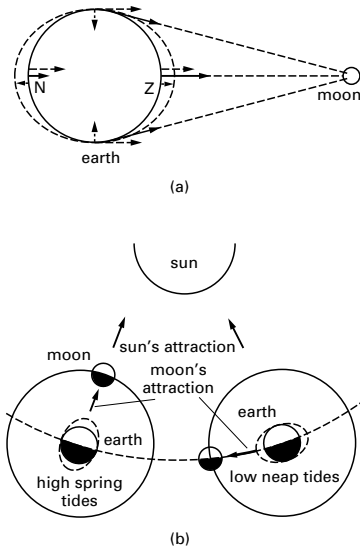

**thyroxine ( $T_4$ )** The principal hormone secreted by the \*thyroid gland. See also THYROGLOBULIN.

**tibia 1.** The larger of the two bones of the lower hindlimb of terrestrial vertebrates (compare FIBULA). It articulates with the \*femur at the knee and with the \*tarsus at the ankle. The tibia is the major load-bearing bone of the lower leg. **2.** The fourth segment of an insect's leg, which is attached to the femur.

**tidal energy** See TIDES.

**tidal volume** The volume of air taken in or expelled by an animal breathing normally at rest during each cycle of \*ventilation. The average human has a tidal volume of approximately 500 cm<sup>3</sup>.

**tides** The regular rise and fall of the water level in the earth's oceans as a result of the gravitational forces between the earth, moon, and sun. The forces involved are complex, but the moon is approximately twice as effective as the sun in causing tides. In illustration (a) the resultant gravitational forces between the moon and various points on the earth (solid lines) are shown as the vector sums of the tide-generating forces (broken lines) and a constant force (dotted lines) that is the same at all points on the earth and is equal to the moon's attraction on the earth's centre. The resultant force when the moon is in zenith (Z in the illustration) is greater than that at nadir (N) be-

### Tides

cause Z is closer to the moon than N and the force is inversely proportional to the square of the distance according to \*Newton's law of gravitation. Illustration (b) shows how at full and new moon the sun and moon act together to produce the high-range **spring tides**, while at quarter moon the forces are at right angles to each other causing the low-range **neap tides**.

The use of **tidal energy**, estimated at some  $4 \times 10^{18}$  J per annum at known tidal sites, dates back to medieval tidal mills. Modern tidal power stations use specially designed turbines, operated by tidal waters, to drive generators.

**timbres** See QUALITY OF SOUND.

**time** A dimension that enables two otherwise identical events that occur at the same point in space to be distinguished (see SPACE-TIME). The interval between two such events forms the basis of time measurement. For general purposes, the earth's rotation on its axis provides the units of the clock (see DAY) and the earth's orbit round the sun (see YEAR) provides the units of the calendar. For scientific purposes, intervals of time are now defined in

terms of the frequency of a specified electromagnetic radiation (see SECOND). See also TIME DILATION; TIME REVERSAL.

**timebase** A voltage applied to the electron beam in a \*cathode-ray tube at regular intervals so that the luminous spot on the screen is deflected in a predetermined manner. The timebase is usually designed to make the beam sweep the screen horizontally, the period during which the spot returns to its starting point (the **flyback**) being suppressed in some contexts (e.g. in television) although in a \*cathode-ray oscilloscope the timebase can be put to more complicated uses.

**time dilation (time dilatation)** The principle, predicted by Einstein's special theory of \*relativity, that intervals of time are not absolute but are relative to the motion of the observers. If two identical clocks are synchronized and placed side by side in an inertial frame of reference they will read the same time for as long as they both remain side by side. However, if one of the clocks has a velocity relative to the other, which remains beside a stationary observer, the travelling clock will show, to that observer, that less time has elapsed than the stationary clock. In general, the travelling clock goes more slowly by a factor  $\sqrt{1 - v^2/c^2}$ , when measured in a frame of reference travelling at a velocity  $v$  relative to another frame of reference;  $c$  is the speed of light. The principle has been verified in a number of ways; for example, by comparing the lifetimes of fast muons, which increase with the speed of the particles to an extent predicted by this factor.

**time-lapse photography** A form of photography used to record a slow process, such as plant growth. A series of single exposures of the object is made on film at predetermined regular intervals. The film produced can then be projected at normal cine speeds and the process appears to be taking place at an extremely high rate.

**time reversal** Symbol T. The operation of replacing time  $t$  by time  $-t$ . The \*symmetry of time reversal is known as **T invariance**. As with CP violation, **T violation** occurs in certain weak interactions, no-

tably kaon decay. *See also* CP INVARIANCE; CPT THEOREM.

**time sharing** A means by which several jobs – data plus the programs to manipulate the data – share the processing time and other resources of a computer. A brief period is allocated to each job by the computer's operating system, and the computer switches rapidly between jobs. A \*multiaccess system relies on time sharing.

**tin** Symbol Sn. A silvery malleable metallic element belonging to \*group 14 (formerly IVB) of the periodic table; a.n. 50; r.a.m. 118.69; r.d. 7.28; m.p. 231.88°C; b.p. 2260°C. It is found as tin(IV) oxide in ores, such as cassiterite, and is extracted by reduction with carbon. The metal (called **white tin**) has a powdery nonmetallic allotrope **grey tin**, into which it changes below 18°C. The formation of this allotrope is called **tin plague**; it can be reversed by heating to 100°C. The natural element has 21 isotopes (the largest number of any element); five radioactive isotopes are also known. The metal is used as a thin protective coating for steel plate and is a constituent of a number of alloys (e.g. phosphor bronze, gun metal, solder, Babbitt metal, and pewter). Chemically it is reactive. It combines directly with chlorine and oxygen and displaces hydrogen from dilute acids. It also dissolves in alkalis to form \*stannates. There are two series of compounds with tin in the +2 and +4 oxidation states.

**Tinbergen, Niko(laas)** (1907–88) Dutch-born British zoologist and ethologist. Working first at Leiden University, he moved to Oxford in 1947, becoming professor of animal behaviour in 1966. With Konrad \*Lorenz he was a pioneer of ethology, working with animals in their natural setting. In later years Tinbergen attempted to apply ethological principles to human beings, especially autistic children. He shared the Nobel Prize for physiology or medicine with Lorenz and Karl von Frisch (1886–1982).

**tin(II) chloride** A white solid,  $\text{SnCl}_2$ , soluble in water and ethanol. It exists in the anhydrous form (rhombic; r.d. 3.95; m.p. 246°C; b.p. 652°C) and as a dihydrate,  $\text{SnCl}_2 \cdot 2\text{H}_2\text{O}$  (monoclinic; r.d. 2.71; m.p.

37.7°C). The compound is made by dissolving metallic tin in hydrochloric acid and is partially hydrolysed in solution.

Excess acid must be present to prevent the precipitation of basic salts. In the presence of additional chloride ions the pyramidal ion  $[\text{SnCl}_3]^-$  is formed; in the gas phase the  $\text{SnCl}_2$  molecule is bent. It is a reducing agent in acid solutions and oxidizes slowly in air:

**tin(IV) chloride** A colourless fuming liquid,  $\text{SnCl}_4$ , hydrolysed in cold water, decomposed by hot water, and soluble in ethers; r.d. 2.226; m.p. –33°C; b.p. 114°C. Tin(IV) chloride is a covalent compound, which may be prepared directly from the elements. It dissolves sulphur, phosphorus, bromine, and iodine, and there is evidence for the presence of species such as  $\text{SnCl}_2\text{I}_2$ . In hydrochloric acid and in chloride solutions the coordination is extended from four to six by the formation of the  $\text{SnCl}_6^{2-}$  ion.

**tincture** A solution with alcohol as the solvent (e.g. tincture of iodine).

**tin(IV) hydride (stannane)** A highly reactive and volatile gas (b.p. –53°),  $\text{SnH}_4$ , which decomposes on moderate heating (150°C). It is prepared by the reduction of tin chlorides using lithium tetrahydridoaluminate(III) and is used in the synthesis of some organo-tin compounds. The compound has reducing properties.

**tin(IV) oxide (tin dioxide)** A white solid,  $\text{SnO}_2$ , insoluble in water; tetrahedral; r.d. 6.95; m.p. 1127°C; sublimes between 1800°C and 1900°C. Tin(IV) oxide is trimorphic: the common form, which occurs naturally as the ore \*cassiterite, has a rutile lattice but hexagonal and rhombic forms are also known. There are also two so-called dihydrates,  $\text{SnO}_2 \cdot 2\text{H}_2\text{O}$ , known as  $\alpha$ - and  $\beta$ -stannic acid. These are essentially tin hydroxides. Tin(IV) oxide is amphoteric, dissolving in molten alkalis to form \*stannates; in the presence of sulphur, thiostannates are produced.

**tin plague** *See* TIN.

**tin(II) sulphide** A grey-black cubic or

monoclinic solid, SnS, virtually insoluble in water; r.d. 5.22; m.p. 882°C; b.p. 1230°C. It has a layer structure similar to that of black phosphorus. Its heat of formation is low and it can be made by heating the elements together. Above 265°C it slowly decomposes (disproportionates) to tin(IV) sulphide and tin metal. The compound reacts with hydrochloric acid to give tin(II) chloride and hydrogen sulphide.

**tin(IV) sulphide (mosaic gold)** A bronze or golden yellow crystalline compound, SnS<sub>2</sub>, insoluble in water and in ethanol; hexagonal; r.d. 4.5; decomposes at 600°C. It is prepared by the reaction of hydrogen sulphide with a soluble tin(IV) salt or by the action of heat on thioostannic acid, H<sub>2</sub>SnS<sub>3</sub>. The golden-yellow form used for producing a gilded effect on wood is prepared by heating tin, sulphur, and ammonium chloride.

**T invariance** See TIME REVERSAL.

**Ti plasmid** See AGROBACTERIUM TUMEFACIENS.

**tissue** A collection of similar cells organized to carry out one or more particular functions. For example, in animals nervous tissue is specialized to perceive and transmit stimuli. An organ, such as a lung or kidney, contains many different types of tissues.

**tissue culture** The growth of the tissues of living organisms outside the body in a suitable culture medium. Culture (or nutrient) media contain a mixture of nutrients either in solid form (e.g. in \*agar) or in liquid form (e.g. in \*physiological saline). Tissue culture has proved to be invaluable for gaining information about factors that control the growth and differentiation of cells. Culture of plant tissues has resulted in the regeneration of complete plants, enabling commercial propagation (e.g. of orchids) and – through culture of meristem tissues – the production of virus-free crop plants. See also EXPLANTATION; TISSUE ENGINEERING.

**tissue engineering** The creation of synthetic or semisynthetic tissue that can be used instead of human tissue in surgery. Different kinds of tissue have been developed or are currently being re-

searched, including skin, bone, cartilage, cornea, and spinal tissue. For example, the first such product to gain approval for clinical use was a form of artificial skin consisting of a thin sheet of collagen gel infiltrated with two layers of cultured human cells – keratinocytes on the outer surface to form the 'epidermis', and fibroblasts on the inner surface to form the 'dermis'. More rigid tissues, such as synthetic bone and cartilage, are typically based on a biopolymer scaffold, which is treated with growth factors and seeded with cultured bone cells or cartilage cells to secrete the natural tissue material.

**tissue fluid** The fluid, consisting of water, ions, and dissolved gases and food substances, that is formed when blood is ultrafiltered (see ULTRAFILTRATION) from the capillaries into the intercellular spaces. The pressure in the arterial capillaries causes most components of the blood to pass across the capillary walls; blood cells and most of the plasma proteins are retained in the capillaries. The tissue fluid surrounds the body cells, facilitating the exchange of nutrients and waste materials. At the venous end of the capillaries, the tissue fluid is drawn into the capillaries by \*osmosis.

**Titan** See SATURN.

**titania** See TITANIUM(IV) OXIDE.

**titanium** Symbol Ti. A white metallic \*transition element; a.n. 22; r.a.m. 47.9; r.d. 4.5; m.p. 1660±10°C; b.p. 3287°C. The main sources are rutile (TiO<sub>2</sub>) and, to a lesser extent, ilmenite (FeTiO<sub>3</sub>). The element also occurs in numerous other minerals. It is obtained by heating the oxide with carbon and chlorine to give TiCl<sub>4</sub>, which is reduced by the \*Kroll process. The main use is in a large number of strong light corrosion-resistant alloys for aircraft, ships, chemical plant, etc. The element forms a passive oxide coating in air. At higher temperatures it reacts with oxygen, nitrogen, chlorine, and other nonmetals. It dissolves in dilute acids. The main compounds are titanium(IV) salts and complexes; titanium(II) and titanium(III) compounds are also known. The element was first discovered by William Gregor (1761–1817) in 1789.

**titanium dioxide** See TITANIUM(IV) OXIDE.

**titanium(IV) oxide (titania; titanium dioxide)** A white oxide,  $TiO_2$ , occurring naturally in various forms, particularly the mineral rutile. It is used as a white pigment and as a filler for plastics, rubber, etc.

**Titius-Bode law** See BODE, JOHANN ELERT.

**titration** A method of volumetric analysis in which a volume of one reagent (the **titrant**) is added to a known volume of another reagent slowly from a burette until an end point is reached (see INDICATOR). The volume added before the end point is reached is noted. If one of the solutions has a known concentration, that of the other can be calculated.

**titre** **1.** The number of infectious virus particles present in a suspension. **2.** A measure of the amount of \*antibody present in a sample of serum, given by the highest dilution of the sample that results in the formation of visible clumps with the appropriate antigen (see AGGLUTINATION). **3.** The concentration of a solution as measured by \*titration. **4.** The minimum quantity of solution required to complete a reaction in a titration.

**T lymphocyte** See T CELL.

**TNT** See TRINITROTOLUENE.

**toads** See AMPHIBIA.

**tobacco mosaic virus (TMV)** A rigid rod-shaped RNA-containing virus that causes distortion and blistering of leaves in a wide range of plants, especially the tobacco plant. It is transmitted by insects when they feed on plant tissue. TMV was the first virus to be discovered.

**tocopherol** See VITAMIN E.

**tokamak** See THERMONUCLEAR REACTOR.

**Tollens reagent** A reagent used in testing for aldehydes. It is made by adding sodium hydroxide to silver nitrate to give silver(I) oxide, which is dissolved in aqueous ammonia (giving the complex ion  $[Ag(NH_3)_2]^+$ ). The sample is warmed with the reagent in a test tube. Aldehydes reduce the complex  $Ag^+$  ion to metallic sil-

ver, forming a bright silver mirror on the inside of the tube (hence the name **silver-mirror test**). Ketones give a negative result. It is named after Bernhard Tollens (1841–1918).

**toluene** See METHYLBENZENE.

**tomography** The use of X-rays to photograph a selected plane of a human body with other planes eliminated. The **CT (computerized tomography) scanner** is a ring-shaped X-ray machine that rotates through  $180^\circ$  around the horizontal patient, making numerous X-ray measurements every few degrees. The vast amount of information acquired is built into a three-dimensional image of the tissues under examination by the scanner's own computer. The patient is exposed to a dose of X-rays only some 20% of that used in a normal diagnostic X-ray.

**tone (tonus)** The state of sustained tension in muscles that is necessary for the maintenance of posture. In a tonic muscle contraction, only a certain proportion of the muscle fibres are contracting at any given time; the rest are relaxed and recovering for subsequent contractions. The fibres involved in tone contract more slowly than the fast fibres used for rapid responses by the same muscle. The proportions of slow and fast fibres depend on the function of the muscle.

**tongue** A muscular organ of vertebrates that in most species is attached to the floor of the mouth. It plays an important role in manipulating food during chewing and swallowing and in terrestrial species it bears numerous \*taste buds on its upper surface. In some advanced vertebrates the tongue is used in the articulation of sounds, particularly in human speech.

**tonoplast (vacuole membrane)** The single membrane that bounds the \*vacuole of plant cells.

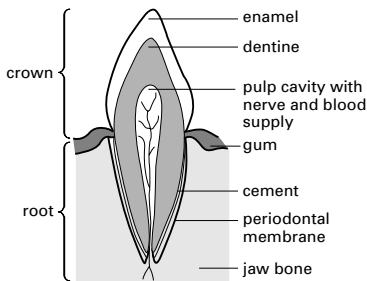

**tonsil** A mass of \*lymphoid tissue, several of which are situated at the back of the mouth and throat in higher vertebrates. In humans there are the **palatine tonsils** at the back of the mouth, **lingual tonsils** below the tongue, and **pharyngeal tonsils** (or **adenoids**) in the pharynx. They are concerned with the production of

\*lymphocytes and therefore with defence against infection.

**tonus** See TONE.

**tooth** Any of the hard structures in vertebrates that are used principally for biting and chewing food but also for attack, grooming, and other functions. In fish and amphibians the teeth occur all over the palate, but in higher vertebrates they are concentrated on the jaws. They evolved in cartilaginous fish as modified placoid \*scales, and this is reflected in their structure: a body of bony \*dentine with a central \*pulp cavity and an outer covering of \*enamel on the exposed surface (**crown**). The portion of the tooth embedded in the jawbone is the **root** (see illustration).

In mammals there are four different types of teeth, specialized for different functions (see CANINE TOOTH; INCISOR; MOLAR; PREMOLAR). Their number varies with the species (see DENTAL FORMULA). See also DECIDUOUS TEETH; PERMANENT TEETH.

Section through an incisor tooth

**topaz** A variably coloured aluminium silicate mineral,  $Al_2(SiO_4)(OH)_2$ , that forms orthorhombic crystals. It occurs chiefly in acid igneous rocks, such as granites and pegmatites. Topaz is valued as a gemstone because of its transparency, variety of colours (the wine-yellow variety being most highly prized), and great hardness (8 on the Mohs' scale). When heated, yellow or brownish topaz often becomes a rose-pink colour. The main sources of topaz are Brazil, Russia, and the USA.

**top carnivore** See CONSUMER.

**topography** The relief and position of the natural and cultural features of the earth's surface.

**topology** The branch of geometry concerned with the properties of geometrical objects that are unchanged by continuous deformations, such as twisting or stretching. Mathematical approaches employing topology are of great importance in modern theories of the \*fundamental interactions.

**topsoil** See SOIL.

**tornado** A violently rotating column of air, 10–100 m in diameter, usually made visible by a funnel cloud, that extends below cloud, usually cumulonimbus, and is in contact with the ground surface. Wind speeds of up to 100 metres per second may occur, but the damage to meteorological instruments caused by the passage of tornadoes makes exact measurement difficult. Tornadoes frequently occur in groups and are most common in the central USA and Australia, where they cause considerable destruction.

**torque (moment of a force or couple)**

The product of a force and its perpendicular distance from a point about which it causes rotation or \*torsion. The unit of torque is the newton metre, a vector product, unlike the joule, also equal to a newton metre, which is a scalar product. A turbine produces a torque on its central rotating shaft. See also COUPLE.

**torr** A unit of pressure, used in high-vacuum technology, defined as 1 mmHg. 1 torr is equal to 133.322 pascals. The unit is named after Evangelista Torricelli (1609–47).

**Torrillian vacuum** The vacuum formed when a long tube, closed at one end and filled with mercury, is inverted into a mercury reservoir so that the open end of the tube is below the surface of the mercury. The pressure inside the Torrillian vacuum is the vapour pressure of mercury, about  $10^{-3}$  torr.

**torsion** A twisting deformation produced by a \*torque or \*couple. A **torsion bar** is a form of spring in which one end of a bar is fixed and a torque is applied to

the other end. Torsion bars are used in the suspension systems of motor vehicles.

**torsion balance** An instrument for measuring very weak forces. It consists of a horizontal rod fixed to the end of a vertical wire or fibre or to the centre of a taut horizontal wire. The forces to be measured are applied to the end or ends of the rod. The turning of the rod may be measured by the displacement of a beam of light reflected from a plane mirror attached to it. The best-known form is that used by Henry Cavendish (1731–1810) and later by Sir Charles Boys (1855–1944) to determine the \*gravitational constant; in this form the balance is calibrated by determining the torsional coefficient of the suspension by treating the device as a torsional pendulum.

**torus 1.** (in mathematics) A solid generated by rotating a circle about an external line in its plane, also called an **anchor ring**. It has the shape of the inner tube of a tyre. If  $r$  is the radius of the rotating circle and  $R$  the distance between the centre of the circle and the axis of rotation, the volume of the torus is  $2\pi^2Rr^2$  and the surface area is  $4\pi^2Rr$ . In Cartesian coordinates, if the  $z$ -axis is the axis of rotation, the equation of the torus is  $[\sqrt{(x^2 + y^2)} - R]^2 + z^2 = r^2$ . **2.** (in botany) See RECEPTACLE.

**total internal reflection** The total reflection of a beam of light at the interface of one medium and another medium of lower refractive index, when the angle of incidence to the second medium exceeds a specific **critical angle**.

If a beam of light passing through a medium  $A$  (say glass) strikes the boundary to a medium  $B$  of lower refractive index (say air) with a small angle of incidence  $i$ ,

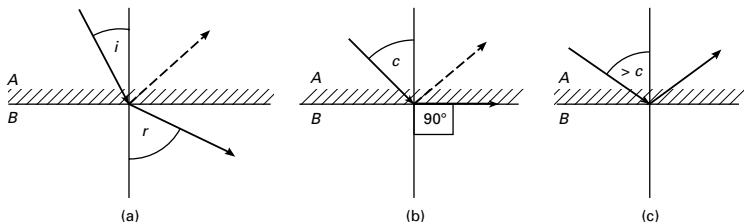

part will be refracted, with an angle of refraction  $r$ , and part will be reflected (see illustration a). If  $i$  is increased it will reach a critical angle  $c$ , at which  $r = 90^\circ$  (see illustration b). If  $i$  is now increased further, no refraction can occur and all the light energy is reflected by the interface (see illustration c). This total internal reflection occurs when  $c$  (given by  $n \sin c = 1$ ) is exceeded ( $n$  is the refractive index of  $A$  relative to  $B$ ). The critical angle of optical glass is usually about  $40^\circ$  and total internal reflection is made use of by incorporating prisms in some optical instruments instead of mirrors.

**totality** The period during a total \*eclipse of the sun in which the view of the sun's surface from a point on the earth is totally obscured by the moon. The maximum duration of totality is 7.67 minutes, but it is usually less.

**total-radiation pyrometer** See PYROMETRY.

**touch** The sense that enables the texture of objects and substances to be perceived. Touch receptors occur in the \*skin, being concentrated in the tips of the finger in humans.

**tourmaline** A group of minerals composed of complex cyclosilicates containing boron with the general formula  $\text{NaR}_3^{2+}\text{Al}_6\text{B}_3\text{Si}_6\text{O}_{27}(\text{H,F})_4$ , where  $R = \text{Fe}^{2+}$ ,  $\text{Mg}$ , or  $(\text{Al} + \text{Li})$ . The crystals are trigonal, elongated, and variably coloured, the two ends of the crystals often having different colours. Tourmaline is used as a gemstone and because of its double refraction and piezoelectric properties is also used in polarizers and some pressure gauges.

Total internal reflection

**Townes, Charles** See BASOV, NIKOLAI GENNEDIYEVITCH.

**toxicology** The science of the study of poisons. Originally developed by Paracelsus (1493–1541), toxicology is concerned with the investigation of the deleterious effects of all foreign substances (\*xenobiotics) on living organisms.

**toxin** A poison produced by a living organism, especially a bacterium. An **endotoxin** is released only when the bacterial cell dies or disintegrates. An **exotoxin** is secreted by a bacterial cell into the surrounding medium. In the body a toxin acts as an \*antigen, producing an \*immune response.

**trace element** See ESSENTIAL ELEMENT.

**trace fossil** See FOSSIL.

**trachea** **1.** (**windpipe**) The tube in air-breathing vertebrates that conducts air from the throat to the \*bronchi. It is strengthened with incomplete rings of cartilage. **2.** An air channel in insects and most other terrestrial arthropods. Tracheae occur as ingrowths of the body wall. They open to the exterior by **spiracles** and branch into finer channels (**tracheoles**) that terminate in the tissues (see also AIR SAC). Pumping movements of the abdominal muscles cause air to be drawn into and out of the tracheae.

**tracheid** A type of cell occurring within the \*xylem of conifers, ferns, and related plants. Tracheids are elongated and their walls are usually extensively thickened by deposits of lignin. Water flows from one tracheid to another through unthickened regions (pits) in the cell walls. Compare VESSEL ELEMENT.

**tracheophyte** Any plant that has elaborate tissues, including \*vascular tissue; a conspicuous \*sporophyte generation; and complex leaves with waterproof cuticles. Tracheophytes include plants of the phyla \*Lycophyta, \*Sphenophyta, \*Filicinophyta, \*Coniferophyta, and \*Anthophyta. In traditional classification systems these were regarded as classes of the division Tracheophyta.

**tracing (radioactive tracing)** See LABELLING.

**trajectory** See PHASE SPACE.

**transactinide elements** Elements with an atomic number greater than 103, i.e. elements above lawrencium in the \*periodic table. So far, elements up to 112 have been detected. Because of the highly radioactive and transient nature of these elements, there has been much dispute about priority of discovery and, consequently, naming of the elements. The International Union of Pure and Applied Chemistry (IUPAC) introduced a set of systematic temporary names based on affixes, as shown in the table.

Affix	Number	Symbol
nil	0	n
un	1	u
bi	2	b
tri	3	t
quad	4	q
pent	5	p
hex	6	h
sept	7	s
oct	8	o
enn	9	e

All these element names end in -ium. So, for example, element 109 in this system is called un + nil + enn + ium, i.e. unnilennium, and given the symbol u+n+e, i.e. Une.

One long-standing dispute was about the element 104 (rutherfordium), which has also been called kurchatovium (Ku). There have also been disputes between IUPAC and the American Chemical Union about element names.

In 1994 IUPAC suggested the following list:

mendelevium (Md, 101)  
 nobelium (No, 102)  
 lawrencium (Lr, 103)  
 dubnium (Db, 104)  
 joliotium (Jl, 105)  
 rutherfordium (Rf, 106)  
 bohrium (Bh, 107)  
 hahnium (Hn, 108)  
 meitnerium (Mt, 109)

The ACU favoured a different set of names:

mendelevium (Md, 101)  
 nobelium (No, 102)

lawrencium (Lr, 103)  
 rutherfordium (Rf, 104)  
 hahnium (Ha, 105)  
 seaborgium (Sg, 106)  
 nielsbohrium (Ns, 107)  
 hassium (Hs, 108)  
 meitnerium (Mt, 109)

A compromise list was adopted by IUPAC in 1997 and is generally accepted:

mendelevium (Md, 101)  
 nobelium (No, 102)  
 lawrencium (Lr, 103)  
 rutherfordium (Rf, 104)  
 dubnium (Db, 105)  
 seaborgium (Sg, 106)  
 bohrium (Bh, 107)  
 hassium (Hs, 108)  
 meitnerium (Mt, 109)

Element 110 was named as darmstadtium in 2003 and element 111 was named roentgenium in 2004. So far elements 112 (ununbium, Uub), 113 (ununtrium, Uut), 114 (ununquadium, Uuq), 115 (ununpentium, Uup), and 116 (ununhexium, Uuh) are not officially named. All these elements are unstable and have very short half-lives.

**transamination** A biochemical reaction in amino acid metabolism in which an amine group is transferred from an amino acid to a keto acid to form a new amino acid and keto acid. The coenzyme required for this reaction is pyridoxal phosphate.

**transcendental number** A number that is not algebraic, such as  $\pi$  or  $e$ .  
**transcendental function** is also nonalgebraic, such as  $a^x$ ,  $\sin x$ , or  $\log x$ .

**transcriptase** See REVERSE TRANSCRIPTASE.

**transcription** The process in living cells in which the genetic information of \*DNA is transferred to a molecule of messenger \*RNA (mRNA) as the first step in \*protein synthesis (see also GENETIC CODE). Transcription takes place in the cell nucleus or nuclear region. It involves the action of RNA \*polymerase enzymes in assembling the nucleotides necessary to form a complementary strand of mRNA from the DNA template, and (in eukaryote cells) the subsequent removal of the noncoding sequences from this primary transcript (see GENE SPLICING) to form a functional

mRNA molecule. See also REVERSE TRANSCRIPTASE. Compare TRANSLATION.

**transcription factor** Any of a group of proteins that regulate gene activity by increasing or decreasing the binding of RNA \*polymerases to the DNA molecule during the process of \*transcription. This is achieved by the ability of the transcription factors to bind to the DNA molecule.

**transcriptome** The full complement of RNA transcripts of the genes of a cell or organism. The types and relative abundance of different transcripts, i.e. the messenger RNAs (mRNAs), can be obtained by analysing cell contents using complementary DNA probes, particularly in the form of \*DNA microarrays. Such an analysis provides a 'snapshot' of the expression pattern of the cell's genes. See TRANSCRIPTOMICS.

**transcriptomics** The study of the RNA transcripts of a cell, tissue, or organism (i.e. the \*transcriptome). Transcriptomics is concerned with determining how the transcriptome, and hence pattern of gene expression, changes with respect to various factors, such as type of tissue, stage of development, hormones, drugs, or disease. It complements and overlaps with \*proteomics.

**transducer** A device for converting a nonelectrical signal, such as sound, light, heat, etc., into an electrical signal, or vice versa. Thus microphones and loudspeakers are **electroacoustic transducers**. An **active transducer** is one that can itself introduce a power gain and has its own power source. A **passive transducer** has no power source other than the actuating signal and cannot introduce gain.

**transduction 1.** The transfer of genetic material from one bacterial cell to another by means of a \*bacteriophage.

**2.** The conversion of stimuli detected in sensory \*receptor cells into electric impulses, which are transmitted to the brain by the nervous system. **3. (signal transduction)** (in cell biology) Any mechanism by which binding of a \*signal molecule to a cell-surface receptor triggers a response inside the cell. It often involves \*second messengers.

**transect** A straight line across an ex-

panse of ground along which ecological measurements are taken, continuously or at regular intervals. Thus an ecologist wishing to study the numbers and types of organisms at different distances above the low-tide line might sample at five-metre intervals along a number of transects perpendicular to the shore.

**trans effect** An effect in the substitution of inorganic square-planar complexes, in which certain ligands in the original complex are able to direct the incoming ligand into the trans position. The order of ligands in decreasing trans-directing power is:

$\text{CN}^- > \text{NO}_2^- > \text{I}^- > \text{Br}^- > \text{Cl}^- > \text{NH}_3 > \text{H}_2\text{O}$ .

**transferase** Any of a class of enzymes that catalyse the transfer of a group of atoms from one molecule to another.

**transfer RNA** See RNA.

**transformer** A device for transferring electrical energy from one alternating-current circuit to another with a change of voltage, current, phase, or impedance. It consists of a primary winding of  $N_p$  turns magnetically linked by a ferromagnetic core or by proximity to the secondary winding of  $N_s$  turns. The **turns ratio** ( $N_s/N_p$ ) is approximately equal to  $V_s/V_p$  and to  $I_p/I_s$ , where  $V_p$  and  $I_p$  are the voltage and current fed to the primary winding and  $V_s$  and  $I_s$  are the voltage and current induced in the secondary winding, assuming that there are no power losses in the core. In practice, however, there are \*eddy-current and \*hysteresis losses in the core, incomplete magnetic linkage between the coils, and heating losses in the coils themselves. By the use of a \*laminated core and careful design, transformers with 98% efficiency can be achieved.

**transgene** A gene that is taken from one organism and inserted into the germ line of another organism so that it is replicated as part of the genome and present in all the recipient's cells. See TRANSGENIC.

**transgenic** Describing an organism whose genome incorporates and expresses genes from another species (\*transgenes). See GENETICALLY MODIFIED ORGANISMS (Feature).

**transient** A brief disturbance or oscilla-

tion in a circuit caused by a sudden rise in the current or e.m.f.

**trans-isomer** See ISOMERISM.

**transistor** A \*semiconductor device capable of amplification in addition to rectification. It is the basic unit in radio, television, and computer circuits, having almost completely replaced the \*thermionic valve. The **point-contact transistor**, which is now obsolete, was invented in 1948. It consists of a small germanium crystal with two rectifying point contacts attached to it; a third contact, called the **base**, makes a low-resistance nonrectifying (ohmic) connection with the crystal. Current flowing through the device between the point contacts is modulated by the signal fed to the base. This type of transistor was replaced by the **junction transistor**, which was developed in 1949–50. The **field-effect transistor (FET)** was a later invention. **Bipolar transistors**, such as the junction transistor, depend on the flow of both majority and minority carriers, whereas in **unipolar transistors**, such as the FET, the current is carried by majority carriers only.

In the bipolar junction transistor, two  $p$ -type semiconductor regions are separated by a thin  $n$ -type region, making a  $p$ - $n$ - $p$  structure. Alternatively, an  $n$ - $p$ - $n$  structure can also be used. In both cases the thin central region is called the base and one outer region of the sandwich is called the **emitter**, the other the **collector**. The emitter-base junction is forward-biased and the collector-base junction is reverse-biased. In the  $p$ - $n$ - $p$  transistor, the forward bias causes holes in the emitter region to flow across the junction into the base; as the base is thin, the majority of holes are swept right across it (helped by the reverse bias), into the collector. The minority of holes that do not flow from the base to the collector combine with electrons in the  $n$ -type base. This recombination is balanced by a small electron flow in the base circuit. The diagram illustrates the (conventional) current flow using the **common-base** type of connection. If the emitter, base, and collector currents are  $I_e$ ,  $I_b$ , and  $I_c$ , respectively, then  $I_e = I_b + I_c$  and the current gain is  $I_c/I_b$ .

Field-effect transistors are of two kinds, the **junction FET (JFET or JUGFET)** and the

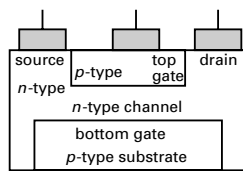

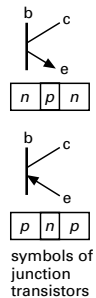

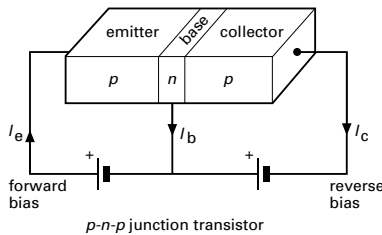

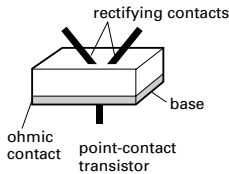

**insulated-gate FET (IGFET;** also known as a **MOSFET**, i.e. metal-oxide-semiconductor FET). Both are unipolar devices and in both the current flows through a narrow **channel** between two electrodes (the **gate**) from one region, called the **source**, to another, called the **drain**. The modulating signal is applied to the gate. In the **JFET**, the channel consists of a semiconductor material of relatively low conductivity sandwiched between two regions of high conductivity of the opposite polarity. When the junctions between these regions are reverse-biased, depletion layers form, which narrow the channel. At high bias the depletion layers meet and pinch-off the channel completely. Thus the voltage applied to the two gates controls the thickness of the channel and thus its conductivity. JFETs are made with both *n*-type and *p*-type channels.

In the IGFET, a wafer of semiconductor material has two highly doped regions of opposite polarity diffused into it, to form the source and drain regions. An insulating layer of silicon dioxide is formed on

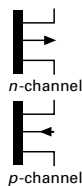

the surface between these regions and a metal conductor is evaporated on to the top of this layer to form the gate. When a positive voltage is applied to the gate, electrons move along the surface of the *p*-type substrate below the gate, producing a thin surface of *n*-type material, which forms the channel between the source and drain. This surface layer is called an **inversion layer**, as it has opposite conductivity to that of the substrate. The number of induced electrons is directly proportional to the gate voltage, thus the conductivity of the channel increases with gate voltage. IGFETs are also made with both *p*-type and *n*-type channels. Because MOS devices cannot be formed on gallium arsenide (there are no stable native oxides of GaAs), metal semiconductor FETs (MES-FET) devices are used. This makes use of Schottky barrier (see **SCHOTTKY EFFECT**) as the gate electrode rather than a semiconductor junction.

**transition** A change of a system from one quantum state to another.

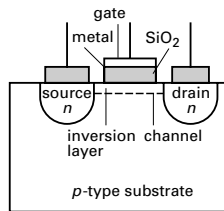

**transition elements** A set of elements

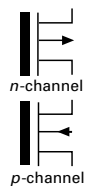

JFET

symbols of JFET

IGMET (MOSFET)

symbols of IGFET

in the \*periodic table in which filling of electrons in an inner *d*- or *f*-level occurs. With increasing proton number, electrons fill atomic levels up to argon, which has the electron configuration  $1s^2 2s^2 2p^6 3s^2 3p^6$ . In this shell, there are 5 *d*-orbitals, which can each contain 2 electrons. However, at this point the subshell of lowest energy is not the 3*d* but the 4*s*. The next two elements, potassium and calcium, have the configurations  $[\text{Ar}]4s^1$  and  $[\text{Ar}]4s^2$  respectively. For the next element, scandium, the 3*d* level is of lower energy than the 4*p* level, and scandium has the configuration  $[\text{Ar}]3d^1 4s^2$ . This filling of the inner *d*-level continues up to zinc  $[\text{Ar}]3d^{10} 4s^2$ , giving the first transition series. There is a further series of this type in the next period of the table: between yttrium ( $[\text{Kr}]4d^1 5s^2$ ) and cadmium ( $[\text{Kr}]4d^{10} 5s^2$ ). This is the second transition series. In the next period of the table the situation is rather more complicated. Lanthanum has the configuration  $[\text{Xe}]5d^1 6s^2$ . The level of lowest energy then becomes the 4*f* level and the next element, cerium, has the configuration  $[\text{Xe}]4f^1 5d^1 6s^2$ . There are 7 of these *f*-orbitals, each of which can contain 2 electrons, and filling of the *f*-levels continues up to lutetium ( $[\text{Xe}]4f^{14} 5d^1 6s^2$ ). Then the filling of the 5*d* levels continues from hafnium to mercury. The series of 14 elements from cerium to lutetium is a 'series within a series' called an **inner transition series**. This one is the \*lanthanoid series. In the next period there is a similar inner transition series, the \*actinoid series, from thorium to lawrencium. Then filling of the *d*-level continues from element 104 onwards.

In fact, the classification of chemical elements is valuable only in so far as it illustrates chemical behaviour, and it is conventional to use the term 'transition elements' in a more restricted sense. The elements in the inner transition series from cerium (58) to lutetium (71) are called the lanthanoids; those in the series from thorium (90) to lawrencium (103) are the actinoids. These two series together make up the *f*-block in the periodic table. It is also common to include scandium, yttrium, and lanthanum with the lanthanoids (because of chemical similarity) and to include actinium with the actinoids. Of the remaining transition el-

ements, it is usual to speak of three **main transition series**: from titanium to copper; from zirconium to silver; and from hafnium to gold. All these elements have similar chemical properties that result from the presence of unfilled *d*-orbitals in the element or (in the case of copper, silver, and gold) in the ions. The elements from 104 to 109 and the undiscovered elements 110 and 111 make up a fourth transition series. The elements zinc, cadmium, and mercury have filled *d*-orbitals both in the elements and in compounds, and are usually regarded as nontransition elements forming group 12 of the periodic table.

The elements of the three main transition series are all typical metals (in the nonchemical sense), i.e. most are strong hard materials that are good conductors of heat and electricity and have high melting and boiling points. Chemically, their behaviour depends on the existence of unfilled *d*-orbitals. They exhibit variable valency, have coloured compounds, and form \*coordination compounds. Many of their compounds are paramagnetic as a result of the presence of unpaired electrons. Many of them are good catalysts. They are less reactive than the *s*- and *p*-block metals.

**transition point (transition temperature)** **1.** The temperature at which one crystalline form of a substance changes to another form. **2.** The temperature at which a substance changes phase. **3.** The temperature at which a substance becomes superconducting (see SUPERCONDUCTIVITY). **4.** The temperature at which some other change, such as a change of magnetic properties (see also CURIE POINT), takes place.

#### **transition state (activated complex)**

The association of atoms of highest energy formed during a chemical reaction. The transition state can be regarded as a short-lived intermediate that breaks down to give the products. For example, in a  $S_N2$  substitution reaction, one atom or group approaches the molecule as the other leaves. The transition state is an intermediate state in which both attacking and leaving groups are partly bound to the molecule, e.g.

In the theory of reaction rates, the reactants are assumed to be in equilibrium with this activated complex, which decomposes to the products.

**transition zone** See HYPOCOTYL.

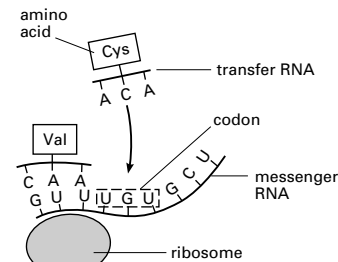

**translation 1.** (in biochemistry) The process in living cells in which the genetic information encoded in messenger \*RNA (mRNA) in the form of a sequence of nucleotide triplets (\*codons) is translated into a sequence of amino acids in a polypeptide chain during \*protein synthesis (see illustration). Translation takes place on \*ribosomes in the cell cytoplasm. The ribosomes move along the mRNA 'reading' each codon in turn. Molecules of transfer RNA (tRNA), each bearing a particular amino acid, are brought to their correct positions along the mRNA molecule: base pairing occurs between the bases of the codons and the complementary base triplets of tRNA (see ANTICODON). In this way amino acids are assembled in the correct sequence to form the polypeptide chain. **2.** (in physics) Motion of a body in which all the points in the body follow parallel paths.

**translocation 1.** (in botany) The movement of minerals and chemical compounds within a plant. There are two main processes. The first is the uptake of soluble minerals from the soil and their passage upwards from the roots to various organs by means of the water-conducting vessels (\*xylem). The second is the transfer of organic compounds, synthesized by the leaves, both upwards and downwards to various organs, particularly the growing points. This movement occurs within the \*phloem tubes. See also MASS FLOW. **2.** (in genetics) A type of \*chromosome mutation in which a section of one chromosome is broken off and becomes attached to another chromosome, resulting in a loss of genetic information from the first chromosome.

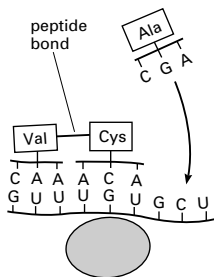

**translucent** Permitting the passage of radiation but not without some scattering or diffusion. For example, frosted glass allows light to pass through it but an object cannot be seen clearly through it because

the light rays are scattered by it. Compare TRANSPARENT.

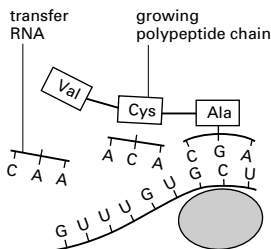

**transmission 1.** (in neurophysiology) The one-way transfer of a nerve \*impulse from one neuron to another across a \*synapse. See also NEUROTRANSMITTER.

(a)

(b)

(c)

The stages of translation in protein synthesis

*Compare* PROPAGATION. **2.** (in medicine) The spread of an \*infection from person to person. This can occur in various ways, such as close contact with an infected person, including sexual contact (*see* SEXUALLY TRANSMITTED DISEASE); contact with a \*vector or a \*carrier of the disease; consuming food or drink contaminated with the infecting microorganism; and breathing in contaminated droplets of moisture, produced by coughing and sneezing.

**3.** (in radio) *See* TRANSMITTER.

**transmission coefficient** *See* TRANSMITTANCE.

**transmission electron microscope**  
*See* ELECTRON MICROSCOPE.

**transmittance (transmission coefficient)**  
The ratio of the energy of some form of radiation transmitted through a surface to the energy falling on it. The reciprocal of the transmittance is the **opacity**.

**transmitter 1.** The equipment used to generate and broadcast radio-frequency electromagnetic waves for communication purposes. In **transmitted-carrier transmission** it consists of a carrier-wave generator, a device for modulating the carrier wave in accordance with the information to be broadcast, amplifiers, and an aerial system. In **suppressed-carrier transmission**, the carrier component of the carrier wave is not transmitted; one \*sideband (**single-sideband transmission**) or both sidebands (**double-sideband transmission**) are transmitted and a local oscillator in the receiver regenerates the carrier frequency and mixes it with the received signal to detect the modulating wave. **2.** The part of a telephone system that converts sound into electrical signals. **3.** *See* NEUROTRANSMITTER.

**transmutation** The transformation of one element into another by bombardment of nuclei with particles. For example, plutonium is obtained by the neutron bombardment of uranium.

**transparent** Permitting the passage of radiation without significant deviation or absorption. *Compare* TRANSLUCENT. A substance may be transparent to radiation of one wavelength but not to radiation of another wavelength. For example, some forms of glass are transparent to light but

not to ultraviolet radiation, while other forms of glass may be transparent to all visible radiation except red light. *See also* RADIOTRSPARENT.

**transpiration** The loss of water vapour by plants to the atmosphere. It occurs mainly from the leaves through pores (stomata) whose primary function is gas exchange. The water is replaced by a continuous column of water (and dissolved nutrients) moving upwards from the roots within the \*xylem vessels. The flow of this column of water is known as the **transpiration stream**, which is maintained by \*root pressure and a combination of cohesive and adhesive forces in the xylem vessels according to the **cohesion-tension theory** (*see* COHESION). *See also* POTOMETER.

**transplantation** *See* GRAFT.

**transport coefficients** Quantities that characterize transport in a system. Examples of transport coefficients include electrical and thermal \*conductivity. One of the main purposes of non-equilibrium \*statistical mechanics is to calculate such coefficients from first principles. It is difficult to calculate transport coefficients exactly for non-interacting systems and it is therefore necessary to use \*approximation techniques and/or \*model systems. A transport coefficient gives a measure for flow in a system. An **inverse transport coefficient** gives a measure of resistance to flow in a system. An example of an inverse transport coefficient is \*resistivity.

**transport number** Symbol *t*. The fraction of the total charge carried by a particular type of ion in the conduction of electricity through electrolytes.

**transport protein** A protein that penetrates or spans a cell membrane to permit the passage of a substance through the membrane. Some transport proteins form pores, or \*channels, through which particular ions or molecules can pass. Other types of transport protein bind the substance on one face of the membrane, then change shape so that the substance is carried by the protein through the membrane to be released at the other face. Transport proteins often require energy to drive the transport process; this is provided by hydrolysis of ATP or by an exist-

ing concentration gradient. See ACTIVE TRANSPORT.

**transport theory** The theory of phenomena involving the transfer of matter or heat. The calculation of \*transport coefficients and inverse transport coefficients, such as \*conductivity and \*viscosity, is an aim of transport theory. Calculations from first principles in transport theory start from \*non-equilibrium statistical mechanics. Because of the difficulties involved in calculations in non-equilibrium statistical mechanics, transport theory uses approximate methods, including the \*kinetic theory of gases and \*kinetic equations, such as the \*Boltzmann equation.

**transposon (transposable genetic element)** A mobile genetic element, known informally as a 'jumping gene', that can become integrated at many different sites along a chromosome. The simplest types of transposon are known as **insertion sequences** typically consisting of some 700–1500 base pairs and with numerous short repeated nucleotide sequences at either end. Larger and more complex are the **composite transposons**, which consist of a central portion, possibly containing functional genes, flanked by insertion sequences at either end. Transposons were first discovered by Barbara McClintock in maize in the 1940s and have since been found in other eukaryotes and in bacteria. They can disrupt gene expression or cause deletions and inversions, and hence affect both the genotype and phenotype of the organisms concerned. Most eukaryotic transposons are \*retrotransposons. Transposons account for a sizable proportion of the \*repetitive DNA in eukaryotes.

**transuranic elements** Elements with an atomic number greater than 92, i.e. elements above uranium in the \*periodic table. Most of these elements are unstable and have short half-lives. See also TRANSACTINIDE ELEMENTS.

**transverse wave** See WAVE.

**travelling wave** See WAVE.

**travelling-wave accelerator** See LINEAR ACCELERATOR.

**Travers, Morris** See RAMSAY, SIR WILLIAM.

**Trematoda** A class of parasitic flatworms (see PLATHELMINTHES) comprising the flukes, such as *Fasciola* (liver fluke). Flukes have suckers and hooks to anchor themselves to the host and their body surface is covered by a protective cuticle. The whole life cycle may either occur within one host or require one or more intermediate hosts to transmit the infective eggs or larvae. *Fasciola hepatica*, for example, undergoes larval development in a land snail (the intermediate host) and infects sheep (the primary host) when contaminated grass containing the larvae is swallowed.

**triacylglycerol** See TRIGLYCERIDE.

**trial-and-error learning** See LEARNING.

**triangle of vectors** A triangle constructed so that each of its sides represents one of three coplanar \*vectors acting at a point with no resultant. If the triangle is completed, with the sides representing the vectors in both magnitude and direction, so that there are no gaps between the sides, then the vectors are in equilibrium. If the three vectors are forces, the figure is called a **triangle of forces**; if they are velocities, it is a **triangle of velocities**.

**Triassic** The earliest period of the Mesozoic era. It began about 248 million years ago, following the Permian, the last period of the Palaeozoic era, and extended until about 213 million years ago when it was succeeded by the Jurassic. It was named, by F. von Alberti in 1834, after the sequence of three divisions of strata that he studied in central Germany – Bunter, Muschelkalk, and Keuper. The Triassic rocks are frequently difficult to distinguish from the underlying Permian strata and the term **New Red Sandstone** is often applied to rocks of the Permo-Triassic. During the period marine animals diversified: molluscs were the dominant invertebrates – ammonites were abundant and bivalves replaced the declining brachiopods. Reptiles were the dominant vertebrates and included turtles, phytosaurs, dinosaurs, and the marine ichthyosaurs.

**triatomic molecule** A molecule

formed from three atoms (e.g.  $\text{H}_2\text{O}$  or  $\text{CO}_2$ ).

**triazine** See AZINE.

**tribe** A category used in the \*classification of plants and animals that consists of several similar or closely related genera within a family. For example the Bambuseae, Oryzaceae, Paniceae, and Aveneae are tribes of grasses.

**triboelectricity** \*Static electricity produced as a result of friction.

**tribology** The study of friction, lubrication, and lubricants.

**triboluminescence** \*Luminescence caused by friction; for example, some crystalline substances emit light when they are crushed as a result of static electric charges generated by the friction.

**tribromomethane (bromoform)** A colourless liquid \*haloform,  $\text{CHBr}_3$ ; r.d. 2.9; m.p.  $8^\circ\text{C}$ ; b.p.  $150^\circ\text{C}$ .

**tricarbon dioxide (carbon suboxide)** A colourless gas,  $\text{C}_3\text{O}_2$ , with an unpleasant odour; r.d. 1.114 (liquid at  $0^\circ\text{C}$ ); m.p.  $-111.3^\circ\text{C}$ ; b.p.  $7^\circ\text{C}$ . It is the acid anhydride of malonic acid, from which it can be prepared by dehydration using phosphorus(V) oxide. The molecule is linear (O:C:C:C:O).

**tricarboxylic acid cycle** See KREBS CYCLE.

**trichloroethanal (chloral)** A liquid aldehyde,  $\text{CCl}_3\text{CHO}$ ; r.d. 1.51; m.p.  $-57.5^\circ\text{C}$ ; b.p.  $97.8^\circ\text{C}$ . It is made by chlorinating ethanal and used in making DDT. See also 2,2,2-TRICHLOROETHANEDIOL.

**2,2,2-trichloroethanediol (chloral hydrate)** A colourless crystalline solid,  $\text{CCl}_3\text{CH}(\text{OH})_2$ ; r.d. 1.91; m.p.  $57^\circ\text{C}$ ; b.p.  $96.3^\circ\text{C}$ . It is made by the hydrolysis of trichloroethanal and is unusual in having two -OH groups on the same carbon atom. Gem diols of this type are usually unstable; in this case the compound is stabilized by the presence of the three Cl atoms. It is used as a sedative.

**trichloroethene (trichlorethylene)** A colourless liquid,  $\text{CCl}_2=\text{CHCl}$ , b.p.  $87^\circ\text{C}$ . It is toxic and nonflammable, with a smell resembling that of chloroform

(trichloromethane). It is widely used as a solvent in dry cleaning and degreasing. It is also used to extract oils from nuts and fruit, as an anaesthetic, and as a fire extinguisher.

**trichloromethane (chloroform)** A colourless volatile sweet-smelling liquid \*haloform,  $\text{CHCl}_3$ ; r.d. 1.48; m.p.  $-63.5^\circ\text{C}$ ; b.p.  $61.7^\circ\text{C}$ . It can be made by chlorination of methane (followed by separation of the mixture of products) or by the haloform reaction. It is an effective anaesthetic but can cause liver damage and it has now been replaced by other halogenated hydrocarbons. Chloroform is used as a solvent and raw material for making other compounds.

**trichome** A hairlike projection from a plant epidermal cell. Examples include root hairs and the stinging hairs of nettle leaves.

**triclinal** See CRYSTAL SYSTEM.

**tricuspid valve** A valve, consisting of three flaps, situated between the right atrium and the right ventricle of the mammalian heart. When the right ventricle contracts, forcing blood into the pulmonary artery, the tricuspid valve closes the aperture to the atrium, thereby preventing any backflow of blood. The valve reopens to allow blood to flow from the atrium into the ventricle. Compare BICUSPID VALVE.

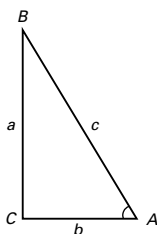

**tridymite** A mineral form of \*silicon(IV) oxide,  $\text{SiO}_2$ .

**triglyceride (triacylglycerol)** An ester of glycerol (propane-1,2,3-triol) in which all three hydroxyl groups are esterified with a fatty acid. Triglycerides are the major constituent of fats and oils and provide a concentrated food energy store in living organisms as well as cooking fats and oils, margarines, etc. Their physical and chemical properties depend on the nature of their constituent fatty acids. In **simple triglycerides** all three fatty acids are identical; in **mixed triglycerides** two or three different fatty acids are present.

**trigonal bipyramid** See illustration at COMPLEX.

**trigonometric functions** Functions defined in terms of a right-angled triangle

## Trigonometric functions

(see diagram) and widely used in the solution of many mathematical problems.

They are defined as:

tangent of angle A, written  $\tan A = a/b$

sine of angle A, written  $\sin A = a/c$

cosine of angle A, written  $\cos A = b/c$ ,

where  $a$  is the length of the side opposite the angle A,  $b$  is the length of the side opposite the angle B, and  $c$  is the hypotenuse of the triangle.

The reciprocal functions are:

cotangent of angle A, written  $\cot A =$

$$1/\tan A = b/a$$

secant of angle A, written  $\sec A = 1/\cos A =$

$$c/b$$

cosecant of angle A, written  $\operatorname{cosec} A =$

$$1/\sin A = c/a.$$

**trihydrate** A crystalline hydrate that contains three moles of water per mole of compound.

**trihydric alcohol** See TRIOL.

**triiodomethane (iodoform)** A yellow volatile solid sweet-smelling \*haloform,  $\text{CHI}_3$ ; r.d. 4.1; m.p. 115°C. It is made by the haloform reaction.

**triiodothyronine ( $\text{T}_3$ )** A hormone secreted by the \*thyroid gland. See also THYROGLOBULIN.

**triiron tetroxide (ferrosferric oxide)** A black magnetic oxide,  $\text{Fe}_3\text{O}_4$ ; r.d. 5.2. It is formed when iron is heated in steam and also occurs naturally as the mineral \*magnetite. The oxide dissolves in acids to give a mixture of iron(II) and iron(III) salts.

**trilobite** An extinct marine arthropod belonging to the class Trilobita (some 4000 species), fossils of which are found in deposits dating from the Precambrian to the Permian period (590–280 million years ago). Trilobites were typically small

(1–7 cm long); the oval flattened body comprised a head (covered by a semicircular dorsal shield) and a thorax and abdomen, which were protected by overlapping dorsal plates with a raised central part and flattened lateral portions, presenting a three-lobed appearance. The head bore a pair of antenna-like appendages and a pair of compound eyes; nearly all body segments bore a pair of Y-shaped (biramous) appendages – one branch for locomotion and the other fringed for respiratory exchange. Trilobites were bottom-dwelling scavengers.

**trimethylaluminium (aluminium trimethyl)** A colourless liquid,  $\text{Al}(\text{CH}_3)_3$ , which ignites in air and reacts with water to give aluminium hydroxide and methane, usually with extreme vigour; r.d. 0.752; m.p. 0°C; b.p. 130°C. Like other aluminium alkyls it may be prepared by reacting a Grignard reagent with aluminium trichloride. Aluminium alkyls are used in the \*Ziegler process for the manufacture of high-density polyethylene (polythene).

**2,4,6-trinitrophenol** See PICRIC ACID.

**trinitrotoluene (TNT)** A yellow highly explosive crystalline solid,  $\text{CH}_3\text{C}_6\text{H}_2(\text{NO}_2)_3$ ; r.d. 1.65; m.p. 82°C. It is made by nitrating toluene (methylbenzene), the systematic name being 1-methyl-2,4,6-trinitrobenzene.

**triode** A \*thermionic valve with three electrodes. Electrons produced by the heated cathode flow to the anode after passing through the negatively biased \*control grid. Small voltage fluctuations superimposed on the grid bias cause large fluctuations in the anode current. The triode was thus the first electronic device capable of amplification. Its role has now been taken over by the transistor, except where high power (radio-frequency transmitters producing more than 1 kW in power) is required.

**triol (trihydric alcohol)** An \*alcohol containing three hydroxyl groups per molecule.

**triose** A sugar molecule that contains three carbon atoms. See MONOSACCHARIDE.

**trioxoboric(III) acid** See BORIC ACID.

**trioxosulphuric(IV) acid** See SULPHUROUS ACID.

**trioxygen** See OZONE.

**triple bond** See CHEMICAL BOND.

**triple point** The temperature and pressure at which the vapour, liquid, and solid phases of a substance are in equilibrium. For water the triple point occurs at 273.16 K and 611.2 Pa. This value forms the basis of the definition of the \*kelvin and the thermodynamic \*temperature scale.

**triple product** Either a \*scalar product or a \*vector product each having three components. A **scalar triple product** is obtained by multiplying three \*vectors **a**, **b** and **c** in the manner  $\mathbf{a} \cdot (\mathbf{b} \times \mathbf{c})$ ; the result is a scalar. If the three vectors represent the positions of three points with respect to the origin, the magnitude of the scalar triple product is the volume of the parallelepiped with corners at the three points and the origin. A **vector triple product** is obtained by multiplying three vectors **a**, **b** and **c** in the manner  $\mathbf{a} \times (\mathbf{b} \times \mathbf{c})$ ; the result is a vector. It also equals  $(\mathbf{a} \cdot \mathbf{c})\mathbf{b} - (\mathbf{a} \cdot \mathbf{b})\mathbf{c}$  (but note it does not equal  $(\mathbf{a} \times \mathbf{b}) \times \mathbf{c}$ ).

**triplet code** See CODON; GENETIC CODE.

**triploblastic** Describing an animal having a body composed of three embryonic cell layers: the \*ectoderm, \*mesoderm, and \*endoderm. Most multicellular animals are triploblastic; the coelenterates, which are \*diploblastic, are an exception.

**triploid** Describing a nucleus, cell, or organism that has three times ( $3n$ ) the haploid number ( $n$ ) of chromosomes (see also POLYPLIOD). Triploid organisms are normally sterile as their lack of \*homologous chromosomes prevents pairing during meiosis. This can be useful to plant breeders, for example in banana cultivation: sterile triploid bananas can be propagated asexually and will not contain any seeds.

**trisilane** See SILANE.

**trisodium phosphate(V) (sodium orthophosphate)** A colourless crystalline compound,  $\text{Na}_3\text{PO}_4$ , soluble in water and insoluble in ethanol. It is known both as the decahydrate (octagonal; r.d. 2.54) and the dodecahydrate (trigonal; r.d. 1.62) The

dodecahydrate loses water at about 76°C and the decahydrate melts at 100°C. Trisodium phosphate may be prepared by boiling sodium carbonate with the stoichiometric amount of phosphoric acid and subsequently adding sodium hydroxide to the disodium salt thus formed. It is useful as an additive for high-pressure boiler feed water (for removal of calcium and magnesium as phosphates), in emulsifiers, as a water-softening agent, and as a component in detergents and cleaning agents. Sodium phosphate labelled with the radioactive isotope  $^{32}\text{P}$  is used in the study of the role of phosphate in biological processes and is also used (intravenously) in the treatment of polycythaemia.

**trisomy** The condition of a nucleus, cell, or organism in which one of the pairs of homologous chromosomes has gained an additional chromosome, resulting in a chromosome number of  $2n + 1$ . Trisomy is the cause of a number of human genetic abnormalities, including \*Down's syndrome; Patau's syndrome, in which there is an extra chromosome 13 (**trisomy 13**); and Edwards' syndrome, in which there is an extra chromosome 18 (**trisomy 18**).

**tritiated compound** See LABELLING.

**tritium** Symbol T. An isotope of hydrogen with mass number 3; i.e. the nucleus contains 2 neutrons and 1 proton. It is radioactive (half-life 12.3 years), undergoing beta decay to helium-3. Tritium is used in \*labelling.

**triton** The nucleus of a tritium atom.

**trivalent (tervalent)** Having a valency of three.

**tRNA** See RNA.

**trochanter 1.** Any of several bony knobs on the femur of vertebrates to which muscles are attached. **2.** The second segment of an insect's leg, between the \*coxa and the \*femur.

**trona** A mineral form of sodium sesquicarbonate, consisting of a mixed hydrated sodium carbonate and sodium hydrogen carbonate,  $\text{Na}_2\text{CO}_3 \cdot \text{NaHCO}_3 \cdot 2\text{H}_2\text{O}$ .

**trophic level** The position that an organism occupies in a \*food chain. For ex-

ample, green plants (which obtain their energy directly from sunlight) are the primary \*producers; herbivores are primary \*consumers (and secondary producers). A carnivore that eats only herbivores is a secondary consumer and a tertiary producer. Many animals feed at several different trophic levels.

**tropical cyclone** A \*cyclone that develops over tropical or subtropical waters, in which sea temperatures are above 27°C and at least 5° of latitude away from the equator. The term encompasses tropical depression, with wind speeds of 33 knots (62 km/h) or less, and tropical storm, with wind speeds of 34–63 knots (63–117 km/h). A tropical cyclone with wind speeds of over 64 knots (117 km/h) is known as a \*hurricane where it occurs in the North Atlantic Ocean, Caribbean Sea, Gulf of Mexico, and the east and central North Pacific Ocean (east of the dateline); as a typhoon where it occurs in the North Pacific Ocean; and as a severe tropical cyclone where it occurs in the southwest Pacific Ocean (west of 160°E) and southeast Indian Ocean (east of 90°E).

**tropical year** See YEAR.

**tropism** The directional growth of a plant organ in response to an external stimulus, such as light, touch, or gravity. Growth towards the stimulus is a **positive tropism**; growth away from the stimulus is a **negative tropism**. See also GEOTROPISM; HYDROTROPISM; ORTHOTROPISM; PHOTOTROPISM; PLAGIOTROPISM; THIGMOTROPISM. Compare NASTIC MOVEMENTS; TAXIS.

**tropomyosin** A protein found in the \*actin filaments in muscles. The molecule consists of two elongated strands that run along the length of the filament. When the muscle is at rest, the tropomyosin molecule covers the region of the actin molecule where interaction with myosin occurs. On contraction of the muscle, the tropomyosin is displaced by another protein, \*troponin, allowing the interaction of actin with myosin.

**troponin** A complex of three polypeptide chains that are found at regular intervals along the length of an \*actin filament. During muscle contraction, troponin binds to calcium ions, displacing

\*tropomyosin and exposing the active site on the actin filament. This allows the interaction of actin and myosin to occur.

**troposphere** See EARTH'S ATMOSPHERE.

**troplyium ion** The positive ion  $C_7H_7^+$ , having a ring of seven carbon atoms. The ion is symmetrical and has characteristic properties of \*aromatic compounds.

**truth table** A table that summarizes all possible outcomes of a logical operation. For example, for an AND \*gate with inputs A and B and output C, the truth table is

A	B	C
0	0	0
0	1	0
1	0	0
1	1	1

This indicates that the output will be 0 unless both inputs are 1.

**trypsin** An enzyme that digests proteins (see ENDOPEPTIDASE; PROTEASE). It is secreted in an inactive form (**trypsinogen**) by the pancreas into the duodenum. There, trypsinogen is acted on by an enzyme (**enterokinase**) produced in the duodenum to yield trypsin. The active enzyme plays an important role in the digestion of proteins in the anterior portion of the small intestine. It also activates other proteases in the pancreatic juice (see CARBOXYPEPTIDASE; CHYMOTRYPSIN).

**trypsinogen** See TRYPSIN.

**tryptophan** See AMINO ACID.

**TSH** See THYROID-STIMULATING HORMONE.

**tsunami** A large sea wave usually generated by a submarine earthquake or volcanic eruption. It may also be caused by a mass underwater mudslide. The waves, which can be over 10 m high, spread in concentric circles from the focus of the earthquake, often travelling hundreds of kilometres and reaching speeds of 700 km/h. A tsunami can be extremely destructive when it breaks on the shore. A devastating tsunami followed a powerful earthquake of magnitude 9.0 (see RICHTER SCALE) off the west coast of N Sumatra, Indonesia, on 26 December 2004. It swept over land causing widespread destruction in Indonesia, Sri Lanka, Thailand, Malaysia, Myanmar, S India, and the Maldives,

with lesser effects as faraway as E Africa, and resulted in over 283 100 deaths.

**T Tauri star** An unstable young variable star in its pre-main sequence phase (see HERTZSPRUNG-RUSSELL DIAGRAM). The instability, brought about by the beginning of nuclear fusion in the core of the star, causes pulsations and stellar winds, possibly with \*bipolar outflows. Groups of such stars, often associated with \*Herbig-Haro objects, are called T Tauri associations.

**tuber** A swollen underground stem or root in certain plants. It enables the plant to survive the winter or dry season and is also a means of propagation. A **stem tuber**, such as the potato, forms at the end of an underground stem. Each tuber represents several nodes and internodes. The following season several new plants develop from the terminal and axillary buds (eyes). **Root tubers**, such as those of the dahlia, are modified food-storing adventitious roots and may also give rise to new plants.

**tubulin** A protein of which the \*microtubules of cells are formed.

**Tullgren funnel** A device used to remove and collect small animals, such as insects, from a sample of soil or leaf litter. The sample is placed on a coarse sieve fixed across the wide end of a funnel and a 100-watt light bulb, in a metal reflector, is placed about 25 cm above the funnel. The heat from the bulb dries and warms the sample, causing the animals to move downwards and fall through the sieve into the funnel, which directs them into a collecting dish or tube below. The dish can contain water or alcohol to prevent the animals from escaping.

**tumour** See NEOPLASM.

**tundra** A terrestrial \*biome characterized by a lack of trees and a permanently frozen subsoil. Tundra lies to the north of the \*taiga in North America and Eurasia; the vegetation is dominated by grasses, sedges, lichens, mosses, heathers, and low shrubs. The growing season, which occurs during the warmest part of the year when the average daily mean temperature is about 10°C, lasts only 2–4 months, during which the topsoil thaws to a depth of 30 cm, allowing roots to penetrate it.

However, below this level the soil is permanently frozen (**permafrost**); water cannot filter through the soil and may lie in surface depressions during the growing season. Compare TAIGA.

**tuneable laser** See DYE LASER.

**tungsten** Symbol W. A white or grey metallic \*transition element (formerly called **wolfram**); a.n. 74; r.a.m. 183.85; r.d. 19.3; m.p. 3410°C; b.p. 5660°C. It is found in a number of ores, including the oxides wolframite, (Fe,Mn)WO<sub>4</sub>, and scheelite, CaWO<sub>4</sub>. The ore is heated with concentrated sodium hydroxide solution to form a soluble **tungstate**. The oxide WO<sub>3</sub> is precipitated from this by adding acid, and is reduced to the metal using hydrogen. It is used in various alloys, especially high-speed steels (for cutting tools) and in lamp filaments. Tungsten forms a protective oxide in air and can be oxidized at high temperature. It does not dissolve in dilute acids. It forms compounds in which the oxidation state ranges from +2 to +6. The metal was first isolated by Juan and Fausto d'Elhuyer in 1783.

**tungsten carbide** A black powder, WC, made by heating powdered tungsten metal with lamp black at 1600°C. It is extremely hard (9.5 on Mohs' scale) and is used in dies and cutting tools. A ditungsten carbide, W<sub>2</sub>C, also exists.

**tuning fork** A metal two-pronged fork that when struck produces an almost pure tone of a predetermined frequency. It is used for tuning musical instruments and in experiments in acoustics.

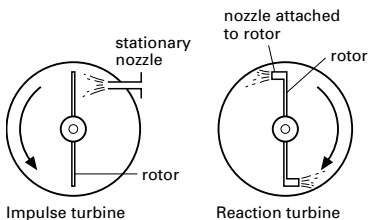

**tunnel diode (Esaki diode)** A semiconductor diode, discovered in 1957 by L. Esaki (1925– ), based on the \*tunnel effect. It consists of a highly doped *p-n* semiconductor junction, which short circuits with negative bias and has negative resistance over part of its range when forward biased. Its fast speed of operation makes it a useful device in many electronic fields.

**tunnel effect** An effect in which electrons are able to tunnel through a narrow \*potential barrier that would constitute a forbidden region if the electrons were treated as classical particles. That there is a finite probability of an electron tun-

nelling from one classically allowed region to another arises as a consequence of \*quantum mechanics. The effect is made use of in the \*tunnel diode. Alpha decay (see ALPHA PARTICLE) is an example of a tunnelling process.

**Turbellaria** A class of free-living flatworms (see PLATYHELMINTHES) comprising the planarians, which occur in wet soils, fresh water, and marine environments. Their undersurface is covered with cilia, used for gliding over stones and weeds. Planarians can also swim by means of undulations of the body.

**turbine** A machine in which a fluid is used to produce rotational motion. The most widely used turbines are the **steam turbines** and **water turbines** that provide some 95% of the world's electric power (in the form of \*turbogenerators) and the **gas turbines** that power all the world's jet-propelled aircraft. In the **impulse turbine** a high-pressure low-velocity fluid is expanded through stationary nozzles, producing low-pressure high-velocity jets, which are directed onto the blades of a rotor. The rotor blades reduce the speed of the jets and thus convert some of the fluid's kinetic energy into rotational kinetic energy of the rotor shaft. In the **reaction turbine** the discharge nozzles are themselves attached to the rotor. The acceleration of the fluid leaving the nozzles produces a force of reaction on the pipes, causing the rotor to move in the opposite direction to that of the fluid. (See illustrations.) Many turbines work on a combination of the impulse and reaction principles.

Principle of the turbine

**turbogenerator** A steam turbine driving an electric generator. This is the normal method of generating electricity in

power stations. In a conventional power station the steam is raised by burning a fossil fuel (coal, oil, or natural gas); in a nuclear power station the steam is raised by heat transfer from a nuclear reactor.

**turbojet** See JET PROPULSION.

**turbulence** A form of fluid flow in which the particles of the fluid move in a disordered manner in irregular paths, resulting in an exchange of momentum from one portion of a fluid to another. Turbulent flow takes over from \*laminar flow when high values of the \*Reynolds number are reached.

**turgor** The condition in a plant cell when its \*vacuole is distended with water, pushing the protoplast against the cell wall. In this condition the force causing water to enter the cell by \*osmosis is balanced by the hydrostatic pressure of the protoplast against the cell wall (see also WATER POTENTIAL). Turgidity assists in maintaining the rigidity of plants; a decrease in turgidity leads to \*wilting. Compare PLASMOLYSIS.

**Turing, Alan Mathison** (1912–54) British mathematician, who after studying at Cambridge University went to Princeton, where in 1937 he published his most important work on computable numbers, which contained a description of the hypothetical \*Turing machine. He returned to Britain at the outbreak of World War II and worked on cracking German codes. This led to his involvement in the development of computers. He committed suicide after being convicted of indecency (as a homosexual).

**Turing machine** A hypothetical machine that determines whether or not a problem is computable. It has an infinite memory represented by an infinitely long ribbon of paper tape passing through the machine, which can be in several discrete internal states. The tape is divided into cells that can each hold one of a given number of symbols. The machine can move left or right along the tape, acting on one cell at a time. It is programmed by a set of instructions that make it change symbols, change state, and move one cell left or right (or remain at the same cell). If an operation can be performed by using

an algorithm (i.e. if it is computable), a Turing machine can do it. It was devised by Alan Turing.

**turion 1.** A winter bud, covered with scale leaves and mucilage, that is produced by certain aquatic plants, such as frogbit. Turions become detached and remain dormant on the pond or lake bottom during the winter before developing into new plants the following season.

**2.** See SUCKER.

**Turner's syndrome** A genetic disorder of women caused by the absence of the second \*sex chromosome (such women are XO, rather than the normal XX). It is characterized by a lack of ovaries and menstrual cycle. Affected women are sterile and lack secondary sexual characteristics, although the external genitalia are present. The syndrome is named after the US endocrinologist Henry Turner (1892–1970), who first described it.

**turns ratio** See TRANSFORMER.

**turpentine** An oily liquid extracted from pine resin. It contains pinene,  $C_{10}H_{16}$ , and other terpenes and is mainly used as a solvent.

**turquoise** A mineral consisting of a hydrated phosphate of aluminium and copper,  $CuAl_6(PO_4)_4(OH)_8 \cdot 4H_2O$ , that is prized as a semiprecious stone. It crystallizes in the triclinic system and is generally blue in colour, the 'robin's egg' blue variety being the most sought after. It usually occurs in veinlets and as masses and is formed by the action of surface waters on aluminium-rich rocks. The finest specimens are obtained from Iran.

**T violation** See TIME REVERSAL.

**tweeter** A small loudspeaker capable of reproducing sounds of relatively high frequency, i.e. 5 kilohertz upwards. In high-fidelity equipment a tweeter is used in conjunction with a \*woofer.

**twinning** A process in which two crystals of the same material form with orientations such that the two crystals are related to each other by a symmetry operation. This may be either reflection in a plane (the **twinning plane**) or rotation

about an axis (the **twinning axis**). The plane or axis is common to the two crystals.

**twins** Two individuals born to the same mother at the same time. Twins can develop from the same egg (see IDENTICAL TWINS) or from two separately fertilized eggs (see FRATERNAL TWINS).

**tympanic cavity** See MIDDLE EAR.

**tympanium (tympanic membrane; eardrum)** The membrane that separates the \*outer ear from the \*middle ear. It vibrates in response to sound waves and transmits these vibrations via the \*ear ossicles of the middle ear to the site of hearing (the \*cochlea of the \*inner ear). In amphibians and some reptiles there is no external ear and the tympanium is exposed at the skin surface.

**Tyndall effect** The scattering of light as it passes through a medium containing small particles. If a polychromatic beam of light is passed through a medium containing particles with diameters less than about one-twentieth of the wavelength of the light, the scattered light appears blue. This accounts for the blue appearance of tobacco smoke. At higher particle diameters, the scattered light remains polychromatic. It is named after John Tyndall (1820–93). See also SCATTERING OF ELECTROMAGNETIC RADIATION.

**type specimen** The specimen used for naming and describing a \*species or subspecies. If this is the original specimen collected by the author who named the species it is termed a **holotype**. The type specimen is not necessarily the most characteristic representative of the species. The term **type** is also applied to any taxon selected as being representative of the rank to which it belongs. For example, the genus *Solanum* (potato) is said to be the type genus of the family Solanaceae.

**typhoon** A \*tropical cyclone or \*hurricane that occurs in the W and N Pacific Ocean and the South China Sea.

**tyrosine** See AMINO ACID.

**ubiquinone (coenzyme Q)** Any of a group of related quinone-derived compounds that serve as electron carriers in the \*electron transport chain reactions of cellular respiration. Ubiquinone molecules have side chains of different lengths in different types of organisms but function in similar ways.

**ulna** The larger of the two bones in the forearm of vertebrates (*compare* RADIUS). It articulates with the outer carpals at the wrist and with the humerus at the elbow.

**ultracentrifuge** A high-speed centrifuge used to measure the rate of sedimentation of colloidal particles or to separate macromolecules, such as proteins or nucleic acids, from solutions. Ultracentrifuges are electrically driven and capable of speeds up to 60 000 rpm.

**ultradian rhythm** *See* BIORHYTHM.

**ultrafiltration** The process in which hydrostatic pressure causes water and small dissolved molecules and ions to move across a membrane against a \*concentration gradient. Ultrafiltration is responsible for the formation of \*tissue fluid and \*glomerular filtrate from blood. In both these processes the ultrafiltered fluid has the same composition as the plasma except that it does not contain blood cells or large protein molecules.

**ultrahigh frequency (UHF)** A radio frequency in the range  $3 \times 10^9$ – $0.3 \times 10^9$  Hz; i.e. having a wavelength in the range 10 cm to 1 m.

**ultramicroscope** A form of microscope that uses the \*Tyndall effect to reveal the presence of particles that cannot be seen with a normal optical microscope. Colloidal particles, smoke particles, etc., are suspended in a liquid or gas in a cell with a black background and illuminated by an intense cone of light that enters the cell from the side and has its apex in the field of view. The particles then produce

diffraction-ring systems, appearing as bright specks on the dark background.

**ultramicrotome** *See* MICROTOME.

**ultrasonics** The study and use of pressure waves that have a frequency in excess of 20 000 Hz and are therefore inaudible to the human ear. **Ultrasonic generators** make use of the \*piezoelectric effect, \*ferroelectric materials, or \*magnetostriction to act as transducers in converting electrical energy into mechanical energy. Ultrasonics are used in medicine for diagnosis, particularly in conditions such as pregnancy, in which X-rays could have a harmful effect, and for treatment, the vibratory effect being used to break up kidney stones, etc. Ultrasonic techniques are also used industrially to test for flaws in metals, to clean surfaces, to test the thickness of parts, and to form colloids.

**ultrastructure** The submicroscopic, almost molecular, structure of living cells, which is revealed by the use of an electron microscope.

**ultraviolet microscope** A \*microscope that has quartz lenses and slides and uses \*ultraviolet radiation as the illumination. The use of shorter wavelengths than the visible range enables the instrument to resolve smaller objects and to provide greater magnification than the normal optical microscope. The final image is either photographed or made visible by means of an \*image converter.

**ultraviolet radiation (UV)** Electromagnetic radiation having wavelengths between that of violet light and long X-rays, i.e. between 400 nanometres and 4 nm. In the range 400–300 nm the radiation is known as the **near ultraviolet**. In the range 300–200 nm it is known as the **far ultraviolet**. Below 200 nm it is known as the **extreme ultraviolet** or the **vacuum ultraviolet**, as absorption by the oxygen in the air makes the use of evacuated ap-

paratus essential. The sun is a strong emitter of UV radiation but only the near UV reaches the surface of the earth as the \*ozone layer of the atmosphere absorbs all wavelengths below 290 nm. Ultraviolet radiation is classified in three ranges according to its effect on the skin. The ranges are:

UV-A (320–400 nm);

UV-B (290–320 nm);

UV-C (230–290 nm).

The longest-wavelength range, UV-A, is not harmful in normal doses and is used clinically in the treatment of certain skin complaints, such as psoriasis. It is also used to induce \*vitamin D formation in patients that are allergic to vitamin D preparations. UV-B causes reddening of the skin followed by pigmentation (tanning). Excessive exposure can cause severe blistering. UV-C, with the shortest wavelengths, is particularly damaging. It is thought that short-wavelength ultraviolet radiation causes skin cancer and that the risk of contracting this has been increased by the depletion of the ozone layer.

Most UV radiation for practical use is produced by various types of \*mercury-vapour lamps. Ordinary glass absorbs UV radiation and therefore lenses and prisms for use in the UV are made from quartz.

**ultraviolet-visible spectroscopy (UV-visible spectroscopy)** A technique for chemical analysis and the determination of structure. It is based on the principle that electronic transitions in molecules occur in the visible and ultraviolet regions of the electromagnetic spectrum, and that a given transition occurs at a characteristic wavelength. The spectrometer has two sources, one of ultraviolet and the other of white visible light, which together cover the whole wavelength range of the instrument. If the whole wavelength range is used, the source is changed over at the appropriate point. The radiation from the source is split into two beams of equal intensity. One beam is passed through a dilute solution of the sample while the other is passed through the pure solvent and is used as a reference against which the first is compared after transmittance. The cells used for the sam-

ple and reference solutions are usually made of silica and are matched.

**umbel** A type of \*racemose inflorescence in which stalked flowers arise from the same point on the flower axis, resembling the spokes of an umbrella. An involucre (cluster) of bracts may occur at the point where the stalks emerge. This arrangement is characteristic of the family Umbelliferae (Apiaceae; e.g. carrot, hogweed, parsley, parsnip), in which the inflorescence is usually a compound umbel.

**umbilical cord** The cord that connects the embryo to the \*placenta in mammals. It contains a vein and two arteries that carry blood between the embryo and placenta. It is severed after birth to free the newly born animal from the placenta, and shrivels to leave a scar, the navel, on the animal.

**umbra** See SHADOW.

**uncertainty principle (Heisenberg uncertainty principle; principle of indeterminism)** The principle that it is not possible to know with unlimited accuracy both the position and momentum of a particle. This principle, discovered in 1927 by Werner Heisenberg, is usually stated in the form:  $\Delta x \Delta p_x \geq \hbar/4\pi$ , where  $\Delta x$  is the uncertainty in the  $x$ -coordinate of the particle,  $\Delta p_x$  is the uncertainty in the  $x$ -component of the particle's momentum, and  $\hbar$  is the \*Planck constant. An explanation of the uncertainty is that in order to locate a particle exactly, an observer must be able to bounce off it a photon of radiation; this act of location itself alters the position of the particle in an unpredictable way. To locate the position accurately, photons of short wavelength would have to be used. These would have associated large momenta and cause a large effect on the position. On the other hand, using long-wavelength photons would have less effect on the particle's position, but would be less accurate because of the longer wavelength. The principle has had a profound effect on scientific thought as it appears to upset the classical relationship between cause and effect at the atomic level.

**underdamped** See DAMPING.

**undernourishment** See MALNUTRITION.

**undulipodium** (*pl.* undulipodia) A slender flexible outgrowth of a eukaryote cell used for locomotion or propelling fluids over the surface of the cell. The term 'undulipodium' is used to designate a eukaryotic 'flagellum' or a \*cilium (which have the same structure), to emphasize the distinction between these structures and the \*flagellum of a bacterium. Many protists and sperm cells swim by means of undulipodia, and various organisms use them to establish feeding currents, or to clear debris from epithelial surfaces. All undulipodia have a shaft, about 0.25  $\mu\text{m}$  in diameter, consisting of a longitudinal array of \*microtubules, the **axoneme**, which is surrounded by an extension of the cell's plasma membrane. The axoneme has two single microtubules running down the middle surrounded by nine pairs of microtubules. At its base the axoneme connects with a **basal body** (or **kinetosome**), which organizes assembly of the axoneme microtubules. Cilia are shorter than flagella and move by a whip-like power stroke followed by a recovery stroke in the opposite direction. Flagella generate successive waves that pass from the base to the tip. In both cases, flexing of the shaft is produced by a sliding motion of the microtubule pairs relative to each other. This involves the successive formation and breakage of molecular bridges between adjacent pairs. The bridges are composed of a protein, dynein, and their formation requires energy in the form of ATP.

**ungulate** A herbivorous mammal with hoofed feet (see UNGULIGRADE). Ungulates are grouped into two orders: \*Artiodactyla and \*Perissodactyla.

**unguligrade** Describing the gait of ungulates (e.g. horses and cows), in which only the tips of the digits (i.e. the hooves) are on the ground and the rest of the foot is off the ground. Compare DIGITIGRADE; PLANTIGRADE.

**uniaxial crystal** A double-refracting crystal (see DOUBLE REFRACTION) having only one \*optic axis.

**unicellular** Describing tissues, organs, or organisms consisting of a single cell.

For example, the reproductive organs of some algae and fungi are unicellular. Unicellular organisms include bacteria, protozoans, and certain algae. Compare ACELLULAR; MULTICELLULAR.

**unified-field theory** A comprehensive theory that would relate the electromagnetic, gravitational, strong, and weak interactions (see FUNDAMENTAL INTERACTIONS) in one set of equations. In its original context the expression referred only to the unification of general \*relativity and classical electromagnetic theory. No such theory has yet been found but some progress has been made in the unification of the electromagnetic and weak interactions (see ELECTROWEAK THEORY).

Einstein attempted to derive \*quantum mechanics from unified-field theory, but it is now thought that any unified-field theory has to start with quantum mechanics. Attempts to construct unified-field theories, such as \*supergravity and \*Kaluza-Klein theory, have run into great difficulties. At the present time it is not clear whether the framework of relativistic \*quantum field theory is adequate to give a unified theory for all the known fundamental interactions and elementary particles, or whether one has to go to extended objects, such as superstrings or supermembranes. Unified-field theories and other fundamental theories, such as \*superstring theory and \*supermembrane theory, are of great importance in understanding cosmology, particularly the \*early universe. In turn cosmology puts constraints on unified-field theories. See also GRAND UNIFIED THEORY.

**unimolecular reaction** A chemical reaction or step involving only one molecule. An example is the decomposition of dinitrogen tetroxide:

Molecules colliding with other molecules acquire sufficient activation energy to react, and the activated complex only involves the atoms of a single molecule.

**union** See SETS.

**unisexual** Describing animals or plants with either male or female reproductive organs but not both. Most of the more ad-

vanced animals are unisexual but plants are often \*hermaphrodite. Flowers that contain either stamens or carpels but not both are also described as unisexual. *See also* MONOECIOUS; DIOECIOUS.

**unit** A specified measure of a physical quantity, such as length, mass, time, etc., specified multiples of which are used to express magnitudes of that physical quantity. For many scientific purposes previous systems of units have now been replaced by \*SI units.

**unit cell** The group of particles (atoms, ions, or molecules) in a crystal that is repeated in three dimensions in the \*crystal lattice. *See also* CRYSTAL SYSTEM.

**unit magnetic pole** *See* MAGNETIC POLES.

**unit vector** A vector that has the magnitude 1. If **a** is any non-zero vector the unit vector in the direction of **a** is given by  $\mathbf{a}/|\mathbf{a}|$  and is denoted  $\hat{\mathbf{a}}$ .

**univalent (monovalent)** Having a valency of one.

**universal constants** *See* FUNDAMENTAL CONSTANTS.

**universal indicator** A mixture of acid-base \*indicators that changes colour (e.g. red-yellow-orange-green-blue) over a range of pH.

**universality** *See* PHASE TRANSITION.

**universal motor** *See* ELECTRIC MOTOR.

**universe** All the matter, energy, and space that exists. *See* COSMOLOGY; EARLY UNIVERSE; HEAT DEATH OF THE UNIVERSE.

**UNIX** A general-purpose \*computer operating system that allows several users, at different terminals, to use the machine at the same time. It was developed in 1969 and became generally available in 1971.

**unnil-** *See* TRANSACTINIDE ELEMENTS.

**Unruh effect** The phenomenon, predicted in 1976 by William Unruh, that an accelerating body would seem to be surrounded by particles at a non-zero temperature, which is proportional to the acceleration. The vacuum state of a non-accelerating observer is different to that of an accelerating observer because of distortion of the zero-point fluctuations.

There is **Unruh radiation** associated with this effect. The effect itself is very small and has not been verified experimentally.

**unsaturated 1.** (of a compound) Having double or triple bonds in its molecules. Unsaturated compounds can undergo addition reactions as well as substitution. *Compare* SATURATED. **2.** (of a solution) *See* SATURATED.

**unstable equilibrium** *See* EQUILIBRIUM.

**upper atmosphere** The upper part of the \*earth's atmosphere above about 30 km. This is the part of the atmosphere that cannot be reached by balloons.

**upthrust** *See* ARCHIMEDES' PRINCIPLE.

**UPVC** Unplasticized PVC: a tough hardwearing form of PVC used for window frames and similar applications.

**upwelling** In the oceans and some inland seas, the process by which colder water, often rich in nutrients, is brought up from a lower depth to the surface layers. Coastal upwelling occurs where persistent surface winds blow parallel to the coastline, with the coast to the left of the wind in the northern hemisphere and to the right in the southern hemisphere. The warmer surface water is deflected away from the coast and colder water rises to replace it. Regions of coastal upwelling often support important fisheries and birdlife, e.g. off the coasts of California, Peru, and Ghana. Equatorial upwelling occurs in the Atlantic and Pacific Oceans along the equator as a result of the effects of the trade winds.

**uracil** A \*pyrimidine derivative and one of the major component bases of \*nucleotides and the nucleic acid \*RNA.

**uraninite** A mineral form of uranium(IV) oxide, containing minute amounts of radium, thorium, polonium, lead, and helium. When uraninite occurs in a massive form with a pitchy lustre it is known as **pitchblende**, the chief ore of uranium. Uraninite occurs in Saxony (east central Germany), Romania, Norway, the UK (Cornwall), E Africa (Congo), USA, and Canada (Great Bear Lake).

**uranium** Symbol U. A white radioactive metallic element belonging to the \*acti-

noids; a.n. 92; r.a.m. 238.03; r.d. 19.05 (20°C); m.p. 1132±1°C; b.p. 3818°C. It occurs as \*uraninite, from which the metal is extracted by an ion-exchange process. Three isotopes are found in nature: uranium-238 (99.28%), uranium-235 (0.71%), and uranium-234 (0.006%). As uranium-235 undergoes \*nuclear fission with slow neutrons it is the fuel used in \*nuclear reactors and \*nuclear weapons; uranium has therefore assumed enormous technical and political importance since their invention. It was discovered by Martin Klaproth (1743-1817) in 1789.

**uranium(VI) fluoride (uranium hexafluoride)** A volatile white solid, UF<sub>6</sub>; r.d. 4.68; m.p. 64.5°C. It is used in the separation of uranium isotopes by gas diffusion.

**uranium hexafluoride** See URANIUM(VI) FLUORIDE.

**uranium-lead dating** A group of \*dating techniques for certain rocks that depends on the decay of the radioisotopes uranium-238 to lead-206 (half-life  $4.5 \times 10^9$  years) or the decay of uranium-235 to lead-207 (half-life  $7.1 \times 10^8$  years). One form of uranium-lead dating depends on measuring the ratio of the amount of helium trapped in the rock to the amount of uranium present (since the decay  $^{238}\text{U} \rightarrow ^{206}\text{Pb}$  releases eight alpha particles). Another method of calculating the age of the rocks is to measure the ratio of radiogenic lead ( $^{206}\text{Pb}$ ,  $^{207}\text{Pb}$ , and  $^{208}\text{Pb}$ ) present to nonradiogenic lead ( $^{204}\text{Pb}$ ). These methods give reliable results for ages of the order  $10^7$ - $10^9$  years.

**uranium(IV) oxide** A black solid, UO<sub>2</sub>; r.d. 10.96; m.p. 2500°C. It occurs naturally as \*uraninite and is used in nuclear reactors.

**uranium series** See RADIOACTIVE SERIES.

**Uranus** A planet having its orbit between Saturn and Neptune. Its mean distance from the sun is  $2870.97 \times 10^6$  km and its mean diameter is 51 118 km; it has a \*sidereal period of 83.75 years. The equator of Uranus is tilted at 98° with respect to its orbit, so that each pole is almost facing the sun during part of each orbit. The temperature of Uranus is very low, about 35 K, and its atmosphere is thought to contain methane and hydro-

gen. The planet itself is believed to have an ice mantle some 8000 km thick surrounding a rocky core. The planet has 27 known satellites and a system of about 20 rings, nine of which were discovered in 1977 with the rest being photographed in 1986 by the US Voyager 2 probe.

**urea (carbamide)** A white crystalline solid, CO(NH<sub>2</sub>)<sub>2</sub>; r.d. 1.3; m.p. 135°C. It is soluble in water but insoluble in certain organic solvents. Urea is the major end product of nitrogen excretion in mammals, being synthesized by the \*urea cycle. Urea is synthesized industrially from ammonia and carbon dioxide for use in \*urea-formaldehyde resins and pharmaceuticals, as a source of nonprotein nitrogen for ruminant livestock, and as a nitrogen fertilizer.

**urea cycle (ornithine cycle)** The series of biochemical reactions that converts ammonia, which is highly toxic, and carbon dioxide to the much less toxic \*urea during the excretion of metabolic nitrogen. These reactions take place in the liver in mammals and, to a lesser extent, in some other animals. The urea is ultimately excreted in solution in \*urine.

**urea-formaldehyde resins** Synthetic resins made by copolymerizing urea with formaldehyde (methanal). They are used as adhesives or thermosetting plastics.

**ureter** The duct in vertebrates that conveys urine from the \*kidney to the \*bladder.

**urethane resins (polyurethanes)** Synthetic resins containing the repeating group -NH-CO-O-. There are numerous types made by copolymerizing isocyanate esters with polyhydric alcohols. They have a variety of uses in plastics, paints, and solid foams.

**urethra** The duct in mammals that conveys urine from the \*bladder to be discharged to the outside of the body. In males the urethra passes through the penis and is joined by the \*vas deferens; it therefore also serves as a channel for sperm.

**Urey, Harold Clayton** (1894-1981) US physical chemist, who became a professor at the University of California in 1958. His

best-known work was the discovery of \*deuterium (heavy hydrogen) in 1932, for which he was awarded the 1939 Nobel Prize for physics.

**uric acid** The end product of purine breakdown in most mammals, birds, terrestrial reptiles, and insects and also (except in mammals; see UREA) the major form in which metabolic nitrogen is excreted. Being fairly insoluble, uric acid can be expelled in solid form, which conserves valuable water in arid environments. The accumulation of uric acid in the synovial fluid of joints causes gout.

**uridine** A nucleoside consisting of one uracil molecule linked to a D-ribose sugar molecule. The derived nucleotide uridine diphosphate (UDP) is important in carbohydrate metabolism.

**urinary system** The collection of organs and tissues that perform \*osmoregulation and \*excretion. The mammalian urinary system consists of two \*kidneys each linked to the bladder by a ureter.

**urine** The aqueous fluid formed by the excretory organs of animals for the removal of metabolic waste products. In higher animals, urine is produced by the \*kidneys, stored in the \*bladder, and excreted through the \*urethra or \*cloaca. Apart from water, the major constituents of urine are one or more of the end products of nitrogen metabolism – ammonia, urea, uric acid, and creatinine. It may also contain various inorganic ions, the pigments urochrome and urobilin, amino acids, and purines. Precise composition depends on many factors, especially the habitat of a particular species: aquatic animals produce copious volumes; terrestrial animals need to conserve water and produce much less (about 1.0–1.5 litres per day in humans).

**uriniferous tubule** See NEPHRON.

**URL** See WORLD WIDE WEB.

**USB drive** In general, any storage device that can be attached to a computer through a special type of connection (universal serial bus connection). The term is particularly used for small portable storage devices typically sealed in plastic. Their physical size is reflected in the vari-

ous names for this type of device – **thumb drive**, **pen drive**, **keyring drive**. They have capacities as high as 1 gigabyte and on most modern personal computers they can be recognized as an additional drive without the need for a special driver. Storage devices of this type are increasingly used for backup, data transfer, storage of photographs or MP3 files, etc.

**uterus (womb)** The organ of female mammals in which the embryo develops. Paired in most mammals but single in humans, it is situated between the bladder and rectum and is connected to the \*fallopian tubes and to the \*vagina. The lining (see ENDOMETRIUM) shows cyclical changes (see MENSTRUAL CYCLE; OESTROUS CYCLE) associated with egg production and provides a thick spongy layer in which the fertilized egg becomes embedded. The outer wall of the uterus is thick and muscular; by contracting, it forces the fully grown fetus through the vagina to the outside.

**utriculus (utricle)** A chamber of the \*inner ear from which the \*semicircular canals arise. It bears patches of sensory epithelium concerned with detecting changes in the direction and speed of movement (see MACULA).

**UV** See ULTRAVIOLET RADIATION.

**UV-visible spectroscopy** See ULTRAVIOLET-VISIBLE SPECTROSCOPY.

**vacancy** See CRYSTAL DEFECT.

**vaccination** See IMMUNIZATION.

**vaccine** A liquid preparation of treated disease-producing microorganisms or their products used to stimulate an \*immune response in the body and so confer resistance to the disease (see IMMUNIZATION). Vaccines are administered orally or by injection (**inoculation**). They take the form of dead viruses or bacteria that can still act as antigens, live but weakened microorganisms (see ATTENUATION), specially treated \*toxins, or antigenic extracts of the microorganism.

**vacuole** A space within the cytoplasm of a living \*cell that is filled with air, water or other liquid, sap, or food particles. In plant cells there is usually one large vacuole bounded by a single-layered mem-

brane (**tonoplast** or **vacuole membrane**); animal cells usually have several small vacuoles. *See also* CONTRACTILE VACUOLE.

**vacuum** A space in which there is a low pressure of gas, i.e. relatively few atoms or molecules. A **perfect vacuum** would contain no atoms or molecules, but this is unobtainable as all the materials that surround such a space have a finite \*vapour pressure. In a **soft** (or **low**) **vacuum** the pressure is reduced to about  $10^{-2}$  pascal, whereas a **hard** (or **high**) vacuum has a pressure of  $10^{-2}$ – $10^{-7}$  pascal. Below  $10^{-7}$  pascal is known as an **ultrahigh vacuum**. *See also* VACUUM PUMP.

**vacuum distillation** Distillation under reduced pressure. The depression in the boiling point of the substance distilled means that the temperature is lower, which may prevent the substance from decomposing.

**vacuum pump** A pump used to reduce the gas pressure in a container. The normal laboratory rotary oil-seal pump can maintain a pressure of  $10^{-1}$  Pa. For pressures down to  $10^{-7}$  Pa a \*diffusion pump is required. \*Ion pumps can achieve a pressure of  $10^{-9}$  Pa and a \*cryogenic pump combined with a diffusion pump can reach  $10^{-13}$  Pa.

**vacuum state** The ground state in a relativistic \*quantum field theory. A vacuum state does not mean a state of nothing. Because one is dealing with \*quantum mechanics, the vacuum state has a \*zero-point energy, which gives rise to **vacuum fluctuations**. The existence of vacuum fluctuations has observable consequences in \*quantum electrodynamics.

**vacuum tube** *See* THERMIONIC VALVE.

**vagina** The tube leading from the uterus to the outside. Sperm are deposited in the vagina during copulation and the fully developed fetus is born through it. In a number of mammals the vagina may be sealed when the animal is not sexually receptive and only open during oestrus. Its lining produces mucus, which prevents friction and the entry of infective organisms.

**vagus nerve** The tenth \*cranial nerve: a paired nerve that supplies branches to

many major internal organs. It carries motor nerve fibres to the heart, lungs, and viscera and sensory fibres from the viscera.

**valence** *See* VALENCY.

**valence band** *See* ENERGY BAND.

**valence electron** An electron in one of the outer shells of an atom that takes part in forming chemical bonds.

**valency (valence)** The combining power of an atom or radical, equal to the number of hydrogen atoms that the atom could combine with or displace in a chemical compound (hydrogen has a valency of 1). It is equal to the ionic charge in ionic compounds; for example, in  $\text{Na}_2\text{S}$ , sodium has a valency of 1 ( $\text{Na}^+$ ) and sulphur a valency of 2 ( $\text{S}^{2-}$ ). In covalent compounds it is equal to the number of bonds formed; in  $\text{CO}_2$  oxygen has a valency of 2 and carbon has a valency of 4.

**valine** *See* AMINO ACID.

**valve 1.** (in anatomy) Any of various structures for restricting the flow of a fluid through an aperture or along a tube to one direction. Valves in the heart (*see* BICUSPID VALVE; TRICUSPID VALVE), veins, and lymphatic vessels consist of two or three flaps of tissue (**cusps**) fastened to the walls. The cusps are flattened to the walls to allow the normal passage of blood or lymph, but a reverse flow causes them to block the vessel or aperture, so preventing further backflow. **2.** (in biology)

**a.** Any of the parts that make up a capsule or other dry fruit that sheds its seeds.

**b.** One of the two halves of the cell wall of a diatom. **c.** Either of the two hinged portions of the shell of a bivalve mollusc.

**3.** (in electronics) *See* THERMIONIC VALVE.

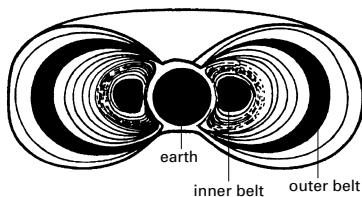

**vanadium** Symbol V. A silvery-white metallic \*transition element; a.n. 23; r.a.m. 50.94; r.d. 5.96; m.p.  $1890^\circ\text{C}$ ; b.p.  $3380^\circ\text{C}$ . It occurs in a number of complex ores, including vanadinite ( $\text{Pb}_5\text{Cl}(\text{VO}_4)_3$ ) and carnotite ( $\text{K}_2(\text{ClO}_2)_2(\text{VO}_4)_2$ ). The pure metal can be obtained by reducing the oxide with calcium. The element is used in a large number of alloy steels. Chemically, it reacts with nonmetals at high temperatures but is not affected by hydrochloric acid or alkalis. It forms a range of

complexes with oxidation states from +2 to +5. Vanadium was discovered in 1801 by Andrés del Río (1764–1849), who allowed himself to be persuaded that what he had discovered was an impure form of chromium. The element was rediscovered and named by Nils Sefström (1787–1854) in 1830.

**vanadium(V) oxide (vanadium pentoxide)** A crystalline compound,  $V_2O_5$ , used extensively as a catalyst in industrial gas-phase oxidation processes.

**vanadium pentoxide** See VANADIUM(V) OXIDE.

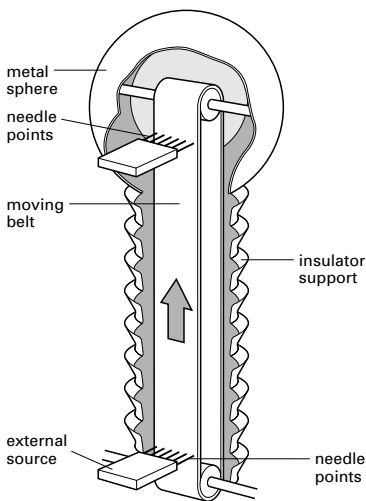

**Van Allen belts (radiation belts)** Belts that are sources of intense radiation surrounding the earth, consisting of high-energy charged particles trapped in the earth's magnetic field within which they follow roughly helical paths. They were discovered in 1958 by James Van Allen (1914– ) as a result of radiation detectors carried by Explorer satellites. The lower belt, extending from 1000 to 5000 km above the equator, contains electrons and protons, while the upper belt, 15 000–25 000 km above the equator, contains mainly electrons (see illustration).

Van Allen belts

**Van de Graaff accelerator** See LINEAR ACCELERATOR.

**Van de Graaff generator** An electrostatic generator used to produce a high voltage, usually in the megavolt range. It consists of a large metal dome-shaped terminal mounted on a hollow insulating support. An endless insulating belt runs through the support from the base to a pulley within the spherical terminal. In the original type, charge is sprayed by point discharge from metal needles, held at a potential of about 10 kV, on to the

Van de Graaff generator

bottom of the belt. A row of needles near the upper belt pulley removes the charge from the belt and passes it to the outer surface of the spherical terminal. The voltage achieved by the device is proportional to the radius of the spherical terminal. A typical device with a terminal having a radius of 1 m will produce about 1 MV. However, terminals can be made smaller, for a given voltage, by enclosing the apparatus in nitrogen at a pressure of 10–20 atmospheres (1–2 MPa) to reduce sparking. Generators having a positive-ion source are fitted with an evacuated tube through which the particles can be accelerated for research purposes (see LINEAR ACCELERATOR). Machines having an electron source are used for various medical and industrial purposes. The generator was invented by Robert Van de Graaff (1901–67).

Modern patterns of the generator have a chainlike belt of alternate links of metal and insulator. The metal links are charged by contact with a metal pulley, and discharge to the dome in the same way. This permits much higher current drain than the point discharge.

**van der Waals' equation** See EQUATION OF STATE.

**van der Waals' force** An attractive force between atoms or molecules, named after Johannes van der Waals (1837–1923). The force accounts for the term  $a/V^2$  in the van der Waals equation (see EQUATION OF STATE). These forces are much weaker than those arising from valence bonds and are inversely proportional to the seventh power of the distance between the atoms or molecules. They are the forces responsible for nonideal behaviour of gases and for the lattice energy of molecular crystals. There are three factors causing such forces: (1) dipole–dipole interaction, i.e. electrostatic attractions between two molecules with permanent dipole moments; (2) dipole-induced dipole interactions, in which the dipole of one molecule polarizes a neighbouring molecule; (3) dispersion forces arising because of small instantaneous dipoles in atoms.

**vanillin (4-hydroxy-3-methoxybenzaldehyde)** A white crystalline solid,  $C_8H_8O_3$ , m.p. 82°C. It has the characteristic taste and smell of vanilla, in which it occurs; it is also made from the by-products of wood pulp manufacture. It is widely used in flavourings and perfumes, and in some pharmaceutical products.

**van't Hoff factor** Symbol  $i$ . A factor appearing in equations for \*colligative properties, equal to the ratio of the number of actual particles present to the number of undissociated particles. It was first suggested by Jacobus van't Hoff (1852–1911).

**van't Hoff's isochore** An equation for the variation of equilibrium constant with temperature:

$$(d \log_e K)/dT = \Delta H/RT^2,$$

where  $K$  is the equilibrium constant,  $R$  is the gas constant,  $T$  is the thermodynamic temperature, and  $\Delta H$  the enthalpy of the reaction.

**vapour density** The density of a gas or vapour relative to hydrogen, oxygen, or air. Taking hydrogen as the reference substance, the vapour density is the ratio of the mass of a particular volume of a gas to the mass of an equal volume of hydrogen under identical conditions of pressure and temperature. Taking the density of hydrogen as 1, this ratio is equal to half the relative molecular mass of the gas.

**vapour pressure** The pressure exerted by a vapour. All solids and liquids give off vapours, consisting of atoms or molecules of the substances that have evaporated from the condensed forms. These atoms or molecules exert a vapour pressure. If the substance is in an enclosed space, the vapour pressure will reach an equilibrium value that depends only on the nature of the substance and the temperature. This equilibrium value occurs when there is a dynamic equilibrium between the atoms or molecules escaping from the liquid or solid and those that strike the surface of the liquid or solid and return to it. The vapour is then said to be a **saturated vapour** and the pressure it exerts is the **saturated vapour pressure**.

**variable star** Any star that varies in brightness. There are various types, depending on the cause of the variation. Some, such as eclipsing \*binary stars, are actually a pair of stars whose combined light output varies as one star passes in front (or behind) the other. Intrinsic variables are caused by some internal phenomenon. The brightness of \*Cepheid variables, \*Mira-type variables, and \*RR Lyrae variables alternates regularly (with timescales from hours to years); \*flare stars and \*T Tauri stars vary irregularly. Other irregular variable stars, sometimes called cataclysmic variables, include \*novae and \*supernovae.

**variance** In \*statistics, the square of the \*standard deviation, usually written  $\sigma^2$ . It represents the dispersion of a random variable's distribution, equal to  $E[(X - E(X))^2]$ , where  $X$  is the random variable and  $E$  is the expected value of the square of the difference between the variable and its mean (see AVERAGE). See also COVARIANCE.

**variation 1.** (in biology) The differences between individuals of a plant or animal species. Variation may be the result of environmental conditions; for example, water supply and light intensity affect the height and leaf size of a plant. Differences of this kind, acquired during the lifetime of an individual, are not transmitted to succeeding generations since the genes are not affected. **Genetic variation**, due to differences in genetic constitution, is in-

herited (see CONTINUOUS VARIATION; DISCONTINUOUS VARIATION). The most important sources of genetic variation are \*mutation and \*recombination (see also CROSSING OVER). It is also increased by \*outbreeding. Wide genetic variation improves the ability of a species to survive in a changing environment, since the chances that some individuals will tolerate a particular change are increased. Such individuals will survive and transmit the advantageous genes to their offspring. **2.** (in magnetism) See GEOMAGNETISM.

**variegation** The occurrence of differently coloured patches, spots, or streaks in plant leaves, petals, or other parts, due to absence of pigment or different combinations of pigment in the affected area of the part. Variegation may be brought about by infection, for example \*tobacco mosaic virus infection, or by genetic differences between the cells of the variegated part.

**variety** A category used in the \*classification of plants and animals below the \*species level. A variety consists of a group of individuals that differ distinctly from but can interbreed with other varieties of the same species. The characteristics of a variety are genetically inherited. Examples of varieties include breeds of domestic animals and the human \*races. See also CULTIVAR. Compare SUBSPECIES.

**variometer 1.** A variable inductor consisting of two coils connected in series and able to move relative to each other. It is used to measure inductance as part of an a.c. bridge. **2.** Any of several devices for detecting and measuring changes in the geomagnetic elements (see GEOMAGNETISM).

**varve dating (geochronology)** An absolute \*dating technique using thin sedimentary layers of clays called **varves**. The varves, which are particularly common in Scandinavia, have alternate light and dark bands corresponding to winter and summer deposition. Most of them are found in the Pleistocene series, where the edges of varve deposits can be correlated with the annual retreat of the ice sheet, although some varve formation is taking place in the present day. By counting varves it is possible to establish an abso-

lute time scale for fossils up to about 20 000 years ago.

**vascular bundle (fascicle)** A long continuous strand of conducting (vascular) tissue in tracheophyte plants that extends from the roots through the stem and into the leaves. It consists of \*xylem and \*phloem, which are separated by a \*cambium in plants that undergo secondary thickening. See VASCULAR TISSUE.

**vascular cambium** See CAMBIUM.

**vascular plants** All plants possessing organized \*vascular tissue. See TRACHEOPHYTE.

**vascular system 1.** A specialized network of vessels for the circulation of fluids throughout the body tissues of an animal. All animals, apart from simple invertebrate groups, possess a **blood vascular system**, which enables the passage of respiratory gases, nutrients, excretory products, and other metabolites into and out of the cells. In vertebrates it consists of a muscular \*heart, which pumps blood through major blood vessels (\*arteries) into increasingly finer branches until in the \*capillaries it is in intimate contact with tissues. It then returns to the heart via another network of vessels (the \*veins). This \*circulation also enables a stable \*internal environment for tissue function (see HOMEOSTASIS), the transmission of chemical messengers (\*hormones) around the body, and a means of defending the body against pathogens and damage via the immune system. A **water vascular system** is characteristic of the \*Echinodermata. **2.** The system of \*vascular tissue in plants.

**vascular tissue (vascular system)** The tissue that conducts water and nutrients through the plant body in higher plants (\*tracheophytes). It consists of \*xylem and \*phloem. Since the xylem and phloem tissues are always in close proximity to each other, distinct regions of vascular tissue can be identified (see VASCULAR BUNDLE). The possession of vascular tissue has enabled the higher plants to attain a considerable size and dominate most terrestrial habitats.

**vas deferens** One of a pair of ducts carrying sperm from the testis (or \*epi-

didymis) to the outside, in mammals through the \*urethra.

**vas efferens** Any of various small ducts carrying sperm. In reptiles, birds, and mammals they convey sperm from the seminiferous tubules of the testis to the \*epididymis; in invertebrates they carry sperm from the testis to the vas deferens.

**vasoactive intestinal peptide** See VIP.

**vasoconstriction** The reduction in the internal diameter of blood vessels, especially arterioles or capillaries. The constriction of arterioles is mediated by the action of nerves on the smooth muscle fibres of the arteriole walls and results in an increase in blood pressure.

**vasodilation (vasodilatation)** The increase in the internal diameter of blood vessels, especially arterioles or capillaries. The vasodilation of arterioles is mediated by the action of nerves on the smooth muscle fibres of the arteriole walls and results in a decrease in blood pressure.

**vasomotor nerves** The nerves of the \*autonomic nervous system that control the diameter of blood vessels. **Vasoconstrictor nerves** decrease the diameter (see VASOCONSTRICTION); **vasodilator nerves** increase it (see VASODILATION).

**vasopressin** See ANTIDIURETIC HORMONE.

**vector 1.** (in mathematics) A quantity in which both the magnitude and the direction must be stated (compare SCALAR QUANTITY). Force, velocity, and field strength are examples of vector quantities. Note that distance and speed are scalar quantities, whereas displacement and velocity are vector quantities. Vector quantities must be treated by **vector algebra**, for example, the resultant of two vectors may be found by a \*parallelogram of vectors. A (three-dimensional) vector  $\mathbf{V}$  may be written in terms of components  $V_1$ ,  $V_2$ , and  $V_3$  along the  $x$ ,  $y$ , and  $z$  axes (say) as  $V_1\mathbf{i} + V_2\mathbf{j} + V_3\mathbf{k}$ , where  $\mathbf{i}$ ,  $\mathbf{j}$ , and  $\mathbf{k}$  are **unit vectors** (i.e. vectors of unit length) along the  $x$ ,  $y$ , and  $z$  axes. See also TRIANGLE OF VECTORS.

**2.** (in medicine) An animal, usually an insect, that passively transmits disease-causing microorganisms from one animal or plant to another or from an animal to a

human. Compare CARRIER. **3. (cloning vector)** (in genetics) A vehicle used in \*gene cloning to insert a foreign DNA fragment into the genome of a host cell. For bacterial hosts various different types of vector are used: \*bacteriophages, \*artificial chromosomes, \*plasmids, and their hybrid derivatives, \*cosmids. The foreign DNA is spliced into the vector using specific \*restriction enzymes and \*ligases to cleave the vector DNA and join the foreign DNA to the two ends created (**insertional vectors**). In some phage vectors, part of the viral genome is enzymically removed and replaced with the foreign DNA (**replacement vectors**). \*Retroviruses can be effective vectors for introducing recombinant DNA into mammalian cells. In plants, derivatives of the tumour-inducing (Ti) plasmid of the crown gall bacterium, \**Agrobacterium tumefaciens*, are used as vectors.

**vector product (cross product)** The product of two \*vectors  $\mathbf{U}$  and  $\mathbf{V}$ , with components  $U_1$ ,  $U_2$ ,  $U_3$  and  $V_1$ ,  $V_2$ ,  $V_3$ , respectively, given by:

$$\mathbf{U} \times \mathbf{V} = (U_2V_3 - U_3V_2)\mathbf{i} + (U_3V_1 - U_1V_3)\mathbf{j} + (U_1V_2 - U_2V_1)\mathbf{k}.$$

It is itself a vector, perpendicular to both  $\mathbf{U}$  and  $\mathbf{V}$ , and of length  $UV\sin\theta$ , where  $U$  and  $V$  are the lengths of  $\mathbf{U}$  and  $\mathbf{V}$ , respectively, and  $\theta$  is the angle between them. Compare SCALAR PRODUCT.

**vector space** A set of \*vectors for which an operation of addition is defined so that if  $\mathbf{v}_1$  and  $\mathbf{v}_2$  are vectors, the sum  $\mathbf{v}_1 + \mathbf{v}_2$  is also a vector; an operation of \*scalar multiplication is defined so that if  $\mathbf{v}$  is a vector and  $c$  is a scalar, the product  $c\mathbf{v}$  is also a vector. See also HILBERT SPACE.

**vector triple product** See TRIPLE PRODUCT.

**vegetative propagation (vegetative reproduction) 1.** A form of \*asexual reproduction in plants whereby new individuals develop from specialized multicellular structures (e.g. \*tubers, \*bulbs) that become detached from the parent plant. Examples are the production of strawberry plants from \*runners and of gladioli from daughter \*corms. Artificial methods of vegetative propagation include grafting (see GRAFT), \*budding, and

making \*cuttings. **2.** Asexual reproduction in animals, e.g. budding in *Hydra*.

**vein 1.** A blood vessel that carries blood towards the heart. Most veins carry deoxygenated blood (the \*pulmonary vein is an exception). The largest veins are fed by smaller ones, which are formed by the merger of \*venules. Veins have thin walls and a relatively large internal diameter. \*Valves within the veins ensure that the flow of blood is always towards the heart. Compare ARTERY. **2.** A vascular bundle in a leaf (see VENATION). **3.** Any of the tubes of chitin that strengthen an insect's wing.

**velamen** A whitish spongy sheath of dead empty cells that surrounds the aerial roots of epiphytic plants, such as certain orchids. It absorbs any surface water on the roots.

**velocity** Symbol *v*. The rate of displacement of a body. It is the \*speed of a body in a specified direction. Velocity is thus a \*vector quantity, whereas speed is a scalar quantity.

**velocity modulation** See KLYSTRON.

**velocity ratio (distance ratio)** The ratio of the distance moved by the point of application effort in a simple \*machine to the distance moved by the point of application load in the same time.

**velum** See ANNULUS.

**vena cava** Either of the two large veins that carry deoxygenated blood into the right atrium of the heart. The **precaval vein (anterior or superior vena cava)** receives blood from the head and forelimbs; the **postcaval vein (posterior or inferior vena cava)** drains blood from the trunk and hindlimbs.

**venation 1.** The arrangement of veins (vascular bundles) in a leaf. The leaves of dicotyledons have a central main vein (midrib) with side branches that themselves further subdivide to form a network (**net or reticulate venation**). The leaves of monocotyledons have parallel veins (**parallel venation**). **2.** The arrangement of the veins in an insect's wing, which is often important in classification.

**Venn diagram** See SETS.

**venter** (in botany) The swollen base of

an \*archegonium, in which the egg cell (oosphere) develops.

**ventilation** The process by which a continuous exchange of gases is maintained across respiratory surfaces. Often called external \*respiration, this is achieved by \*respiratory movements; in air-breathing vertebrates it is movement of air into and out of the lungs (see also AIR SAC; EXPIRATION; INSPIRATION; TRACHEA). The **ventilation rate (or respiration rate)** of an animal is the volume of air breathed per minute, i.e. \*tidal volume  $\times$  number of breaths per minute. It can be measured with the aid of a \*respirometer.

**ventilation centre** The group of neurons in the \*medulla oblongata of the brain that controls the process of \*ventilation. The partial pressure of carbon dioxide in the blood and the pH of the blood are monitored by chemoreceptors in the arteries. These include the \*carotid bodies in the carotid arteries and the **aortic bodies** in the wall of the aorta close to the heart. The ventilation centre responds to an increase in the amount of carbon dioxide in the blood by increasing the rate of breathing. Within the ventilation centre are subcentres that control inspiration (**inspiratory centre**) and expiration (**expiratory centre**).

**ventral** Describing the surface of a plant or animal that is nearest or next to the ground or other support, i.e. the lower surface. In bipedal animals, such as humans, it is the forward-directed (\*anterior) surface. Compare DORSAL.

**ventral root** The part of a \*spinal nerve that leaves the spinal cord on the ventral side and contains motor fibres. Compare DORSAL ROOT. See SPINAL CORD.

**ventricle 1.** A chamber of the \*heart that receives blood from an \*atrium and pumps it into the arterial system. Amphibians and fish have a single ventricle, but mammals, birds, and reptiles have two, pumping deoxygenated blood to the lungs and oxygenated blood to the rest of the body, respectively. **2.** Any of the four linked fluid-filled cavities in the brain of vertebrates. One of these cavities is in the \*medulla oblongata, two are in the cerebral hemispheres (see CEREBRUM), and the

fourth is in the posterior part of the \*fore-brain. The ventricles contain cerebrospinal fluid filtered from the blood by the \*choroid plexus.

**Venturi tube** A device for mixing a fine spray of liquid with a gas or measuring a flow rate of a gas. It consists of two tapered sections of pipe joined by a narrow throat. The fluid velocity in the throat is increased and the pressure is therefore reduced. By attaching manometers to the three sections of the tube, the pressure drop can be measured and the flow rate through the throat can be calculated. In a carburettor, the petrol from the float chamber is made into a fine spray by being drawn through a jet into the low pressure in the throat of a Venturi tube, where it mixes with the air being drawn into the engine. The device was invented by Giovanni Venturi (1746–1822).

**venule** A small blood vessel that receives blood from the capillaries and transports it to a vein.

**Venus** A planet having its orbit between Mercury and the earth. Its mean distance from the sun is  $108.21 \times 10^6$  km and its mean diameter 12 103.6 km. It has a \*sidereal period of 224.46 days. US Mariner and Pioneer spacecraft and Soviet Venera spacecraft have provided a considerable amount of information about the planet. The atmosphere is 98% carbon dioxide and most of the remainder is nitrogen. There is a dense layer of cloud about 20 km thick covering the whole of the planet. This cloud layer consists largely of concentrated sulphuric acid. Some photographs of the surface have been obtained by a Venera spacecraft that functioned for a short time after landing on Venus, but the dim sunlight revealed only the presence of many rocks rounded by wind-blown sand. The high surface temperature of 730 K is a result of the \*greenhouse effect, not proximity to the sun. The atmospheric pressure on the surface of Venus is about 90 times that on earth. Venus is almost unique among the planets in rotating in the opposite direction to the earth's rotation. It also rotates very slowly – with a period of 243 days.

**verdigris** A green patina of basic copper salts formed on copper. The composition

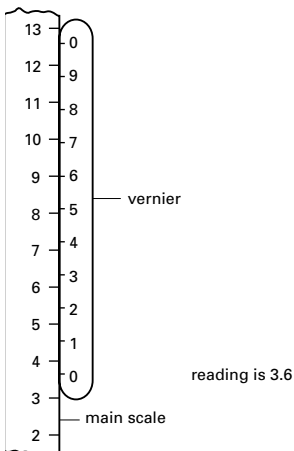

of verdigris varies depending on the atmospheric conditions, but includes the basic carbonate  $\text{CuCO}_3 \cdot \text{Cu}(\text{OH})_2$ , the basic sulphate  $\text{CuSO}_4 \cdot \text{Cu}(\text{OH})_2 \cdot \text{H}_2\text{O}$ , and in some cases the basic chloride  $\text{CuCl}_2 \cdot \text{Cu}(\text{OH})_2$ .

**vermiculite** See CLAY MINERALS.

**vermiform appendix** See APPENDIX.

**vernalization** The promotion of flowering by exposure of a plant to low temperatures. For example, winter cereals will not flower unless subjected to a period of chilling early in their development. Winter cereals are therefore sown in the autumn for flowering the following year. However, if germinating seeds are artificially vernalized they can be sown in the spring for flowering the same year. Some studies have suggested that plant growth substances, including gibberellins and a hypothetical substance called 'vernalin', might be involved in the vernalization mechanism, but no conclusive picture has so far emerged.

**vernier** A short auxiliary scale placed beside the main scale on a measuring instrument to enable subdivisions of the main scale to be read accurately. The vernier scale is usually calibrated so that each of its divisions is 0.9 of the main scale divisions. The zero on the vernier scale is set to the observed measurement

Vernier scale

on the main scale and by noting which division on the vernier scale is exactly in line with a main scale division, the second decimal place of the measurement is obtained (see illustration). The device was invented by Pierre Vernier (1580–1637) in about 1630.

**vertebra** Any of the bones that make up the \*vertebral column. In mammals each vertebra typically consists of a main body, or **centrum**, from which arises a **neural arch** through which the spinal cord passes, and **transverse processes** projecting from the side. In all vertebrates there are five groups of vertebrae, specialized for various functions and varying in number with the species. In humans, for example, there are 7 \*cervical vertebrae, 12 \*thoracic vertebrae, 5 \*lumbar vertebrae, 5 fused \*sacral vertebrae, and 5 fused \*caudal vertebrae (forming the \*coccyx).

**vertebral column (backbone; spinal column; spine)** A flexible bony column in vertebrates that extends down the long axis of the body and provides the main skeletal support. It also encloses and protects the \*spinal cord and provides attachment for the muscles of the back. The vertebral column consists of a series of bones (see VERTEBRA) separated by discs of cartilage (\*intervertebral discs). It articulates with the skull by means of the \*atlas vertebra, with the ribs at the \*thoracic vertebrae, and with the pelvic girdle at the sacrum (see SACRAL VERTEBRAE).

**vertebrate** Any one of a large group of animals comprising all those members of the phylum \*Chordata that have backbones (see VERTEBRAL COLUMN). Vertebrates include the fishes, amphibians, reptiles, birds, and mammals.

**very high frequency (VHF)** A radio frequency in the range  $3 \times 10^8$ – $0.3 \times 10^9$  Hz, i.e. having a wavelength in the range 1–10 m.

**very low frequency (VLF)** A radio frequency in the range  $3 \times 10^4$ – $0.3 \times 10^4$  Hz, i.e. having a wavelength in the range 10–100 km.

**Vesalius, Andreas** (1514–64) Belgian physician and anatomist, who was a professor at Padua for six years before becoming a physician to the Habsburg court. He

is remembered for producing in 1538–43 definitive text and anatomical drawings of the human body, which were made from actual dissections.

**vesicle** A small, usually fluid-filled, membrane-bound sac within the cytoplasm of a living cell. Vesicles occur, for example, as part of the \*Golgi apparatus.

**vessel 1.** (in botany) A tube within the \*xylem composed of joined \*vessel elements. Vessels facilitate the efficient movement of water from the roots to the shoots and leaves of a plant. **2.** (in zoology) Any of various tubular structures through which substances are transported, especially a blood vessel or a lymphatic vessel.

**vessel element** A type of cell occurring within the \*xylem of flowering plants, many of which, end to end, form water-conducting **vessels**. Vessel elements are frequently very broad and have side walls thickened by deposits of lignin over most of the surface area. However, the end walls are broken down to provide connections with the cells both above and below them. *Compare* TRACHEID.

**vestibular apparatus** The part of the inner ear that is responsible for balance. The vestibular apparatus is continuous with the cochlea. It consists of the three \*semicircular canals, which detect movements of the head (see AMPULLA), and the \*utricle and \*sacculus, which detect the position of the head (see MACULA). See EAR.

**vestigial organ** Any part of an organism that has diminished in size during its evolution because the function it served decreased in importance or became totally unnecessary. Examples are the human appendix and the wings of the ostrich.

**vibrio** Any comma-shaped bacterium. Generally, vibrios are Gram-negative (see GRAM'S STAIN), motile, and aerobic. They are widely distributed in soil and water and while most feed on dead organic matter some are parasitic, e.g. *Vibrio cholerae*, the causal agent of cholera.

**vicinal (vic)** Designating a molecule in which two atoms or groups are linked

to adjacent atoms. For example, 1,2-dichloroethane ( $\text{CH}_2\text{ClCH}_2\text{Cl}$ ) is a vicinal (or vic) dihalide and can be named vic-dichloroethane.

**Victor Meyer's method** A method of measuring vapour density, devised by Victor Meyer (1848–97). A weighed sample in a small tube is dropped into a heated bulb with a long neck. The sample vaporizes and displaces air, which is collected over water and the volume measured. The vapour density can then be calculated.

**video recording** The recording of films, television programmes, etc., on magnetic tape. Because the demodulated video (vision) signal can have frequencies in the megahertz range, a video tape cannot be run like a sound tape. Sound has a maximum frequency of 15–20 kHz, which means that using the same system as sound, a video tape would need to run 1000 times faster than a sound tape. As this would be impractical the signal is recorded diagonally on the tape (each diagonal line representing one line of the picture) and the tape is run slowly over a drum on which the recording and reading heads rotate at high speeds. Devices using this mechanism are available for use with domestic television sets and video cameras (camcorders).

**villiaumite** A mineral form of sodium fluoride, NaF.

**villus** A microscopic outgrowth from the surface of some tissues and organs, which serves to increase the surface area of the organ. Numerous villi line the interior of the small intestine. Their shape may vary from finger-like (in the \*duodenum) to spadelike (in the \*ileum). Intestinal villi are specialized for the absorption of soluble food material: each contains blood vessels and a lymph vessel (see LACTEAL).

**Chorionic villi** occur on the chorion of the mammalian placenta, where they increase the surface area for the exchange of materials between the fetal and maternal blood.

**vinyl acetate** See ETHENYL ETHANOATE.

**vinyl chloride** See CHLOROETHENE.

**vinyl group** The organic group  $\text{CH}_2\text{:CH-}$ .

**VIP (vasoactive intestinal peptide)** A peptide hormone secreted by endocrine cells of the upper part of the small intestine in response to the entry of partially digested food from the stomach. VIP, along with \*secretin, stimulates the pancreas to produce a thin watery secretion containing bicarbonate. This raises the pH in the intestine in preparation for secretion of pancreatic enzymes. VIP also inhibits gastric secretion and occurs as a \*neuropeptide in central nervous tissue.

**virial equation** A gas law that attempts to account for the behaviour of real gases, as opposed to an ideal gas. It takes the form

$$pV = RT + Bp + Cp^2 + Dp^3 + \dots$$

where  $B$ ,  $C$ , and  $D$  are known as **virial coefficients**.

**virion** See VIRUS.

**viroid** Any of various small naked single-stranded RNA molecules that infect plant cells and cause disease. Smaller than viruses, viroids are not enclosed in a protein coat of any kind: they generally consist of less than 400 nucleotides and do not contain any genes. The circular RNA strand undergoes extensive base pairing within itself, forming a double-stranded structure that mimics DNA and is apparently replicated by the host cell's enzymes. This behaviour is similar to that of certain \*introns, prompting the suggestion that viroids are escaped introns. Viroids include many commercially important disease agents, such as coconut cadang-cadang, citrus exocortis, and potato spindle tuber viroid.

**virology** The scientific study of \*viruses. See MICROBIOLOGY.

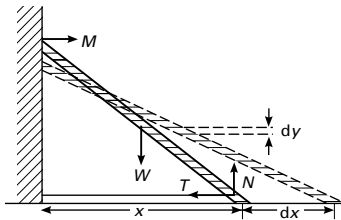

**virtual image** See IMAGE.

**virtual reality** A form of computer simulation in which the user has the impression of being in an artificial environment. Typically, the user wears a visor into which are built two small screens, one for each eye, giving a three-dimensional view of a computer-generated environment. Sensors in the visor detect head movements and cause the perspective of the scene to change. It is also possible to wear special gloves (known as 'datagloves') con-

taining sensors. These allow the user to move objects in the environment by making hand movements. Virtual-reality systems are used for training purposes as well as for entertainment.

**virtual state** The state of the **virtual particles** that are exchanged between two interacting charged particles. These particles, called \*photons, are not in the real state, i.e. directly observable; they are constructs to enable the phenomenon to be explained in terms of \*quantum mechanics.

**virtual work** The imaginary work done when a system is subjected to infinitesimal hypothetical displacements. According to the **principle of virtual work**, the total work done by all the forces acting on a system in equilibrium is zero. This principle can be used to determine the forces acting on a system in equilibrium. For example, the illustration shows a ladder leaning against a wall, with the bottom of the ladder attached to the wall by a horizontal weightless string. The tension,  $T$ , in the string can be calculated by assuming that infinitesimal movement  $dx$  and  $dy$  take place as shown. Then by applying the principle of virtual work,  $Tdx + Wdy = 0$ . As  $dx$  and  $dy$  can be calculated from the geometry,  $T$  can be found.

Virtual work

**virulence** The disease-producing ability of a microorganism. *See also* PATHOGEN.

**virus 1.** (in microbiology) A particle that is too small to be seen with a light microscope or to be trapped by filters but is capable of independent metabolism and reproduction within a living cell. Outside its host cell a virus is completely inert. A mature virus (a **virion**) ranges in size from 20 to 400 nm in diameter. It consists of a

core of nucleic acid (DNA or RNA) surrounded by a protein coat (**capsid**). Some bear an outer envelope (**enveloped viruses**). Inside its host cell the virus initiates the synthesis of viral proteins and undergoes replication. The new virions are released when the host cell disintegrates. Viruses are parasites of animals, plants, and some bacteria (*see* BACTERIOPHAGE). Viral diseases of animals include the common cold, influenza, smallpox, AIDS, herpes, hepatitis, polio, and rabies (*see* ADENOVIRUS; ARBOVIRUS; HERPESVIRUS; HIV; MYXOVIRUS; PAPOVAVIRUS; PICORNAVIRUS; POXVIRUS); some viruses are also implicated in the development of cancer (*see* RETROVIRUS). Plant viral diseases include various forms of yellowing and blistering of leaves and stems (*see* TOBACCO MOSAIC VIRUS). \*Antiviral drugs are effective against certain viral diseases and \*vaccines (if available) provide protection against others.

**2.** (in computing) A computer program that can replicate itself and be transferred from one computer to another without the user being aware of it. Viruses are often designed to destroy or damage the data on the user's computer. They generally spread by exchange of floppy disks or by telephone links.

**visceral** Relating to the internal organs (the **viscera**) that lie in the coelomic cavities of animals, i.e. in the thoracic and abdominal cavities of mammals. *Compare* SOMATIC.

**viscometer** An instrument for measuring the viscosity of a fluid. In the **Ostwald viscometer**, used for liquids, a bulb in a capillary tube is filled with the liquid and the time taken for the meniscus to reach a mark on the capillary, below the bulb, is a measure of the viscosity. The **falling-sphere viscometer**, based on \*Stokes' law, enables the speed of fall of a ball falling through a sample of the fluid to be measured. Various other devices are used to measure viscosity.

**viscose** Cellulose xanthate, the sticky brown liquid formed by adding carbon disulphide and sodium hydroxide to cellulose from wood pulp. It is forced through spinnarets into an acid bath, which re-

forms cellulose fibres as rayon (artificial silk).

**viscose process** See RAYON.

**viscosity** A measure of the resistance to flow that a fluid offers when it is subjected to shear stress. For a \*Newtonian fluid, the force,  $F$ , needed to maintain a velocity gradient,  $dv/dx$ , between adjacent planes of a fluid of area  $A$  is given by:  $F = \eta A(dv/dx)$ , where  $\eta$  is a constant, the coefficient of viscosity. In \*SI units it has the unit pascal second (in the c.g.s. system it is measured in \*poise). Non-Newtonian fluids, such as clays, do not conform to this simple model. See also KINEMATIC VISCOSITY.

**visible spectrum** The \*spectrum of electromagnetic radiations to which the human eye is sensitive. See COLOUR.

**vision** The sense that enables perception of objects in the environment by means of the \*eyes.

**visual acuity** Sharpness of vision: the ability of the eye to distinguish between objects that lie close together. This hinges on the ability of the eye to focus incoming light to form a sharp image on the retina. Visual acuity depends on the \*cone cells, which are most densely packed in the \*fovea, close to the centre of the retina, and are therefore in the optimum position to receive focused light. In addition, each cone cell synapses with a single nerve cell and is thus able to send a separate signal, via the optic nerve fibres, to the brain.

**visual binary** See BINARY STARS.

**visual-display unit (VDU)** The part of a \*computer system or word processor on which text or diagrams are displayed. It consists of a \*cathode-ray tube and usually has its own input keyboard attached.

**visual purple** See RHODOPSIN.

**vital capacity** The total amount of air that can be exhaled after maximum inspiration. The vital capacity of an average human is about 4.5 litres; in trained male athletes it can be 6 litres or more. However, some air always remains in the lungs (see RESIDUAL VOLUME).

**vital staining** A technique in which a

harmless dye is used to stain living tissue for microscopical observation. The stain may be injected into a living animal and the stained tissue removed and examined (**intravital staining**) or the living tissue may be removed directly and subsequently stained (**supravital staining**). Microscopic organisms, such as protozoa, may be completely immersed in the dye solution. Vital stains include trypan blue, vital red, and Janus green, the latter being especially suitable for observing mitochondria.

**vitamin** One of a number of organic compounds required by living organisms in relatively small amounts to maintain normal health. There are some 14 generally recognized major vitamins: the water-soluble \*vitamin B complex (containing 9) and \*vitamin C and the fat-soluble \*vitamin A, \*vitamin D, \*vitamin E, and \*vitamin K. Most B vitamins and vitamin C occur in plants, animals, and microorganisms; they function typically as \*coenzymes. Vitamins A, D, E, and K occur only in animals, especially vertebrates, and perform a variety of metabolic roles. Animals are unable to manufacture many vitamins themselves and must have adequate amounts in the diet. Foods may contain vitamin precursors (called **provitamins**) that are chemically changed to the actual vitamin on entering the body. Many vitamins are destroyed by light and heat, e.g. during cooking. See Chronology.

**vitamin A (retinol)** A fat-soluble vitamin that cannot be synthesized by mammals and other vertebrates and must be provided in the diet. Green plants contain precursors of the vitamin, notably carotenes, that are converted to vitamin A in the intestinal wall and liver. The aldehyde derivative of vitamin A, **retinal**, is a constituent of the visual pigment \*rhodopsin. Deficiency affects the eyes, causing night blindness, xerophthalmia, and eventually total blindness. The role of vitamin A in other aspects of metabolism is less clear; it may be involved in controlling \*ATP production and the growth of epithelial cells.

**vitamin B complex** A group of water-soluble vitamins that characteristically

**VITAMINS**

- 1897 Dutch physician Christiaan Eijkman (1858–1930) cures beriberi in chickens with diet of whole rice.
- 1906–07 British biochemist Sir Frederick Hopkins demonstrates existence of accessory dietary elements essential for growth.
- 1912 Polish-born US biochemist Casimir Funk (1884–1967) extracts antiberiberi factor (an amine) from rice husks and coins the term 'vitamine' (vital amine; later changed to 'vitamin').
- 1913 US biochemist Elmer McCollum (1879–1967) discovers and names vitamin A (retinol) and names antiberiberi factor vitamin B.
- 1920 McCollum names antirachitic factor vitamin D.
- 1922 US embryologist Herbert Evans (1882–1971) discovers vitamin E (tocopherol).
- 1926 German chemist Adolf Windaus (1876–1959) discovers that ergosterol is converted to vitamin D in the presence of sunlight.
- 1931 German chemist Paul Karrer (1889–1971) determines the structure of (and synthesizes) vitamin A.
- 1932 Hungarian-born US biochemist Albert Szent-Györgyi (1893–1986) and US biochemist Charles King (1896–1986) independently isolate vitamin C (ascorbic acid).
- 1933 Polish-born Swiss chemist Tadeus Reichstein (1897–1996) and British chemist Walter Haworth (1883–1950) independently synthesize vitamin C.  
US chemist Roger Williams (1893–1988) discovers the B vitamin pantothenic acid.
- 1934 Danish biochemist Carl Dam (1895–1976) discovers vitamin K.
- 1935 Karrer and Austrian-born German chemist Richard Kuhn (1900–67) independently synthesize vitamin B<sub>2</sub> (riboflavin).
- 1937 US chemist Robert Williams (1886–1965) synthesizes vitamin B<sub>1</sub> (thamin).
- 1938 Karrer synthesizes vitamin E.  
Kuhn isolates and synthesizes vitamin B<sub>6</sub> (pyridoxine).
- 1939 Dam and Karrer isolate vitamin K.
- 1940 Szent-Györgyi and US biochemist Vincent Du Vigneaud (1901–78) discover 'vitamin H' (the B vitamin biotin).  
Roger Williams determines the structure of pantothenic acid.  
US biochemist Edward Doisey synthesizes vitamin K.
- 1948 US biochemist Karl Folkers (1906– ) isolates vitamin B<sub>12</sub> (cyanocobalamin).
- 1956 British chemist Dorothy Hodgkin (1910–94) determines the structure of vitamin B<sub>12</sub>.
- 1971 US chemist Robert Woodward (1917–79) and Swiss chemist Albert Eschenmoser (1925– ) synthesize vitamin B<sub>12</sub>.

serve as components of \*coenzymes. Plants and many microorganisms can manufacture B vitamins but dietary sources are essential for most animals. Heat and light tend to destroy B vitamins.

**Vitamin B<sub>1</sub> (thiamine(e))** is a precursor of the coenzyme thiamine pyrophosphate, which functions in carbohydrate metabolism. Deficiency leads to \*beriberi in humans and to polyneuritis in birds. Good sources include brewer's yeast, wheatgerm, beans, peas, and green vegetables.

**Vitamin B<sub>2</sub> (riboflavin)** occurs in green vegetables, yeast, liver, and milk. It is a constituent of the coenzymes \*FAD and FMN, which have an important role in the metabolism of all major nutrients as well as in the oxidative phosphorylation reactions of the \*electron transport chain. Deficiency of B<sub>2</sub> causes inflammation of the tongue and lips and mouth sores.

**Vitamin B<sub>6</sub> (pyridoxine)** is widely distributed in cereal grains, yeast, liver, milk, etc. It is a constituent of a coenzyme (pyridoxal phosphate) involved in amino acid metabolism. Deficiency causes retarded growth, dermatitis, convulsions, and other symptoms.

**Vitamin B<sub>12</sub> (cyanocobalamin or cobalamin)** is manufactured only by microorganisms and natural sources are entirely of animal origin. Liver is especially rich in it. One form of B<sub>12</sub> functions as a coenzyme in a number of reactions, including the oxidation of fatty acids and the synthesis of DNA. It also works in conjunction with \*folic acid (another B vitamin) in the synthesis of the amino acid methionine and it is required for normal production of red blood cells. Vitamin B<sub>12</sub> can only be absorbed from the gut in the presence of a glycoprotein called **intrinsic factor**; lack of this factor or deficiency of B<sub>12</sub> results in pernicious anaemia.

Other vitamins in the B complex include \*nicotinic acid, \*pantothenic acid, \*biotin, and \*lipoic acid. *See also* CHOLINE; INOSITOL.

**vitamin C (ascorbic acid)** A colourless crystalline water-soluble vitamin found especially in citrus fruits and green vegetables. Most organisms synthesize it from glucose, but humans and other primates and various other species must obtain it

from their diet. It is required for the maintenance of healthy connective tissue; deficiency leads to \*scurvy. Vitamin C is readily destroyed by heat and light.

**vitamin D** A fat-soluble vitamin occurring in the form of two steroid derivatives: **vitamin D<sub>2</sub> (ergocalciferol or calciferol)**, found in yeast; and **vitamin D<sub>3</sub> (cholecalciferol)**, which occurs in animals. Vitamin D<sub>2</sub> is formed from a steroid by the action of ultraviolet light and D<sub>3</sub> is produced by the action of sunlight on a cholesterol derivative in the skin. Fish-liver oils are the major dietary source. The active form of vitamin D is manufactured in response to the secretion of \*parathyroid hormone, which occurs when blood calcium levels are low. It causes increased uptake of calcium from the gut, which increases the supply of calcium for bone synthesis. Vitamin D deficiency causes \*rickets in growing animals and osteomalacia in mature animals. Both conditions are characterized by weak deformed bones.

**vitamin E (tocopherol)** A fat-soluble vitamin consisting of several closely related compounds, deficiency of which leads to a range of disorders in different species, including muscular dystrophy, liver damage, and infertility. Good sources are cereal grains and green vegetables. Vitamin E prevents the oxidation of unsaturated fatty acids in cell membranes, so maintaining their structure.

**vitamin K** A fat-soluble vitamin consisting of several related compounds that act as coenzymes in the synthesis of several proteins (including prothrombin) necessary for blood clotting. Deficiency of vitamin K, which leads to extensive bleeding, is rare because a form of the vitamin is manufactured by intestinal bacteria. Green vegetables and egg yolk are good sources.

**vitelline membrane** *See* EGG MEMBRANE.

**vitreous** Having a glasslike appearance or structure.

**vitreous humour** The colourless jelly that fills the space between the lens and the retina of the vertebrate eye.

**vitriol (oil of vitriol)** An old name for sulphuric acid. As a result, hydrated iron(II) (ferrous) sulphate was known as **green vitriol**, and hydrated copper(II) (cupric) sulphate as **blue vitriol**.

**viviparity 1.** (in zoology) A form of reproduction in animals in which the developing embryo obtains its nourishment directly from the mother via a \*placenta or by other means. Viviparity occurs in some insects and other arthropods, in certain fishes, amphibians, and reptiles, and in the majority of mammals. *Compare* OVIPARITY; OVOVIPARITY. **2.** (in botany) **a.** A form of \*asexual reproduction in certain plants, such as the onion, in which the flower develops into a budlike structure that forms a new plant when detached from the parent. **b.** The development of young plants on the inflorescence of the parent plant, as seen in certain grasses and the spider plant.

**vocal cords** A pair of elastic membranes that project into the \*larynx in air-breathing vertebrates. Vocal sounds are produced when expelled air passing through the larynx vibrates the cords. The pitch of the sound produced depends on the tension of the cords, which is controlled by muscles and cartilages in the larynx.

**void** A large region of space at the centre of a collection of galaxy superclusters; there are hardly any galaxies in the void itself, indeed there is little evidence of any matter at all. Empty 'corridors' connect voids, rather like the holes in a piece of sponge, making them part of the large-scale structure of the universe.

**volcano** A fissure or vent in the earth's surface, connected to a magma source in the earth's interior by a conduit or series of fractures, from which solid, molten, and gaseous material is ejected. The resultant geological structure, also called volcano, can take a number of forms. **Central volcanoes**, which have a circular vent or number of vents, may be composite volcanoes or stratovolcanoes, comprising alternate layers of tephra (fragmental material including ash) and lava (e.g. Vesuvius, Italy), or (where only solid material is ejected) steep-sided cinder cones. **Shield volcanoes** are large structures with gentle

slopes (e.g. the islands of Hawaii). **Fissure volcanoes** are linear fractures in the earth's surface where fluid material is emitted and, on land, spreads over large areas (e.g. volcanoes in Iceland). A number of types of volcanic eruption are recognized: Hawaiian, which are generally quiet with fluid lava erupted freely from fissures or pits, and – with increasing viscosity of magma – Strombolian, Vulcanian, Vesuvian, Plinian, and Peléean, which are more explosive. An exceptionally large form is the **supervolcano**, in which magma rises to form a vast reservoir in the earth's crust and builds in pressure over time before erupting in devastating explosions. The last supervolcano to erupt was Toba Caldera in Sumatra, 74 000 years ago. The \*caldera of Yellowstone National Park is one of the largest in the world. Volcanoes occur principally along constructive or destructive plate margins (see PLATE TECTONICS) but some volcanic activity occurs away from the margins.

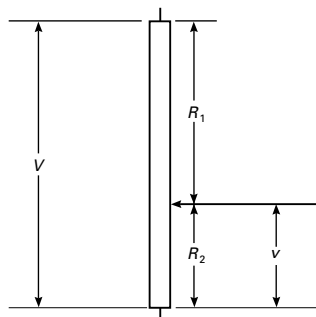

**volcanology (vulcanology)** The scientific study of volcanism, i.e. the processes by which magma and associated gases rise from the earth's interior and are emitted from the surface, and the resultant structures (see VOLCANO).

**volt** Symbol V. The SI unit of electric potential, potential difference, or e.m.f. defined as the difference of potential between two points on a conductor carrying a constant current of one ampere when the power dissipated between the points is one watt. It is named after Alessandro Volta.

**Volta, Alessandro Giuseppe Antonio Anastasio** (1745–1827) Italian physicist. In 1774 he began teaching in Como and in that year invented the \*electrophorus. He moved to Pavia University in 1778. In 1800 he made the \*voltaic cell, thus providing the first practical source of electric current (see also GALVANI, LUIGI). The SI unit of voltage is named after him.

**voltage** Symbol V. An e.m.f. or potential difference expressed in volts.

**voltage divider (potential divider; potentiometer)** A resistor or a chain of resistors connected in series that can be

Voltage divider

tapped at one or more points to obtain a known fraction of the total voltage across the whole resistor or chain. In the illustration,  $V$  is the total voltage across the divider and  $v$  is required voltage, then

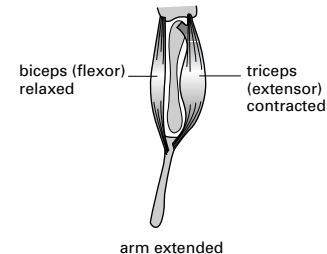

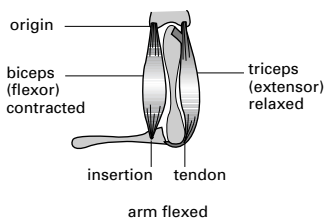

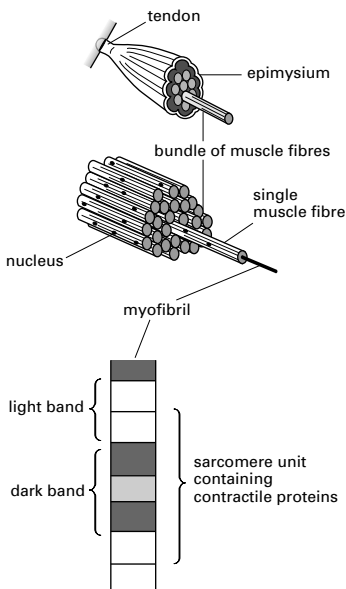

$$v/V = R_2/(R_1 + R_2).$$

**voltaic cell (galvanic cell)** A device that produces an e.m.f. as a result of chemical reactions that take place within it. These reactions occur at the surfaces of two electrodes, each of which dips into an electrolyte. The first voltaic cell, devised by Alessandro Volta (1745–1827), had electrodes of two different metals dipping into brine. See PRIMARY CELL; SECONDARY CELL.

**voltaic pile** An early form of battery, devised by Alessandro Volta, consisting of a number of flat \*voltaic cells joined in series. The liquid electrolyte was absorbed into paper or leather discs.

**voltmeter (coulometer) 1.** An electrolytic cell formerly used to measure quantity of electric charge. The increase in mass ( $m$ ) of the cathode of the cell as a result of the deposition on it of a metal from a solution of its salt enables the charge ( $Q$ ) to be determined from the relationship  $Q = m/z$ , where  $z$  is the electrochemical equivalent of the metal. **2.** Any other type of electrolytic cell used for measurement.

**voltmeter** An instrument used to measure voltage. \*Moving-coil instruments are widely used for this purpose; generally a galvanometer is used in series with a resistor of high values (sometimes called a

Structure and action of a voluntary muscle

**multiplier**). To measure an alternating potential difference a rectifier must be included in the circuit. A moving-iron instrument can be used for either d.c. or a.c. without a rectifier. \*Cathode-ray oscilloscopes are also used as voltmeters. The electronic **digital voltmeter** displays the value of the voltage in digits. The input is repeatedly sampled by the voltmeter and the instantaneous values are displayed.

**volume** Symbol *V*. The space occupied by a body or mass of fluid.

**volumetric analysis** A method of quantitative analysis using measurement of volumes. For gases, the main technique is in reacting or absorbing gases in graduated containers over mercury, and measuring the volume changes. For liquids, it involves \*titrations.

**voluntary** (in biology) Controlled by conscious thought. See VOLUNTARY MUSCLE. Compare INVOLUNTARY.

**voluntary muscle** (**skeletal, striped, or striated muscle**) Muscle that is under the control of the will and is generally attached to the skeleton. An individual muscle consists of bundles of long **muscle fibres**, each containing many nuclei, the whole muscle being covered with a strong connective tissue sheath (**epimysium**) and attached at each end to a bone by inextensible \*tendons. Each fibre contains smaller fibres (**myofibrils**) having alternate

light and dark bands, which contain protein filaments responsible for the muscle's contractile ability and give the muscle its typical striped appearance under the microscope. The functional unit of a myofibril is the \*sarcomere. See illustration.

The end of the muscle that is attached to a nonmoving bone is called the **origin** of the muscle; the end attached to a moving bone is the **insertion**. As a muscle contracts it becomes shorter and fatter, moving one bone closer to the other. Since a muscle cannot expand, another muscle (the **extensor**) is required to move the bone in the opposite direction and stretch the first muscle (known as the **flexor**). The flexor and extensor are described as **antagonistic muscles**. See illustration.

**von Laue, Max** See LAUE, MAX VON.

**vulcanite (ebonite)** A hard black insulating material made by the vulcanization of rubber with a high proportion of sulphur (up to 30%).

**vulcanization** A process for hardening rubber by heating it with sulphur or sulphur compounds.

**vulcanology** See VOLCANOLOGY.

**vulva** The female external genitalia, comprising in women two pairs of fleshy folds of tissue, the labia (see LABIUM); the \*clitoris; and the vaginal opening.

**Wacker process** A process for the manufacture of ethanal by the air oxidation of ethene. A mixture of air and ethene is bubbled through a solution containing palladium(II) chloride and copper(II) chloride. The  $\text{Pd}^{2+}$  ions form a complex with the ethene in which the ion is bound to the pi electrons in the C=C bond. This decreases the electron density in the bond, making it susceptible to nucleophilic attack by water molecules. The complex formed breaks down to ethanal and palladium metal. The  $\text{Cu}^{2+}$  ions oxidize the palladium back to  $\text{Pd}^{2+}$ , being reduced to  $\text{Cu}^+$  ions in the process. The air present oxidizes  $\text{Cu}^+$  back to  $\text{Cu}^{2+}$ . Thus the copper(II) and palladium(II) ions effectively act as catalysts in the process, which is now the main source of ethanal and, by further oxidation, ethanoic acid. It can also be applied to other alkenes. It is named after Alexander von Wacker (1846–1922).

**Wallace, Alfred Russel** (1823–1913) British naturalist, who in 1848 went on an expedition to the Amazon, and in 1854 travelled to the Malay Archipelago. There he noticed the differences between the animals of Asia and Australasia and devised \*Wallace's line, which separates them. This led him to develop a theory of \*evolution through \*natural selection, which coincided with the views of Charles \*Darwin; their theories were presented jointly to the Linnaean Society in 1858.

**Wallace's line** An imaginary line that runs between the Indonesian islands of Bali and Lombok and represents the separation of the Australian and Oriental faunas. It was proposed by Alfred Russel Wallace, who had noted that the mammals in SE Asia are different from and more advanced than their Australian counterparts. He suggested this was because the Australian continent had split away from Asia before the better adapted

placental mammals evolved in Asia. Hence the isolated Australian marsupials and monotremes were able to thrive while those in Asia were driven to extinction by competition from placental mammals. *See also* ZOOGEOGRAPHY.

**wall effect** Any effect resulting from the nature or presence of the inside wall of a container on the system it encloses.

**Walton, Ernest** *See* COCKCROFT, SIR JOHN DOUGLAS.

**warfarin** 3-(alpha-acetylnbenzyl)-4-hydroxycoumarin: a synthetic \*anticoagulant used both therapeutically in clinical medicine and, in lethal doses, as a rodenticide (*see* PESTICIDE).

**warm-blooded animal** *See* ENDO-THERM.

**warm front** *See* FRONT.

**warning coloration (aposematic coloration)** The conspicuous markings of an animal that make it easily recognizable and warn would-be predators that it is a poisonous, foul-tasting, or dangerous species. For example, the yellow-and-black striped abdomen of the wasp warns of its sting. *See also* MIMICRY.

**washing soda** \*Sodium carbonate decahydrate,  $\text{Na}_2\text{CO}_3 \cdot 10\text{H}_2\text{O}$ .

**waste product** **1.** Any product of metabolism that is not required for further metabolic processes and is therefore excreted from the body. Common waste products include nitrogenous compounds (such as \*urea and ammonia), carbon dioxide, and \*bile. **2.** *See* RADIOACTIVE WASTE.

**water** A colourless liquid,  $\text{H}_2\text{O}$ ; r.d. 1.000 ( $4^\circ\text{C}$ ); m.p.  $0.000^\circ\text{C}$ ; b.p.  $100.000^\circ\text{C}$ . In the gas phase water consists of single  $\text{H}_2\text{O}$  molecules in which the H-O-H angle is  $105^\circ$ . The structure of liquid water is still controversial; hydrogen bonding of the type  $\text{H}_2\text{O} \dots \text{H}-\text{O}-\text{H}$  imposes a high de-

gree of structure and current models supported by X-ray scattering studies have short-range ordered regions, which are constantly disintegrating and re-forming. This ordering of the liquid state is sufficient to make the density of water at about 0°C higher than that of the relatively open-structured ice; the maximum density occurs at 3.98°C. This accounts for the well-known phenomenon of ice floating on water and the contraction of water below ice, a fact of enormous biological significance for all aquatic organisms.

Ice has nine distinct structural modifications of which ordinary ice, or ice I, has an open structure built of puckered six-membered rings in which each H<sub>2</sub>O unit is tetrahedrally surrounded by four other H<sub>2</sub>O units.

Because of its angular shape the water molecule has a permanent dipole moment and in addition it is strongly hydrogen bonded and has a high dielectric constant. These properties combine to make water a powerful solvent for both polar and ionic compounds. Species in solution are frequently strongly hydrated and in fact ions frequently written as, for example, Cu<sup>2+</sup> are essentially [Cu(H<sub>2</sub>O)<sub>6</sub>]<sup>2+</sup>. Crystalline \*hydrates are also common for inorganic substances; polar organic compounds, particularly those with O-H and N-H bonds, also form hydrates.

Pure liquid water is very weakly dissociated into H<sub>3</sub>O<sup>+</sup> and OH<sup>-</sup> ions by self ionization:

(see IONIC PRODUCT) and consequently any species that increases the concentration of the positive species, H<sub>3</sub>O<sup>+</sup>, is acidic and species increasing the concentration of the negative species, OH<sup>-</sup>, are basic (see ACID). The phenomena of ion transport in water and the division of materials into **hydrophilic** (water loving) and **hydrophobic** (water hating) substances are central features of almost all biological chemistry. A further property of water that is of fundamental importance to the whole planet is its strong absorption in the infrared range of the spectrum and its transparency to visible and near ultraviolet radiation. This allows solar radiation to reach the earth during hours of daylight but restricts rapid heat loss at night. Thus

atmospheric water prevents violent diurnal oscillations in the earth's ambient temperature. See also GREENHOUSE EFFECT.

**water cycle** See HYDROLOGICAL CYCLE.

**water gas** A mixture of carbon monoxide and hydrogen produced by passing steam over hot carbon (coke):

The reaction is strongly endothermic but the reaction can be used in conjunction with that for \*producer gas for making fuel gas. The main use of water gas before World War II was in producing hydrogen for the \*Haber process. Here the above reaction was combined with the **water-gas shift reaction** to increase the amount of hydrogen:

Most hydrogen for the Haber process is now made from natural gas by steam \*reforming.

**water glass** A viscous colloidal solution of sodium silicates in water, used to make silica gel and as a size and preservative.

**water of crystallization** Water present in crystalline compounds in definite proportions. Many crystalline salts form hydrates containing 1, 2, 3, or more moles of water per mole of compound, and the water may be held in the crystal in various ways. Thus, the water molecules may simply occupy lattice positions in the crystal, or they may form bonds with the anions or the cations present. In the pentahydrate of copper sulphate (CuSO<sub>4</sub>·5H<sub>2</sub>O), for instance, each copper ion is coordinated to four water molecules through the lone pairs on the oxygen to form the \*complex [Cu(H<sub>2</sub>O)<sub>4</sub>]<sup>2+</sup>. Each sulphate ion has one water molecule held by hydrogen bonding. The difference between the two types of bonding is demonstrated by the fact that the pentahydrate converts to the monohydrate at 100°C and only becomes anhydrous above 250°C.

**Water of constitution** is an obsolete term for water combined in a compound (as in a metal hydroxide M(OH)<sub>2</sub> regarded as a hydrated oxide MO·H<sub>2</sub>O).

**water potential** Symbol Ψ. The difference between the chemical potential of

the water in a biological system and the chemical potential of pure water at the same temperature and pressure. It is manifested as a force acting on water molecules in a solution separated from pure water by a membrane that is permeable to water molecules only. Water potential is measured in kilopascals (kPa). The water potential of pure water is zero; aqueous solutions of increasing concentration have increasingly negative values. Water tends to move from areas of high (less negative) water potential to areas of low (more negative) water potential. \*Osmosis in plants is now described in terms of water potential.

**water softening** See HARDNESS OF WATER.

**Watson, James Dewey** (1928– ) US biochemist, who moved to the Cavendish Laboratory, Cambridge, in 1951 to study the structure of \*DNA. In 1953 he and Francis \*Crick announced the now accepted two-stranded helical structure for the DNA molecule. In 1962 they shared the Nobel Prize for physiology or medicine with Maurice Wilkins (1916– ), who with Rosalind Franklin (1920–58) had made X-ray diffraction studies of DNA.

**Watson–Crick model** The double-stranded twisted ladder-like molecular structure of \*DNA as determined by James Watson and Francis Crick at Cambridge, England, in 1953. It is commonly known as the **double helix**.

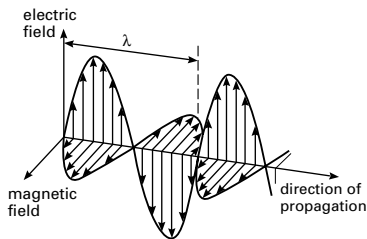

**watt** Symbol W. The SI unit of power, defined as a power of one joule per second. In electrical contexts it is equal to the rate of energy transformation by an electric current of one ampere flowing through a conductor the ends of which are maintained at a potential difference of one volt. The unit is named after James Watt (1736–1819).

**wattmeter** An instrument for measuring the power in watts in an alternating-current electric circuit. In a direct-current circuit, power is usually determined by separate measurements of the voltage and the current.

The **electrodynamometer wattmeter** consists of two coils, one fixed (current) coil and one movable (potential) coil. The fixed coil

carries the load current, and the movable coil carries a current proportional to the voltage applied to the measured circuit. The deflection of the needle attached to the movable coil indicates the power.

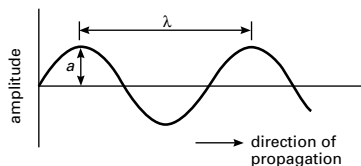

**wave** A periodic disturbance in a medium or in space. In a **travelling wave** (or **progressive wave**) energy is transferred from one place to another by the vibrations (see also STATIONARY WAVE). In a wave passing over the surface of water, for example, the water rises and falls as the wave passes but the particles of water on average do not move forward with the wave. This is called a **transverse wave** because the disturbances are at right angles to the direction of propagation. The water surface moves up and down while the waves travel across the surface of the water. Electromagnetic waves (see diagram) are also of this kind, with electric and magnetic fields varying in a periodic way at right angles to each other and to the direction of propagation. In sound waves, the air is alternately compressed and rarefied by displacements in the direction of propagation. Such waves are called **longitudinal waves**.

Electromagnetic waves

The chief characteristics of a wave are its **speed of propagation**, its **frequency**, its **wavelength**, and its **amplitude**. The speed of propagation is the distance covered by the wave in unit time. The frequency is the number of complete disturbances (cycles) in unit time, usually expressed in \*hertz. The wavelength is the distance in metres between successive points of equal phase in a wave. The amplitude is the maximum difference of the disturbed quantity from its mean value.

Generally, the amplitude ( $a$ ) is half the

Sine wave

peak-to-peak value. There is a simple relationship between the wavelength ( $\lambda$ ) and the frequency ( $f$ ), i.e.  $\lambda = cf$ , where  $c$  is the speed of propagation. The energy transferred by a progressive \*sine wave (see diagram) is proportional to  $a^2f^2$ . See also SIMPLE HARMONIC MOTION.

**wave equation** A partial differential equation of the form:

$$\nabla^2 u = (1/c^2)\partial^2 u/\partial t^2$$

where

$$\nabla^2 = \partial^2/\partial x^2 + \partial^2/\partial y^2 + \partial^2/\partial z^2$$

is the Laplace operator (see LAPLACE EQUATION). It represents the propagation of a wave, where  $u$  is the displacement and  $c$  the speed of propagation. See also SCHRÖDINGER EQUATION.

**wave form** The shape of a wave or the pattern representing a vibration. It can be illustrated by drawing a graph of the periodically varying quantity against distance for one complete wavelength. See also SINE WAVE.

**wavefront** A line or surface within a two- or three-dimensional medium through which waves are passing, being the locus of all adjacent points at which the disturbances are in phase. At large distances from a small source in a uniform medium, the fronts are small parts of a sphere of very large radius and they can be considered as plane. For example, sunlight reaches the earth with plane wavefronts.

**wave function** A function  $\psi(x,y,z)$  appearing in the \*Schrödinger equation in \*quantum mechanics. The wave function is a mathematical expression involving the coordinates of a particle in space. If the Schrödinger equation can be solved for a particle in a given system (e.g. an electron in an atom) then, depending on

the boundary conditions, the solution is a set of allowed wave functions (**eigenfunctions**) of the particle, each corresponding to an allowed energy level (**eigenvalue**). The physical significance of the wave function is that the square of its absolute value,  $|\psi|^2$ , at a point is proportional to the probability of finding the particle in a small element of volume,  $dx dy dz$ , at that point. For an electron in an atom, this gives rise to the idea of atomic and molecular \*orbitals.

**wave guide** A hollow tube through which microwave electromagnetic radiation can be transmitted with relatively little attenuation. They often have a rectangular cross section, but some have a circular cross section. In transverse electric (TE) modes the electric vector of the field has no component in the direction of propagation. In transverse magnetic (TM) modes, the magnetic vector has no such component.

**wavelength** See WAVE.

**wave mechanics** A formulation of \*quantum mechanics in which the dual wave-particle nature (see COMPLEMENTARITY) of such entities as electrons is described by the \*Schrödinger equation. Schrödinger put forward this formulation of quantum mechanics in 1926 and in the same year showed that it was equivalent to \*matrix mechanics. Taking into account the \*de Broglie wavelength, Schrödinger postulated a wave mechanics that bears the same relation to \*Newtonian mechanics as physical optics does to geometrical optics (see OPTICS).

**wavemeter** A device for measuring the wavelength of electromagnetic radiation. For frequencies up to about 100 MHz a wavemeter consists of a tuned circuit with a suitable indicator to establish when resonance occurs. Usually the tuned circuit includes a variable capacitor calibrated to read wavelengths and resonance is indicated by a current-detecting instrument. At higher frequencies a cavity-resonator in a waveguide is often used. The cavity resonator is fitted with a piston, the position of which determines the resonant frequency of the cavity.

**wave number** Symbol  $k$ . The number

of cycles of a wave in unit length. It is the reciprocal of the wavelength (see WAVE).

**wave-particle duality** The concept that waves carrying energy may have a corpuscular aspect and that particles may have a wave aspect; which of the two models is the more appropriate will depend on the properties the model is seeking to explain. For example, waves of electromagnetic radiation need to be visualized as particles, called \*photons, to explain the \*photoelectric effect while electrons need to be thought of as de Broglie waves in \*electron diffraction. See also COMPLEMENTARITY; DE BROGLIE WAVELENGTH; LIGHT.

**wave power** The use of wave motion in the sea to generate energy. The technique used is to anchor a series of bobbing floats offshore; the energy of the motion of the floats is used to turn a generator. It has been estimated that there are enough suitable sites to generate over 100 GW of electricity in the UK.

**wave theory** See LIGHT.

**wave-vector** A quantity that simultaneously defines the magnitude of a \*wave and its direction. The magnitude is equal to  $2\pi/\lambda$ , where  $\lambda$  is the wavelength, or  $2\pi k$ , where  $k$  is the \*wave number.

**wax** Any of various solid or semisolid substances. There are two main types. Mineral waxes are mixtures of hydrocarbons with high molecular weights. Paraffin wax, obtained from \*petroleum, is an example. Waxes secreted by plants or animals are mainly esters of fatty acids and usually have a protective function. Examples are the beeswax forming part of a honeycomb and the wax coating on some leaves, fruits, and seed coats, which acts as a protective water-impermeable layer supplementing the functions of the cuticle. The seeds of a few plants contain wax as a food reserve.

**W boson (W particle)** Either of a pair of elementary particles ( $W^+$  or  $W^-$ ), classified as **intermediate vector bosons**, that are believed to transmit the weak interaction (see FUNDAMENTAL INTERACTIONS) in much the same way as photons transmit the electromagnetic interaction. They are not, however, massless like photons, and are

believed to have a rest mass of the order of  $10^{-25}$  kg (806 GeV). W bosons were discovered at CERN in 1983 with the expected mass. See also Z BOSON.

**weak acid** An \*acid that is only partially dissociated in aqueous solution.

**weak interaction** See FUNDAMENTAL INTERACTIONS.

**weakly interacting massive particle (WIMP)** See MISSING MASS.

**weather** The state of atmospheric conditions, including humidity, precipitation (e.g. rain, snow, hail), temperature, pressure, cloud cover, visibility, and wind, at any one place and time. A **weather forecast** is a prediction of the weather conditions to be expected at a particular place over a given period. These may be short-range (1-2 days), medium-range (5-7 days), or long-range (1 month or a season). The two chief methods employed in obtaining short-range and medium-range forecasts are **synoptic forecasting** and **numerical forecasting**. Synoptic forecasting involves the simultaneous observation of weather elements at a series of weather stations, the collection of data, and the plotting of the information obtained on synoptic charts (weather maps), from which forecasts can be made. Since the early 1960s data collected by satellites, such as pictures of cloud cover and infrared measurements, have been increasingly used in forecasting. Numerical forecasting involves the numerical solution of equations governing the motions and changes of atmospheric conditions. Computers are used to carry out the vast number of calculations. Both synoptic and numerical methods are unsuitable for long-range forecasts and instead statistical and analogue methods are used.

**weathering** The process of breakdown and alteration of rocks on the earth's surface by mechanical or chemical processes. Mechanical (physical) weathering includes the splitting of rocks through the action of frost and extreme temperature changes. Chemical weathering includes solution (the dissolving of solid materials by water); carbonation (the dissolving of soluble rocks and minerals by a weak carbonic acid formed by the combination of

water with atmospheric carbon dioxide); oxidation (the combination of atmospheric oxygen with rock materials); and hydration (the chemical combination of rock materials with water). Organic weathering, which may involve both chemical and mechanical processes, is caused by plants and animals. For example, burrowing animals and plant roots may physically break up rocks; lichens, which can exist on bare rock surfaces, cause decomposition through the removal of nutrients.

**Web** See WORLD WIDE WEB.

**weber** Symbol Wb. The SI unit of magnetic flux equal to the flux that, linking a circuit of one turn, produces in it an e.m.f. of one volt as it is reduced to zero at a uniform rate in one second. It is named after Wilhelm Weber.

**Weber, Wilhelm Eduard** (1804–91) German physicist, who became a professor at Göttingen. In 1833 he and Karl \*Gauss built an electric telegraph between their laboratories. In 1843 Weber moved to Leipzig, where his main work was to develop a system of self-consistent electrical units (as Gauss had already done for magnetism). Both systems were adopted in 1881. The SI unit of magnetic flux is named after him.

**weed** See PEST.

**Wegener, Alfred Lothar** (1880–1930) German geologist and meteorologist, who became a professor at the University of Graz in 1924. He is best known for his theory of \*continental drift, which he formulated in 1915.

**weight** The force by which a body is attracted to the earth. See also MASS.

**weightlessness** A condition of a body when it is an infinite distance from any other body. In practice the appearance of weightlessness occurs in space when the gravitational attraction of the earth on a body in space is equal to the centripetal force required by its orbital motion so that the body is effectively in free fall. Weightlessness can also be simulated for short periods in an aircraft flying a parabolic flight path, so that its occupants are again in free fall.

**Weinberg–Salam model (WS model)**

See ELECTROWEAK THEORY.

**Weismannism** The theory of the **continuity of the germ plasm** published by August Weismann (1834–1914) in 1886. It proposes that the contents of the reproductive cells (sperms and ova) are passed on unchanged from one generation to the next, unaffected by any changes undergone by the rest of the body. It thus rules out any possibility of the inheritance of acquired characteristics, and has become fundamental to neo-Darwinian theory.

**Western blotting (protein blotting)** An \*immunoassay for determining very small amounts of a particular protein in tissue samples or cells. The sample is subjected to electrophoresis on SDS-polyacrylamide gel to separate constituent proteins. The resultant protein bands are then 'blotted' onto a polymer sheet. A radiolabelled antibody specific for the target protein is added; this binds to the protein, which can then be detected by autoradiography. A variation of this technique is used to screen bacterial colonies containing cDNA clones in order to isolate those colonies expressing a particular protein. The name is derived by analogy to that of \*Southern blotting.

**Weston cell (cadmium cell)** A type of primary \*voltaic cell, which is used as a standard; it produces a constant e.m.f. of 1.0186 volts at 20°C. The cell is usually made in an H-shaped glass vessel with a mercury anode covered with a paste of cadmium sulphate and mercury(I) sulphate in one leg and a cadmium amalgam cathode covered with cadmium sulphate in the other leg. The electrolyte, which connects the two electrodes by means of the bar of the H, is a saturated solution of cadmium sulphate. In some cells sulphuric acid is added to prevent the hydrolysis of mercury sulphate. It is named after Edward Weston (1850–1936).

**wet-and-dry bulb hygrometer** See HYGROMETER.

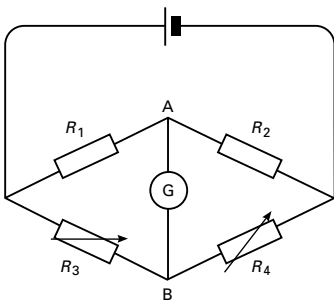

**whalebone (baleen)** Transverse horny plates hanging down from the upper jaw on each side of the mouth of the toothless whales (see CETACEA), forming a sieve. Water, containing plankton on which the

whale feeds, enters the open mouth and is then expelled with the mouth slightly closed, so that food is retained on the baleen plates.

**whales** See CETACEA.

**Wheatstone, Sir Charles** (1802–75) British physicist, who set up as a musical instrument-maker in London. He studied acoustics and optics, inventing a stereoscope in 1838. His most important work, done with William Cooke (1806–79), was the development of an electric telegraph, which they achieved in 1837. He gave his name to the \*Wheatstone bridge, although he did not invent it.

**Wheatstone bridge** An electrical circuit for measuring the value of a resistance. In the illustration,  $R_1$  is a resistance of unknown value,  $R_2$  is a fixed resistance of known value,  $R_3$  and  $R_4$  are variable resistances with known values. When no current flows between A and B the bridge is said to be balanced, the galvanometer registers no deflection, and  $R_1/R_2 = R_3/R_4$ .  $R_1$  can therefore be calculated. The Wheatstone bridge is used in various forms. In the **metre bridge**, a wire 1 metre long of uniform resistance is attached to the top of a board alongside a metre rule. A sliding contact is run along the wire, which corresponds to  $R_3$  and  $R_4$ , until the galvanometer registers zero. Most practical forms use one or more rotary rheostats to provide the variation. The device was popularized though not invented by Sir Charles Wheatstone.

Wheatstone bridge

**why** See CURD.

**white arsenic** See ARSENIC(III) OXIDE.

**white blood cell** See LEUCOCYTE.

**white dwarf** A compact stellar object that is supported against collapse under self-gravity by the \*degeneracy pressure of electrons. White dwarfs are formed as the end products of the evolution of stars of relatively low mass (about that of the sun); high-mass stars may end up as \*neutron stars or \*black holes (see STELLAR EVOLUTION). White dwarfs consist of helium nuclei (and carbon and oxygen nuclei in the more massive cases) and a \*degenerate gas of electrons. A typical white-dwarf density is  $10^9 \text{ kg m}^{-3}$ ; white dwarf masses and radii are in the region of 0.7 solar masses and  $10^3 \text{ km}$  respectively. There is a maximum mass for white dwarfs, above which they are unstable to gravitational collapse – this is known as the \*Chandrasekhar limit and is about 1.4 solar masses.

**white hole** See WORMHOLE.

**white matter** Part of the tissue that makes up the central nervous system of vertebrates. It consists chiefly of nerve fibres enclosed in whitish \*myelin sheaths. Compare GREY MATTER.

**white mica** See MUSCOVITE.

**white spirit** A liquid mixture of petroleum hydrocarbons used as a solvent for paint ('turpentine substitute').

**Wiedemann–Franz law** The ratio of the thermal conductivity of any pure metal to its electrical conductivity is approximately constant at a given temperature. The law is fairly well obeyed, except at low temperatures.

**Wien formula** See PLANCK'S RADIATION LAW.

**Wien's displacement law** For a \*black body,  $\lambda_m T = \text{constant}$ , where  $\lambda_m$  is the wavelength corresponding to the maximum radiation of energy and  $T$  is the thermodynamic temperature of the body. Thus as the temperature rises the maximum of the spectral energy distribution curve is displaced towards the short-wavelength end of the spectrum. The law was stated by Wilhelm Wien (1864–1928).

**Wigner energy** Energy stored in a crystalline substance as a result of irradiation.

This phenomenon is known as the **Wigner effect**. For example, some of the energy lost by neutrons in a \*nuclear reactor is stored by the graphite moderator. As a result, the crystal lattice is changed and there is a consequent change in the physical dimensions of the moderator. It is named after Eugene Wigner (1902–95).

**Wigner nuclides** Pairs of isobars with odd nucleon numbers in which the atomic number and the neutron number differ by one.  $^3\text{H}$  and  $^3\text{He}$  are examples.

**Wigner's friend** See SCHRÖDINGER'S CAT.

**wild type** Describing the form of an \*allele possessed by most members of a population in their natural environment. Wild-type alleles are usually \*dominant.

**Wilkins, Maurice** See CRICK, FRANCIS HARRY COMPTON.

**Williamson's synthesis** Either of two methods of producing ethers, both named after the British chemist Alexander Williamson (1824–1904).

**1.** The dehydration of alcohols using concentrated sulphuric acid. The overall reaction can be written

The method is used for making ethoxyethane ( $\text{C}_2\text{H}_5\text{OC}_2\text{H}_5$ ) from ethanol by heating at  $140^\circ\text{C}$  with excess of alcohol (excess acid at  $170^\circ\text{C}$  gives ethene). Although the steps in the reaction are all reversible, the ether is distilled off so the reaction can proceed to completion. This is **Williamson's continuous process**. In general, there are two possible mechanisms for this synthesis. In the first (favoured by primary alcohols), an alkylhydrogen sulphate is formed

This reacts with another alcohol molecule to give an oxonium ion

This loses a proton to give ROR.

The second mechanism (favoured by tertiary alcohols) is formation of a carboonium ion

This is attacked by the lone pair on the other alcohol molecule

and the oxonium ion formed again gives the product by loss of a proton.

The method can be used for making symmetric ethers (i.e. having both R groups the same). It can successfully be used for mixed ethers only when one alcohol is primary and the other tertiary (otherwise a mixture of the three possible products results).

**2.** A method of preparing ethers by reacting a haloalkane with an alkoxide. The reaction, discovered in 1850, is a nucleophilic substitution in which the negative alkoxide ion displaces a halide ion; for example:

A mixture of the reagents is refluxed in ethanol. The method is particularly useful for preparing mixed ethers, although a possible side reaction under some conditions is an elimination to give an alcohol and an alkene.

**Wilson, Charles Thomson Rees**

(1869–1959) British physicist, born in Scotland, who studied physics with J. J. \*Thomson in Cambridge. His best-known achievement was the development of the \*cloud chamber in 1911, for which he was awarded the 1927 Nobel Prize for physics.

**Wilson cloud chamber** See CLOUD CHAMBER.

**wilting** The condition that arises in plants when more water is lost by evaporation than is absorbed from the soil. This causes the cells to lose their \*turgor and the plant structure droops. Plants can normally recover from wilting if water is added to the soil, but permanent wilting and possible death can result if the plant does not have access to water for a long period of time. In certain plants wilting is important as a mechanism to avoid overheating: when the leaves droop they are taken out of direct contact with the sun's rays. When the sun sets the plant can begin to transpire at the normal rate and the cells of the leaves regain their turgor.

**WIMP** Weakly interacting massive particle. See MISSING MASS.

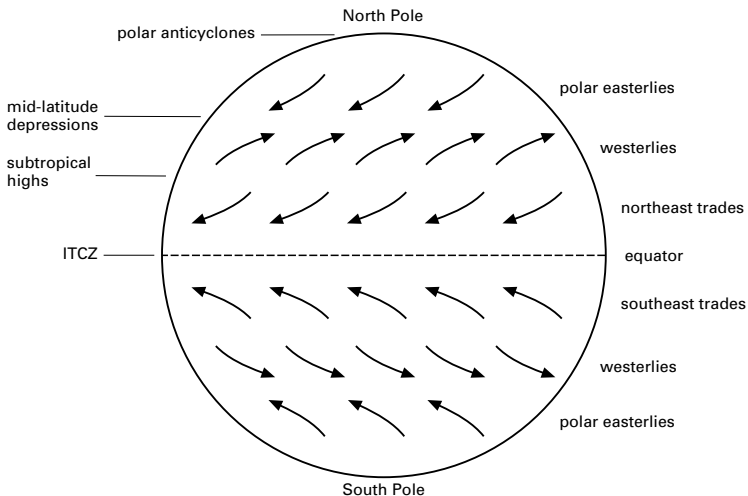

**Wimshurst machine** A laboratory electrostatic generator. It consists of two insulating discs to which radial strips of metal foil are attached. After a few strips have been charged individually, the discs are rotated in opposite directions and the charge produced on the strips by induction is collected by metal combs or brushes. It was invented by James Wimshurst (1836–1903).

**wind** The motion (usually horizontal) of air relative to the earth's surface. The **general circulation of the atmosphere** – the large-scale patterns of wind and pressure that persist throughout the year or recur seasonally – results largely from differences in the net radiation received at the earth's surface. However, it is modified by the rotation of the earth, the presence of mountain barriers, the relative distribution of land and sea, and the positions of the ocean currents. Although the resulting wind circulation patterns are complex, they can be simplified into a series of belts (see illustration). Surface heating, which is at its greatest along the equator, creates a belt of low pressure – the inter-tropical convergence zone (ITCZ) – to-

wards which the airstreams of the northern and southern hemispheres converge. On either side of the ITCZ lie the trade wind belts: the northeast trade winds in the northern hemisphere and the southeast trade winds of the southern hemisphere. The trade winds are separated from the westerlies – the predominant winds in the mid-latitudes of both hemispheres – by the subtropical high-pressure belt (the horse latitudes), which lies between about 30° and 35° latitude. Near to the poles are the polar easterlies, separated from the westerlies by the subpolar low-pressure troughs.

**window 1.** A band of electromagnetic wavelengths that is able to pass through a particular medium with little reflection or absorption. For example, there is a **radio window** in the atmosphere allowing radio waves of wavelengths 5 mm to 30 m to pass through. This radio window enables \*radio telescopes to be used on the surface of the earth. **2.** A period of time during which an event may occur in order to achieve a desired result. For example a **launch window** is the period during which a space vehicle must be launched to achieve a planned encounter.

**windpipe** See TRACHEA.

Global surface wind and pressure systems

**wind pollination** See ANEMOPHILY.

**wind power** The use of winds in the earth's atmosphere to drive machinery, especially to drive an electrical generator. Practical land-based **wind generators** (**aerogenerators**) are probably capable of providing some  $10^{20}$  J ( $10^{14}$  kW h) of energy per year throughout the world and interest in this form of renewable energy is increasing. The power,  $P$ , available to drive a wind generator is given by  $P = kd^2v^3$ , where  $k$  is the air density,  $d$  is the diameter of the blades, and  $v$  is the average wind speed. Wind farms now exist in many parts of the world; California, for example, has the capacity to produce over 1200 MW from wind energy.

**wing** See FLIGHT.

**wino** See SUPERSYMMETRY.

**withdrawal reflex** See REFLEX.

**witherite** A mineral form of \*barium carbonate,  $\text{BaCO}_3$ .

**WMAP (Wilkinson Microwave Anisotropy Probe)** A satellite launched in 2002 to investigate the \*microwave background radiation. In 2003 a full-sky picture was obtained of the early universe (380 000 years after the big bang) showing temperature fluctuations at high resolution. The results supported the big-bang and inflation theories, and gave an age for the universe of  $13.7 \times 10^9$  years. WMAP is named in honour of the US cosmologist and WMAP team member David Wilkinson, who died in 2002.

**Wöhler, Friedrich** (1800–82) German physician and chemist, who became a professor of chemistry at Göttingen. In 1828 he made his best-known discovery, the synthesis of urea (an organic compound) from ammonium cyanate (an inorganic salt); see WÖHLER'S SYNTHESIS. This finally disproved the assertion that organic substances can be formed only in living things. Wöhler also isolated \*aluminium (1827), \*beryllium (1828), and \*yttrium (1828).

**Wöhler's synthesis** A synthesis of urea performed by Friedrich Wöhler in 1828. He discovered that urea ( $\text{CO}(\text{NH}_2)_2$ ) was formed when a solution of ammonium isocyanate ( $\text{NH}_4\text{NCO}$ ) was evaporated. At

the time it was believed that organic substances such as urea could be made only by living organisms, and its production from an inorganic compound was a notable discovery. It is sometimes (erroneously) cited as ending the belief in vitalism.

**wolfram** See TUNGSTEN.

**wolframite (iron manganese tungsten)**

A mineral consisting of a mixed iron-manganese tungstate,  $(\text{FeMn})\text{WO}_4$ , crystallizing in the monoclinic system; the principal ore of tungsten. It commonly occurs as blackish or brownish tabular crystal groups. It is found chiefly in quartz veins associated with granitic rocks. China is the major producer of wolframite.

**Wolf-Rayet star** An extremely hot bright type of star, often found inside a developing planetary nebula. Strong stellar winds give rise to a large loss of mass, which takes the form of a cloud of gas surrounding the star. As a result, its spectrum contains emission lines caused because the starlight has to pass through this gas. They were discovered in 1867 by C. J. E. Wolf and G. Rayet.

**Wollaston prism** A type of quartz prism for producing plane-polarized light. It deviates the ordinary and extraordinary rays in opposite directions by approximately the same amount. The Wollaston prism, like the \*Rochon prism, can be used with ultraviolet radiation. It is named after the inventor William Wollaston (1766–1828).

**womb** See UTERUS.

**wood** The hard structural and water-conducting tissue that is found in many perennial plants and forms the bulk of trees and shrubs. It is composed of secondary \*xylem and associated cells, such as fibres. The wood of angiosperms is termed **hardwood**, e.g. oak and mahogany, and that of gymnosperms **softwood**, e.g. pine and fir. New wood is added to the outside of the old wood each growing season by divisions of the vascular cambium (see GROWTH RING). Only the outermost new wood (\*sapwood) functions in water conduction; the inner wood

(\*heartwood) provides only structural support.

**wood alcohol** See METHANOL.

**Wood's metal** A low-melting (71°C) alloy of bismuth (50%), lead (25%), tin (12.5%), and cadmium (12.5%). It is used for fusible links in automatic sprinkler systems. The melting point can be changed by varying the composition. It is named after William Wood (1671-1730).

**Woodward-Hoffmann rules** Rules governing the formation of products during certain types of organic concerted reactions. The theory of such reactions was put forward in 1969 by the American chemists Robert Burns Woodward (1917-79) and Roald Hoffmann (1937- ), and is concerned with the way that orbitals of the reactants change continuously into orbitals of the products during reaction and with conservation of orbital symmetry during this process. See also FRONTIER-ORBITAL THEORY.

**woofer** A large loudspeaker designed to reproduce sounds of relatively low frequency, in conjunction with a \*tweeter and often a mid-range speaker, in a high-fidelity sound reproducing system.

**word** A number of \*bits, often 32, 48, or 64, processed by a computer as a single unit.

**work** The work done by a force acting on a body is the product of the force and the distance moved by its point of application in the direction of the force. If a force  $F$  acts in such a way that the displacement  $s$  is in a direction that makes an angle  $\theta$  with the direction of the force, the work done is given by:  $W = F\cos\theta s$ . Work is the scalar product of the force and displacement vectors. It is measured in joules.

**work function** A quantity that determines the extent to which \*thermionic or photoelectric emission will occur according to the Richardson equation or Einstein's photoelectric equation (see EINSTEIN EQUATION). It is sometimes expressed as a potential difference (symbol  $\phi$ ) in volts and sometimes as the energy required to remove an electron (symbol  $W$ ) in electronvolts or joules. The former has been called the **work function poten-**

**tial** and the latter the **work function energy**.

**work hardening** An increase in the hardness of metals as a result of working them cold. It causes a permanent distortion of the crystal structure and is particularly apparent with iron, copper, aluminium, etc., whereas with lead and zinc it does not occur as these metals are capable of recrystallizing at room temperature.

**World Wide Web (WWW; Web)** A computer-based information service developed at CERN in the early 1990s. It is a hypermedia system (see HYPERTEXT) distributed over a large number of computer sites that allows users to view and retrieve information from 'documents' containing 'links'. It is accessed by a computer connected to the \*Internet that is running a suitable program.

Web documents may consist of textual material or a number of other forms, such as graphics, still or moving images, or audio clips. Within a document there will be material to be displayed and usually one or more links, which in a text document appear as highlighted words or phrases, or as icons. The links 'point' to other documents located elsewhere on the Web by means of a **URL** (universal resource locator), which contains information specifying, for example, the network address of the device holding the document and the local index entry for that document. Activating a link will result in the display of the requested document.

**wormhole** A theoretical structure in space-time bridging two universes. Early calculations on the physics of black holes indicated that such structures might exist as a result of extreme distortion of space-time. Matter falling into a black hole in one universe could then appear pouring out of a **white hole** in another universe. It is now thought that such links do not occur and that white holes, which spontaneously generate matter, do not exist.

**W particle** See W BOSON.

**wrought iron** A highly refined form of iron containing 1-3% of slag (mostly iron silicate), which is evenly distributed throughout the material in threads and

fibres so that the product has a fibrous structure quite dissimilar to that of crystalline cast iron. Wrought iron rusts less readily than other forms of metallic iron and it welds and works more easily. It is used for chains, hooks, tubes, etc.

**WS model** Weinberg–Salam model. See ELECTROWEAK THEORY.

**Wurtz reaction** A reaction to prepare alkanes by reacting a haloalkane with sodium:

The haloalkane is refluxed with sodium in dry ether. The method is named after the French chemist Charles-Adolphe Wurtz (1817–84). The analogous reaction using a haloalkane and a haloarene, for example:

is called the **Fittig reaction** after the German chemist Rudolph Fittig (1835–1910).

**xanthates** Salts or esters containing the group  $-SCS(OR)$ , where R is an organic group. Cellulose xanthate is an intermediate in the manufacture of \*rayon by the viscose process.

**xanthophyll** A member of a class of oxygen-containing \*carotenoid pigments, which provide the characteristic yellow and brown colours of autumn leaves.

**X chromosome** See SEX CHROMOSOME.

**xenobiotic** Any substance foreign to living systems. Xenobiotics include drugs, pesticides, and carcinogens. \*Detoxification of such substances occurs mainly in the liver.

**xenolith** A piece of pre-existing rock that occurs as an inclusion within an igneous \*intrusion. Often it is a fragment of the country rock surrounding the inclusion, although it may have been modified to a hybrid rock by the intense heat of the intruding magma.

**xenon** Symbol Xe. A colourless odourless gas belonging to group 18 of the periodic table (see NOBLE GASES); a.n. 54; r.a.m. 131.30; d.  $5.887 \text{ g dm}^{-3}$ ; m.p.  $-111.9^\circ\text{C}$ ; b.p.  $-107.1^\circ\text{C}$ . It is present in the atmosphere (0.00087%) from which it is extracted by distillation of liquid air. There are nine natural isotopes with mass numbers 124, 126, 128–132, 134, and 136. Seven radioactive isotopes are also known. The element is used in fluorescent lamps and bubble chambers. Liquid xenon in a supercritical state at high temperatures is used as a solvent for infrared spectroscopy and for chemical reactions. The compound  $\text{Xe}^+\text{PtF}_6^-$  was the first noble-gas compound to be synthesized. Several other compounds of xenon are known, including  $\text{XeF}_2$ ,  $\text{XeF}_4$ ,  $\text{XeSiF}_6$ ,  $\text{XeO}_2\text{F}_2$ , and  $\text{XeO}_3$ . Recently, compounds have been isolated that contain xenon-carbon bonds, such as  $[\text{C}_6\text{H}_5\text{Xe}][\text{B}(\text{C}_6\text{H}_5)_3\text{F}]$  (pentafluorophenylxenon fluoroborate), which is stable under normal conditions.

The element was discovered in 1898 by Ramsey and Travers.

**xeric** Denoting conditions characterized by an inadequate supply of water. Xeric conditions exist in arid habitats, extremely cold habitats, and in salt marshes. Certain plants are adapted to live in such conditions. See HALOPHYTE; XEROPHYTE.

**xeromorphic** Describing the structural modifications of certain plants (\*xerophytes) that enable them to reduce water loss, particularly from their leaves and stems.

**xerophyte** A plant that is adapted to live in conditions in which there is either a scarcity of water in the soil, or the atmosphere is dry enough to provoke excessive transpiration, or both. Xerophytes have special structural (**xeromorphic**) and functional modifications, including swollen water-storing stems or leaves (see SUCULENT) and specialized leaves that may be hairy, rolled, or reduced to spines or have a thick cuticle to lower the rate of transpiration. Examples of xerophytes are desert cacti and many species that grow on sand dunes and exposed moorlands. Some \*halophytes have xeromorphic features. Compare MESOPHYTE; HYDROPHYTE.

**X-ray astronomy** The study of \*X-ray sources by rockets and balloons in the earth's atmosphere and by satellites beyond it. The first nonsolar X-ray source was detected during a rocket flight in 1962, and this observation heralded an entirely new branch of astronomy which developed rapidly with the availability of satellites in the 1970s.

**X-ray crystallography** The use of \*X-ray diffraction to determine the structure of crystals or molecules, such as nucleic acids. The technique involves directing a beam of X-rays at a crystalline sample and recording the diffracted X-rays on a photographic plate. The diffraction pattern con-

sists of a pattern of spots on the plate, and the crystal structure can be worked out from the positions and intensities of the diffraction spots. X-rays are diffracted by the electrons in the molecules and if molecular crystals of a compound are used, the electron density distribution in the molecule can be determined. *See also* NEUTRON DIFFRACTION.

**X-ray diffraction** The diffraction of X-rays by a crystal. The wavelengths of X-rays are comparable in size to the distances between atoms in most crystals, and the repeated pattern of the crystal lattice acts like a diffraction grating for X-rays. Thus, a crystal of suitable type can be used to disperse X-rays in a spectrometer. X-ray diffraction is also the basis of X-ray crystallography. *See also* BRAGG'S LAW.

**X-ray fluorescence** The emission of \*X-rays from excited atoms produced by the impact of high-energy electrons, other particles, or a primary beam of other X-rays. The wavelengths of the fluorescent X-rays can be measured by an X-ray spectrometer as a means of chemical analysis. X-ray fluorescence is used in such techniques as \*electron probe microanalysis.

**X-rays** Electromagnetic radiation of shorter wavelength than ultraviolet radiation produced by bombardment of atoms by high-quantum-energy particles. The range of wavelengths is  $10^{-11}$  m to  $10^{-9}$  m. Atoms of all the elements emit a characteristic **X-ray spectrum** when they are bombarded by electrons. The X-ray photons are emitted when the incident electrons knock an inner orbital electron out of an atom. When this happens an outer electron falls into the inner shell to replace it, losing potential energy ( $\Delta E$ ) in doing so. The wavelength  $\lambda$  of the emitted photon will then be given by  $\lambda = hc/\Delta E$ , where  $c$  is the speed of light and  $h$  is the Planck constant. *See also* BREMSSTRAHLUNG.

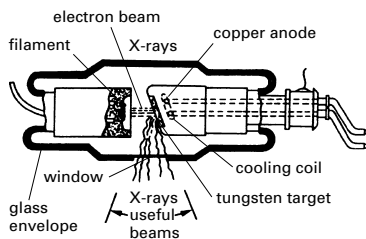

X-rays can pass through many forms of matter and they are therefore used medically and industrially to examine internal structures. X-rays are produced for these purposes by an \*X-ray tube.

**X-ray sources** Sources of X-radiation from outside the solar system. Some 100 sources within the Galaxy have been observed as objects that emit most of their

energy in the X-ray region of the electromagnetic spectrum and only a relatively small proportion of their energy in the visible spectrum. Many of these X-ray sources appear to be members of a binary system, consisting of one optically visible star and one very compact object; it is thought that the latter is either a \*neutron star or (if very massive) a \*black hole. Owing to the absorption of X-rays by the earth's atmosphere these X-ray sources are only visible by **X-ray telescopes** carried by space probes and satellites, although some high-energy X-rays can penetrate the upper atmosphere and are detectable by X-ray telescopes mounted on balloons.

**X-ray spectrum** *See* X-RAYS.

**X-ray tube** A device for generating \*X-rays by accelerating electrons to a high energy by an electrostatic field and making them strike a metal target either in a tube containing a low-pressure gas or, as in modern tubes, in a high vacuum. The target is made from a heavy metal, usually tungsten, and is backed by a massive metal anode to conduct the heat away (see illustration showing a liquid-cooled copper anode). The electron beam is produced by heating the cathode by means of a white-hot tungsten filament. A transformer supplies the high voltage, often 100 kV, the tube acting as its own rectifier. On the half-cycles when the target is negative nothing happens. When the target becomes positive, the electrons bombarding it generate X-rays.

X-ray tube

**xylem** A tissue that transports water and dissolved mineral nutrients in vascular plants. In flowering plants it consists of hollow **vessels** that are formed from cells (\*vessel elements) joined end to end. The

end walls of the vessel elements are perforated to allow the passage of water. In less advanced vascular plants, such as conifers and ferns, the constituent cells of the xylem are called \*tracheids. In young plants and at the shoot and root tips of older plants the xylem is formed by the apical meristems. In plants showing secondary growth this xylem is replaced in most of the plant by secondary xylem, formed by the vascular \*cambium. The walls of the xylem cells are thickened with lignin, the extent of this thickening being greatest in secondary xylem. Xylem contributes greatly to the mechanical strength of the plant: \*wood is mostly made up of secondary xylem. *See also* FIBRE. *Compare* PHLOEM.

**xylenes** *See* DIMETHYLBENZENES.

**YAC** *See* ARTIFICIAL CHROMOSOME.

**Yagi aerial** A directional aerial array widely used for television and \*radio telescopes. It consists of one or two dipoles, a parallel reflector, and a series of closely spaced directors (0.15–0.25 wavelength apart) in front of the dipole. When used for reception this arrangement focuses the incoming signal on the dipole. For transmission, the output of the dipole is reinforced by the directors. It is named after Hidetsuga Yagi (1886–1976).

**Yang–Mills theory** *See* GAUGE THEORY.

**yard** The former Imperial standard unit of length. In 1963 the yard was redefined as 0.9144 metre exactly.

**Y chromosome** *See* SEX CHROMOSOME.

**year** The measure of time on which the calendar is based. It is the time taken for the earth to complete one orbit of the sun. The **calendar year** consists of an average of 365.25 mean solar days – three successive years of 365 days followed by one (leap) year of 366 days. The **solar year** (or **astronomical year**) is the average interval between two successive returns of the sun to the first point of Aries; it is 365.242 mean solar days. The **sidereal year** is the average period of revolution of the earth with respect to the fixed stars; it is 365.256 mean solar days. The **anomalous year** is the average interval between suc-

cessive perihelions; it is 365.259 mean solar days. *See also* EPHEMERIS TIME.

**yeast artificial chromosome (YAC)**

*See* ARTIFICIAL CHROMOSOME.

**yeasts** A group of unicellular fungi within the class Hemiascomycetae of the phylum \*Ascomycota. They occur as single cells or as groups or chains of cells; yeasts reproduce asexually by \*budding and sexually by producing ascospores. Yeasts of the genus \**Saccharomyces* ferment sugars and are used in the baking and brewing industries (*see* BAKER'S YEAST).

**yellow body** *See* CORPUS LUTEUM.

**yield point** *See* ELASTICITY.

**yocto-** Symbol y. A prefix used in the metric system to indicate  $10^{-24}$ . For example,  $10^{-24}$  second = 1 yoctosecond (ys).

**yolk** The food stored in an egg for the use of the embryo. It can consist mainly of protein (**protein yolk**) or of phospholipids and fats (**fatty yolk**). The eggs of oviparous animals (e.g. birds) contain a relatively large yolk.

**yolk sac** One of the protective membranes surrounding the embryos of birds, reptiles, and mammals (*see* EXTRAEMBRYONIC MEMBRANES). The embryo derives nourishment from the yolk sac via a system of blood vessels. In birds and reptiles the yolk sac encloses the yolk; in most mammals a fluid replaces the yolk.

**yotta-** Symbol Y. A prefix used in the metric system to indicate  $10^{24}$ . For example,  $10^{24}$  metres = 1 yottametre (Ym).

**Young, Thomas** (1773–1829) British physician and physicist, who was a child prodigy and could speak 14 languages before he was 19. His early researches concerned the eye and vision, but he is best known for establishing the wave theory of \*light (1800–1804) and explaining the phenomenon of \*interference (1807).

**Young modulus of elasticity** *See* ELASTIC MODULUS.

**Young's slits** *See* INTERFERENCE.

**ytterbium** Symbol Yb. A silvery metallic element belonging to the \*lanthanoids; a.n. 70; r.a.m. 173.04; r.d. 6.965 (20°C); m.p. 819°C; b.p. 1194°C. It occurs in

gadolinite, monazite, and xenotime. There are seven natural isotopes and ten artificial isotopes are known. It is used in certain steels. The element was discovered by Jean de Marignac (1817–94) in 1878.

**yttrium** Symbol Y. A silvery-grey metallic element belonging to group 3 (formerly IIIA) of the periodic table; a.n. 39; r.a.m. 88.905; r.d. 4.469 (20°C); m.p. 1522°C; b.p. 3338°C. It occurs in uranium ores and in \*lanthanoid ores, from which it can be extracted by an ion exchange process. The natural isotope is yttrium-89, and there are 14 known artificial isotopes. The metal is used in superconducting alloys and in alloys for strong permanent magnets (in both cases, with cobalt). The oxide (Y<sub>2</sub>O<sub>3</sub>) is used in colour-television phosphors, neodymium-doped lasers, and microwave components. Chemically it resembles the lanthanoids, forming ionic compounds containing Y<sup>3+</sup> ions. The metal is stable in air below 400°C. It was discovered in 1828 by Friedrich Wöhler.

**Z boson** An electrically neutral elementary particle, Z<sup>0</sup>, which – like \*W bosons – is thought to mediate the weak interactions in the \*electroweak theory. The Z<sup>0</sup> boson was discovered at CERN in 1983 and has a mass of about 90 GeV as had been predicted from theory.

**Zeeman effect** The splitting of the lines in a spectrum when the source of the spectrum is exposed to a magnetic field. It was discovered in 1896 by Pieter Zeeman (1865–1943). In the **normal Zeeman effect** a single line is split into three if the field is perpendicular to the light path or two lines if the field is parallel to the light path. This effect can be explained by classical electromagnetic principles in terms of the speeding up and slowing down of orbital electrons in the source as a result of the applied field. The **anomalous Zeeman effect** is a complicated splitting of the lines into several closely spaced lines, so called because it does not agree with classical predictions. This effect is explained by quantum mechanics in terms of electron spin.

**Zeilinger's principle** The principle that any elementary system carries just one bit of information. This principle was

put forward by the Austrian physicist Anton Zeilinger in 1999 and subsequently developed by him to derive several aspects of quantum mechanics.

**Zeisel reaction** A method of determining the number of methoxy (–OCH<sub>3</sub>) groups in an organic compound. The compound is heated with excess hydriodic acid, forming an alcohol and iodo-methane

The iodomethane is distilled off and led into an alcoholic solution of silver nitrate, where it precipitates silver iodide. This is filtered and weighed, and the number of iodine atoms and hence methoxy groups can be calculated. The method was developed by S. Zeisel in 1886.

**Zeise's salt** A complex of platinum and ethene, PtCl<sub>3</sub>(CH<sub>2</sub>CH<sub>2</sub>), in which the Pt coordinates to the pi bond of the ethene. It was synthesized by W. C. Zeise in 1827.

**Zener diode** A type of semiconductor diode, consisting of a *p-n* junction with high doping concentrations on either side of the junction. It acts as a rectifier until the applied reverse voltage reaches a certain value, the **Zener breakdown voltage**, when the device becomes conducting. This effect occurs as a result of electrons being excited directly from the valence band into the conduction band (see ENERGY BAND). Zener diodes are used in voltage-limiting circuits; they are named after C. M. Zener (1905–93).

**zenith** The point on the \*celestial sphere that lies directly above an observer. Compare NADIR.

**zeolite** A natural or synthetic hydrated aluminosilicate with an open three-dimensional crystal structure, in which water molecules are held in cavities in the lattice. The water can be driven off by heating and the zeolite can then absorb other molecules of suitable size. Zeolites are used for separating mixtures by selective absorption – for this reason they are often called **molecular sieves**. They are also used in sorption pumps for vacuum systems and certain types (e.g. Permutit) are used in ion-exchange (e.g. water-softening).

**zepto-** Symbol z. A prefix used in the metric system to indicate  $10^{-21}$ . For example,  $10^{-21}$  second = 1 zeptosecond (zs).

**zero order** See ORDER.

**zero-point energy** The energy remaining in a substance at the \*absolute zero of temperature (0 K). This is in accordance with quantum theory, in which a particle oscillating with simple harmonic motion does not have a stationary state of zero kinetic energy. Moreover, the \*uncertainty principle does not allow such a particle to be at rest at exactly the centrepoint of its oscillations.

**zeroth law of thermodynamics** See THERMODYNAMICS.

**zetta-** Symbol Z. A prefix used in the metric system to indicate  $10^{21}$ . For example,  $10^{21}$  metres = 1 zettametre (Zm).

**Ziegler process** An industrial process for manufacturing high-density polyethylene using catalysts of titanium(IV) chloride ( $\text{TiCl}_4$ ) and aluminium alkyls (e.g. triethylaluminium,  $\text{Al}(\text{C}_2\text{H}_5)_3$ ). The process was introduced in 1953 by the German chemist Karl Ziegler (1898–1973). It allowed the manufacture of polythene at lower temperatures (about  $60^\circ\text{C}$ ) and pressures (about 1 atm.) than used in the original process. Moreover, the polyethene produced had more straight-chain molecules, giving the product more rigidity and a higher melting point than the earlier low-density polyethene. The reaction involves the formation of a titanium alkyl in which the titanium can coordinate directly to the pi bond in ethene.

In 1954 the process was developed further by the Italian chemist Giulio Natta (1903–79), who extended the use of Ziegler's catalysts (and similar catalysts) to other alkenes. In particular he showed how to produce stereospecific polymers of propene.

**zinc** Symbol Zn. A blue-white metallic element; a.n. 30; r.a.m. 65.38; r.d. 7.1; m.p.  $419.88^\circ\text{C}$ ; b.p.  $907^\circ\text{C}$ . It occurs in sphalerite (or zinc blende, ZnS), which is found associated with the lead sulphide, and in smithsonite ( $\text{ZnCO}_3$ ). Ores are roasted to give the oxide and this is reduced with carbon (coke) at high temperature, the zinc vapour being condensed. Alterna-

tively, the oxide is dissolved in sulphuric acid and the zinc obtained by electrolysis. There are five stable isotopes (mass numbers 64, 66, 67, 68, and 70) and six radioactive isotopes are known. The metal is used in galvanizing and in a number of alloys (brass, bronze, etc.). Chemically it is a reactive metal, combining with oxygen and other nonmetals and reacting with dilute acids to release hydrogen. It also dissolves in alkalis to give \*zincates. Most of its compounds contain the  $\text{Zn}^{2+}$  ion.

**zincate** A salt formed in solution by dissolving zinc or zinc oxide in alkali. The formula is often written  $\text{ZnO}_2^{2-}$  although in aqueous solution the ions present are probably complex ions in which the  $\text{Zn}^{2+}$  is coordinated to  $\text{OH}^-$  ions.  $\text{ZnO}_2^{2-}$  ions may exist in molten sodium zincate, but most solid 'zincates' are mixed oxides.

**zinc blende** A mineral form of \*zinc sulphide, ZnS, the principal ore of zinc (see SPHALERITE). The **zinc-blende structure** is the crystal structure of this compound (and of other compounds). It has zinc atoms surrounded by four sulphur atoms at the corners of a tetrahedron. Each sulphur is similarly surrounded by four zinc atoms. The crystals belong to the cubic system.

**zinc chloride** A white crystalline compound,  $\text{ZnCl}_2$ . The anhydrous salt, which is deliquescent, can be made by the action of hydrogen chloride gas on hot zinc; r.d. 2.9; m.p.  $283^\circ\text{C}$ ; b.p.  $732^\circ\text{C}$ . It has a relatively low melting point and sublimes easily, indicating that it is a molecular compound rather than ionic. Various hydrates also exist. Zinc chloride is used as a catalyst, dehydrating agent, and flux for hard solder. It was once known as **butter of zinc**.

**zinc chloride cell** See DRY CELL.

**zinc group** The group of elements in the periodic table forming group 12 and consisting of zinc (Zn), cadmium (Cd), and mercury (Hg). They were formerly classified in group IIB of the table (see GROUP 2 ELEMENTS).

**zincite** A mineral form of \*zinc oxide, ZnO.

**zinc oxide** A powder, white when cold

and yellow when hot, ZnO; r.d. 5.606; m.p. 1975°C. It occurs naturally as a reddish orange ore **zincite**, and can also be made by oxidizing hot zinc in air. It is amphoteric, forming \*zincates with bases. It is used as a pigment (**Chinese white**) and a mild antiseptic in zinc ointments. An archaic name is **philosopher's wool**.

**zinc sulphate** A white crystalline water-soluble compound made by heating zinc sulphide ore in air and dissolving out and recrystallizing the sulphate. The common form is the heptahydrate,  $ZnSO_4 \cdot 7H_2O$ ; r.d. 1.9. This loses water above 30°C to give the hexahydrate and more water is lost above 70°C to form the monohydrate. The anhydrous salt forms at 280°C and this decomposes above 500°C. The compound, which was formerly called **white vitriol**, is used as a mordant and as a styptic (to check bleeding).

**zinc sulphide** A yellow-white water-soluble solid, ZnS. It occurs naturally as \*sphalerite (see also ZINC BLENDE) and wurtzite. The compound sublimates at 1180°C. It is used as a pigment and phosphor.

**zino** See SUPERSYMMETRY.

**zirconia** See ZIRCONIUM.

**zirconium** Symbol Zr. A grey-white metallic \*transition element; a.n. 40; r.a.m. 91.22; r.d. 6.49; m.p. 1852°C; b.p. 4377°C. It is found in zircon ( $ZrSiO_4$ ; the main source) and in baddeleyite ( $ZnO_2$ ). Extraction is by chlorination to give  $ZrCl_4$  which is purified by solvent extraction and reduced with magnesium (Kroll process). There are five natural isotopes (mass numbers 90, 91, 92, 94, and 96) and six radioactive isotopes are known. The element is used in nuclear reactors (it is an effective neutron absorber) and in certain alloys. The metal forms a passive layer of oxide in air and burns at 500°C. Most of its compounds are complexes of zirconium(IV). **Zirconium(IV) oxide (zirconia)** is used as an electrolyte in fuel cells. The element was identified in 1789 by Klaproth and was first isolated by Berzelius in 1824.

**zirconium(IV) oxide** See ZIRCONIUM.

**zodiac** A band that passes round the \*celestial sphere, extending 9° on either side

of the \*ecliptic. It includes the apparent paths of the sun, moon, and planets (except Pluto). The band is divided into the twelve **signs of the zodiac**, each 30° wide. These signs indicate the sun's position each month in the year and were named by the ancient Greeks after the **zodiacal constellations** that occupied the signs some 2000 years ago. However, as a result of the \*precession of the equinoxes the constellations have since moved eastwards by over 30° and no longer coincide with the signs.

**zodiacal light** A faint luminous glow in the sky that can be observed on a moonless night on the western horizon after sunset or on the eastern horizon before sunrise. It is caused by the scattering of sunlight by dust particles in interplanetary space.

**zonation** The distribution of the different species of a community into separate zones, which are created by variations in the environment. A clear example of zonation occurs on a rocky shore, where different species of seaweed (*Fucus*) occupy different zones, according to their ability to withstand desiccation. For example, the species found in the splash zone, which is never completely submerged in water, is better adapted to exposure than those found in zones lower down the shore, where they are submerged for longer periods. Animals, particularly stationary species, such as barnacles, also exhibit zonation on a rocky shore; as with the seaweeds, this may depend on the ability of different species to withstand desiccation. Competition between species may also contribute to zonation.

**zone fossil** See INDEX FOSSIL.

**zone refining** A technique used to reduce the level of impurities in certain metals, alloys, semiconductors, and other materials. It is based on the observation that the solubility of an impurity may be different in the liquid and solid phases of a material. To take advantage of this observation, a narrow molten zone is moved along the length of a specimen of the material, with the result that the impurities are segregated at one end of the bar and the pure material at the other. In general, if the impurities lower the melting point

of the material they are moved in the same direction as the molten zone moves, and vice versa.

**zoogeography** The study of the geographical distributions of animals. The earth can be divided into several zoogeographical regions separated by natural barriers, such as oceans, deserts, and mountain ranges. The characteristics of the fauna of each region are believed to depend particularly on the process of \*continental drift and the stage of evolution reached when the various land masses became isolated. For example Australia, which has been isolated since Cretaceous times, has the most primitive native mammalian fauna, consisting solely of marsupials and monotremes. See also WALLACE'S LINE.

**zoology** The scientific study of animals, including their anatomy, physiology, biochemistry, genetics, ecology, evolution, and behaviour.

**zooplankton** The animal component of \*plankton. All major animal phyla are represented in zooplankton, as adults, larvae, or eggs; some are just visible to the naked eye but most cannot be seen without magnification. Near the surface of the sea there may be many thousands of such animals per cubic metre.

**zoospore** A spore that possesses one or more flagella and is therefore motile. Released from a sporangium (called a **zoosporangium**), zoospores are produced by many algae and certain other protocists, such as the potato blight (*Phytophthora infestans*).

**zwitterion (ampholyte ion)** An ion that has a positive and negative charge on the same group of atoms. Zwitterions can be formed from compounds that contain both acid groups and basic groups in their molecules. For example, aminoethanoic acid (the amino acid glycine) has the formula  $\text{H}_2\text{N}\cdot\text{CH}_2\cdot\text{COOH}$ . However, under neutral conditions, it exists in the form of the zwitterion  $^+\text{H}_3\text{N}\cdot\text{CH}_2\cdot\text{COO}^-$ , which can

be regarded as having been produced by an internal neutralization reaction (transfer of a proton from the carboxyl group to the amino group). Aminoethanoic acid, as a consequence, has some properties characteristic of ionic compounds; e.g. a high melting point and solubility in water. In acid solutions, the positive ion  $^+\text{H}_3\text{NCH}_2\text{COOH}$  is formed. In basic solutions, the negative ion  $\text{H}_2\text{NCH}_2\text{COO}^-$  predominates. The name comes from the German *zwei*, two.

**zygomorphy** See BILATERAL SYMMETRY.

**Zygomycota** A phylum of saprotrophic or parasitic fungi that includes the bread mould (*Mucor*). Their hyphae lack cross walls and they can reproduce asexually by sporangiospores formed within a \*sporangium or sexually by means of \*zygospores.

**zygospore** A zygote with a thick resistant wall, formed by some algae and fungi (see ZYGOMYCOTA). It results from the fusion of two gametes, neither of which is retained by the parent in any specialized sex organ (such as an oogonium). It enters a resting phase before germination. Compare OOSPORE.

**zygote** A fertilized female \*gamete: the product of the fusion of the nucleus of the ovum or ovule with the nucleus of the sperm or pollen grain. See FERTILIZATION.

**zygotene** The second phase of the first \*prophase of meiosis, in which \*pairing (synapsis) of homologous chromosomes takes place. Intimate contact is made between identical regions of homologues, in a process involving proteins and DNA organized to form a **synaptonemal complex**.

**zymogen** Any inactive enzyme precursor that, following secretion, is chemically altered to the active form of the enzyme. For example, the protein-digesting enzyme \*trypsin is secreted by the pancreas as the zymogen trypsinogen. This is changed in the small intestine by the action of another enzyme, enterokinase, to the active form.

## Appendix 1. SI units

**TABLE 1.1 Base and dimensionless SI units**

Physical quantity	Name	Symbol
length	metre	m
mass	kilogram	kg
time	second	s
electric current	ampere	A
thermodynamic temperature	kelvin	K
luminous intensity	candela	cd
amount of substance	mole	mol
*plane angle	radian	rad
*solid angle	steradian	sr

## Appendix 8. Useful websites

**BioMedNet** <http://gateways.bmn.com>

An innovative and useful portal for bioscientists with research news, profiles, and Web resources.

**Chemdex** [www.chemdex.org](http://www.chemdex.org)

An online directory of chemistry on the web established in 1993 and containing over 5000 links to further resources.

**Human Proteome Organization** [www.hupo.org](http://www.hupo.org)

A starting point for insights into the pioneering and rapidly developing world of proteomics. HUPO is the international body responsible for consolidating and coordinating the work of national and regional proteomics groups.

**IUPAC Nomenclature** [www.chem.qmul.ac.uk/iupac](http://www.chem.qmul.ac.uk/iupac)

A large amount of information on organic and biochemical nomenclature held at Queen Mary College, University of London.

**Nature Magazine Online** [www.nature.com](http://www.nature.com)

An online weekly journal that offers news articles and features, complete reference works online, and information on the latest science research.

**NASA** [www.nasa.gov/home](http://www.nasa.gov/home)

Contains a large amount of information on the solar system and space science.

**National Institute of Standards and Technology** [www.nist.gov](http://www.nist.gov)

A large amount of information about units and constants.

**New Scientist** [www.newscientist.com](http://www.newscientist.com)

A popular news and archive site for all branches of science.

**Nobel Foundation** [www.nobel.se](http://www.nobel.se)

Information about Nobel prize winners and their work.

**Physics Central** [www.physicscentral.com](http://www.physicscentral.com)

A site run by the American Physical Society. It contains a searchable collection of articles on all branches of physics.

**Royal Botanic Gardens, Kew** [www.rbgekew.org.uk](http://www.rbgekew.org.uk)

Besides an introduction and special features about the UK's premier plant collection, there is a wealth of information about horticulture, plant conservation, and other plant sciences.

**Royal Society of Chemistry** [www.chemsoc.org/timeline](http://www.chemsoc.org/timeline)

An exploration of key events in the history of science with a particular emphasis on chemistry.

**Scientific American** [www.sciam.com](http://www.sciam.com)

A popular science news site containing selected recent articles.

**Society for Conservation Biology** <http://conbio.net>

An information site from the international professional organization dedicated to promoting the scientific study of the phenomena that affect the maintenance, loss, and restoration of biological diversity.

**Webelements** [www.webelements.com](http://www.webelements.com)

A periodic table at the University of Sheffield linked to a very comprehensive database of the elements and their compounds.

**ZSL (Zoological Society of London)** [www.zsl.org](http://www.zsl.org)

This site contains links to London Zoo, Whipsnade Wild Animal Park, and the ZSL's research division, the Institute of Zoology.

# Preface

This fifth edition of *A Dictionary of Science*, like its predecessors, aims to provide school and first-year university students with accurate explanations of any unfamiliar words they might come across in the course of their studies, in their own or adjacent disciplines. For example, students of the physical sciences will find all they are likely to need to know about the life sciences, and vice versa. The dictionary is also designed to provide non-scientists with a useful reference source to explain the scientific terms that they may encounter in their work or in their general reading.

At this level the dictionary provides full coverage of terms, concepts, and laws relating to physics, chemistry, biology, biochemistry, palaeontology, and the earth sciences. There is also coverage of key terms in astronomy, cosmology, mathematics, biotechnology, and computer technology. In addition, the dictionary includes:

- over 160 short biographical entries on the most important scientists in the history of the subject
- ten features (each of one or two pages) on concepts of special significance in modern science
- ten chronologies showing the development of selected concepts, fields of study, and industries
- eight Appendices, including the periodic table, tables of SI units and conversion tables to and from other systems of units, summary classifications of the plant and animal kingdoms, and useful websites.

For this fifth edition over 300 new entries have been added to the text, incorporating recent advances in all the major fields and increased coverage of climatology, seismology, and computing.

In compiling the dictionary, the contributors and editors have made every effort to make the entries as concise and comprehensible as possible, always bearing in mind the needs of the readers. Particular features of the book are its lack of unnecessary scientific jargon and its extensive network of cross-references. An asterisk placed before a word used in an entry indicates that this word can be looked up in the dictionary and will provide further explanation or clarification. However, not every word that is defined in the dictionary has an asterisk placed before it when it is used in an entry. Some entries simply refer the reader to another entry, indicating either that they are synonyms or abbreviations or that they are most conveniently explained in one of the dictionary's longer articles. Synonyms and abbreviations are usually placed within brackets immediately after the headword. Terms that are explained within an entry are highlighted by being printed in boldface type. Where appropriate, the entries have been supplemented by fully labelled line-drawings or tables *in situ*.

**aa** See LAVA.

**AAS** See ATOMIC ABSORPTION SPECTROSCOPY.

**ab-** A prefix attached to the name of a practical electrical unit to provide a name for a unit in the electromagnetic system of units (see ELECTROMAGNETIC UNITS), e.g. abampere, abcoulomb, abvolt. The prefix is an abbreviation of the word 'absolute' as this system is also known as the **absolute system**. Compare STAT-. In modern practice both absolute and electrostatic units have been replaced by \*SI units.

**abdomen** The posterior region of the body trunk of animals. In vertebrates it contains the stomach and intestines and the organs of excretion and reproduction. It is particularly well defined in mammals, being separated from the \*thorax by the \*diaphragm. In many arthropods, such as insects and spiders, it may be segmented.

**Abelian group** See GROUP.

**aberration 1.** (in optics) A defect in the image formed by a lens or curved mirror. In **chromatic aberration** the image formed by a lens (but not a mirror) has coloured fringes as a result of the different extent to which light of different colours is refracted by glass. It is corrected by using an \*achromatic lens. In **spherical aberration**, the rays from the object come to a focus in slightly different positions as a result of the curvature of the lens or mirror. For a mirror receiving light strictly parallel with its axis, this can be corrected by using a parabolic surface rather than a spherical surface. Spherical aberration in lenses is minimized by making both surfaces contribute equally to the ray deviations, and can (though with reduced image brightness) be reduced by the use of diaphragms to let light pass only through the centre part of the lens. See also ASTIGMATISM; COMA. **2.** (in astronomy) The apparent displacement in the

position of a star as a result of the earth's motion round the sun. Light appears to come from a point that is slightly displaced in the direction of the earth's motion. The angular displacement  $\alpha = v/c$ , where  $v$  is the earth's orbital velocity and  $c$  is the speed of light.

**abiogenesis** The origin of living from nonliving matter, as by \*biopoiesis. See also SPONTANEOUS GENERATION.

**abiotic factor** Any of the nonliving factors that make up the **abiotic environment** in which living organisms occur. They include all the aspects of climate, geology, and atmosphere that may affect the biotic environment. Compare BIOTIC FACTOR.

**abomasum** The fourth and final chamber of the stomach of ruminants. It leads from the \*omasum and empties into the small intestine. The abomasum is referred to as the 'true stomach' as it is in this chamber that protein digestion occurs, in acidic conditions. See RUMINANTIA.

**ABO system** One of the most important human \*blood group systems. The system is based on the presence or absence of \*antigens A and B on the surface of red blood cells and of \*antibodies against these in blood serum. A person whose blood contains either or both these antibodies cannot receive a transfusion of blood containing the corresponding antigens as this would cause the red cells to clump (see AGGLUTINATION). The table illustrates the basis of the system: people of blood group O are described as 'universal donors' as they can give blood to those of any of the other groups. See also IMMUNE RESPONSE.

**abscisic acid** A naturally occurring plant \*growth substance that appears to be involved primarily in seed maturation, stress responses (e.g. to heat and water-logging), and in regulating closure of leaf

Group	Antigens on red cell surface	Antibodies in serum	Blood group of people donor can receive blood from	Blood group of people donor can give blood to
A	A	anti-B	A, O	A, AB
B	B	anti-A	B, O	B, AB
AB	A and B	none	A, B, AB, O	AB
O	neither A nor B	anti-A and anti-B	O	A, B, AB, O

### The ABO blood group system

pores (stomata). In seeds, it promotes the synthesis of storage protein and prevents premature germination. In leaves, abscisic acid is produced in large amounts when the plant lacks sufficient water, promoting closure of stomata and hence reducing further water losses. It was formerly believed to play a role in \*abscission, hence the name.

**abscissa** See CARTESIAN COORDINATES.

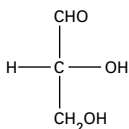

**abscission** The separation of a leaf, fruit, or other part from the body of a plant. It involves the formation of an **abscission zone**, at the base of the part, within which a layer of cells (**abscission layer**) breaks down. This process is suppressed so long as sufficient amounts of \*auxin, a plant growth substance, flow from the part through the abscission zone. However, if the auxin flow declines, for example due to injury or ageing, abscission is activated and the part becomes separated.

**absolute 1.** Not dependent on or relative to anything else, e.g. \*absolute zero. **2.** Denoting a temperature measured on an **absolute scale**, a scale of temperature based on absolute zero. The usual absolute scale now is that of thermodynamic \*temperature; its unit, the kelvin, was formerly called the degree absolute (°A) and is the same size as the degree Celsius. In British engineering practice an absolute scale with Fahrenheit-size degrees has been used: this is the Rankine scale.

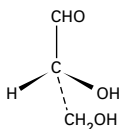

**absolute alcohol** See ETHANOL.

**absolute configuration** A way of denoting the absolute structure of an optical isomer (see OPTICAL ACTIVITY). Two conventions are in use: The D-L convention re-

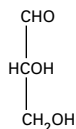

lates the structure of the molecule to some reference molecule. In the case of sugars and similar compounds, the dextrorotatory form of glyceraldehyde ( $\text{HOCH}_2\text{CH}(\text{OH})\text{CHO}$ ), 2,3-dihydroxypropanal) was used. The rule is as follows. Write the structure of this molecule down with the asymmetric carbon in the centre, the -CHO group at the top, the -OH on the right, the -CH<sub>2</sub>OH at the bottom, and the -H on the left. Now imagine that the central carbon atom is at the centre of a tetrahedron with the four groups at the corners and that the -H and -OH come out of the paper and the -CHO and -CH<sub>2</sub>OH groups go into the paper. The resulting three-dimensional structure was taken to be that of *d*-glyceraldehyde and called *D*-glyceraldehyde. Any compound that contains an asymmetric carbon atom having this configuration belongs to the *D*-series. One having the opposite configuration belongs to the *L*-series. It is important to note that the prefixes *D*- and *L*- do not stand for dextrorotatory and laevorotatory (they are not the same as *d*- and *l*-). In fact the arbitrary configuration assigned to *D*-glyceraldehyde is now known to be the correct one for the dextrorotatory form, although this was not known at the time. However, all *D*-compounds are not dextrorotatory. For instance, the acid obtained by oxidizing the -CHO group of glyceraldehyde is glyceric acid (1,2-dihydroxypropanoic acid). By convention, this belongs to the *D*-series, but it is in fact laevorotatory; i.e. its name can be written as *D*-glyceric acid or *l*-glyceric acid. To avoid confusion it is better to use + (for dextrorotatory) and - (for laevorotatory), as in *D*(+)-glyceraldehyde and *D*(-)-glyceric acid.

planar formula

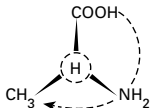

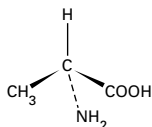

structure in 3 dimensions

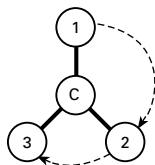

Fischer projection

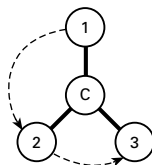

D-L convention: D-(+)-glyceraldehyde (2,3-dihydroxypropanal)

D-L convention: D-alanine (R is  $\text{CH}_2$  in the CORN rule); the molecule is viewed with H on top

R-configuration

S-configuration

R-S system: the lowest priority group is behind the chiral carbon atom

The D-L convention can also be used with alpha amino acids (compounds with the  $-\text{NH}_2$  group on the same carbon as the  $-\text{COOH}$  group). In this case the molecule is imagined as being viewed along the H-C bond between the hydrogen and the asymmetric carbon atom. If the clockwise order of the other three groups is  $-\text{COOH}$ ,  $-\text{R}$ ,  $-\text{NH}_2$ , the amino acid belongs to the D-series; otherwise it belongs to the L-series. This is known as the **CORN rule**.

The R-S convention is a convention based on priority of groups attached to the chiral carbon atom. The order of priority is I, Br, Cl,  $\text{SO}_3\text{H}$ ,  $\text{OCOCH}_3$ ,  $\text{OCH}_3$ , OH,  $\text{NO}_2$ ,  $\text{NH}_2$ ,  $\text{COOCH}_3$ ,  $\text{CONH}_2$ ,  $\text{COCH}_3$ , CHO,  $\text{CH}_2\text{OH}$ ,  $\text{C}_6\text{H}_5$ ,  $\text{C}_2\text{H}_5$ ,  $\text{CH}_3$ , H, with hydrogen lowest. The molecule is viewed with the group of lowest priority behind the chiral atom. If the clockwise arrangement of the other three groups is in descending priority, the compound belongs

to the R-series; if the descending order is anticlockwise it is in the S-series. D-(+)-glyceraldehyde is R-(+)-glyceraldehyde. See illustration.

**absolute expansivity** See EXPANSIVITY.

**absolute humidity** See HUMIDITY.

**absolute permittivity** See PERMITTIVITY.

**absolute pitch (perfect pitch)** The ability of a person to identify and reproduce a note without reference to a tuned musical instrument.

**absolute temperature** See ABSOLUTE; TEMPERATURE.

**absolute value (modulus)** The square root of the sum of the squares of the real numbers in a complex number, i.e. the absolute value of the complex number  $z = x + iy$  is  $|z| = \sqrt{x^2 + y^2}$ .

**absolute zero** Zero of thermodynamic \*temperature (0 kelvin) and the lowest temperature theoretically attainable. It is the temperature at which the kinetic energy of atoms and molecules is minimal. It is equivalent to  $-273.15^{\circ}\text{C}$  or  $-459.67^{\circ}\text{F}$ . See also ZERO-POINT ENERGY; CRYOGENICS.

**absorbed dose** See DOSE.

**absorptance** Symbol  $\alpha$ . The ratio of the radiant or luminous flux absorbed by a body to the flux falling on it. Formerly called **absorptivity**, the absorptance of a \*black body is by definition 1.

**absorption 1.** (in chemistry) The take up of a gas by a solid or liquid, or the take up of a liquid by a solid. Absorption differs from \*adsorption in that the absorbed substance permeates the bulk of the absorbing substance. **2.** (in physics) The conversion of the energy of electromagnetic radiation, sound, streams of particles, etc., into other forms of energy on passing through a medium. A beam of light, for instance, passing through a medium, may lose intensity because of two effects: \*scattering of light out of the beam, and absorption of photons by atoms or molecules in the medium. When a photon is absorbed, there is a transition to an excited state. **3.** (in biology) The movement of fluid or a dissolved substance across a plasma membrane. In many animals, for example, soluble food material is absorbed into cells lining the alimentary canal and thence into the blood. In plants, water and mineral salts are absorbed from the soil by the \*roots. See OSMOSIS; TRANSPORT PROTEIN.

**absorption coefficient 1.** (in physics) See LAMBERT'S LAWS. **2.** (in chemistry) The volume of a given gas, measured at standard temperature and pressure, that will dissolve in unit volume of a given liquid.

**absorption indicator** See ADSORPTION INDICATOR.

**absorption spectrum** See SPECTRUM.

**absorptivity** See ABSORPTANCE.

**ABS plastic** Any of a class of plastics based on acrylonitrile-butadiene-styrene copolymers.

**abundance 1.** The ratio of the total

mass of a specified element in the earth's crust to the total mass of the earth's crust, often expressed as a percentage. For example, the abundance of aluminium in the earth's crust is about 8%. **2.** The ratio of the number of atoms of a particular isotope of an element to the total number of atoms of all the isotopes present, often expressed as a percentage. For example, the abundance of uranium-235 in natural uranium is 0.71%. This is the **natural abundance**, i.e. the abundance as found in nature before any enrichment has taken place.

**abyssal zone** The lower depths of the ocean (below approximately 2000 metres), where there is effectively no light penetration. Abyssal organisms are adapted for living under high pressures in cold dark conditions. See also APHOTIC ZONE.

**a.c.** See ALTERNATING CURRENT.

**acceleration** Symbol  $a$ . The rate of increase of speed or velocity. It is measured in  $\text{m s}^{-2}$ . For a body moving linearly with constant acceleration  $a$  from a speed  $u$  to a speed  $v$ ,

$$a = (v - u)/t = (v^2 - u^2)/2s$$

where  $t$  is the time taken and  $s$  the distance covered.

If the acceleration is not constant it is given by  $dv/dt = d^2s/dt^2$ . If the motion is not linear the vector character of displacement, velocity, and acceleration must be considered. See also ROTATIONAL MOTION.

**acceleration of free fall** Symbol  $g$ . The acceleration experienced by any massive object falling freely in the earth's gravitational field. Experimentally this is almost constant for all positions near the earth's surface, independent of the nature of the falling body (provided air resistance is eliminated). This is taken to indicate the strict proportionality of \*weight (the force causing the acceleration) and \*inertial mass, on the basis of \*Newton's second law of motion. There is some variation of  $g$  with latitude, because of the earth's rotation and because the earth is not completely spherical. The standard value is taken as  $9.80665 \text{ m s}^{-2}$ . The acceleration of free fall is also called the **acceleration due to gravity**.

**accelerator 1.** (in physics) An apparatus for increasing the kinetic energies of charged particles, used for research in nuclear and particle physics. *See* CYCLOTRON; LINEAR ACCELERATOR; SYNCHROCYCLOTRON; SYNCHROTRON. **2.** (in chemistry) A substance that increases the rate of a chemical reaction, i.e. a catalyst.

**acceptor 1.** (in chemistry and biochemistry) A compound, molecule, ion, etc., to which electrons are donated in the formation of a coordinate bond. **2.** (in biochemistry) A \*receptor that binds a hormone without any apparent biological response. **3.** (in physics) A substance that is added as an impurity to a \*semiconductor because of its ability to accept electrons from the valence bands, causing *p*-type conduction by the mobile positive holes left. *Compare* DONOR.

**acceptor levels** Energy levels of an acceptor atom in a \*semiconductor, such as aluminium, in silicon. These energy levels are very near the top of the valence band, and therefore cause *p*-type conduction. *See also* ENERGY BAND.

**acclimation** The physiological changes occurring in an organism in response to a change in a particular environmental factor (e.g. temperature), especially under laboratory conditions. Thermal acclimation studies reveal how such properties as metabolic rate, muscle contractility, nerve conduction, and heart rate differ between cold- and warm-acclimated members of the same species. These changes occur naturally during \*acclimatization and equip the organism for living in, say, cold or warm conditions.

**acclimatization 1.** The progressive adaptation of an organism to any change in its natural environment that subjects it to physiological stress. **2.** The overall sum of processes by which an organism attempts to compensate for conditions that would substantially reduce the amount of oxygen delivered to its cells. *Compare* ACCLIMATION.

**accommodation 1.** (in animal physiology) Focusing: the process by which the focal length of the \*lens of the eye is changed so that clear images of objects at a range of distances are displayed on the

retina. In humans and some other mammals accommodation is achieved by reflex adjustments in the shape of the lens brought about by relaxation and contraction of muscles within the \*ciliary body.

**2.** (in animal behaviour) Adjustments made by an animal's nervous or sensory systems in response to continuously changing environmental conditions.

**accretion** The way in which collisions with relatively slow-moving smaller objects add to the mass of a larger celestial object. The process accelerates as the increased mass strengthens the gravitational field of the larger object. For example, the planets are thought to have formed by the accretion of dust particles onto \*planetesimals. Other accreting objects probably include black holes and protostars.

**accretion disc** A disc-shaped rotating mass formed by gravitational attraction. *See* BLACK HOLE; NEUTRON STAR; WHITE DWARF.

**accumulator (secondary cell; storage battery)** A type of \*voltaic cell or battery that can be recharged by passing a current through it from an external d.c. supply. The charging current, which is passed in the opposite direction to that in which the cell supplies current, reverses the chemical reactions in the cell. The common types are the \*lead-acid accumulator and the \*nickel-iron and nickel-cadmium accumulators. *See also* SODIUM-SULPHUR CELL.

**acellular** Describing tissues or organisms that are not made up of separate cells but often have more than one nucleus (*see* SYNCYTIUM). Examples of acellular structures are muscle fibres. *Compare* UNICELLULAR.

**acentric** Describing an aberrant chromosome fragment that lacks a centromere. Such fragments are normally lost because they are unable to orientate properly during cell division.

**acetaldehyde** *See* ETHANAL.

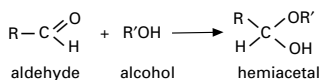

**acetaldo** *See* ALDOL REACTION.

**acetals** Organic compounds formed by addition of alcohol molecules to aldehyde molecules. If one molecule of aldehyde

a

(RCHO) reacts with one molecule of alcohol (R'OH) a **hemiacetal** is formed (RCH(OH)OR'). The rings of aldose sugars are hemiacetals. Further reaction with a second alcohol molecule produces a full acetal (RCH(OR')<sub>2</sub>). It is common to refer to both types of compounds simply as 'acetals'. The formation of acetals is reversible; acetals can be hydrolysed back to aldehydes in acidic solutions. In synthetic organic chemistry aldehyde groups are often converted into acetal groups to protect them before performing other reactions on different groups in the molecule. See also KETALS.

Formation of acetals

**acetamide** See ETHANAMIDE.

**acetanilide** A white crystalline primary amide of ethanoic acid, CH<sub>3</sub>C(=O)NH<sub>2</sub>; r.d. 1.2; m.p. 114.3°C; b.p. 304°C. It is made by reacting phenylamine (aniline) with excess ethanoic acid or ethanoic anhydride and is used in the manufacture of dyestuffs and rubber. The full systematic name is **N-phenylethanamide**.

**acetate** See ETHANOATE.

**acetate process** See RAYON.

**acetic acid** See ETHANOIC ACID.

**acetoacetic acid** See 3-OXOBUTANOIC ACID.

**acetoacetic ester** See ETHYL 3-OXOBUTANOATE.

**acetone** See PROPANONE; KETONE BODY.

**acetylation** See ACYLATION.

**acetyl chloride** See ETHANOYL CHLORIDE.

**acetylcholine (ACh)** One of the main \*neurotransmitters of the vertebrate nervous system. It is released at some (cholinergic) nerve endings and may be excitatory or inhibitory; it initiates mus-

cular contraction at \*neuromuscular junctions. Once acetylcholine has been released it has only a transitory effect because it is rapidly broken down by the enzyme \*cholinesterase.

**acetylcholinesterase** See CHOLINESTERASE.

**acetyl coenzyme A (acetyl CoA)** A compound formed in the mitochondria when an acetyl group (CH<sub>3</sub>CO-), derived from the breakdown of fats, proteins, or carbohydrates (via \*glycolysis), combines with the thiol group (-SH) of \*coenzyme A. Acetyl CoA feeds into the energy generating \*Krebs cycle and also plays a role in the synthesis and oxidation of fatty acids.

**acetylene** See ETHYNE.

**acetylenes** See ALKYNES.

**acetyl group** See ETHANOYL GROUP.

**acetylide** See CARBIDE.

**achene** A dry indehiscent fruit formed from a single carpel and containing a single seed. An example is the feathery achene of clematis. Variants of the achene include the \*caryopsis, \*cypsela, \*nut, and \*samara. See also ETAERIO.

**Acheson process** An industrial process for the manufacture of graphite by heating coke mixed with clay. The reaction involves the production of silicon carbide, which loses silicon at 4150°C to leave graphite. The process was patented in 1896 by the US inventor Edward Goodrich Acheson (1856–1931).

**achondrite** A stony meteorite that has no spherical silicate particles (chondrules) found in the meteorites called chondrites. Achondrites do not contain iron or nickel and have a coarser crystal structure than chondrites.

**achromatic lens** A lens that corrects for chromatic \*aberration by using a combination of two lenses, made of different kinds of glass, such that their \*dispersions neutralize each other although their \*refractions do not. The aberration can be reduced further by using an **apochromatic lens**, which consists of three or more different kinds of glass.

**acid 1.** A type of compound that con-

tains hydrogen and dissociates in water to produce positive hydrogen ions. The reaction, for an acid HX, is commonly written:

In fact, the hydrogen ion (the proton) is solvated, and the complete reaction is:

The ion  $\text{H}_3\text{O}^+$  is the **oxonium ion** (or **hydroxonium ion** or **hydronium ion**). This definition of acids comes from the **Arrhenius theory**. Such acids tend to be corrosive substances with a sharp taste, which turn litmus red and give colour changes with other \*indicators. They are referred to as **protonic acids** and are classified into **strong acids**, which are almost completely dissociated in water (e.g. sulphuric acid and hydrochloric acid), and **weak acids**, which are only partially dissociated (e.g. ethanoic acid and hydrogen sulphide). The strength of an acid depends on the extent to which it dissociates, and is measured by its \*dissociation constant. See also BASE.

**2.** In the **Lowry–Brønsted theory** of acids and bases (1923), the definition was extended to one in which an acid is a proton donor, and a base is a proton acceptor. For example, in

the HCN is an acid, in that it donates a proton to  $\text{H}_2\text{O}$ . The  $\text{H}_2\text{O}$  is acting as a base in accepting a proton. Similarly, in the reverse reaction  $\text{H}_3\text{O}^+$  is an acid and  $\text{CN}^-$  a base. In such reactions, two species related by loss or gain of a proton are said to be **conjugate**. Thus, in the reaction above HCN is the **conjugate acid** of the base  $\text{CN}^-$ , and  $\text{CN}^-$  is the **conjugate base** of the acid HCN. Similarly,  $\text{H}_3\text{O}^+$  is the conjugate acid of the base  $\text{H}_2\text{O}$ . An equilibrium, such as that above, is a competition for protons between an acid and its conjugate base. A strong acid has a weak conjugate base, and vice versa. Under this definition water can act as both acid and base. Thus in

the  $\text{H}_2\text{O}$  is the conjugate acid of  $\text{OH}^-$ . The definition also extends the idea of acid-base reaction to solvents other than water. For instance, liquid ammonia, like water, has a high dielectric constant and

is a good ionizing solvent. Equilibria of the type

can be studied, in which  $\text{NH}_3$  and HCl are acids and  $\text{NH}_2^-$  and  $\text{Cl}^-$  are their conjugate bases.

**3.** A further extension of the idea of acids and bases was made in the **Lewis theory** (G. N. Lewis, 1923). In this, a **Lewis acid** is a compound or atom that can accept a pair of electrons and a **Lewis base** is one that can donate an electron pair. This definition encompasses 'traditional' acid-base reactions. In

the reaction is essentially

i.e. donation of an electron pair by  $\text{OH}^-$ . But it also includes reactions that do not involve ions, e.g.

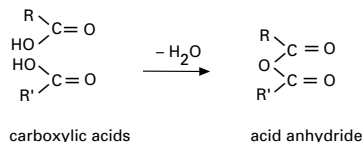

in which  $\text{NH}_3$  is the base (donor) and  $\text{BCl}_3$  the acid (acceptor). The Lewis theory establishes a relationship between acid-base reactions and \*oxidation–reduction reactions. See also AQUA ACID; HYDROXOACID; OXOACID.

**acid anhydrides (acyl anhydrides)** Compounds that react with water to form an acid. For example, carbon dioxide reacts with water to give carbonic acid:

A particular group of acid anhydrides are anhydrides of carboxylic acids. They have a general formula of the type  $\text{R.CO.O.CO.R}'$ , where R and R' are alkyl or aryl groups. For example, the compound ethanoic anhydride ( $\text{CH}_3\text{CO.O.CO.CH}_3$ ) is the acid anhydride of ethanoic (acetic) acid. Organic acid anhydrides can be produced by dehydrating acids (or mixtures of acids). They are usually made by react-

Formation of a carboxylic acid anhydride

ing an acyl halide with the sodium salt of the acid. They react readily with water, alcohols, phenols, and amines and are used in \*acylation reactions.

**acid-base balance** The regulation of the concentrations of acids and bases in blood and other body fluids so that the pH remains within a physiologically acceptable range. This is achieved by the presence of natural \*buffer systems, such as the haemoglobin, hydrogencarbonate ions, and carbonic acid in mammalian blood. By acting in conjunction, these effectively mop up excess acids and bases and therefore prevent any large shifts in blood pH. The acid-base balance is also influenced by the selective removal of certain ions by the kidneys and the rate of removal of carbon dioxide from the lungs.

**acid-base indicator** See INDICATOR.

**acid dissociation constant** See DISSOCIATION.

**acid dye** See DYES.

**acid halides** See ACYL HALIDES.

**acidic 1.** Describing a compound that is an acid. **2.** Describing a solution that has an excess of hydrogen ions. **3.** Describing a compound that forms an acid when dissolved in water. Carbon dioxide, for example, is an acidic oxide.

**acidic hydrogen (acid hydrogen)** A hydrogen atom in an \*acid that forms a positive ion when the acid dissociates. For instance, in methanoic acid

the hydrogen atom on the carboxylate group is the acidic hydrogen (the one bound directly to the carbon atom does not dissociate).

**acidic stains** See STAINING.

**acidimetry** Volumetric analysis using standard solutions of acids to determine the amount of base present.

**acidity constant** See DISSOCIATION.

**acid rain** Precipitation having a pH value of less than about 5.0, which has adverse effects on the fauna and flora on which it falls. Rainwater typically has a pH value of 5.6, due to the presence of dissolved carbon dioxide (forming carbonic

acid). Acid rain results from the emission into the atmosphere of various pollutant gases, in particular sulphur dioxide and various oxides of nitrogen, which originate from the burning of fossil fuels and from car exhaust fumes, respectively. These gases dissolve in atmospheric water to form sulphuric and nitric acids in rain, snow, or hail (**wet deposition**). Alternatively, the pollutants are deposited as gases or minute particles (**dry deposition**). Both types of acid deposition affect plant growth - by damaging the leaves and impairing photosynthesis and by increasing the acidity of the soil, which results in the leaching of essential nutrients. This acid pollution of the soil also leads to acidification of water draining from the soil into lakes and rivers, which become unable to support fish life. Lichens are particularly sensitive to changes in pH and can be used as indicators of acid pollution (see INDICATOR SPECIES).

**acid rock** A low-density igneous rock containing a preponderance (more than 65%) of light-coloured \*silicate minerals. Examples include granite and rhyolite.

**acid salt** A salt of a polybasic acid (i.e. an acid having two or more acidic hydrogens) in which not all the hydrogen atoms have been replaced by positive ions. For example, the dibasic acid carbonic acid ( $\text{H}_2\text{CO}_3$ ) forms acid salts (hydrogencarbonates) containing the ion  $\text{HCO}_3^-$ . Some salts of monobasic acids are also known as acid salts. For instance, the compound potassium hydrogendifluoride,  $\text{KHF}_2$ , contains the ion  $[\text{F}\dots\text{H}\text{-F}]^-$ , in which there is hydrogen bonding between the fluoride ion  $\text{F}^-$  and a hydrogen fluoride molecule.

**acid value** A measure of the amount of free acid present in a fat, equal to the number of milligrams of potassium hydroxide needed to neutralize this acid. Fresh fats contain glycerides of fatty acids and very little free acid, but the glycerides decompose slowly with time and the acid value increases.

**acinus** The smallest unit of a multilobular gland, such as the pancreas. Each acinus in the pancreas is made up of a hollow cluster of **acinar cells**, which produce the digestive enzymes secreted in pancreatic juice. Minute ducts from the

pancreatic acini eventually drain into the pancreatic duct.

**acoustics** **1.** The study of sound and sound waves. **2.** The characteristics of a building, especially an auditorium, with regard to its ability to enable speech and music to be heard clearly within it. For this purpose there should be no obtrusive echoes or resonances and the reverberation time should be near the optimum for the hall. Echoes are reduced by avoiding sweeping curved surfaces that could focus the sound and by breaking up large plane surfaces or covering them with sound-absorbing materials. Resonance is avoided by avoiding simple ratios for the main dimensions of the room, so that no one wavelength of sound is a factor of more than one of them. If the reverberation time is too long, speech will sound indistinct and music will be badly articulated, with one note persisting during the next. However, if it is too short, music sounds dead. It is long in a bare room with hard walls, and can be deliberately reduced by carpets, soft furnishings and sound-absorbent ('acoustic') felt. Reverberation times tend to be reduced by the presence of an audience and this must be taken into account in the design of the building.

**acoustoelectronic devices (electro-acoustic devices)** Devices in which electronic signals are converted into acoustic waves. Acoustoelectronic devices are used in constructing \*delay lines and also in converting digital data from computers for transmission by telephone lines.

**acquired characteristics** Features that are developed during the lifetime of an individual, e.g. the enlarged arm muscles of a tennis player. Such characteristics are not genetically controlled and cannot be passed on to the next generation. *See also* LAMARCKISM; NEO-LAMARCKISM.

**acquired immune deficiency syndrome** *See* AIDS.

**Acrilan** A trade name for a synthetic fibre. *See* ACRYLIC RESINS.

**acrolein** *See* PROPENAL.

**acromegaly** A chronic condition developing in adulthood due to overproduction of (or oversensitivity to) \*growth hor-

mone, usually caused by a tumour in the pituitary gland. This leads to a gradual enlargement of the bones, causing characteristic coarsening of the facial features and large hands and feet.

**acrosome** *See* SPERMATOZOON.

**acrylamide** An inert gel (polyacrylamide) employed as a medium in \*electrophoresis. It is used particularly in the separation of macromolecules, such as nucleic acids and proteins.

**acrylate** *See* PROPENOATE.

**acrylic acid** *See* PROPENOIC ACID.

**acrylic resins** Synthetic resins made by polymerizing esters or other derivatives of acrylic acid (propenoic acid). Examples are poly(propenenitrile) (e.g. **Acrilan**), and poly(methyl 2-methylpropenoate) (polymethylmethacrylate, e.g. **Perspex**).

**acrylonitrile** *See* PROPENONITRILE.

**ACTH (adrenocorticotrophic hormone; corticotrophin)** A hormone, produced by the anterior \*pituitary gland, that controls secretion of certain hormones (the \*corticosteroids) by the adrenal glands. Its secretion, which is controlled by corticotrophin-releasing hormone and occurs in short bursts every few hours, is increased by stress.

**actin** A contractile protein found in muscle tissue, in which it occurs in the form of filaments (called thin filaments). Each thin filament consists of two chains of globular actin molecules, around which is twisted a strand of \*tropomyosin and interspersed \*troponin. Units of muscle fibre (*see* SARCOMERE) consist of actin and \*myosin filaments, which interact to bring about muscle contraction. Actin is also found in the microfilaments that form part of the \*cytoskeleton of all cells.

**actinic radiation** Electromagnetic radiation that is capable of initiating a chemical reaction. The term is used especially of ultraviolet radiation and also to denote radiation that will affect a photographic emulsion.

**actinides** *See* ACTINOIDES.

**actinium** Symbol Ac. A silvery radioactive metallic element belonging to

group 3 (formerly IIIA) of the periodic table; a.n. 89; mass number of most stable isotope 227 (half-life 21.7 years); m.p.  $1050 \pm 50^\circ\text{C}$ ; b.p.  $3200^\circ\text{C}$  (estimated). Actinium-227 occurs in natural uranium to an extent of about 0.715%. Actinium-228 (half-life 6.13 hours) also occurs in nature. There are 22 other artificial isotopes, all radioactive and all with very short half-lives. Its chemistry is similar to that of lanthanum. Its main use is as a source of alpha particles. The element was discovered by A. Debierne in 1899.

**actinium series** See RADIOACTIVE SERIES.

**Actinobacteria (Actinomycetes; Actinomycota)** A phylum of Gram-positive mostly anaerobic nonmotile bacteria. Many species are fungus-like, with filamentous cells producing reproductive spores on aerial branches similar to the spores of certain moulds. The phylum includes bacteria of the genera *Actinomyces*, some species of which cause disease in animals (including humans); and *Streptomyces*, which are a source of many important antibiotics (including streptomycin).

**actinoid contraction** A smooth decrease in atomic or ionic radius with increasing proton number found in the \*actinoids.

**actinoids (actinides)** A series of elements in the \*periodic table, generally considered to range in atomic number from thorium (90) to lawrencium (103) inclusive. The actinoids all have two outer *s*-electrons (a  $7s^2$  configuration), follow actinium, and are classified together by the fact that increasing proton number corresponds to filling of the  $5f$  level. In fact, because the  $5f$  and  $6d$  levels are close in energy the filling of the  $5f$  orbitals is not smooth. The outer electron configurations are as follows:

- 89 actinium (Ac)  $6d^1 7s^2$
- 90 thorium (Th)  $6d^2 7s^2$
- 91 protactinium (Pa)  $5f^0 6d^1 7s^2$
- 92 uranium (Ur)  $5f^0 6d^1 7s^2$
- 93 neptunium (Np)  $5f^5 7s^2$  (or  $5f^4 6d^1 7s^2$ )
- 94 plutonium (Pu)  $5f^6 7s^2$
- 95 americium (Am)  $5f^7 7s^2$
- 96 curium (Cm)  $5f^7 6d^1 s^2$
- 97 berkelium (Bk)  $5f^8 6d^1 7s^2$  (or  $5f^9 7s^2$ )

- 98 californium (Cf)  $5f^{10} 7s^2$
- 99 einsteinium (Es)  $5f^{11} 7s^2$
- 100 fermium (Fm)  $5f^{12} 7s^2$
- 101 mendelevium (Md)  $5f^{13} 7s^2$
- 102 nobelium (Nb)  $5f^{14} 7s^2$
- 103 lawrencium (Lw)  $5f^{14} 6d^1 s^2$

The first four members (Ac to Ur) occur naturally. All are radioactive and this makes investigation difficult because of self-heating, short lifetimes, safety precautions, etc. Like the \*lanthanoids, the actinoids show a smooth decrease in atomic and ionic radius with increasing proton number. The lighter members of the series (up to americium) have *f*-electrons that can participate in bonding, unlike the lanthanoids. Consequently, these elements resemble the transition metals in forming coordination complexes and displaying variable valency. As a result of increased nuclear charge, the heavier members (curium to lawrencium) tend not to use their inner *f*-electrons in forming bonds and resemble the lanthanoids in forming compounds containing the  $M^{3+}$  ion. The reason for this is pulling of these inner electrons towards the centre of the atom by the increased nuclear charge. Note that actinium itself does not have a  $5f$  electron, but it is usually classified with the actinoids because of its chemical similarities. See also TRANSITION ELEMENTS.

**actinometer** Any of various instruments for measuring the intensity of electromagnetic radiation. Recent actinometers use the \*photoelectric effect but earlier instruments depended either on the fluorescence produced by the radiation on a screen or on the amount of chemical change induced in some suitable substance.

**actinomorphism** See RADIAL SYMMETRY.

**Actinomycetes** See ACTINOBACTERIA.

**action at a distance** The direct interaction between bodies that are not in physical contact with each other. The concept involves the assumption that the interactions are instantaneous. This assumption is not consistent with the special theory of \*relativity, which states that nothing (including interactions) can travel through space faster than the \*speed of light in a vacuum. For this reason it is more logical to describe interactions be-

tween bodies by \*quantum field theories or by the exchange of virtual particles (see VIRTUAL STATE) rather than theories based on action at a distance.

**action potential** The change in electrical potential that occurs across a plasma membrane during the passage of a nerve \*impulse. As an impulse travels in a wave-like manner along the \*axon of a nerve, it causes a localized and transient switch in electric potential across the membrane from  $-60$  mV (millivolts; the \*resting potential) to  $+45$  mV. The change in electric potential is caused by an influx of sodium ions. Nervous stimulation of a muscle fibre has a similar effect.

**action spectrum** A graphical plot of the efficiency of electromagnetic radiation in producing a photochemical reaction against the wavelength of the radiation used. For example, the action spectrum for photosynthesis using light shows a peak in the region  $670$ – $700$  nm. This corresponds to a maximum absorption in the absorption \*spectrum of chlorophylls in this region.

**activated adsorption** Adsorption that involves an activation energy. This occurs in certain cases of chemisorption.

**activated alumina** See ALUMINIUM HYDROXIDE.

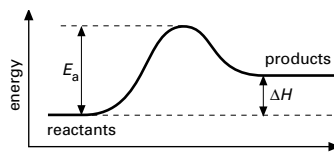

**activated charcoal** See CHARCOAL.

**activated complex** The association of atoms of highest energy formed in the \*transition state of a chemical reaction.

**activation analysis** An analytical technique that can be used to detect most elements when present in a sample in milligram quantities (or less). In **neutron activation analysis** the sample is exposed to a flux of thermal neutrons in a nuclear reactor. Some of these neutrons are captured by nuclides in the sample to form nuclides of the same atomic number but a higher mass number. These newly formed nuclides emit gamma radiation, which can be used to identify the element present by means of a gamma-ray spectrometer. Activation analysis has also been employed using high-energy charged particles, such as protons or alpha particles.

**activation energy** Symbol  $E_a$ . The min-

imum energy required for a chemical reaction to take place. In a reaction, the reactant molecules come together and chemical bonds are stretched, broken, and formed in producing the products. During this process the energy of the system increases to a maximum, then decreases to the energy of the products (see illustration). The activation energy is the difference between the maximum energy and the energy of the reactants; i.e. it is the energy barrier that has to be overcome for the reaction to proceed. The activation energy determines the way in which the rate of the reaction varies with temperature (see ARRHENIUS EQUATION). It is usual to express activation energies in joules per mole of reactants.

Reaction profile (for an endothermic reaction)

**activator 1.** A type of \*transcription factor that enhances the transcription of a gene by binding to a region of DNA called an **enhancer**. Compare REPRESSOR. **2.** A substance that - by binding to an allosteric site on an enzyme (see INHIBITION) - enables the active site of the enzyme to bind to the substrate. **3.** Any compound that potentiates the activity of a drug or other foreign substance in the body.

**active device 1.** An electronic component, such as a transistor, that is capable of amplification. **2.** An artificial \*satellite that receives information and retransmits it after amplification. **3.** A radar device that emits microwave radiation and provides information about a distant body by receiving a reflection of this radiation. Compare PASSIVE DEVICE.

**active immunity** \*Immunity acquired due to the body's response to a foreign antigen.

**active mass** See MASS ACTION.

**active site (active centre) 1.** A site on the surface of a catalyst at which activity occurs. **2.** The site on the surface of an

\*enzyme molecule that binds and acts on the substrate molecule. The properties of an active site are determined by the three-dimensional arrangement of the polypeptide chains of the enzyme and their constituent amino acids. These govern the nature of the interaction that takes place and hence the degree of substrate specificity and susceptibility to \*inhibition.

**active transport** The movement of substances through membranes in living cells, often against a \*concentration gradient: a process requiring metabolic energy. Organic molecules and inorganic ions are transported into and out of both cells and their organelles. The substance binds to a \*transport protein embedded in the membrane, which carries it through the membrane and releases it on the opposite side. Active transport serves chiefly to maintain the normal balance of ions in cells, especially the concentration gradients of sodium and potassium ions crucial to the activity of nerve and muscle cells. *Compare* FACILITATED DIFFUSION.

**activity 1.** Symbol  $a$ . A thermodynamic function used in place of concentration in equilibrium constants for reactions involving nonideal gases and solutions. For example, in a reaction

the true equilibrium constant is given by

$$K = a_B a_C / a_A$$

where  $a_A$ ,  $a_B$ , and  $a_C$  are the activities of the components, which function as concentrations (or pressures) corrected for nonideal behaviour. **Activity coefficients** (symbol  $\gamma$ ) are defined for gases by  $\gamma = a/p$  (where  $p$  is pressure) and for solutions by  $\gamma = aX$  (where  $X$  is the mole fraction). Thus, the equilibrium constant of a gas reaction has the form

$$K_p = \gamma_B \gamma_C \gamma_C / \gamma_A \gamma_A$$

The equilibrium constant of a reaction in solution is

$$K_c = \gamma_B \gamma_B \gamma_C X_C / \gamma_A X_A$$

The activity coefficients thus act as correction factors for the pressures or concentrations. *See also* FUGACITY.

**2.** Symbol  $A$ . The number of atoms of a radioactive substance that disintegrate per

unit time. The **specific activity** ( $a$ ) is the activity per unit mass of a pure radioisotope. *See* RADIATION UNITS.

**activity series** *See* ELECTROMOTIVE SERIES.

**acyclic** Describing a compound that does not have a ring in its molecules.

**acyclovir (acycloguanosine)** A drug used to treat cold sores, shingles, genital blisters, or other lesions caused by herpesvirus infection. It is an analogue of the base guanine and acts by interfering with DNA replication of the virus.

**acyl anhydrides** *See* ACID ANHYDRIDES.

**acylation** The process of introducing an acyl group ( $\text{RCO}-$ ) into a compound. The usual method is to react an alcohol with an acyl halide or a carboxylic acid anhydride; e.g.

The introduction of an acetyl group ( $\text{CH}_3\text{CO}-$ ) is **acetylation**, a process used for protecting  $-\text{OH}$  groups in organic synthesis.

**acyl fission** The breaking of the carbon-oxygen bond in an acyl group. It occurs in the hydrolysis of an \*ester to produce an alcohol and a carboxylic acid.

**acylglycerol** *See* GLYCERIDE.

**acyl group** A group of the type  $\text{RCO}-$ , where  $\text{R}$  is an organic group. An example is the acetyl group  $\text{CH}_3\text{CO}-$ .

**acyl halides (acid halides)** Organic compounds containing the group  $-\text{COX}$ , where  $\text{X}$  is a halogen atom (see formula). Acyl chlorides, for instance, have the general formula  $\text{RCOCl}$ . The group  $\text{RCO}-$  is the **acyl group**. In systematic chemical nomenclature acyl-halide names end in the suffix *-oyl*; for example, ethanoyl chloride,  $\text{CH}_3\text{COCl}$ . Acyl halides react readily with water, alcohols, phenols, and amines and are used in \*acylation reactions. They are made by replacing the  $-\text{OH}$  group in a carboxylic acid by a halogen using a halogenating agent such as  $\text{PCl}_5$ .

Acyl halide:  $\text{X}$  is a halogen atom

**Ada** A high-level computer programming language developed in the late 1970s for the US military. It was originally employed in missile control systems and is now used in various other real-time applications. Ada was named after Augusta Ada Lovelace (1815–52), the mathematician daughter of Lord Byron, who worked with Charles \*Babbage on his mechanical computer, the ‘analytical engine’.

**Adams, John Couch** (1819–92) British astronomer who became professor of astronomy and geometry at Cambridge University in 1858. He is best known for his prediction (1845) of the existence and position of the planet \*Neptune, worked out independently the following year by Urbain Leverrier (1811–77). The planet was discovered in 1846 by Johann Galle (1812–1910), using Leverrier’s figures. Adams’s priority was not acknowledged.

**adaptation 1.** (in evolution) Any change in the structure or functioning of an organism that makes it better suited to its environment. \*Natural selection of inheritable adaptations ultimately leads to the development of new species. Increasing adaptation of a species to a particular environment tends to diminish its ability to adapt to any sudden change in that environment. **2.** (in physiology) The alteration in the degree of sensitivity (either an increase or a decrease) of a sense organ to suit conditions more extreme than normally encountered. An example is the adjustment of the eye to vision in very bright or very dim light.

**adaptive radiation (divergent evolution)** The evolution from one species of animals or plants of a number of different forms. As the original population increases in size it spreads out from its centre of origin to exploit new habitats and food sources. In time this results in a number of populations each adapted to its particular habitat: eventually these populations will differ from each other sufficiently to become new species. A good example of this process is the evolution of the Australian marsupials into species adapted as carnivores, herbivores, burrowers, fliers, etc. On a smaller scale, the adaptive radiation of the Galapagos finches provided Darwin with crucial evi-

dence for his theory of evolution (see DARWIN’S FINCHES).

**addition polymerization** See POLYMERIZATION.

**addition reaction** A chemical reaction in which one molecule adds to another. Addition reactions occur with unsaturated compounds containing double or triple bonds, and may be \*electrophilic or \*nucleophilic. An example of electrophilic addition is the reaction of hydrogen chloride with an alkene, e.g.

An example of nucleophilic addition is the addition of hydrogen cyanide across the carbonyl bond in aldehydes to form \*cyanohydrins. **Addition–elimination** reactions are ones in which the addition is followed by elimination of another molecule (see CONDENSATION REACTION).

**additive** A substance added to another substance or material to improve its properties in some way. Additives are often present in small amounts and are used for a variety of purposes, as in preventing corrosion, stabilizing polymers, etc. **Food additives** are used to enhance the taste and colour of foods and improve their texture and keeping qualities. See FOOD PRESERVATION.

**additive process** See COLOUR.

**adduct** A compound formed by an addition reaction. The term is used particularly for compounds formed by coordination between a Lewis acid (acceptor) and a Lewis base (donor). See ACID.

**adenine** A \*purine derivative. It is one of the major component bases of \*nucleotides and the nucleic acids \*DNA and \*RNA.

**adenosine** A nucleoside comprising one adenine molecule linked to a D-ribose sugar molecule. The phosphate-ester derivatives of adenosine, AMP, ADP, and \*ATP, are of fundamental biological importance as carriers of chemical energy.

**adenosine diphosphate (ADP)** See ATP.

**adenosine monophosphate (AMP)** See ATP.

**adenosine triphosphate** See ATP.

a

**adenovirus** One of a group of DNA-containing viruses found in rodents, fowl, cattle, monkeys, and humans. In humans they produce acute respiratory-tract infections with symptoms resembling those of the common cold. They are also implicated in the formation of tumours (see ONCOGENIC).

**adenylate cyclase** The enzyme that catalyses the formation of \*cyclic AMP. It is bound to the inner surface of the plasma membrane. Many hormones and other chemical messengers exert their physiological effects by increased synthesis of cyclic AMP through the activation of adenylyl cyclase. The hormone binds to a receptor on the outer surface of the plasma membrane, which then activates adenylyl cyclase on the inner surface via \*G protein.

**ADH** See ANTIDIURETIC HORMONE.

**adhesive** A substance used for joining surfaces together. Adhesives are generally colloidal solutions, which set to gels. There are many types including animal glues (based on collagen), vegetable mucilages, and synthetic resins (e.g. \*epoxy resins).

**adiabatic approximation** An approximation used in \*quantum mechanics when the time dependence of parameters such as the inter-nuclear distance between atoms in a molecule is slowly varying. This approximation means that the solution of the \*Schrödinger equation at one time goes continuously over to the solution at a later time. This approximation was formulated by Max Born and the Soviet physicist Vladimir Alexandrovich Fock (1898–1974) in 1928. The \*Born–Oppenheimer approximation is an example of the adiabatic approximation.

**adiabatic demagnetization** A technique for cooling a paramagnetic salt, such as potassium chrome alum, to a temperature near \*absolute zero. The salt is placed between the poles of an electromagnet and the heat produced during magnetization is removed by liquid helium. The salt is then isolated thermally from the surroundings and the field is switched off; the salt is demagnetized adiabatically and its temperature falls. This is

because the demagnetized state, being less ordered, involves more energy than the magnetized state. The extra energy can come only from the internal, or thermal, energy of the substance. It is possible to obtain temperatures as low as 0.005 K in this way.

**adiabatic process** Any process that occurs without heat entering or leaving a system. In general, an adiabatic change involves a fall or rise in temperature of the system. For example, if a gas expands under adiabatic conditions, its temperature falls (work is done against the retreating walls of the container). The **adiabatic equation** describes the relationship between the pressure ( $p$ ) of an ideal gas and its volume ( $V$ ), i.e.  $pV^\gamma = K$ , where  $\gamma$  is the ratio of the principal specific \*heat capacities of the gas and  $K$  is a constant.

**adipic acid** See HEXANEDIOIC ACID.

**adipose tissue** A body tissue comprising cells containing \*fat and oil. It is found chiefly below the skin (see SUBCUTANEOUS TISSUE) and around major organs (such as the kidneys and heart), acting as an energy reserve, providing insulation and protection, and generating heat. See BROWN FAT; THERMOGENESIS.

**admittance** Symbol  $Y$ . The reciprocal of \*impedance. It is measured in siemens.

**adolescence** The period in human development that occurs during the teenage years, between the end of childhood and the start of adulthood, and is characterized by various physical and emotional changes associated with development of the reproductive system. It starts at **puberty**, when the reproductive organs begin to function, and is marked by the start of menstruation (see MENSTRUAL CYCLE) in females and the appearance of the \*secondary sexual characteristics in both sexes. In males the secondary sexual characteristics are controlled by the hormone testosterone and include deepening of the voice due to larynx enlargement, the appearance of facial and pubic hair, rapid growth of the skeleton and muscle, and an increase in \*sebaceous gland secretions. In females the secondary sexual characteristics are controlled by oestrogens and include growth of the breasts,

broadening of the pelvis, redistribution of fat in the body, and appearance of pubic hair.

**ADP** See ATP.

**adrenal cortex** The outer layer of the \*adrenal gland, in which several steroid hormones, the \*corticosteroids, are produced.

**adrenal glands** A pair of endocrine glands situated immediately above the kidneys (hence they are also known as the **suprarenal glands**). The inner portion of the adrenals, the **medulla**, secretes the hormones \*adrenaline and \*noradrenaline; the outer **cortex** secretes small amounts of sex hormones (\*androgens and \*oestrogens) and various \*corticosteroids, which have a wide range of effects on the body. See also ACTH.

**adrenaline (epinephrine)** A hormone, produced by the medulla of the \*adrenal glands, that increases heart activity, improves the power and prolongs the action of muscles, and increases the rate and depth of breathing to prepare the body for 'fright, flight, or fight'. At the same time it inhibits digestion and excretion. Similar effects are produced by stimulation of the \*sympathetic nervous system. Adrenaline can be administered by injection to relieve bronchial asthma and reduce blood loss during surgery by constricting blood vessels.

**adrenal medulla** The inner part of the \*adrenal gland, in which \*adrenaline is produced.

**adrenergic 1.** Describing a cell (especially a neuron) or a cell receptor that is stimulated by \*adrenaline, \*noradrenaline, or related substances. See ADRENOCEPTOR. **2.** Describing a nerve fibre or neuron that releases adrenaline or noradrenaline when stimulated. Compare CHOLINERGIC.

**adrenoceptor (adrenoreceptor; adrenergic receptor)** Any cell receptor that binds and is activated by the catecholamines adrenaline or noradrenaline. Adrenoceptors are therefore crucial in mediating the effects of catecholamines as neurotransmitters or hormones. There are two principal types of adrenoceptor, alpha ( $\alpha$ ) and

beta ( $\beta$ ). The **alpha adrenoceptors** fall into two main subtypes:  $\alpha_1$ -adrenoceptors, which mediate the contraction of smooth muscle and hence cause constriction of blood vessels; and  $\alpha_2$ -adrenoceptors, which occur, for example, in presynaptic neurons at certain nerve synapses, where they inhibit release of noradrenaline from the neuron. The **beta adrenoceptors** also have two main subtypes:  $\beta_1$ -adrenoceptors, which stimulate cardiac muscle causing a faster and stronger heartbeat; and  $\beta_2$ -adrenoceptors, which mediate relaxation of smooth muscle in blood vessels, bronchi, the uterus, bladder, and other organs. Activation of  $\beta_2$ -adrenoceptors thus causes widening of the airways (bronchodilation) and blood vessels (vasodilation). See also BETA BLOCKER.

**adrenocorticotrophic hormone** See ACTH.

**Adrian, Edgar Douglas, Baron** (1889–1977) British neurophysiologist, who became a professor at Cambridge in 1937, where he remained until his retirement. He is best known for his work on nerve impulses, establishing that messages are conveyed by changes in the frequency of the impulses. He shared the 1932 Nobel Prize for physiology or medicine with Sir Charles \*Sherrington for this work.

**ADSL (asymmetric digital subscriber line)** A mechanism by which \*broadband communication via the Internet can be made available via pre-existing telephone lines, while allowing simultaneous use of the line for normal telephone calls. Data communication via ADSL is asymmetric in that upstream (transmitting) communication is slower than downstream (receiving) communication, typically half as fast. Commonly available downstream data rates in the UK are 512 Kbps, 1 Mbps, and 2 Mbps. Faster rates are available in other countries. ADSL coexists with standard telephone operation on the same line by the use of band separation filters at each telephone socket.

**adsorbate** A substance that is adsorbed on a surface.

**adsorbent** A substance on the surface of which a substance is adsorbed.

a

**adsorption** The formation of a layer of gas, liquid, or solid on the surface of a solid or, less frequently, of a liquid. There are two types depending on the nature of the forces involved. In **chemisorption** a single layer of molecules, atoms, or ions is attached to the adsorbent surface by chemical bonds. In **physisorption** adsorbed molecules are held by the weaker \*van der Waals' forces. Adsorption is an important feature of surface reactions, such as corrosion, and heterogeneous catalysis. The property is also utilized in adsorption \*chromatography.

**adsorption indicator (absorption indicator)** A type of indicator used in reactions that involve precipitation. The yellow dye fluorescein is a common example, used for the reaction

As silver nitrate solution is added to the sodium chloride, silver chloride precipitates. As long as  $\text{Cl}^-$  ions are in excess, they adsorb on the precipitate particles. At the end point, no  $\text{Cl}^-$  ions are left in solution and negative fluorescein ions are then adsorbed, giving a pink colour to the precipitate.

**adsorption isotherm** An equation that describes how the amount of a substance adsorbed onto a surface depends on its pressure (if a gas) or its concentration (if in a solution), at a constant temperature. Several theoretical adsorption isotherms are used in surface chemistry with different assumptions about the surface and the adsorbed molecules.

**advanced gas-cooled reactor (AGR)**  
See NUCLEAR REACTOR.

**adventitious** Describing organs or other structures that arise in unusual positions. For example, ivy has adventitious roots growing from its stems.

**aerial (antenna)** The part of a radio or television system from which radio waves are transmitted into the atmosphere or space (**transmitting aerial**) or by which they are received (**receiving aerial**). A **directional** or **directive aerial** is one in which energy is transmitted or received more effectively from some directions

than others, whereas an **omnidirectional aerial** transmits and receives equally well in all directions.

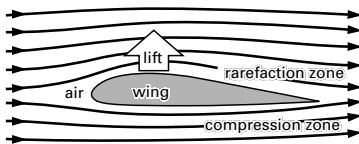

**aerobe** See AEROBIC RESPIRATION.

**aerobic respiration** A type of \*respiration in which foodstuffs (usually carbohydrates) are completely oxidized to carbon dioxide and water, with the release of chemical energy, in a process requiring atmospheric oxygen. The reaction can be summarized by the equation:

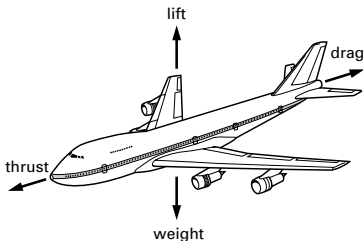

The chemical energy released is stored mainly in the form of \*ATP. The first stage of aerobic respiration is \*glycolysis, which takes place in the cytosol of cells and also occurs in fermentations and other forms of \*anaerobic respiration. Further oxidation in the presence of oxygen is via the \*Krebs cycle and \*electron transport chain, enzymes for which are located in the \*mitochondria of eukaryote cells. Most organisms have aerobic respiration (i.e. they are **aerobes**); exceptions include certain bacteria and yeasts.

**aerodynamics** The study of the motion of gases (particularly air) and the motion of solid bodies in air. Aerodynamics is particularly concerned with the motion and

section through an aircraft wing

forces on an aircraft

Aerodynamics

stability of aircraft. Another application of aerodynamics is to the \*flight of birds and insects. The branch of aerodynamics concerned with the flow of gases through compressors, ducts, fans, orifices, etc., is called **internal aerodynamics**.

**Aerodynamic drag** is the force that opposes the motion of a body moving relative to a gas and is a function of the density of the gas, the square of the relative velocity, the surface area of the body, and a quantity called the **drag coefficient**, which is a function of the \*Reynolds number. **Aerodynamic lift** is an upward force experienced by a body moving through a gas and is a function of the same variables as aerodynamic drag.

**aerogel** A low-density porous transparent material that consists of more than 90% air. Usually based on metal oxides or silica, aerogels are used as drying agents and insulators.

**aerogenerator** See WIND POWER.

**aerosol** A colloidal dispersion of a solid or liquid in a gas. The commonly used aerosol sprays contain an inert propellant liquefied under pressure. Halogenated alkanes containing chlorine and fluorine (\*chlorofluorocarbons, or CFCs) have been used in aerosol cans. This use has been criticized on the grounds that these compounds persist in the atmosphere and lead to depletion of the \*ozone layer.

**aerospace** The earth's atmosphere and the space beyond it.

**aerotaxis** See TAXIS.

**aestivation 1.** (in zoology) A state of inactivity occurring in some animals, notably lungfish, during prolonged periods of drought or heat. Feeding, respiration, movement, and other bodily activities are considerably slowed down. See also DORMANCY. Compare HIBERNATION. **2.** (in botany) The arrangement of the parts of a flower bud, especially of the sepals and petals.

**aetiology** The study of causes, especially the causes of medical conditions.

**afferent** Carrying (nerve impulses, blood, etc.) from the outer regions of a body or organ towards its centre. The

term is usually applied to types of nerve fibres or blood vessels. Compare EFFERENT.

**aflatoxin** Any of four related toxic compounds produced by the mould *Aspergillus flavus*. Aflatoxins bind to DNA and prevent replication and transcription. They can cause acute liver damage and cancers: humans may be poisoned by eating stored peanuts and cereals contaminated with the mould.

**AFM** See ATOMIC FORCE MICROSCOPE.

**afterbirth** The \*placenta, \*umbilical cord, and \*extraembryonic membranes, which are expelled from the womb after a mammalian fetus is born. In most non-human mammals the afterbirth, which contains nutrients and might otherwise attract predators, is eaten by the female.

**after-heat** Heat produced by a nuclear reactor after it has been shut down. The after-heat is generated by radioactive substances formed in the fuel elements.

**agamosperry** See APOMIXIS.

**agar** An extract of certain species of red seaweeds that is used as a gelling agent in microbiological \*culture media, food-stuffs, medicines, and cosmetic creams and jellies. **Nutrient agar** consists of a broth made from beef extract or blood that is gelled with agar and used for the cultivation of bacteria, fungi, and some algae.

**agate** A variety of \*chalcedony that forms in rock cavities and has a pattern of concentrically arranged bands or layers that lie parallel to the cavity walls. These layers are frequently alternating tones of brownish-red. **Moss agate** does not show the same banding and is a milky chalcedony containing mosslike or dendritic patterns formed by inclusions of manganese and iron oxides. Agates are used in jewellery and for ornamental purposes.

**ageing** See SENESCENCE.

**age of the earth** The time since the earth emerged as a planet of the sun, estimated by \*dating techniques to be about  $4.6 \times 10^9$  years. The oldest known rocks on earth are estimated by their \*radioactive age to be about  $3.5 \times 10^9$  years old. The earth is older than this because of the

long time it took to cool. An estimate for the cooling time is included in the estimate for the age of the earth.

**age of the universe** A time determined by the reciprocal of the value of the \*Hubble constant to be about 13.7 billion years. The calculation of the Hubble constant, and hence the age of the universe, depends on which theory of \*cosmology is used. Usually, the age of the universe is calculated by assuming that the \*expansion of the universe can be described by the \*big-bang theory.

**agglutination** The clumping together by antibodies of microscopic foreign particles, such as red blood cells or bacteria, so that they form a visible pellet-like precipitate. Agglutination is a specific reaction, i.e. a particular antigen will only clump in the presence of its specific antibody; it therefore provides a means of identifying unknown bacteria and determining \*blood group. When blood of incompatible blood groups (e.g. group A and group B – see ABO SYSTEM) is mixed together agglutination of the red cells occurs (**haemagglutination**). This is due to the reaction between antibodies in the plasma (**agglutinins**) and \*agglutinogens (antigens) on the surface of the red cells.

**agglutinin** Any of the antigens that are present on the outer surface of red blood cells (erythrocytes). There are more than 100 different agglutinogens and they form the basis for identifying the different \*blood groups. Antibodies in the plasma, known as **agglutinins**, react with the agglutinogens in blood of an incompatible blood group (see AGGLUTINATION).

**aggression** Behaviour aimed at intimidating or injuring another animal of the same or a competing species. Aggression between individuals of the same species often starts with a series of ritualized displays or contests that can end at any stage if one of the combatants withdraws, leaving the victor with access to a disputed resource (e.g. food, a mate, or \*territory) or with increased social dominance (see DOMINANT). It is also often seen in \*courtship. Aggression or threat displays usually appear to exaggerate the performer's size or strength; for example, many fish erect their fins and mammals and birds may

erect hairs or feathers. Special markings may be prominently exhibited, and **intention movements** may be made: dogs bare their teeth, for example. Some animals have evolved special structures for use in aggressive interactions (e.g. antlers in deer) but these are seldom used to cause actual injury; the opponent usually flees first or adopts \*appeasement postures. Fights 'to the death' are comparatively rare. See AGONISTIC BEHAVIOUR; DISPLAY BEHAVIOUR; RITUALIZATION.

**Agnatha** A subphylum or superclass of marine and freshwater vertebrates that lack jaws. They are fishlike animals with cartilaginous skeletons and well-developed sucking mouthparts with horny teeth. The only living agnathans are lampreys and hagfishes (class Cyclostomata), which are parasites or scavengers. Fossil agnathans, covered in an armour of bony plates, are the oldest known fossil vertebrates. They have been dated from the Silurian and Devonian periods, 440–345 million years ago. Compare GNATHOSTOMATA.

**agonist** A drug, hormone, neurotransmitter, or other signal molecule that forms a complex with a \*receptor site, thereby triggering an active response from a cell. Compare ANTAGONIST.

**agonistic behaviour** Any form of behaviour associated with \*aggression, including threat, attack, \*appeasement, or flight. It is often associated with defence of a territory; for example, a threat display by the defending individual is often met with an appeasement display from the intruder, thus avoiding harmful conflict.

**AGR** Advanced gas-cooled reactor. See NUCLEAR REACTOR.

**agranulocyte** Any white blood cell (see LEUCOCYTE) with a nongranular cytoplasm and a large spherical nucleus; \*lymphocytes and \*monocytes are examples. Agranulocytes are produced either in the lymphatic system or in the bone marrow and account for 30% of all leucocytes. Compare GRANULOCYTE.

**agriculture** The study and practice of cultivating land for the growing of crops and the rearing of livestock. The increas-

ing demands for food production since the mid-20th century have seen many developments in agricultural technology and practices that have greatly increased crop and livestock production. However, these advances in modern **intensive farming** techniques have had their impact on the environment, particularly with increased use of \*fertilizers and \*pesticides. The now widespread practice of crop **monoculture** (in which one crop is grown densely over an extensive area) has required an increase in the use of \*pesticides, as monoculture provides an ideal opportunity for crop pests. Monoculture also requires vast areas of land, which has meant that natural habitats have been destroyed. \*Deforestation has resulted from the clearing of forests for crop production and cattle rearing. Advances in technology have included ploughing machines with hydraulic devices that can control the depth to which the soil is ploughed, and seed drills that automatically implant seeds in the soil so that ploughing is not necessary. Food supply in many less-developed countries relies on **subsistence farming**, in which the crops and livestock produced are used solely to feed the farmer and his family. In such countries a system known as **slash and burn** is common, in which the vegetation in an area is cut down and then burnt, thus returning the minerals to the soil. The area can then be used for crop cultivation until the soil fertility drops, at which point it is then abandoned for a number of years and another site is cultivated.

The selective \*breeding of crop plants and farm animals has had an enormous impact on productivity in agriculture. Modern varieties of crop plants have increased nutritional value and greater resistance to disease, while animals have been selectively bred to enhance their yields of milk, meat, and other products. Developments in genetic engineering have enabled the introduction to commercial cultivation of genetically modified crop plants, such as tomatoes and soya, which contain foreign genes to enhance crop growth, nutritional properties, or storage characteristics. Genetic modification can also confer resistance to herbicides, thereby allowing more effective weed control, as well as improved resis-

tance to insects and other pests and to diseases. The application of similar technology to animal production is being researched. *See also* GENETICALLY MODIFIED ORGANISMS (Feature).

**Agrobacterium tumefaciens** A Gram-negative soil bacterium that infects a wide range of plants and causes \*galls, especially at the root/stem junction (crown gall). It is of interest because the bacterial cells contain a \*plasmid, the **Ti plasmid** (tumour-inducing plasmid), a segment of which is transferred to cells of the plant host. This T-DNA (transfer DNA) segment, which comprises the genes responsible for the gall, becomes integrated into the genome of infected plant cells. Possession of the Ti plasmid has made *A. tumefaciens* an important tool in genetic engineering for the introduction of foreign genes into plant tissue. The tumour-inducing genes are usually replaced with the gene of interest, and a marker gene (e.g. the antibiotic resistance gene) is added to enable selection of transformed cells. *See* GENETICALLY MODIFIED ORGANISMS (Feature).

**AI 1.** *See* ARTIFICIAL INTELLIGENCE. **2.** *See* ARTIFICIAL INSEMINATION.

**AIDS (acquired immune deficiency syndrome)** A disease of humans characterized by defective cell-mediated \*immunity and increased susceptibility to infections. It is caused by the retrovirus \*HIV (human immunodeficiency virus). This infects and destroys helper \*T cells, which are essential for combating infections. HIV is transmitted in blood, semen, and vaginal fluid; the major routes of infection are unprotected vaginal and anal intercourse, intravenous drug abuse, and the administration of contaminated blood and blood products. A person infected with HIV is described as **HIV-positive**; after the initial infection the virus can remain dormant for up to ten years before AIDS develops. \*Antiviral drugs can delay the development of full-blown AIDS, in some cases for many years.

**air** *See* EARTH'S ATMOSPHERE.

**air bladder** *See* SWIM BLADDER.

**air mass** (in meteorology) An area of the atmosphere that in the horizontal field possesses more or less uniform properties,

a

especially temperature and humidity, and extends for hundreds of kilometres. The transition zone at which one air mass meets another is known as a \*front. Air masses develop over extensive areas of the earth's surface, known as source regions, where conditions are sufficiently uniform to impart similar characteristics to the overlying air. These areas are chiefly areas of high pressure. As an air mass moves away from its source region it undergoes modification.

#### air pollution (atmospheric pollution)

The release into the atmosphere of substances that cause a variety of harmful effects to the natural environment. Most air pollutants are gases that are released into the troposphere, which extends about 8 km above the surface of the earth. The burning of \*fossil fuels, for example in power stations, is a major source of air pollution as this process produces such gases as sulphur dioxide and carbon dioxide. Released into the atmosphere, both these gases (especially carbon dioxide) contribute to the \*greenhouse effect. Sulphur dioxide and nitrogen oxides, released in car exhaust fumes, are air pollutants that are responsible for the formation of \*acid rain; nitrogen oxides also contribute to the formation of \*photochemical smog. See also OZONE LAYER; POLLUTION.

**air sac 1.** Any one of a series of thin-walled sacs in birds that are connected to the lungs and increase the efficiency of ventilation. Some of the air sacs penetrate the internal cavities of bones. **2.** A structural extension to the \*trachea in insects, which increases the surface area available for the exchange of oxygen and carbon dioxide in respiration.

**alabaster** See GYPSUM.

**alanine** See AMINO ACID.

**albedo 1.** The ratio of the radiant flux reflected by a surface to that falling on it. **2.** The probability that a neutron entering a body of material will be reflected back through the same surface as it entered.

**albinism** Hereditary lack of pigmentation (see MELANIN) in an organism. Albino animals and human beings have no colour in their skin, hair, or eyes (the irises

appear pink from underlying blood vessels). The \*allele responsible is \*recessive to the allele for normal pigmentation.

**albumen** See ALBUMIN.

**albumin** One of a group of globular proteins that are soluble in water but form insoluble coagulates when heated. Albumins occur in egg white (the protein component of which is known as **albumen**), blood, milk, and plants. Serum albumins, which constitute about 55% of blood plasma protein, help regulate the osmotic pressure and hence plasma volume. They also bind and transport fatty acids.  $\alpha$ -lactalbumin is a protein in milk.

**albuminous cell** See COMPANION CELL.

**alburnum** See SAPWOOD.

**alcoholic fermentation** See FERMENTATION.

**alcohols** Organic compounds that contain the -OH group. In systematic chemical nomenclature alcohol names end in the suffix -ol. Examples are methanol,  $\text{CH}_3\text{OH}$ , and ethanol,  $\text{C}_2\text{H}_5\text{OH}$ . **Primary alcohols** have two hydrogen atoms on the carbon joined to the -OH group (i.e. they contain the group  $-\text{CH}_2-\text{OH}$ ); **secondary alcohols** have one hydrogen on this carbon (the other two bonds being to carbon atoms, as in  $(\text{CH}_3)_2\text{CHOH}$ ); **tertiary alcohols** have no hydrogen on this carbon (as in  $(\text{CH}_3)_3\text{COH}$ ): see formulae. The different types of alcohols may differ in the way they react chemically. For example, with potassium dichromate(VI) in sulphuric acid the following reactions occur  
primary alcohol  $\rightarrow$  aldehyde  $\rightarrow$  carboxylic acid  
secondary alcohol  $\rightarrow$  ketone

primary alcohol (methanol)

secondary alcohol (propan-2-ol)

tertiary alcohol (2-methylpropan-2-ol)

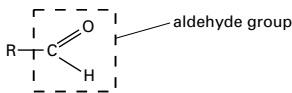

Examples of alcohols

tertiary alcohol – no reaction

Other characteristics of alcohols are reaction with acids to give \*esters and dehydration to give \*alkenes or \*ethers.

Alcohols that have two –OH groups in their molecules are **diols** (or **dihydric alcohols**), those with three are **triols** (or **trihydric alcohols**), etc.

**aldehydes** Organic compounds that contain the group –CHO (the **aldehyde group**; i.e. a carbonyl group (C=O) with a hydrogen atom bound to the carbon atom). In systematic chemical nomenclature, aldehyde names end with the suffix *-al*. Examples of aldehydes are methanal (formaldehyde), HCOH, and ethanal (acetaldehyde), CH<sub>3</sub>CHO. Aldehydes are formed by oxidation of primary \*alcohols; further oxidation yields carboxylic acids. They are reducing agents and tests for aldehydes include \*Fehling's test and \*Tollens reagent. Aldehydes have certain characteristic addition and condensation reactions. With sodium hydrogensulphate(IV) they form addition compounds of the type [RCOH(SO<sub>3</sub>H)]<sup>-</sup> Na<sup>+</sup>. Formerly these were known as **bisulphite addition compounds**. They also form addition compounds with hydrogen cyanide to give \*cyanohydrins and with alcohols to give \*acetals and undergo condensation reactions to yield \*oximes, \*hydrazones, and \*semicarbazones. Aldehydes readily polymerize. See also KETONES.

Aldehyde structure

**aldohexose** See MONOSACCHARIDE.

**aldol** See ALDOL REACTION.

**aldol reaction** A reaction of aldehydes of the type

where R is a hydrocarbon group. The resulting compound is a hydroxy-aldehyde, i.e. an aldehyde–alcohol or **aldol**, containing alcohol (–OH) and aldehyde (–CHO) groups on adjacent carbon atoms. The reaction is base-catalysed, the first step being the formation of a carbanion of the

type  $\text{RHC}^-\text{CHO}$ , which adds to the carbonyl group of the other aldehyde molecule. For the carbanion to form, the aldehyde must have a hydrogen atom on the carbon next to the carbonyl group.

Aldols can be further converted to other products; in particular, they are a source of unsaturated aldehydes. For example, the reaction of ethanal gives 3-hydroxybutenal (**acetaldol**):

This can be further dehydrated to 2-butenal (**crotonaldehyde**):

**aldose** See MONOSACCHARIDE.

**aldosterone** A hormone produced by the adrenal glands (see CORTICOSTEROID) that controls excretion of sodium by the kidneys and thereby maintains the balance of salt and water in the body fluids. See also ANGIOTENSIN.

**algae** Any of various simple organisms that contain chlorophyll (and can therefore carry out photosynthesis) and live in aquatic habitats and in moist situations on land. The algal body may be unicellular or multicellular (filamentous, ribbon-like, or platelike). Formerly regarded as plants, algae are now classified as members of the kingdom \*Protoctista; they are assigned to separate phyla based primarily on the composition of the cell wall, the nature of the stored food reserves, and the other photosynthetic pigments present. See BACILLARIOPHYTA; CHLOROPHYTA; PHAEOPHYTA; RHODOPHYTA.

The organisms formerly known as blue-green algae are now classified as bacteria (see CYANOBACTERIA).

**algal bloom (bloom)** The rapid increase in populations of algae and other phytoplankton, in particular the \*cyanobacteria, that occurs in inland water systems, such as lakes. The density of the organisms may be such that it may prevent light from passing to lower depths in the water system. Blooms are caused by an increase in levels of nitrate, a mineral ion essential for algal and bacterial growth. The source of increased nitrate may be from agricultural \*fertilizers, which are

leached into water systems from the land, or \*sewage effluent. Blooms contribute to the eutrophication of water systems. See also EUTROPHIC.

**algebra** The branch of mathematics in which variable quantities and numbers are represented by symbols. Statements are usually made in the form of equations, which are manipulated into convenient forms and solved according to a set of strictly logical rules.

**algebraic sum** The total of a set of quantities paying due regard to sign, e.g. the algebraic sum of 3 and -4 is -1.

**Algol** An early high-level block-structured computer programming language. Algol 60 dates from about 1960. Algol 68, of 1968, is a more powerful abstract language. The final version, Algol W, was the precursor of Pascal. The name is short for *algorithmic language*.

**algorithm** A method of solving a problem, involving a finite series of steps. In computing practice the algorithm denotes the expression on paper of the proposed computing process (often by means of a flowchart) prior to the preparation of the program. If no algorithm is possible a \*heuristic solution has to be sought.

**alicyclic compound** A compound that contains a ring of atoms and is aliphatic. Cyclohexane,  $C_6H_{12}$ , is an example.

**alimentary canal (digestive tract; gut)** A tubular organ in animals that is divided into a series of zones specialized for the ingestion, \*digestion, and \*absorption of food and for the elimination of indigestible material (see illustration). In most animals the canal has two openings, the mouth (for the intake of food) and the \*anus (for the elimination of waste). Simple animals, such as cnidarians (e.g. *Hydra* and jellyfish) and flatworms, have only one opening to their alimentary canal, which must serve both functions.

**aliphatic compounds** Organic compounds that are \*alkanes, \*alkenes, or \*alkynes or their derivatives. The term is used to denote compounds that do not have the special stability of \*aromatic compounds. All noncyclic organic com-

pounds are aliphatic. Cyclic aliphatic compounds are said to be **alicyclic**.

**alizarin** An orange-red dye,  $C_{14}H_8O_4$ , which forms \*lakes when heavy metal salts are added to its alkaline solutions. It occurs naturally in madder, but is generally synthesized from \*anthraquinone.

**alkali** A \*base that dissolves in water to give hydroxide ions.

**alkali metals (group 1 elements)** The elements of group 1 (formerly IA) of the \*periodic table: lithium (Li), sodium (Na), potassium (K), rubidium (Rb), caesium (Cs), and francium (Fr). All have a characteristic electron configuration that is a noble gas structure with one outer *s*-electron. They are typical metals (in the chemical sense) and readily lose their outer electron to form stable  $M^+$  ions with noble-gas configurations. All are highly reactive, with the reactivity (i.e. metallic character) increasing down the group. There is a decrease in ionization energy from lithium ( $520 \text{ kJ mol}^{-1}$ ) to caesium ( $380 \text{ kJ mol}^{-1}$ ). The second ionization energies are much higher and divalent ions are not formed. Other properties also change down the group. Thus, there is an increase in atomic and ionic radius, an increase in density, and a decrease in melting and boiling point. The standard electrode potentials are low and negative, although they do not show a regular trend because they depend both on ionization energy (which decreases down the group) and the hydration energy of the ions (which increases).

All the elements react with water (lithium slowly; the others violently) and tarnish rapidly in air. They can all be made to react with chlorine, bromine, sulphur, and hydrogen. The hydroxides of the alkali metals are strongly alkaline (hence the name) and do not decompose on heating. The salts are generally soluble. The carbonates do not decompose on heating, except at very high temperatures. The nitrates (except for lithium) decompose to give the nitrite and oxygen:

Lithium nitrate decomposes to the oxide. In fact lithium shows a number of dissimilarities to the other members of group 1

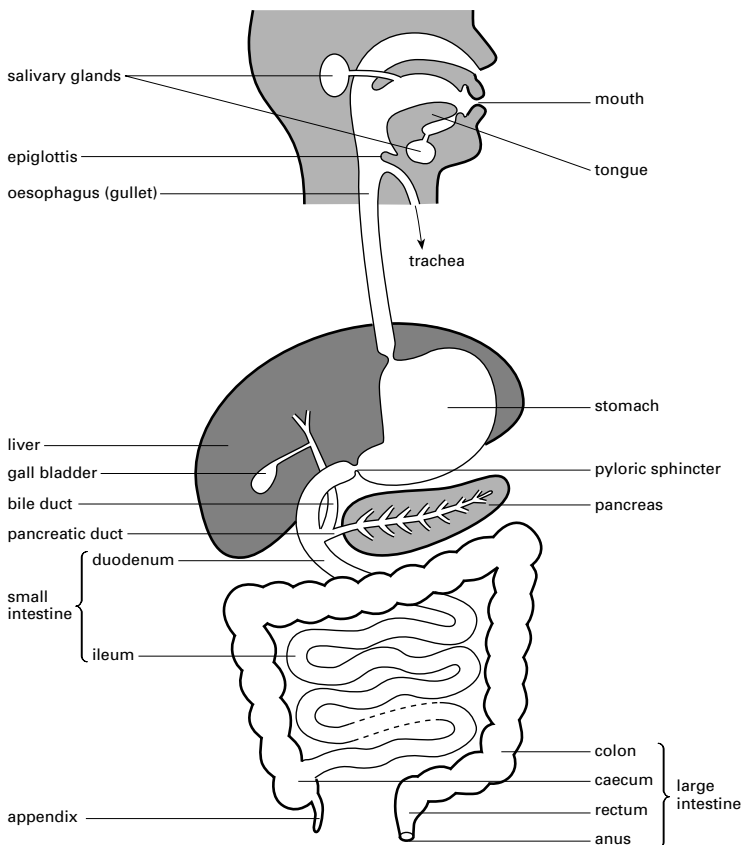

and in many ways resembles magnesium (see **DIAGONAL RELATIONSHIP**). In general, the stability of salts of oxo acids increases down the group (i.e. with increasing size of the  $M^+$  ion). This trend occurs because the smaller cations (at the top of the group) tend to polarize the oxo anion more effectively than the larger cations at the bottom of the group.

**alkalimetry** Volumetric analysis using standard solutions of alkali to determine the amount of acid present.

**alkaline 1.** Describing an alkali. **2.** De-

scribing a solution that has an excess of hydroxide ions (i.e. a pH greater than 7).

**alkaline-earth metals (group 2 elements)** The elements of group 2 (formerly IIA) of the \*periodic table: beryllium (Be), magnesium (Mg), calcium (Ca), strontium (Sr), and barium (Ba). The elements are sometimes referred to as the 'alkaline earths', although strictly the 'earths' are the oxides of the elements. All have a characteristic electron configuration that is a noble-gas structure with two outer s-electrons. They are typical metals (in the chemical sense) and readily lose

The human alimentary canal

a

both outer electrons to form stable  $M^{2+}$  ions; i.e. they are strong reducing agents. All are reactive, with the reactivity increasing down the group. There is a decrease in both first and second ionization energies down the group. Although there is a significant difference between the first and second ionization energies of each element, compounds containing univalent ions are not known. This is because the divalent ions have a smaller size and larger charge, leading to higher hydration energies (in solution) or lattice energies (in solids). Consequently, the overall energy change favours the formation of divalent compounds. The third ionization energies are much higher than the second ionization energies, and trivalent compounds (containing  $M^{3+}$ ) are unknown.

Beryllium, the first member of the group, has anomalous properties because of the small size of the ion; its atomic radius (0.112 nm) is much less than that of magnesium (0.16 nm). From magnesium to radium there is a fairly regular increase in atomic and ionic radius. Other regular changes take place in moving down the group from magnesium. Thus, the density and melting and boiling points all increase. Beryllium, on the other hand, has higher boiling and melting points than calcium and its density lies between those of calcium and strontium. The standard electrode potentials are negative and show a regular small decrease from magnesium to barium. In some ways beryllium resembles aluminium (see DIAGONAL RELATIONSHIP).

All the metals are rather less reactive than the alkali metals. They react with water and oxygen (beryllium and magnesium form a protective surface film) and can be made to react with chlorine, bromine, sulphur, and hydrogen. The oxides and hydroxides of the metals show the increasing ionic character in moving down the group: beryllium hydroxide is amphoteric, magnesium hydroxide is only very slightly soluble in water and is weakly basic, calcium hydroxide is sparingly soluble and distinctly basic, strontium and barium hydroxides are quite soluble and basic. The hydroxides decompose on heating to give the oxide and water:

The carbonates also decompose on heating to the oxide and carbon dioxide:

The nitrates decompose to give the oxide:

As with the \*alkali metals, the stability of salts of oxo acids increases down the group. In general, salts of the alkaline-earth elements are soluble if the anion has a single charge (e.g. nitrates, chlorides). Most salts with a doubly charged anion (e.g. carbonates, sulphates) are insoluble. The solubilities of salts of a particular acid tend to decrease down the group. (Solubilities of hydroxides increase for larger cations.)

**alkaloid** One of a group of nitrogenous organic compounds derived from plants and having diverse pharmacological properties. Alkaloids include morphine, cocaine, atropine, quinine, and caffeine, most of which are used in medicine as analgesics (pain relievers) or anaesthetics. Some alkaloids are poisonous, e.g. strychnine and coniine, and \*colchicine inhibits cell division.

**alkanal** An aliphatic aldehyde.

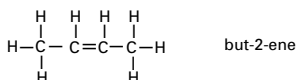

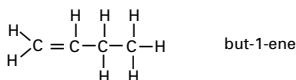

**alkanes (paraffins)** Saturated hydrocarbons with the general formula  $C_nH_{2n+2}$ . In systematic chemical nomenclature alkane names end in the suffix *-ane*. They form a \*homologous series (the **alkane series**) methane ( $CH_4$ ), ethane ( $C_2H_6$ ), propane ( $C_3H_8$ ), butane ( $C_4H_{10}$ ), pentane ( $C_5H_{12}$ ), etc. The lower members of the series are gases; the high-molecular weight alkanes are waxy solids. Alkanes are present in natural gas and petroleum. They can be made by heating the sodium salt of a carboxylic acid with soda lime:

Other methods include the \*Wurtz reaction and \*Kolbe's method. Generally the alkanes are fairly unreactive. They form haloalkanes with halogens when irradiated with ultraviolet radiation.

**alkanol** An aliphatic alcohol.

**alkenes (olefines; olefins)** Unsaturated hydrocarbons that contain one or more

#### Butene isomers

double carbon-carbon bonds in their molecules. In systematic chemical nomenclature alkene names end in the suffix *-ene*. Alkenes that have only one double bond form a homologous series (the **alkene series**) starting ethene (ethylene),  $\text{CH}_2:\text{CH}_2$ , propene,  $\text{CH}_3\text{CH}:\text{CH}_2$ , etc. The general formula is  $\text{C}_n\text{H}_{2n}$ . Higher members of the series show isomerism depending on position of the double bond; for example, butene ( $\text{C}_4\text{H}_8$ ) has two isomers, which are (1) but-1-ene ( $\text{C}_2\text{H}_5\text{CH}:\text{CH}_2$ ) and (2) but-2-ene ( $\text{CH}_3\text{CH}:\text{CHCH}_3$ ); see formulae.

Alkenes can be made by dehydration of alcohols (passing the vapour over hot pumice):

An alternative method is the removal of a hydrogen atom and halogen atom from a haloalkane by potassium hydroxide in hot alcoholic solution:

Alkenes typically undergo *\*addition reactions* to the double bond. See also HYDROGENATION; OXO PROCESS; OZONOLYSIS; ZIEGLER PROCESS.

**alkoxides** Compounds formed by reaction of alcohols with sodium or potassium metal. Alkoxides are saltlike compounds containing the ion  $\text{R}-\text{O}^-$ .

**alkyd resin** A type of *\*polyester resin* used in paints and other surface coating. The original alkyd resins were made by copolymerizing phthalic anhydride with glycerol, to give a brittle cross-linked polymer. The properties of such resins can be modified by adding monobasic acids or alcohols during the polymerization.

**alkylation** A chemical reaction that introduces an *\*alkyl group* into an organic

molecule. The *\*Friedel-Crafts reaction* results in alkylation of aromatic compounds.

**alkylbenzenes** Organic compounds that have an alkyl group bound to a benzene ring. The simplest example is methylbenzene (toluene),  $\text{CH}_3\text{C}_6\text{H}_5$ . Alkyl benzenes can be made by the *\*Friedel-Crafts reaction*.

**alkyl group** A group obtained by removing a hydrogen atom from an alkane, e.g. methyl group,  $\text{CH}_3^-$ , derived from methane.

**alkyl halides** See HALOALKANES.

**alkynes (acetylenes)** Unsaturated hydrocarbons that contain one or more triple carbon-carbon bonds in their molecules. In systematic chemical nomenclature alkyne names end in the suffix *-yne*.

Alkynes that have only one triple bond form a *\*homologous series*: ethyne (acetylene),  $\text{CH}\equiv\text{CH}$ , propyne,  $\text{CH}_3\text{CH}\equiv\text{CH}$ , etc. They can be made by the action of potassium hydroxide in alcohol solution on haloalkanes containing halogen atoms on adjacent carbon atoms; for example:

Like *\*alkenes*, alkynes undergo addition reactions.

**allantois** One of the membranes that develops in embryonic reptiles, birds, and mammals as a growth from the hindgut. It acts as a urinary bladder for the storage of waste excretory products in the egg (in reptiles and birds) and as a means of providing the embryo with oxygen (in reptiles, birds, and mammals) and food (in mammals; see PLACENTA). See also EXTRAEMBRYONIC MEMBRANES.

**allele (allelomorph)** One of the alternative forms of a gene. In a diploid cell there are usually two alleles of any one gene (one from each parent), which occupy the same relative position (*\*locus*) on *\*homologous chromosomes*. These alleles may be the same, or one allele may be *\*dominant* to the other (known as the *\*recessive*), i.e. it determines which aspects of a particular characteristic the organism will display. Within a population

a

there may be many alleles of a gene; each has a unique nucleotide sequence.

**allelomorph** See ALLELE.

**allelopathy** The secretion by plants of chemicals, such as phenolic and terpenoid compounds, that inhibit the growth or germination of other plants, with which they are competing. For example, the aromatic oils released by certain shrubs of the Californian chaparral pass into the soil and inhibit the growth of herbaceous species nearby. Some plants produce chemicals that are toxic to grazing herbivorous animals.

**allenes** Compounds that contain the group  $>C=C=C<$ , in which three carbon atoms are linked by two adjacent double bonds. The outer carbon atoms are each linked to two other atoms or groups by single bonds. The simplest example is 1,2-propadiene,  $CH_2CCH_2$ . Allenes are  $\ast$ dienes with typical reactions of alkenes. Under basic conditions, they often convert to alkynes. In an allene, the two double bonds lie in planes that are perpendicular to each other. Consequently, in an allene of the type  $R_1R_2C:C:CR_3R_4$ , the groups  $R_1$  and  $R_2$  lie in a plane perpendicular to the plane containing  $R_3$  and  $R_4$ . Under these circumstances, the molecule is chiral and can show optical activity.

**allergen** An antigen that provokes an abnormal  $\ast$ immune response. Common allergens include pollen and dust (see ALLERGY).

**allergy** A condition in which the body produces an abnormal  $\ast$ immune response to certain  $\ast$ antigens (called **allergens**), which include dust, pollen, certain foods and drugs, or fur. In allergic individuals these substances, which in a normal person would be destroyed by antibodies, stimulate the release of  $\ast$ histamine and  $\ast$ serotonin, leading to inflammation and other characteristic symptoms of the allergy (e.g. asthma or hay fever). See also ANAPHYLAXIS; MAST CELLS.

**alogamy** Cross-fertilization in plants. See FERTILIZATION.

**allograft** See GRAFT.

**allometric growth** The regular and systematic pattern of growth such that

the mass or size of any organ or part of a body can be expressed in relation to the total mass or size of the entire organism according to the allometric equation:  $Y = bx^\alpha$ , where  $Y$  = mass of the organ,  $x$  = mass of the organism,  $\alpha$  = growth coefficient of the organ, and  $b$  = a constant.

**allopatric** Describing or relating to groups of similar organisms that could interbreed but do not because they are geographically separated. Compare SYMPATRIC. See SPECIATION.

**allopolyploid** A  $\ast$ polyploid organism, usually a plant, that contains multiple sets of chromosomes derived from different species. Hybrids are usually sterile, because they do not have sets of  $\ast$ homologous chromosomes and therefore  $\ast$ pairing cannot take place. However, if doubling of the chromosome number occurs in a hybrid derived from two diploid ( $2n$ ) species, the resulting tetraploid ( $4n$ ) is a fertile plant. This type of tetraploid is known as an **allotetraploid**; as it contains two sets of homologous chromosomes, pairing and crossing over are now possible. Allopolyploids are of great importance to plant breeders as advantages possessed by different species can be combined. The species of wheat, *Triticum aestivum*, used to make bread is an **allohexaploid** ( $6n$ ), possessing 42 chromosomes, which is six times the original haploid number ( $n$ ) of 7. Compare AUTOPOLYPLOID.

**all-or-none response** A type of response that may be either complete and of full intensity or totally absent, depending on the strength of the stimulus; there is no partial response. For example, a nerve cell is either stimulated to transmit a complete nervous impulse or else it remains in its resting state; a stinging  $\ast$ thread cell of a cnidarian is either completely discharged or it is not.

**allosteric enzyme** An enzyme that has two structurally distinct forms, one of which is active and the other inactive. In the active form, the quaternary structure (see PROTEIN) of the enzyme is such that a substrate can interact with the enzyme at the active site (see ENZYME-SUBSTRATE COMPLEX). The conformation of the substrate-binding site becomes altered in the

inactive form and interaction with the substrate is not possible. Allosteric enzymes tend to catalyse the initial step in a pathway leading to the synthesis of molecules. The end product of this synthesis can act as a feedback inhibitor (see INHIBITION) and the enzyme is converted to the inactive form, thereby controlling the amount of product synthesized.

**allotropy** The existence of elements in two or more different forms (**allotropes**). In the case of oxygen, there are two forms: 'normal' dioxygen ( $O_2$ ) and ozone, or trioxygen ( $O_3$ ). These two allotropes have different molecular configurations. More commonly, allotropy occurs because of different crystal structures in the solid, and is particularly prevalent in groups 14, 15, and 16 of the periodic table. In some cases, the allotropes are stable over a temperature range, with a definite transition point at which one changes into the other. For instance, tin has two allotropes: white (metallic) tin stable above  $13.2^\circ\text{C}$  and grey (nonmetallic) tin stable below  $13.2^\circ\text{C}$ . This form of allotropy is called **enantiotropy**. Carbon also has two allotropes - diamond and graphite - although graphite is the stable form at all temperatures. This form of allotropy, in which there is no transition temperature at which the two are in equilibrium, is called **monotropy**. See also POLYMORPHISM.

**allowed bands** See ENERGY BAND.

**allowed transitions** See SELECTION RULES.

**alloy** A material consisting of two or more metals (e.g. brass is an alloy of copper and zinc) or a metal and a nonmetal (e.g. steel is an alloy of iron and carbon, sometimes with other metals included). Alloys may be compounds, \*solid solutions, or mixtures of the components.

**alloy steels** See STEEL.

**alluvial deposits** Sediments deposited in a river, which range in particle size from fine silts to coarse gravels.

**allyl group** See PROPENYL GROUP.

**Alnico** A trade name for a series of alloys, containing iron, aluminium, nickel, cobalt, and copper, used to make permanent magnets.

**alpha-iron** See IRON.

**alpha-naphthol test** A biochemical test to detect the presence of carbohydrates in solution, also known as **Molisch's test** (after the Austrian chemist H. Molisch (1856-1937), who devised it). A small amount of alcoholic alpha-naphthol is mixed with the test solution and concentrated sulphuric acid is poured slowly down the side of the test tube. A positive reaction is indicated by the formation of a violet ring at the junction of the liquids.

**alpha particle** A helium-4 nucleus emitted by a larger nucleus during the course of the type of radioactive decay known as **alpha decay**. As a helium-4 nucleus consists of two protons and two neutrons bound together as a stable entity the loss of an alpha particle involves a decrease in \*nucleon number of 4 and decrease of 2 in the \*atomic number, e.g. the decay of a uranium-238 nucleus into a thorium-234 nucleus. A stream of alpha particles is known as an **alpha-ray** or **alpha-radiation**.

**alternating current (a.c.)** An electric current that reverses its direction with a constant \*frequency ( $f$ ). If a graph of the current against time has the form of a \*sine wave, the current is said to be **sinusoidal**. Alternating current, unlike direct current, is therefore continuously varying and its magnitude is either given as its peak value ( $I_0$ ) or its \*root-mean-square value ( $I_0/\sqrt{2}$  for a sinusoidal current). This r.m.s. value is more useful as it is comparable to a d.c. value in being a measure of the ability of the current to transmit power. The instantaneous value of a sinusoidal current ( $I$ ) is given by  $I = I_0 \sin 2\pi ft$ .

If a direct current is supplied to a circuit the only opposition it encounters is the circuit's \*resistance. However, an alternating current is opposed not only by the resistance of the circuit but also by its \*reactance. This reactance is caused by \*capacitance and \*inductance in the circuit. In a circuit consisting of a resistance ( $R$ ), an inductance ( $L$ ), and a capacitance ( $C$ ) all in series, the reactance ( $X$ ) is equal to  $(2\pi fL) - (1/2\pi fC)$ . The total opposition to the current, called the \*impedance ( $Z$ ), is then equal to the ratio of the r.m.s. ap-

plied p.d. to the r.m.s. current and is given by  $\sqrt{(R^2 + X^2)}$ .

**alternation of generations** The occurrence within the \*life cycle of an organism of two or more distinct forms (generations), which differ from each other in appearance, habit, and method of reproduction. The phenomenon occurs in some protocists, certain lower animals (e.g. cnidarians and parasitic flatworms), and in plants. The malaria parasite (*Plasmodium*), for example, has a complex life cycle involving the alternation of sexually and asexually reproducing generations. In plants the generation with sexual reproduction is called the \*gametophyte and the asexual generation is the \*sporophyte, either of which may dominate the life cycle, and there is also alternation of the haploid and diploid states. Thus in vascular plants the dominant plant is the diploid sporophyte; it produces spores that germinate into small haploid gametophytes. In mosses the gametophyte is the dominant plant and the sporophyte is the spore-bearing capsule.

**alternator** An \*alternating-current generator consisting of a coil or coils that rotate in the magnetic field produced by one or more permanent magnets or electromagnets. The electromagnets are supplied by an independent direct-current source. The frequency of the alternating current produced depends on the speed at which the coil rotates and the number of pairs of magnetic poles. In the large alternators of power stations the electromagnets rotate inside fixed coils; many bicycle dynamos are alternators with rotating permanent magnets inside fixed coils.

**altimeter** A device used to measure height above sea level. It usually consists of an aneroid \*barometer measuring atmospheric pressure. Aircraft are fitted with altimeters, which are set to the atmospheric pressure at a convenient level, usually sea level, before take off. The height of the aircraft can then be read off the instrument as the aircraft climbs and the pressure falls.

**altitude** In horizontal coordinate systems, the distance of a celestial object above or below the observer's horizon, ex-

pressed as an angle i.e. its elevation. Compare AZIMUTH.

**altruism** Behaviour by an animal that decreases its chances of survival or reproduction while increasing those of another member of the same species. For example, a lapwing puts itself at risk by luring a predator away from the nest through feigning injury, but by so doing saves its offspring. Altruism in its biological sense does not imply any conscious benevolence on the part of the performer. Altruism can evolve through \*kin selection, if the recipients of altruistic acts tend on average to be more closely related to the altruist than the population as a whole. See also INCLUSIVE FITNESS.

**ALU (arithmetic/logic unit)** The part of the central processor of a \*computer in which simple arithmetic and logical operations are performed electronically. For example, the ALU can add, subtract, multiply, or compare two numbers, or negate a number.

**alum** See ALUMINIUM POTASSIUM SULPHATE; ALUMS.

**alumina** See ALUMINIUM OXIDE; ALUMINIUM HYDROXIDE.

**aluminate** A salt formed when aluminium hydroxide or  $\gamma$ -alumina is dissolved in solutions of strong bases, such as sodium hydroxide. Aluminates exist in solutions containing the aluminate ion, commonly written  $[\text{Al}(\text{OH})_4]^-$ . In fact the ion probably is a complex hydrated ion and can be regarded as formed from a hydrated  $\text{Al}^{3+}$  ion by removal of four hydrogen ions:

Other aluminates and polyaluminates, such as  $[\text{Al}(\text{OH})_6]^{3-}$  and  $[(\text{HO})_3\text{AlOAl}(\text{OH})_3]^{2-}$ , are also present. See also ALUMINIUM HYDROXIDE.

**aluminium** Symbol Al. A silvery-white lustrous metallic element belonging to \*group 3 (formerly IIIB) of the periodic table; a.n. 13; r.a.m. 26.98; r.d. 2.7; m.p. 660°C; b.p. 2467°C. The metal itself is highly reactive but is protected by a thin transparent layer of the oxide, which forms quickly in air. Aluminium and its

oxide are amphoteric. The metal is extracted from purified bauxite ( $\text{Al}_2\text{O}_3$ ) by electrolysis; the main process uses a \*Hall-Heroult cell but other electrolytic methods are under development, including conversion of bauxite with chlorine and electrolysis of the molten chloride. Pure aluminium is soft and ductile but its strength can be increased by work-hardening. A large number of alloys are manufactured; alloying elements include copper, manganese, silicon, zinc, and magnesium. Its lightness, strength (when alloyed), corrosion resistance, and electrical conductivity (62% of that of copper) make it suitable for a variety of uses, including vehicle and aircraft construction, building (window and door frames), and overhead power cables. Although it is the third most abundant element in the earth's crust (8.1% by weight) it was not isolated until 1825 by H. C. Oersted (1777–1851).

**aluminium acetate** See ALUMINIUM ETHANOATE.

**aluminium chloride** A whitish solid,  $\text{AlCl}_3$ , which fumes in moist air and reacts violently with water (to give hydrogen chloride). It is known as the anhydrous salt (hexagonal; r.d. 2.44 (fused solid); m.p.  $190^\circ\text{C}$  (2.5 atm.); sublimes at  $178^\circ\text{C}$ ) or the hexahydrate  $\text{AlCl}_3 \cdot 6\text{H}_2\text{O}$  (rhombic; r.d. 2.398; loses water at  $100^\circ\text{C}$ ), both of which are deliquescent. Aluminium chloride may be prepared by passing hydrogen chloride or chlorine over hot aluminium or (industrially) by passing chlorine over heated aluminium oxide and carbon. The chloride ion is polarized by the small positive aluminium ion and the bonding in the solid is intermediate between covalent and ionic. In the liquid and vapour phases dimer molecules exist,  $\text{Al}_2\text{Cl}_6$ , in which there are chlorine bridges making coordinate bonds to aluminium atoms (see formula). The  $\text{AlCl}_3$  molecule can also form compounds with other molecules that donate pairs of elec-

trons (e.g. amines or hydrogen sulphide); i.e. it acts as a Lewis \*acid. At high temperatures the  $\text{Al}_2\text{Cl}_6$  molecules in the vapour dissociate to (planar)  $\text{AlCl}_3$  molecules. Aluminium chloride is used commercially as a catalyst in the cracking of oils. It is also a catalyst in certain other organic reactions, especially the Friedel-Crafts reaction.

**aluminium ethanoate (aluminium acetate)** A white solid,  $\text{Al}(\text{OOCCH}_3)_3$ , which decomposes on heating, is very slightly soluble in cold water, and decomposes in warm water. The normal salt,  $\text{Al}(\text{OOCCH}_3)_3$ , can only be made in the absence of water (e.g. ethanoic anhydride and aluminium chloride at  $180^\circ\text{C}$ ); in water it forms the basic salts  $\text{Al}(\text{OH})(\text{OOCCH}_3)_2$  and  $\text{Al}_2(\text{OH})_2(\text{OOCCH}_3)_4$ . The reaction of aluminium hydroxide with ethanoic acid gives these basic salts directly. The compound is used extensively in dyeing as a mordant, particularly in combination with aluminium sulphate (known as **red liquor**); in the paper and board industry for sizing and hardening; and in tanning. It was previously used as an antiseptic and astringent.

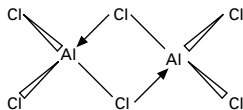

**aluminium hydroxide** A white crystalline compound,  $\text{Al}(\text{OH})_3$ ; r.d. 2.42–2.52. The compound occurs naturally as the mineral **gibbsite** (monoclinic). In the laboratory it can be prepared by precipitation from solutions of aluminium salts. Such solutions contain the hexaquoaluminium(III) ion with six water molecules coordinated,  $[\text{Al}(\text{H}_2\text{O})_6]^{3+}$ . In neutral solution this ionizes:

The presence of a weak base such as  $\text{S}^{2-}$  or  $\text{CO}_3^{2-}$  (by bubbling hydrogen sulphide or carbon dioxide through the solution) causes further ionization with precipitation of aluminium hydroxide

The substance contains coordinated water molecules and is more correctly termed **hydrated aluminium hydroxide**. In addition, the precipitate has water molecules trapped in it and has a characteristic gelatinous form. The substance is ampho-

Structure of aluminium trichloride dimer

teric. In strong bases the \*aluminate ion is produced by loss of a further proton:

On heating, the hydroxide transforms to a mixed oxide hydroxide,  $\text{AlO.OH}$  (rhombohedral; r.d. 3.01). This substance occurs naturally as **diaspore** and **boehmite**. Above  $450^\circ\text{C}$  it transforms to  $\gamma$ -alumina.

In practice various substances can be produced that are mixed crystalline forms of  $\text{Al}(\text{OH})_3$ ,  $\text{AlO.OH}$ , and aluminium oxide ( $\text{Al}_2\text{O}_3$ ) with water molecules. These are known as **hydrated alumina**. Heating the hydrated hydroxide causes loss of water, and produces various **activated aluminas**, which differ in porosity, number of remaining  $-\text{OH}$  groups, and particle size. These are used as catalysts (particularly for organic dehydration reactions), as catalyst supports, and in chromatography. Gelatinous freshly precipitated aluminium hydroxide was formerly widely used as a mordant for dyeing and calico printing because of its ability to form insoluble coloured \*lakes with vegetable dyes. See also ALUMINIUM OXIDE.

**aluminium oxide (alumina)** A white or colourless oxide of aluminium occurring in two main forms. The stable form  $\alpha$ -alumina (r.d. 3.97; m.p.  $2015^\circ\text{C}$ ; b.p.  $2980 \pm 60^\circ\text{C}$ ) has colourless hexagonal or rhombohedral crystals;  $\gamma$ -alumina (r.d. 3.5–3.9) transforms to the  $\alpha$ -form on heating and is a white microcrystalline solid. The compound occurs naturally as **corundum** or **emery** in the  $\alpha$ -form with a hexagonal-close-packed structure of oxide ions with aluminium ions in the octahedral interstices. The gemstones ruby and sapphire are aluminium oxide coloured by minute traces of chromium and cobalt respectively. A number of other forms of aluminium oxide have been described ( $\beta$ -,  $\delta$ -, and  $\zeta$ -alumina) but these contain alkali-metal ions. There is also a short-lived spectroscopic suboxide  $\text{AlO}$ . The highly protective film of oxide formed on the surface of aluminium metal is yet another structural variation, being a defective rock-salt form (every third Al missing).

Pure aluminium oxide is obtained by dissolving the ore bauxite in sodium hydroxide solution; impurities such as iron

oxides remain insoluble because they are not amphoteric. The hydrated oxide is precipitated by seeding with material from a previous batch and this is then roasted at  $1150$ – $1200^\circ\text{C}$  to give pure  $\alpha$ -alumina, or at  $500$ – $800^\circ\text{C}$  to give  $\gamma$ -alumina. The bonding in aluminium hydroxide is not purely ionic due to polarization of the oxide ion. Although the compound might be expected to be amphoteric,  $\alpha$ -alumina is weakly acidic, dissolving in alkalis to give solutions containing aluminate ions; it is resistant to acid attack. In contrast  $\gamma$ -alumina is typically amphoteric dissolving both in acids to give aluminium salts and in bases to give aluminates.  $\alpha$ -alumina is one of the hardest materials known (silicon carbide and diamond are harder) and is widely used as an abrasive in both natural (corundum) and synthetic forms. Its refractory nature makes alumina brick an ideal material for furnace linings and alumina is also used in cements for high-temperature conditions. See also ALUMINIUM HYDROXIDE.

#### aluminium potassium sulphate

**(potash alum; alum)** A white or colourless crystalline compound,  $\text{Al}_2(\text{SO}_4)_3 \cdot \text{K}_2\text{SO}_4 \cdot 24\text{H}_2\text{O}$ ; r.d. 1.757; loses  $18\text{H}_2\text{O}$  at  $92.5^\circ\text{C}$ ; becomes anhydrous at  $200^\circ\text{C}$ . It forms cubic or octahedral crystals that are soluble in cold water, very soluble in hot water, and insoluble in ethanol and acetone. The compound occurs naturally as the mineral **kalinite**. It is a double salt and can be prepared by recrystallization from a solution containing equimolar quantities of potassium sulphate and aluminium sulphate. It is used as a mordant for dyeing and in the tanning and finishing of leather goods (for white leather). See also ALUMS.

#### aluminium sulphate

A white or colourless crystalline compound,  $\text{Al}_2(\text{SO}_4)_3$ , known as the anhydrous compound (r.d. 2.71; decomposes at  $770^\circ\text{C}$ ) or as the hydrate  $\text{Al}_2(\text{SO}_4)_3 \cdot 18\text{H}_2\text{O}$  (monoclinic; r.d. 1.69; loses water at  $86.5^\circ\text{C}$ ). The anhydrous salt is soluble in water and slightly soluble in ethanol; the hydrate is very soluble in water and insoluble in ethanol. The compound occurs naturally in the rare mineral **alunogenite** ( $\text{Al}_2(\text{SO}_4)_3 \cdot 18\text{H}_2\text{O}$ ). It may be prepared by dissolving aluminium hydroxide or china

clays (aluminosilicates) in sulphuric acid. It decomposes on heating to sulphur dioxide, sulphur trioxide, and aluminium oxide. Its solutions are acidic because of hydrolysis.

Aluminium sulphate is commercially one of the most important aluminium compounds; it is used in sewage treatment (as a flocculating agent) and in the purification of drinking water, the paper industry, and in the preparation of mordants. It is also a fire-proofing agent. Aluminium sulphate is often wrongly called **alum** in these industries.

**aluminium trimethyl** See TRIMETHYLALUMINIUM.

**aluminosilicate** The chief rock-forming mineral in, for example, some clays, feldspar, mica, and zeolite. Aluminosilicates are also key constituents of china, glass, and cement. Most have a tetrahedral silicate structure with aluminium atoms replacing some of the silicon.

**alums** A group of double salts with the formula  $A_2SO_4 \cdot B_2(SO_4)_3 \cdot 24H_2O$ , where A is a monovalent metal and B a trivalent metal. The original example contains potassium and aluminium (called **potash alum** or simply **alum**); its formula is often written  $AlK(SO_4)_2 \cdot 12H_2O$  (aluminium potassium sulphate-12-water). **Ammonium alum** is  $AlNH_4(SO_4)_2 \cdot 12H_2O$ . **chrome alum** is  $KCr(SO_4)_2 \cdot 12H_2O$  (see POTASSIUM CHROMIUM SULPHATE), etc. The alums are isomorphous and can be made by dissolving equivalent amounts of the two salts in water and recrystallizing. See also ALUMINIUM SULPHATE.

**alunogenite** A mineral form of hydrated \*aluminium sulphate,  $Al_2(SO_4)_3 \cdot 18H_2O$ .

**Alvarez, Luis Walter** (1911–88) US physicist most of whose working life was spent at the University of California, Berkeley. After working on radar and the atomic bomb during World War II, he concentrated on particle physics. In 1959 he built the first large \*bubble chamber and developed the technique for using it to study charged particles, for which he was awarded the 1968 Nobel Prize for physics.

**Alvarez event** The collision of a giant

meteorite with the earth 65 million years ago that caused catastrophic changes to the earth's climate and environment and a \*mass extinction of species, including the dinosaurs. This hypothesis was advanced in 1980 by Luis Walter \*Alvarez and his geologist son Walter Jr, based on the unusually high concentration of the element iridium in a thin layer of clay deposited at the end of the Cretaceous (see IRIDIUM ANOMALY). This clay marks the boundary between the Cretaceous period and the more recent Tertiary (the so-called **K–T boundary**). Subsequently, geologists discovered a possible impact crater, roughly 160 km in diameter, along the coast of eastern Mexico, and other evidence has tended to support the hypothesis. Such a collision would have produced a massive tidal wave and fireball and sent a vast cloud of rock and other debris into the atmosphere. The resulting upheaval in the climate is estimated to have caused the extinction of some 75% of all species.

**alveolus 1.** The tiny air sac in the \*lung of mammals and reptiles at the end of each \*bronchiole. It is lined by a delicate moist membrane, has many blood capillaries, and is the site of exchange of respiratory gases (carbon dioxide and oxygen). **2.** The socket in the jawbone in which a tooth is rooted by means of the \*periodontal membrane.

**Alzheimer's disease** A neurological disease characterized by progressive loss of intellectual ability. The disease, which is named after German physician Alois Alzheimer (1864–1915), is associated with general shrinkage of the brain tissue – with deposits of  $\beta$ -amyloid peptide (a glycoprotein) and abnormal filaments of tau protein associated with \*microtubules – and changes in the neurotransmitter systems within the brain that include a loss in the activity of \*cholinergic neurons.

**AM (amplitude modulation)** See MODULATION.

**amalgam** An alloy of mercury with one or more other metals. Most metals form amalgams (iron and platinum are exceptions), which may be liquid or solid. Some contain definite intermetallic compounds, such as  $NaHg_2$ .

**amatol** A high explosive consisting of a mixture of ammonium nitrate and trinitrotoluene.

**amber** A yellow or reddish-brown fossil resin. The resin was exuded by certain trees and other plants and often contains preserved insects, flowers, or leaves that were trapped by its sticky surface before the resin hardened. Amber is used for jewellery and ornaments. It also has the property of acquiring an electrical charge when rubbed (the term electricity is derived from *electron*, the Greek name for amber). It occurs throughout the world in rock strata from the Cretaceous to the Pleistocene, but most commonly in Cretaceous and Tertiary rocks.

**ambidentate** Describing a ligand that can coordinate at two different sites. For example, the  $\text{NO}_2$  molecule can coordinate through the N atom (the **nitro ligand**) or through an O atom (the **nitrido ligand**). Complexes that differ only in the way the ligand coordinates display **linkage isomerism**.

**ambient** Denoting the immediate surroundings or environment. **Ambient light** is light generated by outside sources, such as the sun, in relation to the environment of a specific optical system. **Ambient noise** is the background noise in relation to a particular sound, such as music. **Ambient pressure** and **ambient temperature** are the pressure and temperature of the surroundings, e.g. of the atmosphere, in relation to a specific object or system.

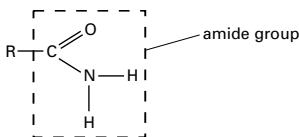

**americium** Symbol Am. A radioactive metallic transuranic element belonging to the  $\alpha$ -actinoids; a.n. 95; mass number of most stable isotope 243 (half-life  $7.95 \times 10^3$  years); r.d. 13.67 ( $20^\circ\text{C}$ ); m.p.  $994 \pm 4^\circ\text{C}$ ; b.p.  $2607^\circ\text{C}$ . Ten isotopes are known. The element was discovered by G. T. Seaborg and associates in 1945, who obtained it by bombarding uranium-238 with alpha particles.

**Ames test** (*Salmonella mutagenesis test*) A test to determine the effects of a chemical on the rate of mutation in bacterial cells, and hence its likely potential for causing cancer in other organisms, including humans. Devised by US biologist Bruce Ames (1928–), it is widely used in

screening chemicals occurring in the environment for possible carcinogenic activity. The chemical is applied to plates inoculated with a special mutant strain of bacteria, usually *Salmonella typhimurium*, and cells that mutate back to the wild type are detected by the occurrence of colonies able to grow on the medium.

**amethyst** The purple variety of the mineral  $\alpha$ -quartz. It is found chiefly in Brazil, the Urals (Russia), Arizona (USA), and Uruguay. The colour is due to impurities, especially iron oxide. It is used as a gemstone.

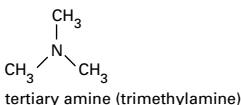

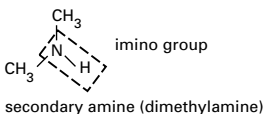

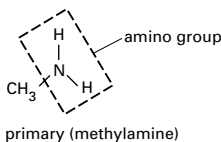

**amides 1.** Organic compounds containing the group  $-\text{CO.NH}_2$  (the **amide group**). Compounds containing this group are **primary amides**. **Secondary and tertiary amides** can also exist, in which the hydrogen atoms on the nitrogen are replaced by one or two other organic groups respectively. Simple examples of primary amides are ethanamide,  $\text{CH}_3\text{CONH}_2$ , and propanamide,  $\text{C}_2\text{H}_5\text{CONH}_2$ . They are made by heating the ammonium salt of the corresponding carboxylic acid. Amides can also be made by reaction of ammonia (or an amine) with an acyl halide. *See also* HOFMANN'S REACTION. **2.** Inorganic compounds containing the ion  $\text{NH}_2^-$ , e.g.  $\text{KNH}_2$ . They are formed by the reaction of ammonia with electropositive metals.

Amide structure

**amination** A chemical reaction in which an amino group ( $-\text{NH}_2$ ) is introduced into a molecule. Examples of amination reaction include the reaction of halogenated hydrocarbons with ammonia (high pressure and temperature) and the reduction of nitro compounds and nitriles.

**amines** Organic compounds derived by replacing one or more of the hydrogen atoms in ammonia by organic groups (see illustration). **Primary amines** have one hydrogen replaced, e.g. methylamine,

#### Examples of amines

$\text{CH}_3\text{NH}_2$ . They contain the functional group  $-\text{NH}_2$  (the **amino group**). **Secondary amines** have two hydrogens replaced, e.g. methylethylamine,  $\text{CH}_3(\text{C}_2\text{H}_5)\text{NH}$ . **Tertiary amines** have all three hydrogens replaced, e.g. trimethylamine,  $(\text{CH}_3)_3\text{N}$ . Amines are produced by the decomposition of organic matter. They can be made by reducing nitro compounds or amides. *See also* IMINES.

**amine salts** Salts similar to ammonium salts in which the hydrogen atoms attached to the nitrogen are replaced by one or more organic groups. Amines readily form salts by reaction with acids, gaining a proton to form a positive ammonium ion. They are named as if they were substituted derivatives of ammonium compounds; for example, dimethylamine ( $(\text{CH}_3)_2\text{NH}$ ) will react with hydrogen chloride to give dimethylammonium chloride, which is an ionic compound  $[(\text{CH}_3)_2\text{NH}_2]^+\text{Cl}^-$ . When the amine has a common nonsystematic name the suffix *-ium* can be used; for example, phenylamine (aniline) would give  $[\text{C}_6\text{H}_5\text{NH}_3]^+\text{Cl}^-$ , known as anilinium chloride. Formerly, such compounds were sometimes called **hydrochlorides**, e.g. ani-

line hydrochloride with the formula  $\text{C}_6\text{H}_5\text{NH}_2\cdot\text{HCl}$ .

Salts formed by amines are crystalline substances that are readily soluble in water. Many insoluble *\*alkaloids* (e.g. quinine and atropine) are used medicinally in the form of soluble salts ('hydrochlorides'). If alkali (sodium hydroxide) is added to solutions of such salts the free amine is liberated.

If all four hydrogen atoms of an ammonium salt are replaced by organic groups a **quaternary ammonium compound** is formed. Such compounds are made by reacting tertiary amines with halogen compounds; for example, trimethylamine ( $(\text{CH}_3)_3\text{N}$ ) with chloromethane ( $\text{CH}_3\text{Cl}$ ) gives tetramethylammonium chloride,  $(\text{CH}_3)_4\text{N}^+\text{Cl}^-$ . Salts of this type do not liberate the free amine when alkali is added, and quaternary hydroxides (such as  $(\text{CH}_3)_4\text{N}^+\text{OH}^-$ ) can be isolated. Such compounds are strong alkalis, comparable to sodium hydroxide.

**amino acid** Any of a group of water-soluble organic compounds that possess both a carboxyl ( $-\text{COOH}$ ) and an amino ( $-\text{NH}_2$ ) group attached to the same carbon atom, called the  $\alpha$ -carbon atom. Amino acids can be represented by the general formula  $\text{R}-\text{CH}(\text{NH}_2)\text{COOH}$ . R may be hydrogen or an organic group and determines the properties of any particular amino acid. Through the formation of peptide bonds, amino acids join together to form short chains (*\*peptides*) or much longer chains (*\*polypeptides*). Proteins are composed of various proportions of about 20 commonly occurring amino acids (see table). The sequence of these amino acids in the protein polypeptides determines the shape, properties, and hence biological role of the protein. Some amino acids that never occur in proteins are nevertheless important, e.g. *\*ornithine* and *citulline*, which are intermediates in the urea cycle.

Plants and many microorganisms can synthesize amino acids from simple inorganic compounds, but animals rely on adequate supplies in their diet. The *\*essential* amino acids must be present in the diet whereas others can be manufactured from them.

**aminobenzene** *See* PHENYLAMINE.

a

amino acid	abbreviation	formula

\*an essential amino acid

The amino acids occurring in proteins

**amino group** See AMINES.

**aminopeptidase** Any enzyme that cleaves amino acids from the N-terminus of peptides or polypeptides. For example, membrane-bound aminopeptidases in the small intestine break down peptides and dipeptides into amino acids.

**amino sugar** Any sugar containing an amino group in place of a hydroxyl group. The **hexosamines** are amino derivatives of

hexose sugars and include **glucosamine** (based on glucose) and **galactosamine** (based on galactose). The former is a constituent of \*chitin and the latter occurs in cartilage.

**α-aminotoluene** See BENZYLAMINE.

**ammeter** An instrument that measures electric current. The main types are the **moving-coil** ammeter, the **moving-iron** ammeter, and the **thermoammeter**. The

a

moving-coil instrument is a moving-coil \*galvanometer fitted with a \*shunt to reduce its sensitivity. It can only be used for d.c., but can be adapted for a.c. by using a \*rectifier. In moving-iron instruments, a piece of soft iron moves in the magnetic field created when the current to be measured flows through a fixed coil. They can be used with a.c. or d.c. but are less accurate (though more robust) than the moving-coil instruments. In thermoammeters, which can also be used with a.c. or d.c., the current is passed through a resistor, which heats up as the current passes. This is in contact with a thermocouple, which is connected to a galvanometer. This indirect system is mainly used for measuring high frequency a.c. In the **hot-wire** instrument the wire is clamped at its ends and its elongation as it is heated causes a pointer to move over a scale.

**amine** A coordination \*complex in which the ligands are ammonia molecules. An example of an ammine is the tetraamminecopper(II) ion  $[\text{Cu}(\text{NH}_3)_4]^{2+}$ .

**ammonia** A colourless gas,  $\text{NH}_3$ , with a strong pungent odour; r.d. 0.59 (relative to air); m.p.  $-77.7^\circ\text{C}$ ; b.p.  $-33.35^\circ\text{C}$ . It is very soluble in water and soluble in alcohol. The compound may be prepared in the laboratory by reacting ammonium salts with bases such as calcium hydroxide, or by the hydrolysis of a nitride. Industrially it is made by the \*Haber process and over 80 million tonnes per year are used either directly or in combination. Major uses are the manufacture of nitric acid, ammonium nitrate, ammonium phosphate, and urea (the last three as fertilizers), explosives, dyestuffs, and resins.

Liquid ammonia has some similarity to water as it is hydrogen bonded and has a moderate dielectric constant, which permits it to act as an ionizing solvent. It is weakly self-ionized to give ammonium ions,  $\text{NH}_4^+$  and amide ions,  $\text{NH}_2^-$ . It also dissolves electropositive metals to give blue solutions, which are believed to contain solvated electrons. Ammonia is extremely soluble in water giving basic solutions that contain solvated  $\text{NH}_3$  molecules and small amounts of the ions  $\text{NH}_4^+$  and  $\text{OH}^-$ . The combustion of ammonia in air yields nitrogen and water. In the presence of catalysts  $\text{NO}$ ,  $\text{NO}_2$ , and water

are formed; this last reaction is the basis for the industrial production of nitric acid. Ammonia is a good proton acceptor (i.e. it is a base) and gives rise to a series of ammonium salts, e.g.  $\text{NH}_3 + \text{HCl} \rightarrow \text{NH}_4^+ + \text{Cl}^-$ . It is also a reducing agent.

The participation of ammonia in the \*nitrogen cycle is a most important natural process. Nitrogen-fixing bacteria are able to achieve similar reactions to those of the Haber process, but under normal conditions of temperature and pressure. These release ammonium ions, which are converted by nitrifying bacteria into nitrite and nitrate ions.

**ammoniacal** Describing a solution in which the solvent is aqueous ammonia.

**ammonia clock** A form of atomic clock in which the frequency of a quartz oscillator is controlled by the vibrations of excited ammonia molecules (see EXCITATION). The ammonia molecule ( $\text{NH}_3$ ) consists of a pyramid with a nitrogen atom at the apex and one hydrogen atom at each corner of the triangular base. When the molecule is excited, once every 20.9 microseconds the nitrogen atom passes through the base and forms a pyramid the other side: 20.9 microseconds later it returns to its original position. This vibration back and forth has a frequency of 23 870 hertz and ammonia gas will only absorb excitation energy at exactly this frequency. By using a \*crystal oscillator to feed energy to the gas and a suitable feedback mechanism, the oscillator can be locked to exactly this frequency.

**ammonia-soda process** See SOLVAY PROCESS.

**ammonite** An extinct aquatic mollusc of the class \*Cephalopoda. Ammonites were abundant in the Mesozoic era (225–65 million years ago) and are commonly found as fossils in rock strata of that time, being used as \*index fossils for the Jurassic period. They were characterized by a coiled shell divided into many chambers, which acted as a buoyancy aid. The external suture lines on these shells increased in complexity with the advance of the group.

**ammonium alum** See ALUMS.

**ammonium carbonate** A colourless or

white crystalline solid,  $(\text{NH}_4)_2\text{CO}_3$ , usually encountered as the monohydrate. It is very soluble in cold water. The compound decomposes slowly to give ammonia, water, and carbon dioxide. Commercial 'ammonium carbonate' is a double salt of ammonium hydrogencarbonate and ammonium aminomethanoate (carbamate),  $\text{NH}_4\text{HCO}_3 \cdot \text{NH}_2\text{COONH}_4$ . This material is manufactured by heating a mixture of ammonium chloride and calcium carbonate and recovering the product as a sublimed solid. It readily releases ammonia and is the basis of sal volatile. It is also used in dyeing and wool preparation and in baking powders.

**ammonium chloride (sal ammoniac)** A white or colourless cubic solid,  $\text{NH}_4\text{Cl}$ ; r.d. 1.53; sublimes at  $340^\circ\text{C}$ . It is very soluble in water and slightly soluble in ethanol but insoluble in ether. It may be prepared by fractional crystallization from a solution containing ammonium sulphate and sodium chloride or ammonium carbonate and calcium chloride. Pure samples may be made directly by the gas-phase reaction of ammonia and hydrogen chloride. Because of its ease of preparation it can be manufactured industrially alongside any plant that uses or produces ammonia. The compound is used in dry cells, metal finishing, and in the preparation of cotton for dyeing and printing.

**ammonium ion** The monovalent cation  $\text{NH}_4^+$ . It may be regarded as the product of the reaction of ammonia (a Lewis base) with a hydrogen ion. The ion has tetrahedral symmetry. The chemical properties of ammonium salts are frequently very similar to those of equivalent alkali-metal salts.

**ammonium nitrate** A colourless crystalline solid,  $\text{NH}_4\text{NO}_3$ ; r.d. 1.72; m.p.  $169.6^\circ\text{C}$ ; b.p.  $210^\circ\text{C}$ . It is very soluble in water and soluble in ethanol. The crystals are rhombic when obtained below  $32^\circ\text{C}$  and monoclinic above  $32^\circ\text{C}$ . It may be readily prepared in the laboratory by the reaction of nitric acid with aqueous ammonia. Industrially, it is manufactured by the same reaction using ammonia gas. Vast quantities of ammonium nitrate are used as fertilizers (over 20 million tonnes

per year) and it is also a component of some explosives.

**ammonium sulphate** A white rhombic solid,  $(\text{NH}_4)_2\text{SO}_4$ ; r.d. 1.77; decomposes at  $235^\circ\text{C}$ . It is very soluble in water and insoluble in ethanol. It occurs naturally as the mineral **mascagnite**. Ammonium sulphate was formerly manufactured from the 'ammoniacal liquors' produced during coal-gas manufacture but is now produced by the direct reaction between ammonia gas and sulphuric acid. It is decomposed by heating to release ammonia (and ammonium hydrogensulphate) and eventually water, sulphur dioxide, and ammonia. Vast quantities of ammonium sulphate are used as fertilizers.

**amniocentesis** The taking of a sample of amniotic fluid from a pregnant woman to determine the condition of an unborn baby. A hollow needle is inserted through the woman's abdomen and wall of the uterus and the fluid drawn off. Chemical and microscopical examination of cells shed from the embryo's skin into the fluid are used to detect spina bifida, \*Down's syndrome, or other serious biochemical or chromosomal abnormalities.

**amnion** A membrane that encloses the embryo of reptiles, birds, and mammals within the **amniotic cavity**. This cavity is filled with **amniotic fluid**, in which the embryo is protected from desiccation and from external pressure. *See also* EXTRA-EMBRYONIC MEMBRANES.

**amniote** A vertebrate whose embryos are totally enclosed in a fluid-filled sac – the \*amnion. The evolution of the amnion provided the necessary fluid environment for the developing embryo and therefore allowed animals to breed away from water. Amniotes comprise the reptiles, birds, and mammals. *Compare* ANAMNIOTE.

**Amoeba** A genus of protoctists (*see also* PROTOZOA) of the phylum Rhizopoda, members of which have temporary body projections called \*pseudopodia. These are used for locomotion and feeding and result in a constantly changing body shape (*see* AMOEBOID MOVEMENT). Most species are free-living in soil, mud, or water, where they feed on smaller protoc-

tists and other single-celled organisms, but a few are parasitic. The best known species is the much studied *A. proteus*.

**amoebocyte** An animal cell whose location is not fixed and is therefore able to wander through the body tissues. Amoebocytes are named after their resemblance, especially in their movement, to *Amoeba* (see AMOEBOID MOVEMENT) and they feed on foreign particles (including invading bacteria). They occur, for example, in sponges and mammalian blood (e.g. some \*leucocytes).

**amoeboid movement** The mechanism of movement demonstrated by \**Amoeba* and other cells that are capable of changing their shape (e.g. \*phagocytes). The cytoplasm of *Amoeba* consists of a central fluid endoplasm surrounded by a more viscous ectoplasm. The fluid endoplasm slides towards the front of the cell, forming a \*pseudopodium and propelling the cell forward. On reaching the tip of the pseudopodium, the endoplasm is converted into ectoplasm; at the same time the ectoplasm at the rear of the cell is converted into endoplasm and streams forward, thus maintaining continuous movement.

**amorphous** Describing a solid that is not crystalline; i.e. one that has no long-range order in its lattice. Many powders that are described as 'amorphous' in fact are composed of microscopic crystals, as can be demonstrated by X-ray diffraction. \*Glasses are examples of true amorphous solids.

**amount concentration** See CONCENTRATION.

**amount of substance** Symbol *n*. A measure of the number of entities present in a substance. The specified entity may be an atom, molecule, ion, electron, photon, etc., or any specified group of such entities. The amount of substance of an element, for example, is proportional to the number of atoms present. For all entities, the constant of proportionality is the \*Avogadro constant. The SI unit of amount of substance is the \*mole.

**AMP** See ATP; CYCLIC AMP.

**ampere** Symbol A. The SI unit of electric

current. The constant current that, maintained in two straight parallel infinite conductors of negligible cross section placed one metre apart in a vacuum, would produce a force between the conductors of  $2 \times 10^{-7} \text{ N m}^{-1}$ . This definition replaced the earlier international ampere defined as the current required to deposit 0.001 118 00 gram of silver from a solution of silver nitrate in one second. The unit is named after A. M. Ampère.

**Ampère, André Marie** (1775–1836) French physicist who from 1809 taught at the Ecole Polytechnique in Paris. He is best known for putting electromagnetism (which he called 'electrodynamics') on a mathematical basis. In 1825 he formulated \*Ampère's law. The \*ampere is named after him.

**ampere-hour** A practical unit of electric charge equal to the charge flowing in one hour through a conductor passing one ampere. It is equal to 3600 coulombs.

**Ampère's law** A law of the form

$$dB = (\mu_0 I \sin \theta dl) / 4\pi r^2,$$

where *dB* is the infinitesimal element of the magnitude of the magnetic flux density at a distance *r* at a point P from the element length *dl* of a conductor,  $\mu_0$  is the magnetic \*permeability of free space, *I* is the current flowing through the conductor, and  $\theta$  is the angle between the direction of the current and the line joining the element of the conductor and P. It is also called the **Ampère-Laplace law** after the French mathematician Pierre-Simon de Laplace (1749–1827).

**Ampère's rule** A rule that relates the direction of the electric current passing through a conductor and the magnetic field associated with it. The rule states that if the electric current is moving away from an observer, the direction of the lines of force of the magnetic field surrounding the conductor is clockwise and that if the electric current is moving towards an observer, the direction of the lines of force is counter-clockwise. An equivalent statement to Ampère's rule is known as the **corkscrew rule**. A corkscrew, or screwdriver, is said to be right-handed if turning the corkscrew in a clockwise direction drives the screw into

the object (such as the cork of a bottle). The corkscrew rule states that a right-handed corkscrew is analogous to an electric current and its magnetic field with the direction of the screw being analogous to electric current; the direction in which the corkscrew is being turned is analogous to the direction of lines of force of the field.

**ampere-turn** The SI unit of \*magnetomotive force equal to the magnetomotive force produced when a current of one ampere flows through one turn of a magnetizing coil.

**amphetamine** A drug, 1-phenyl-2-aminopropane (or a derivative of this compound), that stimulates the central nervous system by causing the release of the transmitters noradrenaline and dopamine from nerve endings. It inhibits sleep, suppresses the appetite, and has variable effects on mood; prolonged use can lead to addiction.

**Amphibia** The class of vertebrate chordates (see CHORDATA) that contains the frogs, toads, newts, and salamanders. The amphibians evolved in the Devonian period (about 370 million years ago) as the first vertebrates to occupy the land, and many of their characteristics are adaptations to terrestrial life. All adult amphibians have a passage linking the roof of the mouth with the nostrils so they may breathe air and keep the mouth closed. The moist scaleless skin is used to supplement the lungs in gas exchange. They have no diaphragm, and therefore the muscles of the mouth and pharynx provide the pumping action for breathing. Fertilization is usually external and the eggs are soft and prone to desiccation, therefore reproduction commonly occurs in water. Amphibian larvae are aquatic, having gills for respiration; they undergo metamorphosis to the adult form.

**amphiboles** A large group of rock-forming metasilicate minerals. They have a structure of silicate tetrahedra linked to form double endless chains, in contrast to the single chains of the \*pyroxenes, to which they are closely related. They are present in many igneous and metamorphic rocks. The amphiboles show a wide range of compositional variation but all of

them conform to the general formula:  $X_{2-3}Y_5Z_8O_{22}(OH)_2$ , where X = Ca, Na, K, Mg, or  $Fe^{2+}$ ; Y = Mg,  $Fe^{2+}$ ,  $Fe^{3+}$ , Al, Ti, or Mn; and Z = Si or Al. The hydroxyl ions may be replaced by F, Cl, or O. Most amphiboles are monoclinic, including: cummingtonite,

tremolite,

actinolite,

\*hornblende,

edenite,

riebeckite,

The minerals anthophyllite,

and gedrite,

are orthorhombic amphiboles.

**amphimixis** True sexual reproduction, involving the fusion of male and female gametes and the formation of a zygote. Compare APOMIXIS.

**amphioxus** Another name for the lancelet: see CHORDATA.

**amphiprotic** See AMPHOTERIC; SOLVENT.

**ampholyte** A substance that can act as either an acid, in the presence of a strong base, or a base, when in the presence of a strong acid.

**ampholyte ion** See ZWITTERION.

**amphoteriC** Describing a compound that can act as both an acid and a base (in the traditional sense of the term). For instance, aluminium hydroxide is amphoteriC: as a base  $Al(OH)_3$  it reacts with acids to form aluminium salts; as an acid  $H_3AlO_3$  it reacts with alkalis to give \*aluminate. Oxides of metals are typically basic and oxides of nonmetals tend to be

acidic. The existence of amphoteric oxides is sometimes regarded as evidence that an element is a \*metalloid. Compounds such as the amino acids, which contain both acidic and basic groups in their molecules, can also be described as amphoteric. Solvents, such as water, that can both donate and accept protons are usually described as **amphiprotic** (see SOLVENT).

**amplifier** A device that increases the strength of an electrical signal by drawing energy from a separate source to that of the signal. The original device used in electronic amplifiers was the \*triode valve, in which the cathode-anode current is varied in accordance with the low-voltage signal applied to the valve's control grid. In the more recent \*transistor, the emitter-collector current is controlled in much the same way by the signal applied to the transistor's base region. In the most modern devices the complete amplifier circuit is manufactured as a single \*integrated circuit. The ratio of the output amplitude (of p.d. or current) of an amplifier (or stage of an amplifier) to the corresponding input amplitude is called the **gain** of the amplifier.

**amplitude** See WAVE.

**amplitude modulation (AM)** See MODULATION; RADIO.

**ampulla** **1.** An enlargement at one end of each of the \*semicircular canals of the inner ear. Each ampulla contains a group of receptors - sensory hair cells - embedded in a gelatinous cap (**cupula**), which detects movement in one particular dimension, corresponding to the plane of the canal. Movement of the head causes the cupula (and the hairs within it) to bend in a direction opposite to that of the head movement; this stimulates nerve impulses in the receptors, which are interpreted by the brain as movement in a particular dimension. **2.** Any small vesicle or saclike process.

**a.m.u.** See ATOMIC MASS UNIT.

**amylase** Any of a group of closely related enzymes that degrade starch, glycogen, and other polysaccharides. Plants contain both  $\alpha$ - and  $\beta$ -amylases; the name **diastase** is given to the component of malt containing  $\beta$ -amylase, important in

the brewing industry. Animals possess only  $\alpha$ -amylases, found in pancreatic juice (as **pancreatic amylase**) and also (in humans and some other species) in saliva (as **salivary amylase** or **ptyalin**). Amylases cleave the long polysaccharide chains, producing a mixture of glucose and maltose.

**amyl group** Formerly, any of several isomeric groups with the formula  $C_5H_{11}$ -.

**amylopectin** A \*polysaccharide comprising highly branched chains of glucose molecules. It is one of the constituents (the other being amylose) of \*starch.

**amylose** A \*polysaccharide consisting of linear chains of between 100 and 1000 linked glucose molecules. Amylose is a constituent of \*starch. In water, amylose reacts with iodine to give a characteristic blue colour.

**anabolic steroid** Any steroid compound that promotes tissue growth, especially of muscles. Naturally occurring anabolic steroids include the male sex hormones (\*androgens). Synthetic forms of these are used medically to help weight gain after debilitating diseases; their use by athletes to build up body muscles can cause liver damage and is banned by most athletic authorities.

**anabolism** The metabolic synthesis of proteins, fats, and other constituents of living organisms from molecules or simple precursors. This process requires energy in the form of ATP. Drugs that promote such metabolic activity are described as **anabolic** (see ANABOLIC STEROID). See METABOLISM. Compare CATABOLISM.

**anaerobe** See ANAEROBIC RESPIRATION.

**anaerobic respiration** A type of \*respiration in which foodstuffs (usually carbohydrates) are partially oxidized, with the release of chemical energy, in a process not involving atmospheric oxygen. Since the substrate is never completely oxidized the energy yield of this type of respiration is lower than that of \*aerobic respiration. It occurs in some yeasts and bacteria and in muscle tissue when oxygen is absent (see OXYGEN DEBT). **Obligate anaerobes** are organisms that cannot use free oxygen for respiration; **facultative**

**anaerobes** are normally aerobic but can respire anaerobically during periods of oxygen shortage. Alcoholic \*fermentation is a type of anaerobic respiration in which one of the end products is ethanol.

**Analar reagent** A chemical reagent of high purity with known contaminants for use in chemical analyses.

**analgesic** A substance that reduces pain without causing unconsciousness, either by reducing the pain threshold or by increasing pain tolerance. There are several categories of analgesic drugs, including morphine and its derivatives (see OPIATE), which produce analgesia by acting on the central nervous system; nonsteroidal anti-inflammatory drugs (e.g. \*aspirin); and local anaesthetics.

**analogous** Describing features of unrelated organisms that are superficially similar but have evolved in very different ways. The wings of butterflies and birds are analogous organs.

**analyser** A device, used in the \*polarization of light, that is placed in the eyepiece of a \*polarimeter to observe plane-polarized light. The analyser, which may be a \*Nicol prism or \*Polaroid, can be oriented in different directions to investigate in which plane an incoming wave is polarized or if the light is plane polarized. If there is one direction from which light does not emerge from the analyser when it is rotated, the incoming wave is plane polarized. If the analyser is horizontal when extinction of light takes place, the polarization of light must have been in the vertical plane. The intensity of a beam of light transmitted through an analyser is proportional to  $\cos^2\theta$ , where  $\theta$  is the angle between the plane of polarization and the plane of the analyser. Extinction is said to be produced by 'crossing' the \*polarizer and analyser.

**analysis** The determination of the components in a chemical sample. **Qualitative analysis** involves determining the nature of a pure unknown compound or the compounds present in a mixture. Various chemical tests exist for different elements or types of compound, and systematic analytical procedures can be used for mixtures. **Quantitative analysis** involves

measuring the proportions of known components in a mixture. Chemical techniques for this fall into two main classes: \*volumetric analysis and \*gravimetric analysis. In addition, there are numerous physical methods of qualitative and quantitative analysis, including spectroscopic techniques, mass spectrometry, polarography, chromatography, activation analysis, etc.

**analytical geometry (coordinate geometry)** A form of geometry in which points are located in a two-dimensional, three-dimensional, or higher-dimensional space by means of a system of coordinates. Curves are represented by an equation for a set of such points. The geometry of figures can thus be analysed by algebraic methods. See CARTESIAN COORDINATES; POLAR COORDINATES.

**anamniote** A vertebrate that lacks an \*amnion and whose embryos and larvae must therefore develop in water. Anamniotes comprise the agnathans, fishes, and amphibians. Compare AMNIOTE.

**anaphase** One of several stages of cell division. In \*mitosis the chromatids of each chromosome move apart to opposite ends of the spindle. In the first anaphase of \*meiosis, the paired homologous chromosomes separate and move to opposite ends; in the second anaphase the chromatids move apart, as in mitosis.

**anaphylaxis** An abnormal \*immune response that occurs when an individual previously exposed to a particular \*antigen is re-exposed to the same antigen. Anaphylaxis may follow an insect bite or the injection of a drug (such as penicillin). It is caused by the release of \*histamine and similar substances and may produce a localized reaction or a more generalized and severe one, with difficulty in breathing, pallor, or drop in blood pressure, unconsciousness, and possibly heart failure and death. See also ALLERGY.

**anastigmatic lens** **1.** An objective lens for an optical instrument in which all \*aberrations, including \*astigmatism, are reduced greatly. **2.** A spectacle lens designed to correct astigmatism. It has different radii of curvature in the vertical and horizontal planes.

**anatomy** The study of the structure of living organisms, especially of their internal parts by means of dissection and microscopic examination. *Compare* MORPHOLOGY.

**anchor ring** *See* TORUS.

**AND circuit** *See* LOGIC CIRCUITS.

**Anderson, Carl David** (1905–91) US physicist who became a professor at the California Institute of Technology, where he worked mainly in particle physics. In 1937 he discovered the \*positron in \*cosmic radiation, and four years later was awarded the Nobel Prize. In 1939 he discovered the mu-meson (muon).

**androecium** The male sex organs (\*stamens) of a flower. *Compare* GYNOCÆCIUM.

**androgen** One of a group of male sex hormones that stimulate development of the testes and of male \*secondary sexual characteristics (such as growth of facial and pubic hair in men). **Testosterone** is the most important. Androgens are produced principally by the testes when stimulated with \*luteinizing hormone but they are also secreted in smaller amounts by the adrenal glands and the ovaries. Injections of natural or synthetic androgens are used to treat hormonal disorders of the testes and breast cancer and to build up body tissue (*see* ANABOLIC STEROID).

**anechoic** Having a low degree of reverberation with little or no reflection of sound. An **anechoic** chamber is one designed for experiments in acoustics. The walls are covered with small pyramids to avoid the formation of stationary waves between facing surfaces and the whole of the interior surface is covered with an absorbent material to avoid reflections.

**anemometer** An instrument for measuring the speed of the wind or any other flowing fluid. The simple **vane anemometer** consists of a number of cups or blades attached to a central spindle so that the air, or other fluid, causes the spindle to rotate. The instrument is calibrated to give a wind speed directly from a dial. It can be mounted to rotate about a vertical axis and in this form it also gives an indication of the direction of the wind. A **hot-wire anemometer** consists of an

electrically heated wire that is cooled by the flow of fluid passing round it. The faster the flow the lower the temperature of the wire and the lower its resistance. Thus the rate of flow can be calculated by measuring the resistance of the wire.

**anemophily** Pollination of a flower in which the pollen is carried by the wind. Examples of anemophilous flowers are those of grasses and conifers. *Compare* ENTOMOPHILY; HYDROPHILY.

**aneroid barometer** *See* BAROMETER.

**angiosperms** *See* ANTHOPHYTA.

**angiotensin** Any of three related peptide hormones. Angiotensin I is derived, by the action of the enzyme \*renin, from a protein ( $\alpha$ -globulin) secreted by the liver into the bloodstream. As blood passes through the lungs, another enzyme (**angiotensin-converting enzyme; ACE**) splits angiotensin I, forming angiotensin II. This causes constriction of blood vessels and stimulates the release of \*antidiuretic hormone and \*aldosterone, which increase blood pressure. Angiotensin III, formed by removal of a single amino acid from angiotensin II, also stimulates aldosterone release by the adrenal gland.

**angle modulation** *See* MODULATION.

**angle of incidence** **1.** The angle between a ray falling on a surface and the perpendicular (normal) to the surface at the point at which the ray strikes the surface. **2.** The angle between a wavefront and a surface that it strikes.

**angle of reflection** **1.** The angle between a ray leaving a reflecting surface and the perpendicular (normal) to the surface at the point at which the ray leaves the surface. **2.** The angle between a wavefront and a surface that it leaves.

**angle of refraction** **1.** The angle between a ray that is refracted at a surface between two different media and the perpendicular (normal) to the surface at the point of refraction. **2.** The angle between a wavefront and a surface at which it has been refracted.

**angle-resolved photoelectron spectroscopy (ARPES)** A technique for studying the composition and structure of

surfaces by measuring both the kinetic energy and angular distribution of photoelectrons ejected from a surface by electromagnetic radiation. *See also* PHOTOELECTRON SPECTROSCOPY.

**anglesite** A mineral form of \*lead(II) sulphate,  $\text{PbSO}_4$ .

**angstrom** Symbol Å. A unit of length equal to  $10^{-10}$  metre. It was formerly used to measure wavelengths and intermolecular distances but has now been replaced by the nanometre.  $1 \text{ Å} = 0.1$  nanometre. The unit is named after Anders Ångström.

**Ångström, Anders Jonas** (1814–74) Swedish astronomer and physicist who became professor of physics at the University of Uppsala from 1858 until his death. He worked mainly with emission \*spectra, demonstrating the presence of hydrogen in the sun. He also worked out the wavelengths of \*Fraunhofer lines. Since 1905 spectral wavelengths have been expressed in \*angstroms.

**angular displacement, velocity, and acceleration** *See* ROTATIONAL MOTION.

**angular distance** A way of expressing sizes or distances in astronomy. Angular diameter is the size of a celestial object; angular distance is the distance between two objects. Both are measured as angles on the \*celestial sphere (expressed in degrees, arc-minutes, or arc-seconds).

**angular frequency (pulsance)** A quantity proportional to the \*frequency of a periodic phenomenon but having the dimensions of angular velocity. The angular frequency in radians per second = frequency in hertz  $\times 2\pi$  radians per cycle.

**angular magnification (magnifying power)** *See* MAGNIFICATION.

**angular momentum** Symbol  $L$ . The product of the angular velocity of a body and its \*moment of inertia about the axis of rotation, i.e.  $L = I\omega$ .

**anharmonic oscillator** An oscillating system (in either \*classical physics or \*quantum mechanics) that is not oscillating in \*simple harmonic motion. In general, the problem of an anharmonic oscillator is not exactly soluble, although many systems approximate to harmonic

oscillators and for such systems the **anharmonicity** (the deviation of the system from being a \*harmonic oscillator) can be calculated using \*perturbation theory. If the anharmonicity is large other approximate or numerical techniques have to be used to solve the problem.

**anhydride** A compound that produces a given compound on reaction with water. For instance, sulphur trioxide is the (acid) anhydride of sulphuric acid

*See also* ACID ANHYDRIDES.

**anhydrite** An important rock-forming anhydrous mineral form of calcium sulphate,  $\text{CaSO}_4$ . It is chemically similar to \*gypsum but is harder and heavier and crystallizes in the rhombic form (gypsum is monoclinic). Under natural conditions anhydrite slowly hydrates to form gypsum. It occurs chiefly in white and greyish granular masses and is often found in the caprock of certain salt domes. It is used as a raw material in the chemical industry and in the manufacture of cement and fertilizers.

**anhydrous** Denoting a chemical compound lacking water: applied particularly to salts lacking their water of crystallization.

**aniline** *See* PHENYLAMINE.

**anilinium ion** The ion  $\text{C}_6\text{H}_5\text{NH}_3^+$ , derived from \*phenylamine.

**animal** Any member of the kingdom Animalia, which comprises multicellular organisms that develop from embryos formed by the fusion of haploid eggs and sperm. Unable to manufacture their own food, they feed on other organisms or organic matter (holozoic nutrition; *see* HETEROTROPHIC NUTRITION). Animals are therefore typically mobile (to search for food) and have evolved specialized sense organs for detecting changes in the environment; a \*nervous system coordinates information received by the sense organs and enables rapid responses to environmental stimuli. Animal \*cells lack the cellulose cells walls of \*plant cells. For a classification of the animal kingdom, *see* Appendix.

a

**animal behaviour** The activities that constitute an animal's response to its external environment. Certain categories of behaviour are seen in all animals (e.g. feeding, reproduction) but these activities involve different movements in different species and develop in different ways. Some movements are highly characteristic of a species (see **INSTINCT**) whereas others are more variable and depend on the interaction between innate tendencies and \*learning during the individual's lifetime. Physiologists study how changes in the body (e.g. hormone levels) affect behaviour, psychologists study the mechanisms of learning, and ethologists study the behaviour of the whole animal: how this develops during the individual's lifetime and how it evolved through natural selection (see **ETHOLOGY**).

**animal charcoal** See **CHARCOAL**.

**animal starch** See **GLYCOGEN**.

**anion** A negatively charged \*ion, i.e. an ion that is attracted to the \*anode in \*electrolysis. Compare **CATION**.

**anionic detergent** See **DETERGENT**.

**anionic resin** See **ION EXCHANGE**.

**anisogamy** Sexual reproduction involving the fusion of gametes that differ in size and sometimes also in form. See also **OOGAMY**. Compare **ISOGAMY**.

**anisotropic** Denoting a medium in which certain physical properties are different in different directions. Wood, for instance, is an anisotropic material: its strength along the grain differs from that perpendicular to the grain. Single crystals that are not cubic are anisotropic with respect to some physical properties, such as the transmission of electromagnetic radiation. Compare **ISOTROPIC**.

**annealing** A form of heat treatment applied to a metal to soften it, relieve internal stresses and instabilities, and make it easier to work or machine. It consists of heating the metal to a specified temperature for a specified time, both of which depend on the metal involved, and then allowing it to cool slowly. It is applied to both ferrous and nonferrous metals and a similar process can be applied to other materials, such as glass.

**Annelida** A phylum of invertebrates comprising the segmented worms (e.g. the earthworm). Annelids have cylindrical soft bodies showing \*metameric segmentation, obvious externally as a series of rings separating the segments. Each segment is internally separated from the next by a membrane and bears stiff bristles (see **CHAETA**). Between the gut and other body organs there is a fluid-filled cavity called the \*coelom, which acts as a hydrostatic skeleton. Movement is by alternate contraction of circular and longitudinal muscles in the body wall. The phylum contains three classes: \*Polychaeta, \*Oligochaeta, and \*Hirudinea.

**annihilation** The destruction of a particle and its \*antiparticle as a result of a collision between them. The **annihilation radiation** produced is carried away by \*photons or \*mesons. For example, in a collision between an electron and a positron the energy produced is carried away by two photons, each having an energy of 0.511 MeV, which is equivalent to the rest-mass energies of the annihilated particles plus their kinetic energies. When nucleons annihilate each other the energy is carried away by mesons.

**annual** A plant that completes its life cycle in one year, during which time it germinates, flowers, produces seeds, and dies. Examples are the sunflower and marigold. Compare **BIENNIAL**; **EPHEMERAL**; **PERENNIAL**.

**annual rhythm** The occurrence of a process or a function in a living organism on a yearly basis. Events that display an annual rhythm can include life cycles, such as those of \*annual plants; mating behaviour; some kinds of movement, such as \*migration; or growth patterns, such as the \*growth rings of woody plant stems. See also **BIORHYTHM**.

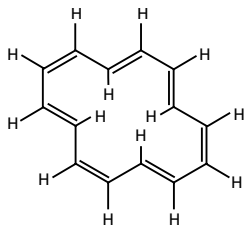

**annual ring** See **GROWTH RING**.

**annular parallax** Symbol  $\pi$ . The \*parallax of a celestial object resulting from the movement of the earth in its orbit during a year. It is equal to the semimajor axis of the parallax ellipse described by the apparent movement of the object against the background of distant stars. Annular parallax (in arc-seconds) is also approxi-

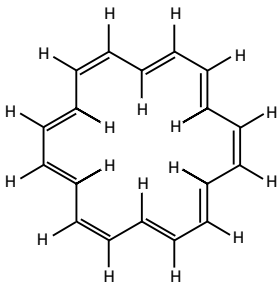

mately equal to the reciprocal of the distance to the object (in parsecs).

**annulenes** Organic hydrocarbons that have molecules containing simple single rings of carbon atoms linked by alternating single and double bonds. Such compounds have even numbers of carbon atoms. Cyclooctatetraene,  $C_8H_8$ , is the next in the series following benzene. Higher annulenes are usually referred to by the number of carbon atoms in the ring, as in [10]-annulene,  $C_{10}H_{10}$ , [12]-annulene,  $C_{12}H_{12}$ , etc. The lower members are not stable as a result of the interactions between hydrogen atoms inside the ring. This is true even for molecules that have the necessary number of pi electrons to be aromatic compounds. Thus, [10]-annulene has  $4n + 2$  pi electrons with  $n = 2$ , but is not aromatic because it is not planar. [14]-annulene also has a suitable number of pi electrons to be aromatic ( $n = 3$ ) but is not planar because of interaction between the inner hydrogens.

The compound [18]-annulene is large

[14]-annulene

[18]-annulene

Annulenes

enough to be planar and obeys the Hückel rule ( $4n + 2 = 18$ , with  $n = 4$ ). It is a brownish red fairly stable reactive solid. NMR evidence shows that it has aromatic character. The annulene with  $n = 7$ , [30]-annulene, can also exist in a planar form but is highly unstable. See also PSEUDOAROMATIC.

**annulus 1.** (in mathematics) The plane figure formed between two concentric circles of different radii,  $R$  and  $r$ . Its area is  $\pi(R^2 - r^2)$ . **2.** (in botany) **a.** A ragged ring of tissue that remains on the stalk of a mushroom or toadstool. Also called a **velum**, it is formed from the ruptured membrane that originally covered the lower surface of the cap. **b.** The region of the wall of a fern sporangium that is specialized for spore dispersal. It consists of cells that are thickened except on their outer walls. On drying out, the cells contract and the sporangium ruptures, releasing the spores. The annulus springs back into position when the residual water in the cells vaporizes and any remaining spores are dispersed. **3.** (in zoology) Any of various ring-shaped structures in animals, such as any of the segments of an earthworm or other annelid.

**anode** A positive electrode. In electrolysis anions are attracted to the anode. In an electronic vacuum tube it attracts electrons from the cathode and it is therefore from the anode that electrons flow out of the device. In these instances the anode is made positive by external means; however in a voltaic cell the anode is the electrode that spontaneously becomes positive and therefore attracts electrons to it from the external circuit.

**anode sludge** See ELECTROLYTIC REFINING.

**anodizing** A method of coating objects made of aluminium with a protective oxide film, by making them the anode in an electrolytic bath containing an oxidizing electrolyte. Anodizing can also be used to produce a decorative finish by formation of an oxide layer that can absorb a coloured dye.

**anomaly** An angle used to fix the position of a body, such as a planet, in an elliptical orbit. The true anomaly of a planet

is the angle between the \*perihelion, the sun, and the planet in the direction of the planet's motion. The **mean anomaly** is the angle between the perihelion, the sun, and an imaginary planet having the same period as the real planet, but assumed to be moving at constant speed.

**Anoplura** See SIPHUNCULATA.

**ANS** See AUTONOMIC NERVOUS SYSTEM.

**ANSI** American National Standards Institute: a US body that accredits organizations to write industrial standards – publicly available definitions, requirements, criteria, etc. – following the rules established by ANSI.

**antagonism 1.** The interaction of two substances (e.g. drugs, hormones, or enzymes) having opposing effects in a system in such a way that the action of one partially or completely inhibits the effects of the other. For example, one group of anti-cancer drugs acts by antagonizing the effects of certain enzymes controlling the activities of the cancer cells. See also ANTAGONIST. **2.** An interaction between two muscles, known as **antagonistic muscles**, in which contraction of one prevents that of the other. For example, the \*biceps and triceps are an antagonistic pair. See VOLUNTARY MUSCLE. **3.** An interaction between two organisms (e.g. moulds or bacteria) in which the growth of one is inhibited by the other. Compare SYNERGISM.

**antagonist** A drug that inhibits the effect of an \*agonist in such a way that the combined biological effect of the two substances becomes smaller than the sum of their individual effects. **Competitive antagonists** act by binding to agonist receptors, while **noncompetitive antagonists** do not bind to the same receptor sites as the agonist. A **functional antagonist** binds to other receptors that elicit an effect opposite to that of the agonist.

**antenna 1.** (in zoology) A long whiplike jointed mobile paired appendage on the head of many arthropods, usually concerned with the senses of smell, touch, etc. In insects, millipedes, and centipedes they are the first pair of head appendages and are specialized and modified in many insects. In crustaceans they are the second pair of head appendages, the first pair (the

**antennules**) having the sensory function, while the antennae are modified for swimming and for attachment. **2.** (in radio) See AERIAL.

**antennule** See ANTENNA.

**anterior 1.** Designating the part of an animal that faces to the front, i.e. that leads when the animal is moving. In humans and other bipedal animals the anterior surface corresponds to the \*ventral surface. **2.** Designating the side of a flower or axillary bud that faces away from the flower stalk or main stem, respectively. Compare POSTERIOR.

**anther** The upper two-lobed part of a plant \*stamen, usually yellow in colour. Each lobe contains two pollen sacs within which are numerous pollen grains, which are released when the anther ruptures.

**antheridium** The male sex organ of algae, fungi, bryophytes, and pteridophytes. It produces the male gametes (**antherozoids**). It may consist of a single cell or it may have a wall that is made up of one or several layers forming a sterile jacket around the developing gametes. Compare ARCHEGONIUM.

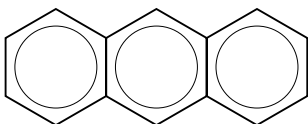

**antherozoid (spermatozoid)** The motile male gamete of algae, fungi, bryophytes, clubmosses, horsetails, ferns, and certain gymnosperms. Antherozoids usually develop in an \*antheridium but in certain gymnosperms, such as *Ginkgo* and *Cycas*, they develop from a cell in the pollen tube.

**anthocyanin** One of a group of \*flavonoid pigments. Anthocyanins occur in the cell vacuoles of various plant organs and are responsible for many of the blue, red, and purple colours in plants (particularly in flowers).

**Anthophyta (Angiospermophyta; Magnoliophyta)** A phylum comprising the flowering plants (angiosperms). Their gametes are produced within \*flowers and the ovules (and the seeds into which they develop) are enclosed in a carpel (compare CONIFEROPHYTA). The angiosperms are the dominant plant forms of the present day. They show the most advanced structural organization in the plant kingdom, enabling them to inhabit a very diverse

range of habitats. There are two classes within this group: the \*Monocotyledoneae with one seed leaf (cotyledon) in the seed, and the \*Dicotyledoneae with two seed leaves.

**anthracene** A white crystalline solid,  $C_{14}H_{10}$ ; r.d. 1.28; m.p. 215.8°C; b.p. 341.4°C. It is an aromatic hydrocarbon with three fused rings (see formula), and is obtained by the distillation of crude oils. The main use is in the manufacture of dyes.

Anthracene

**anthracite** See COAL.

**anthraquinone** A colourless stable crystalline solid,  $C_{14}H_8O_2$ , m.p. 285°C. It is made from benzene or naphthalene and used in the manufacture of a large range of dyes.

**anthropic principle** The principle that the observable universe has to be as it is, rather than any other way, otherwise we would not be able to observe it. There are many versions of the anthropic principle. The **weak anthropic principle** is specifically concerned with the conditions necessary for conscious life on earth and asserts that numerical relations found for fundamental constants, such as the \*gravitational constant, have to hold at the present epoch because at any other epoch there would be no intelligent lifeform to measure the constants. The **strong anthropic principle** is concerned with all possible universes and whether intelligent life could exist in any other universe, including the possibility of different fundamental constants and laws of physics. The anthropic principle is viewed with considerable scepticism by many physicists.

**antiaromatic** See PSEUDOAROMATIC.

**antiatom** An atom in which all the particles of an ordinary atom are replaced by their \*antiparticles, i.e. electrons by positrons, protons by antiprotons, and

neutrons by antineutrons. An antiatom cannot co-exist with an ordinary atom since the atom and the antiatom would annihilate each other with the production of energy in the form of high-energy \*photons.

**antibiotics** Substances that destroy or inhibit the growth of microorganisms, particularly disease-producing bacteria. Antibiotics are obtained from microorganisms (especially moulds) or synthesized. Common antibiotics include the \*penicillins, **streptomycin**, and the **tetracyclines**. They are used to treat various infections but tend to weaken the body's natural defence mechanisms and can cause allergies. Overuse of antibiotics can lead to the development of resistant strains of microorganisms.

**antibody** A protein (see IMMUNOGLOBULIN) produced by certain white blood cells (\*lymphocytes) in response to entry into the body of a foreign substance (\*antigen) in order to render it harmless. An antibody-antigen reaction is highly specific. Antibody production is one aspect of the \*immune response and is stimulated by such antigens as invading bacteria, foreign red blood cells (see ABO SYSTEM), inhaled pollen grains or dust, and foreign tissue \*grafts. See also IMMUNITY; MONOCLONAL ANTIBODY.

**antibonding orbital** See ORBITAL.

**anticholinesterase** Any substance that inhibits the enzyme \*cholinesterase, which is responsible for the breakdown of the neurotransmitter acetylcholine at nerve synapses. Anticholinesterases, which include certain drugs, nerve gases, and insecticides, cause a build-up of acetylcholine within the synapses, leading to disruption of nerve and muscle function. In vertebrates, these agents often cause death by paralysing the respiratory muscles. See PESTICIDE.

**anticline** See FOLD.

**anticoagulant** A substance that prevents the formation of blood clots. \*Heparin is a natural anticoagulant, which is extracted to treat such conditions as thrombosis and embolism. Synthetic anticoagulants include \*warfarin.

a

**anticodon** A sequence of three nucleotides (trinucleotide) on a strand of transfer \*RNA that can form base pairs (see BASE PAIRING) with a specific trinucleotide sequence (see CODON) on a strand of messenger RNA during \*translation. See also PROTEIN SYNTHESIS.

**anticyclone (high)** An area of the atmosphere that is at a higher pressure than the surrounding air. It appears on synoptic charts with a roughly circular closed \*isobar at its centre. Winds, which are generally light, circulate in a clockwise direction around the high-pressure centre in the northern hemisphere and in an anticlockwise direction in the southern hemisphere. An anticyclone is characteristically slow moving and is associated with settled weather.

**antidiuretic hormone (ADH; vasopressin)** A hormone, secreted by the posterior \*pituitary gland, that stimulates reabsorption of water by the kidneys and thus controls the concentration of body fluids. ADH is produced by specialized nerve cells in the hypothalamus of the brain and is transported to the posterior pituitary in the bloodstream. Deficiency of ADH results in a disorder known as **diabetes insipidus**, in which large volumes of urine are excreted; it is treated by administration of natural or synthetic hormone.

**antiferromagnetism** See MAGNETISM.

**antifreeze** A substance added to the liquid (usually water) in the cooling systems of internal-combustion engines to lower its freezing point so that it does not solidify at sub-zero temperatures. The commonest antifreeze is \*ethane-1,2-diol (ethylene glycol).

**antifreeze molecule** Any substance produced by an organism in order to prevent freezing of its tissues or body fluids when subject to subzero environmental temperatures. Many animals living in cold climates produce relatively inert molecules, notably glycerol and other polyhydric alcohols (polyols), such as sorbitol and ribitol, which accumulate in their blood, thereby raising the osmotic concentration and so depressing the \*supercooling point. Some families of teleost fish inhabiting polar regions manufacture

**antifreeze peptides** or **antifreeze glycopeptides**, which bind to the edges of ice crystal lattices and prevent the addition of further water molecules.

**antigen** Any substance that the body regards as foreign and that therefore elicits an \*immune response, particularly the formation of specific antibodies capable of binding to it. Antigens may be formed in, or introduced into, the body. They are usually proteins. **Histocompatibility antigens** are associated with the tissues and are involved in the rejection of tissue or organ \*grafts (see HISTOCOMPATIBILITY); an example is the group of antigens encoded by the \*HLA system. A graft will be rejected if the recipient's body regards such antigens on the donor's tissues as foreign. See also ANTIBODY.

**antigorite** See SERPENTINE.

**antihistamine** Any drug that inhibits the effects of \*histamine in the body and is therefore used to relieve and prevent the symptoms associated with allergic reactions, such as hay fever. Since one of the side-effects produced by antihistamines is sleepiness, some are used to prevent motion sickness and induce sleep.

**anti-isomer** See ISOMERISM.

**antiknock agent** See KNOCKING.

**antilogarithm** See LOGARITHM.

**antimatter** See ANTIPARTICLE.

**antimonic compounds** Compounds of antimony in its +5 oxidation state; e.g. antimonic chloride is antimony(V) chloride ( $\text{SbCl}_5$ ).

**antimonous compounds** Compounds of antimony in its +3 oxidation state; e.g. antimonous chloride is antimony(III) chloride ( $\text{SbCl}_3$ ).

**antimony** Symbol Sb. An element belonging to \*group 15 (formerly VB) of the periodic table; a.n. 51; r.a.m. 121.75; r.d. 6.68; m.p. 630.5°C; b.p. 1750°C. Antimony has several allotropes. The stable form is a bluish-white metal. Yellow antimony and black antimony are unstable nonmetallic allotropes made at low temperatures. The main source is stibnite ( $\text{Sb}_2\text{S}_3$ ), from which antimony is extracted by reduction with iron metal or by roasting (to give the

oxide) followed by reduction with carbon and sodium carbonate. The main use of the metal is as an alloying agent in lead-accumulator plates, type metals, bearing alloys, solders, Britannia metal, and pewter. It is also an agent for producing pearlitic cast iron. Its compounds are used in flame-proofing, paints, ceramics, enamels, glass dyestuffs, and rubber technology. The element will burn in air but is unaffected by water or dilute acids. It is attacked by oxidizing acids and by halogens. It was first reported by Tholden in 1450.

**antinode** See STATIONARY WAVE.

**antioxidants** Substances that slow the rate of oxidation reactions. Various antioxidants are used to preserve foodstuffs and to prevent the deterioration of rubber, synthetic plastics, and many other materials. Some antioxidants act as chelating agents to sequester the metal ions that catalyse oxidation reactions. Others inhibit the oxidation reaction by removing oxygen free radicals. Naturally occurring antioxidants include \*vitamin E,  $\beta$ -\*carotene, and \*glutathione; they limit the cell and tissue damage caused by foreign substances, such as toxins and pollutants, in the body.

**antiparallel spins** Neighbouring spinning electrons in which the \*spins, and hence the magnetic moments, of the electrons are aligned in the opposite direction. The interaction between the magnetic moments of electrons in atoms is dominated by exchange interactions. Under some circumstances the exchange interactions between magnetic moments favour \*parallel spins, while under other conditions they favour antiparallel spins. The case of antiferromagnetism (see MAGNETISM) is an example of a system with antiparallel spins.

**antiparallel vectors** Vectors directed along the same line but in opposite directions.

**antiparticle** A subatomic particle that has the same mass as another particle and equal but opposite values of some other property or properties. For example, the antiparticle of the electron is the positron, which has a positive charge equal in mag-

nitude to the electron's negative charge. The antiproton has a negative charge equal to the proton's positive charge. The neutron and the antineutron have \*magnetic moments opposite in sign relative to their \*spins. The existence of antiparticles is predicted by relativistic \*quantum mechanics. When a particle and its corresponding antiparticle collide \*annihilation takes place. **Antimatter** is postulated to consist of matter made up of antiparticles. For example, antihydrogen would consist of an antiproton with an orbiting positron. It appears that the universe consists overwhelmingly of (normal) matter, and explanations of the absence of large amounts of antimatter have been incorporated into cosmological models that involve the use of \*grand unified theories of elementary particles.

**antipyretic** A drug that reduces fever by lowering body temperature. Certain \*analgesic drugs, notably paracetamol, \*aspirin, and phenylbutazone, also have antipyretic properties.

**antisense DNA** A single-stranded DNA molecule that can bind to a complementary base sequence in a particular messenger RNA (mRNA) molecule and so prevent synthesis of the protein encoded by the mRNA. Antisense DNA thus has therapeutic potential for blocking the expression of disease-causing genes. A short DNA strand, called an **antisense oligodeoxynucleotide** (ODN), is constructed consisting of 15–20 deoxynucleotides complementary to a segment of the target mRNA. By binding to the mRNA, the ODN may either prevent translation of the mRNA by ribosomes or trigger degradation of the mRNA by cellular enzymes. An antisense ODN product has already been approved in the USA for the treatment of cytomegalovirus infections of the eye. See also ANTISENSE RNA.

**antisense RNA** An RNA molecule whose base sequence is complementary to that of the RNA transcript of a gene, i.e. the 'sense' RNA, such as a messenger RNA (mRNA). Hence, an antisense RNA can undergo base pairing with its complementary mRNA sequence. This blocks gene expression, either by preventing access for ribosomes to translate the mRNA or

by triggering degradation of the double-stranded RNA by ribonuclease enzymes. Like \*antisense DNA, antisense RNA has therapeutic potential for modifying the activity of disease-causing genes. Also, genes encoding antisense RNAs can be used in genetic engineering to alter the makeup of organisms. For example, the FlavrSavr tomato was engineered with an artificial gene for antisense RNA that prevented expression of a gene for an enzyme involved in ripening, in order to retard spoilage.

**antiseptic** Any substance that kills or inhibits the growth of disease-causing microorganisms but is essentially non-toxic to cells of the body. Common antiseptics include hydrogen peroxide, the detergent cetrimide, and ethanol. They are used to treat minor wounds. *Compare* DISINFECTANT.

**antiserum** Serum containing antibodies, either raised against particular antigens, and hence of known specificity, or a broad mixture of antibodies. It is used to provide short-term passive immunity, e.g. against hepatitis A virus, and to treat an infection to which the patient has no immunity. Antisera may be obtained from large animals, such as horses, that have been inoculated with particular antigens, or from pooled donated human serum.

**antitail** A small tail on a \*comet that points towards the sun, unlike the comet's main tail. It is thought to consist of large particles, which scatter sunlight, and is prominent only when observed from the plane of the comet's orbit.

**antitoxin** An antibody produced in response to a bacterial \*toxin.

**antiviral** Describing a drug or other agent that kills or inhibits viruses and is used to treat viral infections. Several types of antiviral drug are now in use, such as \*acyclovir, effective against herpesviruses, and **antiretroviral drugs** (e.g. \*reverse transcriptase inhibitors and protease inhibitors), used to treat HIV infection. The body's own natural antiviral agents, \*interferons, can now be produced by genetic engineering and are sometimes used therapeutically. However, many antiviral agents are extremely toxic, and viruses

evolve rapidly so that a drug's effectiveness can soon be lost.

**anus** The terminal opening of the \*alimentary canal in most animals, through which indigestible material (\*faeces) is expelled.

**anyon** *See* QUANTUM STATISTICS.

**aorta** The major blood vessel in higher vertebrates through which oxygenated blood leaves the \*heart from the left ventricle. The aorta branches to form many smaller arteries, which in turn branch many times to supply oxygen and essential nutrients to all living cells in the body.

**apastron** The point at which the distance between the two components of a \*binary star is greatest. The point of closest approach is called periastron.

**apatite** A highly complex mineral form of \*calcium phosphate,  $\text{Ca}_5(\text{PO}_4)_3(\text{OH}, \text{F}, \text{Cl})$ ; the commonest of the phosphate minerals. It has a hexagonal structure and occurs widely as an accessory mineral in igneous rocks (e.g. pegmatite) and often in regional and contact metamorphic rocks, especially limestone. Large deposits occur in the Kola Peninsula, Russia. It is used in the production of fertilizers and is a major source of phosphorus. The enamel of teeth is composed chiefly of apatite.

**aperture** The effective diameter of a lens or mirror. The ratio of the effective diameter to the focal length is called the **relative aperture**, which is commonly known as the aperture, especially in photographic usage. The reciprocal of the relative aperture is called the **focal ratio**. The numerical value of the focal ratio is known as the **f-number** of a lens. For example, a camera lens with a 40 mm focal length and a 10 mm aperture has a relative aperture of 0.25 and a focal ratio of 4. Its f-number would be  $f/4$ , often written  $f4$ .

The light-gathering power of a telescope depends on the area of the lens, i.e. it is related to the square of the aperture. However, the larger the relative aperture the greater the \*aberrations. In microscopy large-aperture objectives (corrected for aberrations) are preferred, since they

reduce the blurring caused by \*diffraction of light waves.

**aperture synthesis** See RADIO TELESCOPE.

**aphelion** The point in the orbit of a planet, comet, or artificial satellite in solar orbit at which it is farthest from the sun. The earth is at aphelion on about July 3. Compare PERIHELION.

**aphotic zone (bathypelagic zone)** The region of a lake or sea where no light penetrates; it is situated beneath the \*euphotic zone. The aphotic zone contains no algae or phytoplankton, and its inhabitants are exclusively carnivorous animals or organisms that feed on sediment or detritus, all reliant on energy inputs from the euphotic zone. It extends downwards from a depth of about 1000 m, or less in turbid waters, and includes the \*abyssal zone.

**apical dominance** Inhibition of the growth of lateral buds in a plant by the presence of a growing apical bud. It is brought about by the action of auxins (produced by the apical bud) and abscisic acid.

**apical meristem** A region at the tip of each shoot and root of a plant in which cell divisions are continually occurring to produce new stem and root tissue, respectively. The new tissues produced are known collectively as the **primary tissues** of the plant. See also MERISTEM. Compare CAMBIUM.

**aplanatic lens** A lens that reduces both spherical \*aberration and \*coma.

**apocarp** The condition in which the female reproductive organs (\*carpels) of a flower are not joined to each other. It occurs, for example, in the buttercup. Compare SYNCARPY.

**apochromatic lens** See ACHROMATIC LENS.

**apocrine secretion** See SECRETION.

**apocynthion** The point in the orbit around the moon of a satellite launched from the earth that is furthest from the moon. For a satellite launched from the moon the equivalent point is the **apolune**. Compare PERICYNTHION.

**apoenzyme** An inactive enzyme that must associate with a specific \*cofactor molecule or ion in order to function. Compare HOLOENZYME.

**apogee** The point in the orbit of the moon, or an artificial earth satellite, at which it is furthest from the earth. At apogee the moon is 406 700 km from the earth, some 42 000 km further away than at **perigee**, the nearest point to the earth.

**apolune** See APOCYNTHION.

**apomixis (agamosperry)** A reproductive process in plants that superficially resembles normal sexual reproduction but in which there is no fusion of gametes. In apomictic flowering plants there is no fertilization by pollen, and the embryos develop simply by division of a \*diploid cell of the ovule. See also PARTHENOCLARPY; PARTHENOGENESIS.

**apoplast** An interconnected system in plants that consists of all the cell walls and the water that exists in them (the cell wall is composed of cellulose fibres, between which are spaces filled with water). The movement of water (and dissolved ions and solutes) through the cell walls is known as the **apoplast pathway**. This is the main route by which water taken up by a plant travels across the root cortex to the \*endodermis. Compare SYMPLAST.

**apoptosis (programmed cell death)** The process of cell death that occurs naturally as part of the normal development, maintenance, and renewal of tissues within an organism. During embryonic development it plays a vital role in determining the final size and form of tissues and organs. For example, the fingers are 'sculpted' on the spadelike embryonic hand by apoptosis of the cells between them; the tubules of the embryonic kidney are hollowed out by a similar process. Apoptosis involves the action of enzymes called **caspases**, cellular proteins that - when activated (e.g. by cell damage) - initiate a series of events that results in digestion of the cytoskeleton, DNA, and other cell components. Apoptosis is normally suppressed as long as cells continue to receive extracellular survival signals in the form of trophic factors (e.g. \*nerve growth factor). In the absence of such sig-

nals, the cell embarks on a 'suicide' programme. Sometimes, other cells, for example immune cells, release specific 'murder' signals, which activate apoptosis in target cells. Cancer is associated with the suppression of apoptosis, which also occurs when viruses infect cells - in order to inhibit the activity of \*killer cells. Apoptosis differs from cell \*necrosis, in which cell death may be stimulated by a toxic substance.

**aposematic coloration** See WARNING COLORATION.

**apparent expansivity** See EXPANSIVITY.

**appeasement** Behaviour that inhibits aggression from another animal of the same species, frequently taking the form of a special posture or \*display emphasizing the weakness of the performer. Threatening structures (e.g. antlers) and markings are covered or turned away, and vulnerable parts of the body may be exposed. Appeasement is seen in \*courtship, in greeting ceremonies, and often (from the loser) after a fight.

**appendicular skeleton** The components, collectively, of the vertebrate skeleton that are attached to the main supporting, or \*axial, skeleton. The appendicular skeleton is made up of paired appendages (e.g. legs, wings, arms) together with the \*pelvic girdle and \*pectoral girdle.

**appendix (vermiform appendix)** An outgrowth of the \*caecum in the alimentary canal. In humans it is a \*vestigial organ containing lymphatic tissue and serves no function in normal digestive processes. Appendicitis is caused by inflammation of the appendix.

**Appleton layer** See EARTH'S ATMOSPHERE.

**applications software** Computer programs, or collections of programs, designed to meet the needs of the users of computer systems by directly contributing to the performance of specific roles. Examples include a word-processing or spreadsheet program, or a company's payroll package. In contrast, **systems software**, such as an operating system, are

the group of programs required for effective use of a computer system.

**approximation technique** A method used to solve a problem in mathematics, or its physical applications, that does not give an exact solution but that enables an approximate solution to be found.

**aprotic** See SOLVENT.

**apsides** The two points in an astronomical orbit that lie closest to (**periapsis**) and farthest from (**apoapsis**) the centre of gravitational attraction. The **line of apsides** is the straight line that joins the two apsides. If the orbit is elliptical the line of apsides is the major axis of the ellipse.

**aqua acid** A type of acid in which the acidic hydrogen is on a water molecule coordinated to a metal ion. For example,

**aquamarine** A variety of the mineral \*beryl that has a transparent blue-green colour, valued as a gemstone. It is found as an accessory mineral in pegmatite, sometimes as very large crystals.

**aqua regia** A mixture of concentrated nitric acid and concentrated hydrochloric acid in the ratio 1:3 respectively. It is a very powerful oxidizing mixture and will dissolve all metals (except silver, which forms an insoluble chloride) including such noble metals as gold and platinum, hence its name ('royal water'). Nitrosyl chloride (NOCl) is believed to be one of the active constituents.

**aquation** The process in which water molecules solvate or form coordination complexes with ions.

**aqueous** Describing a solution in water.

**aqueous humour** The fluid that fills the space between the cornea and the lens of the vertebrate eye. In addition to supplying the cornea and lens with nutrients, the aqueous humour helps to maintain the shape of the eye. It is produced and renewed every four hours by the \*ciliary body.

**aquifer** A deposit of rock that yields economic supplies of water to wells or springs as a result of its porosity or per-

meability. It may be, for example, a zone of sandstone, unconsolidated gravels, or jointed limestone.

**aquo ion** A hydrated positive ion present in a crystal or in solution.

**Arabidopsis** A genus of flowering plants of the family Cruciferae (Brassicaceae). The species *A. thaliana* (Thale cress) is widely used as a research tool in molecular genetics and developmental biology because it has a small and simple genome (five pairs of chromosomes), over half of which codes for protein, and it can be easily cultured, having a life cycle of only 6–8 weeks. Its full genome sequence was published in 2000.

**arachidonic acid** An unsaturated fatty acid,  $\text{CH}_3(\text{CH}_2)_3(\text{CH}_2\text{CH}=\text{CH})_4(\text{CH}_2)_3\text{COOH}$ , that is essential for growth in mammals. It can be synthesized from \*linoleic acid. Arachidonic acid acts as a precursor to several biologically active compounds, including \*prostaglandins, and plays an important role in membrane production and fat metabolism. The release of arachidonic acid from membrane \*phospholipids is triggered by certain hormones.

**Arachnida** A class of terrestrial \*arthropods of the phylum Chelicerata, comprising about 65 000 species and including spiders, scorpions, harvestmen, ticks, and mites. An arachnid's body is divided into an anterior \*cephalothorax (**prosoma**) and a posterior abdomen (**opisthosoma**). The prosoma bears a pair of grasping or piercing appendages (the **chelicerae**), a pair of **pedipalps** used for manipulation or as sensory structures, and four pairs of walking legs. The opisthosoma may bear various sensory or silk-spinning appendages (see SPINNERET). Arachnids are generally carnivorous, feeding on the body fluids of their prey or secreting enzymes to digest prey externally. Spiders immobilize their prey with poison injected by the fanglike chelicerae, while scorpions grasp their prey in large clawed pedipalps and may poison it using the posterior stinging organ. Ticks and some mites are parasitic but most arachnids are free-living. They breathe either via \*tracheae (like insects) or by means of thin highly folded regions of the body wall called **lung books**.

**arachnoid membrane** One of the three membranes (\*meninges) that surround the brain and spinal cord of vertebrates. It lies between the \*pia mater and the \*dura mater. The arachnoid membrane is very delicate and carries \*cerebrospinal fluid, which sustains and cushions the nervous tissue.

**arachno-structure** See BORANE.

**aragonite** A rock-forming anhydrous mineral form of calcium carbonate,  $\text{CaCO}_3$ . It is much less stable than \*calcite, the commoner form of calcium carbonate, from which it may be distinguished by its greater hardness and specific gravity. Over time aragonite undergoes recrystallization to calcite. Aragonite occurs in cavities in limestone, as a deposit in limestone caverns, as a precipitate around hot springs and geysers, and in high-pressure low-temperature metamorphic rocks; it is also found in the shells of a number of molluscs and corals and is the main constituent of pearls. It is white or colourless when pure but the presence of impurities may tint it grey, blue, green, or pink.

**arbovirus** Obsolete name for any RNA-containing virus that is transmitted from animals to humans through the bite of mosquitoes and ticks (i.e. arthropods, hence arthropod-borne viruses). They cause various forms of encephalitis (inflammation of the brain) and serious fevers, such as dengue and yellow fever.

**arccos, arcsin, arctan** See INVERSE FUNCTIONS.

**Archaea** A \*domain (or subkingdom) of prokaryotic organisms containing the archaeobacteria, including the \*methanogens, which produce methane; the thermoacidophilic bacteria, which live in extremely hot and acidic environments (such as hot springs); and the halophilic bacteria, which can only function at high salt concentrations and are abundant in the world's oceans. The archaeobacteria are grouped together principally on the basis of similarities in the base sequence of their ribosomal RNA. This molecular evidence shows them to be phylogenetically distinct from either the eubacteria (see BACTERIA) or the eukaryotes, and they are now usually regarded as constituting a

separate domain of life. They are possibly descendants of the earliest forms of life, predating the earliest known microbial fossils.

**Archaeon** The earliest eon of geological time, in which there is the first evidence of life on earth. It follows the \*Hadean eon of pregeological time and extends from the time of the earliest known rocks, roughly 3800 million years ago, to the beginning of the \*Proterozoic eon, about 2600 million years ago. Rock formations called \*stromatolites, dated at 3500 million years old or older, are among the oldest of all fossil remains. They are thought to have been produced by the activities of microbial mats of filamentous purple and green bacteria. These prokaryotes performed photosynthesis anaerobically, perhaps using hydrogen sulphide as an electron donor instead of water. Some of their descendants evolved the ability to use water as an electron donor, producing oxygen as a by-product, and eventually brought about the change in atmospheric conditions necessary for aerobic life.

**archaeobacteria** See ARCHAEA.

**archegonium** The multicellular flask-shaped female sex organ of bryophytes, clubmosses, horsetails, ferns, and many gymnosperms. Such plants are described as **archegoniate** to distinguish them from algae, which do not possess archegonia. The dilated base, the **venter**, contains the oosphere (female gamete). The cells of the narrow neck liquefy to allow the male gametes to swim towards the oosphere. The archegonium is thus an adaptation to the terrestrial environment as it provides a means for the male gametes to reach the female gamete. Compare ANTERIDIUM.

**archenteron (gastrocoel)** A cavity within an animal embryo at the \*gastrula stage of development. All or part of the archenteron eventually forms the cavity of the gut. It is connected to the outside by an opening (the **blastopore**), which becomes either the mouth, the mouth and anus, or the anal opening of the animal.

**Archimedes of Syracuse** (287–212 BC) Greek mathematician, who spent most of his life at his birthplace. He worked on levers and other aspects of mechanics. In

hydrostatics he devised a pump (the **Archimedian screw**) and formulated \*Archimedes' principle. His method of successive approximation allowed him to determine the value of  $\pi$  to a good approximation. He was killed by a soldier in the Roman siege of Syracuse.

**Archimedes' principle** The weight of the liquid displaced by a floating body is equal to the weight of the body. The principle was not in fact stated by Archimedes, though it has some connection with his discoveries. The principle is often stated in the form: when a body is (partially or totally) immersed in a fluid, the upthrust on the body is equal to the weight of fluid displaced.

**arc lamp** See ELECTRIC LIGHTING.

**arcosh, arsinh, artanh** See INVERSE FUNCTIONS.

**area** A measure of the size of a two-dimensional shape. The areas of common geometrical figures are given below, where  $l$  = length,  $h$  = altitude or height,  $r$  = radius, and  $s$  = slant height:

square	$l^2$
rectangle	$lh$
parallelogram	$lh$
triangle	$\frac{1}{2}lh$
circle	$\pi r^2$
sphere	$4\pi r^2$
cone	$\pi rs$ (curved surface)
	$\pi r^2 + \pi rs$ (total surface)
cylinder	$2\pi rh$ (curved surface)
	$2\pi rh + 2\pi r^2$ (total surface)

**arenes** Aromatic hydrocarbons, such as benzene, toluene, and naphthalene.

**Argand diagram** See COMPLEX NUMBER.

**argentic compounds** Compounds of silver in its higher (+2) oxidation state; e.g. argentic oxide is silver(II) oxide (AgO).

**argentite** A sulphide ore of silver,  $\text{Ag}_2\text{S}$ . It crystallizes in the cubic system but most commonly occurs in massive form. It is dull grey-black in colour but bright when first cut and occurs in veins associated with other silver minerals. Important deposits occur in Mexico, Peru, Chile, Bolivia, and Norway.

**argentous compounds** Compounds of

silver in its lower (+1) oxidation state; e.g. argentous chloride is silver(I) chloride.

**arginine** See AMINO ACID.

**argon** Symbol Ar. A monatomic noble gas present in air (0.93%); a.n. 18; r.a.m. 39.948; d. 0.00178 g cm<sup>-3</sup>; m.p. -189°C; b.p. -185°C. Argon is separated from liquid air by fractional distillation. It is slightly soluble in water, colourless, and has no smell. Its uses include inert atmospheres in welding and special-metal manufacture (Ti and Zr), and (when mixed with 20% nitrogen) in gas-filled electric-light bulbs. The element is inert and has no true compounds. Lord Rayleigh and Sir William Ramsey identified argon in 1894.

**argument 1.** A sequence of logical propositions based on a set of premisses and leading to a conclusion. **2.** See COMPLEX NUMBER.

**aril** An outgrowth that grows around and may completely enclose the testa (seed coat) of a seed. It develops from the placenta, funicle, or micropyle of an ovule. The aril surrounding the nutmeg seed forms the spice mace. See also CARUNCLE.

**arithmetic average (arithmetic mean)** See AVERAGE.

**arithmetic/logic unit** See ALU.

**arithmetic series (arithmetic progression)** A series or progression of numbers in which there is a common difference between terms, e.g. 3, 9, 15, 21, ... is an arithmetic series with a common difference of 6. The general formula for the *n*th term is

$$[a + (n - 1)d]$$

and the sum of *n* terms is

$$n[2a + (n - 1)d]/2.$$

Compare GEOMETRIC SERIES.

**armature** Any moving part in an electrical machine in which a voltage is induced by a magnetic field, especially the rotating coils in an electric motor or generator and the ferromagnetic bar attracted by an electromagnet in a \*relay.

**aromatic compound** An organic compound that contains a benzene ring in its molecules or that has chemical properties

similar to benzene. Aromatic compounds are unsaturated compounds, yet they do not easily partake in addition reactions. Instead they undergo electrophilic substitution.

Benzene, the archetypal aromatic compound, has an hexagonal ring of carbon atoms and the classical formula (the Kekulé structure) would have alternating double and single bonds. In fact all the bonds in benzene are the same length intermediate between double and single C-C bonds. The properties arise because the electrons in the  $\pi$ -orbitals are delocalized over the ring, giving an extra stabilization energy of 150 kJ mol<sup>-1</sup> over the energy of a Kekulé structure. The condition for such delocalization is that a compound should have a planar ring with  $(4n + 2)$  pi electrons - this is known as the **Hückel rule**. Aromatic behaviour is also found in heterocyclic compounds such as pyridine. Aromatic character can be detected by the presence of a ring current using NMR. See also ANNULENES; NONBENZENOID AROMATICS; PSEUDOAROMATIC.

**aromaticity** The property characteristic of \*aromatic compounds.

**arousal** A level of physiological and behavioural responsiveness in an animal, which tends to vary between sleep and full alertness. It is controlled by a particular part of the brain (the **reticular activating system**) and can be detected by changes in brain electrical activity, heart rate and muscle tone, responsiveness to new stimuli, and general activity.

**ARPES** See ANGLE-RESOLVED PHOTOELECTRON SPECTROSCOPY.

**Arrhenius equation** An equation of the form

$$k = A \exp(-E_a/RT)$$

where *k* is the rate constant of a given reaction and  $E_a$  the \*activation energy. *A* is a constant for a given reaction, called the **pre-exponential factor**. Often the equation is written in logarithmic form

$$\ln k = \ln A - E_a/RT$$

A graph of  $\ln k$  against  $1/T$  is a straight line with a gradient  $-E_a/R$  and an intercept on the  $\ln k$  axis of  $\ln A$ . It is named after Svante Arrhenius (1859-1927).

**Arrhenius theory** See ACID.

**arsenate(III)** See ARSENIC(III) OXIDE.

**arsenate(V)** See ARSENIC(V) OXIDE.

**arsenic** Symbol As. A metalloid element of \*group 15 (formerly VB) of the periodic table; a.n. 33; r.a.m. 74.92; r.d. 5.7; sublimes at 613°C. It has three allotropes – yellow, black, and grey. The grey metallic form is the stable and most common one. Over 150 minerals contain arsenic but the main sources are as impurities in sulphide ores and in the minerals orpiment ( $\text{As}_2\text{S}_3$ ) and realgar ( $\text{As}_4\text{S}_4$ ). Ores are roasted in air to form arsenic oxide and then reduced by hydrogen or carbon to metallic arsenic. Arsenic compounds are used in insecticides and as doping agents in semiconductors. The element is included in some lead-based alloys to promote hardening. Confusion can arise because  $\text{As}_4\text{O}_6$  is often sold as white arsenic. Arsenic compounds are accumulative poisons. The element will react with halogens, concentrated oxidizing acids, and hot alkalis. Albertus Magnus is believed to have been the first to isolate the element in 1250.

**arsenic acid** See ARSENIC(V) OXIDE.

**arsenic(III) acid** See ARSENIC(III) OXIDE.

**arsenic hydride** See ARSINE.

**arsenic(III) oxide (arsenic trioxide; arsenious oxide; white arsenic)** A white or colourless compound,  $\text{As}_4\text{O}_6$ , existing in three solid forms. The commonest has cubic or octahedral crystals (r.d. 3.87; sublimes at 193°C) and is soluble in water, ethanol, and alkali solutions. It occurs naturally as **arsenolite**. A vitreous form can be prepared by slow condensation of the vapour (r.d. 3.74); its solubility in cold water is more than double that of the cubic form. The third modification, which occurs naturally as **claudetite**, has monoclinic crystals (r.d. 4.15). Arsenic(III) oxide is obtained commercially as a byproduct from the smelting of nonferrous sulphide ores; it may be produced in the laboratory by burning elemental arsenic in air. The structure of the molecule is similar to that of  $\text{P}_4\text{O}_6$ , with a tetrahedral arrangement of As atoms edge linked by oxygen bridges. Arsenic(III) oxide is acidic; its solutions were formerly called **arsenious**

**acid** (technically, **arsenic(III) acid**). It forms **arsenate(III)** salts (formerly called **arsenites**). Arsenic(III) oxide is extremely toxic and is used as a poison for vermin; trace doses are used for a variety of medicinal purposes. It is also used for producing opalescent glasses and enamels.

**arsenic(V) oxide (arsenic oxide)** A white amorphous deliquescent solid,  $\text{As}_2\text{O}_5$ ; r.d. 4.32; decomposes at 315°C. It is soluble in water and ethanol. Arsenic(V) oxide cannot be obtained by direct combination of arsenic and oxygen; it is usually prepared by the reaction of arsenic with nitric acid followed by dehydration of the arsenic acid thus formed. It readily loses oxygen on heating to give arsenic(III) oxide. Arsenic(V) oxide is acidic, dissolving in water to give arsenic(V) acid (formerly called **arsenic acid**),  $\text{H}_3\text{AsO}_4$ ; the acid is tribasic and slightly weaker than phosphoric acid and should be visualized as  $(\text{HO})_3\text{AsO}$ . It gives **arsenate(V)** salts (formerly called **arsenates**).

**arsenic trioxide** See ARSENIC(III) OXIDE.

**arsenious acid** See ARSENIC(III) OXIDE.

**arsenious oxide** See ARSENIC(III) OXIDE.

**arsenite** See ARSENIC(III) OXIDE.

**arsenolite** A mineral form of \*arsenic(III) oxide,  $\text{As}_4\text{O}_6$ .

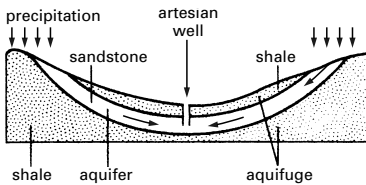

**arsine (arsenic hydride)** A colourless gas,  $\text{AsH}_3$ ; m.p.  $-116.3^\circ\text{C}$ ; b.p.  $-55^\circ\text{C}$ . It is soluble in water, chloroform, and benzene. Liquid arsine has a relative density of 1.69. Arsine is produced by the reaction of mineral acids with arsenides of electropositive metals or by the reduction of many arsenic compounds using nascent hydrogen. It is extremely poisonous and, like the hydrides of the heavier members of group 15 (formerly VB), is readily decomposed at elevated temperatures (around 260–300°C). Like ammonia and phosphine, arsine has a pyramidal structure.

Arsine gas has a very important commercial application in the production of modern microelectronic components. It is used in a dilute gas mixture with an inert gas and its ready thermal decomposition is exploited to enable other growing crystals to be doped with minute traces of arsenic to give *n*-type semiconductors.

**arteriole** A small muscular blood vessel that receives blood from the arteries and carries it to the capillaries.

**artery** A blood vessel that carries blood away from the heart towards the other body tissues. Most arteries carry oxygenated blood (the \*pulmonary artery is an exception). The large arteries branch to form smaller ones, which in turn branch into \*arterioles. All arteries have muscular walls, whose contraction aids in pumping blood around the body. The accumulation of fatty deposits in the walls of the arteries leads to **atherosclerosis**, which limits and may eventually block the flow of blood. *Compare* VEIN.

**artesian basin** A structural basin in the earth's crust in which a zone of permeable water-bearing rock (an \*aquifer) is confined between impermeable beds. Water enters the aquifer where it reaches the surface and becomes trapped. As the point of intake of the water is above the level of the ground surface a well sunk into the aquifer through the overlying impermeable rock will result in water being forced up to the surface by hydrostatic pressure. However, the number of wells sunk into artesian basins often considerably lowers the level of water so that pumping is frequently required. Artesian wells were named after the region of Artois in France, where they were first observed. Other examples include the London Basin where chalk and Lower Eocene sandstones lie confined below the London clay and above the Gault clay.

Artesian basin

**Arthropophyta** See SPHENOPHYTA.

**arthropod** Any invertebrate animal that characteristically possesses an outer body layer - the \*cuticle - that functions as a rigid protective exoskeleton; growth is thus possible only by periodic moults (see

ECDYSLIS). There are over one million species of arthropods, inhabiting marine, freshwater, and terrestrial habitats worldwide. The arthropod body is composed of segments (see METAMERIC SEGMENTATION) usually forming distinct specialized body regions, e.g. head, thorax, and abdomen. These segments may possess hardened jointed appendages, modified variously as \*mouthparts, limbs, wings, reproductive organs, or sense organs. The main body cavity, containing the internal organs, is a blood-filled \*haemocoel, within which lies the heart. Although in some classifications arthropods are placed in a single phylum, Arthropoda, the origins and relationships of the various groups of arthropods remain uncertain, and they are now often placed in three separate phyla according to the basic structure of their appendages: \*Crustacea (shrimps, barnacles, crabs, etc.); Uniramia (or Mandibulata), including the classes \*Hexapoda (insects), \*Chilopoda (centipedes), and \*Diplopoda (millipedes); and Chelicerata, including the classes \*Arachnida (spiders, scorpions, mites, and ticks) and Merostomata (horseshoe crabs).

**articulation** The attachment of two bones, usually by means of a \*joint. The thigh bone (femur), for instance, articulates with the pelvic girdle.

**artificial chromosome** A type of cloning \*vector that has some features of true chromosomes and is used to clone relatively large fragments of DNA. **Bacterial artificial chromosomes (BACs)** are based on the F (fertility) plasmid found naturally in *E. coli* bacteria with the addition of several bacterial genes necessary for replication of the plasmid by the host cell and a gene (usually for resistance to an antibiotic) that allows selection of BAC-containing cells. They can accommodate inserts of foreign DNA up to about 300 kilobase (kb) in length. Larger DNA fragments are cloned using **yeast artificial chromosomes (YACs)**. These are linear vectors derived from a circular plasmid found naturally in baker's yeast (*Saccharomyces cerevisiae*) and capable of accommodating DNA inserts of up to 1000 kb. YACs have a \*centromere, enabling them to undergo normal segregation in the yeast host during cell division, and \*telomeres; thus

they behave like mini-chromosomes. YACs are used for cloning eukaryotic genes or gene segments, for making \*DNA libraries of organisms with large genomes (e.g. mammals), and for studying gene function.

**artificial insemination (AI)** The deposition of semen, using a syringe, at the mouth of the uterus to make conception possible. It is used in the selective \*breeding of domestic animals and also in humans in some cases of impotence and infertility. It is timed to coincide with ovulation in the female.

**artificial intelligence (AI)** A field of computing concerned with the production of programs that perform tasks requiring intelligence when done by people. These tasks include playing games, such as chess or draughts, forming plans, understanding speech and natural languages, interpreting images, reasoning, and learning.

**artificial selection** The modification of species, traditionally by selective \*breeding. Animals or plants with desirable characteristics are interbred with the aim of altering the \*genotype and producing a new strain of the organism for a specific purpose. For example, sheep are bred by means of artificial selection in order to improve wool quality. Traditional breeding techniques have been supplemented, and in many cases supplanted, by genetic engineering, genetic testing, and embryo manipulation. Sequencing the genomes of commercially important animal and plant species has enabled the inheritance of desired genes to be monitored directly by molecular methods, instead of by phenotypic analysis. These methods have simultaneously opened up new approaches to selection and enabled it to become more refined and focused.

**artinite** A mineral form of basic \*magnesium carbonate,

**Artiodactyla** An order of hooved mammals comprising the even-toed ungulates, in which the third and fourth digits are equally developed and bear the weight of the body. The order includes cattle and

other ruminants (see RUMINANTIA), camels, hippopotamuses, and pigs. All except the latter are herbivorous, having an elongated gut and teeth with enamel ridges for grinding tough grasses. Compare PERISODACTYLA.

**aryl group** A group obtained by removing a hydrogen atom from an aromatic compound, e.g. phenyl group,  $\text{C}_6\text{H}_5^-$ , derived from benzene.

**aryne** A compound that can be regarded as formed from an arene by removing two adjacent hydrogen atoms to convert a double bond into a triple bond. Arynes are transient intermediates in a number of reactions. The simplest example is \*benzynes.

**asbestos** Any one of a group of fibrous amphibole minerals (amosite, crocidolite (blue asbestos), tremolite, anthophyllite, and actinolite) or the fibrous serpentine mineral chrysotile. Asbestos has widespread commercial uses because of its resistance to heat, chemical inertness, and high electrical resistance. The fibres may be spun and woven into fireproof cloth for use in protective clothing, curtains, brake linings, etc., or moulded into blocks. Since the 1970s short asbestos fibres have been recognized as a cause of asbestosis, a serious lung disorder, and mesothelioma, a fatal form of lung cancer. These concerns have limited its use and imposed many safety procedures when it is used. Canada is the largest producer of asbestos; others include Russia, South Africa, Zimbabwe, and China.

**ASCII** (pronounced askey) American standard code for information interchange: a standard scheme for encoding the letters A-Z, a-z, digits 0-9, punctuation marks, and other special and control characters in binary form. Originally developed in the US, it is widely used in many computers and for interchanging information between computers. Characters are encoded as strings of seven \*bits, providing  $2^7$  or 128 different bit patterns. International 8-bit codes that are extensions of ASCII have been published by the International Standards Organization; these allow the accented Roman letters used in European languages, as well as

Cyrillic, Arabic, Greek, and Hebrew characters, to be encoded.

**Ascomycota** A phylum of fungi, formerly classified as a class (Ascomycetes) or a subdivision (Ascomycotina). It includes the \*yeasts, some species of edible fungi, and *Claviceps purpurea*, which causes ergot in rye. Many are fungal partners of \*lichens. Sexual reproduction is by means of **ascospores**, eight of which are characteristically produced within a spherical or cylindrical cell, the **ascus**. The asci are usually grouped together in an **ascocarp**.

**ascorbic acid** See VITAMIN C.

**asexual reproduction** Reproduction in which new individuals are produced from a single parent without the formation of gametes. It occurs chiefly in lower animals, microorganisms, and plants. In microorganisms and lower animals the chief methods are \*fission (e.g. in protocists), \*fragmentation (e.g. in some aquatic annelid worms), and \*budding (e.g. in cnidarians and yeasts). The principal methods of asexual reproduction in plants are by \*vegetative propagation (e.g. bulbs, corms, tubers) and by the formation of \*spores. Spore formation occurs in mosses, ferns, and other plants showing alternation of generations, as a dormant stage between sporophyte and gametophyte, and in some algae and fungi, to produce replicas of the organism. Compare SEXUAL REPRODUCTION.

**asparagine** See AMINO ACID.

**aspartic acid** See AMINO ACID.

**Aspect experiment** An experiment conducted by the French physicist Alain Aspect (1947– ) and his colleagues in the early 1980s to test Bell's inequality (see BELL'S THEOREM). The experiment involves producing pairs of photons from a source of excited calcium ions. The photons have different wavelengths and filters are used to ensure that the photons in a pair travel to different detectors in different directions. The photons are circularly polarized and the net angular momentum of the pair is zero. Two polarizing filters are used, each placed at an angle in the path of the photons. These filters either reflect or transmit photons of different linear polarization to one of four detectors (two for

each polarizing filter). Coincidence measurements are made using these detectors and the experiment is organized so that the measurements apply only to photons separated to a point at which they cannot communicate by sending a signal at the speed of light. The results are generally believed to show that there are no local \*hidden variables in quantum mechanics.

**aspirin (acetylsalicylic acid)** A drug that reduces inflammation, combats fever, and alleviates pain. Aspirin works by inhibiting the formation of \*prostaglandins, which are major factors in the inflammation process. It also reduces the aggregation of blood platelets, hence its use in maintaining blood flow following heart and circulatory disorders.

**assimilation** The utilization by a living organism of absorbed food materials in the processes of growth, reproduction, or repair.

**association 1.** (in ecology) An ecological unit in which two or more species occur in closer proximity to one another than would be expected on the basis of chance. Early plant ecologists recognized associations of fixed composition on the basis of the \*dominant species present (e.g. a coniferous forest association). Associations now tend to be detected by using more objective statistical sampling methods. See also CONSOCIATION. **2.** (in chemistry) The combination of molecules of one substance with those of another to form chemical species that are held together by forces weaker than normal chemical bonds. For example, ethanol and water form a mixture (an **associated liquid**) in which hydrogen bonding holds the different molecules together.

**association centre** The part of the brain that links a primary sensory area (the part of the cerebral cortex that receives primary sensory impulses) with other parts of the brain, such as memory and motor areas, and deals with the interpretation and meaning of the primary sensory input. For example, the auditory association area interprets a 'moo' sound as that coming from a cow.

**associative law** The mathematical law stating that the value of an expression is

independent of the grouping of the numbers, symbols, or terms in the expression. The **associative law for addition** states that numbers may be added in any order, e.g.  $(x + y) + z = (x + z) + y$ . The **associative law for multiplication** states that numbers can be multiplied in any order, e.g.  $x(yz) = (xy)z$ . Subtraction and division are not associative. *Compare* COMMUTATIVE LAW; DISTRIBUTIVE LAW.

**astatic galvanometer** A sensitive form of moving-magnet \*galvanometer in which any effects of the earth's magnetic field are cancelled out. Two small oppositely directed magnets are suspended at the centres of two oppositely wound coils. As its resultant moment on the magnets is zero, the earth's field has no effect and the only restoring torque on the magnets is that provided by the suspending fibre. This makes a sensitive but delicate instrument.

**astatine** Symbol At. A radioactive \*halogen element; a.n. 85; r.a.m. 211; m.p. 302°C; b.p. 337°C. It occurs naturally by radioactive decay from uranium and thorium isotopes. Astatine forms at least 20 isotopes, the most stable astatine-210 has a half-life of 8.3 hours. It can also be produced by alpha bombardment of bismuth-200. Astatine is stated to be more metallic than iodine; at least 5 oxidation states are known in aqueous solutions. It will form interhalogen compounds, such as AtI and AtCl. The existence of At<sub>2</sub> has not yet been established. The element was synthesized by nuclear bombardment in 1940 by D. R. Corson, K. R. MacKenzie, and E. Segrè at the University of California.

**aster** A starlike arrangement of microtubules radiating from a \*centrosome. Asters become conspicuous in animal cells at the ends of the \*spindle when cell division starts. They are believed to help locate the spindle in relation to the cell's boundaries and to trigger cleavage of the cytoplasm when nuclear division is completed.

**asterism** A pattern of stars that forms a separate entity within a larger constellation. For example, the Plough forms an asterism within the constellation Ursa Major (Great Bear).

**asteroids (minor planets; planetoids)** A number of small bodies that revolve around the sun between the orbits of Mars and Jupiter in a zone between 1.7 and 4.0 astronomical units from the sun (the **asteroid belt**). The size of the bodies varies from the largest, Ceres (with a diameter of 933 km), to objects less than 1 km in diameter. It is estimated that there are about 10 bodies with diameters in excess of 250 km and some 120 bodies with diameters over 130 km.

**asthenosphere** A layer of the earth's mantle (*see* EARTH) that underlies the lithosphere at a depth of about 70 km. The velocity of \*seismic waves is considerably reduced in the asthenosphere and it is thought to be a zone of partial melting. It extends to a depth of about 250 km where rocks are solid.

**astigmatism** A lens defect in which rays in one plane are in focus when those in another plane are not. In lenses and mirrors it occurs with objects not on the axis and is best controlled by reducing the \*aperture to restrict the use of the lens or mirror to its central portion. The eye can also suffer from astigmatism, usually when the cornea is not spherical. It is corrected by using an \*anastigmatic lens.

**Aston, Francis William** (1877-1945) British chemist and physicist, who until 1910 worked at Mason College (later Birmingham University) and then with J. J. \*Thomson at Cambridge University. In 1919 Aston designed the mass spectrograph (*see* MASS SPECTROSCOPY), for which he was awarded the Nobel Prize for chemistry in 1922. With it he discovered the \*isotopes of neon, and was thus able to explain nonintegral atomic weights.

**astrobleme** A fairly ancient circular crater in the earth's crust formed by the impact of a meteorite. It is caused by the explosion of the meteorite on impact and characteristically gives rise to shatter cones in the adjacent rocks. The largest astroblemes range in size from 6 to 40 kilometres across.

**astrometry** The branch of astronomy concerned with the measurement of the positions of the celestial bodies on the \*celestial sphere.

**astronomical telescope** See

TELESCOPE.

**astronomical unit (AU)** The mean distance between the sun and the earth. It is equal to 149 597 870 km (499 light seconds).

**astronomy** The study of the universe beyond the earth's atmosphere. The main branches are \*astrometry, \*celestial mechanics, and \*astrophysics.

**astrophysics** The study of the physical and chemical processes involving astronomical phenomena. Astrophysics deals with stellar structure and evolution (including the generation and transport of energy within stars), the properties of the interstellar medium and its interactions with stellar systems, and the structure and dynamics of systems of stars (such as clusters and galaxies), and of systems of galaxies. See also COSMOLOGY.

**asymmetric atom** See OPTICAL ACTIVITY.

**asymptote** A line that a curve approaches but only touches at infinity.

**asymptotic freedom** The consequence of certain \*gauge theories, particularly \*quantum chromodynamics, that the forces between such particles as quarks become weaker at shorter distances (i.e. higher energies) and vanish as the distance between particles tends to zero. Only non-Abelian gauge theories with unbroken gauge symmetries can have asymptotic freedom (see GROUP). In contrast, \*quantum electrodynamics implies that the interaction between particles decreases as a result of dielectric screening; asymptotic freedom for quarks implies that antiscreening occurs. Physically, asymptotic freedom postulates that the \*vacuum state for gluons is a medium that has colour paramagnetism, i.e. the vacuum antiscreen colour charges.

Asymptotic freedom explains the successes of the \*parton model of pointlike objects inside hadrons and enables systematic corrections to the parton model to be calculated using perturbation theory. That the interaction between quarks increases as the distance between them increases has given rise to the hypothesis of \*quark confinement. It ap-

pears that if a theory requires the presence of Higgs bosons, asymptotic freedom is destroyed. Thus, \*electroweak theory does not have asymptotic freedom.

**asymptotic series** A series formed by the expansion of a function in the form  $a_0 + a_1/x + a_2/x^2 + \dots + a_n/x^n + \dots$ , such that the error resulting from terminating the series at the term  $a_n/x^n$  tends to zero more rapidly than  $1/x^n$  as  $x$  tends to infinity. An asymptotic series expansion is not necessarily a \*convergent series.

**atactic polymer** See POLYMER.

**atlas** The first \*cervical vertebra, a ring-like bone that joins the skull to the vertebral column in terrestrial vertebrates. In advanced vertebrates articulation between the skull and atlas permits nodding movements of the head. See also AXIS.

**atm.** See ATMOSPHERE.

**atmolysis** The separation of a mixture of gases by means of their different rates of diffusion. Usually, separation is effected by allowing the gases to diffuse through the walls of a porous partition or membrane.

**atmosphere 1.** Symbol atm. A unit of pressure equal to 101 325 pascals. This is equal to 760.0 mmHg. The actual \*atmospheric pressure fluctuates around this value. The unit is usually used for expressing pressures well in excess of standard atmospheric pressure, e.g. in high-pressure chemical or physical processes. **2.** See EARTH'S ATMOSPHERE.

**atmospheric pressure** The pressure exerted by the weight of the air above it at any point on the earth's surface. At sea level the atmosphere will support a column of mercury about 760 mm high. This decreases with increasing altitude. The standard value for the atmospheric pressure at sea level in SI units is 101 325 pascals.

**atoll** A circular or elliptical coral reef that encloses a shallow central lagoon. It may be continuous or, more often, broken into closely spaced islets. The water outside the reef is deep. Atolls range in size from a few kilometres to more than 100 km across and are most often found in the Pacific Ocean. They represent the

craters of volcanic islands that have sunk as coral grew on or around the rim.

**atom** The smallest part of an element that can exist. Atoms consist of a small dense nucleus of protons and neutrons surrounded by moving electrons. The number of electrons equals the number of protons so the overall charge is zero. The electrons may be thought of as moving in circular or elliptical orbits (see BOHR THEORY) or, more accurately, in regions of space around the nucleus (see ORBITAL).

The **electronic structure** of an atom refers to the way in which the electrons are arranged about the nucleus, and in particular the \*energy levels that they occupy. Each electron can be characterized by a set of four quantum numbers, as follows:

(1) The **principal quantum number**  $n$  gives the main energy level and has values 1, 2, 3, etc. (the higher the number, the further the electron from the nucleus). Traditionally, these levels, or the orbits corresponding to them, are referred to as **shells** and given letters K, L, M, etc. The K-shell is the one nearest the nucleus. The maximum number of electrons in a given shell is  $2n^2$ .

(2) The **orbital quantum number**  $l$ , which governs the angular momentum of the electron. The possible values of  $l$  are  $(n - 1), (n - 2), \dots, 1, 0$ . Thus, in the first shell ( $n = 1$ ) the electrons can only have angular momentum zero ( $l = 0$ ). In the second shell ( $n = 2$ ), the values of  $l$  can be 1 or 0, giving rise to two **subshells** of slightly different energy. In the third shell ( $n = 3$ ) there are three subshells, with  $l = 2, 1, 0$ . The subshells are denoted by letters  $s$  ( $l = 0$ ),  $p$  ( $l = 1$ ),  $d$  ( $l = 2$ ),  $f$  ( $l = 3$ ). The number of electrons in each subshell is written as a superscript numeral to the subshell symbol, and the maximum number of electrons in each subshell is  $s^2, p^6, d^{10}$ , and  $f^{14}$ . The orbital quantum number is sometimes called the **azimuthal quantum number**.

(3) The **magnetic quantum number**  $m$ , which governs the energies of electrons in an external magnetic field. This can take values of  $+l, +(l - 1), \dots, 1, 0, -1, \dots, -(l - 1), -l$ . In an  $s$ -subshell (i.e.  $l = 0$ ) the value of  $m = 0$ . In a  $p$ -subshell ( $l = 1$ ),  $m$  can have values  $+1, 0$ , and  $-1$ ; i.e. there are three

$p$ -orbitals in the  $p$ -subshell, usually designated  $p_x, p_y$ , and  $p_z$ . Under normal circumstances, these all have the same energy level.

(4) The **spin quantum number**  $m_s$ , which gives the spin of the individual electrons and can have the values  $+\frac{1}{2}$  or  $-\frac{1}{2}$ .

According to the \*Pauli exclusion principle, no two electrons in the atom can have the same set of quantum numbers. The numbers define the **quantum state** of the electron, and explain how the electronic structures of atoms occur. See Chronology: Atomic Theory.

#### **atomic absorption spectroscopy**

**(AAS)** An analytical technique in which a sample is vaporized and the nonexcited atoms absorb electromagnetic radiation at characteristic wavelengths.

**atomic bomb** See NUCLEAR WEAPONS.

**atomic clock** An apparatus for measuring or standardizing time that is based on periodic phenomena within atoms or molecules. See AMMONIA CLOCK; CAESIUM CLOCK.

**atomic emission spectroscopy** An analytical technique in which a sample is vaporized and the atoms present are detected by their emission of electromagnetic radiation at characteristic wavelengths.

**atomic energy** See NUCLEAR ENERGY.

#### **atomic force microscope (AFM)**

A type of microscope in which a small probe, consisting of a tiny chip of diamond, is held on a spring-loaded cantilever in contact with the surface of the sample. The probe is moved slowly across the surface and the tracking force between the tip and the surface is monitored. The probe is raised and lowered so as to keep this force constant, and a profile of the surface is produced. Scanning the probe over the sample gives a computer-generated contour map of the surface. The instrument is similar to the \*scanning tunnelling microscope, but uses mechanical forces rather than electrical signals. It can resolve individual molecules and, unlike the scanning tunnelling microscope, can be used with nonconducting samples, such as biological specimens.

**ATOMIC THEORY**

- c.430 BC Greek natural philosopher Empedocles (d. c. 430 BC) proposes that all matter consists of four elements: earth, air, fire, and water.
- c.400 BC Greek natural philosopher Democritus of Abdera (c. 460–370 BC) proposes that all matter consists of atoms.
- 306 BC Greek philosopher Epicurus (c. 342–270 BC) champions Democritus' atomic theory.
- 1649 French philosopher Pierre Gassendi (1592–1655) proposes an atomic theory (having read Epicurus).
- 1803 John Dalton proposes Dalton's atomic theory.
- 1897 J. J. Thomson discovers the electron.
- 1904 J. J. Thomson proposes his 'plum pudding' model of the atom, with electrons embedded in a nucleus of positive charges.  
Japanese physicist Hantaro Nagaoka (1865–1950) proposes a 'Saturn' model of the atom with a central nucleus having a ring of many electrons.
- 1911 Ernest Rutherford discovers the atomic nucleus.
- 1913 Niels Bohr proposes model of the atom with a central nucleus surrounded by orbiting electrons.  
British physicist Henry Moseley (1887–1915) equates the positive charge on the nucleus with its atomic number.  
Frederick Soddy discovers isotopes.
- 1916 German physicist Arnold Sommerfeld (1868–1951) modifies Bohr's model of the atom specifying elliptical orbits for the electrons.
- 1919 Ernest Rutherford discovers the proton.
- 1920 Ernest Rutherford postulates the existence of the neutron.
- 1926 Erwin Schrödinger proposes a wave-mechanical model of the atom (with electrons represented as wave trains).
- 1932 James Chadwick discovers the neutron.  
Werner Heisenberg proposes a model of the atomic nucleus in which protons and neutrons exchange electrons to achieve stability.
- 1936 Niels Bohr proposes a 'liquid drop' model of the atomic nucleus.
- 1948 German-born US physicist Maria Goeppert-Mayer (1906–72) and German physicist Hans Jensen (1907–73) independently propose the 'shell' structure of the nucleus.
- 1950 Danish physicist physicist Aage Bohr (1922– ) and US physicists Benjamin Mottelson (1926– ) and Leo Rainwater (1917–86) combine the 'liquid-drop' and 'shell' models of the nucleus into a single theory.

**atomicity** The number of atoms in a given molecule. For example, oxygen ( $O_2$ ) has an atomicity of 2, ozone ( $O_3$ ) an atomicity of 3, benzene ( $C_6H_6$ ) an atomicity of 12, etc.

**atomic mass unit (a.m.u.)** A unit of

mass used to express \*relative atomic masses. It is  $1/12$  of the mass of an atom of the isotope carbon-12 and is equal to  $1.660\ 33 \times 10^{-27}$  kg. This unit superseded both the physical and chemical mass units based on oxygen-16 and is some-

a

times called the **unified mass unit** or the **dalton**.

**atomic number (proton number)** Symbol  $Z$ . The number of protons in the nucleus of an atom. The atomic number is equal to the number of electrons orbiting the nucleus in a neutral atom.

**atomic orbital** See ORBITAL.

**atomic pile** An early form of \*nuclear reactor using graphite as a \*moderator.

**atomic volume** The relative atomic mass of an element divided by its density.

**atomic weight** See RELATIVE ATOMIC MASS.

**ATP (adenosine triphosphate)** A nucleotide that is of fundamental importance as a carrier of chemical energy in all living organisms. It consists of adenine linked to D-ribose (i.e. adenosine); the D-ribose component bears three phosphate groups, linearly linked together by covalent bonds (see formula). These bonds can undergo hydrolysis to yield either a molecule of ADP (**adenosine diphosphate**) and inorganic phosphate or a molecule of AMP (**adenosine monophosphate**) and pyrophosphate (see ATPASE). Both these reactions yield a large amount of energy (about  $30.6 \text{ kJ mol}^{-1}$ ) that is used to bring about such biological processes as muscle \*contraction, the \*active transport of ions and molecules across cell membranes, and the synthesis of biomolecules. The reactions bringing about these processes often involve the enzyme-catalysed transfer of the phosphate group to intermedi-

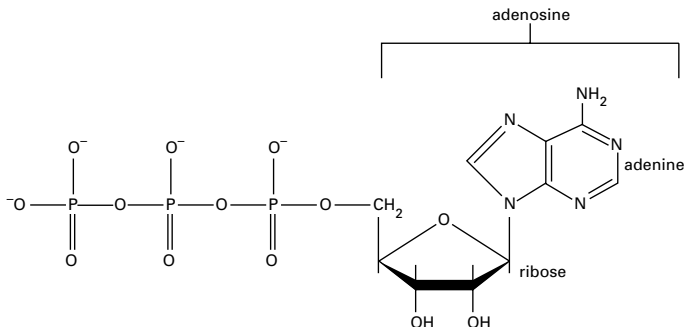

ate substrates. Most ATP-mediated reactions require  $\text{Mg}^{2+}$  ions as \*cofactors.

ATP is regenerated by the rephosphorylation of AMP and ADP using the chemical energy obtained from the oxidation of food. This takes place during \*glycolysis and the \*Krebs cycle but, most significantly, is also a result of the reduction-oxidation reactions of the \*electron transport chain, which ultimately reduces molecular oxygen to water (\*oxidative phosphorylation). ATP is also formed by the light-dependent reactions of \*photosynthesis.

**ATPase** An enzyme that brings about the hydrolysis of ATP. This results in the cleavage of either one phosphate group, with the formation of ADP and inorganic phosphate ( $\text{P}_i$ ), or of two phosphate groups, with the formation of AMP and pyrophosphate ( $\text{PP}_i$ ); the second reaction yields twice as much energy as the first. ATPase activity is associated with many energy-consuming processes; for example, in muscle contraction it is associated with \*myosin when activated by actin.

**atrioventricular node (AVN)** A specialized group of \*cardiac muscle fibres situated in the fibrous ring between the right atrium and ventricle of the heart. The AVN is the only pathway between the atria and the ventricles through which electrical impulses can pass. Thus, following the contraction of the atria, the AVN initiates a wave of contraction in the ventricles via the \*bundle of His.

**atrium 1. (auricle)** A chamber of the

\*heart that receives blood from the veins and forces it by powerful muscular contraction into the \*ventricle(s). Fish have a single atrium but all other vertebrates have two. **2.** Any of various cavities or chambers in animals, such as the chamber surrounding the gill slits of the lancelet and other invertebrate chordates.

**atrophy** The degeneration or withering of an organ or part of the body.

**atropine** A poisonous crystalline alkaloid,  $C_{17}H_{23}NO_3$ ; m.p. 118–119°C. It can be extracted from deadly nightshade and other solanaceous plants and is used in medicine to treat colic, to reduce secretions, and to dilate the pupil of the eye.

**attenuation 1.** (in physics) **a.** A loss of intensity suffered by sound, radiation, etc., as it passes through a medium. It may be caused by absorption or scattering. **b.** The drop in voltage or current experienced by a signal as it passes through a circuit. **2.** (in medicine) A process of reducing the disease-producing ability of a microorganism. It can be achieved by chemical treatment, heating, drying, irradiation, by growing the organism under adverse conditions, or by serial passage through another organism. Attenuated bacteria or viruses are used for some \*vaccines. **3.** (in mycology) The conversion by yeasts of carbohydrates to alcohol, as in brewing and wine and spirit production.

**atto-** Symbol a. A prefix used in the metric system to denote  $10^{-18}$ . For example,  $10^{-18}$  second = 1 attosecond (as).

**attractor** The set of points in \*phase space to which the representative point of a dissipative system (i.e. one with internal friction) tends as the system evolves. The attractor can be: a single point; a closed curve (a **limit cycle**), which describes a system with periodic behaviour; or a \*fractal (or **strange attractor**), in which case the system exhibits \*chaos. *See also* BRUSSELTATOR.

**AU** *See* ASTRONOMICAL UNIT.

**audibility** The state of being perceptible to hearing. The limits of audibility of the human ear are between about 20 hertz (a low rumble) and 20 000 hertz (a shrill

whistle). With increased age the upper limit falls quite considerably.

**audiofrequency** A frequency that is audible to the human ear. *See* AUDIBILITY.

**audiometer** An instrument that generates a sound of known frequency and intensity in order to measure an individual's hearing ability.

**auditory** Of or relating to the \*ear. For example, the **auditory meatus** is the canal leading from the pinna to the tympanum (eardrum).

**auditory nerve** The nerve that transmits sensory information from the ear to the brain.

**Aufbau principle** A principle that gives the order in which orbitals are filled in successive elements in the periodic table. The order of filling is 1s, 2s, 2p, 3s, 3p, 4s, 3d, 4p, 5s, 4d, 5p, 6s, 4f, 5d, 6p, 7s, 5f, 6d. *See* ATOM.

**Auger effect** The ejection of an electron from an atom without the emission of an X- or gamma-ray photon, as a result of the de-excitation of an excited electron within the atom. This type of transition occurs in the X-ray region of the emission spectrum. The kinetic energy of the ejected electron, called an **Auger electron**, is equal to the energy of the corresponding X-ray photon minus the binding energy of the Auger electron. The effect was discovered by Pierre Auger (1899–1994) in 1925.

**auric compounds** Compounds of gold in its higher (+3) oxidation state; e.g. auric chloride is gold(III) chloride ( $AuCl_3$ ).

**auricle 1.** *See* ATRIUM. **2.** *See* PINNA.

**aurora** The luminous phenomena seen in the night sky in high latitudes, occurring most frequently near the earth's geomagnetic poles. The displays of aurora appear as coloured arcs, rays, bands, streamers, and curtains, usually green or red. The aurora is caused by the interaction of the atoms (mainly atomic oxygen) and molecules in the upper atmosphere (above about 100 km) with charged particles streaming from the sun, attracted to the auroral regions by the earth's magnetic field. The aurora is known as the

**aurora borealis** (or northern lights) in the northern hemisphere and as the **aurora australis** (or southern lights) in the southern hemisphere.

**aurous compounds** Compounds of gold in its lower (+1) oxidation state; e.g. aurous chloride is gold(I) chloride (AuCl).

**austenite** See STEEL.

**Australopithecus** A genus of fossil primates that lived 4–2 million years ago, co-existing for some of this time with early forms of humans (see HOMO). They walked erect and had teeth resembling those of modern humans, but the brain capacity was less than one-third that of a modern human. Various finds have been made, chiefly in East and South Africa (hence the name, which means 'southern ape'). The earliest belong to the species *A. afarensis*, which includes the specimen of a female, dubbed 'Lucy', found at Laetoli in Tanzania. *Australopithecus* and related genera are known as **australopithecines**.

**autecology** The study of ecology at the level of the species. An autecological study aims to investigate the ecology of \*populations or individuals of a particular species, including habitat, distribution, life cycle, etc. This should enable a full description of the \*ecological niche of the organism to be made. Compare SYNECOLOGY.

**autocatalysis** \*Catalysis in which one of the products of the reaction is a catalyst for the reaction. Reactions in which autocatalysis occurs have a characteristic S-shaped curve for reaction rate against time – the reaction starts slowly and increases as the amount of catalyst builds up, falling off again as the products are used up.

**autoclave** A strong steel vessel used for carrying out chemical reactions, sterilizations, etc., at high temperature and pressure.

**autogamy 1.** A type of reproduction that occurs in single isolated individuals of ciliate protozoans of the genus *Paramecium*. The nucleus divides into two genetically identical haploid nuclei, which then fuse to form a diploid zygote. The onset of autogamy is associated with changing en-

vironmental conditions and may be necessary to maintain cell vitality. **2.** Self-fertilization in plants. See FERTILIZATION.

**autograft** See GRAFT.

**autoimmunity** A disorder of the body's defence mechanisms in which an \*immune response is elicited against its own tissues, which are thereby damaged or destroyed. Rheumatoid arthritis, systemic lupus erythematosus, myasthenia gravis, and several forms of thyroid dysfunction are examples of autoimmune diseases.

**autolysis** The process of self-destruction of a cell, cell organelle, or tissue. It occurs by the action of enzymes within or released by \*lysosomes. See also LYSIS.

**autonomic nervous system (ANS)**

The part of the vertebrate \*peripheral nervous system that supplies stimulation via motor nerves to the smooth and cardiac muscles (the involuntary muscles) and to the glands of the body. It is divided into the \*parasympathetic and the \*sympathetic nervous systems, which tend to work antagonistically on the same organs. The activity of the ANS is controlled principally by the \*medulla oblongata and \*hypothalamus of the brain.

**autopolyploid** A \*polyploid organism in which the multiple sets of chromosomes are all derived from the same species. For example, doubling of the chromosome number during mitotic cell division, possibly induced by \*colchicine, gives rise to a tetraploid known as an **autotetraploid**. Compare ALLOPOLYPLOID.

**autoradiography** An experimental technique in which a radioactive specimen is placed in contact with (or close to) a photographic plate, so as to produce a record of the distribution of radioactivity in the specimen. The film is darkened by the ionizing radiation from radioactive parts of the sample. Autoradiography has a number of applications, being used particularly to study the distribution of particular substances in living tissues, cells, and cultures. A radioactive isotope of the substance is introduced into the organism or tissue, which is killed, sectioned, and examined after enough time has elapsed for the isotope to be incorporated into the substance. Autoradiography is also used to

locate radioactively labelled DNA probes or antibodies in such techniques as \*Southern blotting and \*Western blotting.

**autosome** Any of the chromosomes in a cell other than the \*sex chromosomes.

**autotomy** The shedding by an animal of part of its body followed by the regeneration of the lost part. Autotomy is achieved by the contraction of muscles at specialized regions in the body. It serves as a protective mechanism if the animal is damaged or attacked (e.g. tail loss in certain reptiles) and is common as a method of asexual reproduction in polychaete worms, in which both new head and tail regions may be regenerated.

**autotrophic nutrition** A type of nutrition in which organisms synthesize the organic materials they require from inorganic sources. Chief sources of carbon and nitrogen are carbon dioxide and nitrates, respectively. All green plants are autotrophic and use light as a source of energy for the synthesis, i.e. they are **photoautotrophic** (see PHOTOSYNTHESIS). Some bacteria are also photoautotrophic; others are **chemoautotrophic**, using energy derived from chemical processes (see CHEMOSYNTHESIS). Compare HETEROTROPHIC NUTRITION.

**auxanometer** Any mechanical instrument or measuring device used to study the growth or movement of plant organs. One type of auxanometer consists of a recording device that translates any increase in stem height into movement of a needle across a scale.

**auxin** Any of a group of plant \*growth substances responsible for such processes as the promotion of growth by cell enlargement, the maintenance of \*apical dominance, and the initiation of root formation in cuttings. Auxins are also involved in suppressing the \*abscission of leaves, fruits, or other plant organs and in the development of flowers and fruits. Naturally occurring auxins, principally **indoleacetic acid (IAA)**, are synthesized in actively growing regions of the plant, from where they are transported to other parts. Synthetic auxins include **2,4-D**, which is used as a weedkiller, and **indole-**

**butyric acid** and **naphthaleneacetic acid**, which are sold in preparations of 'rooting hormones'.

**auxochrome** A group in a dye molecule that influences the colour due to the \*chromophore. Auxochromes are groups, such as -OH and -NH<sub>2</sub>, containing lone pairs of electrons that can be delocalized along with the delocalized electrons of the chromophore. The auxochrome intensifies the colour of the dye. Formerly, the term was also used of such groups as -SO<sub>2</sub>O<sup>-</sup>, which make the molecule soluble and affect its application.

**avalanche** A shower of ionized particles created by a single \*ionization as a result of secondary ionizations caused by the original electron and ion being accelerated in an electric field. Each ionization leads to the formation of more electrons and ions, which themselves cause further ionizations. Such avalanches occur in a \*Geiger counter.

**average (mean)** **1.** The **arithmetic average** of a set of  $n$  numbers is the sum of the numbers divided by  $n$ . **2.** The **geometric average** of a set of  $n$  numbers is the  $n$ th root of their product. See also ROOT-MEAN-SQUARE VALUE.

**Aves** The birds: a class of bipedal vertebrate chordates (see CHORDATA) with \*feathers, wings, and a beak. They evolved from reptilian ancestors, probably in the Jurassic period (190-136 million years ago), and modern birds still have scaly legs, like reptiles. Birds are warm-blooded (see HOMIOOTHERMY). The skin is dry and loose and has no sweat glands, so cooling is effected by panting. Their efficient lungs and four-chambered heart (which completely separates oxygenated and deoxygenated blood) ensure a good supply of oxygen to the tissues. Birds can therefore sustain a high body temperature and level of activity necessary for \*flight. The breastbone bears a keel for the attachment of flight muscles. The skeleton is very light; many of the bones are tubular, having internal struts to provide strength and air sacs to reduce weight and provide extra oxygen in flight. Their feathers are vital for flight, streamlining the body, and insulation against heat loss.

Many birds show a high degree of social

behaviour in forming large flocks and pair bonding for nesting, egg incubation, and rearing young. Fertilization is internal and the female lays hard-shelled eggs. *See also* RATITAE.

**AVN** *See* ATRIOVENTRICULAR NODE.

**Avogadro, Amedeo** (1776–1856) Italian chemist and physicist. In 1811 he published his hypothesis (*see* AVOGADRO'S LAW), which provided a method of calculating molecular weights from vapour densities. The importance of the work remained unrecognized, however, until championed by Stanislao Cannizzaro (1826–1910) in 1860.

**Avogadro constant** Symbol  $N_A$  or  $L$ . The number of atoms or molecules in one \*mole of substance. It has the value  $6.022\ 1367(36) \times 10^{23}$ . Formerly it was called **Avogadro's number**.

**Avogadro's law** Equal volumes of all gases contain equal numbers of molecules at the same pressure and temperature. The law, often called **Avogadro's hypothesis**, is true only for ideal gases. It was first proposed in 1811 by Amedeo Avogadro.

**axenic culture** A \*culture medium in which only one type of microorganism is growing. Such cultures are widely used in microbiology to determine the basic growth requirements or degree of inhibition by antibiotics or other chemicals of a particular species.

**axial period** The time taken for a celestial object to rotate once on its axis. For a planet, measured with respect to the direction of a fixed star, it is equal to a sidereal \*day.

**axial skeleton** The main longitudinal section of the vertebrate \*skeleton, including the \*skull, the \*vertebral column, and the rib cage. *Compare* APPENDICULAR SKELETON.

**axial vector (pseudo-vector)** A \*vector that does not reverse its sign when the coordinate system is changed to a new system by a reflection in the origin (i.e.  $x'_i = -x_i$ ). An example of an axial vector is the \*vector product of two \*polar vectors, such as  $\mathbf{L} = \mathbf{r} \times \mathbf{p}$ , where  $\mathbf{L}$  is the \*angular momentum of a particle,  $\mathbf{r}$  is its position

vector, and  $\mathbf{p}$  is its momentum vector.

*Compare* PSEUDO-SCALAR.

**axil** The angle between a branch or leaf and the stem it grows from. **Axillary** (or **lateral**) **buds** develop in the axil of a leaf. The presence of axillary buds distinguishes a leaf from a leaflet.

**axillary bud** *See* AXIL.

**axion** A hypothetical elementary particle postulated to explain why there is no observed CP violation (*see* CP INVARIANCE) in the strong interaction (*see* FUNDAMENTAL INTERACTIONS). Axions have not been detected experimentally, although it has been possible to put limits on their mass and other properties from the effects that they would have on some astrophysical phenomena (e.g. the cooling of stars). It has also been suggested that they may account for some or all of the \*missing mass in the universe.

**axis 1.** (in mathematics) **a.** One of a set of reference lines used to locate points on a graph or in a coordinate system. *See* CARTESIAN COORDINATES; POLAR COORDINATES. **b.** A line about which a figure, curve, or body is symmetrical (**axis of symmetry**) or about which it rotates (**axis of rotation**). **2.** (in anatomy) The second \*cervical vertebra, which articulates with the \*atlas (the first cervical vertebra, which articulates with the skull). The articulation between the axis and atlas in reptiles, birds, and mammals permits side-to-side movement of the head. The body of the axis is elongated to form a peg (the **odontoid process**), which extends into the ring of the atlas and acts as a pivot on which the atlas (and skull) can turn.

**axon** The long threadlike part of a nerve cell (\*neuron). It carries the nerve impulse (in the form of an \*action potential) away from the \*cell body of a neuron towards either an effector organ or the brain. *See also* NERVE FIBRE.

**azeotrope (azeotropic mixture; constant-boiling mixture)** A mixture of two liquids that boils at constant composition; i.e. the composition of the vapour is the same as that of the liquid. Azeotropes occur because of deviations in Raoult's law leading to a maximum or minimum in the \*boil-

ing-point-composition diagram. When the mixture is boiled, the vapour initially has a higher proportion of one component than is present in the liquid, so the proportion of this in the liquid falls with time. Eventually, the maximum and minimum point is reached, at which the two liquids distil together without change in composition. The composition of an azeotrope depends on the pressure.

**azeotropic distillation** A technique for separating components of an azeotrope by adding a third liquid to form a new azeotrope with one of the original components. It is most commonly used to separate ethanol from water, adding benzene to associate with the ethanol.

**azides** Compounds containing the ion  $N_3^-$  or the group  $-N_3$ .

**azimuth** **1.** In horizontal coordinate systems used in astronomy, the angular distance measured eastwards along the observer's horizon from the south point or sometimes the north point to the intersection of the vertical circle through a celestial body. **2.** See POLAR COORDINATES.

**azimuthal quantum number** See ATOM.

**azine** An organic heterocyclic compound containing a six-membered ring formed from carbon and nitrogen atoms. Pyridine is an example containing one nitrogen atom ( $C_5H_5N$ ). **Diazines** have two nitrogen atoms in the ring (e.g.  $C_4H_4N_2$ ), and isomers exist depending on the relative positions of the nitrogen atoms. **Triazines** contain three nitrogen atoms.

**azo compounds** Organic compounds containing the group  $-N=N-$  linking two other groups. They can be formed by reaction of a diazonium ion with a benzene ring.

**azo dye** See DYES.

**azoimide** See HYDROGEN AZIDE.

**azurite** A secondary mineral consisting of hydrated basic copper carbonate,  $Cu_3(OH)_2(CO_3)_2$ , in monoclinic crystalline form. It is generally formed in the upper zone of copper ore deposits and often occurs with \*malachite. Its intense azure-blue colour made it formerly important as a pigment. It is a minor ore of copper and is used as a gemstone.

# B

**Babbage, Charles** (1792–1871) British mathematician who is best known for his early work on mechanical calculating machines. He began work on his first 'difference engine' in 1823, but abandoned it ten years later due to lack of funds. His second machine of 1834 was a programmable punched-card 'analytical engine', but this too was never completed.

**Babbit metal** Any of a group of related alloys used for making bearings. They consist of tin containing antimony (about 10%) and copper (1–2%), and often lead. The original alloy was invented in 1839 by the US inventor Isaac Babbit (1799–1862).

**Babo's law** The vapour pressure of a liquid is decreased when a solute is added, the amount of the decrease being proportional to the amount of solute dissolved. The law was discovered in 1847 by the German chemist Lambert Babo (1818–99). *See also* **RAOULT'S LAW**.

**BAC** *See* (BACTERIAL) **ARTIFICIAL CHROMOSOME**.

**Bacillariophyta** A phylum of \*algae comprising the diatoms. These marine or freshwater unicellular organisms have cell walls composed of pectin impregnated with silica and consisting of two halves, one overlapping the other. Diatoms are found in huge numbers in plankton and are important in the food chains of seas and rivers. Past deposition has resulted in diatomaceous earths (kieselguhr) and the oil reserves of these species have contributed to oil deposits.

**bacillus** Any rod-shaped bacterium. Generally, bacilli are large, Gram-positive, spore-bearing, and have a tendency to form chains and produce a \*capsule. Some are motile, bearing flagella. They are ubiquitous in soil and air and many are responsible for food spoilage. The group also includes *Bacillus anthracis*, which causes anthrax.

**backbiting** A rearrangement that can occur in some polymerization reactions involving free radicals. A radical that has an unpaired electron at the end of the chain changes into a radical with the unpaired electron elsewhere along the chain, the new radical being more stable than the one from which it originates. For example, the radical  $\text{RCH}_2\text{CH}_2\text{CH}_2\cdot$  may change into  $\text{RCH}_2\text{CH}\cdot\text{CH}_2\text{CH}_2\text{CH}_3$ . The rearrangement is equivalent to a hydrogen atom being transferred within the molecule. The new unpaired electron initiates further polymerization, with the production of polymers with butyl ( $\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}_2\cdot$ ) side chains.

**backbone** *See* **VERTEBRAL COLUMN**.

**back cross** A mating between individuals of the parental generation (P) and the first generation of offspring ( $F_1$ ) in order to identify hidden \*recessive alleles. If an organism displays a \*dominant characteristic, it may possess two dominant alleles (i.e. it is homozygous) or a dominant and a recessive allele for that characteristic (i.e. it is heterozygous). To find out which is the case, the organism is crossed with one displaying the recessive characteristic. If all the offspring show the dominant characteristic then the organism is homozygous, but if half show the recessive characteristic, then the organism is heterozygous. *See also* **TEST CROSS**.

**back donation** A form of chemical bonding in which a \*ligand forms a sigma bond to an atom or ion by donating a pair of electrons, and the central atom donates electrons back by overlap of its *d*-orbitals with empty *p*- or *d*-orbitals on the ligand.

**back e.m.f.** An electromotive force that opposes the main current flow in a circuit. For example, when the coils of the armature in an electric motor are rotated a back e.m.f. is generated in these coils by

their interaction with the field magnet (see **INDUCTANCE**). Also, in an electric cell, \*polarization causes a back e.m.f. to be set up, in this case by chemical means.

**background radiation** Low intensity \*ionizing radiation present on the surface of the earth and in the atmosphere as a result of \*cosmic radiation and the presence of radioisotopes in the earth's rocks, soil, and atmosphere. The radioisotopes are either natural or the result of nuclear fallout or waste gas from power stations. Background counts must be taken into account when measuring the radiation produced by a specified source. See also **MICROWAVE BACKGROUND RADIATION**.

**backing store** Supplementary computer memory, usually in the form of magnetic disks, in which data and programs are held permanently for reference; small sections of this information can then be copied into the main memory (\*RAM) of a computer when required for processing. Backing store is less costly and can hold more information than semiconductor RAM, but the speed of access of information in RAM is considerably faster. Use of a hierarchy of different memory devices, including backing store and RAM, greatly improves performance, efficiency, and economy in a computer.

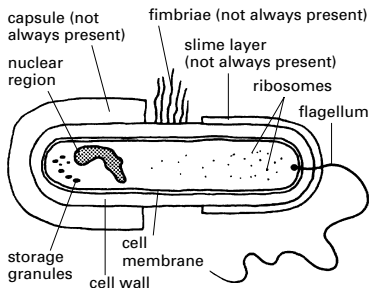

**back titration** A technique in \*volumetric analysis in which a known excess amount of a reagent is added to the solution to be estimated. The unreacted amount of the added reagent is then determined by titration, allowing the amount of substance in the original test solution to be calculated.

**backup** A resource that can be used as a substitute in the event of, say, a fault in a component or system or loss of data from a computer file. A backup file is a copy of a file taken in case the original is destroyed or unintentionally altered and the data lost.

**bacteria** A diverse group of ubiquitous microorganisms all of which consist of only a single \*cell that lacks a distinct nuclear membrane and has a \*cell wall of a unique composition (see illustration). Bacteria constitute the prokaryotic organisms of the living world and were traditionally

placed in a single kingdom, variously named Bacteria or Prokaryotae. However, it is now recognized, on the basis of differences in ribosomal RNA structure and nucleotide sequences (see **MOLECULAR SYSTEMATICS**), that prokaryotes form two groups so evolutionarily distinct that they should each be raised to the status of \*domain: \*Archaea (the archaeobacteria, containing a variable number of kingdoms) and **Bacteria** (containing a single kingdom, **Eubacteria**). The two groups also differ in the composition of their cell walls and the molecular structure of their membrane lipids.

Generally speaking, the term 'bacteria' includes both archaeobacteria and eubacteria. Bacteria can be characterized in a number of ways, for example by their reaction with \*Gram's stain or on the basis of their metabolic requirements (e.g. whether or not they require oxygen: see **AEROBIC RESPIRATION**; **ANAEROBIC RESPIRATION**) and shape. A bacterial cell may be spherical (see **COCCUS**), rodlike (see **BACILLUS**), spiral (see **SPIRILLUM**), comma-shaped (see **VIBRIO**), corkscrew-shaped (see **SPIROCHAETE**), or filamentous, resembling a fungal cell. The majority of bacteria range in size from 0.5 to 5  $\mu\text{m}$ . Many are motile, bearing \*flagella, possess an outer slimy \*capsule, and produce resistant spores (see **ENDOSPORE**). In general bacteria reproduce only asexually, by simple division of cells, but a few groups undergo a form of sexual reproduction (see **CONJUGATION**). Bacteria are largely responsible for decay and decomposition of organic matter, producing a cycling of such chemicals as carbon (see **CARBON CYCLE**), oxygen, ni-

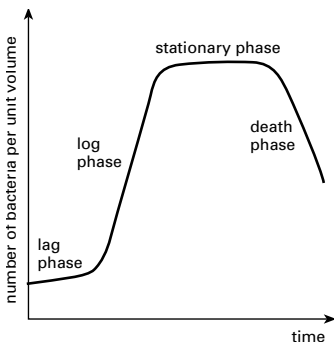

A generalized bacterial cell

trogen (see NITROGEN CYCLE), and sulphur (see SULPHUR CYCLE). A few bacteria obtain their food by means of \*photosynthesis, including the \*Cyanobacteria; some are saprotrophs; and others are parasites, causing disease. The symptoms of bacterial infections are produced by \*toxins.

**bacterial artificial chromosome** See ARTIFICIAL CHROMOSOME.

**bacterial growth curve** A curve on a graph that shows the changes in size of a bacterial population over time in a culture. The bacteria are cultured in sterile nutrient medium and incubated at the optimum temperature for growth. Samples are removed at intervals and the number of viable bacteria is counted. A logarithmic growth curve is plotted, which shows various phases (see graph).

In the **lag** (or **latent**) **phase** there is only a small increase in numbers as the bacteria imbibe water, and synthesize ribosomal RNA and subsequently enzymes, in adjusting to the new conditions. The length of this phase depends on which medium was used to culture the bacteria before the investigation and which phase the cells are already in. As the life span (generation time) of the cells decreases, they enter the **log** (or **exponential**) **phase**, in which the cells reach a maximum rate of reproduction and the number of bacteria increases directly with time, giving a straight slope on a logarithmic scale (see EXPONENTIAL GROWTH). For example, the fastest generation time for *E. coli* is 21 minutes. Growth rate can be estimated in

Bacterial growth curve

this phase. With time, as the population grows, it enters the **stationary phase**, when the nutrients and electron acceptors are depleted and the pH drops as carbon dioxide and other waste poisons accumulate. As the cell's energy stores are depleted the rate of cell division decreases. The **death** (or **final**) **phase** occurs when the rate at which the bacteria die exceeds the rate at which they are produced; the population declines as the levels of nutrients fall and toxin levels increase. See also POPULATION GROWTH.

**bactericidal** Capable of killing bacteria. Common bactericides are some \*antibiotics, \*antiseptics, and \*disinfectants. Compare BACTERIOSTATIC.

**bacteriochlorophyll** A form of chlorophyll found in photosynthetic bacteria, notably the purple and green bacteria. There are several types, designated *a* to *g*. For example, bacteriochlorophyll *a* and bacteriochlorophyll *b* are structurally similar to the chlorophyll *a* and chlorophyll *b* found in plants. Bacteriochlorophyll is located in specialized membrane systems (**chromatophores**).

**bacteriology** The study of bacteria, including their identification, form, function, reproduction, and classification. Much attention is focused on the role of bacteria as agents of disease in animals, including humans, and in plants, and on methods of controlling pathogenic bacteria in the food chain and elsewhere in the environment. However, bacteriologists also investigate the many benefits of bacteria, e.g. in the production of antibiotics, enzymes, and amino acids, and in sewage treatment.

**bacteriophage** (**phage**) A virus that is parasitic within a bacterium. Each phage is specific for only one type of bacterium. Most phages (**virulent phages**) infect, quickly multiply within, and destroy (lyse) their host cells. However, some (**temperate phages**) remain dormant in their hosts after initial infection: their nucleic acid becomes integrated into that of the host and multiplies with it, producing infected daughter cells. Lysis may eventually be triggered by environmental factors. Phages are used experimentally to identify bacteria, to control manufacturing

processes (such as cheese production) that depend on bacteria, and, because they can alter the genetic make-up of bacterial cells, they are important tools in genetic engineering as cloning \*vectors.

**bacteriostatic** Capable of inhibiting or slowing down the growth and reproduction of bacteria. Some \*antibiotics are bacteriostatic. *Compare* BACTERICIDAL.

**Baer, Karl Ernst von** (1792–1876) Estonian-born German biologist. He studied medicine and comparative anatomy before becoming professor of zoology at Königsberg University in 1817. Ten years later he discovered the mammalian ovum, and traced its development from the Graafian follicle to the embryo. He also noted the similarities between the young embryos of widely different species (the biogenetic law).

**Bakelite** A trade name for certain phenol-formaldehyde resins, first introduced in 1909 by the Belgian-US chemist Leo Hendrik Baekeland (1863–1944).

**baker's yeast** Strains of the yeast \**Saccharomyces cerevisiae* that are used in bread-making to enable the dough to rise. Water is added to flour, which activates the \*amylase enzymes that hydrolyse the starch in flour to glucose. Baker's yeast is then added, which uses the glucose as a substrate for \*aerobic respiration. The carbon dioxide produced from yeast respiration causes bubbles to form in the dough; these become larger during heating in an oven, giving bread its typical texture.

**baking soda** *See* SODIUM HYDROGENCARBONATE.

**balance 1.** An accurate weighing device. The simple **beam balance** consists of two pans suspended from a centrally pivoted beam. Known masses are placed on one pan and the substance or body to be weighed is placed in the other. When the beam is exactly horizontal the two masses are equal. An accurate laboratory balance weighs to the nearest hundredth of a milligram. Specially designed balances can be accurate to a millionth of a milligram. More modern **substitution balances** use the substitution principle. In this calibrated weights are removed from the single lever arm to bring the single pan

suspended from it into equilibrium with a fixed counter weight. The substitution balance is more accurate than the two-pan device and enables weighing to be carried out more rapidly. In automatic electronic balances, mass is determined not by mechanical deflection but by electronically controlled compensation of an electric force. A scanner monitors the displacement of the pan support generating a current proportional to the displacement. This current flows through a coil forcing the pan support to return to its original position by means of a magnetic force. The signal generated enables the mass to be read from a digital display. The mass of the empty container can be stored in the balance's computer memory and automatically deducted from the mass of the container plus its contents. *See also* SPRING BALANCE. **2.** (in animal physiology) Equilibrium in the posture of the body. In vertebrates balance is sensed and maintained by the \*vestibular apparatus of the inner ear. **3.** (in nutrition) *See* DIET.

**baleen** *See* WHALEBONE.

**ballistic galvanometer** A moving-coil \*galvanometer designed for measuring charge by detecting a surge of current. It has a heavy coil with minimal damping. When a surge of current is passed through the coil, the initial maximum deflection (the 'throw') is proportional to the total charge that has passed.

**ballistic pendulum** A device used to measure the velocity of a projectile, such as a bullet. A large mass of relatively soft material is suspended from a horizontal bar and the angle through which this mass is displaced when it is struck by the projectile in flight enables the momentum and hence the velocity of the projectile to be calculated by successive application of the laws of conservation of linear momentum and of energy.

**ballistics** The study of the flight of projectiles, especially those that have a parabolic flight path from one point on the earth's surface to another.

**ball lightning** A white or reddish luminous sphere, about 50 cm in diameter, that sometimes appears at ground level in a thunderstorm. Ball lightning is slow

moving and usually disappears without detonation. *See also* LIGHTNING.

**Balmer series** *See* HYDROGEN SPECTRUM.

**banana bond** Informal name for the type of electron-deficient three-centre bond holding the B-H-B bridges in \*boranes and similar compounds.

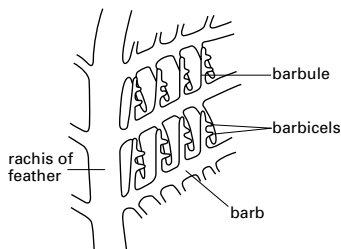

**band spectrum** *See* SPECTRUM.

**band theory** *See* ENERGY BAND.

**bandwidth** The frequency range over which a radio signal of specified frequency spreads. For example, in a \*modulation system it is the range of frequencies occupied by the modulating signal on either side of the carrier wave. In an amplifier, it is the range of frequencies over which the power amplification falls within a specified fraction of the maximum value. In an aerial it is the range of frequencies that an aerial system can handle without mismatch.

**bar** A c.g.s. unit of pressure equal to  $10^6$  dynes per square centimetre or  $10^5$  pascals (approximately 750 mmHg or 0.987 atmosphere). The **millibar** (100 Pa) is commonly used in meteorology.

**barb 1.** (in zoology) Any one of the stiff filaments forming a row on each side of the longitudinal shaft of a feather (see illustration). Together the barbs form the expanded part (**vane**) of the feather. *See* BARBULE. **2.** (in botany) A hooked hair.

Interlocking barbs of a contour feather

**barbiturate** Any one of a group of drugs derived from barbituric acid, which have a depressant effect on the central nervous system. Barbiturates were originally used as sedatives and sleeping pills but their clinical use is now limited due to

their toxic side-effects; prolonged use can lead to addiction. Specific barbiturates still in clinical use include butobarbital, used to treat insomnia, and thiopental, used to induce general anaesthesia.

**barbule** Any of the minute filaments forming a row on each side of the \*barb of a feather. In a \*contour feather adjacent barbules interlock by means of hooks (**barbicels**) and grooves, forming a firm vane. Down feathers have no barbicels.

**barchan** *See* DUNE.

**Bardeen, John** (1908–91) US physicist, who worked at Harvard, Minnesota University, and Bell Telephone Labs before becoming a professor at the University of Illinois in 1951. At Bell, with Walter Brattain (1902–87) and William Shockley (1910–89), he developed the point-contact transistor. The three scientists shared the 1956 Nobel Prize for physics for this work. In 1956, with Leon Cooper (1930– ) and John Schrieffer (1931– ), he formulated the BCS theory of \*superconductivity, for which they shared the 1972 Nobel Prize.

**Barfoed's test** A biochemical test to detect monosaccharide (reducing) sugars in solution, devised by the Swedish physician Christen T. Barfoed (1815–99). **Barfoed's reagent**, a mixture of ethanoic (acetic) acid and copper(II) acetate, is added to the test solution and boiled. If any reducing sugars are present a red precipitate of copper(II) oxide is formed. The reaction will be negative in the presence of disaccharide sugars as they are weaker reducing agents.

**barite** *See* BARYTES.

**barium** Symbol Ba. A silvery-white reactive element belonging to \*group 2 (formerly IIA) of the periodic table; a.n. 56; r.a.m. 137.34; r.d. 3.51; m.p. 725°C; b.p. 1640°C. It occurs as the minerals barytes ( $\text{BaSO}_4$ ) and witherite ( $\text{BaCO}_3$ ). Extraction is by high-temperature reduction of barium oxide with aluminium or silicon in a vacuum, or by electrolysis of fused barium chloride. The metal is used as a getter in vacuum systems. It oxidizes readily in air and reacts with ethanol and water. Soluble barium compounds are extremely poisonous. It was first identified in 1774

by Karl Scheele, and was extracted by Humphry Davy in 1808.

**barium bicarbonate** See BARIUM HYDROGENCARBONATE.

**barium carbonate** A white insoluble compound,  $\text{BaCO}_3$ ; r.d. 4.43. It decomposes on heating to give barium oxide and carbon dioxide:

The compound occurs naturally as the mineral **witherite** and can be prepared by adding an alkaline solution of a carbonate to a solution of a barium salt. It is used as a raw material for making other barium salts, as a flux for ceramics, and as a raw material in the manufacture of certain types of optical glass.

**barium chloride** A white compound,  $\text{BaCl}_2$ . The anhydrous compound has two crystalline forms: an  $\alpha$  form (monoclinic; r.d. 3.856), which transforms at  $962^\circ\text{C}$  to a  $\beta$  form (cubic; r.d. 3.917; m.p.  $963^\circ\text{C}$ ; b.p.  $1560^\circ\text{C}$ ). There is also a dihydrate,  $\text{BaCl}_2 \cdot 2\text{H}_2\text{O}$  (cubic; r.d. 3.1), which loses water at  $113^\circ\text{C}$ . It is prepared by dissolving barium carbonate (witherite) in hydrochloric acid and crystallizing out the dihydrate. The compound is used in the extraction of barium by electrolysis.

**barium hydrogencarbonate (barium bicarbonate)** A compound,  $\text{Ba}(\text{HCO}_3)_2$ , which is only stable in solution. It can be formed by the action of carbon dioxide on a suspension of barium carbonate in cold water:

On heating, this reaction is reversed.

**barium hydroxide (baryta)** A white solid,  $\text{Ba}(\text{OH})_2$ , sparingly soluble in water. The common form is the octahydrate,  $\text{Ba}(\text{OH})_2 \cdot 8\text{H}_2\text{O}$ ; monoclinic; r.d. 2.18; m.p.  $78^\circ\text{C}$ . It can be produced by adding water to barium monoxide or by the action of sodium hydroxide on soluble barium compounds and is used as a weak alkali in volumetric analysis.

**barium oxide** A white or yellowish solid,  $\text{BaO}$ , obtained by heating barium in oxygen or by the thermal decomposition of barium carbonate or nitrate; cubic; r.d.

5.72; m.p.  $1923^\circ\text{C}$ ; b.p.  $2000^\circ\text{C}$ . When barium oxide is heated in oxygen the peroxide,  $\text{BaO}_2$ , is formed in a reversible reaction that was once used as a method for obtaining oxygen (the **Brin process**). Barium oxide is now used in the manufacture of lubricating-oil additives.

**barium peroxide** A dense off-white solid,  $\text{BaO}_2$ , prepared by carefully heating \*barium oxide in oxygen; r.d. 4.96; m.p.  $450^\circ\text{C}$ . It is used as a bleaching agent. With acids, hydrogen peroxide is formed and the reaction is used in the laboratory preparation of hydrogen peroxide.

**barium sulphate** An insoluble white solid,  $\text{BaSO}_4$ , that occurs naturally as the mineral \*barytes (or **heavy spar**) and can be prepared as a precipitate by adding sulphuric acid to barium chloride solution; r.d. 4.50; m.p.  $1580^\circ\text{C}$ . The rhombic form changes to a monoclinic form at  $1149^\circ\text{C}$ . It is used as a raw material for making other barium salts, as a pigment extender in surface coating materials (called **blanc fixe**), and in the glass and rubber industries. Barium compounds are opaque to X-rays, and a suspension of the sulphate in water is used in medicine to provide a contrast medium for X-rays of the stomach and intestine. Although barium compounds are extremely poisonous, the sulphate is safe to use because it is very insoluble.

**bark** The protective layer of mostly dead cells that covers the outside of woody stems and roots. It includes the living and dead tissues external to the xylem, including the phloem and periderm. The term can be used more specifically to describe the periderm together with other tissues isolated by the activity of the \*cork cambium. In some species, such as birch, there is one persistent cork cambium but in the older stems of certain other species a second cork cambium becomes active beneath the periderm and further periderm layers are formed every few years. The result is a composite tissue called **rhytidome**, composed of cork, dead cortex, and dead phloem cells.

**Barkhausen effect** The magnetization of a ferromagnetic substance by an increasing magnetic field takes place in discontinuous steps rather than

continuously. The effect results from the orientation of magnetic domains (see MAGNETISM). It was first observed by H. Barkhausen (1881–1956) in 1919.

**Barlow wheel** See HOMOPOLAR GENERATOR.

**barn** A unit of area sometimes used to measure \*cross sections in nuclear interactions involving incident particles. It is equal to  $10^{-28}$  square metre. The name comes from the phrase 'side of a barn' (something easy to hit).

**barograph** A meteorological instrument that records on paper variations in atmospheric pressure over a period. It often consists of an aneroid barometer operating a pen that rests lightly on a rotating drum to which the recording paper is attached.

**barometer** A device for measuring \*atmospheric pressure. The **mercury barometer** in its simplest form consists of a glass tube about 80 cm long sealed at one end and filled with mercury. The tube is then inverted and the open end is submerged in a reservoir of mercury; the mercury column is held up by the pressure of the atmosphere acting on the surface of mercury in the reservoir. This type of device was invented by the Italian scientist Evangelista Torricelli (1608–47), who first noticed the variation in height from day to day, and constructed a barometer in 1644.

In such a device, the force exerted by the atmosphere balanced the weight of the mercury column. If the height of the column is  $h$  and the cross-sectional area of the tube is  $A$ , then the volume of the mercury in the column is  $hA$  and its weight is  $hA\rho$ , where  $\rho$  is the density of mercury. The force is thus  $hA\rho g$ , where  $g$  is the acceleration of free fall and the pressure exerted is this force divided by the area of the tube; i.e.  $h\rho g$ . Note that the height of the mercury is independent of the diameter of the tube. At standard atmospheric pressure the column is 760 mm high. The pressure is then expressed as 760 mmHg (101 325 pascals).

Mercury barometers of this type, with a reservoir of mercury, are known as **cistern barometers**. A common type is the **Fortin barometer**, in which the mercury is held in a leather bag so that the level in the

reservoir can be adjusted. The height is read from a scale along the side of the tube in conjunction with a vernier scale that can be moved up and down. Corrections are made for temperature.

The second main type of barometer is the **aneroid barometer**, in which the cumbersome mercury column is replaced by a metal box with a thin corrugated lid. The air is removed from the box and the lid is supported by a spring. Variations in atmospheric pressure cause the lid to move against the spring. This movement is magnified by a system of delicate levers and made to move a needle around a scale. The aneroid barometer is less accurate than the mercury type but much more robust and convenient, hence its use in \*altimeters.

**baroreceptor** A \*receptor that responds to changes in pressure. The \*carotid sinus in the carotid artery contains baroreceptors that respond to changes in arterial pressure and are therefore involved in the regulation of blood pressure and heart beat.

**Barr body** A structure consisting of a condensed X chromosome (see SEX CHROMOSOME) that is found in nondividing nuclei of female mammals. The presence of a Barr body is used to confirm the sex of athletes in sex determination tests. It is named after the Canadian anatomist M. L. Barr (1908–95), who identified it in 1949.

**barrel** A measurement of volume, widely used in the chemical industry, equal to 35 UK gallons (approximately 159 litres).

**barycentre** The \*centre of mass of a system.

**barye** A c.g.s. unit of pressure equal to one dyne per square centimetre (0.1 pascal).

**baryon** A \*hadron with half-integral spin. Nucleons comprise a subclass of baryons. According to currently accepted theory, baryons are made up of three quarks (**antibaryons** are made up of three antiquarks) held together by gluons (see ELEMENTARY PARTICLES). Baryons possess a quantum number, called the **baryon number**, which is +1 for baryons, -1 for antibaryons, 1/3 for quarks, -1/3 for

antiquarks, and 0 for all other particles such as electrons, neutrinos, and photons. Baryon number has always appeared to have been conserved experimentally, but \*grand unified theories postulate interactions at very high energies that allow it not to be conserved. It is thought that non-conservation of baryon number at the high energies characteristic of the early universe may provide an explanation for the asymmetry between matter and antimatter in the universe. See PROTON DECAY.

**baryta** See BARIUM HYDROXIDE.

**barytes (barite)** An orthorhombic mineral form of \*barium sulphate,  $\text{BaSO}_4$ ; the chief ore of barium. It is usually white but may also be yellow, grey, or brown. Large deposits occur in Andalusia, Spain, and in the USA.

**basal body** See UNDULIPODIUM.

**basal ganglia** Small masses of nervous tissue within the brain that connect the \*cerebrum with other parts of the nervous system. They are involved with the subconscious regulation of voluntary movements.

**basal metabolic rate (BMR)** The rate of energy metabolism required to maintain an animal at rest. BMR is measured in terms of heat production per unit time and is usually expressed in kilojoules of heat released per square metre of body surface per hour ( $\text{kJ m}^{-2} \text{h}^{-1}$ ). It indicates the energy consumed in order to sustain such vital functions as heartbeat, breathing, nervous activity, active transport, and secretion. Different tissues have different metabolic rates (e.g. the BMR of brain tissue is much greater than that of bone tissue) and therefore the tissue composition of an animal determines its overall BMR. For any comparable group of animals (such as mammals) BMR is proportional to body weight according to the allometric equation (see ALLOMETRIC GROWTH); small animals tend to have a higher metabolic rate per unit weight than large ones.

**basalt** A fine-grained basic igneous rock. It is composed chiefly of calcium-rich plagioclase feldspar and pyroxene; other minerals present may be olivine, magnetite, and apatite. Basalt is the commonest type of lava.

**base 1.** (in chemistry) A compound that reacts with a protonic acid to give water (and a salt). The definition comes from the Arrhenius theory of acids and bases. Typically, bases are metal oxides, hydroxides, or compounds (such as ammonia) that give hydroxide ions in aqueous solution. Thus, a base may be either: (1) An insoluble oxide or hydroxide that reacts with an acid, e.g.

Here the reaction involves hydrogen ions from the acid

(2) A soluble hydroxide, in which case the solution contains hydroxide ions. The reaction with acids is a reaction between hydrogen ions and hydroxide ions:

(3) A compound that dissolves in water to produce hydroxide ions. For example, ammonia reacts as follows:

Similar reactions occur with organic \*amines (see also NITROGENOUS BASE; AMINE SALTS). A base that dissolves in water to give hydroxide ions is called an **alkali**. Ammonia and sodium hydroxide are common examples.

The original Arrhenius definition of a base has been extended by the Lowry-Brønsted theory and by the Lewis theory. See ACID.

**2.** (in mathematics) **a.** The number of different symbols in a number system. In the decimal system the base is 10; in \*binary notation it is 2. **b.** The number that when raised to a certain power has a \*logarithm equal to that power. For example if 10 is raised to the power of 3 it is equal to 1000; 3 is then the (common) logarithm of 1000 to the base 10. In natural or Napierian logarithms the base is e. To change the base from common to natural logarithms the formula used is:  $\log_{10} y = \log_e y \times \log_{10} e = 0.43429 \log_e y$ .

**3.** (in electronics) See TRANSISTOR.

**base dissociation constant** See DISSOCIATION.

**basement membrane** A thin sheet of fibrous proteins that underlies and sup-

ports the cells of an \*epithelium, separating this from underlying tissue. Such membranes also surround muscle cells, Schwann cells, and fat cells, and a thick basement membrane is found in the kidney glomerulus, where it acts as a filter (see ULTRAFILTRATION). Basement membranes are components of the \*extracellular matrix and help to regulate passage of materials between epithelial cells and adjacent blood vessels. Each consists of a framework of \*collagen fibrils, within which are \*glycosaminoglycans (mucopolysaccharides) and laminins, proteins that bind the basement membrane to neighbouring cells.

**base metal** A common relatively inexpensive metal, such as iron or lead, that corrodes, oxidizes, or tarnishes on exposure to air, moisture, or heat, as distinguished from precious metals, such as gold and silver.

**base pair** Symbol bp. A unit used at the molecular level for measuring distances along a duplex polynucleotide and corresponding to the number of paired bases in a particular segment of DNA (or duplex RNA). See also BASE PAIRING; KILOBASE.

**base pairing** The chemical linking of two complementary nitrogenous bases in \*DNA and in certain types of \*RNA molecules. Of the four such bases in DNA, adenine pairs with thymine and cytosine with guanine. In RNA, thymine is replaced by uracil. Base pairing is responsible for holding together the two strands of a DNA molecule to form a double helix and for faithful reproduction and reading of the \*genetic code. The links between bases take the form of \*hydrogen bonds.

**base unit** A unit that is defined arbitrarily rather than being defined by simple combinations of other units. For example, the ampere is a base unit in the SI system defined in terms of the force produced between two current-carrying conductors, whereas the coulomb is a **derived unit**, defined as the quantity of charge transferred by one ampere in one second.

**basic 1.** Describing a compound that is a base. **2.** Describing a solution containing an excess of hydroxide ions; alkaline.

**BASIC** A high-level computer program-

ming language. The name is short for beginner's all-purpose symbolic instruction code. It dates from the 1960s, is easy to learn and use, and is mainly employed in teaching programming. There are several variants, including **Visual Basic**, which is used to program graphic user interfaces.

**basic dye** See DYES.

**basicity constant** See DISSOCIATION.

**basic-oxygen process (BOP process)** A high-speed method of making high-grade steel. It originated in the **Linz-Donawitz (L-D) process**. Molten pig iron and scrap are charged into a tilting furnace, similar to the Bessemer furnace except that it has no tuyeres. The charge is converted to steel by blowing high-pressure oxygen onto the surface of the metal through a water-cooled lance. The excess heat produced enables up to 30% of scrap to be incorporated into the charge. The process has largely replaced the Bessemer and open-hearth processes.

**basic rock** An igneous rock containing a comparatively low amount of silica (up to 45–52%) but rich in calcium or magnesium and iron. Examples include basalt, dolerite, and gabbro.

**basic salt** A compound that can be regarded as being formed by replacing some of the oxide or hydroxide ions in a base by other negative ions. Basic salts are thus mixed salt-oxides (e.g. bismuth(III) chloride oxide, BiOCl) or salt-hydroxides (e.g. lead(II) chloride hydroxide, Pb(OH)Cl).

**basic slag** \*Slag formed from a basic flux (e.g. calcium oxide) in a blast furnace. The basic flux is used to remove acid impurities in the ore and contains calcium silicate, phosphate, and sulphide. If the phosphorus content is high the slag can be used as a fertilizer.

**basic stains** See STAINING.

**Basidiomycota** A phylum of fungi, formerly classified as a class (Basidiomycetes) or a subdivision (Basidiomycotina). Sexual reproduction is by means of **basidiospores** (spores produced externally on a club-shaped or cylindrical cell, the **basidium**). Basidia are often grouped together forming fruiting structures, such as mushrooms, puffballs, and bracket fungi.

Exceptions are the \*rusts and \*smuts, which do not produce obvious fruiting bodies.

**basophil** A type of white blood cell (\*leucocyte) that has a lobed nucleus surrounded by granular cytoplasm (see GRANULOCYTE). Basophils are produced continually by stem cells in the red bone marrow; they are \*phagocytes and – like \*mast cells – produce histamine and heparin as part of the body's defences at the site of an infection or injury (see INFLAMMATION).

**Basov, Nikolai Gennediyevitch** (1922–2001) Russian physicist best known for the development of the \*maser, the precursor of the laser. In 1955, while working as a research student with Aleksandr Prokhorov (1916–2000) at the Soviet Academy of Sciences, he devised a microwave amplifier based on ammonia molecules. The two scientists shared the 1964 Nobel Prize with American Charles Townes (1915– ), who independently developed a maser.

**bast** An old name for \*phloem.

**Bateson, William** (1861–1926) British geneticist, who worked at Cambridge University. In 1900 he translated and championed the rediscovered work of \*Mendel and went on to study inheritance in chickens. He found that some traits are controlled by more than one gene. He also coined the term 'genetics'.

**batholith** A large \*intrusion of igneous rock, often surrounded by metamorphic rock, with a surface area in excess of 100 sq km. It is an irregular mass, which may penetrate to a great depth (up to 30 km), and is usually associated with a mountain belt (see OROGENESIS). Many batholiths are composed of granite and there are often veins of useful ores in the surrounding country rock.

**bats** See CHIROPTEA.

**battery** A number of electric cells joined together. The common car battery, or \*accumulator, usually consists of six secondary cells connected in series to give a total e.m.f. of 12 volts. A torch battery is usually a \*dry cell, two of which are often connected in series. Batteries may also

have cells connected in parallel, in which case they have the same e.m.f. as a single cell, but their capacity is increased, i.e. they will provide more total charge. The capacity of a battery is usually specified in ampere-hours, the ability to supply 1 A for 1 hr. or the equivalent.

**baud** A unit for measuring signal speed in a computer or communications system. When the signal is a sequence of \*bits, the baud rate is given in bits per second (bps). The unit is named after Jean-Maurice-Emile Baudot (1845–1903).

**bauxite** The chief ore of aluminium, consisting of hydrous aluminium oxides and aluminous laterite. It is a claylike amorphous material formed by the weathering of silicate rocks under tropical conditions. The chief producers are Australia, Guinea, Jamaica, Russia, Brazil, and Surinam.

**Bayesian statistics and probability** A method of interpreting \*probability in terms of a number indicating how much confidence is placed in a proposition, i.e. how true it is. The \*entropy of a probability distribution is maximized to assign a probability. A hypothesis can be confirmed by an observation that is likely if the hypothesis is true and unlikely if it is false. See also BAYES' THEOREM.

**Bayes' theorem** A theorem that deals with conditional \*probabilities of propositions or events. Given an event A the conditional probability of an event E is formulated as  $P(A|E) = P(E)/P(A)$ . Bayes' theorem enables prior estimates of probability to be updated when further information becomes available. It was named after the British mathematician Thomas Bayes (1702–61).

**b.c.c.** Body-centred cubic. See CUBIC CRYSTAL.

**B cell (B lymphocyte)** A \*lymphocyte that is derived from stem cells in the bone marrow but does not mature in the thymus (compare T CELL); in birds it matures in the bursa of the cloaca (hence B cell). Each B cell has a unique set of receptor molecules on its surface, designed to recognize a specific antigen. Binding of the appropriate antigen to class II MHC receptors on the B cell (see HISTOCOMPATIBILITY)

Beaufort number	description of wind	wind speed	
		(knots)	(metres per second)
0	calm	<1	0.0– 0.2
1	light air	1– 3	0.3– 1.5
2	light breeze	4– 6	1.6– 3.3
3	gentle breeze	7–10	3.4– 5.4
4	moderate breeze	11–16	5.5– 7.9
5	fresh breeze	17–21	8.0–10.7
6	strong breeze	22–27	10.8–13.8
7	near gale	28–33	13.9–17.1
8	gale	34–40	17.2–20.7
9	strong gale	41–47	20.8–24.4
10	storm	48–55	24.5–28.4
11	violent storm	56–63	28.5–32.6
12	hurricane	≥64	≥32.7

### Beaufort wind scale

is recognized by helper T cells, which themselves bind to the antigen–receptor complex. This triggers the T cells to release \*lymphokines, which cause the B cell to undergo repeated division to form a clone of cells. These mature into \*plasma cells, capable of producing large amounts of specific antibody (see IMMUNOGLOBULIN), which circulates in the blood and lymph and binds to the corresponding antigen. After a few days of antibody production the plasma cells die. However, some cells from the clone remain in the form of **memory cells**, which initiate a more rapid immune response on subsequent exposure to the same antigen. See also CLONAL SELECTION THEORY.

**BCS theory** See SUPERCONDUCTIVITY.

**Beadle, George Wells** (1903–89) US geneticist who, after holding several professorships, went to Stanford University, where he worked with Edward Tatum (1909–75). Using moulds, they deduced that the function of genes is to control the production of enzymes, which in turn control metabolic processes. They found that mutant genes result in abnormal (and non-operative) enzymes. For this 'one gene–one enzyme' theory (see ONE GENE–ONE POLYPEPTIDE HYPOTHESIS), they were awarded the 1958 Nobel Prize in physiology or medicine.

**beam** A group of rays moving in an organized manner. It may consist of particles (e.g. an electron beam) or of electromagnetic radiation (e.g. a radar beam).

**beam balance** See BALANCE.

**beam hole** A hole through the shielding of a \*nuclear reactor to enable a beam of neutrons or other particles to escape for experimental purposes.

**beats** A periodic increase and decrease in loudness heard when two notes of slightly different frequency are sounded at the same time. If a note of frequency  $n$  is heard at the same time as a note of frequency  $m$ , the resulting note will have a frequency of about  $(n + m)/2$ . However the amplitude of this note will vary from the difference to the sum of the amplitudes of the  $m$  and  $n$  notes and the frequency (called the **beat frequency**) of this variation will be  $(m - n)$ . The beating sound produced occurs as the waves successively reinforce and oppose each other as they move in and out of phase. Beating also occurs with radio-frequency waves and is made use of in \*heterodyne devices. See also INTERFERENCE.

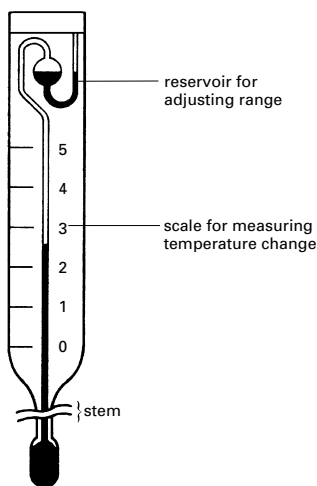

**Beaufort wind scale** A scale of wind speed that was devised in the early 19th century by Rear Admiral Sir Francis Beaufort (1774–1857). Originally based on observations of the effect of various wind speeds on the sails of a full-rigged frigate, it has since been modified and is now based on observations of the sea surface or, on land, such easily observable indicators as smoke and tree movement. The scale ranges from 0 (calm) to 12 (hurricane).

**Becklin–Neugebauer object (BN object)** A point in the star-forming part of

the Orion nebula that emits infrared radiation (but no visible radiation, probably because it is scattered by the dense dust of the nebula). It is thought to be a young near main-sequence star of type B spectral classification, and one of the youngest stars so far observed.

**Beckmann rearrangement** The chemical conversion of a ketone *\*oxime* into an *\*amide*, usually using sulphuric acid as a catalyst. The reaction, used in the manufacture of nylon and other polyamides, is named after the German chemist Ernst Beckmann (1853–1923).

**Beckmann thermometer** A thermometer for measuring small changes of temperature (see illustration). It consists of a mercury-in-glass thermometer with a scale covering only 5 or 6°C calibrated in hundredths of a degree. It has two mercury bulbs, the range of temperature to be measured is varied by running mercury from the upper bulb into the larger lower bulb. It is used particularly for measuring *\*depression of freezing point* or *\*elevation of boiling point* of liquids when solute is added, in order to find relative molecular masses.

Beckmann thermometer

**becquerel** Symbol Bq. The SI unit of ac-

tivity (see RADIATION UNITS). The unit is named after A. H. Becquerel.

**Becquerel, Antoine Henri** (1852–1908) French physicist. His early researches were in optics; in 1896 he accidentally discovered *\*radioactivity* in fluorescent salts of uranium. Three years later he showed that it consists of charged particles that are deflected by a magnetic field. For this work he was awarded the 1903 Nobel Prize, which he shared with Pierre and Marie *\*Curie*.

**bees** See HYMENOPTERA.

**beetles** See COLEOPTERA.

**beet sugar** See SUCROSE.

**behaviour** The sum of the responses of an organism to internal or external stimuli. The behaviour of an animal can be either instinctive (see INSTINCT) or learned. See ANIMAL BEHAVIOUR; LEARNING.

**behavioural genetics** The branch of genetics concerned with determining the relative importance of the genetic constitution of animals as compared to environmental factors in influencing animal behaviour.

**bel** Ten *\*decibels*.

**bell metal** A type of *\*bronze* used in casting bells. It consists of 60–85% copper alloyed with tin, often with some zinc and lead included.

**Bell's theorem** A theorem stating that no local *\*hidden-variables* theory can make predictions in agreement with those of *\*quantum mechanics*. Local hidden variables theories give rise to a result, called **Bell's inequality**, which is one of many similar results concerning the probabilities of two events both occurring in well-separated parts of a system. The British physicist John S. Bell (1928–90) showed in 1964 that quantum mechanics predicts a violation of the inequalities, which are consequences of local hidden-variables theories. Experiments are in agreement with quantum mechanics rather than local hidden variables theories by violating Bell's inequality, in accordance with Bell's theorem.

**Belousov-Zhabotinskii reaction** See B-Z REACTION.

**Bénard cell** A structure associated with a layer of liquid that is confined by two horizontal parallel plates, in which the lateral dimensions are much larger than the width of the layer. Before heating the liquid is homogeneous. However, if after heating from below the temperatures of the plates are  $T_1$  and  $T_2$ , at a critical value of the temperature gradient  $\Delta T = T_1 - T_2$  the liquid abruptly starts to convect. The liquid spontaneously organizes itself into a set of convection rolls, i.e. the liquid goes round in a series of 'cells'. The existence of such cells was discovered by a French scientist, Henri Bénard, around 1900. See also COMPLEXITY.

**bending moment** (about any point or section of a horizontal beam under load) The algebraic sum of the moments of all the vertical forces to either side of that point or section.

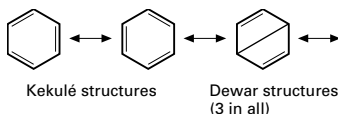

**Benedict's test** A biochemical test to detect \*reducing sugars in solution, devised by the US chemist S. R. Benedict (1884–1936). **Benedict's reagent** – a mixture of copper(II) sulphate and a filtered mixture of hydrated sodium citrate and hydrated sodium carbonate – is added to the test solution and boiled. A high concentration of reducing sugars induces the formation of a red precipitate; a lower concentration produces a yellow precipitate. Benedict's test is a more sensitive alternative to \*Fehling's test.

**beneficiation (ore dressing)** The separation of an ore into the valuable components and the waste material (gangue). This may be achieved by a number of processes, including crushing, grinding, magnetic separation, froth flotation, etc. The dressed ore, consisting of a high proportion of valuable components, is then ready for smelting or some other refining process.

**benthos** Flora and fauna occurring on the bottom of a sea or lake. Benthic organisms may crawl, burrow, or remain attached to a substrate. Compare PELAGIC.

**bent sandwich** See SANDWICH COMPOUND.

**benzaldehyde** See BENZENECARBALDEHYDE.

Benzene

**benzene** A colourless liquid hydrocarbon,  $C_6H_6$ ; r.d. 0.88; m.p.  $5.5^\circ C$ ; b.p.  $80.1^\circ C$ . It is now made from gasoline from petroleum by catalytic reforming (formerly obtained from coal tar). Benzene is the archetypal \*aromatic compound. It has an unsaturated molecule, yet will not readily undergo addition reactions. On the other hand, it does undergo substitution reactions in which hydrogen atoms are replaced by other atoms or groups. This behaviour occurs because of delocalization of *p*-electrons over the benzene ring, and all the C–C bonds in benzene are equivalent and intermediate in length between single and double bonds. It can be regarded as a resonance hybrid of Kekulé and Dewar structures (see formulae). In formulae it can be represented by a hexagon with a ring inside it.

**benzenecarbaldehyde (benzaldehyde)** A yellowish volatile oily liquid,  $C_6H_5CHO$ ; r.d. 1.04; m.p.  $-26^\circ C$ ; b.p.  $178.1^\circ C$ . The compound occurs in almond kernels and has an almond-like smell. It is made from methylbenzene (by conversion to dichloromethyl benzene,  $C_6H_5CH_2Cl_2$ , followed by hydrolysis). Benzenecarbaldehyde is used in flavourings, perfumery, and the dyestuffs industry.

**benzenecarbonyl chloride (benzoyl chloride)** A colourless liquid,  $C_6H_5COCl$ ; r.d. 1.21; m.p.  $0^\circ C$ ; b.p.  $197.2^\circ C$ . It is an \*acyl halide, used to introduce benzenecarbonyl groups into molecules. See ACYLATION.

**benzenecarbonyl group (benzoyl group)** The organic group  $C_6H_5CO-$ .

**benzenecarboxylate (benzoate)** A salt or ester of benzenecarboxylic acid.

**benzenecarboxylic acid (benzoic acid)** A white crystalline compound,  $C_6H_5COOH$ ; r.d. 1.27; m.p.  $122.4^\circ C$ ; b.p.  $249^\circ C$ . It occurs naturally in some plants and is used as a food preservative. Benzenecarboxylic acid has a carboxyl group

bound directly to a benzene ring. It is a weak carboxylic acid ( $K_a = 6.4 \times 10^{-5}$  at 25°C), which is slightly soluble in water. It also undergoes substitution reactions on the benzene ring.

**benzene-1,4-diol (hydroquinone; quinol)** A white crystalline solid,  $C_6H_4(OH)_2$ ; r.d. 1.33; m.p. 173–174°C; b.p. 285°C. It is used in making dyes. *See also* QUINHYDRONE ELECTRODE.

**benzene hexachloride (BHC)** A crystalline substance,  $C_6H_6Cl_6$ , made by adding chlorine to benzene. It is used as a pesticide and, like \*DDT, concern has been expressed at its environmental effects.

**benzenesulphonic acid** A colourless deliquescent solid,  $C_6H_5SO_2OH$ , m.p. 43–44°C, usually found as an oily liquid. It is made by treating benzene with concentrated sulphuric acid. Its alkyl derivatives are used as \*detergents.

**benzil** 1,2-diphenylethan-1,2-dione. *See* BENZILIC ACID REARRANGEMENT.

**benzilic acid rearrangement** An organic rearrangement reaction in which **benzil** (1,2-diphenylethan-1,2-dione) is treated with hydroxide and then acid to give **benzilic acid** (2-hydroxy-2,2-diphenylethanoic acid):

In the reaction a phenyl group ( $C_6H_5-$ ) migrates from one carbon atom to another. The reaction was discovered in 1828 by Justus von \*Liebig; it was the first rearrangement reaction to be described.

**benzoate** *See* BENZENECARBOXYLATE.

**benzoic acid** *See* BENZENECARBOXYLIC ACID.

**benzoquinone** *See* CYCLOHEXADIENE-1,4-DIONE.

**benzoylation** A chemical reaction in which a benzoyl group (benzenecarbonyl group,  $C_6H_5CO$ ) is introduced into a molecule. *See* ACYLATION.

**benzoyl chloride** *See* BENZENECARBONYL CHLORIDE.

**benzoyl group** *See* BENZENECARBONYL GROUP.

**benzpyrene** A pale yellow solid,  $C_{20}H_{12}$ , m.p. 179°C, whose molecules consist of five fused benzene rings. It occurs in tars from coal and tobacco smoke and is a \*carcinogen.

**benzyl alcohol** *See* PHENYLMETHANOL.

**benzylamine ( $\alpha$ -aminotoluene; phenylmethylamine)** A colourless liquid,  $C_6H_5CH_2NH_2$ ; r.d. 0.981; b.p. 185°C. It behaves in the same way as primary aliphatic amines.

**benzynes** A highly reactive short-lived compound,  $C_6H_4$ , having a hexagonal ring of carbon atoms containing two double bonds and one triple bond. Benzynes, which is the simplest example of an \*aryne, is thought to be an intermediate in a number of reactions.

**Bergius, Friedrich Karl Rudolf** (1884–1949) German organic chemist. While working with Fritz \*Haber in Karlsruhe, he became interested in reactions at high pressures. In 1912 he devised an industrial process for making light hydrocarbons by the high-pressure hydrogenation of coal or heavy oil. The work earned him a share of the 1931 Nobel Prize for chemistry with Carl Bosch (1874–1940). The Bergius process proved important for supplying petrol for the German war effort in World War II.

**Bergius process** A process for making hydrocarbon mixtures (for fuels) from coal by heating powdered coal mixed with tar and iron(III) oxide catalyst at 450°C under hydrogen at a pressure of about 200 atmospheres. In later developments of the process, the coal was suspended in liquid hydrocarbons and other catalysts were used. The process was developed by Friedrich Bergius during World War I as a source of motor fuel.

**beriberi** A disease caused by a low intake of vitamin  $B_1$  (thiamine; *see* VITAMIN B COMPLEX), resulting in damage to peripheral nerves and heart failure. Beriberi is most common in regions of the Far East where the diet is based on polished white rice, which lacks the thiamine-rich seed coat.

**berkelium** Symbol Bk. A radioactive metallic transuranic element belonging to

the \*actinoids; a.n. 97; mass number of the most stable isotope 247 (half-life  $1.4 \times 10^3$  years); r.d. (calculated) 14. There are eight known isotopes. It was first produced by G. T. Seborg and associates in 1949 by bombarding americium-241 with alpha particles.

**Bernoulli, Daniel** (1700–82) Swiss mathematician. In 1724 he published a work on differential equations, which earned him a professorship at St Petersburg. He returned to Basel, Switzerland, in 1733 and began researches on hydrodynamics (see BERNOULLI THEOREM), the work for which he is best known. He also initiated the kinetic theory of matter.

**Bernoulli theorem** At any point in a pipe through which a fluid is flowing the sum of the pressure energy, the kinetic energy, and the potential energy of a given mass of the fluid is constant. This is equivalent to a statement of the law of the conservation of energy. The law was published in 1738 by Daniel Bernoulli.

**berry** A fleshy fruit formed from either one carpel or from several fused together and containing many seeds. The fruit wall may have two or three layers but the inner layer is never hard and stony (as in some drupes). Examples of berries are grapes and tomatoes. A berry, such as a cucumber, that develops a hard outer rind is called a **pepo**. One that is segmented and has a leathery rind, such as a citrus fruit, is called a **hesperidium**. The rind contains oil glands and is lined by the white mesocarp, commonly called **pith**.

**Berthollide compound** See NONSTOICHIOMETRIC COMPOUND.

**beryl** A hexagonal mineral form of beryllium aluminium silicate,  $\text{Be}_3\text{Al}_2\text{Si}_6\text{O}_{18}$ ; the chief ore of beryllium. It may be green, blue, yellow, or white and has long been used as a gemstone. Beryl occurs throughout the world in granite and pegmatites. \*Emerald, the green gem variety, occurs more rarely and is of great value. Important sources of beryl are found in Brazil, Madagascar, and the USA.

**beryllate** A compound formed in solution when beryllium metal, or the oxide or hydroxide, dissolves in strong alkali.

The reaction (for the metal) is often written

The ion  $\text{BeO}_2^{2-}$  is the beryllate ion. In fact, as with the \*aluminates, the ions present are probably hydroxy ions of the type  $\text{Be}(\text{OH})_4^{2-}$  (the **tetrahydroxyberyllate(II) ion**) together with polymeric ions.

**beryllia** See BERYLLIUM OXIDE.

**beryllium** Symbol Be. A grey metallic element of \*group 2 (formerly IIA) of the periodic table; a.n. 4; r.a.m. 9.012; r.d. 1.85; m.p. 1278°C; b.p. 2970°C. Beryllium occurs as beryl ( $3\text{BeO} \cdot \text{Al}_2\text{O}_3 \cdot 6\text{SiO}_2$ ) and chrysoberyl ( $\text{BeO} \cdot \text{Al}_2\text{O}_3$ ). The metal is extracted from a fused mixture of  $\text{BeF}_2/\text{NaF}$  by electrolysis or by magnesium reduction of  $\text{BeF}_2$ . It is used to manufacture Be-Cu alloys, which are used in nuclear reactors as reflectors and moderators because of their low absorption \*cross section. Beryllium oxide is used in ceramics and in nuclear reactors. Beryllium and its compounds are toxic and can cause serious lung diseases and dermatitis. The metal is resistant to oxidation by air because of the formation of an oxide layer, but will react with dilute hydrochloric and sulphuric acids. Beryllium compounds show high covalent character. The element was isolated independently by F. Wohler and A. A. Bussy in 1828.

**beryllium bronze** A hard, strong type of \*bronze containing about 2% beryllium, in addition to copper and tin.

**beryllium hydroxide** A white crystalline compound,  $\text{Be}(\text{OH})_2$ , precipitated from solutions of beryllium salts by adding alkali. Like the oxide, it is amphoteric and dissolves in excess alkali to give \*beryllates.

**beryllium oxide (beryllia)** An insoluble solid compound,  $\text{BeO}$ ; hexagonal; r.d. 3.01; m.p. 2530°C; b.p. 3900°C. It occurs naturally as **bromellite**, and can be made by burning beryllium in oxygen or by the decomposition of beryllium carbonate or hydroxide. It is an important amphoteric oxide, reacting with acids to form salts and with alkalis to form compounds known as \*beryllates. Beryllium oxide is used in the production of beryllium and

beryllium-copper refractories, transistors, and integrated circuits.

**Berzelius, Jöns Jacob** (1779–1848) Swedish chemist. After moving to Stockholm he worked with mining chemists and, with them, discovered several elements, including \*cerium (1803), \*selenium (1817), \*lithium (1818), \*thorium (1828), and \*vanadium (1830). He also worked on atomic weights and electrochemistry and devised the current notation for chemical elements.

**Bessel, Friedrich Wilhelm** (1784–1846) German astronomer. As an unqualified amateur he catalogued the positions of 50 000 stars and calculated the distance to 61 Cygni from its \*parallax. In 1844 he discovered that Sirius is a binary star with a dark companion. Solving the complex mathematics in these studies led him to develop \*Bessel functions.

**Bessel function** A type of function that occurs as a solution to problems involving waves in systems with cylindrical symmetry. Bessel functions have been extensively studied and tabulated and are used in many branches of mathematical physics. They are named after the German astronomer Friedrich Wilhelm Bessel (1784–1846).

**Bessemer process** A process for converting \*pig iron from a \*blast furnace into \*steel. The molten pig iron is loaded into a refractory-lined tilting furnace (**Bessemer converter**) at about 1250°C. Air is blown into the furnace from the base and \*spiegel is added to introduce the correct amount of carbon. Impurities (especially silicon, phosphorus, and manganese) are removed by the converter lining to form a slag. Finally the furnace is tilted so that the molten steel can be poured off. In the modern VLN (very low nitrogen) version of this process, oxygen and steam are blown into the furnace in place of air to minimize the absorption of nitrogen from the air by the steel. The process is named after the British engineer Sir Henry Bessemer (1813–98), who announced it in 1856. *See also* BASIC-OXYGEN PROCESS.

**beta adrenoceptor (beta adrenergic receptor)** *See* ADRENOCEPTOR.

**beta blocker (beta-adrenoceptor antagonist)** Any of a group of drugs that bind preferentially to beta \*adrenoceptors and hence block their stimulation by the body's own neurotransmitters, adrenaline and noradrenaline. Beta blockers, such as propranolol, oxprenolol, and atenolol, are used to treat disorders of the cardiovascular system, including high blood pressure (hypertension), angina pectoris, and irregularities of heartbeat (arrhythmias). They are also effective in treating anxiety and glaucoma (as eye drops) and in preventing migraine. They tend to dampen the effects of exercise or stress on heart rate, heart output, and blood pressure, as well as improving the oxygenation of the heart muscles. The release of the enzyme \*renin from the kidneys is also reduced, leading to an overall fall in arterial blood pressure.

**beta decay** A type of weak interaction (*see* FUNDAMENTAL INTERACTIONS) in which an unstable atomic nucleus changes into a nucleus of the same nucleon number (*A*) but different proton number (*Z*). There are three types of beta decay: negative beta decay, positive beta decay, and electron capture.

**Negative beta decay:**

A neutron in the nucleus *X* has decayed into a proton forming a new nucleus *Y* with the emission of an electron and antineutrino. This process involves a decrease in mass and is energetically favourable; it can also occur outside the nucleus – free neutrons decay with a mean lifetime of about 15 minutes.

**Positive beta decay:**

A proton in the nucleus *X* transforms into a neutron and a new nucleus *Y* is formed with the emission of an antimatter electron (positron) and neutrino. This process involves an effective increase in mass for the proton and is not energetically favourable. It cannot occur outside the nucleus – free protons do not undergo this kind of interaction. The process is allowed within the environment of the nucleus because when the nucleus as a whole is taken into account the interaction represents an overall decrease in mass.

**Electron capture:**

A proton in the nucleus X captures an electron from the atomic environment and becomes a neutron, emitting in the process a neutrino. This process also involves an effective increase in mass for the proton and is not energetically favourable; again, it cannot also occur outside the nucleus – free protons do not undergo this kind of interaction. The process is allowed within the environment of the nucleus because, taking into account the whole nucleus, the interaction represents an overall decrease in mass.

**beta-iron** A nonmagnetic allotrope of iron that exists between 768°C and 900°C.

**beta particle** An electron or positron emitted during  $\beta$  beta decay. A stream of beta particles is known as **beta radiation**.

**betatron** A particle  $\beta$  accelerator for producing high-energy electrons (up to 340 MeV) for research purposes, including the production of high-energy X-rays. The electrons are accelerated by electromagnetic induction in a doughnut-shaped (toroidal) ring from which the air has been removed. This type of accelerator was first developed by D. W. Kerst (1911– ) in 1939; the largest such machine, at the University of Illinois, was completed in 1950.

**Bevatron** A colloquial name for the proton  $\beta$  synchrotron at the Berkeley campus of the University of California. It produces energies up to 6 GeV.

**BHC** See BENZENE HEXACHLORIDE.

**biaxial crystal** See DOUBLE REFRACTION.

**bicarbonate** See HYDROGENCARBONATE.

**bicarbonate of soda** See SODIUM HYDROGENCARBONATE.

**biceps** A muscle that runs along the large bone of the upper arm ( $\beta$  humerus) and is connected to the  $\beta$  radius at one end and the shoulder bone ( $\beta$  scapula) at the other. Contraction of the biceps causes the arm to flex at the elbow joint (see FLEXOR). It works antagonistically with the triceps, which contracts to extend the arm (see ANTAGONISM). See also VOLUNTARY MUSCLE.

**biconcave** See CONCAVE.

**bicuspid valve (mitral valve)** A valve, consisting of two flaps, situated between the left atrium and the left ventricle of the heart of birds and mammals. When the left ventricle contracts, forcing blood into the aorta, the bicuspid valve closes the aperture to the left atrium, thereby preventing any backflow of blood. The valve reopens to allow blood to flow from the atrium into the ventricle. Compare TRICUSPID VALVE.

**biennial** A plant that requires two growing seasons to complete its life cycle. During the first year it builds up food reserves, which are used during the second year in the production of flowers and seeds. Examples are carrot and parsnip.

**big-bang theory** The cosmological theory that all the matter and energy in the universe originated from a state of enormous density and temperature that exploded at a finite moment in the past. See Feature.

**bilateral symmetry** A type of arrangement of the parts and organs of an animal in which the body can be divided into two halves that are mirror images of each other along one plane only (usually passing through the midline at right angles to the dorsal and ventral surfaces). Bilaterally symmetrical animals are characterized by a type of movement in which one end of the body always leads. In botany this type of symmetry is usually called **zygomorphy** when applied to flowers (e.g. foxglove and antirrhinum flowers are zygomorphic). Compare RADIAL SYMMETRY.

**bile (gall)** A bitter-tasting greenish-yellow alkaline fluid produced by the  $\beta$  liver, stored in the  $\beta$  gall bladder, and secreted into the  $\beta$  duodenum of vertebrates. It assists the digestion and absorption of fats by the action of **bile salts**, which chemically reduce fatty substances and decrease the surface tension of fat droplets so that they are broken down and emulsified. Bile may also stimulate gut muscle contraction ( $\beta$  peristalsis). Bile also contains the **bile pigments**, **bilirubin** and **biliverdin**, which are produced by the breakdown of the blood pigment  $\beta$  haemoglobin.

**bile duct** The tube through which bile

passes from the \*liver or (when present) the \*gall bladder to the duodenum.

**bilirubin** See BILE.

**biliverdin** See BILE.

**billion** **1.** (in the UK and Germany) One million million,  $10^{12}$ . **2.** (in the USA and France) One thousand million,  $10^9$ .

**bimetallic strip** A strip consisting of two metals of different \*expansivity riveted or welded together so that the strip bends on heating. If one end is fixed the other end can be made to open and close an electric circuit, as in a \*thermostat.

**bimolecular reaction** A step in a chemical reaction that involves two molecules. See MOLECULARITY.

**bimorph cell** A device consisting of two plates of piezoelectric material, such as Rochelle salt, joined together so that one expands on the application of a potential difference and the other contracts. The cell thus bends as a result of the applied p.d. The opposite effect is also used, in which the mechanical bending of the cell is used to produce a p.d., as in the crystal microphone and some types of record-player pickups.

**binary** Describing a compound or alloy formed from two elements.

**binary acid** An \*acid in which the acidic hydrogen atom(s) are bound directly to an atom other than oxygen. Examples are hydrogen chloride (HCl) and hydrogen sulphide ( $H_2S$ ). Such compounds are sometimes called **hydracids**. Compare OXO ACID.

**binary fission** See FISSION.

**binary notation** A number system using only two different digits, 0 and 1. Instead of units, tens, hundreds, etc., as used in the decimal system, digits in the binary notation represent units, twos, fours, eights, etc. Thus one in decimal notation is represented by 0001, two by 0010, four by 0100, and eight by 1000. Because 0 and 1 can be made to correspond to off and on conditions in an electric circuit, the binary notation is widely used in computers.

**binary prefixes** A set of prefixes for bi-

nary powers designed to be used in data processing and data transmission contexts. They were suggested in 1998 by the International Electrotechnical Commission (IEC) as a way of resolving the ambiguity in use of kilo-, mega-, giga-, etc., in computing. In scientific usage, these prefixes indicate  $10^3$ ,  $10^6$ ,  $10^9$ , etc. (see SI UNITS). In computing, it became common to use the prefix "kilo-" to mean  $2^{10}$ , so one kilobit was 1024 bits (not 1000 bits). This was extended to larger prefixes, so "mega-" in computing is taken to be  $2^{20}$  (1 048 576) rather than  $10^6$  (1 000 000). However, there is a variation in usage depending on the context. In discussing memory capacities megabyte generally means  $2^{20}$  bytes, but in disk storage (and data transmission) megabyte is often taken to mean  $10^6$  bytes. (In some contexts, as in the capacity of a floppy disk, it has even been quoted as 1 024 000 bytes, i.e. 1000 times a (binary) kilobyte.) The IEC attempted to resolve this confusion by introducing binary prefixes, modelled on the normal decimal prefixes, as follows:

kibi-  $2^{10}$   
mebi-  $2^{20}$   
gebi-  $2^{30}$   
tebi-  $2^{40}$   
pebi-  $2^{50}$   
exbi-  $2^{60}$

These names are contractions of "kilobinary", "megabinary", etc., but are pronounced so that the second syllable rhymes with "bee". Using these prefixes, one gibibyte would be 1 073 741 824 bytes and one gigibyte would (unambiguously) be 1 000 000 000 bytes.

**binary stars** A pair of stars revolving about a common centre of mass. In a **visual binary** the stars are far enough apart to be seen separately by an optical telescope. In an **astrometric binary** one component is too faint to be seen and its presence is inferred from the perturbations in the motion of the other. In a **spectroscopic binary** the stars cannot usually be resolved by a telescope, but the motions can be detected by different Doppler shifts in the spectrum at each side of the binary, according to whether the components are approaching or receding from the observer.

**binding energy** The energy equivalent

## THE BIG-BANG THEORY

b

Newton's work gave a mathematical basis for the universe on a large scale. However, the data available at the time suggested a static unchanging universe. This could not easily be explained in the context of the law of gravitation, since all bodies in the universe attract all other bodies with the force of gravity. Newton realized that there was only one solution to this problem: in a static universe, matter had to be uniformly spread throughout an infinitely large space. In 1826, Heinrich Olbers published a paper containing what is known as \*Olbers' paradox; such a universe would lead to a perpetually bright sky on earth.

### Space-time

Cosmologists now believe that Newton's model was based on incorrect assumptions about the structure of space, time, and matter. Einstein in his general theory of \*relativity (1915) proposed that the universe exists in four-dimensional space-time. This space-time is curved by the presence of matter, and the matter moves by following the resulting curves.

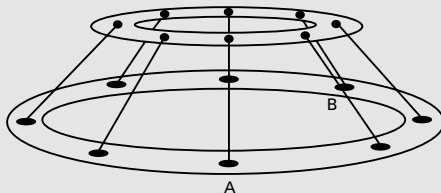

### The expanding universe

The discovery by Hubble in 1929 that the universe is expanding provided a starting point for the ideas on which our present understanding of the universe is based. Hubble made his discovery by analysing the \*spectra of light from distant galaxies and noting a persistent \*red shift, which he explained in terms of the \*Doppler effect; an increase in observed wavelengths of light occurs because the light source is receding from the observer. The larger the speed, of recession, the larger the red shifts. Hubble discovered a pattern in his data: the further away the galaxy, the greater the speed of recession. Known as \*Hubble's law, this provided the evidence that the universe is expanding and a resolution to Olbers' paradox. If the galaxies and the earth are moving apart, the radiation falling on the earth from the galaxies is reduced. The further galaxies are away from the earth, the smaller their contribution to the radiation falling on the earth.

This model might seem to place the earth at the centre of the universe again. However, it is space itself that is expanding and the galaxies are imbedded in this space. The ring (space) in the diagram has dots (the galaxies). The expansion of the ring means that the view from any one dot is that the other dots are receding at a speed proportional to their distance away. No single dot is at the centre of the system but all dots see the same thing.

### Age of the universe

Hubble's law may be stated in the form:  $H_0 = v/d$ , where  $v$  is the speed of recession of the galaxy,  $d$  is the earth-galaxy distance, and  $H_0$  is called the

The expansion leads to the recession of B from A along the ring. The speed of recession will be directly proportional to the distance of B from A along the ring.

**Hubble constant.** Assuming that the galaxies have always been moving apart, the age of the universe ( $T$ ) can be estimated, i.e.  $T = 1/H_0$ . On this basis the age of the universe would be between 15–18 billion years.

### The origin of the universe

This view of the origin of the universe is called the **big-bang theory**. The theory suggests that the universe originated as a minute but very hot body and that the temperature has been falling as the expansion has continued. In 1945 George Gamow predicted that there should be a \*microwave background corresponding to a black-body temperature a few degrees above absolute zero. This microwave background was discovered 20 years later. The big-bang theory also explains the amount of helium in the universe.

In 1992, the COBE satellite discovered that there were very small variations in the microwave background. This discovery helped to explain why the universe formed into galaxies and stars. The non-uniformities that began the nucleation of galactic matter in the early universe now appear as the small variations in the microwave background.

### Fundamental forces

It is thought that the four \*fundamental interactions in the universe are all manifestations of the same force. This force existed when the big bang, occurred at a temperature above  $10^{15}$ K. As the universe cooled the forces separated as the original symmetries were broken. Gravity was the first to separate, followed by the strong nuclear force, and the weak and electromagnetic forces (see table).

Time from big bang	Temperature (K)	State of the universe/forces
0 second	infinite	The universe is infinitesimally small and infinitely dense (i.e. a mathematical singularity).
$10^{-12}$ second	$10^{15}$	Weak and electromagnetic forces begin to separate.
$10^{-6}$ second	$10^{14}$	Quarks and leptons begin to form.
$10^{-3}$ second	$10^{12}$	Quarks form the hadrons; quark confinement begins.
$10^2$ second	$10^7$	Helium nuclei formed by fusion.
$10^5$ years	$10^4$	Atomic era; atoms form as protons combine with electrons.
$10^6$ years	$10^3$	Matter undergoes gravitational collapse.
$.5-1.8 \times 10^{10}$ years	2.7	Present day: cosmic background corresponds to about 2.7K.

### The future

Research into the future of the universe is clearly speculative. Whether the universe will continue to expand indefinitely depends on its mean density. Below a critical level (the critical density), gravitational attraction will not be enough to stop the expansion. However, if the mean density is above the critical density the universe is **bound** and an eventual contraction will occur resulting in a **big crunch**. This may precede another big bang initiating the whole cycle again.

to the \*mass defect when nucleons bind together to form an atomic nucleus. When a nucleus is formed some energy is released by the nucleons, since they are entering a more stable lower-energy state. Therefore the energy of a nucleus consists of the energy equivalent of the mass of its individual nucleons minus the binding energy. The binding energy per nucleon plotted against the mass number provides a useful graph showing that up to a mass number of 50–60, the binding energy per nucleon increases rapidly, thereafter it falls slowly. Energy is released both by fission of heavy elements and by fusion of light elements because both processes entail a rearrangement of nuclei in the lower part of the graph to form nuclei in the higher part of the graph.

**binoculars** Any optical instrument designed to serve both the observer's eyes at once. **Binocular field glasses** consist of two refracting astronomical \*telescopes inside each of which is a pair of prisms to increase the effective length and produce an upright image. Simpler binoculars, such as **opera glasses**, consist of two Galilean telescopes which produce upright images without prisms. Commonly, binoculars are specified by a pair of numbers, such as 10 × 50. The first number indicates the angular \*magnification produced. The second is the diameter of the objective lens in millimetres, and indicates the amount of light gathered by the instrument.

**Binocular microscopes** are used in biology and surgery to enable the observer to obtain a stereoscopic view of small objects or parts.

**binocular vision** The ability, found only in animals with forward-facing eyes, to produce a focused image of the same object simultaneously on the retinas of both eyes. This permits three-dimensional vision and contributes to distance judgment.

**binomial nomenclature** The system of naming organisms using a two-part Latinized (or scientific) name that was devised by the Swedish botanist Linnaeus (Carl Linné); it is also known as the **Linnaean system**. The first part is the generic name (see GENUS), the second is the specific epithet or name (see SPECIES). The

Latin name is usually printed in italics, starting with a capital letter. For example, in the scientific name of the common frog, *Rana temporaria*, *Rana* is the generic name and **temporaria** the specific name. The name of the species may be followed by an abbreviated form of the name of its discoverer; for example, the common daisy is *Bellis perennis* L. (for Linnaeus). There are several International Codes of Taxonomic Nomenclature that lay down the rules for naming organisms. See also CLASSIFICATION; TAXONOMY.

**binomial theorem (binomial expansion)** A rule for the expansion of a binomial expression (expression consisting of the sum of two variables raised to a given power). The general binomial expression  $(x + y)^n$  expands to:

$$x^n + nx^{n-1}y + [n(n-1)/2!]x^{n-2}y^2 + \dots y^n$$

**bioaccumulation** An increase in the concentration of chemicals, such as \*pesticides, in organisms that live in environments contaminated by a wide variety of organic compounds. These compounds are not usually decomposed in the environment (i.e. they are not biodegradable) or metabolized by the organisms, so that their rate of absorption and storage is greater than their rate of excretion. The chemicals are normally stored in fatty tissues. \*DDT is known as a **persistent pesticide**, as it is not easily broken down and bioaccumulates along \*food chains, so that increasing concentrations occur in individual organisms at each trophic level.

**bioassay (biological assay)** A controlled experiment for the quantitative estimation of a substance by measuring its effect in a living organism. For example, the amount of the plant hormone auxin can be estimated by observing its effect on the curvature of oat coleoptiles – the concentration of the hormone is proportional to the curvature of the coleoptile.

**biochemical evolution (molecular evolution)** The changes that occur at the molecular level in organisms over a period of time. Brought about by \*mutations in genes or chromosomes, it results in functional changes to the proteins encoded by the genes, or even the evolution of novel genes and proteins.

**biochemical fuel cell** A system that exploits biological reactions for the conversion of biomass (chemical energy) to electricity (electrical energy). One potential application is the generation of electricity from industrial waste and \*sewage. **Methylophilic** organisms (i.e. organisms that use methane or methanol as their sole carbon sources) are being investigated for their potential use in biochemical fuel cells.

**biochemical oxygen demand (BOD)** The amount of oxygen taken up by microorganisms that decompose organic waste matter in water. It is therefore used as a measure of the amount of certain types of organic pollutant in water. BOD is calculated by keeping a sample of water containing a known amount of oxygen for five days at 20°C. The oxygen content is measured again after this time. A high BOD indicates the presence of a large number of microorganisms, which suggests a high level of pollution.

**biochemical taxonomy** See MOLECULAR SYSTEMATICS.

**biochemistry** The study of the chemistry of living organisms, especially the structure and function of their chemical components (principally proteins, carbohydrates, lipids, and nucleic acids). Biochemistry has advanced rapidly with the development, from the mid-20th century, of such techniques as chromatography, spectroscopy, X-ray diffraction, radioisotopic labelling, and electron microscopy. Using these techniques to separate and analyse biologically important molecules, the steps of the metabolic pathways in which they are involved (e.g. \*glycolysis and the \*Krebs cycle) have been determined. This has provided some knowledge of how organisms obtain and store energy, how they manufacture and degrade their biomolecules, how they sense and respond to their environment, and how all this information is carried and expressed by their genetic material. Biochemistry forms an important part of many other disciplines, especially physiology, nutrition, and genetics, and its discoveries have made a profound impact in medicine, agriculture, industry, and many

other areas of human activity. See Chronology.

**biodegradable** See POLLUTION.

**biodiversity (biological diversity)** The existence of a wide variety of species (**species diversity**) or other taxa of plants, animals, and microorganisms in a natural community or habitat, or of communities within a particular environment (**ecological diversity**), or of genetic variation within a species (**genetic diversity**; see VARIATION). The maintenance of a high level of biodiversity is important for the stability of ecosystems. Certain habitats, especially rainforests, have a rich species diversity, which is threatened by the continued destruction of habitats (see DEForestation; DESERTIFICATION). Such ecosystems typically support large numbers of rare species, and population sizes of individual species tend to be small; they are therefore especially vulnerable to habitat destruction. Biodiversity in natural habitats also represents an important pool of species and genetic material of potential use to human societies. For example, wild plants continue to be used as a source of new drugs and other products, and the development of new strains and varieties of crop plants with increased disease resistance usually depends on incorporating genetic material from wild plants.

**bioelement** Any chemical element that is found in the molecules and compounds that make up a living organism. In the human body the most common bioelements (in decreasing order of occurrence) are oxygen, carbon, hydrogen, nitrogen, calcium, and phosphorus. Other bioelements include sodium, potassium, magnesium, and copper. See ESSENTIAL ELEMENT.

**bioenergetics** The study of the flow and the transformations of energy that occur in living organisms. Typically, the amount of energy that an organism takes in (from food or sunlight) is measured and divided into the amount used for growth of new tissues; that lost through death, wastes, and (in plants) transpiration; and that lost to the environment as heat (through respiration).

**BIOCHEMISTRY**

- 1833 French chemist Anselme Payen (1795–1871) discovers diastase (the first enzyme to be discovered).
- 1836 Theodor Schwann discovers the digestive enzyme pepsin.
- c.1860 Louis Pasteur demonstrates fermentation is caused by ‘ferments’ in yeasts and bacteria.
- 1869 German biochemist Johann Friedrich Miescher (1844–95) discovers nucleic acid.
- 1877 Pasteur’s ‘ferments’ are designated as enzymes.
- 1890 German chemist Emil Fischer (1852–1919) proposes the ‘lock-and-key’ mechanism to explain enzyme action.
- 1901 Japanese chemist Jokichi Takamine (1854–1922) isolates adrenaline (the first hormone to be isolated).
- 1903 German biologist Eduard Buchner (1860–1917) discovers the enzyme zymase (causing fermentation).
- 1904 British biologist Arthur Harden (1865–1940) discovers coenzymes.
- 1909 Russian-born US biochemist Phoebus Levene (1869–1940) identifies ribose in RNA.
- 1921 Canadian physiologist Frederick Banting (1891–1941) and US physiologist Charles Best (1899–1978) isolate insulin.
- 1922 Alexander Fleming discovers the enzyme lysozyme.
- 1925 Russian-born British biologist David Keilin (1887–1963) discovers cytochrome.
- 1926 US biochemist James Sumner (1877–1955) crystallizes urease (the first enzyme to be isolated).
- 1929 German chemist Hans Fischer (1881–1945) determines the structure of haem (in haemoglobin).  
K. Lohman isolates ATP from muscle.
- 1930 US biochemist John Northrop (1891–1987) isolates the enzyme pepsin.
- 1932 Swedish biochemist Hugo Theorell (1903–82) isolates the muscle protein myoglobin.
- 1937 Hans Krebs discovers the Krebs cycle.
- 1940 German-born US biochemist Fritz Lipmann (1899–1986) proposes that ATP is the carrier of chemical energy in many cells.
- 1943 US biochemist Britton Chance (1913– ) discovers how enzymes work (by forming an enzyme–substrate complex).
- 1952 US biologist Alfred Hershey (1908– ) proves that DNA carries genetic information.

**bioengineering 1.** The use of artificial tissues, organs, and organ components to replace parts of the body that are damaged, lost, or malfunctioning, e.g. artificial limbs, heart valves, and heart pacemakers. *See also* TISSUE ENGINEERING. **2.** The

application of engineering knowledge to medicine and zoology.

**biofeedback** The technique whereby a subject can learn to control certain body functions, such as heart rate or blood

- 1953 Francis Crick and James Watson discover the structure of DNA.
- 1955 Frederick Sanger discovers the amino acid sequence of insulin.
- 1956 US biochemist Arthur Kornberg (1918– ) discovers DNA polymerase. US molecular biologist Paul Berg (1926– ) identifies the nucleic acid later known as transfer RNA.
- 1957 British biologist Alick Isaacs (1921–67) discovers interferon.
- 1959 Austrian-born British biochemist Max Perutz (1914– ) determines the structure of haemoglobin.
- 1960 South African-born British molecular biologist Sydney Brenner (1927– ) and French biochemist François Jacob (1920– ) discover messenger RNA.
- 1961 British biochemist Peter Mitchell (1920–92) proposes the chemiosmotic theory. Brenner and Crick discover that the genetic code consists of a series of base triplets.
- 1969 US biochemist Gerald Edelman (1929– ) discovers the amino acid sequence of immunoglobulin G.
- 1970 US virologists Howard Temin (1934–94) and David Baltimore (1938– ) discover the enzyme reverse transcriptase.
- 1970 US molecular biologist Hamilton Smith (1931– ) discovers restriction enzymes.
- 1973 US biochemists Stanley Cohen (1935– ) and Herbert Boyer (1936– ) use restriction enzymes to produce recombinant DNA.
- 1977 Sanger determines the complete base sequence of DNA in bacteriophage  $\phi$ X174.
- 1984 British biochemist Alec Jeffreys (1950– ) devises DNA fingerprinting.
- 1985 US biochemist Kary Mullis (1944– ) invents the polymerase chain reaction.
- 1986 US pharmacologists Robert Furchgott (1916– ) and Louis Ignarro (1941– ) demonstrate the importance of nitric oxide as a signal molecule in the blood vascular system.
- 1988 US biochemist Peter Agre (1949– ) identifies a water-channel protein (aquaporin) in the plasma membrane of cells.
- 1994 Beginnings of DNA chip technology.
- 1998 US biochemist Roderick MacKinnon (1956– ) reveals detailed three-dimensional structure of potassium-ion channel in brain cells.
- 2001 US molecular biologist Harry Noller and colleagues produce first detailed X-ray crystallographic image of a complete ribosome.

pressure, that are usually unconsciously regulated by the autonomic nervous system. It is facilitated by the use of monitoring devices, such as pulse monitors, electroencephalographs, and electromyographs, and can be useful in treating high

blood pressure, migraine, epilepsy, and other disorders.

**biofuel** A gaseous, liquid, or solid fuel that contains an energy content derived from a biological source. The organic mat-

ter that makes up living organisms provides a potential source of trapped energy that is beginning to be exploited to supply the ever-increasing energy demand around the world. An example of a biofuel is rapeseed oil, which can be used in place of diesel fuel in modified engines. The methyl ester of this oil, **rapeseed methyl ester (RME)**, can be used in unmodified diesel engines and is sometimes known as **biodiesel**. Other biofuels include \*biogas and \*gasohol.

**biogas** A mixture of methane and carbon dioxide resulting from the anaerobic decomposition of such waste materials as domestic, industrial, and agricultural sewage. The decomposition is carried out by methanogenic bacteria (see METHANOGEN); these obligate anaerobes produce methane, the main component of biogas, which can be collected and used as an energy source for domestic processes, such as heating, cooking, and lighting. The production of biogas is carried out in special **digesters**, which are widely used in China and India. As well as providing a source of fuel, these systems also enable \*sewage, which contains pathogenic bacteria, to be digested, thereby removing the danger to humans that could otherwise result from untreated domestic and agricultural waste.

**biogenesis** The principle that a living organism can only arise from other living organisms similar to itself (i.e. that like gives rise to like) and can never originate from nonliving material. Compare SPONTANEOUS GENERATION.

**biogeochemical cycle (nutrient cycle)** The cyclical movement of elements between living organisms (the biotic phase) and their nonliving (abiotic) surroundings (e.g. rocks, water, air). Examples of biogeochemical cycles are the \*carbon cycle, \*nitrogen cycle, \*oxygen cycle, \*phosphorus cycle, and \*sulphur cycle.

**biogeography** The branch of biology that deals with the geographical distribution of plants and animals. See PLANT GEOGRAPHY; ZOOGEOGRAPHY.

**bioinformatics** The collection, storage, and analysis of DNA- and protein-sequence data using computerized sys-

tems. Much of the data generated by genome sequencing projects and protein studies is held in various databanks and made available to researchers throughout the world via the Internet. Many computer programs have been developed to analyse sequence data, enabling the user to identify similarities between newly sequenced material and existing sequences. This allows, for example, predictions about the structure and function of a protein from its amino-acid sequence data or from the nucleotide sequence of its gene. Also, genome-wide sequence analysis allows comparisons to be made between genomes of different species, which provides information about their possible evolutionary relationships. See GENOMICS.

**bioinorganic chemistry** Biochemistry involving compounds that contain metal atoms or ions. Two common examples of bioinorganic compounds are haemoglobin (which contains iron) and chlorophyll (which contains magnesium). Many enzymes contain metal atoms and bioinorganics are important in a number of biochemical processes, including oxygen transport, electron transfer, and protein folding.

**biological clock** The mechanism, presumed to exist within many animals and plants, that produces regular periodic changes in behaviour or physiology. Biological clocks underlie many of the \*biorhythms seen in organisms (e.g. hibernation in animals). They continue to run even when conditions are kept artificially constant, but eventually drift out of step with the natural environment without the specific signals that normally keep them synchronized. Studies in the fruit fly *Drosophila* have revealed the molecular basis of the biological clock, and similar mechanisms are thought to occur in other animals, including mammals.

**biological control** The control of \*pests by biological (rather than chemical) means. This may be achieved, for example, by breeding disease-resistant crops or by introducing a natural enemy of the pest, such as a predator or a parasite. This technique, which may offer substantial advantages over the use of pesticides or herbicides, has been employed success-

fully on a number of occasions. Examples include the control of the prickly pear cactus (*Opuntia*) in Australia by introducing the cactus moth (*Cactoblastis cactorum*), whose caterpillars feed on the plant's growing shoots, and the use of the ladybird to prey upon the scale insect (*Icerya*), which kills citrus fruit trees. Insect pests have also been subjected to genetic control, by releasing large numbers of males of the pest species that have been sterilized by radiation: infertile matings subsequently cause a decline in the pest population. This method has been used to control the screw worm fly (*Cochliomyia hominivora*), which lays its eggs in the open wounds of domestic cattle. Biological control is considered to reduce a number of the problems associated with chemical control using \*pesticides, but care should be taken to avoid upsetting the natural ecological balance; for example, a particular predator may also destroy harmless or beneficial species.

**biological rhythm** See BIORHYTHM.

**biological warfare** The military use of microorganisms, such as bacteria, viruses, fungi, and other microorganisms, including the agents for anthrax and botulism, to induce disease or death among humans, livestock, and crop plants. Though officially banned in most countries, research continues with the aim of developing virulent strains of existing microorganisms, using genetic engineering and other techniques.

**biology** The study of living organisms, which includes their structure (gross and microscopic), functioning, origin and evolution, classification, interrelationships, and distribution.

**bioluminescence** The emission of light without heat (see LUMINESCENCE) by living organisms. The phenomenon occurs in glow-worms and fireflies, bacteria and fungi, and in many deep-sea fish (among others); in animals it may serve as a means of protection (e.g. by disguising the shape of a fish) or species recognition or it may provide mating signals. The light is produced during the oxidation of a compound called **luciferin** (the composition of which varies according to the species), the reaction being catalysed by an enzyme, **lu-**

**ciferase**. Bioluminescence may be continuous (e.g. in bacteria) or intermittent (e.g. in fireflies).

**biomass** The total mass of all the organisms of a given type and/or in a given area; for example, the world biomass of trees, or the biomass of elephants in the Serengeti National Park. It is normally measured in terms of grams of \*dry mass per square metre. See also PYRAMID OF BIOMASS.

**biome** A major ecological community or complex of communities that extends over a large geographical area characterized by a dominant type of vegetation. The organisms of a biome are adapted to the climate conditions associated with the region. There are no distinct boundaries between adjacent biomes, which merge gradually with each other. Examples of biomes are \*tundra, tropical \*rainforest, \*taiga, \*grassland (temperate and tropical), and \*desert.

**biomechanics** The application of the principles of \*mechanics to living systems, particularly those living systems that have coordinated movements. Biomechanics also deals with the properties of biological materials, such as blood and bone. For example, biomechanics would be used to analyse the stresses on bones in animals, both when the animals are static and when they are moving. Other types of problems in biomechanics include the \*fluid mechanics associated with swimming in fish and the \*aerodynamics of birds flying. It is sometimes difficult to perform realistic calculations in biomechanics because of complexity in the shape of animals or the large number of \*degrees of freedom that need to be considered (for example, the large number of muscles involved in the movement of a human leg).

**biomolecule** Any molecule that is involved in the maintenance and metabolic processes of living organisms (see METABOLISM). Biomolecules include carbohydrate, lipid, protein, nucleic acid, and water molecules; some biomolecules are \*macromolecules.

**biophysics** The study of the physical aspects of biology, including the application

of physical laws and the techniques of physics to study biological phenomena. *See also* PHYSICS.

**biopoesis** The development of living matter from complex organic molecules that are themselves nonliving but self-replicating. It is the process by which life is assumed to have begun. *See* ORIGIN OF LIFE.

**bioreactor (industrial fermenter)** A large stainless steel tank used to grow producer microorganisms in the industrial production of enzymes and other chemicals. After the tank is steam-sterilized, an inoculum of the producer cells is introduced into a medium that is maintained by probes at optimum conditions of temperature, pressure, pH, and oxygen levels for enzyme production. An **agitator** (stirrer) mixes the medium, which is constantly aerated. It is essential that the culture medium is sterile and contains the appropriate nutritional requirements for the microorganism. When the nutrients have been utilized the product is separated; if the product is an extracellular compound the medium can be removed during the growth phase of the microorganisms, but an intracellular product must be harvested when the batch culture growth stops. Some bioreactors are designed for \*continuous culture.

**biorhythm (biological rhythm)** A roughly periodic change in the behaviour or physiology of an organism that is generated and maintained by a \*biological clock. Well-known examples are the \*annual and \*circadian rhythms occurring in many animals and plants. **Infradian rhythms**, occurring in many cellular processes, have a periodicity of less than 24 hours. An example of an **ultradian rhythm**, with a periodicity greater than a day, is the reproductive cycle of many animals that corresponds with the 29.5-day lunar cycle.

**biosensor** A device that uses an immobilized agent to detect or measure a chemical compound. The agents include enzymes, antibiotics, organelles, or whole cells. A reaction between the immobilized agent and the molecule being analyzed is transduced into an electronic signal. This signal may be produced in response to the

presence of a reaction product, the movement of electrons, or the appearance of some other factor (e.g. light). Biosensors are used in diagnostic tests: these allow quick, sensitive, and specific analysis of a wide range of biological products, including antibiotics, vitamins, and other important biomolecules (such as glucose), as well as the determination of certain \*xenobiotics, such as synthetic organic compounds.

**biosphere** The whole of the region of the earth's surface, the sea, and the air that is inhabited by living organisms.

**biostratigraphy** The characterization of rock strata on the basis of the fossils they contain. *See also* STRATIGRAPHY.

**biosynthesis** The production of molecules by a living cell, which is the essential feature of \*anabolism.

**biostatistics** *See* SYSTEMATICS.

**biotechnology** The development of techniques for the application of biological processes to the production of materials of use in medicine and industry. For example, the production of antibiotics, cheese, and wine rely on the activity of various fungi and bacteria. \*Genetic engineering can modify bacterial cells to synthesize completely new substances, e.g. hormones, vaccines, \*monoclonal antibodies, etc., or introduce novel traits into plants or animals. *See also* GENETICALLY MODIFIED ORGANISMS (Feature).

**biotic factor** Any of the factors of an organism's environment that consist of other living organisms and together make up the **biotic environment**. These factors may affect an organism in many ways; for example, as competitors, predators, parasites, prey, or symbionts. In time, the distribution and abundance of the organism will be affected by its interrelationships with the biotic environment. *Compare* ABIOTIC FACTOR.

**biotin** A vitamin in the \*vitamin B complex. It is the \*coenzyme for various enzymes that catalyse the incorporation of carbon dioxide into various compounds. Adequate amounts are normally produced by the intestinal bacteria in animals although deficiency can be induced by con-

suming large amounts of raw egg white. This contains a protein, avidin, that specifically binds biotin, preventing its absorption from the gut. Other sources of biotin include cereals, vegetables, milk, and liver.

**biotite** An important rock-forming silicate mineral, a member of the \*mica group of minerals, in common with which it has a sheetlike crystal structure. It is usually black, dark brown, or green in colour.

**bipolar outflow** A type of stellar wind (see SOLAR WIND) that leaves a star mainly from its poles. Such outflows are commonest in protostars, pre-main-sequence stars and red giants, and account for a great loss of stellar mass. They may take the form of radio-emitting molecules or long visible jets of gaseous material. It is thought that a disc of dense gas around the star's equatorial regions prevents the outflow of material elsewhere.

**biprism** A glass prism with an obtuse angle that functions as two acute-angle prisms placed base-to-base. A double image of a single object is thus formed; the device was used by Fresnel to produce two coherent beams for interference experiments.

**bipyramid** See COMPLEX.

**birds** See AVES.

**birefringence** See DOUBLE REFRACTION.

**Birkeland-Eyde process** A process for the fixation of nitrogen by passing air through an electric arc to produce nitrogen oxides. It was introduced in 1903 by the Norwegian chemists Kristian Birkeland (1867–1913) and Samuel Eyde (1866–1940). The process is economic only if cheap hydroelectricity is available.

**birth** See PARTURITION.

**birth control (contraception)** The intentional avoidance of pregnancy by methods that do not normally hinder sexual activity. The methods used can be 'natural' or 'artificial'. Natural methods, often used because of religious or moral objections to artificial methods, include the **rhythm method**, in which sexual intercourse is avoided during times when ovulation oc-

curs; and **coitus interruptus**, an unreliable method in which the penis is withdrawn from the vagina before ejaculation. The rhythm method requires a monitoring of the woman's menstrual cycle and may be unsuitable in those women with irregular cycles. Artificial methods use devices or other agents (**contraceptives**) to prevent pregnancy. They include the **condom**, a rubber sheath placed over the penis to trap the sperm; and the **diaphragm**, a rubber cap placed over the cervix. Contraceptives that prevent \*implantation include the **intrauterine device (IUD)**, a metal or plastic coil placed in the uterus by a doctor (which may cause unacceptable bleeding in some women); and the 'morning-after pill', taken within three days after sexual intercourse. Other \*oral contraceptives prevent ovulation. \*Sterilization is usually considered to be irreversible but attempts at reversing the process are possible. For casual relationships, or relationships involving a partner whose sexual history is not known, health workers advise the use of condoms with all other forms of contraception as this provides the safest means of reducing the risk of infection by \*sexually transmitted diseases.

**birth rate (natality)** The rate at which a particular species or population produces offspring. The birth rate of a species is used to measure its fecundity (reproductive capability). It is also an important factor in controlling the size of a population. Compare DEATH RATE.

**bisexual** (in biology) See HERMAPHRODITE.

**bismuth** Symbol Bi. A white crystalline metal with a pinkish tinge belonging to \*group 15 (formerly VB) of the periodic table; a.n. 83; r.a.m. 208.98; r.d. 9.78; m.p. 271.3°C; b.p. 1560°C. The most important ores are bismuthinite ( $\text{Bi}_2\text{S}_3$ ) and bismite ( $\text{Bi}_2\text{O}_3$ ). Peru, Japan, Mexico, Bolivia, and Canada are major producers. The metal is extracted by carbon reduction of its oxide. Bismuth is the most diamagnetic of all metals and its thermal conductivity is lower than any metal except mercury. The metal has a high electrical resistance and a high Hall effect when placed in magnetic fields. It is used to make low-

melting-point casting alloys with tin and cadmium. These alloys expand on solidification to give clear replication of intricate features. It is also used to make thermally activated safety devices for fire-detection and sprinkler systems. More recent applications include its use as a catalyst for making acrylic fibres, as a constituent of malleable iron, as a carrier of uranium-235 fuel in nuclear reactors, and as a specialized thermocouple material. Bismuth compounds (when lead-free) are used for cosmetics and medical preparations. It is attacked by oxidizing acids, steam (at high temperatures), and by moist halogens. It burns in air with a blue flame to produce yellow oxide fumes. C. G. Junine first demonstrated that it was different from lead in 1753.

**bistability** See OSCILLATING REACTION.

**bistable circuit** See FLIP-FLOP.

**bisulphate** See HYDROGENSULPHATE.

**bisulphite** See HYDROGENSULPHITE; ALDEHYDES.

**bit (binary digit)** Either of the digits 0 or 1 as used in the \*binary notation. Bits are therefore the basic unit of information in a computer system.

**bite angle** See CHELATE.

**Bitnet** A computer network originally linking IBM mainframe systems located in North America and with backing from IBM. The network has been substantially extended to other parts of the world, usually on a region-by-region basis, and has been implemented on other computer systems. Complete messages of any length are transmitted from one computer system to the next, until the destination is reached.

**bittern** The solution of salts remaining when sodium chloride is crystallized from sea water.

**Bitter pattern** A microscopic pattern that forms on the surface of a ferromagnetic material that has been coated with a colloidal suspension of small iron particles. The patterns outline the boundaries of the magnetic domains (see MAGNETISM). They were first observed by F. Bitter in 1931.

**bitumen** See PETROLEUM.

**bituminous coal** See COAL.

**bituminous sand** See OIL SAND.

**biuret test** A biochemical test to detect proteins in solution, named after the substance **biuret** ( $\text{H}_2\text{NCONHCONH}_2$ ), which is formed when urea is heated. Sodium hydroxide is mixed with the test solution and drops of 1% copper(II) sulphate solution are then added slowly. A positive result is indicated by a violet ring, caused by the reaction of \*peptide bonds in the proteins or peptides. Such a result will not occur in the presence of free amino acids.

**bivalent 1.** (in chemistry) (**divalent**) Having a valency of two. **2.** (in genetics) See PAIRING.

**Bivalvia (Pelecypoda; Lamellibranchia)** A class of aquatic molluscs (the bivalves) that include the oysters, mussels, and clams. They are characterized by a laterally flattened body and a shell consisting of two hinged valves (i.e. a bivalved shell). The enlarged gills are covered with cilia and have the additional function of filtering microscopic food particles from the water flowing over them. Bivalves live on the sea bed or lake bottom and are sedentary, so the head and foot are reduced.

**Black, Joseph** (1728–99) British chemist and physician, born in France. He studied at Glasgow and Edinburgh, where his thesis (1754) contained the first accurate description of the chemistry of carbon dioxide. In 1757 he discovered latent heat, and was the first to distinguish between heat and temperature.

**black body** A hypothetical body that absorbs all the radiation falling on it. It thus has an \*absorptance and an \*emissivity of 1. While a true black body is an imaginary concept, a small hole in the wall of an enclosure at uniform temperature is the nearest approach that can be made to it in practice.

**Black-body radiation** is the electromagnetic radiation emitted by a black body. It extends over the whole range of wavelengths and the distribution of energy over this range has a characteristic form with a maximum at a certain wavelength. The position of the maximum depends on

temperature, moving to shorter wavelengths with increasing temperature. *See* STEFAN'S LAW; WIEN'S DISPLACEMENT LAW.

**blackdamp (choke damp)** Air left depleted in oxygen following the explosion of firedamp in a mine.

**black dwarf** A cold celestial object thought to be the remains of a dead star of low mass, that is formed after a \*white dwarf star has radiated away all of its heat energy. Black dwarfs are extremely difficult to detect, and because white dwarfs take so long to cool down, it is possible that the universe may not yet be old enough for any black dwarfs to have formed.

**black earth** *See* CHERNOZEM.

**black hole** An object in space that has collapsed under its own gravitational forces to such an extent that its \*escape velocity is equal to the speed of light. Black holes are believed to be formed in the gravitational collapse of massive stars at the ends of their lives (*see* STELLAR EVOLUTION; SUPERNOVA). If the mass of an evolved stellar core is greater than the Chandrasekhar limit for neutron stars then neutron degeneracy pressure is unable to prevent contraction until the gravitational field is sufficiently strong to prevent the escape of electromagnetic radiation. The boundary of the black hole, which is known as the **event horizon**, is the surface in space at which the gravitational field reaches this critical value. Events occurring within this horizon (i.e. in the interior of the black hole) cannot be observed from outside.

The theoretical study of black holes involves the use of general \*relativity. It has been shown that a black hole can be characterized uniquely by just three properties: its mass, angular momentum, and electrical charge (this is known as the no-hair theorem). Mathematical expressions have been derived for describing black holes; these are the **Schwarzschild solution** (uncharged nonrotating hole), the **Reissner-Nordström solution** (charged nonrotating hole), the **Kerr solution** (uncharged rotating hole), and the **Kerr-Newman solution** (charged rotating hole).

The ultimate fate of matter inside the black hole's event horizon is as yet un-

known. General relativity predicts that at the centre of the hole there is a **singularity**, a point at which the density becomes infinite and the presently understood laws of physics break down. It is possible that a successful quantum theory of gravity could resolve this problem. However, since any singularity is hidden within the event horizon, it cannot influence the outside universe, so the normal laws of physics, including general relativity, can be used to describe processes outside the black hole.

Observational evidence of objects thought to be black holes comes from their effect on surrounding matter. Thus, if a black hole is part of a binary system with another star it will attract and capture matter from this star. The material leaving the star first forms a rotating **accretion disc** around the black hole, in which the matter becomes compressed and heated to such an extent that it emits X-rays. In the constellation Cygnus there is an X-ray source, Cygnus X-1, which consists of a supergiant star revolving around a small invisible companion with a mass of about ten times that of the sun, and therefore well above the Chandrasekhar limit. The companion is thought to be a black hole. Black holes have also been postulated as the power sources of \*quasars and as possible generators of \*gravitational waves. It appears that there may be very large black holes at the centres of all galaxies. It has been suggested that black-hole formation could be the cause of gamma-ray bursts.

Theoreticians have also postulated the existence of 'mini' black holes (with masses of about  $10^{12}$  kilograms and radii about  $10^{-15}$  metre). Such entities might have been formed shortly after the big bang when the universe was created. Quantum-mechanical effects are important for mini black holes, which emit Hawking radiation (*see* HAWKING PROCESS). *See also* SCHWARZSCHILD RADIUS.

**black lead** *See* CARBON.

**bladder 1.** (in anatomy) **a.** A hollow muscular organ in most vertebrates, also known as the **urinary bladder**, in which urine is stored before being discharged. In mammals urine is conveyed from the \*kidneys to the bladder by the \*ureters

and is discharged to the outside through the \*urethra. **b.** Any of various other saclike organs in animals for the storage of liquid or gas. See GALL BLADDER; SWIM BLADDER. **2.** (in botany) **a.** A modified submerged leaf of certain aquatic insectivorous plants, such as the bladderwort (*Utricularia*). It forms a hollow with a single opening that is sealed by a valve to trap small aquatic invertebrates after they have been sucked in. **b.** An air-filled cavity in the thallus of certain seaweeds, such as the bladderwrack (*Fucus vesiculosus*).

**blanc fixe** See BARIUM SULPHATE.

**Blandford-Znajek process** An astrophysical process in which an external magnetic field is able to 'tap' the rotational energy of a rotating black hole, thereby making the black hole a powerful source of energy. There is some evidence that the process occurs around certain types of black hole. It was proposed by Roger Blandford and Roman Znajek in 1977. See also PENROSE PROCESS.

**blast furnace** A furnace for smelting iron ores, such as haematite ( $\text{Fe}_2\text{O}_3$ ) or magnetite ( $\text{Fe}_3\text{O}_4$ ), to make \*pig iron. The furnace is a tall refractory-lined cylindrical structure that is charged at the top with the dressed ore (see BENEFICIATION), coke, and a flux, usually limestone. The conversion of the iron oxides to metallic iron is a reduction process in which carbon monoxide and hydrogen are the reducing agents. The overall reaction can be summarized thus:

The CO is obtained within the furnace by blasting the coke with hot air from a ring of tuyeres about two-thirds of the way down the furnace. The reaction producing the CO is:

In most blast furnaces hydrocarbons (oil, gas, tar, etc.) are added to the blast to provide a source of hydrogen. In the modern **direct-reduction process** the CO and  $\text{H}_2$  may be produced separately so that the reduction process can proceed at a lower temperature. The pig iron produced by a blast furnace contains about 4% carbon

and further refining is usually required to produce steel or cast iron.

**blasting gelatin** A high explosive made from nitroglycerine and gun cotton (cellulose nitrate).

**blastocoel** See BLASTULA.

**blastocyst** See BLASTULA; IMPLANTATION.

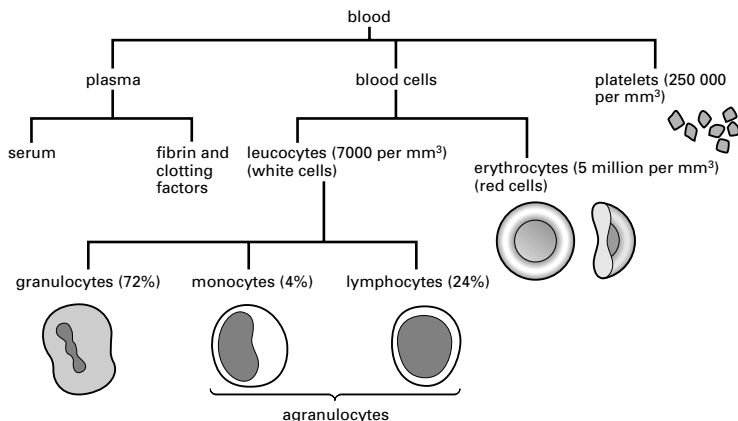

**blastula** The stage of \*development of an animal embryo that results from \*cleavage of a fertilized egg. This stage generally resembles a hollow ball with the dividing cells (**blastomeres**) of the embryo forming a layer (**blastoderm**) around a central cavity (**blastocoel**). Insect eggs have no blastula. In vertebrates the blastula forms a disc (**blastodisc**) on the surface of the yolk. In mammals the blastula stage is known as a **blastocyst**. See also GASTRULA.

**blazar** A very active type of galaxy, named from a combination of BL Lacertae object and quasar. Its light output varies greatly, perhaps caused by jets of gas expelled from the nucleus of the galaxy at speeds approaching the speed of light. This effect is known as relativistic beaming and if it is directed towards the earth, it is seen as violent fluctuations in radiation.

**bleaching powder** A white solid regarded as a mixture of calcium chlorate(I), calcium chloride, and calcium hydroxide. It is prepared on a large scale by passing chlorine gas through a solution of calcium hydroxide. Bleaching powder is sold on the basis of available chlorine, which is liberated when it is treated with a dilute acid. It is used for bleaching paper pulps and fabrics and for sterilizing water.

**blende** A naturally occurring metal sulphide, e.g. zinc blende ZnS.

**blending inheritance** The early theory that assumed that hereditary substances from parents merge together in their offspring. Mendel showed that this does not occur (see MENDEL'S LAWS). In breeding experiments an appearance of blending may result from codominant alleles (see CODOMINANCE) and \*polygenes but close study shows that the alleles retain their identity through successive generations. Compare PARTICULATE INHERITANCE.

Composition of mammalian blood

**blind spot** The portion of the retina at which blood vessels and nerve fibres enter the optic nerve. There are no rods or cones in this area, so no visual image can be transmitted from it.

**block** See PERIODIC TABLE.

**block copolymer** See POLYMER.

**blood** A fluid body tissue that acts as a transport medium within an animal. It is contained within a blood \*vascular system and in vertebrates is circulated by means of contractions of the \*heart. Oxygen and food are carried to tissues, and carbon dioxide and chemical (nitrogenous) waste are transported from tissues to excretory organs for disposal (\*excretion). In addition blood carries \*hormones and also acts as a defence system. Blood consists of a liquid (see BLOOD PLASMA) containing blood cells (see ERYTHROCYTE; LEUCOCYTE) and \*platelets (see illustration).

**blood-brain barrier** The mechanism that controls the passage of substances from the blood to the cerebrospinal fluid bathing the brain and spinal cord. It takes the form of a semipermeable lipid membrane permitting the passage of solutions but excluding particles and large molecules. This barrier provides the central nervous system with a constant environment, while not interfering with the transport of essential metabolites.

**blood capillary** See CAPILLARY.

**blood cell (blood corpuscle)** Any of the cells that are normally found in the blood plasma. These include red cells (see ERYTHROCYTE) and white cells (see LEUCOCYTE).

**blood clotting (blood coagulation)** The production of a mass of semisolid material at the site of an injury that closes the wound, helping to prevent further blood loss and bacterial invasion. The clot is formed by the action of \*clotting factors and \*platelets. Damage to tissue triggers a series of reactions involving **thromboplastin** (a glycoprotein), calcium ions, phospholipids (from platelets), and clotting factors, which results in the conversion of \*prothrombin in the blood to its enzymically active form **thrombin**. Thrombin catalyses the formation of the insoluble protein **fibrin** from soluble **fibrinogen**; the fibrin forms a fibrous network in which blood cells become enmeshed, producing a clot.

**blood groups** The many types into which an individual's blood may be classified, based on the presence or absence of certain antigenic proteins (\*agglutinogens) on the surface of the red blood cells. Blood of one group contains \*antibodies in the serum that react against the agglutinogens on the cells of other groups. **Incompatibility** between groups results in clumping of cells (\*ag-

glutination), so knowledge of blood groups is important for blood transfusions. In man, the two most important blood group systems are the \*ABO system and the system involving the \*rhesus factor.

**blood plasma** The liquid part of the \*blood (i.e. excluding blood cells). It consists of water containing a large number of dissolved substances, including proteins, salts (especially sodium and potassium chlorides and bicarbonates), food materials (glucose, amino acids, fats), hormones, vitamins, and excretory materials. See also BLOOD SERUM; LYMPH.

**blood platelet** See PLATELET.

**blood pressure** The pressure exerted by the flow of blood through the major arteries of the body. This pressure is greatest during the contraction of the ventricles of the heart (**systolic pressure**; see SYSTOLE), which forces blood into the arterial system. Pressure falls to its lowest level when the heart is filling with blood (**diastolic pressure**; see DIASTOLE). Blood pressure is measured in millimetres of mercury using an instrument called a **sphygmomanometer**. Normal blood pressure for a young average adult human is in the region of 120/80 mmHg (the higher number is the systolic blood pressure; the lower number the diastolic blood pressure), but individual variations are common. Abnormally high blood pressure (**hypertension**) may be associated with disease or it may occur without an apparent cause.

**blood serum** Blood plasma from which the fibrin and clotting factors have been removed by centrifugation or vigorous stirring, so that it cannot clot. Serum containing a specific antibody or antitoxin may be used in the treatment or prevention of certain infections. Such serum is generally derived from a nonhuman mammal (e.g. a horse).

**blood vascular system** The tissues and organs of an animal that transport blood through the body. In vertebrates it consists of the heart and blood vessels. See VASCULAR SYSTEM.

**blood vessel** A tubular structure through which the blood of an animal

flows. See ARTERY; ARTERIOLE; CAPILLARY; VENULE; VEIN.

**blooming** The process of depositing a transparent film of a substance, such as magnesium fluoride, on a lens to reduce (or eliminate) the reflection of light at the surface. The film is about one quarter of a wavelength thick and has a lower \*refractive index than the lens. The anti-reflection effect is achieved by destructive interference.

**blue-green bacteria** See CYANOBACTERIA.

**blue vitriol** See COPPER(II) SULPHATE.

**B lymphocyte** See B CELL.

**B-meson** Symbol  $B^0$ . A meson that consists of a down quark and an anti-bottom quark. It is electrically neutral, has spin zero, and a mass of 5.279 GeV. The anti-particle consists of a bottom quark and an anti-down quark. It is hoped that study of the decays of B-mesons will shed light on the problem of \*CP violation.

**boat conformation** See CONFORMATION.

**BOD** See BIOCHEMICAL OXYGEN DEMAND.

**Bode, Johann Elert** (1747-1826) German astronomer, who became director of the Berlin Observatory. In 1766 his compatriot Johann Titius had discovered an apparently coincidental mathematical relationship involving the distances of the planets from the sun. If 4 is added to each number in the series 0, 3, 6, 12, 24, ... and the answers divided by 10, the resulting sequence gives the distances of the planets in astronomical units (earth = 1). Known now as **Bode's law**, or the Titius-Bode law, it fails for Neptune and Pluto.

**body cavity** The internal cavity of the body of an animal, which is present in most invertebrates and all vertebrates and contains the major organs. The body cavity of vertebrates and many invertebrates is the \*coelom. In vertebrates the body cavity is divided by a transverse septum just posterior to the heart into the abdominal and thoracic cavities (see ABDOMEN; THORAX). In mammals the septum is the \*diaphragm.

**body-centred cubic (b.c.c.)** See CUBIC CRYSTAL.

**body fluid** Any of the fluids found within animals, including blood, lymph, tissue fluid, urine, bile, sweat, and synovial fluid. Body fluids are generally involved with the processes of transport, excretion, or lubrication. They allow the distribution of oxygen and nutrients to the tissues and organs and the transport of waste products from the tissues, enabling their elimination from the body.

**boehmite** A mineral form of a mixed aluminium oxide and hydroxide,  $\text{AlO.OH}$ . It is named after the German scientist J. Böhm. See ALUMINIUM HYDROXIDE.

**Bohr, Niels Henrik David** (1885–1962) Danish physicist. In 1913 he published his explanation of how atoms, with electrons orbiting a central nucleus, achieve stability by assuming that their angular momentum is quantized. Movement of electrons from one orbit to another is accompanied by the absorption or emission of energy in the form of light, thus accounting for the series of lines in the emission \*spectrum of hydrogen. For this work Bohr was awarded the 1922 Nobel Prize. See BOHR THEORY.

**Bohr effect** The effect of pH on the dissociation of oxygen from haemoglobin, first discovered by the Danish physiologist Christian Bohr (1855–1911). An increase in carbon dioxide concentration makes the blood more acidic and decreases the efficiency of the uptake of oxygen by haemoglobin molecules. This shifts the \*oxygen dissociation curve to the right and increases the tendency of haemoglobin to release oxygen. Thus in actively respiring tissues, where the concentration of carbon dioxide in the blood is high, haemoglobin readily releases its oxygen, while in the lungs, where blood carbon dioxide is low (due to its continual diffusion into the alveoli), haemoglobin readily binds oxygen.

**bohrium** Symbol Bh. A radioactive \*transactinide element; a.n. 107. It was first made in 1981 by Peter Armbruster and a team in Darmstadt, Germany, by bombarding bismuth-209 nuclei with

chromium-54 nuclei. Only a few atoms of bohrium have ever been detected.

**Bohr theory** The theory published in 1913 by Niels Bohr to explain the line spectrum of hydrogen. He assumed that a single electron of mass  $m$  travelled in a circular orbit of radius  $r$ , at a velocity  $v$ , around a positively charged nucleus. The \*angular momentum of the electron would then be  $mvr$ . Bohr proposed that electrons could only occupy orbits in which this angular momentum had certain fixed values,  $h/2\pi$ ,  $2h/2\pi$ ,  $3h/2\pi$ , ...,  $nh/2\pi$ , where  $h$  is the Planck constant. This means that the angular momentum is quantized, i.e. can only have certain values, each of which is a multiple of  $h/2\pi$ . Each permitted value of  $n$  is associated with an orbit of different radius and Bohr assumed that when the atom emitted or absorbed radiation of frequency  $\nu$ , the electron jumped from one orbit to another; the energy emitted or absorbed by each jump is equal to  $h\nu$ . This theory gave good results in predicting the lines observed in the spectrum of hydrogen and simple ions such as  $\text{He}^+$ ,  $\text{Li}^{2+}$ , etc. The idea of quantized values of angular momentum was later explained by the wave nature of the electron. Each orbit has to have a whole number of wavelengths around it; i.e.  $n\lambda = 2\pi r$ , where  $\lambda$  is the wavelength and  $n$  a whole number. The wavelength of a particle is given by  $h/mv$ , so  $nh/mv = 2\pi r$ , which leads to  $mvr = nh/2\pi$ . Modern atomic theory does not allow subatomic particles to be treated in the same way as large objects, and Bohr's reasoning is somewhat discredited. However, the idea of quantized angular momentum has been retained.

**boiling point (b.p.)** The temperature at which the saturated vapour pressure of a liquid equals the external atmospheric pressure. As a consequence, bubbles form in the liquid and the temperature remains constant until all the liquid has evaporated. As the boiling point of a liquid depends on the external atmospheric pressure, boiling points are usually quoted for standard atmospheric pressure (760 mmHg = 101 325 Pa).

**boiling-point-composition diagram**

A graph showing how the boiling point

and vapour composition of a mixture of two liquids depends on the composition of the mixture. The abscissa shows the range of compositions from 100% A at one end to 100% B at the other. The diagram has two curves: the lower one gives the boiling points (at a fixed pressure) for the different compositions. The upper one is plotted by taking the composition of vapour at each temperature on the boiling-point curve. The two curves would coincide for an ideal mixture, but generally they are different because of deviations from \*Raoult's law. In some cases, they may show a maximum or minimum and coincide at some intermediate composition, explaining the formation of \*azeotropes.

**boiling-point elevation** See ELEVATION OF BOILING POINT.

**boiling-water reactor** See NUCLEAR REACTOR.

**Bok globule** A near-spherical dark \*nebula thought to consist of gas and dust clouds collapsing under gravity. The globules are visible against emission nebulae or stars in the background. The fragments formed, as the globules collapse, form protostars (see STELLAR EVOLUTION), sometimes accompanied by \*bipolar outflows. They are named after Bart Jansen Bok (1906–83).

**bolometer** A sensitive instrument used to measure radiant heat. The original form consists of two elements, each comprising blackened platinum strips (about  $10^{-3}$  mm thick) arranged in series on an insulated frame to form a zigzag. The two elements are connected into the adjacent arms of a \*Wheatstone bridge; one element is exposed to the radiation, the other is shielded from it. The change in the resistance of the exposed element, as detected by the bridge galvanometer, enables the heat reaching it to be calculated.

Modern semiconductor bolometers are now common, in which the platinum is replaced by a strip of semiconductor: this has a much greater (though usually negative) \*temperature coefficient of resistance, and makes the system more sensitive.

**Boltzmann, Ludwig Eduard**

(1844–1906) Austrian physicist. He held professorships in Graz, Vienna, Munich, and Leipzig, where he worked on the kinetic theory of gases (see MAXWELL-BOLTZMANN DISTRIBUTION) and on thermodynamics (see BOLTZMANN EQUATION). He suffered from depression and committed suicide.

**Boltzmann constant** Symbol  $k$  or  $k_B$ . The ratio of the universal gas constant ( $R$ ) to the Avogadro constant ( $N_A$ ). It may be thought of therefore as the gas constant per molecule:

$$k = R/N_A = 1.380\,658(12) \times 10^{-23} \text{ J K}^{-1}$$

It is named after Ludwig Boltzmann.

**Boltzmann equation** An equation used in the study of a collection of particles in \*non-equilibrium statistical mechanics, particularly their transport properties. The Boltzmann equation describes a quantity called the **distribution function**,  $f$ , which gives a mathematical description of the state and how it is changing. The distribution function depends on a position vector  $\mathbf{r}$ , a velocity vector  $\mathbf{v}$ , and the time  $t$ ; it thus provides a statistical statement about the positions and velocities of the particles at any time. In the case of one species of particle being present, Boltzmann's equation can be written

$$\partial f / \partial t + \mathbf{a} \cdot (\partial f / \partial \mathbf{v}) + \mathbf{v} \cdot (\partial f / \partial \mathbf{r}) = (\partial f / \partial t)_{\text{coll}}$$

where  $\mathbf{a}$  is the acceleration of bodies between collisions and  $(\partial f / \partial t)_{\text{coll}}$  is the rate of change of  $f(\mathbf{r}, \mathbf{v}, t)$  due to collisions. The Boltzmann equation can be used to calculate \*transport coefficients, such as \*conductivity. The Boltzmann equation was proposed in 1872.

**Boltzmann formula** An equation concerning the entropy  $S$  of a system derived from statistical mechanics. The formula is  $S = k \ln W$ , where  $k$  is the Boltzmann constant and  $W$  is the number of distinguishable ways of describing the system. It expresses in quantitative terms the concept that entropy is a measure of the disorder of a system.

**bolus** The ball of chewed food bound together with saliva that is formed in the mouth by the action of the tongue. The bolus is shaped to a size that allows it to

pass into the oesophagus after being swallowed (see **DEGLUTITION**).

**bomb calorimeter** An apparatus used for measuring heats of combustion (e.g. calorific values of fuels and foods). It consists of a strong container in which the sample is sealed with excess oxygen and ignited electrically. The heat of combustion at constant volume can be calculated from the resulting rise in temperature.

**bond** See **CHEMICAL BOND**.

**bond energy** An amount of energy associated with a bond in a chemical compound. It is obtained from the heat of atomization. For instance, in methane the bond energy of the C-H bond is one quarter of the enthalpy of the process

Bond energies (or **bond enthalpies**) can be calculated from the standard enthalpy of formation of the compound and from the enthalpies of atomization of the elements. Energies calculated in this way are called **average bond energies** or **bond-energy terms**. They depend to some extent on the molecule chosen; the C-H bond energy in methane will differ slightly from that in ethane. The **bond dissociation energy** is a different measurement, being the energy required to break a particular bond; e.g. the energy for the process:

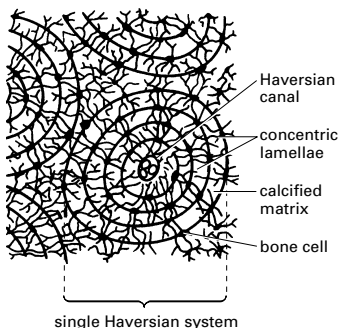

**Bondi, Hermann** See **HOYLE, SIR FRED**.

**bonding orbital** See **ORBITAL**.

**bone** The hard connective tissue of which the \*skeleton of most vertebrates is formed. It comprises a matrix of \*collagen fibres (30%) impregnated with bone salts (70%), mostly calcium phosphate, in which are embedded bone cells (see **OSTEOCYTE**; **OSTEOBLAST**; **OSTEOCLAST**). Bone generally replaces embryonic \*cartilage and is of two sorts - compact bone and spongy bone. The outer **compact bone** is formed as concentric layers (**lamellae**) that surround small holes (\*Haversian canals); see illustration. The inner **spongy bone** is chemically similar but forms a network of bony bars. The spaces between the bars may contain bone marrow or (in birds) air

for lightness. See also **CARTILAGE BONE**; **MEMBRANE BONE**; **PERIOSTEUM**.

Structure of compact bone

**bone black** See **CHARCOAL**.

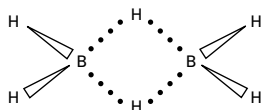

**bone marrow** A soft tissue contained within the central cavity and internal spaces of a bone. At birth and in young animals the marrow of all bones is concerned with the formation of blood cells: it contains \*haemopoietic tissue and is known as **red marrow**. In mature animals the marrow of the long bones ceases producing blood cells and is replaced by fat, being known as **yellow marrow**.

**bony fishes** See **OSTEICHTHYES**.

**bony labyrinth** See **LABYRINTH**.

**Boolean algebra** A form of symbolic logic, devised by George Boole (1815-64) in the middle of the 19th century, which provides a mathematical procedure for manipulating logical relationships in symbolic form. For example in Boolean algebra  $a + b$  means  $a$  or  $b$ , while  $ab$  means  $a$  and  $b$ . It makes use of \*set theory and is extensively used by the designers of computers to enable the bits 0 and 1, as used in the binary notation, to relate to the logical functions the computer needs in carrying out its calculations.

**borane (boron hydride)** Any of a group of compounds of boron and hydrogen, many of which can be prepared by the action of acid on magnesium boride ( $\text{MgB}_2$ ). Others are made by pyrolysis of the products of this reaction in the presence of hy-

Diborane, the simplest of the boranes

drogen and other reagents. They are all volatile, reactive, and oxidize readily in air, some explosively so. The boranes are a remarkable group of compounds in that their structures cannot be described using the conventional two-electron covalent bond model (see ELECTRON-DEFICIENT COMPOUND). The simplest example is **diborane** ( $B_2H_6$ ): see formula. Other boranes include  $B_4H_{10}$ ,  $B_5H_9$ ,  $B_5H_{11}$ ,  $B_6H_{10}$ , and  $B_{10}H_{14}$ . The larger borane molecules have open or closed polyhedra of boron atoms. In addition, there is a wide range of borane derivatives containing atoms of other elements, such as carbon and phosphorus.

**Borohydride ions** of the type  $B_6H_6^{2-}$  also exist. Boranes and borohydride ions are classified according to their structure. Those with a complete polyhedron are said to have a **closo-structure**. Those in which the polyhedron is incomplete by loss of one vertex have a **nido-structure** (from the Greek for 'nest'). Those with open structures by removal of two or more vertices have an **arachno-structure** (from the Greek for 'spider').

**borate** Any of a wide range of ionic compounds that have negative ions containing boron and oxygen (see formulae). Lithium borate, for example, contains the simple anion  $B(OH)_4^-$ . Most borates, however, are inorganic polymers with rings, chains, or other networks based on the planar  $BO_3$  group or the tetrahedral  $BO_3(OH)$  group. 'Hydrated' borates are ones containing  $-OH$  groups; many examples occur naturally. Anhydrous borates, which contain  $BO_3$  groups, can be made by melting together boric acid and metal oxides.

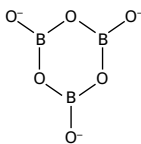

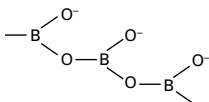

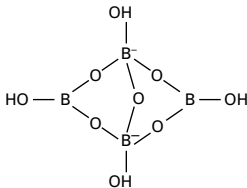

#### borax (disodium tetraborate-10-water)

A colourless monoclinic solid,  $Na_2B_4O_7 \cdot 10H_2O$ , soluble in water and very slightly soluble in ethanol; monoclinic; r.d. 1.73; loses  $8H_2O$  at  $75^\circ C$ ; loses  $10H_2O$  at  $320^\circ C$ . The formula gives a misleading impression of the structure. The com-

pound contains the ion  $[B_4O_5(OH)_4]^{2-}$  (see BORATE). Attempts to recrystallize this compound above  $60.8^\circ C$  yield the pentahydrate. The main sources of borax are the borate minerals **kernite** ( $Na_2B_4O_7 \cdot 4H_2O$ ) and **tincal** ( $Na_2B_4O_7 \cdot 10H_2O$ ). The ores are purified by carefully controlled dissolution and recrystallization. On treatment with mineral acids borax gives boric acid.

Borax is a very important substance in the glass and ceramics industries as a raw material for making borosilicates. It is also important as a metallurgical flux because of the ability of molten borates to dissolve metal oxides. In solution it partially hydrolyses to boric acid and can thus act as a buffer. For this reason it is used as a laundry pre-soak. It is used medicinally as a mild alkaline antiseptic and astringent for the skin and mucous membranes.

Disodium tetraborate is the source of many industrially important boron com-

 $B_3O_6^{3-}$  as in  $Na_3B_3O_6$  $(BO_3)_n^{n-}$  as in  $CaB_2O_4$  $[B_4O_5(OH)_4]^{2-}$   
as in borax  $Na_2B_4O_7 \cdot 10H_2O$ 

Structure of some typical borate ions

pounds, such as barium borate (fungicidal paints), zinc borate (fire-retardant additive in plastics), and boron phosphate (heterogeneous acid catalyst in the petrochemicals industry).

**borax-bead test** A simple laboratory test for certain metal ions in salts. A small amount of the salt is mixed with borax and a molten bead formed on the end of a piece of platinum wire. Certain metals can be identified by the colour of the bead produced in the oxidizing and reducing parts of a Bunsen flame. For example, iron gives a bead that is red when hot and yellow when cold in the oxidizing flame and a green bead in the reducing flame.

**borax carmine** A red dye, used in optical microscopy, that stains nuclei and cytoplasm pink. It is frequently used to stain large pieces of animal tissue.

**borazon** See BORON NITRIDE.

**Bordeaux mixture** A mixture of copper(II) sulphate and calcium hydroxide in water, used as a fungicide.

**boric acid** Any of a number of acids containing boron and oxygen. Used without qualification the term applies to the compound  $H_3BO_3$  (which is also called **orthoboric acid** or, technically, **trioxoboric(III) acid**). This is a white or colourless solid that is soluble in water and ethanol; triclinic; r.d. 1.435; m.p. 169°C. It occurs naturally in the condensate from volcanic steam vents (suffioni). Commercially, it is made by treating borate minerals (e.g. kernite,  $Na_2B_4O_7 \cdot 4H_2O$ ) with sulphuric acid followed by recrystallization.

In the solid there is considerable hydrogen bonding between  $H_3BO_3$  molecules resulting in a layer structure, which accounts for the easy cleavage of the crystals.  $H_3BO_3$  molecules also exist in dilute solutions but in more concentrated solutions polymeric acids and ions are formed (e.g.  $H_4B_2O_7$ ; **pyroboric acid** or **tetrahydroxomaxodiboric(III) acid**). The compound is a very weak acid but also acts as a Lewis \*acid in accepting hydroxide ions:

If solid boric acid is heated it loses water and transforms to another acid at 300°C.

This is given the formula  $HBO_2$  but is in fact a polymer  $(HBO_2)_n$ . It is called **metaboric acid** or, technically, **polydioxoboric(III) acid**.

Boric acid is used in the manufacture of glass (borosilicate glass), glazes and enamels, leather, paper, adhesives, and explosives. It is widely used (particularly in the USA) in detergents, and because of the ability of fused boric acid to dissolve other metal oxides it is used as a flux in brazing and welding. Because of its mild antiseptic properties it is used in the pharmaceutical industry and as a food preservative.

**boride** A compound of boron with a metal. Most metals form at least one boride of the type MB,  $MB_2$ ,  $MB_4$ ,  $MB_6$ , or  $MB_{12}$ . The compounds have a variety of structures; in particular, the hexaborides contain clusters of  $B_6$  atoms. The borides are all hard high-melting materials with metal-like conductivity. They can be made by direct combination of the elements at high temperatures (over 2000°C) or, more usually, by high-temperature reduction of a mixture of the metal oxide and boron oxide using carbon or aluminium. Chemically, they are stable to nonoxidizing acids but are attacked by strong oxidizing agents and by strong alkalis. Magnesium boride ( $MgB_2$ ) is unusual in that it can be hydrolysed to boranes. Industrially, metal borides are used as refractory materials. The most important are CrB,  $CrB_2$ ,  $TiB_2$ , and  $ZnB_2$ . Generally, they are fabricated using high-temperature powder metallurgy, in which the article is produced in a graphite die at over 2000°C and at very high pressure. Items are pressed as near to final shape as possible as machining requires diamond cutters and is extremely expensive.

**Born-Haber cycle** A cycle of reactions used for calculating the lattice energies of ionic crystalline solids. For a compound MX, the lattice energy is the enthalpy of the reaction

The standard enthalpy of formation of the ionic solid is the enthalpy of the reaction

The cycle involves equating this enthalpy (which can be measured) to the sum of

the enthalpies of a number of steps proceeding from the elements to the ionic solid. The steps are:

(1) Atomization of the metal:

(2) Atomization of the nonmetal:

(3) Ionization of the metal:

This is obtained from the ionization potential.

(4) Ionization of the nonmetal:

This is the electron affinity.

(5) Formation of the ionic solids:

Equating the enthalpies gives:

$$\Delta H_f = \Delta H_1 + \Delta H_2 + \Delta H_3 + \Delta H_4 + \Delta H_L$$

from which  $\Delta H_L$  can be found. It is named after the German physicist Max Born (1882–1970) and the chemist Fritz Haber.

**bornite** An important ore of copper composed of a mixed copper-iron sulphide,  $Cu_5FeS_4$ . Freshly exposed surfaces of the mineral are a metallic reddish-brown but a purplish iridescent tarnish soon develops – hence it is popularly known as **peacock ore**. Bornite is mined in Chile, Peru, Bolivia, Mexico, and the USA.

### Born–Oppenheimer approximation

An \*adiabatic approximation used in molecular and solid-state physics in which the motion of atomic nuclei is taken to be so much slower than the motion of electrons that, when calculating the motions of electrons, the nuclei can be taken to be in fixed positions. This approximation was justified using \*perturbation theory by Max Born and the US physicist Julius Robert Oppenheimer (1904–67) in 1927.

**borohydride ion** See BORANE.

**boron** Symbol B. An element of \*group 13 (formerly IIIB) of the periodic table; a.n. 5; r.a.m. 10.81; r.d. 2.34–2.37 (amorphous); m.p. 2300°C; b.p. 2550°C. It forms two allotropes; amorphous boron is a brown powder but metallic boron is black. The metallic form is very hard (9.3

on Mohs' scale) and is a poor electrical conductor at room temperature. At least three crystalline forms are possible; two are rhombohedral and the other tetragonal. The element is never found free in nature. It occurs as orthoboric acid in volcanic springs in Tuscany, as borates in kernite ( $Na_2B_4O_7 \cdot 4H_2O$ ), and as colemanite ( $Ca_2B_6O_{11} \cdot 5H_2O$ ) in California. Samples usually contain isotopes in the ratio of 19.78% boron-10 to 80.22% boron-11. Extraction is achieved by vapour-phase reduction of boron trichloride with hydrogen on electrically heated filaments. Amorphous boron can be obtained by reducing the trioxide with magnesium powder. Boron when heated reacts with oxygen, halogens, oxidizing acids, and hot alkalis. It is used in semiconductors and in filaments for specialized aerospace applications. Amorphous boron is used in flares, giving a green coloration. The isotope boron-10 is used in nuclear reactor control rods and shields. The element was discovered in 1808 by Sir Humphry Davy and by J. L. Gay-Lussac and L. J. Thenard.

**boron carbide** A black solid,  $B_4C$ , soluble only in fused alkali; it is extremely hard, over 9½ on Mohs' scale; rhombohedral; r.d. 2.52; m.p. 2350°C; b.p. >3500°C. Boron carbide is manufactured by the reduction of boric oxide with petroleum coke in an electric furnace. It is used largely as an abrasive, but objects can also be fabricated using high-temperature powder metallurgy. Boron nitride is also used as a neutron absorber because of its high proportion of boron-10.

**boron counter** A \*counter tube containing a **boron chamber**, used for counting slow neutrons. The boron chamber is lined with boron or a boron compound or is filled with the gas boron trifluoride ( $BF_3$ ). As natural boron contains about 18% of the isotope boron-10, and as this isotope absorbs neutrons with the emission of an alpha particle, the chamber can be coupled with a scaler to count the alpha particles emitted when neutrons enter the chamber.

**boron hydride** See BORANE.

**boron nitride** A solid, BN, insoluble in cold water and slowly decomposed by hot water; r.d. 2.25 (hexagonal); sublimes

above 3000°C. Boron nitride is manufactured by heating boron oxide to 800°C on an acid-soluble carrier, such as calcium phosphate, in the presence of nitrogen or ammonia. It is isoelectronic with carbon and, like carbon, it has a very hard cubic form (**borazon**) and a softer hexagonal form; unlike graphite this is a nonconductor. It is used in the electrical industries where its high thermal conductivity and high resistance are of especial value.

**boron trichloride** A colourless fuming liquid,  $\text{BCl}_3$ , which reacts with water to give hydrogen chloride and boric acid; r.d. 1.349; m.p.  $-107^\circ\text{C}$ ; b.p.  $12.5^\circ\text{C}$ . Boron trichloride is prepared industrially by the exothermic chlorination of boron carbide at above  $700^\circ\text{C}$ , followed by fractional distillation. An alternative, but more expensive, laboratory method is the reaction of dry chlorine with boron at high temperature. Boron trichloride is a Lewis  $\ast$ acid, forming stable addition compounds with such donors as ammonia and the amines and is used in the laboratory to promote reactions that liberate these donors. The compound is important industrially as a source of pure boron (reduction with hydrogen) for the electronics industry. It is also used for the preparation of boranes by reaction with metal hydrides.

**borosilicate** Any of a large number of substances in which  $\text{BO}_3$  and  $\text{SiO}_4$  units are linked to form networks with a wide range of structures. Borosilicate glasses are particularly important; the addition of boron to the silicate network enables the glass to be fused at lower temperatures than pure silica and also extends the plastic range of the glass. Thus such glasses as Pyrex have a wider range of applications than soda glasses (narrow plastic range, higher thermal expansion) or silica (much higher melting point). Borosilicates are also used in glazes and enamels and in the production of glass wools.

**Bosch, Carl** See BERGIUS, FRIEDRICH KARL RUDOLF; HABER PROCESS.

**Bosch process** See HABER PROCESS.

**Bose–Einstein condensation** A phenomenon occurring in a macroscopic system consisting of a large number of  $\ast$ bosons at a sufficiently low temperature,

in which a significant fraction of the particles occupy a single quantum state of lowest energy (the ground state). Bose–Einstein condensation can only take place for bosons whose total number is conserved in collisions. Because of the Pauli exclusion principle, it is impossible for two or more fermions to occupy the same quantum state, and so there is no analogous condensation phenomenon for such particles. Bose–Einstein condensation is of fundamental importance in explaining the phenomenon of  $\ast$ superfluidity. At very low temperatures (around  $2 \times 10^{-7}$  K) a Bose–Einstein condensate can form, in which several thousand atoms become a single entity (a **superatom**). This effect has been observed with atoms of rubidium and lithium and certain other atomic systems at very low temperature. The effect is named after the Indian physicist Satyendra Nath Bose (1894–1974) and Albert Einstein.

**Bose–Einstein statistics** See QUANTUM STATISTICS.

**boson** An  $\ast$ elementary particle (or bound state of an elementary particle, e.g. an atomic nucleus or an atom) with integral spin; i.e. a particle that conforms to Bose–Einstein statistics (see QUANTUM STATISTICS), from which it derives its name. Compare FERMION.

**botany** The scientific study of plants, including their anatomy, morphology, physiology, biochemistry, taxonomy, cytology, genetics, ecology, evolution, and geographical distribution.

**botulinum toxin** A nerve toxin produced by the bacterium *Clostridium botulinum*, which can cause fatal  $\ast$ food poisoning. It is the most toxic substance known. In minute doses it is used to treat certain conditions involving muscle dysfunction.

**boulder clay (till)** A mixture of rock and powdered rock formed beneath a moving glacier as it drags rocks beneath it. When the glacier subsequently melts, the boulder clay is left as a surface bed. Its components may be almost any type of rock in a wide range of sizes, from large angular boulders to tiny particles in clay. See also MORaine.

**boundary conditions** In the general solution of a \*differential equation, conditions that are imposed to allow the arbitrary constants to be determined. They thus permit a particular solution to be obtained.

**boundary layer** The thin layer of fluid formed around a solid body or surface relative to which the fluid is flowing. Adhesion between the molecules of the fluid and that of the body or surface causes the molecules of the fluid closest to the solid to be stationary relative to it. The transfer of heat or mass between a solid and a fluid flowing over it is largely controlled by the nature of the boundary layer.

**bound state** A system in which two (or more) parts are bound together in such a way that energy is required to split them. An example of a bound state is a \*molecule formed from two (or more) \*atoms.

**Bourdon gauge** A pressure gauge consisting essentially of a C-shaped or spiral tube with an oval cross section. One end of the tube is connected to the fluid whose pressure is to be measured and the other end is sealed. As the pressure inside the tube is increased, the oval tube tends to become circular and this causes the tube to straighten. The movement of the end of the tube is transferred by a simple mechanism to a needle moving round a dial or to a digital display. With suitable design, Bourdon gauges can be used for high-pressure measurement and also for low pressures. It was invented by Eugène Bourdon (1804–88).

**bovine spongiform encephalopathy (BSE)** A degenerative disease of the brain that affects cattle and is caused by an abnormal form of a cellular protein (see PRION). Known colloquially as 'mad cow disease', it results in a build-up of fibrous tissue in the brain. The infective agent can be transmitted to other cattle via feed containing offal derived from infected animals. It can also, under certain circumstances, be transmitted to other species. See also CREUTZFELDT-JAKOB DISEASE.

**Bowman's capsule (renal capsule)** The cup-shaped end of a kidney \*nephron. Its epithelium contains **podocytes**, cells that facilitate the passage of glomerular filtrate

from the blood into the nephron. It is named after its discoverer, the British physician Sir William Bowman (1816–92).

**Boyle, Robert** (1627–91) English chemist and physicist, born in Ireland. After moving to Oxford in 1654 he worked on gases, using an air pump made by Robert \*Hooke. With it he proved that sound does not travel in a vacuum. In 1662 he discovered \*Boyle's law. In chemistry he worked on \*flame tests and acid-base \*indicators.

**Boyle's law** The volume ( $V$ ) of a given mass of gas at a constant temperature is inversely proportional to its pressure ( $p$ ), i.e.  $pV = \text{constant}$ . This is true only for an \*ideal gas. This law was discovered in 1662 by Robert Boyle. On the continent of Europe it is known as **Mariotte's law** after E. Mariotte (1620–84), who discovered it independently in 1676. See also GAS LAWS.

**bp** See BASE PAIR.

**Brackett series** See HYDROGEN SPECTRUM.

**bract** A modified leaf with a flower or inflorescence in its axil. Bracts are often brightly coloured and may be mistaken for the petals of a flower. For example the showy 'flowers' of poinsettia and *Bougainvillea* are composed of bracts; the true flowers are comparatively inconspicuous. See also INVOLUCRE.

**bracteole** A reduced leaf that arises from the stalk of an individual flower.

**bradykinin** See KININ.

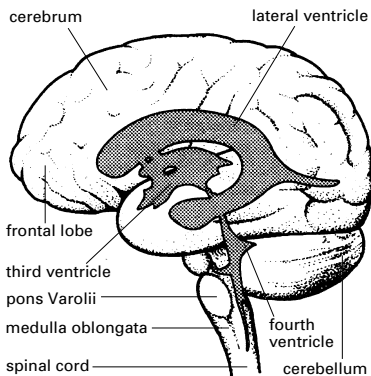

**Bragg, Sir William Henry** (1862–1942) British physicist, who with his son **Sir (William) Lawrence Bragg** (1890–1971) was awarded the 1915 Nobel Prize for physics for their pioneering work on \*X-ray crystallography. He also constructed an X-ray spectrometer for measuring the wavelengths of X-rays. In the 1920s, while director of the Royal Institution in London, he initiated X-ray diffraction studies of organic molecules.

**Bragg's law** When a beam of X-rays (wavelength  $\lambda$ ) strikes a crystal surface in which the layers of atoms or ions are separated by a distance  $d$ , the maximum intensity of the reflected ray occurs when

$\sin\theta = n\lambda/2d$ , where  $\theta$  (known as the **Bragg angle**) is the complement of the angle of incidence and  $n$  is an integer. The law enables the structure of many crystals to be determined. It was discovered in 1912 by Sir Lawrence Bragg.

**Brahe, Tycho** (1546–1601) Danish astronomer. After briefly studying law he turned to astronomy. He studied the nova of 1572 ('Tycho's star') and showed that it was a fixed star. In 1577 he moved to his own observatory on Hven Island (financed by King Frederick II), where without the benefit of a telescope he charted the positions of 777 stars. In 1599 he moved to Prague, with \*Kepler as his assistant.

**brain 1.** The enlarged anterior part of the vertebrate central nervous system, which is encased within the cranium of the skull. Continuous with the spinal cord, the brain is surrounded by three membranes (see MENINGES) and bathed in cerebrospinal fluid, which fills internal cavities (\*ventricles). It functions as the main coordinating centre for nervous activity, receiving information (in the form of nerve impulses) from sense organs, interpreting it, and transmitting 'instructions' to muscles and other \*effectors. It is also the seat of intelligence and memory. The embryonic vertebrate brain is in three sections (see FOREBRAIN; HINDBRAIN; MIDBRAIN), which become further differentiated during development into specialized regions. The main parts of the adult human brain are a highly developed \*cer-

The human brain

ebrium in the form of two cerebral hemispheres, a \*cerebellum, \*medulla oblongata, and \*hypothalamus (see illustration).  
**2.** A concentration of nerve \*ganglia at the anterior end of an invertebrate animal.

**brain death** The permanent absence of vital functions of the brain, which is marked by cessation of breathing and other reflexes controlled by the \*brainstem and by a zero reading on an \*electroencephalogram. Organs may be removed for transplantation when brain death is established, which may not necessarily be associated with permanent absence of heart beat.

**brainstem** The part of the brain comprising the \*medulla oblongata, the \*midbrain, and the \*pons. It resembles and is continuous with the spinal cord. The midbrain controls and integrates reflex activities (such as respiration) that originate in higher centres of the brain via a network of nerve pathways (the **reticular formation**).

**branched chain** See CHAIN.

**brass** A group of alloys consisting of copper and zinc. A typical yellow brass might contain about 67% copper and 33% zinc. See also DELTA BRASS.

**Brattain, Walter** See BARDEEN, JOHN.

**Braun, Karl Ferdinand** (1850–1918) German physicist, who became professor of physics at Strasbourg in 1895. In the early 1900s he used crystals as diodes (later employed in crystal-set radios) and developed the \*cathode-ray tube for use as an oscilloscope. He also worked on radio and in 1909 shared the Nobel Prize for physics with \*Marconi.

**breakdown** The sudden passage of a current through an insulator. The voltage at which this occurs is the **breakdown voltage**.

**breaking stress** See ELASTICITY.

**breathing** See EXPIRATION; INSPIRATION; RESPIRATORY MOVEMENT.

**breed** A domesticated \*variety of an animal or, rarely, a cultivated variety of plant (cultivated plants are usually called varieties or, more correctly, \*cultivars). Exam-

ples of animal breeds are Friesian cattle and Shetland sheepdogs.

**breeder reactor** See NUCLEAR REACTOR.

**breeding** The process of sexual \*reproduction and bearing offspring. **Selective breeding** of both plants and animals is used in \*agriculture to produce offspring that possess the beneficial characters of both parents (see also ARTIFICIAL INSEMINATION). \*Inbreeding is the production of \*homozygous phenotypically uniform offspring by mating between close relatives. Plants that self-fertilize, such as wheat and tomatoes, are inbreeders. \*Outbreeding is the production of \*heterozygous phenotypically variable offspring by mating between unrelated organisms.

**breeding season** A specific season of the year in which many animals, including mammals and birds, mate, which ensures that offspring are produced only at a certain time of the year. This timing is important as it enables animals to give birth at a time of the year when environmental conditions and food supply are at their optimum. The breeding season of most animals is in the spring or summer. The stimulus to mate is the result of a photoperiodic response (see PHOTOPERIODISM), which is thought to be controlled by day length.

**Bremsstrahlung** (German: braking radiation) The X-rays emitted when a charged particle, especially a fast electron, is rapidly slowed down, as when it passes through the electric field around an atomic nucleus. The X-rays cover a whole continuous range of wavelengths down to a minimum value, which depends on the energy of the incident particles. Bremsstrahlung are produced by a metal target when it is bombarded by electrons.

**brewing** The process by which beer is made. Fermentation of sugars from barley grain by the yeasts \**Saccharomyces cerevisiae* and *S. uvarum* (or *S. carlsbergensis*) produces alcohol. In the first stage the barley grain is soaked in water, a process known as **malting**. The grain is then allowed to germinate and the natural enzymes of the grain (the amylases and the maltases) convert the starch to maltose and then to glucose. The next stage is **kilning** or **roasting**,

in which the grains are dried and crushed. The colour of a beer depends on the temperature used for this process: the higher the temperature, the darker the beer. In the next stage, **mashing**, the crushed grain is added to water at a specific temperature and any remaining starch is converted to sugar; the resultant liquid is the raw material of brewing, called **wort**. The yeast is then added to the wort to convert the sugar to alcohol, followed by hops, which give beer its characteristic flavour. Hops are the female flowers of the vine *Humulus lupulus*; they contain resins (humulones, cohumulones, and adhumulones) that give beer its distinctive bitter taste.

**Brewster's law** The extent of the polarization of light reflected from a transparent surface is a maximum when the reflected ray is at right angles to the refracted ray. The angle of incidence (and reflection) at which this maximum polarization occurs is called the **Brewster angle** or **polarizing angle**. For this angle  $i_B$ , the condition is that  $\tan i_B = n$ , where  $n$  is the refractive index of the transparent medium. The law was discovered in 1811 by the British physicist David Brewster (1781–1868).

**bridge 1.** (in chemistry) An atom or group joining two other atoms in a molecule. See ALUMINIUM CHLORIDE; BORANE.

**2.** (in physics) a type of electrical circuit in which four components are linked in a square, with inputs and outputs at pairs of opposite corners. See WHEATSTONE BRIDGE.

**bridge rectifier** See RECTIFIER.

**brighteners** Substances added to detergents or used to treat textiles or paper in order to brighten the colours or, particularly, to enhance whiteness. Blueing agents are used in laundries to give a slight blue cast to white material in order to counteract yellowing. Fluorescent brighteners are compounds that absorb visible or ultraviolet radiation and fluoresce in the blue region of the optical spectrum.

**Brinell hardness** A scale for measuring the hardness of metals introduced around 1900 by the Swedish metallurgist Johann

Brinell (1849–1925). A small chromium-steel ball is pressed into the surface of the metal by a load of known weight. The ratio of the mass of the load in kilograms to the area of the depression formed in square millimetres is the **Brinell number**.

**Brin process** A process formerly used for making oxygen by heating barium oxide in air to form the peroxide and then heating the peroxide at higher temperature (>800°C) to produce oxygen

**Britannia metal** A silvery alloy consisting of 80–90% tin, 5–15% antimony, and sometimes small percentages of copper, lead, and zinc. It is used in bearings and some domestic articles.

**British thermal unit (Btu)** The Imperial unit of heat, being originally the heat required to raise the temperature of 1 lb of water by 1°F. 1 Btu is now defined as 1055.06 joules.

**broadband** Communication by a system that supports a wide range of frequencies, so that identical messages can be carried simultaneously. *See also* ADSL.

**broken symmetry** A situation in which the lowest-energy state of a many-body system or \*vacuum state of a relativistic \*quantum field theory has a lower symmetry than the equations defining the system. Examples in solid-state physics include ferromagnetism, antiferromagnetism, and superconductivity. In particle physics, the Weinberg–Salam model (*see* ELECTROWEAK THEORY) is an important example of a relativistic quantum field theory with broken symmetry.

A result associated with broken symmetry is **Goldstone's theorem**. This states that a relativistic quantum field theory having continuous symmetry that is broken must include the existence of massless particles called **Goldstone bosons**. In many-body theory Goldstone bosons are \*collective excitations. An exception to Goldstone's theorem is provided in the case of broken \*gauge theories, such as the Weinberg–Salam model, in which the Goldstone bosons become massive bosons known as \*Higgs bosons. In many-body theory, long-range forces provide the anal-

ogous exception to Goldstone's theorem, with the Higgs bosons being excitations with a nonzero gap.

**bromate** A salt or ester of a bromic acid.

**bromic(I) acid (hypobromous acid)** A yellow liquid, HBrO. It is a weak acid and a strong oxidizing agent.

**bromic(V) acid** A colourless liquid, HBrO<sub>3</sub>, made by adding sulphuric acid to barium bromate. It is a strong acid.

**bromide** *See* HALIDE.

**bromination** A chemical reaction in which a bromine atom is introduced into a molecule. *See also* HALOGENATION.

**bromine** Symbol Br. A \*halogen element; a.n. 35; r.a.m. 79.909; r.d. 3.13; m.p. -7.2°C; b.p. 58.78°C. It is a red volatile liquid at room temperature, having a red-brown vapour. Bromine is obtained from brines in the USA (displacement with chlorine); a small amount is obtained from sea water in Anglesey. Large quantities are used to make 1,2-dibromoethane as a petrol additive. It is also used in the manufacture of many other compounds. Chemically, it is intermediate in reactivity between chlorine and iodine. It forms compounds in which it has oxidation states of 1, 3, 5, or 7. The liquid is harmful to human tissue and the vapour irritates the eyes and throat. The element was discovered in 1826 by Antoine Balard.

**bromoethane (ethyl bromide)** A colourless flammable liquid, C<sub>2</sub>H<sub>5</sub>Br; r.d. 1.46; m.p. -119°C; b.p. 38.4°C. It is a typical \*haloalkane, which can be prepared from ethene and hydrogen bromide. Bromoethane is used as a refrigerant.

**bromoform** *See* TRIBROMOMETHANE; HALOFORMS.

**bromomethane (methyl bromide)** A colourless volatile nonflammable liquid, CH<sub>3</sub>Br; r.d. 1.68; m.p. -93°C; b.p. 3.56°C. It is a typical \*haloalkane.

**bromothymol blue** An acid-base \*indicator that is yellow in acid solutions and blue in alkaline solutions. It changes colour over the pH range 6–8.

**bronchiole** A fine respiratory tube in

the lungs of reptiles, birds, and mammals. It is formed by the subdivision of a \*bronchus and in reptiles and mammals it terminates in a number of \*alveoli.

**bronchus (bronchial tube)** One of the major air tubes in the \*lung. The \*trachea divides into two main bronchi, one for each lung, which split into smaller bronchi and then into \*bronchioles. The walls of the bronchi are stiffened by rings of cartilage.

**bronze** Any of a group of alloys of copper and tin, sometimes with lead and zinc present. The amount of tin varies from 1% to 30%. The alloy is hard and easily cast and extensively used in bearings, valves, and other machine parts. Various improved bronzes are produced by adding other elements; for instance, **phosphor bronzes** contain up to 1% phosphorus. In addition certain alloys of copper and metals other than tin are called bronzes – **aluminium bronze** is a mixture of copper and aluminium. Other special bronzes include \*bell metal, \*gun metal, and \*beryllium bronze.

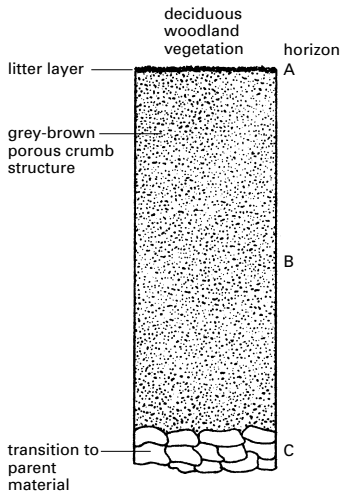

**Brown, Robert** (1773–1858) British botanist, born in Scotland. After serving as an army medical officer he met botanist Joseph Banks (1743–1820) in 1798. Three years later Banks recommended him as naturalist on a survey of the Australian coast, during which he collected 4000 plant specimens; it took him five years to classify them. During this work he was the first to distinguish between gymnosperms and angiosperms. Then in 1827, while observing pollen grains in water, he discovered \*Brownian movement.

**brown algae** See PHAEOPHYTA.

**brown dwarf** An astronomical object with a mass intermediate between the mass of a planet and that of a small star. The mass of a brown dwarf is large enough to generate energy by gravitational pressure, but not large enough to sustain nuclear fusion. The energy is radiated as electromagnetic radiation. Brown dwarfs are faint objects, which are expected to shine for about 100 million years before cooling. Their masses lie between a few times the mass of Jupiter and

80 times the mass of Jupiter. It has been suggested that brown dwarfs may contribute to the \*missing mass of the universe.

**brown earth (brown forest soil)** A type of soil that is characteristic of those mid-latitude parts of the world that were originally covered with deciduous woodland. It is rich in organic matter derived from the annual leaf fall of deciduous trees and from associated shrubs, herbs, and grasses. Brown earths occur in the NE USA, N China, central Japan, and NW and central Europe. They are important agriculturally, possessing a good crumb structure, mild acidity, and free drainage, and consequently most of the original forest has long since been cleared for agricultural use.

Brown earth profile

**brown fat** A darker coloured region of \*adipose tissue found in newborn and hibernating animals (in which it may also be called the **hibernating gland**). Compared to normal white \*fat, deposits of brown fat are more richly supplied with blood vessels and have numerous mitochondria (hence the brown colour, due to the high concentrations of cytochrome oxidase). They can also be more rapidly converted to heat energy – a process that

takes place in the fat cells themselves – especially during arousal from hibernation and during cold stress in young animals. Since the deposits are strategically placed near major blood vessels, the heat they generate warms the blood returning to the heart. Some types of obesity in humans may be linked to a lack of brown fat in affected individuals. See THERMOGENESIS.

**Brownian movement** The continuous random movement of microscopic solid particles (of about 1 micrometre in diameter) when suspended in a fluid medium. First observed by Robert Brown in 1827 when studying pollen grains in water, it was originally thought to be the manifestation of some vital force. It was later recognized to be a consequence of bombardment of the pollen by the continually moving molecules of the liquid. The smaller the particles the more extensive is the motion. The effect is also visible in particles of smoke suspended in a still gas and in the material of dead cells.

**brown-ring test** A test for ionic nitrates. The sample is dissolved and iron(II) sulphate solution added in a test tube. Concentrated sulphuric acid is then added slowly so that it forms a separate layer. A brown ring (of  $\text{Fe(NO)SO}_4$ ) at the junction of the liquids indicates a positive result.

**brucite** A mineral form of \*magnesium hydroxide,  $\text{Mg(OH)}_2$ .

**brush** An electrical contact to a moving commutator on a motor or generator. It is made of a specially prepared form of carbon and is kept in contact with the moving part by means of a spring.

**brush border** A region of surface epithelium that possesses densely packed microvilli (see MICROVILLUS), rather like the bristles of a brush. This greatly increases the surface area of the epithelium and facilitates the absorption of materials. Brush borders are found in the convoluted tubules of the kidney and in the lining of the small intestine.

**brush discharge** A luminous discharge from a conductor that takes the form of luminous branching threads that penetrate into the surrounding gas. It is a form of \*corona and it occurs when the

electric field near the surface of the conductor exceeds a certain value but is not sufficiently high for a spark to appear.

**brusselator** A type of chemical reaction mechanism that leads to an \*oscillating reaction. It involves the conversion of reactants A and B into products C and B by a series of four steps:

Autocatalysis occurs as in the \*Lotka–Volterra mechanism and the \*oregonator. If the concentrations of A and B are maintained constant, the concentrations of X and Y oscillate with time. A graph of the concentration of X against that of Y is a closed loop (the **limit cycle** of the reaction). The reaction settles down to this limit cycle whatever the initial concentrations of X and Y, i.e. the limit cycle is an **attractor** for the system. The reaction mechanism is named after the city of Brussels, where the research group that discovered it is based.

**Bryophyta** A phylum of simple plants – the mosses – possessing no vascular tissue and rudimentary rootlike organs (rhizoids). They grow in a variety of damp habitats, from fresh water to rock surfaces. Some use other plants for support. Mosses show a marked \*alternation of generations between gamete-bearing forms (gametophytes) and spore-bearing forms (sporophytes): they possess erect or prostrate leafy stems (the gametophyte generation, which is \*haploid); these give rise to leafless stalks bearing capsules (the sporophyte generation, which is \*diploid), the latter being dependent on the former for water and nutrients. Spores formed in the capsules are released and grow to produce new plants.

Formerly, this phylum also included the liverworts (see HEPATOPHYTA) and the mosses were classified as a class (Musci) of the Bryophyta. The term ‘bryophytes’ is still used informally to refer to both the mosses and the liverworts.

**Bryozoa (Ectoprocta)** A phylum of aquatic, mainly marine, invertebrates –

the moss animals and sea mats. They live in colonies, 50 cm or more across, which are attached to rocks, seaweeds, or shells. The individuals making up the colonies are about 1 mm long and superficially resemble cnidarian \*polyps, with a mouth surrounded by ciliated tentacles that trap minute particles of organic matter in the water. Some have a horny or calcareous outer skeleton into which the body can be withdrawn.

**BSE** See BOVINE SPONGIFORM ENCEPHALOPATHY.

**bubble chamber** A device for detecting ionizing radiation. It consists of a chamber containing a liquid, often hydrogen, kept at slightly above its boiling point at a preliminary pressure that is high enough to prevent boiling. Immediately before the passage of the ionizing particles the pressure is reduced, and the particles then act as centres for the formation of bubbles, which can be photographed to obtain a record of the particles' tracks. The device was invented in 1952 by Donald Glaser. Compare CLOUD CHAMBER.

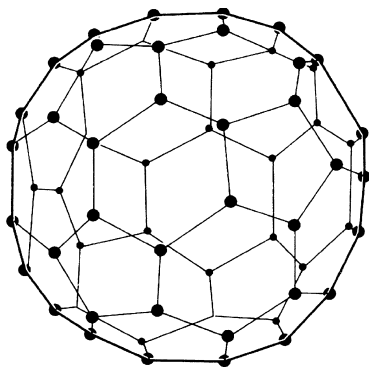

**buccal cavity (oral cavity)** The mouth cavity: the beginning of the \*alimentary canal, which leads to the pharynx and (in vertebrates) to the oesophagus. In vertebrates it is separated from the nasal cavity by the \*palate. In mammals it contains the tongue and teeth, which assist in the mechanical breakdown of food, and the openings of the \*salivary gland ducts.

**Buchner funnel** A type of funnel with an internal perforated tray on which a flat circular filter paper can be placed, used for filtering by suction. It is named after the German chemist Eduard Buchner (1860–1917).

**buckminsterfullerene** A form of carbon composed of clusters of 60 carbon atoms bonded together in a polyhedral structure composed of pentagons and hexagons (see illustration). Originally it was identified in 1985 in products obtained by firing a high-power laser at a graphite target. It can be made by an electric arc struck between graphite electrodes in an inert atmosphere. The molecule,  $C_{60}$ , was named after the US architect Richard Buckminster Fuller

(1895–1983) because of the resemblance of the structure to the geodesic dome, which Fuller invented. The molecules are informally called **buckyballs**; more formally, the substance itself is also called **fullerene**. The substance is a yellow crystalline solid (**fullerite**), soluble in benzene.

Various fullerene derivatives are known in which organic groups are attached to carbon atoms on the sphere. In addition, it is possible to produce novel enclosure compounds by trapping metal ions within the  $C_{60}$  cage. Some of these have semiconducting properties. The electric-arc method of producing  $C_{60}$  also leads to a smaller number of fullerenes such as  $C_{70}$ , which have less symmetrical molecular structures. It is also possible to produce forms of carbon in which the atoms are linked in a cylindrical, rather than spherical, framework with a diameter of a few nanometres. They are known as **buckytubes** (or **nanotubes**).

Buckminsterfullerene structure

**buckyball** See BUCKMINSTERFULLERENE.

**buckytube** See BUCKMINSTERFULLERENE.

**bud 1.** (in botany) A condensed immature shoot with a short stem bearing small folded or rolled leaves. The outer leaves of a bud are often scalelike and protect the delicate inner leaves. A **terminal** (or **apical**) **bud** exists at the tip of a stem or branch while **axillary** (or **lateral**) **buds** develop in the \*axils of leaves. However, in certain circumstances buds can be produced anywhere on the surface of a plant.

Some buds remain dormant, but may become active if the terminal bud is removed. It is common gardening practice to remove the terminal buds of some shoots to induce the development of lateral shoots from axillary buds. *See also* APICAL DOMINANCE. **2.** (in biology) An outgrowth from a parent organism that breaks away and develops into a new individual in the process of \*budding.

**budding 1.** (in biology) A method of asexual reproduction in which a new individual is derived from an outgrowth (**bud**) that becomes detached from the body of the parent. In animals the process is also called **gemmation**; it is common in cnidarians (e.g. *Hydra*) and also occurs in some sponges and other invertebrates. Among fungi, budding is characteristic of the yeasts. **2.** (in horticulture) A method of grafting in which a bud of the scion is inserted onto the stock, usually beneath the bark.

**buffer** A solution that resists change in pH when an acid or alkali is added or when the solution is diluted. Acidic buffers consist of a weak acid with a salt of the acid. The salt provides the negative ion  $A^-$ , which is the conjugate base of the acid HA. An example is carbonic acid and sodium hydrogencarbonate. Basic buffers have a weak base and a salt of the base (to provide the conjugate acid). An example is ammonia solution with ammonium chloride.

In an acidic buffer, for example, molecules HA and ions  $A^-$  are present. When acid is added most of the extra protons are removed by the base:

When base is added, most of the extra hydroxide ions are removed by reaction with undissociated acid:

Thus, the addition of acid or base changes the pH very little. The hydrogen-ion concentration in a buffer is given by the expression

$$K_a = [H^+] = [A^-]/[HA]$$

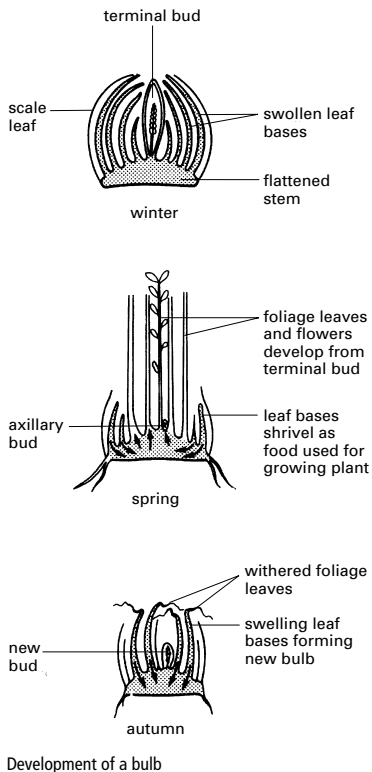

i.e. it depends on the ratio of conjugate base to acid. As this is not altered by dilution, the hydrogen-ion concentration for a

buffer does not change much during dilution.

In the laboratory, buffers are used to prepare solutions of known stable pH. Natural buffers occur in living organisms, where the biochemical reactions are very sensitive to change in pH (*see* ACID-BASE BALANCE). The main natural buffers are  $H_2CO_3/HCO_3^-$  and  $H_2PO_4^-/HPO_4^{2-}$ . Buffer solutions are also used in medicine (e.g. in intravenous injections), in agriculture, and in many industrial processes (e.g. dyeing, fermentation processes, and the food industry).

**bugs** *See* HEMIPTERA.

**bulb** An underground plant organ that enables a plant to survive from one growing season to the next. It is a modified shoot with a short flattened stem. A termi-

b

nal bud develops at the centre of its upper surface, surrounded by swollen leaf bases that contain food stored from the previous growing season. Papery brown scale leaves cover the outside of the bulb. The stored food is used in the growing season when the terminal bud produces foliage leaves and flowers. The new leaves photosynthesize and some of the manufactured food passes into the leaf bases forming a new bulb (see illustration). If more than one bud develops, then additional bulbs form, resulting in vegetative propagation. Examples of bulb-forming plants are daffodil, onion, and tulip. *Compare* CORM.

**bulbil** A small bulblike organ that may develop in place of a flower, from an axillary bud, or at the base of a stem in certain plants. If it becomes detached it develops into a new plant.

**bulk modulus** *See* ELASTIC MODULUS.

**bullae** The rounded hollow projection of bone from the skull that encloses the \*middle ear in mammals.

**bumping** Violent boiling of a liquid caused by superheating so that bubbles form at a pressure above atmospheric pressure. It can be prevented by putting pieces of porous pot in the liquid to enable bubbles of vapour to form at the normal boiling point.

**bundle of His** The specialized cardiac muscle fibres in the mammalian heart that receive electrical stimuli from the \*atrioventricular node and transmit them throughout the network of \*Purkyne fibres. This allows the excitation to reach all parts of the ventricles rapidly and initiates a wave of contraction to expel blood into the aorta and pulmonary artery. It is named after Wilhelm His (1831–1904).

**Bunsen, Robert Wilhelm** (1811–99) German chemist, who held professorships at Kassel, Marburg, and Heidelberg. His early researches on arsenic-containing compounds cost him an eye in an explosion. He then turned to gas analysis and spectroscopy, enabling him and \*Kirchhoff to discover the elements \*caesium (1860) and \*rubidium (1861). He also popularized the use of the \*Bunsen burner.

**Bunsen burner** A laboratory gas burner

having a vertical metal tube into which the gas is led, with a hole in the side of the base of the tube to admit air. The amount of air can be regulated by a sleeve on the tube. When no air is admitted the flame is luminous and smoky. With air, it has a faintly visible hot outer part (the oxidizing part) and an inner blue cone where combustion is incomplete (the cooler reducing part of the flame). The device is named after Robert Bunsen, who used a similar device (without a regulating sleeve) in 1855.

**Bunsen cell** A \*primary cell consisting of a zinc cathode immersed in dilute sulphuric acid and a carbon anode immersed in concentrated nitric acid. The electrolytes are separated by a porous pot. The cell gives an e.m.f. of about 1.9 volts.

**buoyancy** The upward thrust on a body immersed in a fluid. This force is equal to the weight of the fluid displaced (*see* ARCHIMEDES' PRINCIPLE).

**burette** A graduated glass tube with a tap at one end leading to a fine outlet tube, used for delivering known volumes of a liquid (e.g. in titration).

**Burnet, Sir Frank Macfarlane** (1899–1985) Australian virologist, who spent his working life at the Walter and Eliza Hall Institute in Melbourne. In the early 1930s he developed a method of growing influenza virus in chick embryos. He later discovered that immunological tolerance (failure of the immune response) required repeated exposure to the antigen. For this work he shared the 1960 Nobel Prize for physiology or medicine with Sir Peter \*Medawar. He also proposed the \*clonal selection theory.

**bus** A set of conducting paths – wires or optical fibres – connecting several components of a computer system and allowing the components to send signals to each other. The components take it in turns to transmit.

**buta-1,3-diene (butadiene)** A colourless gaseous hydrocarbon,  $\text{CH}_2\text{=CHCH=CH}_2$ ; m.p.  $-109^\circ\text{C}$ ; b.p.  $-4.5^\circ\text{C}$ . It is made by catalytic dehydrogenation of butane (from petroleum or natural gas) and polymerized in the production of synthetic rubbers. The compound is a conjugated

\*diene in which the electrons in the pi orbitals are partially delocalized over the whole molecule. It can have trans and cis forms, the latter taking part in \*Diels-Alder reactions.

**butanal (butyraldehyde)** A colourless flammable liquid aldehyde,  $C_3H_7CHO$ ; r.d. 0.8; m.p.  $-99^\circ C$ ; b.p.  $75.7^\circ C$ .

**butane** A gaseous hydrocarbon,  $C_4H_{10}$ ; d.  $0.58 \text{ g cm}^{-3}$ ; m.p.  $-138^\circ C$ ; b.p.  $0^\circ C$ . Butane is obtained from petroleum (from refinery gas or by cracking higher hydrocarbons). The fourth member of the \*alkane series, it has a straight chain of carbon atoms and is isomeric with 2-methylpropane ( $CH_3CH(CH_3)CH_3$ , formerly called **isobutane**). It can easily be liquefied under pressure and is supplied in cylinders for use as a fuel gas. It is also a raw material for making buta-1,3-diene (for synthetic rubber).

**butanedioic acid (succinic acid)** A colourless crystalline fatty acid,  $(CH_2)_2(COOH)_2$ ; r.d. 1.6; m.p.  $185^\circ C$ ; b.p.  $235^\circ C$ . A weak carboxylic acid, it is produced by fermentation of sugar or ammonium tartrate and used as a sequestrant and in making dyes. It occurs in living organisms as an intermediate in metabolism, especially in the \*Krebs cycle.

**butanoic acid (butyric acid)** A colourless liquid water-soluble acid,  $C_3H_7COOH$ ; r.d. 0.96; b.p.  $163^\circ C$ . It is a weak acid ( $K_a = 1.5 \times 10^{-5} \text{ mol dm}^{-3}$  at  $25^\circ C$ ) with a rancid odour. Its esters are present in butter and in human perspiration. The acid is used to make esters for flavourings and perfumery.

**butanol** Either of two aliphatic alcohols with the formula  $C_4H_9OH$ . **Butan-1-ol**,  $CH_3(CH_2)_3OH$ , is a primary alcohol; r.d. 0.81; m.p.  $-89.5^\circ C$ ; b.p.  $117.3^\circ C$ . **Butan-2-ol**,  $CH_3CH(OH)C_2H_5$ , is a secondary alcohol; r.d. 0.81; m.p.  $-114.7^\circ C$ ; b.p.  $100^\circ C$ . Both are colourless volatile liquids obtained from butane and are used as solvents.

**butanone (methyl ethyl ketone)** A colourless flammable water-soluble liquid,  $CH_3COC_2H_5$ ; r.d. 0.8; m.p.  $-86.4^\circ C$ ; b.p.  $79.6^\circ C$ . It can be made by the catalytic oxidation of butane and is used as a solvent.

**butenedioic acid** Either of two isomers with the formula  $HCOOH:CHCOOH$ . Both compounds can be regarded as derivatives of ethene in which a hydrogen atom on each carbon has been replaced by a  $-COOH$  group. The compounds show cis-trans isomerism. The trans form is **fumaric acid** (r.d. 1.64; sublimates at  $165^\circ C$ ) and the cis form is **maleic acid** (r.d. 1.59; m.p.  $139-140^\circ C$ ). Both are colourless crystalline compounds used in making synthetic resins. The cis form is rather less stable than the trans form and converts to the trans form at  $120^\circ C$ . Unlike the trans form it can eliminate water on heating to form a cyclic anhydride containing a  $-CO.O.CO-$  group (**maleic anhydride**). Fumaric acid is an intermediate in the \*Krebs cycle.

**butterflies** See LEPIDOPTERA.

**butterfly effect** See CHAOS.

**buttress root** See PROP ROOT.

**butyl group** The organic group  $CH_3(CH_2)_3-$ .

**butyl rubber** A type of synthetic rubber obtained by copolymerizing 2-methylpropene ( $CH_2:C(CH_3)CH_3$ ; isobutylene) and methylbuta-1,3-diene ( $CH_2:C(CH_3)CH:CH_2$ , isoprene). Only small amounts of isoprene (about 2 mole %) are used. The rubber can be vulcanized. Large amounts were once used for tyre inner tubes.

**butyraldehyde** See BUTANAL.

**butyric acid** See BUTANOIC ACID.

**Buys Ballot's law** A law relating to winds stating that observers with their backs to the wind will experience a lower pressure on the left than on the right in the northern hemisphere, and lower on the right than on the left in the southern hemisphere. The law was propounded by the Dutch meteorologist Christoph Buys Ballot (1817-90) in 1857.

**by-product** A compound formed during a chemical reaction at the same time as the main product. Commercially useful by-products are obtained from a number of industrial processes. For example, calcium chloride is a by-product of the \*Solvay process for making sodium car-

bonate. Propanone is a by-product in the manufacture of \*phenol.

b

**byte** A subdivision of a \*word in a computer, it usually consists of eight \*bits. A kilobyte is 1024 bytes (not 1000 bytes).

**B-Z reaction (Belousov-Zhabotinskii reaction)** A chemical reaction that shows a periodic colour change between magenta and blue with a period of about one minute. It occurs with a mixture of sulphuric acid, potassium bromate(V),

cerium sulphate, and propanedioic acid. The colour change is caused by alternating oxidation-reductions in which cerium changes its oxidation state ( $\text{Ce}^{3+}$  gives a magenta solution while  $\text{Ce}^{4+}$  gives a blue solution). The B-Z reaction is an example of a chemical \*oscillating reaction - a reaction in which there is a regular periodic change in the concentration of one or more reactants. The mechanism is highly complicated, involving a large number of steps. See BRUSSELATOR.

**C** A high-level general-purpose computer language developed in 1972. It is fast and can be used as an alternative to assembly language, with which it shares some features. It was superseded in the mid-1980s by an object-oriented version known as C++, which is better suited to the design of modular programs.

**cadmium** Symbol Cd. A soft bluish metal belonging to \*group 12 (formerly IIB) of the periodic table; a.n. 48; r.a.m. 112.41; r.d. 8.65; m.p. 320.9°C; b.p. 765°C. The element's name is derived from the ancient name for calamine, zinc carbonate  $ZnCO_3$ , and it is usually found associated with zinc ores, such as sphalerite (ZnS), but does occur as the mineral greenockite (CdS). Cadmium is usually produced as an associate product when zinc, copper, and lead ores are reduced. Cadmium is used in low-melting-point alloys to make solders, in Ni-Cd batteries, in bearing alloys, and in electroplating (over 50%). Cadmium compounds are used as phosphorescent coatings in TV tubes. Cadmium and its compounds are extremely toxic at low concentrations; great care is essential where solders are used or where fumes are emitted. It has similar chemical properties to zinc but shows a greater tendency towards complex formation. The element was discovered in 1817 by F. Stromeyer.

**cadmium cell** See WESTON CELL.

**cadmium sulphide** A water-insoluble compound, CdS; r.d. 4.82. It occurs naturally as the mineral **greenockite** and is used as a pigment and in semiconductors and fluorescent materials.

**caecum** A pouch in the alimentary canal of vertebrates between the \*small intestine and \*colon. The caecum (and its \*appendix) is large and highly developed in herbivorous animals (e.g. rabbits and cows), in which it contains a large population of bacteria essential for the break-

down of cellulose. In humans the caecum is a \*vestigial organ and is poorly developed.

**caesium** Symbol Cs. A soft silvery-white metallic element belonging to \*group 1 (formerly IA) of the periodic table; a.n. 55; r.a.m. 132.905; r.d. 1.88; m.p. 28.4°C; b.p. 678°C. It occurs in small amounts in a number of minerals, the main source being carnallite ( $KCl.MgCl_2.6H_2O$ ). It is obtained by electrolysis of molten caesium cyanide. The natural isotope is caesium-133. There are 15 other radioactive isotopes. Caesium-137 (half-life 33 years) is used as a gamma source. As the heaviest alkali metal, caesium has the lowest ionization potential of all elements, hence its use in photoelectric cells, etc.

**caesium clock** An \*atomic clock that depends on the energy difference between two states of the caesium-133 nucleus when it is in a magnetic field. In one type, atoms of caesium-133 are irradiated with \*radio-frequency radiation, whose frequency is chosen to correspond to the energy difference between the two states. Some caesium nuclei absorb this radiation and are excited to the higher state. These atoms are deflected by a further magnetic field, which causes them to hit a detector. A signal from this detector is fed back to the radio-frequency oscillator to prevent it drifting from the resonant frequency of 9 192 631 770 hertz. In this way the device is locked to this frequency with an accuracy better than 1 part in  $10^{13}$ . The caesium clock is used in the \*SI unit definition of the second.

**cage compound** See CLATHRATE.

**Cainozoic** See CENOZOIC.

**calciferol** See VITAMIN D.

**calcination** The formation of a calcium carbonate deposit from hard water. See HARDNESS OF WATER.

**calcinite** A mineral form of \*potassium hydrogencarbonate,  $\text{KHCO}_3$ .

**calcite** One of the most common and widespread minerals, consisting of crystalline calcium carbonate,  $\text{CaCO}_3$ . Calcite crystallizes in the rhombohedral system; it is usually colourless or white and has a hardness of 3 on the Mohs' scale. It has the property of double refraction, which is apparent in Iceland spar – the transparent variety of calcite. It is an important rock-forming mineral and is a major constituent in limestones, marbles, and carbonatites.

**calcitonin (thyrocalcitonin)** A peptide hormone in vertebrates that lowers the concentration of calcium (and phosphate) in the blood. It operates in opposition to \*parathyroid hormone. Calcitonin is produced by the \*C cells, which in mammals are located in the \*thyroid gland.

**calcium** Symbol Ca. A soft grey metallic element belonging to \*group 2 (formerly IIA) of the periodic table; a.n. 20; r.a.m. 40.08; r.d. 1.54; m.p. 839°C; b.p. 1484°C. Calcium compounds are common in the earth's crust; e.g. limestone and marble ( $\text{CaCO}_3$ ), gypsum ( $\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$ ), and fluorite ( $\text{CaF}_2$ ). The element is extracted by electrolysis of fused calcium chloride and is used as a getter in vacuum systems and a deoxidizer in producing nonferrous alloys. It is also used as a reducing agent in the extraction of such metals as thorium, zirconium, and uranium.

Calcium is an \*essential element for living organisms, being required for normal growth and development. In animals it is an important constituent of bones and teeth and is present in the blood, being required for muscle contraction and other metabolic processes. In plants it is a constituent (in the form of calcium pectate) of the \*middle lamella.

**calcium acetylde** See CALCIUM DICARBIDE.

**calcium bicarbonate** See CALCIUM HYDROGENCARBONATE.

**calcium carbide** See CALCIUM DICARBIDE.

**calcium carbonate** A white solid,  $\text{CaCO}_3$ , which is only sparingly soluble in

water. Calcium carbonate decomposes on heating to give \*calcium oxide (quicklime) and carbon dioxide. It occurs naturally as the minerals \*calcite (rhombohedral; r.d. 2.71) and \*aragonite (rhombic; r.d. 2.93). Rocks containing calcium carbonate dissolve slowly in acidified rainwater (containing dissolved  $\text{CO}_2$ ) to cause temporary hardness. In the laboratory, calcium carbonate is precipitated from \*limewater by carbon dioxide. Calcium carbonate is used in making lime (calcium oxide) and is the main raw material for the \*Solvay process.

**calcium chloride** A white deliquescent compound,  $\text{CaCl}_2$ , which is soluble in water; r.d. 2.15; m.p. 782°C; b.p. >1600°C. There are a number of hydrated forms, including the monohydrate,  $\text{CaCl}_2 \cdot \text{H}_2\text{O}$ , the dihydrate,  $\text{CaCl}_2 \cdot 2\text{H}_2\text{O}$  (r.d. 0.84), and the hexahydrate,  $\text{CaCl}_2 \cdot 6\text{H}_2\text{O}$  (trigonal; r.d. 1.71; the hexahydrate loses  $4\text{H}_2\text{O}$  at 30°C and the remaining  $2\text{H}_2\text{O}$  at 200°C). Large quantities of it are formed as a byproduct of the \*Solvay process and it can be prepared by dissolving calcium carbonate or calcium oxide in hydrochloric acid. Crystals of the anhydrous salt can only be obtained if the hydrated salt is heated in a stream of hydrogen chloride. Solid calcium chloride is used in mines and on roads to reduce dust problems, whilst the molten salt is the electrolyte in the extraction of calcium. An aqueous solution of calcium chloride is used in refrigeration plants.

**calcium cyanamide** A colourless solid,  $\text{CaCN}_2$ , which sublimes at 1300°C. It is prepared by heating calcium dicarbide at 800°C in a stream of nitrogen:

The reaction has been used as a method of fixing nitrogen in countries in which cheap electricity is available to make the calcium dicarbide (the **cyanamide process**). Calcium cyanamide can be used as a fertilizer because it reacts with water to give ammonia and calcium carbonate:

It is also used in the production of melamine, urea, and certain cyanide salts.

**calcium dicarbide (calcium acetylde);**

**calcium carbide; carbide** A colourless solid compound,  $\text{CaC}_2$ ; tetragonal; r.d. 2.22; m.p. 450°C; b.p. 2300°C. In countries in which electricity is cheap it is manufactured by heating calcium oxide with either coke or ethyne at temperatures above 2000°C in an electric arc furnace. The crystals consist of  $\text{Ca}^{2+}$  and  $\text{C}_2^-$  ions arranged in a similar way to the ions in sodium chloride. When water is added to calcium dicarbide, the important organic raw material ethyne (acetylene) is produced:

**calcium fluoride** A white crystalline solid,  $\text{CaF}_2$ ; r.d. 3.2; m.p. 1423°C; b.p. 2500°C. It occurs naturally as the mineral \*fluorite (or flourspar) and is the main source of fluorine. The **calcium fluoride structure (fluorite structure)** is a crystal structure in which the calcium ions are each surrounded by eight fluoride ions arranged at the corners of a cube. Each fluoride ion is surrounded by four calcium ions at the corners of a tetrahedron.

**calcium hydrogencarbonate (calcium bicarbonate)** A compound,  $\text{Ca}(\text{HCO}_3)_2$ , that is stable only in solution and is formed when water containing carbon dioxide dissolves calcium carbonate:

It is the cause of temporary \*hardness of water, because the calcium ions react with soap to give scum. Calcium hydrogencarbonate is unstable when heated and decomposes to give solid calcium carbonate. This explains why temporary hardness is removed by boiling and the formation of 'scale' in kettles and boilers.

**calcium hydroxide (slaked lime)** A white solid,  $\text{Ca}(\text{OH})_2$ , which dissolves sparingly in water (see LIMEWATER); hexagonal; r.d. 2.24. It is manufactured by adding water to calcium oxide, a process that evolves much heat and is known as slaking. It is used as a cheap alkali to neutralize the acidity in certain soils and in the manufacture of mortar, whitewash, bleaching powder, and glass.

**calcium nitrate** A white deliquescent compound,  $\text{Ca}(\text{NO}_3)_2$ , that is very soluble

in water; cubic; r.d. 2.50; m.p. 561°C. It can be prepared by neutralizing nitric acid with calcium carbonate and crystallizing it from solution as the tetrahydrate  $\text{Ca}(\text{NO}_3)_2 \cdot 4\text{H}_2\text{O}$ , which exists in two monoclinic crystalline forms ( $\alpha$ , r.d. 1.9;  $\beta$ , r.d. 1.82). There is also a trihydrate,  $\text{Ca}(\text{NO}_3)_2 \cdot 3\text{H}_2\text{O}$ . The anhydrous salt can be obtained from the hydrate by heating but it decomposes on strong heating to give the oxide, nitrogen dioxide, and oxygen. Calcium nitrate is sometimes used as a nitrogenous fertilizer.

**calcium octadecanoate (calcium stearate)** An insoluble white salt,  $\text{Ca}(\text{CH}_3(\text{CH}_2)_{16}\text{COO})_2$ , which is formed when soap is mixed with water containing calcium ions and is the scum produced in hard-water regions.

**calcium oxide (quicklime)** A white solid compound,  $\text{CaO}$ , formed by heating calcium in oxygen or by the thermal decomposition of calcium carbonate; cubic; r.d. 3.35; m.p. 2580°C; b.p. 2850°C. On a large scale, calcium carbonate in the form of limestone is heated in a tall tower (lime kiln) to a temperature above 550°C:

Although the reaction is reversible, the carbon dioxide is carried away by the upward current through the kiln and all the limestone decomposes. Calcium oxide is used to make calcium hydroxide, as a cheap alkali for treating acid soil, and in extractive metallurgy to produce a slag with the impurities (especially sand) present in metal ores.

**calcium phosphate(V)** A white insoluble powder,  $\text{Ca}_3(\text{PO}_4)_2$ ; r.d. 3.14. It is found naturally in the mineral \*apatite,  $\text{Ca}_5(\text{PO}_4)_3(\text{OH}, \text{F}, \text{Cl})$ , and as rock phosphate. It is also the main constituent of animal bones. Calcium phosphate can be prepared by mixing solutions containing calcium ions and hydrogenphosphate ions in the presence of an alkali:

It is used extensively as a fertilizer. The compound was formerly called **calcium orthophosphate** (see PHOSPHATES).

**calcium stearate** See CALCIUM OCTADECANOATE.

**calcium sulphate** A white solid compound,  $\text{CaSO}_4$ ; r.d. 2.96;  $1450^\circ\text{C}$ . It occurs naturally as the mineral \*anhydrite, which has a rhombic structure, transforming to a monoclinic form at  $200^\circ\text{C}$ . More commonly, it is found as the dihydrate, \*gypsum,  $\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$  (monoclinic; r.d. 2.32). When heated, gypsum loses water at  $128^\circ\text{C}$  to give the hemihydrate,  $2\text{CaSO}_4 \cdot \text{H}_2\text{O}$ , better known as \*plaster of Paris. Calcium sulphate is sparingly soluble in water and is a cause of permanent \*hardness of water. It is used in the manufacture of certain paints, ceramics, and paper. The naturally occurring forms are used in the manufacture of sulphuric acid.

**calculus** A series of mathematical techniques developed independently by Isaac Newton and Gottfried Leibniz (1646–1716). **Differential calculus** treats a continuously varying quantity as if it consisted of an infinitely large number of infinitely small changes. For example, the velocity  $v$  of a body at a particular instant can be regarded as the infinitesimal distance, written  $ds$ , that it travels in the vanishingly small time interval,  $dt$ ; the instantaneous velocity  $v$  is then  $ds/dt$ , which is called the **derivative** of  $s$  with respect to  $t$ . If  $s$  is a known function of  $t$ ,  $v$  at any instant can be calculated by the process of \*differentiation. The differential calculus is a powerful technique for solving many problems concerned with rate processes, maxima and minima, and similar problems.

**Integral calculus** is the opposite technique. For example, if the velocity of a body is a known function of time, the infinitesimal distance  $ds$  travelled in the brief instant  $dt$  is given by  $ds = vdt$ . The measurable distance  $s$  travelled between two instants  $t_1$  and  $t_2$  can then be found by a process of summation, called integration, i.e.

$$s = \int_{t_1}^{t_2} vdt$$

The technique is used for finding areas and volumes and other problems involving the summation of infinitesimals.

**caldera** A crater or large depression at the top of an inactive shield \*volcano,

which may be 1–20 km in diameter. It forms when magma subsides from the summit, sometimes aided by the explosive ejection of material. Often a caldera fills with water, forming a crater lake. Large calderas appear to be characteristic features of the landscapes of Mars and Venus.

**Calgon** Trade name for a water-softening agent. See HARDNESS OF WATER.

**caliche** A mixture of salts found in deposits between gravel beds in the Atacama and Tarapaca regions of Chile. They vary from 4 m to 15 cm thick and were formed by periodic leaching of soluble salts during wet geological epochs, followed by drying out of inland seas in dry periods. They are economically important as a source of nitrates. A typical composition is  $\text{NaNO}_3$  17.6%,  $\text{NaCl}$  16.1%,  $\text{Na}_2\text{SO}_4$  6.5%,  $\text{CaSO}_4$  5.5%,  $\text{MgSO}_4$  3.0%,  $\text{KNO}_3$  1.3%,  $\text{Na}_2\text{B}_4\text{O}_7$  0.94%,  $\text{KClO}_3$  0.23%,  $\text{NaIO}_3$  0.11%, sand and gravel to 100%.

**californium** Symbol Cf. A radioactive metallic transuranic element belonging to the \*actinoids; a.n. 98; mass number of the most stable isotope 251 (half-life about 700 years). Nine isotopes are known; californium-252 is an intense neutron source, which makes it useful in neutron \*activation analysis and potentially useful as a radiation source in medicine. The element was first produced by Glenn Seaborg (1912–99) and associates in 1950.

**calixarenes** Compounds that have molecules with a cuplike structure (the name comes from the Greek *calix*, cup). The simplest, has four phenol molecules joined by four  $-\text{CH}_2-$  groups into a ring (forming the base of the 'cup'). The four phenol hexagons point in the same direction to form a cavity that can bind substrate molecules. Interest has been shown in the potential ability of calixarene molecules to mimic enzyme action.

**callus 1.** (in botany) A protective tissue, consisting of parenchyma cells, that develops over a cut or damaged plant surface. Callus tissue can also be induced to form in cell cultures by hormone treatment.  
**2.** (in pathology) A thick hard area of skin that commonly forms on the palms of the

hands and soles of the feet as a result of continuous pressure or friction. **3.** (in physiology) Hard tissue formed round bone ends following a fracture, which is gradually converted to new bone.

**calomel** See MERCURY(I) CHLORIDE.

**calomel half cell (calomel electrode)** A type of half cell in which the electrode is mercury coated with calomel (HgCl) and the electrolyte is a solution of potassium chloride and saturated calomel. The standard electrode potential is  $-0.2415$  volt ( $25^{\circ}\text{C}$ ). In the calomel half cell the reactions are

The overall reaction is

This is equivalent to a  $\text{Cl}_2(\text{g})|\text{Cl}^{-}(\text{aq})$  half cell.

**caloric theory** A former theory concerning the nature of heat, which was regarded as a weightless fluid (called **caloric**). It was unable to account for the fact that friction could produce an unlimited quantity of heat and it was abandoned when Joule showed that heat is a form of energy.

**calorie** The quantity of heat required to raise the temperature of 1 gram of water by  $1^{\circ}\text{C}$  (1 K). The calorie, a c.g.s. unit, is now largely replaced by the \*joule, an \*SI unit. 1 calorie = 4.186 8 joules.

**Calorie (kilogram calorie; kilocalorie)** 1000 calories. This unit is still in limited use in estimating the energy value of foods, but is obsolescent.

**calorific value** The heat per unit mass produced by complete combustion of a given substance. Calorific values are used to express the energy values of fuels; usually these are expressed in megajoules per kilogram ( $\text{MJ kg}^{-1}$ ). They are also used to measure the energy content of foodstuffs; i.e. the energy produced when the food is oxidized in the body. The units here are kilojoules per gram ( $\text{kJ g}^{-1}$ ), although Calories (kilocalories) are often still used in nontechnical contexts. Calorific values are measured using a \*bomb calorimeter.

**calorimeter** Any of various devices used to measure thermal properties, such as \*calorific value, specific \*heat capacity, specific \*latent heat, etc. See BOMB CALORIMETER.

**Calvin, Melvin** (1911–97) US biochemist. After World War II, at the Lawrence Radiation Laboratory, Berkeley, he investigated the light-independent reactions of \*photosynthesis. Using radioactive carbon-14 to label carbon dioxide, he discovered the \*Calvin cycle, for which he was awarded the 1961 Nobel Prize for chemistry.

**Calvin cycle** The metabolic pathway of the light-independent stages of \*photosynthesis, which occurs in the stroma of the chloroplasts. The pathway was elucidated by Melvin Calvin and his co-workers and involves the fixation of carbon dioxide and its subsequent reduction to carbohydrate. During the cycle, carbon dioxide combines with \*ribulose biphosphate, through the mediation of the enzyme ribulose biphosphate carboxylase/oxygenase (rubisco), to form an unstable six-carbon compound that breaks down to form two molecules of the three-carbon compound glycerate 3-phosphate. This is converted to glyceraldehyde 3-phosphate, which is used to regenerate ribulose biphosphate and to produce glucose and fructose.

**calx** A metal oxide formed by heating an ore in air.

**calyptra 1.** A layer of cells that covers the developing sporophyte of mosses, liverworts, clubmosses, horsetails, and ferns. In mosses it forms a hood over the \*capsule and in liverworts it forms a sheath at the base of the capsule stalk. **2.** See ROOT CAP.

**calypitrogen** The region within the root \*apical meristem that divides to produce the \*root cap (calyptra).

**calyx** The \*sepals of a flower, collectively, forming the outer whorl of the \*perianth. It encloses the petals, stamens, and carpels and protects the flower in bud. See also PAPPUS.

**cambium (lateral meristem)** A plant tissue consisting of actively dividing cells (see

MERISTEM) that is responsible for increasing the girth of the plant, i.e. it causes secondary growth. The two most important cambia are the **vascular** (or **fascicular cambium**) and the **\*cork cambium**. The vascular cambium occurs in the stem and root; it divides to produce secondary **\*xylem** and secondary **\*phloem** (new food- and water-conducting tissues). In mature stems the vascular cambium is extended laterally to form a complete ring; the sections of this ring between the vascular bundles comprises the **interfascicular cambium**. Compare APICAL MERISTEM.

**Cambrian** The earliest geological period of the Palaeozoic era. It is estimated to have begun about 570 million years ago and lasted for some 100 million years. During this period marine animals with mineralized shells made their first appearance and Cambrian rocks are the first to contain an abundance of fossils. Cambrian fossils are all of marine animals; they include **\*trilobites**, which dominated the Cambrian seas, **echinoderms**, **brachiopods**, **molluscs**, and primitive **\*graptolites** (from the mid Cambrian). Trace **\*fossils** also provide evidence for a variety of worms.

**camera 1.** An optical device for obtaining still photographs or for exposing cinematic film. It consists of a light-proof box with a lens at one end and a plate or film at the other. To make an exposure the shutter is opened and an image of the object to be photographed is formed on the light-sensitive film. The length of the exposure is determined by the intensity of light available, the film speed, and the **\*aperture** of the lens. In the simpler cameras the shutter speed and aperture are controlled manually, but in automatic cameras the iris over the lens or the shutter is adjusted on the basis of information provided by a built-in **\*exposure meter**. In ciné cameras the shutter automatically opens as the film comes to rest behind the lens for each frame; the film passes through the camera so that a set number (commonly 16, 18, or 24) of frames are exposed every second. **2.** The part of a television system that converts optical images into electronic signals. It consists of a lens system, which focuses the image to be televised on the photosensitive mosaic of

the camera tube, causing localized discharge of those of its elements that are illuminated. This mosaic is scanned from behind by an electron beam so that the beam current is varied as it passes over areas of light and shade. The signal so picked up by the scanning beam is preamplified in the camera and passed to the transmitter with sound and synchronization signals. In **\*colour television** three separate camera tubes are used, one for each **\*primary colour**.

**camouflage** A high degree of similarity between an animal and its visual environment, which enables it to be disguised or concealed. By blending into the background the animal can elude predators or remain invisible to potential prey. See also CRYPTIC COLORATION; MIMICRY. Compare WARNING COLORATION.

**camphor** A white crystalline cyclic ketone,  $C_{10}H_{16}O$ ; r.d. 0.99; m.p. 179°C; b.p. 204°C. It was formerly obtained from the wood of the Formosan camphor tree, but can now be synthesized. The compound has a characteristic odour associated with its use in mothballs. It is a plasticizer in celluloid.

**Canada balsam** A yellow-tinted resin used for mounting specimens in optical microscopy. It has similar optical properties to glass.

**canaliculus** A very small channel that occurs between the cells of the liver and bone. In the liver the bile canaliculi carry bile to the bile ducts; in bone, canaliculi connect lacunae, the cavities containing bone cells.

**canal rays** Streams of positive ions produced in a **\*discharge tube** by boring holes (canals) in the cathode. The positive ions attracted to the cathode pass through the holes and emerge on the other side as positive rays.

**cancer** Any disorder of cell growth that results in invasion and destruction of surrounding healthy tissue by abnormal cells. Cancer cells arise from normal cells whose nature is permanently changed. They multiply more rapidly than healthy body cells and do not seem subject to normal control by nerves and hormones. They may spread via the bloodstream or

lymphatic system to other parts of the body, where they produce further tissue damage (**metastases**). **Malignant tumour** is another name for cancer. A cancer that arises in epithelium is called a **carcinoma**; one that arises in connective tissue is called a **sarcoma**. **Leukaemia** is cancer of white blood cells; **lymphoma** is cancer of \*lymphoid tissue; and **myeloma** is cancer of \*plasma cells of the bone marrow. Causative agents (**carcinogens**) include various chemicals (including those in tobacco smoke), ionizing radiation, silica and asbestos particles, and \*oncogenic viruses (see also ONCOGENE). Hereditary factors and stress may also play a role.

**candela** Symbol Cd. The \*SI unit of luminous intensity equal to the luminous intensity in a given direction of a source that emits monochromatic radiation of frequency  $540 \times 10^{12}$  Hz and has a radiant intensity in that direction of 1/683 watt per steradian.

**candle power** Luminous intensity as formerly expressed in terms of the international candle but now expressed in candela.

**cane sugar** See SUCROSE.

**canine tooth** A sharp conical \*tooth in mammals that is large and highly developed in carnivores (e.g. dogs) for tearing meat. There are two canines in each jaw, each situated between the second \*incisor and the first \*premolar. In some animals (e.g. herbivores, such as giraffes and rabbits) canine teeth are absent.

**Cannizzaro reaction** A reaction of aldehydes to give carboxylic acids and alcohols. It occurs in the presence of strong bases with aldehydes that do not have alpha hydrogen atoms. For example, benzenecarbaldehyde gives benzenecarboxylic acid and benzyl alcohol:

Aldehydes that have alpha hydrogen atoms undergo the \*aldol reaction instead. The Cannizzaro reaction is an example of a \*disproportionation. It was discovered in 1853 by the Italian chemist Stanislao Cannizzaro (1826–1910).

**canonical form** One of the possible

structures of a molecule that together form a \*resonance hybrid.

**capacitance** The property of a conductor or system of conductors that describes its ability to store electric charge. The capacitance ( $C$ ) is given by  $Q/V$ , where  $Q$  is stored charge on one conductor and  $V$  the potential difference between the two conductors (or between a single conductor and earth); it is measured in farads (or, in practice, microfarads).

An isolated sphere has a capacitance of  $4\pi\epsilon r$ , where  $r$  is the radius and  $\epsilon$  the \*permittivity of the medium surrounding it. Capacitance is more commonly applied to systems of conductors (or semiconductors) separated by insulators (see CAPACITOR).

**capacitation** The final stage in the maturation process of a spermatozoon. This takes place inside the genital tract as the sperm penetrates the ovum.

**capacitor** An arrangement of conductors separated by an insulator (dielectric) used to store charge or introduce \*reactance into an alternating-current circuit. The earliest form was the \*Leyden jar. Capacitors used as circuit elements have two conducting plates separated by the dielectric. The dielectric may be air, paper impregnated with oil or wax, plastic film, or ceramic. The simplest form has two parallel rectangular conducting plates (area  $A$ ) separated by a dielectric (thickness  $d$ , permittivity  $\epsilon$ ). The capacitance of such a capacitor is  $A\epsilon/d$ . **Electrolytic capacitors** are devices in which a thin layer of an oxide is deposited on one of the electrodes to function as the dielectric.

**capacitor microphone** A microphone consisting of a \*capacitor with a steady voltage applied across its parallel plates. One plate is fixed, the other is a thin diaphragm that is moved by the pressure of the sound waves. The movements of the diaphragm cause a variation in the spacing and therefore in the \*capacitance of the device. This variation in capacitance is, in turn, reflected in a similar variation in the charge carried by each plate. The consequent current to and from one plate is carried by a resistor, the varying potential difference across which constitutes the device's output signal. It was formerly known as a **condenser microphone**.

**capillarity** See SURFACE TENSION.

**capillary 1.** A tube of small diameter.

**2. (blood capillary)** The narrowest type of blood vessel in the vertebrate circulatory system. Capillaries conduct blood from \*arterioles to all living cells: their walls are only one cell layer thick, so that oxygen and nutrients can pass through them into the surrounding tissues. Capillaries also transport waste material (e.g. urea and carbon dioxide) to venules for ultimate excretion. Capillaries can be constricted or dilated, according to local tissue requirements.

**capitulum** A type of flowering shoot (see RACEMOSE INFLORESCENCE) characteristic of plants of the family Compositae (Asteraceae), e.g. daisy and dandelion. The tip of the shoot is flattened and bears many small stalkless flowers (**florets**) surrounded by an involucre (ring) of bracts. This arrangement gives the appearance of a single flower.

**capric acid** See DECANOIC ACID.

**caproic acid** See HEXANOIC ACID.

**caprolactam (6-hexanelactam)** A white crystalline substance,  $C_6H_{11}NO$ ; r.d. 1.02; m.p. 69–71°C; b.p. 139°C. It is a \*lactam containing the  $-NH.CO-$  group with five  $CH_2$  groups making up the rest of the seven-membered ring. Caprolactam is used in making \*nylon.

**caprylic acid** See OCTANOIC ACID.

**capsid** The protein coat of a \*virus. The chemical nature of the capsid is important in stimulating the body's \*immune response against the invading virus.

**capsule 1.** (in botany) **a.** A dry fruit that releases its seeds when ripe; it is formed from several fused carpels and contains many seeds. The seeds may be dispersed through pores (as in the poppy), through a lid (as in plantain), or by the splitting and separation of the individual carpels (as in the crocus). Various other forms of capsules include the \*silicula and \*siliqua. **b.** The part of the sporophyte of mosses and liverworts in which the haploid spores are produced. It is borne on a long stalk (**seta**) and sheds its spores when mature (see PERISTOME). **2.** (in microbiology) A thick gelatinous layer completely sur-

rounding the cell wall of certain bacteria. It appears to have a protective function, making ingestion of the bacterial cell by \*phagocytes more difficult and preventing desiccation. **3.** (in animal anatomy) **a.** The membranous or fibrous envelope that surrounds certain organs, e.g. the kidneys, spleen, and lymph nodes. **b.** The ligamentous sheath of connective tissue that surrounds various skeletal joints.

**capture** Any of various processes in which a system of particles absorbs an extra particle. There are several examples in atomic and nuclear physics. For instance, a positive ion may capture an electron to give a neutral atom or molecule. Similarly, a neutral atom or molecule capturing an electron becomes a negative ion. An atomic nucleus may capture a neutron to produce a different (often unstable) nucleus. Another type of nuclear capture is the process in which the nucleus of an atom absorbs an electron from the innermost orbit (the K shell) to transform into a different nucleus. In this process (called **K capture**) the atom is left in an excited state and generally decays by emission of an X-ray photon.

**Radiative capture** is any such process in which the capture results in an excited state that decays by emission of photons. A common example is neutron capture to yield an excited nucleus, which decays by emission of a gamma ray.

**carapace 1.** The dorsal part of the \*exoskeleton of some crustaceans (e.g. crabs), which spreads like a shield over several segments of the head and thorax. **2.** The domed dorsal part of the shell of tortoises and turtles, formed of bony plates fused with the ribs and vertebrae and covered by a horny epidermal layer. The ventral part of the shell (**plastron**) is similar but flatter.

**carat 1.** A measure of fineness (purity) of gold. Pure gold is described as 24-carat gold. 14-carat gold contains 14 parts in 24 of gold, the remainder usually being copper. **2.** A unit of mass equal to 0.200 gram, used to measure the masses of diamonds and other gemstones.

**carbamide** See UREA.

**carbanion** An organic ion with a nega-

tive charge on a carbon atom; i.e. an ion of the type  $R_3C^-$ . Carbanions are intermediates in certain types of organic reaction (e.g. the \*aldol reaction).

**carbene** A species of the type  $R_2C:$ , in which the carbon atom has two electrons that do not form bonds. **Methylene**,  $:CH_2$ , is the simplest example. Carbenes are highly reactive and exist only as transient intermediates in certain organic reactions. They attack double bonds to give cyclopropane derivatives. They also cause insertion reactions, in which the carbene group is inserted between the carbon and hydrogen atoms of a C-H bond:

**carbenium ion** See CARBONIUM ION.

**carbide** Any of various compounds of carbon with metals or other more electropositive elements. True carbides contain the ion  $C^{4-}$  as in  $Al_4C_3$ . These are saltlike compounds giving methane on hydrolysis, and were formerly called **methanides**. Compounds containing the ion  $C_2^{2-}$  are also saltlike and are known as **dicarbides**. They yield ethyne (acetylene) on hydrolysis and were formerly called **acetylides**. The above types of compound are ionic but have partially covalent bond character, but boron and silicon form true covalent carbides, with giant molecular structures. In addition, the transition metals form a range of interstitial carbides in which the carbon atoms occupy interstitial positions in the metal lattice. These substances are generally hard materials with metallic conductivity. Some transition metals (e.g. Cr, Mn, Fe, Co, and Ni) have atomic radii that are too small to allow individual carbon atoms in the interstitial holes. These form carbides in which the metal lattice is distorted and chains of carbon atoms exist (e.g.  $Cr_3C_2$ ,  $Fe_3C$ ). Such compounds are intermediate in character between interstitial carbides and ionic carbides. They give mixtures of hydrocarbons on hydrolysis with water or acids.

**carbocation** See CARBONIUM ION.

**carbocyclic** See CYCLIC.

**carbohydrate** One of a group of organic compounds based on the general

formula  $C_x(H_2O)_y$ . The simplest carbohydrates are the \*sugars (saccharides), including glucose and sucrose. \*Polysaccharides are carbohydrates of much greater molecular weight and complexity; examples are starch, glycogen, and cellulose. Carbohydrates perform many vital roles in living organisms. Sugars, notably glucose, and their derivatives are essential intermediates in the conversion of food to energy. Starch and other polysaccharides serve as energy stores in plants, particularly in seeds, tubers, etc., which provide a major energy source for animals, including man. Cellulose, lignin, and others form the supporting cell walls and woody tissue of plants. Chitin is a structural polysaccharide found in the body shells of many invertebrate animals. Carbohydrates also occur in the surface coat of animal cells and in bacterial cell walls.

**carbolic acid** See PHENOL.

**carbon** Symbol C. A nonmetallic element belonging to \*group 14 (formerly IVB) of the periodic table; a.n. 6; r.a.m. 12.011; m.p.  $-3550^\circ C$ ; b.p.  $-4827^\circ C$ . Carbon has three main allotropic forms (see ALLOTROPY).

\*Diamond (r.d. 3.52) occurs naturally and can be produced synthetically. It is extremely hard and has highly refractive crystals. The hardness of diamond results from the covalent crystal structure, in which each carbon atom is linked by covalent bonds to four others situated at the corners of a tetrahedron. The C-C bond length is 0.154 nm and the bond angle is  $109.5^\circ$ .

Graphite (r.d. 2.25) is a soft black slippery substance (sometimes called **black lead** or **plumbago**). It occurs naturally and can also be made by the \*Acheson process. In graphite the carbon atoms are arranged in layers, in which each carbon atom is surrounded by three others to which it is bound by single or double bonds. The layers are held together by much weaker van der Waals' forces. The carbon-carbon bond length in the layers is 0.142 nm and the layers are 0.34 nm apart. Graphite is a good conductor of heat and electricity. It has a variety of uses including electrical contacts, high-temperature equipment, and as a solid lu-

bricant. Graphite mixed with clay is the 'lead' in pencils (hence its alternative name). The third crystalline allotrope is fullerite (see BUCKMINSTERFULLERENE). There are also several amorphous forms of carbon, such as \*carbon black and \*charcoal.

There are two stable isotopes of carbon (proton numbers 12 and 13) and four radioactive ones (10, 11, 14, 15). Carbon-14 is used in \*carbon dating.

Carbon occurs in all organic compounds and is therefore fundamental to the structure of all living organisms. It is an \*essential element for plants and animals, being ultimately derived from atmospheric carbon dioxide assimilated by plants during photosynthesis (see CARBON CYCLE). The ubiquitous nature of carbon in living organisms is due to its unique ability to form stable covalent bonds with other carbon atoms and also with hydrogen, oxygen, nitrogen, and sulphur atoms, resulting in the formation of a variety of compounds containing chains and rings of carbon atoms.

**carbon assimilation** The incorporation of carbon from atmospheric carbon dioxide into organic molecules. This process occurs during \*photosynthesis. See CARBON CYCLE.

**carbonate** A salt of carbonic acid containing the carbonate ion,  $\text{CO}_3^{2-}$ . The free ion has a plane triangular structure. Metal carbonates may be ionic or may contain covalent metal-carbonate bonds (complex carbonates) via one or two oxygen atoms. The carbonates of the alkali metals are all soluble but other carbonates are insoluble; they all react with mineral acids to release carbon dioxide.

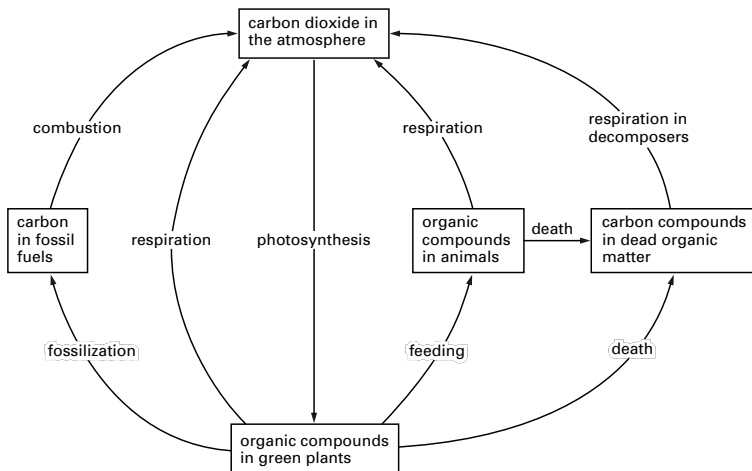

**carbonate minerals** A group of common rock-forming minerals containing the anion  $\text{CO}_3^{2-}$  as the fundamental unit in their structure. The most important carbonate minerals are \*calcite, \*dolomite, and \*magnesite. See also ARAGONITE.

**carbonation** The solution of carbon dioxide in a liquid under pressure.

**carbon bisulphide** See CARBON DISULPHIDE.

**carbon black** A fine carbon powder made by burning hydrocarbons in insufficient air. It is used as a pigment and a filler (e.g. for rubber).

**carbon cycle 1.** (in biology) One of the major cycles of chemical elements in the environment (see BIOGEOCHEMICAL CYCLE). Carbon (as carbon dioxide) is taken up from the atmosphere and incorporated

The carbon cycle in nature

into the tissues of plants in \*photosynthesis. It may then pass into the bodies of animals as the plants are eaten (see FOOD CHAIN). During the respiration of plants, animals, and organisms that bring about decomposition, carbon dioxide is returned to the atmosphere. The combustion of fossil fuels (e.g. coal and peat) also releases carbon dioxide into the atmosphere. See illustration.

**2.** (in physics) A series of nuclear reactions in which four hydrogen nuclei combine to form a helium nucleus with the liberation of energy, two positrons, and two neutrinos. The process is believed to be the source of energy in many stars and to take place in six stages. In this series carbon-12 acts as if it were a catalyst, being reformed at the end of the series:

See STELLAR EVOLUTION.

**carbon dating (radiocarbon dating)** A method of estimating the ages of archaeological specimens of biological origin. As a result of \*cosmic radiation a small number of atmospheric nitrogen nuclei are continuously being transformed by neutron bombardment into radioactive nuclei of carbon-14:

Some of these radiocarbon atoms find their way into living trees and other plants in the form of carbon dioxide, as a result of \*photosynthesis. When the tree is cut down photosynthesis stops and the ratio of radiocarbon atoms to stable carbon atoms begins to fall as the radiocarbon decays. The ratio  ${}^{14}\text{C}/{}^{12}\text{C}$  in the specimen can be measured and enables the time that has elapsed since the tree was cut down to be calculated. The method has been shown to give consistent results for specimens up to some 40 000 years old, though its accuracy depends upon assumptions concerning the

past intensity of the cosmic radiation. The technique was developed by Willard F. Libby (1908–80) and his coworkers in 1946–47.

**carbon dioxide** A colourless odourless gas,  $\text{CO}_2$ , soluble in water, ethanol, and acetone; d.  $1.977 \text{ g dm}^{-3}$  ( $0^\circ\text{C}$ ); m.p.  $-56.6^\circ\text{C}$ ; b.p.  $-78.5^\circ\text{C}$ . It occurs in the atmosphere (0.04% by volume) but has a short residence time in this phase as it is both consumed by plants during \*photosynthesis and produced by \*respiration and by combustion. It is readily prepared in the laboratory by the action of dilute acids on metal carbonates or of heat on heavy-metal carbonates. Carbon dioxide is a by-product from the manufacture of lime and from fermentation processes.

Carbon dioxide has a small liquid range and liquid carbon dioxide is produced only at high pressures. The molecule  $\text{CO}_2$  is linear with each oxygen making a double bond to the carbon. Chemically, it is unreactive and will not support combustion. It dissolves in water to give \*carbonic acid.

Large quantities of solid carbon dioxide (**dry ice**) are used in processes requiring large-scale refrigeration. It is also used in fire extinguishers as a desirable alternative to water for most fires, and as a constituent of medical gases as it promotes exhalation. It is also used in carbonated drinks.

The level of carbon dioxide in the atmosphere has increased by some 12% in the last 100 years, mainly because of extensive burning of fossil fuels and the destruction of large areas of rain forest. This has been postulated as the main cause of the average increase of  $0.5^\circ\text{C}$  in global temperatures over the same period, through the \*greenhouse effect. Atmospheric  $\text{CO}_2$  concentration continues to rise, in spite of some tentative steps to control emissions, giving the prospect of accelerated \*global warming in the foreseeable future.

**carbon disulphide (carbon bisulphide)**

A colourless highly refractive liquid,  $\text{CS}_2$ , slightly soluble in water and soluble in ethanol and ether; r.d. 1.261; m.p.  $-110^\circ\text{C}$ ; b.p.  $46.3^\circ\text{C}$ . Pure carbon disulphide has an ethereal odour but the commercial product is contaminated with a variety of

other sulphur compounds and has a most unpleasant smell. It was previously manufactured by heating a mixture of wood, sulphur, and charcoal; modern processes use natural gas and sulphur. Carbon disulphide is an excellent solvent for oils, waxes, rubber, sulphur, and phosphorus, but its use is decreasing because of its high toxicity and its flammability. It is used for the preparation of xanthates in the manufacture of viscose yarns.

**carbon fibres** Fibres of carbon in which the carbon has an oriented crystal structure. Carbon fibres are made by heating textile fibres and are used in strong composite materials for use at high temperatures.

**carbonic acid** A dibasic acid,  $\text{H}_2\text{CO}_3$ , formed in solution when carbon dioxide is dissolved in water:

The acid is in equilibrium with dissolved carbon dioxide, and also dissociates as follows:

$$K_a = 4.5 \times 10^{-7} \text{ mol dm}^{-3}$$

$$K_a = 4.8 \times 10^{-11} \text{ mol dm}^{-3}$$

The pure acid cannot be isolated, although it can be produced in ether solution at  $-30^\circ\text{C}$ . Carbonic acid gives rise to two series of salts: the \*carbonates and the \*hydrogencarbonates.

**carbonic anhydrase** An enzyme, present in red blood cells and kidney cells, that catalyses the reaction between carbon dioxide with water:

This reaction is one of the fastest known and controls the elimination of carbon dioxide from the body and the pH of urine. It also facilitates the transfer of carbon dioxide from the tissues to the blood and from the blood to the alveoli (air sacs) of the lungs. See also CHLORIDE SHIFT.

**Carboniferous** A geological period in the Palaeozoic era. It began about 360 million years ago, following the Devonian pe-

riod, and extended until the beginning of the Permian period, about 285 million years ago. In Europe the period is divided into the Lower and Upper Carboniferous, which roughly correspond to the Mississippian and Pennsylvanian periods, respectively, of North America. During the Lower Carboniferous a marine transgression occurred and the characteristic rock of this division – the Carboniferous limestone – was laid down in the shallow seas. Fauna included foraminiferans, corals, bryozoans, brachiopods, blastoids, and other invertebrates. The Upper Carboniferous saw the deposition of the millstone grit, a mixture of shale and sandstone formed in deltaic conditions, followed by the coal measures, alternating beds of coal, sandstone, shale, and clay. The coal was formed from the vast swamp forests composed of seed ferns, lycopsids, and other plants. During the period fishes continued to diversify and amphibians became more common.

**carbonium ion (carbenium ion)** An organic ion with a positive charge on a carbon atom; i.e. an ion of the type  $\text{R}_3\text{C}^+$ . Carbonium ions are intermediates in certain types of organic reaction (e.g. \*Williamson's synthesis). Certain fairly stable carbonium ions can be formed (**carbocations**).

**carbonize (carburize)** To change an organic compound into carbon by heating, or to coat something with carbon in this way.

**carbon monoxide** A colourless odourless gas, CO, sparingly soluble in water and soluble in ethanol and benzene; d.  $1.25 \text{ g dm}^{-3}$  ( $0^\circ\text{C}$ ); m.p.  $-199^\circ\text{C}$ ; b.p.  $-191.5^\circ\text{C}$ . It is flammable and highly toxic. In the laboratory it can be made by the dehydration of methanoic acid (formic acid) using concentrated sulphuric acid. Industrially it is produced by the oxidation of natural gas (methane) or (formerly) by the water-gas reaction. It is formed by

Oxides of carbon

the incomplete combustion of carbon and is present in car-exhaust gases.

It is a neutral oxide, which burns in air to give carbon dioxide, and is a good reducing agent, used in a number of metallurgical processes. It has the interesting chemical property of forming a range of transition metal carbonyls, e.g.  $\text{Ni}(\text{CO})_4$ . Carbon monoxide is able to use vacant *p*-orbitals in bonding with metals; the stabilization of low oxidation states, including the zero state, is a consequence of this. This also accounts for its toxicity, which is due to the binding of the CO to the iron in haemoglobin, thereby blocking the uptake of oxygen.

**carbon suboxide** See TRICARBON DIOXIDE.

**carbon tetrachloride** See TETRACHLOROMETHANE.

**carbonyl chloride (phosgene)** A colourless gas,  $\text{COCl}_2$ , with an odour of freshly cut hay. It is used in organic chemistry as a chlorinating agent, and was formerly used as a war gas.

**carbonyl compound** A compound containing the carbonyl group  $>\text{C}=\text{O}$ . Aldehydes, ketones, and carboxylic acids are examples of organic carbonyl compounds. Inorganic carbonyls are complexes in which carbon monoxide has coordinated to a metal atom or ion, as in \*nickel carbonyl,  $\text{Ni}(\text{CO})_4$ . See also LIGAND.

**carbonyl group** The group  $>\text{C}=\text{O}$ , found in aldehydes, ketones, carboxylic acids, amides, etc., and in inorganic carbonyl complexes (see CARBONYL COMPOUND).

**carborundum** See SILICON CARBIDE.

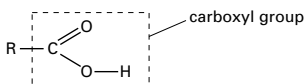

**carboxyhaemoglobin** The highly stable product formed when \*haemoglobin combines with carbon monoxide. Carbon monoxide competes with oxygen for haemoglobin, with which it binds strongly: the affinity of haemoglobin for carbon monoxide is 250 times greater than that for oxygen. This reduces the availability of haemoglobin for combination with (and transport of) oxygen and accounts for the toxic effects of carbon monoxide on the respiratory system.

**carboxylate** An anion formed from a

\*carboxylic acid. For example, ethanoic acid gives rise to the ethanoate ion,  $\text{CH}_3\text{COO}^-$ .

**carboxyl group** The organic group  $-\text{COOH}$ , present in \*carboxylic acids.

**carboxylic acids** Organic compounds containing the group  $-\text{COOH}$  (the **carboxyl group**; i.e. a carbonyl group attached to a hydroxyl group). In systematic chemical nomenclature carboxylic-acid names end in the suffix *-oic*, e.g. ethanoic acid,  $\text{CH}_3\text{COOH}$ . They are generally weak acids. Many long-chain carboxylic acids occur naturally as esters in fats and oils and are therefore also known as \*fatty acids. See also GLYCERIDE.

Carboxylic acid structure

**carboxypeptidase** An \*exopeptidase enzyme in pancreatic juice that is secreted into the duodenum. The enzyme is secreted as an inactive precursor, **procarboxypeptidase**, which is activated by another pancreatic protease, \*trypsin. See also CHYMOTRYPSIN.

**carburize** See CARBONIZE.

**carbylamine reaction** See ISOCYANIDE TEST.

**carcerulus** A dry fruit that is a type of \*schizocarp. It consists of a number of one-seeded fragments (**mericarps**) that adhere to a central axis. It is characteristic of mallow.

**carcinogen** Any agent that produces \*cancer, e.g. tobacco smoke, certain industrial chemicals, and \*ionizing radiation (such as X-rays and ultraviolet rays).

**carcinoma** See CANCER.

**cardiac 1.** Relating to the heart. **2.** Relating to the part of the stomach nearest to the oesophagus.

**cardiac cycle** The sequence of events that occurs in the heart during one full heartbeat. These events comprise contraction (see SYSTOLE) and relaxation (see DIASTOLE) of the chambers of the heart,

associated with opening and closing of the heart valves. When both the atria and the ventricles are relaxed, pressure in the heart is low and blood flows from the vena cava and pulmonary vein into the atria and through to the ventricles. The aortic and pulmonary valves, at the junction between the left ventricle and aorta and the right ventricle and pulmonary artery, respectively, are closed; therefore, blood can enter but not leave the heart, which increases the pressure in the chambers. As the pressure in the heart increases, the atria begin to contract, forcing the blood into the ventricles and closing the \*tricuspid valve and the \*bicuspid valve. A wave of ventricular contraction follows, expelling the blood into the aorta and pulmonary artery to complete the cardiac cycle. At a resting heart rate, the human cardiac cycle lasts approximately 0.85 second.

**cardiac muscle** A specialized form of \*muscle that is peculiar to the vertebrate heart. There are two types of cardiac muscle fibres: contractile fibres, which are striated and contain numerous myofibrils; and conducting fibres, or \*Purkyne fibres, which branch extensively and conduct electrical signals throughout the muscle. The muscle itself shows spontaneous contraction and does not need nervous stimulation (see PACEMAKER). The vagus nerve to the heart can, however, affect the rate of contraction.

**cardiac output** The volume of blood pumped per minute by each ventricle, which is also the total blood flow through the pulmonary circuit. At rest, normal human cardiac output is approximately 5 litres per minute, rising to 22 litres per minute during maximum physical exertion. The cardiac output can be calculated from heart rate (number of beats per minute) and stroke volume (volume of blood expelled from the heart per beat).

**cardiovascular centre** One of the areas in the brain that are responsible for the modification of the cardiovascular system based upon the integration of sensory information from the autonomic nervous system. These centres influence the heart rate via the sympathetic and parasympa-

thetic nerves and by the action of certain hormones.

**Carius method** A method of determining the amount of sulphur and halogens in an organic compound, by heating the compound in a sealed tube with silver nitrate in concentrated nitric acid. The compound is decomposed and silver sulphide and halides are precipitated, separated, and weighed.

**carallite** A mineral consisting of a hydrated mixed chloride of potassium and magnesium,  $KCl.MgCl_2.6H_2O$ .

**carnassial teeth** Molar and premolar teeth modified for shearing flesh by having cusps with sharp cutting edges. They are typical of animals of the order \*Carnivora (e.g. tigers, wolves), in which they are the first molars in the lower jaw and the last premolars in the upper.

**Carnivora** An order of mainly flesh-eating mammals that includes the dogs, wolves, bears, badgers, weasels, and cats. Carnivores typically have very keen sight, smell, and hearing. The hinge joint between the lower jaw and skull is very tight, allowing no lateral movement of the lower jaw. This - together with the arrangement of jaw muscles - enables a very powerful bite. The teeth are specialized for stabbing and tearing flesh: canines are large and pointed and some of the cheek teeth are modified for shearing (see CARNASSIAL TEETH).

**carnivore** An animal that eats meat, especially a member of the order \*Carnivora (e.g. tigers, wolves). Carnivores are specialized by having strong powerful jaws and well-developed canine teeth. They may be \*predators or carrion eaters. See also CONSUMER. Compare HERBIVORE; OMNIVORE.

**carnivorous plant (insectivorous plant)** Any plant that supplements its supply of nitrates in conditions of nitrate deficiency by digesting small animals, especially insects. Such plants are adapted in various ways to attract and trap the insects and produce proteolytic enzymes to digest them. Venus' fly trap (*Dionaea*), for example, has spiny-margined hinged leaves that snap shut on an alighting insect. Sundews (*Drosera*) trap and digest insects by

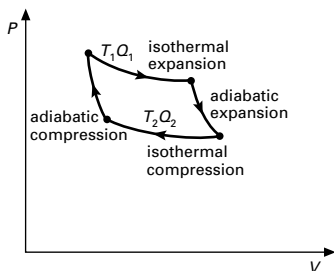

means of glandular leaves that secrete a sticky substance, and pitcher plants (families Nepenthaceae and Sarraceniacae) have leaves modified as pitchers into which insects fall, drowning in the water and digestive enzymes at the bottom.

### Carnot, Nicolas Léonard Sadi

(1796–1832) French physicist, who first worked as a military engineer. He then turned to scientific research and in 1824 published his analysis of the efficiency of heat engines. The key to this analysis is the thermodynamic \*Carnot cycle. He died at an early age of cholera.

**Carnot cycle** The most efficient cycle of operations for a reversible \*heat engine. Published in 1824 by Nicolas Carnot, it consists of four operations on the working substance in the engine (see illustration):

- Isothermal expansion at thermodynamic temperature  $T_1$  with heat  $Q_1$  taken in.
- Adiabatic expansion with a fall of temperature to  $T_2$ .
- Isothermal compression at temperature  $T_2$  with heat  $Q_2$  given out.
- Adiabatic compression with a rise of temperature back to  $T_1$ .

Carnot cycle

According to the **Carnot principle**, the efficiency of any reversible heat engine depends only on the temperature range through which it works, rather than the properties of the working substances. In any reversible engine, the efficiency ( $\eta$ ) is the ratio of the work done ( $W$ ) to the heat input ( $Q_1$ ), i.e.  $\eta = W/Q_1$ . As, according to the first law of \*thermodynamics,  $W = Q_1 - Q_2$ , it follows that  $\eta = (Q_1 - Q_2)/Q_1$ . For the Kelvin temperature scale,  $Q_1/Q_2 =$

$T_1/T_2$  and  $\eta = (T_1 - T_2)/T_1$ . For maximum efficiency  $T_1$  should be as high as possible and  $T_2$  as low as possible.

**carnotite** A radioactive mineral consisting of hydrated uranium potassium vanadate,  $K_2(UO_2)_2(VO_4)_2 \cdot nH_2O$ . It varies in colour from bright yellow to lemon- or greenish-yellow. It is a source of uranium, radium, and vanadium. The chief occurrences are in the Colorado Plateau, USA; Radium Hill, Australia; and Katanga, Democratic Republic of Congo.

**Caro's acid** See PEROXOSULPHURIC(VI) ACID.

**carotene** A member of a class of \*carotenoid pigments. Examples are  $\beta$ -carotene and lycopene, which colour carrot roots and ripe tomato fruits respectively.  $\alpha$ - and  $\beta$ -carotene yield vitamin A when they are broken down during animal digestion.

**carotenoid** Any of a group of yellow, orange, red, or brown plant pigments chemically related to terpenes. Carotenoids are responsible for the characteristic colour of many plant organs, such as ripe tomatoes, carrots, and autumn leaves. They also function as accessory \*photosynthetic pigments in the light-dependent reactions of \*photosynthesis. See CAROTENE; XANTHOPHYLL.

### Carothers, Wallace Hume

(1896–1937) US industrial chemist, who joined the Du Pont company where he worked on polymers. In 1931 he produced \*neoprene, a synthetic rubber. His greatest success came in 1935 with the discovery of the polyamide that came to be known as \*nylon. Carothers, who suffered from depression, committed suicide.

**carotid artery** The major artery that supplies blood to the head. A pair of **common carotid arteries** arise from the aorta (on the left) and the innominate artery (on the right) and run up the neck; each branches into an **external** and an **internal carotid artery**, which supply the head.

**carotid body** One of a pair of tissue masses adjacent to the \*carotid sinus. Each contains receptors that are sensitive to oxygen and pH levels (acidity) in the blood. High levels of carbon dioxide in the

blood lower the pH (i.e. increase the acidity). By responding to fluctuations in pH, the carotid body coordinates reflex changes in respiration rate.

**carotid sinus** An enlarged region of the \*carotid artery at its major branching point in the neck. Its walls contain many receptors that are sensitive to changes in pressure and it regulates blood pressure by initiating reflex changes in heart rate and dilation of blood vessels.

**carpal (carpal bone)** One of the bones that form the wrist (see *CARPUS*) in terrestrial vertebrates.

**carpel** The female reproductive organ of a flower. Typically it consists of a \*stigma, \*style, and \*ovary. It is thought to have evolved by the fusion of the two edges of a flattened megasporophyll (see *SPOROPHYLL*). Each flower may have one carpel (**monocarpellary**) or many (**polycarpellary**), either free (**apocarpous**) or fused together (**syncarpous**). See also *PISTIL*.

**carpus** The wrist (or corresponding part of the forelimb) in terrestrial vertebrates, consisting of a number of small bones (**carpals**). The number of carpal bones varies with the species. The rabbit, for example, has two rows of carpals, the first (proximal) row containing three bones and the second (distal) row five. In humans there are also eight carpals. This large number of bones enables flexibility at the wrist joint, between the hand and forelimb. See also *PENTADACTYL LIMB*.

**carrier 1.** (in radio) See *CARRIER WAVE*. **2.** (in physics) See *CHARGE CARRIER*. **3.** (in medicine) An individual who harbours a particular disease-causing microorganism without ill-effects and who can transmit the microorganism to others. Compare *VECTOR*. **4.** (in genetics) An individual with an \*allele for some defective condition that is masked by a normal \*dominant allele. Such individuals therefore do not suffer from the condition themselves but they may pass on the defective allele to their offspring. In humans, women may be carriers of such conditions as red-green colour blindness and haemophilia, the alleles for which are carried on the X chromosomes (see *SEX LINKAGE*).

**5.** (in biochemistry) See *CARRIER MOLECULE*; *HYDROGEN CARRIER*.

**carrier gas** The gas that carries the sample in \*gas chromatography.

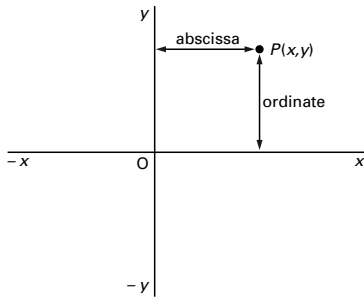

**carrier molecule 1.** A molecule that plays a role in transporting electrons through the \*electron transport chain. Carrier molecules are usually proteins bound to a nonprotein group; they can undergo oxidation and reduction relatively easily, thus allowing electrons to flow through the system. There are four types of carrier: flavoproteins (e.g. \*FAD), \*cytochromes, iron-sulphur proteins (e.g. ferredoxin), and \*ubiquinone. **2.** A lipid-soluble molecule that can bind to lipid-insoluble molecules and transport them across membranes. Carrier molecules have specific sites that interact with the molecules they transport. Several different molecules may compete for transport by the same carrier. See *TRANSPORT PROTEIN*.

**carrier wave** An electromagnetic wave of specified frequency and amplitude that is emitted by a radio transmitter in order to carry information. The information is superimposed onto the carrier by means of \*modulation.

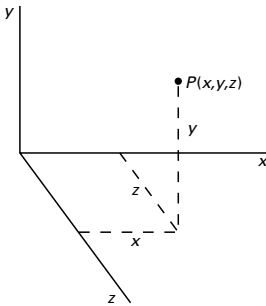

**carrying capacity** Symbol *K*. The maximum population of a particular species that can be supported indefinitely by a given habitat or area without damage to the environment. It can be manipulated by human intervention. For example, the carrying capacity for grazing mammals could be increased by boosting the yield of their grassland habitat by the application of fertilizer. See also *K SELECTION*.

**Cartesian coordinates** A system used in analytical geometry to locate a point *P*, with reference to two or three **axes** (see graphs). In a two-dimensional system the vertical axis is the *y*-axis and the horizontal axis is the *x*-axis. The point at which the axes intersect each other is called the **origin**, *O*. Values of *y* < 0 fall on the *y*-axis below the origin, values of *x* < 0 fall on the *x*-axis to the left of the origin. Any point *P* is located by its perpendicular distances from the two axes. The distance from the *x*-axis is called the **ordinate**; the distance from the *y*-axis is the **abscissa**. The posi-

tion is indicated numerically by enclosing the values of the abscissa and the ordinate in parentheses and separating the two by means of a comma, e.g.  $(x,y)$ . In three dimensions the system can be used to locate a point with reference to a third,  $z$ -axis. It is named after René Descartes (1596–1650).

two-dimensional system

three-dimensional system

Cartesian coordinates

**cartilage (gristle)** A firm flexible connective tissue that forms the adult skeleton of cartilaginous fish (e.g. sharks). In other vertebrates cartilage forms the skeleton of the embryo, being largely replaced by \*bone in mature animals (although it persists in certain areas). Cartilage comprises a matrix consisting chiefly of a glycosaminoglycan (mucopolysaccharide) called **chondroitin sulphate** secreted by cells (**chondroblasts**) that become embedded in

the matrix as **chondrocytes**. It also contains collagenous and elastic fibres.

**Hyaline cartilage** consists largely of glycosaminoglycan, giving it a shiny glasslike appearance; this type of cartilage gives flexibility and support at the joints. **Fibrocartilage**, in which bundles of collagen fibres predominate, is stronger and less elastic than hyaline cartilage; it is found in such areas as the intervertebral discs. **Elastic cartilage** has a yellow appearance due to the presence of numerous elastic fibres (see ELASTIN). This cartilage maintains the shape of certain organs, such as the pinna of the ear.

**cartilage bone (replacing bone)** \*Bone that is formed by replacing the cartilage of an embryo skeleton. The process, called **ossification**, is brought about by the cells (osteoblasts) that secrete bone. Compare MEMBRANE BONE.

**cartilaginous fishes** See CHONDRICTHYES.

**cartography** The science of the production of maps and charts. Maps may be based on original surveys, aerial photographs (photogrammetry), or compiled from existing maps and records. Computer-based information systems are increasingly used in the production of maps (**digital cartography**) in place of more traditional methods. See also MAP PROJECTIONS.

**caruncle** A small outgrowth from the testa of a seed that develops from the placenta, funicle, or micropyle. Examples include the warty outgrowth from the castor-oil seed and the tuft of hairs on the testa of the seed of willowherb. See also ARIL.

**caryopsis** A dry single-seeded indehiscent fruit that differs from an \*achene in that the fruit wall is fused to the testa of the seed. It is the grain of cereals and grasses.

**cascade liquefier** An apparatus for liquefying a gas of low \*critical temperature. Another gas, already below its critical temperature, is liquified and evaporated at a reduced pressure in order to cool the first gas to below its critical temperature. In practice a series of steps is often used,

each step enabling the critical temperature of the next gas to be reached.

**cascade process** Any process that takes place in a number of steps, usually because the single step is too inefficient to produce the desired result. For example, in some uranium-enrichment processes the separation of the desired isotope is only poorly achieved in a single stage; to achieve better separation the process has to be repeated a number of times, in a series, with the enriched fraction of one stage being fed to the succeeding stage for further enrichment. Another example of cascade process is that operating in a \*cascade liquefier.

**case hardening** The hardening of the surface layer of steel, used for tools and certain mechanical components. The commonest method is to carburize the surface layer by heating the metal in a hydrocarbon or by dipping the red hot metal into molten sodium cyanide. Diffusion of nitrogen into the surface layer to form nitrides is also used.

**casein** One of a group of phosphate-containing proteins (phosphoproteins) found in milk. Caseins are easily digested by the enzymes of young mammals and represent a major source of phosphorus. See RENNING.

**Cassegrainian telescope** See TELESCOPE.

**Cassini, Giovanni Domenico** (1625–1712) Italian-born French astronomer, who was professor of astronomy at Bologna. In 1669 he moved to Paris to run the new observatory there, becoming a French citizen in 1673. He is best known for his discovery (1675) of the gap that divides Saturn's ring system into two parts, now called the **Cassini division**. He also discovered four new satellites of Saturn.

**cassiterite** A yellow, brown, or black form of tin(IV) oxide,  $\text{SnO}_2$ , that forms tetragonal, often twinned, crystals; the principal ore of tin. It occurs in hydrothermal veins and metasomatic deposits associated with acid igneous rocks and in alluvial (placer) deposits. The chief producers are Malaysia, Indonesia, Democratic Republic of Congo, and Nigeria.

**caste** A division found in social insects, such as the \*Hymenoptera (ants, bees, wasps) and the Isoptera (termites), in which the individuals are structurally and physiologically specialized to perform a particular function. For example, in honeybees there are queens (fertile females), workers (sterile females), and drones (males). There are several different castes of workers (all sterile females) among ants.

**cast iron** A group of iron alloys containing 1.8 to 4.5% of carbon. It is usually cast into specific shapes ready for machining, heat treatment, or assembly. It is sometimes produced direct from the \*blast furnace or it may be made from remelted \*pig iron.

**castor oil** A pale-coloured oil extracted from the castor-oil plant. It contains a mixture of glycerides of fatty acids, the predominant acid being ricinoleic acid,  $\text{C}_{17}\text{H}_{32}(\text{OH})\text{COOH}$ . It is used as a \*drying oil in paints and varnishes and medically as a laxative.

**catabolism** The metabolic breakdown of large molecules in living organisms to smaller ones, with the release of energy. Respiration is an example of a catabolic series of reactions. See METABOLISM. Compare ANABOLISM.

**catalysis** The process of changing the rate of a chemical reaction by use of a \*catalyst.

**catalyst** A substance that increases the rate of a chemical reaction without itself undergoing any permanent chemical change. Catalysts that have the same phase as the reactants are **homogeneous catalysts** (e.g. \*enzymes in biochemical reactions or transition-metal complexes used in the liquid phase for catalysing organic reactions). Those that have a different phase are **heterogeneous catalysts** (e.g. metals or oxides used in many industrial gas reactions). The catalyst provides an alternative pathway by which the reaction can proceed, in which the activation energy is lower. It thus increases the rate at which the reaction comes to equilibrium, although it does not alter the position of the equilibrium. The catalyst itself takes part in the reaction and conse-

quently may undergo physical change (e.g. conversion into powder). In certain circumstances, very small quantities of catalyst can speed up reactions. Most catalysts are also highly specific in the type of reaction they catalyse, particularly enzymes in biochemical reactions. Generally, the term is used for a substance that increases reaction rate (a **positive catalyst**). Some reactions can be slowed down by **negative catalysts** (see INHIBITION).

**catalytic activity** The increase in the rate of a specified chemical reaction caused by an enzyme or other catalyst under specified assay conditions. It is measured in \*katal or in moles per second.

**catalytic converter** A device used in the exhaust systems of motor vehicles to reduce atmospheric pollution. The three main pollutants produced by petrol engines are: unburnt hydrocarbons, carbon monoxide produced by incomplete combustion of hydrocarbons, and nitrogen oxides produced by nitrogen in the air reacting with oxygen at high engine temperatures. Hydrocarbons and carbon monoxide can be controlled by a higher combustion temperature and a weaker mixture. However, the higher temperature and greater availability of oxygen arising from these measures encourage formation of nitrogen oxides. The use of three-way catalytic converters solves this problem by using platinum and palladium catalysts to oxidize the hydrocarbons and the CO and rhodium catalysts to reduce the nitrogen oxides back to nitrogen. These three-way catalysts require that the air-fuel ratio is strictly stoichiometric. Some catalytic converters promote oxidation reactions only, leaving the nitrogen oxides unchanged. Three-way converters can reduce hydrocarbons and CO emissions by some 85%, at the same time reducing nitrogen oxides by 62%.

**catalytic cracking** See CRACKING.

**catalytic RNA** See RIBOZYME.

**cataphoresis** See ELECTROPHORESIS.

**catastrophe theory** A branch of mathematics dealing with the recent emergence of discontinuities, in contrast to \*calculus, which is concerned with con-

tinuous quantities. Catastrophe theory originated in \*topology in work by the French mathematician René Thom (1923–2002) and was developed by Thom and the Russian mathematician Vladimir Igorevich Arnold (1937– ). There are physical applications of catastrophe theory in \*optics and in systems involving \*complexity, including biological systems.

**catechol** See 1,2-DIHYDROXYBENZENE.

**catecholamine** Any of a class of amines that possess a catechol ( $C_6H_4(OH)_2$ ) ring. Including \*dopamine, \*adrenaline, and \*noradrenaline, they function as \*neurotransmitters and/or hormones.

**category** (in taxonomy) See RANK.

**catenary** A curve formed when a chain or rope of uniform density hangs from two fixed points. If the lowest point on the curve passes through the origin, the equation is  $y = c(\cosh x/c)$ , where  $c$  is the distance between the  $x$ -axis and the directrix.

**catenation** The formation of chains of atoms in chemical compounds.

**catheometer** A telescope or microscope fitted with crosswires in the eyepiece and mounted so that it can slide along a graduated scale. Cathetometers are used for accurate measurement of lengths without mechanical contact. The microscope type is often called a **traveling microscope**.

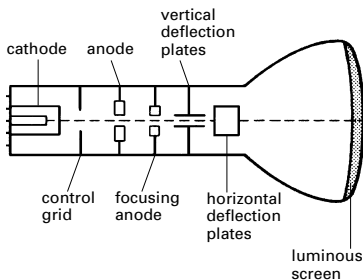

**cathode** A negative electrode. In \*electrolysis cations are attracted to the cathode. In vacuum electronic devices electrons are emitted by the cathode and flow to the \*anode. It is therefore from the cathode that electrons flow into these devices. However, in a primary or secondary cell the cathode is the electrode that spontaneously becomes negative during discharge, and from which therefore electrons emerge.

**cathode-ray oscilloscope (CRO)** An instrument based on the \*cathode-ray tube that provides a visual image of electrical signals. The horizontal deflection is usually provided by an internal \*timebase, which causes the beam to sweep across the screen at a specified rate. The signal to be investigated is fed to the vertical deflec-

tion plates after amplification. Thus the beam traces a graph of the signal amplitude against time.

**cathode rays** Streams of electrons emitted at the cathode in an evacuated tube containing a cathode and an anode. They were first observed in gas \*discharge tubes operated at low pressure. Under suitable conditions electrons produced by secondary emission at the cathode are accelerated down the tube to the anode. In such devices as the \*cathode-ray tube the electrons are produced by \*thermionic emission from a hot cathode in a vacuum.

**cathode-ray tube (CRT)** The device that provides the viewing screen in the television tube, the radar viewer, and the \*cathode-ray oscilloscope. The cathode-ray tube consists of an evacuated tube containing a heated cathode and two or more ring-shaped anodes through which the cathode rays can pass so that they strike the enlarged end of the tube (see illustration). This end of the tube is coated with fluorescent material so that it provides a screen. Any point on the screen that is struck by the cathode ray becomes luminous. A \*control grid between the cathode and the anode enables the intensity of the beam to be varied, thus controlling the brightness of the illumination on the screen. The assembly of cathode, control grid, and anode is called the \*electron gun. The beam emerging from the electron gun is focused and deflected by means of plates providing an electric field or coils providing a magnetic field. This enables the beam to be focused to a small point of light and deflected to produce the

Cathode-ray tube

illusion of an illuminated line as this point sweeps across the tube.

The television tube is a form of cathode-ray tube in which the beam is made to scan the screen 625 times to form a frame, with 25 new frames being produced every second. (These are the figures for standard television tubes in the UK). Each frame creates a picture by variations in the intensity of the beam as it forms each line.

**cathodic protection** See SACRIFICIAL PROTECTION.

**cation** A positively charged ion, i.e. an ion that is attracted to the cathode in \*electrolysis. Compare ANION.

**cationic detergent** See DETERGENT.

**cationic dye** See DYES.

**cationic resin** See ION EXCHANGE.

**catkin** A type of flowering shoot (see RACEMOSE INFLORESCENCE) in which the axis, which is often long, bears many small stalkless unisexual flowers. Usually the male catkins hang down from the stem; the female catkins are shorter and often erect. Examples include birch and hazel. Most plants with catkins are adapted for wind pollination, the male flowers producing large quantities of pollen; willows are an exception, having nectar-secreting flowers and being pollinated by insects.

**caudal vertebrae** The bones (see VERTEBRA) of the tail, which articulate with the \*sacral vertebrae. The number of caudal vertebrae varies with the species. Rabbits, for example, have 15 caudal vertebrae, while in humans these vertebrae are fused to form a single bone, the \*coccyx.

**causality** The principle that effect cannot precede cause. The principle is particularly useful when combined with the principle that the highest attainable speed in the universe is the \*speed of light in a vacuum. Causality is used to analyse the results of scattering experiments and in optics.

**caustic 1.** (in chemistry) Describing a substance that is strongly alkaline (e.g. caustic soda). **2.** (in optics) The curve or surface formed by the reflection of paral-

lel rays of light in a large-aperture concave mirror. The apex of the caustic lies at the principal focus of the mirror. Such a curve can sometimes be seen on the surface of the liquid in a cup as a result of reflection by the curved walls of the cup. A similar curve is formed by a convex lens with spherical surfaces refracting parallel rays of light.

**caustic potash** See POTASSIUM HYDROXIDE.

**caustic soda** See SODIUM HYDROXIDE.

**Cavendish, Henry** (1731–1810) British chemist and physicist, born in France. Although untrained, his inheritance from his grandfather, the Duke of Devonshire, enabled him to live as a recluse and study science. In his experiments with gases (1766), he correctly distinguished between hydrogen and carbon dioxide, and in 1781 synthesized water by exploding hydrogen in oxygen. He also constructed a torsion balance in 1798, with which he measured the mean density (and hence mass) of the earth.

**cavitation** The formation of gas- or vapour-filled cavities in liquids in motion when the pressure is reduced to a critical value while the ambient temperature remains constant. If the velocity of the flowing liquid exceeds a certain value, the pressure can be reduced to such an extent that the \*Bernoulli theorem breaks down. It is at this point that cavitation occurs, causing a restriction on the speed at which hydraulic machinery can be run without noise, vibration, erosion of metal parts, or loss of efficiency.

**cavity resonator** See RESONANT CAVITY.

**C cell (parafollicular cell)** Any one of a group of calcium-secreting cells in vertebrates that are derived from the terminal pair of gill pouches. In mammals these cells are incorporated into the \*thyroid gland and the \*parathyroid gland.

**c.c.p.** Cubic close packing. See CLOSE PACKING.

**CD 1. (cluster of differentiation)** Any group of antigens that is associated with a specific subpopulation of human \*T cells. The differentiation antigens expressed by a T cell vary with its stage of development

and thus with its role in the immune response. Hence, for example, CD4 antigens are expressed by helper T cells, whereas CD8 antigens are expressed by cytotoxic and suppressor T cells. The antigens are glycoproteins and are characterized using \*monoclonal antibodies. **2.** See COMPACT DISK.

**CD-I** CD interactive. A variant of \*CD-ROM in which data, sound, and images can be interleaved on the same disk, i.e. it is a \*multimedia disk. It was designed as a 'buy and play' system for the home.

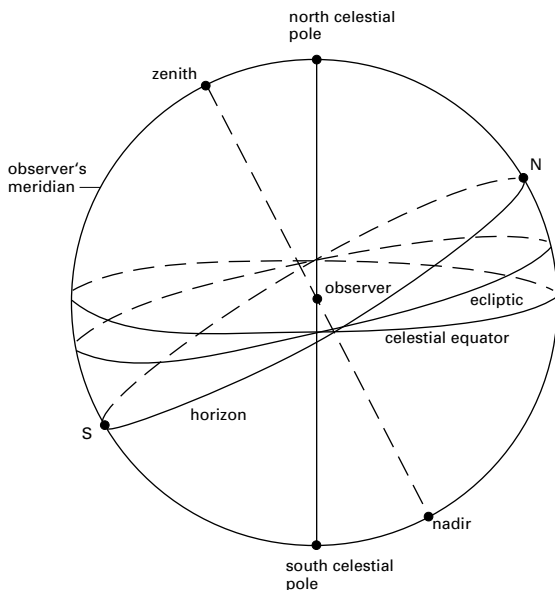

**cDNA** See COMPLEMENTARY DNA.

**CD-ROM** CD read-only memory. A device that is based on the audio \*compact disk and provides read-only access to a large amount of data (up to 640 megabytes) for use on computer systems. The term also refers to the medium in general. A **CD-ROM drive** must be used with the computer system to read the data from disk; the data cannot normally be rewritten. Most drives can also play CD audio disks, but audio disk players cannot handle CD-ROMs. The data may be in any form – text, sound, images, or binary data, or a mixture – and various CD-ROM format standards exist to handle these. CD-ROM is widely used for the distribution of data, images, and software and for archiving data.

**CD-RW** CD-rewritable, a CD format launched around 1997 that enabled recording and re-use of CDs. CD-RW uses a phase change to record data. The recording layer is a special alloy (typically silver/indium/antimony/tellurium). The laser in the CD drive has three power levels. The highest level melts small regions of the recording layer and these cool quickly to an amorphous form, thereby creating small pits in the recording surface. This level is used for writing data to the disk. The intermediate power level heats the surface to a temperature below the melting point, but high enough to cause recrystallization of the amorphous pits. This is used for erasing data. The lowest power level is used for reading data from the disk in the same way that data is read from a CD-ROM.

**celestial equator** See EQUATOR.

Celestial sphere
